J.P. Thornhill[1], J. Hoare[1], S. Peake[1], M. Khan[1], J. Skelton[1], M. Dorner[1], K. Williamson[2], C. Murray[3], J. Frater[2], S. Kinloch[3], S. Fidler[1], & the CHERUB Investigators
[1]Imperial College London, London, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]Royal Free NHS Foundation Trust, London, United Kingdom

Background: Gut-associated lymphoid tissue (GALT) is preferentially infected during primary HIV infection (PHI) & is a key site of HIV persistence. 47 integrin, a gut-homing receptor expressed on CD4 T-cells, facilitates CD4 T-cell trafficking to GALT. A monoclonal antibody against 47 integrin (Vedolizumab, VDZ) is used to treat inflammatory bowel disease (IBD). Data from ART-treated SIV-infected primates showed HIV viral control following VDZ administration. We present 2 cases of HIV+ individuals treated with ART in PHI, who received VDZ for IBD.

Methods: VDZ was administered as licensed for IBD - at 0,2,6 then every 8 weeks. Informed consent for blood sampling & gut biopsy was obtained. Routine clinical monitoring data was captured (CD4,CD8 & HIV VL). Paired blood and gut biopsy samples from the terminal ileum (TI) & rectum were collected at a single time-point from participant A. Comparisons with blood & GALT samples from the HEATHER cohort (15 ART-treated PHI individuals) were made for 7 expression & total HIV DNA measured by flow cytometry and qPCR, respectively.

Results: Clinical characteristics are shown in Table 1. No adverse events were reported, and both patients had clinical IBD response. For Participant A: 7 expression on blood CD4+ cells increased over the 3 study visits (12.7%, 13.7% & 22.1%, respectively); 7 expression on GALT CD4+ cells was lower for participant A compared to HEATHER participants & healthy controls. Blood total HIV DNA for participant A (at biopsy) was comparable to the mean HEATHER HIV DNA (3.4 vs 3.1 Log/10^6 CD4). Despite only 8 months of ART since PHI, total HIV DNA in GALT for participant A (TI 3.7, rectum 3.5 Log/10^6 CD4 was below the mean of HEATHER participants (TI 3.6, rectum 3.5 Log/10^6 CD4) whose median (range) time on ART was longer at 34 (15-96) months.

Conclusions: We report the first 2 cases of HIV+ individuals receiving Vedolizumab for IBD. It was shown to be safe, well-tolerated & associated with good IBD response. These preliminary data support further exploration of 47 integrin antibodies as a strategy to limit GALT HIV reservoir. It remains to be shown if longer treatment period may further impact on reservoirs.

THPEB099

Antiretroviral treatment interruptions in HIV clinical trials: A systematic review

J.S.Y. Lau[1,2], M.Z. Smith[3,4], S.R. Lewin[3,4], J.H. McMahon[1,2]
[1]*The Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia,* [2]*Monash University, Melbourne, Australia,* [3]*The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia,* [4]*Melbourne University, Melbourne, Australia*

Background: Structured treatment interruptions (STIs) were previously used to determine effects of intermittent antiretroviral therapy (ART) in people living with HIV (PLHIV), but studies found this to be associated with worse outcomes. Recently, analytical treatment interruptions (ATI) have tested interventions aiming to achieve virological control without ART. We reviewed the practice of ATI and STI.

Methods: A systematic review was performed of clinical studies from 2000-2017 identified via Ovid MEDLINE, EMBASE and recent HIV conference abstracts. ATI studies assessed interventions aimed at achieving virological control without ART, STI studies investigated whether adverse effects of ART could be minimised. Extracted data included: demographics, frequency of CD4 and HIV viral load (VL) monitoring, criteria to restart ART, TI duration, and adverse outcomes. A descriptive analysis of TI parameters was performed stratifying ATI studies pre- and post-2014 when ART was universally recommended.

Results: The search identified 705 studies, with data extracted from 109 studies; 68(62%) STI and 41(38%) ATI; where therapy was interrupted in 8453 individuals. Most common monitoring strategies for VL and CD4 were: monthly for 18 STI studies and weekly or more frequently for 20 ATI studies (Table). The commonest threshold to restart ART in STI studies was CD4 < 350 cells/mm^3, with 42 STI studies reporting no VL threshold to restart ART. In ATI studies, the commonest threshold was a VL >1000 copies/mL and/or CD4 < 350 cells/mm^3 in 7 studies conducted after 2014, and a VL >50,000 copies/mL in 6 pre-2014 ATI studies. Reported median TI duration ranged from 7 days to 22 months in STI and from 14 to 106 days in ATI. TI-related adverse events pre-2014 were related to immunological decline. In 21 ATI studies post-2014 one adverse event of myocardial infarct was reported.

Conclusions: Marked heterogeneity was noted in study methodology and TI duration. ATI studies had more frequent monitoring and shorter TI duration, compared to STI studies. ATI studies were more likely to re-initiate ART based on VL monitoring and the VL threshold for this has decreased over time. Summary data will assist the design of future trials involving ATI and potentially in standardising an approach to this intervention.

Statin use during effective ART is not associated with lower biomarkers of HIV persistence or immune activation/inflammation

R. Bedimo[1,2], H. Mar[3], R. Bosch[3], H. Drechsler[1,2], J. Cyktor[4], B. Macatangay[4], C. Lalama[3], C. Rinaldo[4], A. Collier[5], C. Godfrey[6], E. Hogg[7], C. Hensel[8], J. Eron[9], D. McMahon[4], J. Mellors[4], P. Tebas[10], R. Gandhi[3], A 5321 Study Team
[1]*VA North Texas Health Care System, Medicine, Dallas, United States,* [2]*University of Texas Southwestern Medical Center, Medicine, Dallas, United States,* [3]*Havard University, Cambridge, United States,* [4]*University of Pittsburgh, Pittsburgh, United States,* [5]*University of Washington, Seattle, United States,* [6]*Division of AIDS, NIAID, National Institutes of Health, Washington, D.C., United States,* [7]*Social & Scientific Systems, Silver Spring, United States,* [8]*Frontier Science & Technology Research Foundation, Inc, Amherst, United States,* [9]*University of North Carolina, Chapel Hill, United States,* [10]*University of Pennsylvania, Philadelphia, United States*

Background: Statins exert pleiotropic anti-inflammatory and immune-modulatory effects. They also have in vitro antiviral effects, and we have shown that statin use is associated with a reduced risk of virologic rebound in people on suppressive antiretroviral therapy (ART). This may reflect a statin-induced decreased HIV-reservoir size. We evaluated whether current statin exposure is associated with lower levels of markers of HIV persistence and immune activation/inflammation.

Methods: We analyzed samples from HIV-infected participants of ACTG A5321 who started ART during chronic infection and maintained virologic suppression (HIV-1 RNA levels ≤50 copies/mL) for ≥3 years. We measured: 1) three markers of HIV-1 persistence (cell-associated HIV RNA [CA-RNA], CA-DNA, and single copy assay [SCA] plasma HIV RNA) and 2) soluble markers of immune activation/inflammation: IL-6, IP-10, ne-

opterin, sCD14, sCD163 and TNF-alpha. Wilcoxon rank-sum tests compared markers between participants receiving versus not receiving statin therapy, and regression models adjusted for variables correlated with markers of HIV persistence.
Results: A total of 303 participants were analyzed. The median age was 48 yrs; 82% were male; 55% were white. At the time of biomarker measurements, median duration of suppressive ART exposure was 7.3 yrs (IQR: 6.1 - 10.1); median CD4 count was 681/mm^3 (515 - 864); 72 (24%) participants reported receiving statins. The median time on the current statin was 2.9 yrs (1.2 - 5.1). There were no differences between statin users and non-users in levels of CA-DNA (median 650 vs. 540 copies/10^6 CD4+ T cells; p=0.58), CA-RNA (53 vs. 37 copies/10^6 CD4+ T cells; p=0.12) or SCA (0.4 vs. 0.4 copies/mL; p=0.45). Similarly, there were no significant differences between statin users and non-users in markers of inflammation/activation, except for IP-10 (137 vs. 118 pg/mL; p=0.028). Findings were unchanged after adjustment for factors including pre-ART CD4 and HIV RNA, and years on ART.
Conclusions: In this cohort of persons on long-term suppressive ART, current statin use was not associated with lower levels of HIV persistence or immune activation/inflammation. These results do not support a major role for statins in reducing HIV persistence although an early transient effect cannot be excluded. Prospective, randomized studies are needed to confirm these findings.

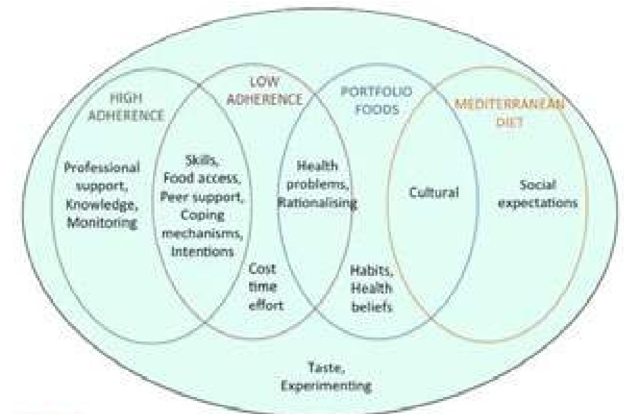
Nutrition

THPEB101

A qualitative analysis of the barriers and facilitators to adopting the Mediterranean diet with Portfolio cholesterol-lowering foods in those with HIV dyslipidaemia - interviews within a randomized controlled trial

C. Stradling[1], S. Taheri[2], N. Thomas[3], S. Taylor[4]
[1]University of Birmingham, Institute of Inflammation & Ageing, Birmingham, United Kingdom, [2]Weill Cornell Medicine in Qatar and New York, Qatar, Qatar, [3]University of Birmingham, Birmingham, United Kingdom, [4]Heart of England NHS Foundation Trust, Birmingham, United Kingdom

Background: Our Best Foods For your heart (BFF) trial found that LDL-cholesterol was 10% lower after 6 months on the Mediterranean Portfolio diet compared to a low saturated fat diet in adults with HIV dyslipidaemia (ISRCTN32090191). Assuming full adherence, complier average causal effect analysis suggested the LDL-cholesterol reduction might be as large as -0.87mmol/l (95%CI -1.79 to 0.05mmol/l). However, individual dietary adherence varied between 11 and 100%. Therefore, this study aimed to explore factors affecting adoption of the Mediterranean Portfolio diet in adults participating in the BFF RCT.
Methods: Sixteen of 29 participants randomized to the Mediterranean Portfolio arm (Mediterranean-style diet incorporating cholesterol-lowering foods: nuts, oats, soya, plant stanols and beans) were purposively sampled to reflect the diversity of the trial population. Semi-structured interviews were conducted and analysed iteratively using a thematic framework.
Results: Proportionally more women were enrolled in the RCT (52%) and 50% of participants were black African. Dietary adherence was high: Portfolio foods (59±21%); Mediterranean Diet Score (68±15%) with 24% improvement in diet quality over 6 months. Participants with high adherence (>70%) were keen to experiment with new tastes, valued the provision of unfamiliar foods and personalized support from a trusted professional. Barriers of cost/time/effort to access foods emerged repeatedly from participants reporting low adherence (< 60%). Participants also identified barriers potentially unique to this population: lack of autonomy in food selection, and fear of disclosure of HIV status when explaining reasons for food choices to friends and family (peer support in Figure).
Adoption of dietary components was approached differently. Plant stanol drinks were viewed as „medication", to compensate for high fat intake. Portfolio foods were generally added as snacks, allowing minimal disturbance to usual eating patterns. The concept of snacking was less acceptable to Africans because of cultural norms of proper meals. African participants embraced the transition towards a Mediterranean style diet by reversing acculturation and returning to their traditional foods.
Conclusions: The Mediterranean Portfolio diet was achievable in a multi-ethnic group. Dietary interventions need to identify and engage personal motivators, address cross-cultural issues, and accommodate social and educational needs. Matching diet style to the individual is important.



[Figure: Themes from participant interviews on barriers and enablers to adopting the Mediterranean Portfolio diet]

Diagnosis of HIV disease in paediatric and adolescent populations

Community-based HIV-free survival in high prevalence settings after introduction of Option B+: Results from Lesotho

A. Tiam[1,2], M. Gill[1], R. Machekano[1], V. Tukei[3], M. Mokone[4], M. Letsie[5], I. Seipati[6], M. Nei[7], F. Mohai[7], L. Guay[1,8]
[1]Elizabeth Glaser Pediatric Aids Foundation, Research, Washington, United States, [2]University of Bergen, Centre for International Health, Bergen, Norway, [3]Employer, Research, Maseru, Lesotho, [4]Elizabeth Glaser Pediatric Aids Foundation, Research, Maseru, Lesotho, [5]Ministry of Health, Disease Control, Maseru, Lesotho, [6]Ministry of Health, Family of Health, Maseru, Lesotho, [7]Elizabeth Glaser Pediatric Aids Foundation, Program, Maseru, Lesotho, [8]George Washington University, Milken Institute School of Public Health, Washington, United States

Background: Population-based HIV-free survival (HFS) at 18-24 months among HIV-exposed infants (HEI) in high prevalence settings with Option B+ is largely unknown. We conducted a community-based survey to determine outcomes of HEI at 18-24 months in Lesotho.
Methods: From November 2015 to December 2016, we conducted a survey among households with a child born 18-24 months before study initiation. Facility catchment areas from 25 health facilities in Butha-Buthe, Maseru, Thaba-Tseka and Mohale's Hoek districts were randomly selected using probability proportional to size sampling. Consecutive households were visited and eligible consenting caregivers were enrolled. Rapid HIV antibody testing was performed for mothers of unknown HIV status (never tested or HIV-negative >3 months prior) and children of HIV-positive or unknown status mothers. Mortality information for mothers and children who died were captured.
Categorical variables were summarized by frequencies and proportions in each category. Continuous variables were summarized using means and standard deviations or medians and interquartile range. The difference in survival between sub-groups of the sample was determined using the log-rank test. Comparisons included HIV-unexposed versus HIV-exposed children.

Results: Of the 11,169 households visited, 2,190 were eligible and 1,852 (84.6%) were enrolled. Of the 374 women documented to be on antiretroviral treatment, 36% (135/374) started ART before ANC and 88% (329/374) were still on treatment at the time of the study. The mother-to-child HIV transmission rate was 5.7% [95% CI: 4.0-8.0]. The mortality rate was 2.6% [95% CI: 1.6-4.2] and 1.4% [95% CI: 0.9-2.3] among HIV-exposed and HIV-unexposed children respectively. HFS was 91.8% [95% CI: 89.2 - 93.8] among HEI. Disclosure of mother's HIV status (aOR = 4.9, 95% CI: 1.3 - 18.2) and initiation of cotrimoxazole prophylaxis in the child (aOR = 3.9, 95% CI: 1.2 - 12.6) were independently associated with increased HIV-free survival while child growth problems (aOR = 0.2, 95% CI: 0.09 - 0.5) was independently associated with reduced HIV-free survival.
Conclusions: Even with Option B+, Lesotho has not reached elimination of mother-to-child transmission. With mortality of HIV-exposed children twice that of HIV-unexposed children, HIV-free survival was only 91.8%. Disclosure of maternal HIV status was associated with survival.

THPEB103

We have left the children behind in the 90- 90- 90 agenda. A case of Churches Health Association of Zambia

D. Mainza, P. Choonga, D. Menda, K. Sichinga
Churches Health Association of Zambia, Health Programs, Lusaka, Zambia

Background: There have been efforts to strengthen the elimination of Mother to Child Transmission (eMTCT) of HIV in church health institutions (CHIs) through strengthening of the Early Infant Diagnosis (EID) program. With Global Fund ATM support, the Churches Health Association of Zambia (CHAZ) has been a key implementing partner of the eMTCT program in Zambia since 2004. In 2016 alone, 54.8% infants were tested for HIV using the Nucleic Acid Test (NAT) at 6 weeks.
Methods: This was a cross sectional study which involved the review of data, from purposely selected nineteen (19) CHIs extracted from Safe Motherhood register, DBS tracking register and DBS laboratory requisition forms, for the period of January to December 2017.
Results: Review of the EID data showed that; in 2016, there were 1,238 HIV positive women who delivered live babies. 88% of these had a poor economic status and were mainly peasant farmers. Out of this number, only 87% infants had the DBS sent to PCR laboratories at 6 weeks. Only 81% results were received back at facilities and out of the results received, 2.9% were HIV positive and out of which only 60% were commenced on ART. Challenges to ART initiation includes infant death prior to ART initiation, and mothers not returning for the results. The average turnaround time for receipt of results by the health facilities in this study was 78 days.
Conclusions: Loss to follow up (LTFUP) at all stages of the EID testing and treatment cascade was identified as the major problem in EID resulting in failure to test and treat all HIV positive infants within two months of age. The other identified factor is the long turnaround time for the results. There is need to enhance the role of treatment supporters to avert the high LTFUP at all stages of the DBS testing and treatment cascade. DBS testing should also be decentralized to district and health facility level. Mother baby pairs should be followed up and no baby should be missed.

THPEB104

Western-blot negative for HIV as a marker of a low reservoir in vertically HIV-infected children

A. Tagarro[1], M.-A. Muñoz Fernández[2], C. Fortuny[3], M.-L. Navarro[4], M.J. Mellado[5], J.-T. Ramos[6], S. Jiménez-De Ory[7], T. Sainz[5], L.-M. Prieto[8], A. Noguera-Julián[9], P. Rojo[10], in behalf of EPIICAL Consortium

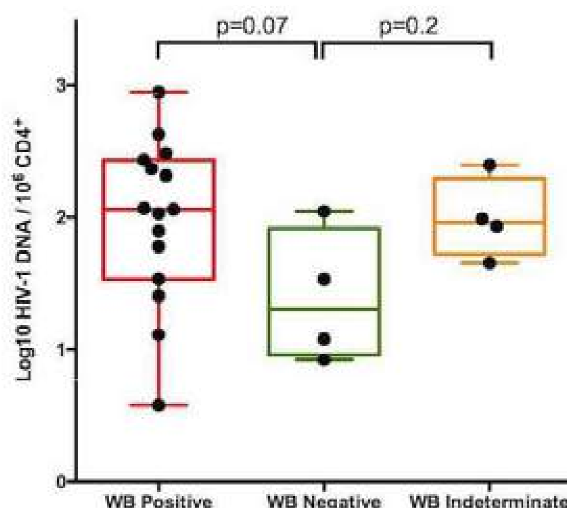
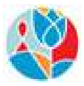
Background: Early and continued treatment against HIV reduces the size of the reservoir in children with vertical transmission. HIV enzimmoimmunoessay (EIA) can be negative in children who initiate antiretroviral treatment (ART) early. The negativization of EIA has been proposed as an indirect marker of a reduced reservoir.
The objective of this study is to investigate if negative Western-Blot (WB) is related to a smaller size of the reservoir in children with vertical infection treated during the first year of life.
Methods: The humoral response to HIV and the reservoir size were analyzed in 23 children treated in the first year of life and with suppression (< 200 copies / mL) for at least one year. The size of the reservoir was determined by measuring total DNA copies of HIV-1 per million CD4 + cells, using digital droplet (dd) PCR. WB was performed on the same samples. The distribution of DNA in negative-WB patients was compared to positive-WB patients using the Mann Whitney (MW) and Kolmogorov-Smirnov (KS) test. Negative results of WB were compared with DNA < 10 copies / million by the chi2 and Fisher tests.



[Figure 1. Reservoir size distribution (Log10 DNA copies / million CD4 +) in patients with positive or undetermined WB versus patients with negative WB]

Results: The reservoir and the humoral response were performed after a median of 4.5 years of suppression [interquartile range (RIC): 3.3-6.9], with a median age of 8 years [RIC: 5.1-10]. Four patients (17%) presented



negative WB, and another 4 (17%) were indeterminate. The size of the reservoir was lower in WB-negative patients (12 copies / million CD4 +, [RIC: 6-72], Log10 = 1.07 [0.7-1.7]) than in the group of patients with positive or indeterminate WB (111 copies/million CD4+ [RIC: 56-255], Log10 = 2.04 [1.7-2.4], Figure 1, p = 0.009, KS, p = 0.02). DNA < 10 copies / million CD4 + was significantly associated with negative WB (OR, 0.14 [95% CI: 0.04-0.4], p = 0.04).
Conclusions: In this study with patients treated in the first year of life and well controlled, 17% of patients had negative WB. Negative WB was significantly associated with a smaller reservoir size. In this type of patient, negative WB could be considered an indirect data of small reservoir size.

THPEB105

Malnutrition, orphan hood, and TB diagnosis are strong predictors of HIV positivity among children less than 15 years in Uganda

A. Kekitiinwa[1], R. Ssebunya[2], D. Damba[2], G.P. Kisitu[2], H. Bitimwine[3], B. Asire[4], P.N. Ntege[2], J. Kabanda[5], E. Nazziwa[5], J. Kalamya[5], M.R. Adler[5]
[1]Baylor College of Medicine Children's Foundation, Pediatrics and Child Health, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Kampala, Uganda, [3]Ministry of Health Uganda, Kampala, Uganda, [4]United Nations Internaational Children's Emergency Fund, Kampala, Uganda, [5]Centre for Disease Control, Entebbe, Uganda

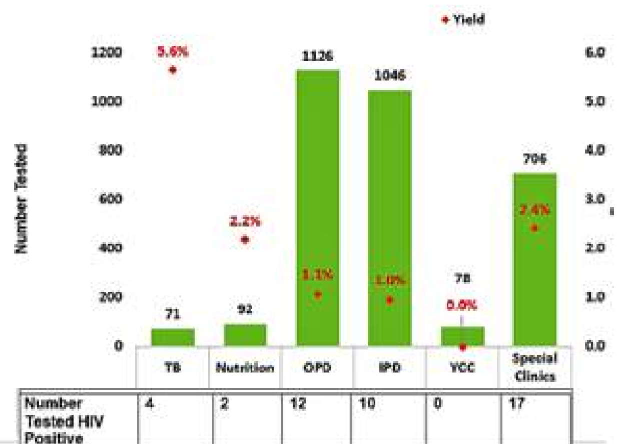
Background: Despite strides in improving pediatric HIV service coverage in Uganda, it is estimated that 32% of children living with HIV have not been identified. Identifying children with higher risk of HIV infection can improve efficiency of HIV testing among this population sub-group. We describe correlates for HIV positivity among children less than 15 years attending health facilities in Uganda.
Methods: HIV testing was offered to 3245 children in 8 health facilities from February 2017 to June 2017. Probability proportional to size was used to distribute the number of children recruited in each of the study sites and entry points. Consecutively sampled children who entered through out-patient department (OPD), in-patient department (IPD), malnutrition, TB and special (HIV, sickle cell, young child, and eye) clinics, whether patients themselves or accompanying patients, were reviewed for HIV status and offered a test if their status was unknown. Characteristics of children who tested positive were described and their correlates were analysed using a binomial generalised linear model factoring in level of facility.
Results: The HIV test uptake was 96% (3119/3245) with an overall yield of 1.4% (45/3119). Females accounted for 49.5% of the children and 49.5% were under 5 years. Children 10-15 years had significantly higher yield (2.5%) than children 18 months-4 years (1.2%, p= 0.0185) or 5-9 years (1.1%, p=0.0165). Yield did not differ by gender. Correlates for HIV positivity included: malnutrition (adjusted odds ratio (AOR)=2.14; 95% Confidence Interval (95%CI)=[1.6, 2.9]); orphan hood (single orphan: AOR=2.13; 95%CI=[1.02, 4.44], double orphan: AOR=6.97; 95%CI=[1.76, 27.66]); TB diagnosis (presumptive & confirmed: AOR=16.1; 95%CI=[13.57, 19.02]); older age (10-15 years: AOR=1.59; 95%CI=[1.56, 1.63]); children escorting their sick siblings (not sick: AOR=2.02; 95%CI=[1.92, 2.13]); and recurrent illness (AOR =2.71; 95%CI=[2.39, 3.08]).
Conclusions: The finding of higher yield in older children reflects the great success of EMTCT efforts in Uganda. Malnutrition, Opharnhood and TB diagnosis should be prioritized in the screening and identification of HIV in children. Furthermore, the significant HIV positive yield observed among children escorting their sick relatives provides an untapped opportunity to increase HIV identification amongst children.

THPEB106

High HIV testing yield found in children attending or accompanying those attending TB, malnutrition and HIV clinics in Uganda, 2017

H. Bitimwine[1], G.P. Kisitu[2], R. N. Ssebunya[2], D. Damba[2], P. Nahirya Ntege[2], B. Asire[3], J.K. Kabanda[4], E. Nazziwa[4], J. Kalamya[4], M. Adler[4], A. Kekitiinwa[2]
[1]Ministry of Health, AIDS Control Program, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Kampala, Uganda, [3]UNICEF, Kampala, Uganda, [4]Centers for Disease control and Prevention, Entebbe, Uganda

Background: Optimizing identification of undiagnosed HIV among children is critical in reducing the global burden of pediatric HIV/AIDS. Understanding the HIV testing yield among children at different facility-based entry points can inform more efficient pediatric HIV testing strategies. We assessed entry point HIV testing yield among children 18 months to 15 years in 4 regions of Uganda.
Methods: HIV testing was offered to 3245 children at 8 health facilities (4 regional referral and 4 district hospitals) from February 2017 to June 2017. All children who entered through outpatient department (OPD), inpatient department (IPD), malnutrition, TB and special (HIV, sickle cell, young child clinic(YCC), and eye clinics, whether patients themselves or accompanying patients, were reviewed for HIV status and offered a test if their status was unknown. A retest for verification was provided for every child that tested HIV positive. HIV testing yield was defined as the proportion of HIV positive children among those tested. Proportions, percentages, chi-square and fisher exact tests were used in the analysis of results.
Results: Uptake for HIV testing was 96% (3119/3245) with an overall yield of 1.4% (45/3119). Among entry points; TB, nutrition and special clinics had the highest HIV testing yield at 5.6% (4/71), 2.2% (2/92) and 2.4% (17/706) respectively (p=0.001). Among special clinics, HIV clinic had the highest yield at 52.9% (9/17). In spite of their low HIV testing yield, OPD 1.1% (12/1126) and IPD 1.0% (10/1046) accounted for the highest number of children testing HIV positive. YCC clinic had low testing volumes and no yield.
Conclusions: TB, nutrition and HIV clinic entry points had the highest HIV test yield while, OPD and IPD accounted for the largest number of HIV positive children identified. This finding further emphasizes the need for HIV testing for all children with TB, malnutrition, and those who have family members living with HIV. In OPD and IPD settings, however, introduction of a screening tool could maximize HIV testing yield while more efficiently utilizing limited testing resources.



[Figure 1: HIV positive yield at the various HTS entry points]

THPEB107

Early infant diagnosis (EID) positivity and time of test, USAID Boresha Afya Southern Zone Tanzania experience

C. Mbelwa[1], B. Christian[2], J. Gamaliel[1], J. Bisimba[3], E. Okechukwu[1], M. Njelekela[4]
[1]FHI 360, USAID Boresha Afya - Southern Zone Program, Dar es Salaam, Tanzania, United Republic of, [2]Management and Development for Health, USAID Boresha Afya - Southern Zone Program, Dar es Salaam, Tanzania, United Republic of, [3]United States Agency for International Development, USAID Boresha Afya - Southern Zone Program, Dar es Salaam, Tanzania, United Republic of, [4]Deloitte Consulting Limited, USAID Boresha Afya - Southern Zone Program, Dar es Salaam, Tanzania, United Republic of

Background: Life Long ART for Pregnant and Lactating women (LLAP-LA) reduces the risk of HIV transmission from mother to child. This depends on mothers' ARV medication adherence. Early Infant Diagnosis (EID) is critical in determining the success of the PMTCT interventions. However, EID for HIV Exposed infants (HEI) has been a major challenge in Tanzania because of the difficulty in reaching the HEIs. In this study, USAID Boresha Afya Southern Zone program assessed EID performance in the project supported facilities.
Methods: Pregnant positive women identified at ANC are followed up till delivery and thereafter as mother-infant pair till 'final outcome' is determined. HEIs are offered DNA-PCR test for EID at 1- 2 months of age. Mother-infant pair that missed the test are then tracked and brought back. EID annual program data (October 2016 - September 2017) from 599 supported facilities in five supported southern regions was extracted from DHIS2 and analyzed using Excel and MedCalc software. Risk of HIV acquisition among HEIs was compared to the time of the DNA-PCR HIV test. The positivity for the two groups was compared and risk assessed using Odds Ratio (OR).
Results: Out of 599 facilities data reviewed, 343 reported on EID. 4619 (94%) out of 5,569 HEIs registered were tested and 137 were found HIV positive with the positivity rate 2%. 84% of HEIs tested within 2 months of age while 16% tested at age 2 - 12 months. Among the tested HEI, those between 2 and 12 months of age had significantly higher positivity rate (7%) compared to HEIs age less than 2 month of age (2%). The Odds Ratio (OR) for HIV acquisition among the group that tested at age less than 2 months was 0.24 (CI 0.17- 0.33), p-value of < 0.0001.
Conclusions: The risk of HIV acquisition was lower among those tested early compared to those tested late (tracked and brought back). The mothers' poor adherence to EID appointment is a sign of poor ART adherence, thus explains the high acquisition rate among HEIs that tested late. Emphasis on medication adherence which should be evidenced by regular clinic appointments is very key.

				Age Less than 2 months			Age 2 - 12 months		
Period	Registered	Total Tested	Positive	Tested	Positive	Positivity	Tested	Positive	Positivity

Screening tools to identify children and adolescents living with HIV: Increasing case finding in high HIV prevalence settings

J. Dunlop, S. Untiedt, C. Makura, L. Levin
Right to Care, Paediatric Programme, Johannesburg, South Africa

Background: South Africa has an HIV prevalence of 2.7% in children aged 5-14 years. While there are existing guidelines for testing children for HIV testing, these are poorly implemented. This screening tool, comprised of ten questions derived from the guidelines and integrated management of childhood illnesses manual, aimed at assisting healthcare workers to identify high risk children for being HIV-infected when they presented to health facilities in Johannesburg, South Africa.
Methods: The screening tool was implemented between April and September 2017 by child and adolescent HIV counsellors at eight health facilities. Screening was performed on children 0-19 years at health facilities, with children 5-14 years being targeted. Excluded on pre-screening were those known to be HIV-infected and those who had tested HIV-negative in the last six months. An unknown HIV status led to screening using the ten questions with a single positive answer being considered a positive screen. They were then consented, counselled and tested for HIV.
Results: Of the 604 children pre-screened, 22 (3.6%) were known to be HIV-positive, 79 (13.1%) were HIV-negative in the last six months and 503 (83.3%) had an unknown HIV status. Of those with an unknown HIV status, 388 (77.1%) had a positive screening question. Of those, 263 (67.8%) were tested for HIV and 17 were positive (testing yield 6%). The number screened to find one positive child was 30 (screening yield=3%). Of the children testing HIV-positive, 8/156 (yield=5%) were 5-9 years, followed by 6/67 19-59 months (yield=9%), 1/24 testing positive 10-14 years (yield=4%), 1/4 between 15-19 years (yield=25%) and one patient of unknown age. Of the 125 (32.2%) who did not test despite a positive screening question, 35 (28%) had the caregiver refuse, 21 (16.8%) the primary caregiver was not present and 69 (55.2%) "other" or "none stated".
Conclusions: Screening tools are useful in high HIV-prevalence settings to identify children requiring HIV testing. The highest yields were seen in children 18m to 9 years and in older adolescents, however the number tested was small (n=4). This screening tool allows HIV testing resources to be focussed on high-risk children.

Age	Total	0-18m	19-59m	5-9y	10-14y	15-19y	Not stated
Number pre-screened	604	20	167	325	75	15	2
A. Known positive	22	0	8	6	7	1	0
B. Negative in last 6 months	79	0	19	42	14	4	0
C. Unknown status	503	20	140	277	54	10	2
C.1 Screening could not be completed	28	0	8	13	7	0	0
C.2 Number with no positive screening question	87	1	7	68	7	4	0
C.3 Number with positive screening question	388	19	125	196	40	6	2
D. Number tested	287	11	67	156	24	4	1
D.1 Positive tests	17	0	6	8	1	1	1

THPEB109

Finding children and adolescents living with HIV in Johannesburg: Optimising HIV testing strategies

J. Dunlop[1], C. Tait[2], C. Fick[3], N. Chandiwana[3], L. Fairlie[3], R. Peters[2]
[1]Right to Care, Paediatric Programme, Johannesburg, South Africa, [2]Anova Health Institute, Paediatrics, Johannesburg, South Africa, [3]Wits Reproductive Health Institute, Paediatrics, Johannesburg, South Africa

Background: In high HIV-prevalence settings such as Johannesburg, South Africa, a substantial number of HIV-positive children may remain undiagnosed until clinical deterioration results in HIV diagnosis. Reasons for delayed diagnosis of older children include missed diagnostic opportunities with the previously suboptimal prevention of mother-to-child transmission (PMTCT) guidelines, poor uptake of paediatric HIV testing services and children that were known to be HIV-positive but dropped out of care. Additionally high HIV incidence rates in adolescent girls and young women are well described. The Paediatric and Adolescent Scale-up Project (PASP) sought to upscale testing of children and adolescents within primary healthcare (PHC) facilities using different approaches per age group.

Description: Between March 2016 and December 2017, HIV case finding interventions were implemented across 41 PHC facilities in Johannesburg. Children and adolescents were screened and tested when they accessed various service points by facility or PASP staff or were requested to come back for testing through index case finding by using an HIV-positive adult or sibling index patient. This data was then analysed to determine which age groups and entry points showed the highest yield.

Lessons learned: In total 14331 children and adolescents were tested, 376 were HIV-positive (yield=3%). Strategies with the highest yield included HIV testing of adolescents in primary care, (9%, n=110) particularly adolescent girls (15-19 years) accessing contraception services (15%, n=66). Index testing also had a high yield with 112/1885 (6%) HIV-positive siblings or children of HIV-infected patients, however testing uptake was low. Lower yields were seen in those < 5 years old and 5-14 years, including in acute care settings such as Integrated Management of childhood illness (IMCI) with the lowest yield in children of 18 months accessing immunisation clinics (1%; n=19).

Conclusions/Next steps: Current PMTCT implementation and immunization clinic-based early infant diagnosis testing is effective in reducing MTCT and identifying HIV-positive children. Targeted HIV-testing can improve identification of older HIV-positive children and adolescents who should particularly be offered PICT at contraception service points. Improved index case finding and testing is effective in identifying HIV-positive children and adolescents however innovative approaches for index testing are required to increase testing uptake in this high-risk group.

	Tested	Tested Positive	Yield
1. Index Patient	1885	112	6%
2. Entry Point	12446	264	2%
2.1. 15-19 years (General Clinic and Contraception Clinic)	1235	110	9%
2.1.1.Contraception Clinic	439	66	15%
2.1.2. General Clinic	796	44	6%
2.2. 5-14 years (General Clinic)	2949	68	2%
2.3. <5 years - Child Health (Immunisation clinic and IMCI)	8262	86	1%
2.3.1.Immunisation Clinic	2956	19	1%
2.3.2. IMCI	5306	67	1%

THPEB110

The impact of the family-centered approach on pediatric HIV in DRC

A. Bollinger[1], D. Chamla[2], F. Kitetele[3], F. Salamu[4], N. Putta[2], L. Tsague[5], S. Villeneuve[5]
[1]UNICEF, HIV and AIDS Section, Dakar, Senegal, [2]UNICEF, New York, United States, [3]Hospital of Kalembelembe, Kinshasa, Congo, Democratic Republic of the, [4]UNICEF, Kinshasa, Congo, Democratic Republic of the, [5]UNICEF, Dakar, Senegal

Background: Identifying HIV-positive children remains a challenge to fast-track pediatric ART in sub-Saharan Africa. In DRC, 70% of children living with HIV are not receiving ART (UNAIDS 2017); most of them have not yet been identified. While the family centered approach has been widely researched in relation to PMTCT, it has less been documented regarding outcomes for children.

Methods: Facility-based study in Kalembelembe and Heal Africa hospitals in Kinshasa and Goma, that employed two methodological designs: a cross-sectional review of the medical records of 748 children and 309 adults without active family HIV testing between 2008 and 2015, and longitudinal follow-up of 266 individuals with family screening using different approaches between August 2016 and February 2017.

Results: Out of 748 child index cases, 367 had 967 family members screened; 408 were found HIV-positive (42.2%) - of which 55.8% were biological mothers, 17% fathers, 16.4% siblings and 9.6% other relatives. In 60.9%, 30.3%, and 8.8% of cases, one, two and three family members were respectively found to be HIV-positive.

Among 309 adult index cases, 631 children were identified, 375 screened (59.4%) and 161 found HIV-positive (42.9%); 159 were put on treatment. 77% were found via their mother, 13.7% their father, 1.2% siblings and 1.2% other relatives.

Of 266 patients (182 children), 717 family members were identified, 309 screened, and 115 identified HIV-positive (38.2%). 91.5% accepted family testing (22% said they would do it later); the majority refused home testing (accepted by 9.3%). Biological mothers were identified in 63.7% and fathers in 18.7% of cases.

At enrollment, without active family screening, 64.2% of children were at WHO clinical stage III against 32% with active family screening.

Conclusions: Family testing improves early identification of children living with HIV, whether through adult or child index cases. Testing needs to be scaled up at health facility level as stigma still impacts on acceptance for home-based testing. While a higher proportion of children are diagnosed through adult index cases, many adults are found through children index cases, particularly biological mothers and fathers. This could have a boomerang effect on PMTCT (future pregnancies) and on children's treatment follow-up (prevention of orphanhood).

Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring in paediatric and adolescent populations

THPEB111

Pharmacokinetics of intracellular stavudine-triphosphate in children after reduced-dose: Can we improve stavudine's safety profile?

L. van der Laan[1], S. Innes[2], M. de Kock[3], P. Anderson[4], M. Cotton[5], P. Denti[3]
[1]Desmond Tutu TB Centre and Family Clinical Research Unit, Paediatrics and Child Health, Cape Town, South Africa, [2]Family Clinical Research Unit (FAM-CRU), AIDS Clinical Trails Group (ACTG), Stellenbosch University, Paediatrics and Child Health, Cape Town, South Africa, [3]University of Cape Town, Clinical Pharmacology, Cape Town, South Africa, [4]University of Colorado Anschutz Medical Campus, Pharmaceutical Sciences, Colorado, United States, [5]Family Clinical Research Unit (FAM-CRU), AIDS Clinical Trails Group (ACTG), Paediatrics and Child Health, Cape Town, South Africa

Background: Stavudine is being phased out as a first-line ART option due to mitochondrial toxicity, but remains an important replacement option for HIV+ children in sub-Saharan Africa. At the recommended dose, it causes stigmatizing lipoatrophy. A lower adult dose of 20mg twice-daily maintains efficacy but with less mitochondrial toxicity. Although the adult dose was formally reduced in 2007, the children's dose was not correspondingly lowered due to concerns about efficacy. We therefore compared intracellular stavudine-triphosphate levels in children receiving a reduced dose to adults receiving 20 or 30mg twice-daily.

Methods: 24 HIV+ children and 24 HIV+ adults from South-Africa received stavudine at 0.5 mg/kg and 20mg twice-daily for 7 days, respectively. Stavudine suspension was used for children and capsules for adults. Blood samples were taken pre-dose and either at 1,2,6 or 3,4,8 hours post-dose. Intracellular stavudine-triphosphate in peripheral blood mononuclear cells was assayed using Liquid Chromatography Tandem Mass Spectrometry. A population pharmacokinetic model was developed to describe the data together with simulations to explore the effect of dose reduction in HIV+ children.

Results: Median (interquartile range) age and weight were 8(7,9) years and 23(20,26) kg in children and 36(30,40) years and 83(70,98) kg for adults. A bi-phasic disposition model with first-order appearance and disappearance described the pharmacokinetics of stavudine-triphosphate. Accounting for the effect of body size using allometric scaling based on fat-free body mass improved the model fit.

No significant differences other than those accounted for with allometric scaling were detected in any pharmacokinetic parameter between adults and children, although a non-significant trend towards children having lower bioavailability was observed.

Using a large unrelated adult dataset, simulations of 30mg twice-daily predicted similar median stavudine-triphosphate C_{min} and lower C_{max} values compared to simulations in HIV+ children receiving newly proposed weight-band dosing (0.5-0.75mg/kg).

	Adults	
Stavudine dose	30mg twice daily	0.5-0.75mg/kg twice daily
Characteristics (IQR= interquartile range)		
Median (IQR) age (years)	43 (31-56)	8 (5-9)
Median (IQR) weight (kg)	67 (56-81)	21 (16-25)
Stavudine-triphosphate concentrations		
Minimum (IQR) (fmol/10^6 cells)	14 (9-19)	14 (10-20)
Maximum (IQR) (fmol/10^6 cells)	45 (38-53)	58 (50-68)

[Simulations in HIV-infected children receiving a decreased stavudine dose compared to adults receiving the WHO recommended dose.]

Conclusions: Pharmacokinetic parameters of stavudine-triphosphate in children receiving the reduced stavudine dose of 0.5 mg/kg twice daily were similar to adults receiving 20mg twice-daily. The trend observed for a lower bioavailability in children may be due to different formulations used. Pharmacokinetic results of reduced weight-band dosing in children > 7 kg, suggest that viral suppression would be maintained with a decreased toxic effect.

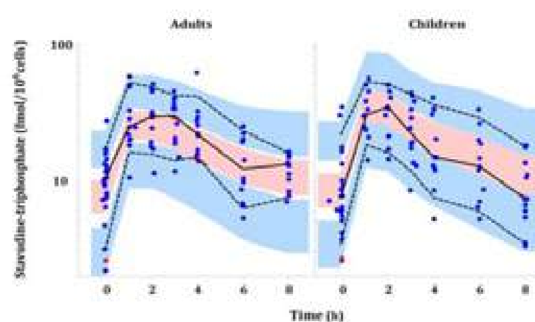

Figure 1. Visual predictive check of the pharmacokinetic model for stavudine-triphosphate stratified by children vs. adults, using 1000 simulations. Observed data are displayed as filled circles, including censored data points (LLOQ) in red. The solid and dashed lines represent the 10th, 50th and 90th percentiles of the observed data, while the shaded areas (pink and blue) are the model-predicted 90% confidence intervals for the same percentiles. The lines summarising the observed values are generally contained within the respective confidence intervals, indicating that the model fits the data well.

[Visual predictive check of the pharmacokinetic model for stavudine-triphosphate stratified by children vs. adults, using 1000 simulations.]

Drug formulations for infants and children

THPEB112

Implementing lopinavir/ritonavir pellets in Mbabane Swaziland: A better solution to the bitter solution?

J. Petrus[1,2], M. Beneus[1,2], M. Hlathswayo[2], N. Mthethwa[3]
[1]Baylor College of Medicine, Houston, United States, [2]Baylor Childrens Foundation Swaziland, Mbabane, Swaziland, [3]Swaziland National AIDS Program, Mbabane, Swaziland

Background: Adherence to Lopinavir/ritonavir (LPV/r) solution in young children living with HIV is challenging due to poor palatability. LPV/r pellets were developed as a hopeful alternative formulation. Tolerability and efficacy of pellets has not been widely documented. Here we describe a pilot of LPV/r pellet implementation within our clinic of children living with HIV in Mbabane, Swaziland.

Methods: 21 children cared for at the Baylor Centre of Excellence in Mbabane, Swaziland were transitioned from LPV/r solution to LPV/r pellets between November 2016- December 2017 due to intolerance, detectable viral load (DVL) or caregiver request. Caregivers were shown a video of pellet administration and were given specific instructions from the medical team. If appropriate, viral load was taken prior to and after the switch. Follow-up evaluations occurred 2-4 weeks post-initiation whereby adherence and tolerability were assessed by pill count and caregiver report.

Results: 21 children were initiated on pellets; 17/21 (81%) of caregivers requested return to solution or transition to tablet. Average age of all children was 2.1 years. Mean days prior to discontinuation was 62 but 10/17 (59%) stopped within 15 days. Of those returning to solution, the average age and dosage was 2.1 years, with a dose of 3.7 pellets twice daily. The reason given for 17/17 (100%) was spitting of the pellets. Adherence data for 6 children seen 3 months before and after initiation was unchanged. 6 children had VL before and after pellet initiation, mean VL log on solution was 3.6 vs. 4.3 on pellets. No children with DVL on solution suppressed or had a > 1 log decline in VL. One child became detectable after pellet initiation and resuppressed back on solution. 4 children were switched to nevirapine solution after intolerability of both formulations.

Conclusions: Among patients transitioned to pellets 81% of caregivers preferred LPV/r solution over pellets. No children with a DVL on LPV/r solution became undetectable or had a significant decline in VL on pel-

lets. Further work is needed to improve pellet administration techniques in order to improve the use of this formulation and retain it as a viable option for our most vulnerable children living with HIV.

THPEB113

Medication errors with Retrovir oral solution in neonates and infants ≤ 23 months

T. Perger[1], B. Shepherd[2], M. Shaefer[3], C. McCoig[4], K. Hayward[1], J. Double[2]
[1]ViiV Healthcare, London, United Kingdom, [2]GlaxoSmithKline, London, United Kingdom, [3]ViiV Healthcare, Research Triangle Park, United States, [4]ViiV Healthcare, Madrid, Spain

Background: Zidovudine (ZDV) is indicated for prevention of maternal-foetal HIV transmission in HIV-positive pregnant women and for primary prophylaxis of HIV infection in infants. Retrovir oral solution/syrup (OS) is available in 50mg/5mL concentration and the prophylactic dose in infants is 2mg/kg (0.2mL/kg) every 6 hours for 6 weeks, i.e. very small volumes of OS are required. Medication errors with ZDV OS was reviewed following reports of tenfold overdose in neonates.
Methods: Cumulative review of ZDV medication error from the company's safety database, disproportionality analysis and review of the published literature.
Results: Most medication error cases reported overdose (59%), most of which occurred in paediatrics ≤ 23 months (67%) using OS formulation. Characteristics of these cases are presented in Table 1. Most of the cases were from France, US, UK and Germany. 73% of cases reported a tenfold overdose. Majority of these were serious - mostly due to hospitalisation or prolongation of hospitalisation - and reported in young newborns. Consistent with the known safety profile of ZDV, the most commonly reported serious adverse events were anaemia, elevated liver enzymes and neutropenia. Most cases were resolved, resolved with sequelae or improved. Three cases were unresolved and two were fatal (one reported hyperlactataemia, the other neutropenia as ZDV associated events). While the underlying reasons were unclear or not reported in many cases, the use of an inappropriate sized syringe or confusion between mg and ml were reported in some.
ZDV overdose was not reported with a higher frequency relative to background reporting in the safety database.
While earlier articles identified in the literature indicated intentional overdoses in adults, a few, more recent publications reported unintentional overdose in neonates during prophylaxis, reflecting the change in ZDV use over time.
Conclusions: In the context of a large post-marketing exposure, tenfold neonatal overdose is rarely reported with ZDV. Sources of error leading to overdose are multifactorial and tenfold medication errors have been reported as a risk in children in general [Doherty, 2012]. Care should be taken when administering small doses of ZDV OS to neonates, including using an appropriate sized syringe, to ensure accurate dosing.

Patient Age (81%[1])	Range	Years	Birth (0) - 1.42
	Median	Days	4
Report Source	Health Care Professional	%	73
	Non-Health Care Professional /Consumer	%	27

Emergence of resistance in HIV-1 Integrase (IN) following dolutegravir (DTG) treatment in 6 to 18 year old participants enrolled in the P1093 study

C. Vavro[1], T. Ruel[2], A. Wiznia[3], C. Alvero[4], S. Popson[5], T. Fenton[4], R. Hazra[6], E. Townley[7,8], A. Buchanan[1], P. Palumbo[9]
[1]ViiV Healthcare, Research Triangle Park, United States, [2]University of California, San Francisco, United States, [3]Jacobi Medical Center, Bronx, United States, [4]Harvard School of Public Health, Statistical & Data Analysis Center, Boston, United States, [5]Frontier Science and Technology Research Foundation (FSTRF), Inc, Amherst, United States, [6]Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), Pediatric, Adolescent and Maternal AIDS Branch, Bethesda, United States, [7]Division of AIDS NIAID/NIH, Maternal Adolescent Pediatric Branch, Rockville, United States, [8]Ctr. Columbus Technologies and Services Inc, Rockville, United States, [9]Dartmouth-Hitchcock Medical Center, Division of Infectious Diseases and International Health, Lebanon, United States

Background: P1093 is a phase I/II, multicenter, open-label pharmacokinetics (PK), safety, dose-finding study of DTG plus optimized background regimen in adolescents and children. Cohorts I and II (12-< 18 and 6-< 12 years old) have completed recruitment. Herein is provided an instream review of virologic failure (VF) for Cohorts I and II and the emergence of integrase strand transfer inhibitor resistance (INSTI) while receiving a dolutegravir containing regimen.
Methods: VF for P1093 is defined as confirmed decrease in HIV-1 RNA (VL) of < 1.0 log_{10} at/after week 12 (unless < 400c/mL), or confirmed >400c/mL at/after Week 24, or confirmed >400c/mL after initial confirmed < 400c/mL or confirmed >1 log_{10} increase above VL nadir (nadir =>400c/mL) At confirmed VF, population and clonal integrase (IN) genotypes and phenotypes and IN replication capacity (RC) were investigated. Adherence was assessed by 3-day recall per visit, and communication with site PI.
Results: P1093 recruited 23 participants each in Cohort I(tablets), and Cohort IIA (tablets) and 15 participants in Cohort IIB (dissolvable granules). VF rates were 12/23, 6/23, and 1/15, respectively. VF was associated with lack of adherence in most cases. For each cohort, treatment emergent INSTI resistance was detected in 2/12, 0/6, and 1/1, respectively. One participant (Cohort I) acquired R263R/K and remained on study for an additional >2 years with subsequent accumulation of additional linked IN substitutions and a modest increase in DTG susceptibility. Two participants acquired G118R mutations, one with L74M and G118R (Cohort I) and one with G118R and E138E/K (Cohort IIB). For each of these latter two participants, DTG susceptibility was decreased by 36- and 12-fold, respectively. A clonal analysis for each participant provides additional linkage information for the INSTI resistance detected (table). Median IN RC are provided, however, they were performed on HIV-1 IN only and may not provide complete characterization of viral fitness.

Patient/ Cohort	Timepoint	HIV-1 RNA c/mL	Clones Tested	IN Linked Substitutions/# clones	Clonal DTG Median FC	Clonal Median IN RC%
1*/Cohort I	Pre-treatment	7739	8	L74V / 4 clones;L74I / 1 clone; L74L / 3 clones	0.97	81
	Week 36	9978	8	R263K / 4 clones; V201I / 3 clones; V201I, R263R / 1 clone	1.26	97
	Week 136	1367	16	A49G, M50V, V201I, R263K / 12 clones; A49G, M50V, E138T, S147G, V201I, R263K / 4 clones	5.25	38
2/Cohort I	Pretreatment	17996	8	WT / 8 clones	0.98	88
	Week 192	1758	8	L74M, G118R / 8 clones	36	8
3/Cohort IIB	Pretreatment	96369	8	V151V / 8 clones	0.84	147
	Week 52	3313	8	V151I, G118R / 8 clones	12	26
*Results previously presented IAS 2015; FC = Fold Change; RC=Replicative Capacity						

[Table 1]

Conclusions: Among 6-18 year old participants receiving DTG containing regimen, INSTI resistance developed in 3 of the 19 who experienced VF. INSTI resistance in these children followed either of two mutational pathways, R263K and G118R, the latter having a greater impact on reduced DTG susceptibility.

Background: In the PROMISE 1077BF trial, breastfeeding women with CD4 >350 cells/mm^3 (or >country-specific ART threshold if higher) and their uninfected neonates were randomized to maternal ART (mART) or infant nevirapine prophylaxis (iNVP) until breastfeeding cessation or 18 months post-delivery, (whichever occurred first) and had low infant HIV-1 infection rates (0.7% overall). We assessed whether maternal viral load (MVL) or CD4 were associated with perinatal HIV transmission risk.
Methods: MVL was measured retrospectively on batched specimens collected at entry (7-14 days postpartum) and weeks 6, 14, 26, and 50 postpartum. CD4 was measured real-time at entry and weeks 14, 26, 38, and 50 postpartum. Infant HIV-1 NAT was obtained at weeks 1, 6, every 4 weeks until week 26, then every 12 weeks. Infant infection was defined as a positive HIV-1 NAT at any two post-entry timepoints. The associations of baseline and time-varying MVL and CD4 with transmission risk were assessed using proportional hazards regression models by randomized treatment arm, with MVL categorized as < 1000 or ≥1,000 copies/ml and CD4 categorized as < 500 or ≥ 500 cells/mm^3, and adjustment for mART receipt during pregnancy.
Results: 2431 mother-infant pairs were randomized. Baseline MVL and CD4 are shown in Table 1. Baseline MVL (p= 0.11) and CD4 (p=0.51) were not significantly associated with infant HIV-1 infection. Time-varying MVL was significantly associated with infant HIV-1 infection in the mART arm (hazard ratio (95% CI): 12.04 (2.54, 57.06) but not in the iNVP arm (hazard ratio (95% CI): 1.04 (0.20 - 5.52)). Time-varying CD4 was not significantly associated with infant HIV-1 infection in either arm (hazard ratio (95% CI): 0.29 (0.05-1.59) in mART arm and 0.33 (0.07-1.57) in iNVP arm). Of 7 postnatal infections in mART arm, 2 had proximal MVL< 40 copies/ml.
Conclusions: With iNVP, MVL was not significantly associated with HIV-1 transmission during breastfeeding. However, among women receiving mART, increased MVL during breastfeeding was associated with increased risk of infant HIV-1 infection. These data emphasize the important role of adherence to mART in controlling MVL and preventing infant infection and suggest that iNVP should be considered in situations with documented poor maternal ART adherence.

	mART n=1,220	iNVP n=1,211
Baseline CD4 count		
< 500 cells/mm3	162 (13%)	170 (14%)
≥ 500 cells/mm3	1,058 (87%)	1,041 (86%)
Baseline Maternal Viral Load		
<400 copies/mL	672 (55%)	604 (50%)
400 - 1,000 copies/mL	239 (20%)	210 (17%)

THPEB116

Developmentally tailored adolescent HIV research: Perspectives from the National Institute of Mental Health

S. Allison[1], T. Senn[1], L. Stubbs[1], P. Brouwers[2]
[1]National Institute of Mental Health, Rockville, United States, [2]NIMH/NIH, Rockville, United States

Background: Adolescents and young adults (AYA) are some of the most vulnerable around the world for acquiring HIV and, among those who are living with HIV, AYA experience some of the worst outcomes along the HIV care continuum. As such, AYA are a high priority for HIV prevention and treatment research at the Division of AIDS Research at the National Institute of Mental Health (NIMH/NIH).
Description: The past two decades have seen an increase in developmentally appropriate HIV prevention and care interventions for AYA, with greater attention to AYA's cognitive abilities and social context. However, disparities in HIV acquisition and HIV health outcomes continue to exist for AYA. Our understanding of adolescence continues to grow and there have been a number of recent findings in adolescent development that have implications for AYA HIV research. For example, research has suggested that some adolescent risk behavior may be due, in part, to the more gradual maturation of cognitive control networks coupled with heightened sensitivity in neural reward systems. Future AYA HIV intervention research should capitalize on these recent findings from adolescent development research to design novel, developmentally-appropriate interventions.
Lessons learned: This presentation will review recent advances in adolescent development that have implications for AYA HIV research, review key developmental constructs from the individual to the structural that could benefit from increased attention in AYA HIV research, and discuss developmentally appropriate research approaches.
Conclusions/Next steps: Through greater attention to the unique developmental context of AYA, HIV prevention and care research will have a greater impact on the health of AYA who are vulnerable to acquiring HIV and those living with HIV.

Immune activation in ART-naïve youth (ages 12-24) with acute or established HIV and high-risk seronegative populations from LA and New Orleans ATN cares: Preliminary results

J. Dock[1], R. Cortado[1], T. Kerin[1], K. Mitchell[1], J. Fournier[2], L. Kozina[2], B. Andrews[2], E. Arnold[3], M.J. Rotheram-Borus[4], S.E. Abdalian[2], K. Nielsen-Saines[1], Y. Bryson[1]
[1]David Geffen School of Medicine, University of California Los Angeles, Department of Pediatrics, Infectious Disease, Los Angeles, United States, [2]Tulane University School of Medicine, Department of Clinical Pediatrics, New Orleans, United States, [3]University of Central Florida, Center for Behavioral Health Research and Training, Orlando, United States, [4]Semel Institute for Neuroscience and Human Behavior, University of California Los Angeles, Department of Psychiatry and Behavioral Sciences, Los Angeles, United States

Background: Recent adult studies indicate early potent ART during acute HIV infection may reduce viral reservoir size, disrupt residual replication, mitigate chronic immune activation/dysregulation and facilitate better long-term HIV control. There is limited data on the large population of HIV infected and high-risk youth. In the ATN CARES study we assess the effect of early potent ART in acutely-infected (AI) youths (ages 12-24) vs established infection (EI) on enhanced immune normalization, viral suppression and reservoir size. Youths treated during AI may have an enhanced immune response presumably due to elevated thymic function and a more naïve immune profile.

Methods: Point-of-care assays screen/detect high-risk youth who are newly diagnosed with acute HIV and ARV naïve (Fiebig 1-6) or established infection > 6 months. In AI, ART is initiated and biomarkers are assessed serially. Three populations of high-risk youth included: ARV-naïve AI, EI and SN controls. Biomarkers assessed from peripheral blood: cell-surface markers of T cell activation/dysregulation, plasma markers of immune activation, pro-viral HIV-DNA, and TCR stability and repertoire perturbation.

Results: To date we have assessed cell surface markers of immune activation/dysregulation by flow cytometry on 31 high-risk youth with AI (n=3), EI (n=5) and high-risk SN controls (n=23). At baseline, AI and EI youth have elevated T cell markers of activation/dysfunction compared to high-risk SN controls (Table 1). Additionally, AI youths have a higher degree of immune activation/dysregulation than EI youths (Table 1). Preliminary follow-up of AI youth (1-3 months following infection) have shown reductions in immune dysregulation/activation and HIV viral RNA. Interestingly, the high-risk SN population had significantly lower CD4:CD8 ratio and higher markers of CD8 T cell activation than an older HIV negative adult population (ages 24-67) (Table 1).

Conclusions: This study demonstrates elevated levels of immune activation in AI and EI youth, which is mitigated by ART, and may help assess long term effects of early ART intervention in AI vs EI. In addition, the increase in immune activation in the high-risk SN group suggests that this population may be at higher risk of acquiring HIV due to young age, behavioral risk factors (STD, drugs) or both.

	AI (n=3) [mean]	EI (n=5) [mean]	SN (n=23) [mean]	SN Adult (n=39) [mean]

Culturally-relevant and personalized disclosure intervention improves pediatric HIV status disclosure in Ghana: The Sankofa randomised controlled trial

E. Paintsil[1], T. Kyriakides[2], S. Antwi[3], L. Renner[4], A. Catlin[5], G. Gan[2], M. Lartey[4], N. Reynolds[6]
[1]Yale University, Pediatrics, New Haven, United States, [2]Yale University, New Haven, United States, [3]Komfo Anokye Teaching Hospital, Kumasi, Ghana, [4]University of Ghana School of Medicine and Dentistry, Accra, Ghana, [5]Purdue University, West Lafayette, United States, [6]Johns Hopkins University, Baltimore, United States

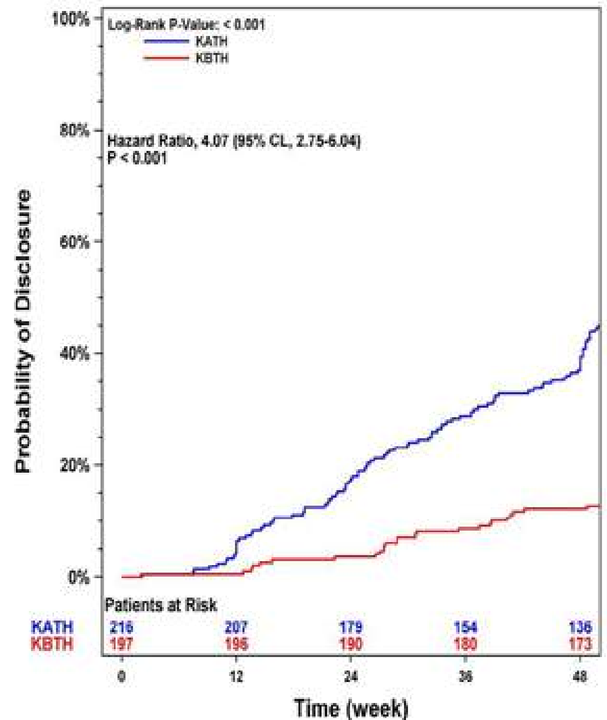
Background: Perinatally HIV-infected children now have access to life-saving antiretroviral therapy (ART) globally and are expected to live into adulthood. Changes in other inter-related elements of pediatric care such as disclosing their HIV status are also needed. We hypothesized that a theory-guided, structured, culturally-relevant, and personalized disclosure intervention would lead to an increase in HIV status disclosure at 48 weeks.

Methods: We randomly assigned two sites in Ghana, one to (Komfo Anokye Teaching Hospital, Kumasi) to receive the Sankofa Pediatric Disclosure intervention and the other (Korle-Bu Teaching Hospital, Accra) to receive enhanced usual care. HIV-infected children aged 7 to 18 years and their caregivers were enrolled. The intervention contained two key elements to target well-documented, modifiable barriers to promote disclosure:

(a) an **ad**herence and **d**isclosure **s**pecialist (**ADDS**); and;

(b) disclosure as a process.

We followed the caregiver-child dyads and assessed the primary outcome (disclosure of HIV to children). All analyses were carried out using a modified intention-to-treat approach. This trial is registered with ClinicalTrials.gov, number NCT01701635.



[Kaplan-Meier plot of pediatric disclosure at 48 weeks by sites (KATH, intervention; KBTH, control)]

Results: Enrollment was from January 23, 2013, to June 30, 2016, and we completed follow up on June 30, 2017. We enrolled 446 child-caregiver dyads (240 at intervention site and 206 at control site). 52% of the children were male, mean age 9.78 (±2.27) years. Compared to the control group, the intervention group had a statistically significant increase in HIV status disclosure at all study time points (12, 24, 36, and 48 weeks) (all p< 0.001). Disclosure at 48 weeks was significantly higher in the intervention group compared to the control group (52% vs 16.24%; p<0.001). Children to whom their HIV status was disclosed by week 48 were more

than 5 times likely to have been in the intervention group than the control group (OR=5.45, 95% CI, 3.43, 8.66). After adjusting for study site (p<0.001), age <11 years (p<0.001), HIV-infected caregiver (p< 0.001), and caregiver's education (p=0.01), the measure of association remained at the same magnitude and statistical significance (adjusted OR=5.11; 95% CI, 3.03, 8.62).
Conclusions: We demonstrate that barriers to disclosure by caregivers can be mitigated by structured, culturally-relevant, and personalized disclosure intervention.

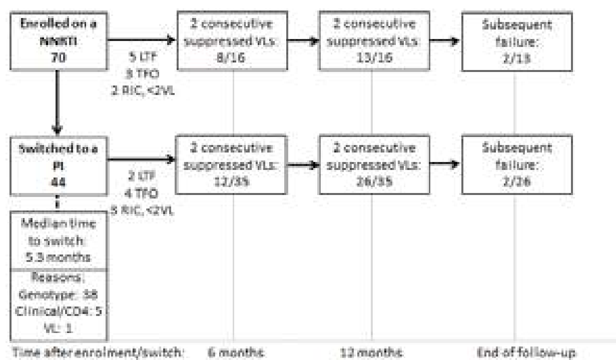
ARV management strategies in paediatric and adolescent populations

THPEB119

Time to Switch? Outcomes of children and adolescents failing NNRTI regimens

T. Cassidy[1,2], R. O'Connell[1], T. Makeleni[1], V. de Azevedo[3], T. Schulz[4], N. Dumile[1], M. Mantangana[1], S.J. Steele[5], N. Mkhosana[1], L. Trivino Duran[1], A. Boulle[6], J. Bernheimer[1]
[1]Médecins Sans Frontières, Khayelitsha, Cape Town, South Africa, [2]University of Cape Town, Division of Public Health Medicine, School of Public Health and Family Medicine, Cape Town, South Africa, [3]City of Cape Town, Department of Health, Cape Town, South Africa, [4]KESS, Western Cape Provincial Health Department, Cape Town, South Africa, [5]Médecins Sans Frontières, Cape Town, South Africa, [6]University of Cape Town, CIDER, School of Public Health and Family Medicine, Cape Town, South Africa

Background: Many children and adolescents failing ART do not access second line therapy in a timely manner. Delays in returning to clinic for confirmatory viral load testing and adherence support prior to treatment switch as required under current guidelines may contribute to delayed switching. Among those who resuppress on first line regimens the durability of resuppression is uncertain. Since 2013, Médecins Sans Frontières has run an enhanced adherence intervention program to address treatment failure in patients 0-19 years in Khayelitsha, South Africa. We describe the outcomes of participants who entered the program failing an NNRTI regimen.
Methods: Participants were enrolled from 2013-2016. Failure was defined as VL>1000 copies/ml once, or >400 on two consecutive occasions. The intervention included: clinical care, genotype, and adherence support via individual and group counseling. ART regimen change was indicated for clinical (advanced HIV), genotypic or virologic reasons. Program success was defined as VL< 400 on two consecutive occasions.
Results: Of 192 participants, 70 enrolled on an NNRTI (5-19 yrs; 53% male; median CD4 524; median time on ART: 4.3 yrs[IQR:2-7.6]). Of the 70 on an NNRTI, 44 switched to a PI (see Figure 1).



[Figure 1: Viral suppression among those switching and those remaining on a NNRTI.]

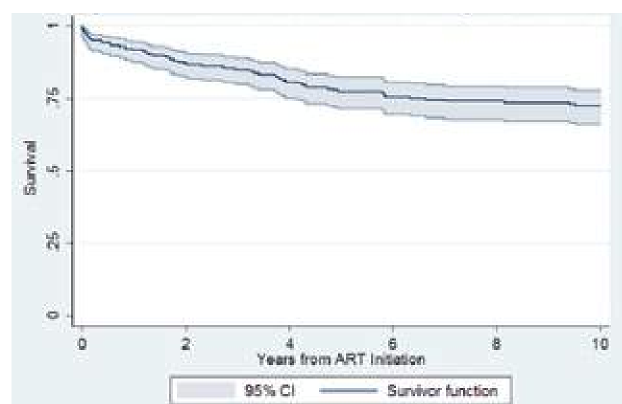
Median time to switch 5.3 months [IQR:3.3-6.4]. Reasons for switch included confirmed NNRTI resistance (n=38) and advanced HIV on entry (n=5). Those who switched were comparable to those who did not in terms of median baseline CD4 (525[IQR:293-797] vs 613 [IQR:442-903]) and age(13.1[IQR:11-15 vs 13.5[IQR:10-16]). Of the 26 who did not switch, 16 remained on an NNRTI for at least 2 VLs, of whom 13 suppressed with enhanced adherence alone. Of these 13, subsequent failure was seen in 2 participants.
Conclusions: Less than 20% of those failing an NNRTI in this programme achieved resuppression without a change of regimen. The need for a second VL among children failing an NNRTI should be reconsidered. During the continuation of our program, we aim to implement rapid switch after one VL>1000 and advocate for dolutegravir as a more robust first line treatment.

THPEB120

Who are the 10-year pediatric AIDS survivors on antiretroviral therapy in Haiti?

V. Rouzier[1], V. Rivera[1], L. Reif[2,3], E.J. Joseph[1], L.C. Francois[1], N. Alcenat[1], B. Charles[1], G. Julmiste[1], E. Abrams[4], D. Fitzgerald[2], J.W. Pape[1,2], M. McNairy[2]
[1]GHESKIO, Port-au-Prince, Haiti, [2]Weill Cornell Medicine, New York, United States, [3]Columbia University, New York, United States, [4]ICAP at Columbia University, New York, United States

Background: Access to antiretroviral therapy (ART) has significantly expanded in resource-poor settings, but long-term pediatric outcomes have not been reported. We describe the 10-year outcomes of the first cohort of children initiating ART in Haiti.
Methods: Children 0-15 years who initiated ART from 2003-2005 at GHESKIO were included. Retention was defined as in care 10 years from ART initiation; lost to follow-up (LTF) was defined as no visit >6 months from the 10-year date of ART initiation; death and transfers were ascertained from medical records. Viral suppression was defined as HIV-1 RNA < 1,000 copies/ml. Kaplan-Meier methods estimated survival. Risk factors were assessed using Cox modeling. Patients retained in care were interviewed on socioeconomic characteristics and assessed for viral load.
Results: Among 259 children, 54% were female, and median age 6 years (IQR 3-10). Median CD4% for patients < 2 years was 21% (IQR 17-26%); median CD4 count for children ≥2 years was 419 cells/uL (IQR 104-705), and 73% of all children had advanced WHO Staging (III/IV). 99% reported vertical transmission.
Ten years after ART initiation, 130 (50%) were retained, 63 (24%) were LTF, 64 (25%) had died, and 1% transferred care for an estimated 10-year survival of 72.4% (95% CI 64.7%-77.2%) (Fig 1).



[Figure 1. Cumulative Survival of Pediatric Patients Initiating ART 2003-2005]

Median time to death was 2 years (IQR 6.7 months to 4.2 years), and median age at death was 15 (IQR 11-18) after the majority of teens transitioned from the pediatric clinic. 85 patients (65% of 130 10-year survivors) completed a 10-year survey. Among this subgroup, median age was 16 (IQR 14-19), 54% were female, and median CD4 count was 606 cells/uL (IQR 398-853).
Half remained on first-line therapy, 61% were virally suppressed, and 33% had stunting (< -2 SD height-for-age by sex). CD4 count ≤200 cells/uL at ART initiation was the only significant predictor of death (p< 0.05).

Conclusions: This analysis documents the effectiveness of an ART program among the first cohort of pediatric ART patients in the region. Excellent survival rates are tempered by suboptimal attrition from care and high mortality during the transition to adolescence underscoring the importance of effective transition models of HIV care.

THPEB121

Impact of anti-retroviral therapy on the immune status of HIV-infected children

X. Bi[1], A. Ishizaki[1], T.B. Nguyen[2], D.T. Nguyen[2], H.P. Nguyen[2], L.V. Nguyen[2], H.V. Pham[2], C.T.T. Phan[2], T.T.B. Phung[2], A.N. Pham[2], D.T.K. Khu[2], H. Ichimura[1]
[1]*Kanazawa University, Ishikawa, Japan,* [2]*National Hospital of Pediatrics, Hanoi, Vietnam*

Background: In a previous cross-sectional study of HIV-infected children, we reported that HIV infection caused a rapid decrease in regulatory T-cells (Treg) and early activation of CD8$^+$ cells, and antiretroviral therapy (ART) induced rapid Th1 recovery and early CD8$^+$-cell activation normalization. This study aimed to investigate the impact of ART on the immune status of HIV-infected children prospectively.

Methods: We have conducted a prospective study at the National Hospital of Pediatrics in Hanoi, Vietnam since 2014. Fifty-four HIV-infected children who newly started ART have been recruited, but 12 dropped out (11 died and 1 stopped ART) by 6 months after ART initiation. The immune status of the remaining 42 children (median age: 3.9 years, range 0.1-12.5 years; female/male 17/25) was analyzed every 6 months. Forty-nine HIV-uninfected children were recruited as healthy control (median age: 4.4 years, range 0.1-12.1 years; female/male 24:25). The CD4$^+$-cell subsets were identified using cell-surface markers: T helper type 1 (Th1, CXCR3$^+$CCR6$^-$CCR4$^-$CD4$^+$), Th2 (CXCR3$^-$CCR6$^-$CCR4$^+$CD4$^+$), Th17 (CXCR3$^-$CCR6$^+$CCR4$^+$CD4$^+$), and Treg (CD25$^+$CD127$^-$CD4$^+$). The activated CD8$^+$-cell were defined as CD38$^+$HLA-DR$^+$CD8$^+$. Wilcoxon signed-ranks test and Mann-Whitney test were used for statistical analysis with SPSS-v23.

Results: Before and after 6 (n=21), 12 (n=23), 18 (n=20), 24 (n=13) months of ART (ART0/ART6/ART12/ART18/ART24), the CD4$^+$-cell counts were 304/894/1039/934/886 cells/µl (control: 1379 cells/µl), Th1: 27/73/88/85/77 (93), Th2: 19/46/53/56/47 (77), Th17: 6/22/28/19/14 (32), and Treg: 23/51/74/71/62 (113), and the activated CD8$^+$-cell proportion was 47.6%/19.7%/13.2%/10.0%/11.4% (8.2%). Before ART, the CD4$^+$-cell and -subset counts were significantly lower than those of control, and the activated CD8$^+$-cell proportion was significantly higher than that of control (all $P< 0.05$). After ART initiation, the CD4$^+$-cell and -subset counts significantly increased, particularly Th1 recovered to control level at ART6, while the activated CD8$^+$-cell proportion decreased significantly and reached control level at ART18. The increased number of CD4$^+$-cells at ART6/12 was associated positively with CD4$^+$-cell counts, but negatively with the age of children at ART0.

Conclusions: Our results indicate that ART induced rapid Th1 recovery and early normalization of CD8$^+$-cell activation in HIV-infected children, and that ART should be initiated as soon as possible after HIV diagnosis in children, as WHO guideline 2016 recommends.

Immune status			HIV-infected			HIV-uninfected

Improving ART initiation among HIV-infected infants in Manzini region of Swaziland

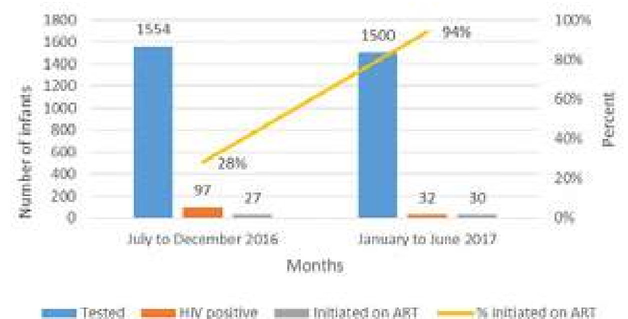
A. Mutiti[1], F. Tsiouris[2], W. Reidy[2], S. Mkhatshwa[1], N. Nxumalo[1], N. Mthethwa[3], R. Mudekereza[1], A. Kidane[1]
[1]*ICAP at Columbia University in Swaziland, Mailman School of Public Health, Mbabane, Swaziland,* [2]*ICAP at Columbia University Mailman School of Public Health, New York, United States,* [3]*Ministry of Health, Mbabane, Swaziland*

Background: Routine HIV testing for HIV-exposed infants (HEI) and prompt ART initiation for HIV-infected infants are both critical to prevent early HIV-related morbidity and mortality. However, in the Manzini Region of Swaziland, while HIV testing coverage among HEI routinely exceeds 95%, only 27% percent of infants diagnosed with HIV in July-December 2016 were initiated on ART. We describe efforts between key stakeholders to determine reasons for low ART initiation among HIV-infected infants in Manzini, and develop and implement interventions to increase timely ART initiation within this population.

Description: From January-June 2017, Swaziland Ministry of Health Regional Health Management Team for Manzini, health facility staff and ICAP, collaborated to conduct a rigorous data-driven performance review and bottleneck analysis of ART initiation among HIV-infected infants in Manzini. This effort informed the design and implementation of interventions, including intensified tracking strategies of HIV-infected infants from the laboratory to facility and community as well as mentorship on infant ART initiation. Additionally, program data reported for early infant diagnosis was validated with the information from laboratory and facility registers to identify reporting errors and improve their accuracy.

Lessons learned: Collaboration between key stakeholders was essential to effectively identify problems across health system elements (e.g., laboratory, facilities) that contributed to low infant ART initiation, and design and implement system-wide strategies to improve performance. A key tool was the use of testing to treatment data cascades, from blood sample collection, laboratory testing, identification of HIV-infected infants to ART initiation. Implementation of active tracking of infected infants was a critical intervention. Overall, ART initiation coverage reached 94% (30/32) for infants aged between 6 weeks -11 months diagnosed with HIV in January-June 2017. Finally, the program data validation identified and eliminated double counting of confirmatory DNA PCR tests.

Conclusions/Next steps: New HIV infections among infants remain evident and efforts must be made to find these infants through early infant testing. High coverage of early and timely ART amongst infants with HIV-infection is feasible provided, health care teams continue to monitor and improve, using quality data, outcomes of early infant diagnosis and ART initiation among this sub-population.



[Infant testing to treatment Cascade]

Cure strategies in paediatric and adolescent populations

THPEB123

Utilization of weekly short message service (SMS) surveys to identify vulnerable youth with acute HIV Infection: ATN CARES project

S.-J. Lee, M. Koussa, E. Almirol, W. Tang, D. Swendeman, M.J. Rotheram-Borus, Adolescent Medicine Trials Network (ATN) CARES
University of California, Psychiatry and Biobehavioral Sciences, Los Angeles, United States

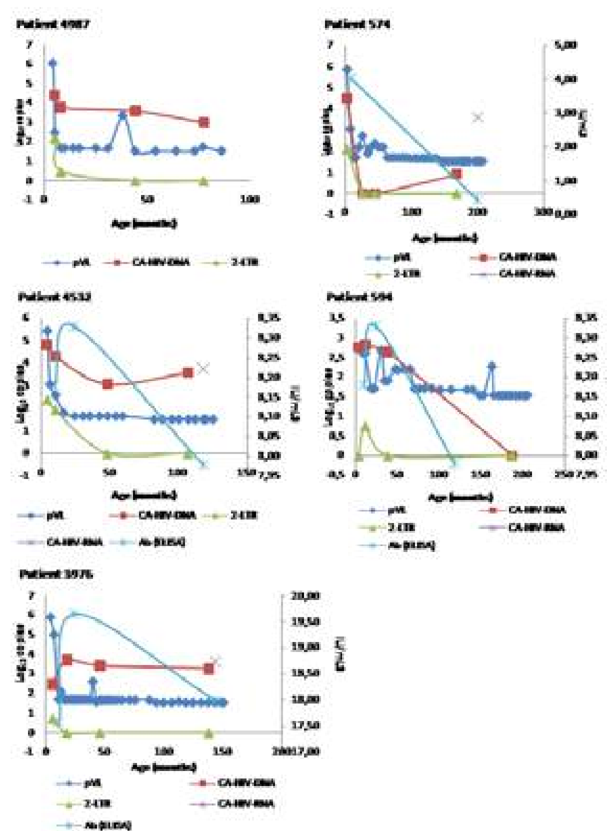
Background: The Centers for Disease Control and Prevention (CDC) estimates that 22% of new HIV infections diagnosed in 2015 were among youth 13 to 24 years of age. Early treatment of HIV infection in this vulnerable group may reduce the severity of acute disease, lower the viral set point, reduce the size of the viral reservoir, delay disease progression, and decrease the rate of viral mutation. However, because most are unaware of their HIV status, identifying acute/recent infections among youth is extremely challenging.
This study highlights ATN CARES' utilization of weekly short message service (SMS) to identify youth 12-24 years of age with acute HIV-infection.
Methods: Youth 12-24 years of age are being recruited through community based organizations serving the homeless, incarcerated, and LGBT youth in Los Angeles and New Orleans. For youth enrolled in the HIV-negative study, we administered a weekly SMS 7-item survey as part of an HIV biobehavioral intervention. HIV-like symptoms were asked as part of the 7-item SMS survey.
Results: To date, ATN CARES enrolled 506 HIV-negative youth and 469 had so far received at least one SMS survey. During the 7-month enrollment period, 262 participants responded to a weekly SMS survey at least once (56%). Among the 262 SMS responders, 157 participants reported potential HIV-like symptoms at least once via the weekly SMS survey (60%).
Once the HIV-like symptoms are reported, the field staff contacted participants for follow-up HIV test. A significantly higher proportion of youth with HIV-like symptoms concurrently reported no condom use (60%), compared to those who did not report symptoms (33%) (p< 0.01).
Those who reported HIV-like symptoms reported a significantly higher history of attending substance abuse treatment program (24%), compared to those who did not report symptoms (11%) (p< 0.01). Among those that came in for follow-up testing, all were HIV-negative.
Conclusions: To date, ATN CARES successfully recruited 11 youth with acute/treatment naïve recent HIV-infections. Despite the high false positive rates of HIV, the weekly SMS survey strategy holds promise to consistently engage and monitor vulnerable HIV-negative youth over time. This strategy optimizes timely identification of youth and enhances our efforts to achieve early treatment.

THPEB124

High level of circulating HIV-1 reservoirs in perinatally HIV-1 infected children with early effective antiretroviral therapy and sustained virological suppression

M. Moragas[1], D. Mecikovsky[2], R. Bologna[2], F. Salama[3], P. Aulicino[1], A. Mangano[1]
[1]Hospital de Pediatría 'Prof. Dr. Juan P. Garrahan', Laboratorio de Biología Celular y Retrovirus - CONICET, Buenos Aires, Argentina, [2]Hospital de Pediatría 'Prof. Dr. Juan P. Garrahan', Servicio de Epidemiología e Infectología, Buenos Aires, Argentina, [3]Hospital de Pediatría 'Prof. Dr. Juan P. Garrahan', Laboratorio Central, Buenos Aires, Argentina

Background: Early effective antiretroviral therapy (ART) limits circulating HIV-1 reservoirs, which is a goal for remission strategies. Our aim was to investigate the impact of early virological suppression (VS) on HIV-1 reservoir size in perinatally HIV-1-infected children with early ART initiation and more than six years of VS.
Methods: This study included 5 perinatally HIV-1 infected children ART-treated and followed up during sustained VS. Cell-associated HIV-1 DNA (CA-HIV-DNA) and two LTR (2-LTR) circles level were analyzed longitudinally: previous to ART initiation, at VS and throughout VS. Cell-associated unspliced HIV-1 RNA (CA-HIV-RNA) level was measured at last visit (after 6 years of VS). All these markers were quantified by semi-nested real time PCR. Antibody level was measured longitudinally (around 24 month of life, at VS and at last visit) using a commercial ELISA. All data were expressed as median (range).
Results: All infants received AZT as prophylaxis for 6 weeks, started ART and achieved VS at 4 (2-7) and 10 (8-11) months of life, respectively. Reservoir size, plasma viral load (pVL) and antibody measurements were illustrated per patient in Figure 1. CA-HIV-DNA showed a little decrease from ART initiation to last visit [time of VS 11 (6-16) yrs]: 4 (2.5-4.8) and 3 (0-3.6) log10 copies per million of peripheral blood mononuclear cells (cpm), respectively. The 2-LTR circles were detected in all, except one, patient at ART initiation [2.11 (0-2.4)], but it was undetectable in most cases throughout VS. Surprisingly, CA-HIV-RNA was detectable at last visit in all patients with a median of 3.6 (1.5-3.76) log10 copies per microgram of RNA. Finally, only one patient had absence of antibodies against HIV throughout the study, considered as a pediatric seroreversion case.
Conclusions: The size of circulating HIV reservoir in perinatally HIV-1 infected with more than 6 years of VS was still high for remission strategies. The high level of CA-HIV-RNA indicates viral activity despite sustained undetectable pVL. This work support the need for a very fast ART initiation, may be during the firsts hours of life, in order to limit significantly the reservoir size and HIV-1 potential replication.



[Figure 1]

Adherence in paediatric and adolescent populations

THPEB125

Characterizing adherence and drug level effects on viral outcomes in HIV-infected Kenyan children

R. Vreeman[1,2,3], W. Nyandiko[2,3], A. DeLong[4], M. Coetzer[5], J. Aluoch[2], C. McAteer[1,2], E. Sang[2], A. Ngeresa[2], S. Ayaya[2,3], J. Hogan[2,6], R. Kantor[5]
[1]Indiana University School of Medicine, Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indianapolis, United States, [2]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [3]College of Health Science, Moi University, Department of Child Health and Paediatrics, Eldoret, Kenya, [4]Brown University, Department of Molecular Biology, Cell Biology and Biochemistry, Providence, United States, [5]Warren Alpert Medical School of Brown University, Medicine, Providence, United States, [6]Brown University, Department of Biostatistics, Providence, United States

Background: In resource-limited settings, associations between pediatric antiretroviral therapy (ART) adherence and viral outcomes are not well-characterized, yet are important to inform interventions. We investigated such associations in perinatally-infected children in Kenya with extensive adherence monitoring.
Methods: Children ≤15 years on or starting NNRTI-based 1st-line ART were enrolled at the Academic Model Providing Access to Healthcare in Kenya. Adherence monitoring included MEMS® electronic monitors, drug levels and validated caregiver questionnaires. Nevirapine (NVP) or efavirenz (EFV) were placed in monthly-monitored MEMS® that electronically captured dose timing data. Blood samples were drawn after 1-3 months (timepoint 1; TP1) for NVP/EFV levels, CD4%, viral load (VL), and resistance, and after 6 months (TP2) for VL. MEMS® adherence was characterized by
(1) > or < 90% doses taken (bottle openings divided by doses prescribed); and
(2) treatment interruptions (TI; >48 hours without opening).
Associations between adherence measures and viral outcomes, adjusting for confounders and other enrollment characteristics, were done using logistic regression models.
Results: Among 207 children, 54% female, median age 8.4 years (range 1.8-15.1), 59% CDC class B/C, median CD4% 26 (range 1-53), on ART mean 2.1 years (range 0.04-8.4), 80% were on NVP-based ART, and 20% EFV. At TP1, 33% (n=68) had treatment failure (VL>1000 copies/mL); 45% had MEMS adherence < 90%, 31% had TI, 21% missed ART doses in past 30 days by caregiver report, and 14%/38%/48% had sub-therapeutic/therapeutic/supra-therapeutic drug levels. Treatment failure was significantly associated with < 90% MEMS adherence, younger age, less time on ART, lower CD4%, TI, and low NVP level. Of the 32/68 with ART failure who had genotyping, 81% had intermediate-high resistance to ≥1 drug. All had high resistance to current ART, and 75% to potential 2nd line ART, including 12% tenofovir, 19% etravirine, 56% rilpivirine. Among 176 children with VL at TP2, 15% had VL>1,000, significantly associated with < 90% MEMS adherence, viral failure at TP1 and TI.
Conclusions: Treatment failure among HIV-infected Kenyan children was associated with less than 90% adherence and TI, with high drug resistance among those failing. Interventions improving pediatric adherence could sustain ART.

THPEB126

Video directly observed therapy to improve adherence of human immunodeficiency infected children and adolescents to combination antiretroviral therapy: A pilot study

N. Nashid[1,2], F. Kordy[1], S. Khan[3,4], S. Read[1,2], G. McDougall[1], D. Louch[1], C. Arneson[1], S.A. Bitnun[1,2]
[1]The Hospital for Sick Children, Pediatric Infectious Diseases, Toronto, Canada, [2]University of Toronto, Pediatrics, Toronto, Canada, [3]McMaster University, Pediatric Infectious Diseases, Hamilton, Canada, [4]Hamilton Health Sciences, Hamilton, Canada

Background: Poor adherence to antiretroviral therapy (ART) is a major problem for adolescents living with HIV. We conducted a pilot study evaluating the feasibility and acceptability of using video directly observed therapy (VDOT) as a method of improving medication adherence in poorly adherent adolescents.
Methods: HIV infected adolescents with a history of poor adherence to ART were eligible for inclusion. The study consisted of four phases: VDOT daily (4 months), daily texting (2 months), weekly texting (3 months) and no intervention (3 months). Monthly clinic assessments were scheduled. Study is ongoing.
Results: Five of 8 eligible subjects consented to participate (median age 17 years [16-19]; 3 male, 2 female). All were perinatally infected and had dual (n=4) or triple class (n=1) resistance. Four were on drug holidays for 5-9 months pre-enrollment. Median baseline viral load and CD4 count were 6,342 copies/mL (82-34,657) and 218 cells/µL (72-265), respectively. Four participants achieved viral suppression in the VDOT phase and one came close (40 copies/ml). Three participants maintained viral suppression during the daily and weekly texting phases. Thus far, the two participants in the no intervention phase have maintained viral suppression. Two participants were withdrawn from the study due to protocol non-compliance during the daily texting phase. During the VDOT phase, the proportion of doses observed taken per-participant ranged from 42% to 98% (n=5). For the daily texting phase, text responses indicating medication taken were received for 96.7%, 85.2% and 44.4% of doses (n=3). For the weekly texting phase, text responses indicating medication taken were received for 91%, 91%, and 83% of doses (n=3). Two subjects fully complied with monthly pill count requirements - this showed 100% and 93% of pills taken (first three phases combined). Participants expressed general satisfaction with the intervention. Healthcare providers felt the intervention was at times burdensome.
Conclusions: VDOT is feasible and acceptable as an intervention to both adolescents living with HIV and care providers to improve adherence in select populations. Barriers to success include variable compliance and time burden for service providers.

THPEB127

Barriers and facilitators to retention in care for adolescents living with HIV in Western Kenya

L.A. Enane[1,2], E. Apondi[3], J.J. Toromo[2], C.I. McAteer[1,2], W.M. Nyandiko[2,4], R.C. Vreeman[1,2,4]
[1]Indiana University School of Medicine, Pediatrics, Indianapolis, United States, [2]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [3]Moi Teaching and Referral Hospital, Eldoret, Kenya, [4]Moi University College of Health Sciences School of Medicine, Child Health and Paediatrics, Eldoret, Kenya

Background: Adolescents living with HIV (ALHIV, ages 10-19) experience poor rates of retention in care, resulting in poor clinical outcomes and HIV-associated mortality. As a global "treat all" strategy is implemented, it is critical to strengthen retention of vulnerable patients in HIV care. We sought to define barriers and facilitators to retention experienced by perinatally infected ALHIV in western Kenya.
Methods: This qualitative study was performed at Moi Teaching and Referral Hospital (MTRH) in Eldoret, Kenya, and the associated HIV treatment clinic, AMPATH MTRH Centre. We purposefully sampled ALHIV and caregivers of ALHIV from the following groups: hospitalized ALHIV (both engaged in care and not currently engaged in care) and ALHIV en-

gaged in outpatient care. A trained facilitator conducted semi-structured key informant interviews and focus group discussions (FGDs) in Kiswahili. These were recorded, and transcripts were coded by 2 study team members and analyzed through thematic analysis.

Results: We conducted interviews with 6 hospitalized ALHIV, 16 caregivers of hospitalized ALHIV, and 11 non-disclosed engaged ALHIV; 8 FGDs with 55 disclosed engaged ALHIV; and 4 FGDs with 28 caregivers of engaged ALHIV. Among 116 ALHIV and caregivers of ALHIV, barriers to retention included the following complex and frequently concomitant issues: poverty; maternal illness or death resulting in other relatives taking on the adolescent's care; non-disclosure to the adolescent or to close family members; family conflict; social isolation and stigma; and mental health challenges. Younger ALHIV were particularly vulnerable to these challenges experienced at the family level. Transportation costs were a frequently reported barrier. Relationships to clinic staff were influential to retention or disengagement from care. Facilitators to retention included motivation to be healthy, HIV education, peer groups, disclosure to the adolescent and to family, and the support that this enables. Participants desired more counseling and education about HIV, access to peer groups and disclosure support, and nutritional and financial support.

Conclusions: Retention and disengagement of ALHIV are influenced by complex, interwoven barriers at the levels of the adolescent, family, clinic, and society. Interventions are needed to mitigate these barriers for those ALHIV at high risk of disengagement.

THPEB128

Targeting the third "90": Are children and adolescents slipping through the net?

G. McHugh[1], V. Simms[2], E. Dauya[1], T. Bandason[1], H. Mujuru[3], S. Munyati[1], H. Weiss[2], A.M. Rehman[2], J. Odland[4,5], R. Ferrand[1,2]

[1]Biomedical Research and Training Institute, Harare, Zimbabwe, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]University of Zimbabwe, Harare, Zimbabwe, [4]Arctic University of Norway, Tromso, Norway, [5]University of Pretoria, Pretoria, South Africa

Background: Achieving virological suppression is critical to ensure optimal outcomes and prevent onward transmission among people living with HIV (PLHIV). We investigated viral suppression among children and adolescents aged 6-19 years who were receiving antiretroviral therapy (ART) treatment for at least six months in public sector HIV clinics in Harare, Zimbabwe.

Methods: Participants were recruited at Harare Central hospital, from June 2016-December 2017. Socio-demographic and HIV history were recorded and CD4 count and viral load were measured. Risk factors for virological failure (viral load ≥400 copies/ml) were analysed using multivariate logistic regression to estimate adjusted odds ratios (aOR) and 95% confidence intervals (CI).

Results: All 155 participants recruited were perinatally infected. Just under half (n=69; 45%) were female, and the median age was 15 (IQR 12-17) years. The median age at ART initiation was 8 (IQR 5-11) years. The median duration on ART was 6 (IQR 4-8) years, with 58 (37%) taking second-line ART. The median CD4 count was 580 (IQR 366-801) cells/mm^3. Half the participants (n=81; 52%) were virally non-suppressed. The median viral load of those non-suppressed was 4,310 (IQR 1,360-43,100) copies /ml. Adolescents 12 years and older were more likely to have virological non-suppression than those under 12 years old (aOR=2.85; 95%CI 1.24-6.56). Being on second line ART was also associated with virological non-suppression (aOR=2.21; 95%CI 1.11-4.38). Sex and duration on ART were not associated with viral non-suppression

Conclusions: Adolescents are a high-risk group for virological non-suppression despite being established on treatment and on second line ART therapy. Interventions to support adolescents to adhere and manage their HIV infection are urgently required to ensure an AIDS free generation but also to prevent onward HIV transmission.

THPEB129

The paediatric continuum of HIV care in the Netherlands: From diagnosis in childhood to viral suppression in adulthood

C. Smit[1], T. Wolfs[2], T.S. Boender[1], A. van Rossum[3], P. Reiss[1,4,5], on behalf of the ATHENA National Observational HIV Cohort

[1]Stichting HIV Monitoring, Amsterdam, Netherlands, [2]UMCU, Department of Paediatrics, Wilhelmina Children's Hospital, Utrecht, Netherlands, [3]Erasmus MC, Department of Paediatrics, Sophia Children's hospital, Rotterdam, Netherlands, [4]Academic Medical Center, and Amsterdam Center for Infection and Immunity, Department of Internal Medicine, Division of Infectious Diseases, Amsterdam, Netherlands, [5]Academic Medical Center, and Amsterdam Institute for Global Health and Development, Department of Global Health, Amsterdam, Netherlands

Background: In the Netherlands, a substantial proportion of children diagnosed with HIV have survived into adulthood. We analysed the outcomes of children with an HIV diagnosis < 18 years of age along the continuum of HIV care (CoC).

Methods: We constructed the CoC for HIV-1-positive individuals who were ever registered < 18 years of age within the ATHENA cohort between 1998 and 2016. Key steps were being:

1) linked to care,
2) retained in care (clinical visit in 2016),
3) on cART,
4) viral suppression (most recent HIV RNA < 100 copies/ml).

Individuals were stratified by age (< /≥ 18 years on 31 December 2016) and HIV-transmission route (vertically-acquired or not).

Results: As of 31 December 2016, 525 individuals had been diagnosed with HIV in childhood, were linked to care, still alive and not reported as having moved abroad. Of these, 204 were < 18 years of age (median 10 years; IQR 7-15) of whom 193 (95%) acquired HIV through MTCT, 154 (75%) were of non-Dutch origin and 109 (53%) were adopted by Dutch parents. Given the low number of 11 children aged < 18 years who non-vertically acquired HIV, these were excluded from the analysis. Among the 321 individuals who were ≥18 years of age (median 29 years; IQR 23-33), 112 (35%) had acquired HIV through MTCT, and 209 (65%) through other means (sexual transmission (n=158), blood-blood contact/drug use (n=36), unknown transmission route but diagnosed when aged>5 years (n=15)), with 69% of the total being of non-Dutch origin. Figure 1 illustrates the CoC for the subgroups; Overall viral suppression rates were 93% in those aged < 18 years, and in those aged ≥18 years, 73% and 65% for those who had acquired HIV vertically and non-vertically, respectively.

Conclusions: The provision of HIV care for children aged less than 18 years has resulted in a high viral suppression rate. However, targeted attention is needed for those currently ≥18 years, particularly those with non-vertically acquired HIV, given much lower viral suppression rates. This illustrates challenges for long-term treatment adherence, which may be of a different nature in those who vertically or behaviourally acquired HIV.

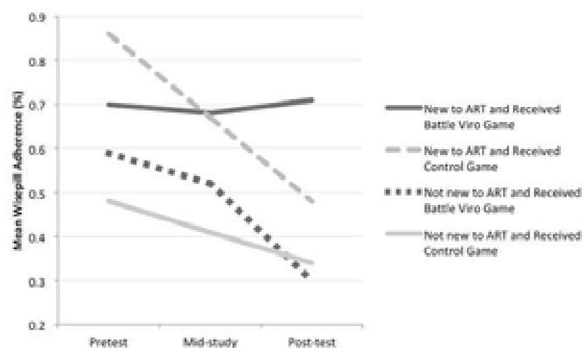
An iPhone app improves medication adherence and viral load among youth living with HIV who are newly starting antiretroviral therapy

L. Whiteley[1], L. Brown[1], L. Craker[1], A. Lowery[1], T. Arnold[2], L. Mena[2]
[1]Rhode Island Hospital / Brown University, Providence, RI, United States, [2]University of Mississippi Medical Center, Jackson, United States

Background: In 2015, youth, ages 13-24, accounted for over 8,000 new HIV infections in the United States. Despite promising outcomes of antiretroviral therapy (ART) medications, improving adherence to ART among youth living with HIV (YLWH) has been challenging. This study examines the moderators of intervention impact of an iPhone game/app on ART adherence and biological outcomes among YLWH in Jackson, MS.
Methods: A RCT with 61 YLWH tested the impact of *Battle Viro*, an ART-related iPhone game, over six months. Participants, ages 13-26, were recruited from HIV clinics and randomly assigned to receive *Battle Viro* or a non-HIV related mobile game. All participants received a medication monitoring device. These analyses explore the impact of moderating variables (newly starting ART, age, gender, and gaming frequency) on ART knowledge and attitudes, adherence and viral load. Chi-square and t-test analyses examined baseline differences between conditions. Continuous outcomes were examined using analyses of covariance (ANCOVAs) controlling for baseline scores. Cohen's *d* effect sizes were calculated.
Results: The sample was 79% male, 75% Black, and 74% non-heterosexual, with a mean age of 22 years. Those newly starting ART (≤ 3 months on ART) represented 36% of the sample. Only time on ART showed interaction effects at the 6-month follow-up. Those newly starting ART in the *Battle Viro* condition experienced a 0.96 log greater decrease in viral load ($F=4.33$, $p=0.04$), showed better adherence at the 6-month post-test (71% vs 48%; $d=1.18$, $F=3.20$, $p=0.05$; see figure below). In ANCOVAs restricted to participants newly starting ART, those in the intervention demonstrated improved HIV knowledge ($d=0.90$; $F=3.23$, $p=0.09$) and ART knowledge ($d=0.73$; $F=1.59$, $p=0.22$) compared to those in the control condition.
Conclusions: The *Battle Viro* intervention showed improved adherence and viral load outcomes at the 6-month follow-up among those newly starting ART. These results support the need for a larger trial to further explore the impact of *Battle Viro,* particularly among YLWH newly starting ART.



[Figure 1. Wisepill Adherence by Intervention Condition by Newly Starting ART]

Challenges to achieving and maintaining sustained viral suppression among HIV infected Canadian children

F. Kakkar[1], J. Brophy[2], T. Lee[3], M. Hawkes[4], L. Samson[5], S. Read[6], H. Soudeyns[7], A. Bitnun[6], EPIC4 Study Team
[1]CHU Sainte-Justine, University of Montreal, Infectious Diseases, Montreal, Canada, [2]Children's Hospital of Eastern Ontario, University of Ottawa, Pediatrics, Montreal, Canada, [3]Canadian HIV Trials Network, Vancouver, Canada, [4]Storey Children's Hospital, University of Alberta, Paediatrics, Edmonton, Canada, [5]Children's Hospital of Eastern Ontario, University of Ottawa, Pediatrics, Ottawa, Canada, [6]The Hospital for Sick Children, University of Toronto, Pediatrics, Toronto, Canada, [7]University of Montreal, Microbiology and Immunology, Montreal, Canada

Background: One of the keys to post-treatment control (viral remission) is thought to be sustained viral suppression (SVS) after early initiation of combination antiretroviral therapy (cART). The objective of this study was to identify predictors of SVS among children in the Early Pediatric Initiation of cART Canada Child Cure Cohort (EPIC[4]).
Methods: The EPIC[4] cohort prospectively enrolled Canadian children living with perinatal HIV from 7 centers beginning in 2014, with the primary objective of quantifying the HIV reservoir in these children. Using data collected retrospectively at enrollment, the proportion of children who had achieved and maintained viral suppression (SVS) were compared, and predictors of SVS determined. Non-SVS was defined as ≥ 1 viral load rebound after ≥ 2 consecutive undetectable viral load (VL) measures at any time after cART initiation.
Results: 211 children were enrolled; mean age was 11.7 years (range 2.2-23 years). Nineteen children were treatment naive; among those on treatment, 44% were on NNRTI, 30% on protease inhibitor, and 26% on integrase inhibitor-based regimens. Only 18.8% were on their initial cART regimen, 21.6% were on their second, and 59.6% had had three or more regimens. Mean age at cART initiation was 4.0 years (SD=4.2) and mean proportion of life on effective cART was 46% (SD: 0.31). Fifty-six percent of children who initiated cART prior to enrollment had achieved SVS, while 33% reported at least one period of previous poor adherence. Children with SVS were more likely to be foreign born than Canadian born (85% vs. 67%, $p=0.03$), and less likely to have received social assistance (9% vs. 29%, $p=0.01$) or to have child protection services involvement (60% vs. 85%, $p< 0.01$). There was no significant difference in SVS according to gender or baseline viral load. There was a higher proportion of SVS among those with any protective HLA allele (from among HLA-B57, HLA-B81, HLA-B27 vs. none, 90 vs. 73%), though not statistically significant ($p=0.12$).
Conclusions: Only 56% of children enrolled in the EPIC[4] cohort achieved SVS. While adherence remains the overwhelming barrier to SVS, broader social determinants including income level and family disruption were identified important potential contributing factors.

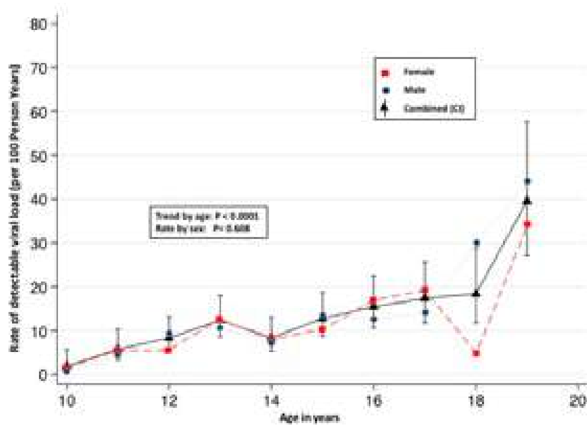
THPEB132

Patterns of detectable viral load in a cohort of HIV-positive adolescents on HAART in Cape Town, South Africa

R. Sher[1], S. Dlamini[2], R. Muloiwa[1]
[1]University of Cape Town, Department of Paediatrics and Child Health, Cape Town, South Africa, [2]University of Cape Town, Division of Infectious Diseases and HIV Medicine, Department of Medicine, Cape Town, South Africa

Background: Despite improved treatment and access to care, adolescent AIDS deaths are decreasing more slowly than in any other age group. There is lack of longitudinal data around adolescent adherence and the dynamics of viraemia over time. We aimed to describe patterns of detectable viral load (DVL) in a cohort of adolescents attending an ARV clinic in Cape Town, South Africa.
Methods: We conducted a retrospective cohort study of all patients on HAART aged 10-19 years. Participants were included if they underwent at least two viral load (VL) measurements and attended the Groote Schuur Hospital HIV Clinic for at least 24 months between 2002 and

2016. The primary outcome was two consecutive HIV viral VL >100 copies/ml, in line with the lower limit of detection of assays in use over the follow-up period.
Results: Of 482 screened subjects, 327 met inclusion criteria. Most subjects were vertically infected (n= 314; 96%), and 170 (52%) were male.
Overall, 203 episodes of confirmed DVL involving 159 (49% [95% CI 43%-54%]) subjects were experienced during the follow-up period. A total of 111 (34%) subjects never experienced DVL, while 16 (5%) never suppressed throughout the follow-up period. Median age at first DVL was 14 (IQR 11-16) years. Of the 159 subjects who experienced DVL, 102 (64%) re-suppressed, of which 38 (37%) had a subsequent DVL.
Six subjects had genotyped resistance to protease inhibitors. Four of these never suppressed, while two suppressed on salvage regimens.
Total follow-up time was 1723 person years (PY), of which 880 (51%) were contributed by the 159 subjects who experienced DVL. Overall time with DVL was 370 PY which comprised 22% of total follow-up time, but 42% of those who experienced DVL.
The rate of DVL was 11.8 (95% CI 10.3-13.5) episodes per 100 PY. The risk increased by 24% for each year of increasing age (RR 1.24 [95% CI 1.17-1.31]; p< 0.0001). Figure 1.
Neither prevalence, duration nor rate of DVL was influenced by gender.
Conclusions: DVL was seen in nearly half of adolescents, with the rate increasing with age. Further study is warranted to correlate these findings with risks and clinical outcomes.



[Figure 1: Rates of detectable viral load by age and sex of adolescents]

THPEB133

Health literacy as a predictor of biological markers of immune functioning in youth with HIV

C. Lynn[1], T. Chenneville[2], K. Bradley-Klug[3], A. St. John Walsh[4], R. Dedrick[3], H. Drake[2], C. Rodriguez[4]
[1]University of South Florida, Education and Psychological Studies, Miami, United States, [2]University of South Florida St. Petersburg, Department of Psychology, St. Petersburg, United States, [3]University of South Florida, Education and Psychological Studies, Tampa, United States, [4]University of South Florida, Department of Pediatrics, Tampa, United States

Background: The definition of health literacy (HL) includes one's ability to acquire information and make health-related decisions. Studies of adults living with HIV have shown a robust relationship between HL and objectively measured treatment adherence and self-reported biological indicators. However, research is needed on HIV-related HL among youth. Thus, the current study explored HL among youth living with HIV (YLWH) and the association between HL and health outcomes.
Methods: Participants included 102 YLWH aged 13 to 25 recruited from an HIV specialty clinic. Participants completed the Brief Estimate of Health Knowledge and Action-HIV Version (BEHKA-HIV) comprised of Knowledge and Action subtests. Biological markers of immune functioning were extracted from the medical record. Data were analyzed using descriptive statistics and multiple linear and logistic regression.
Results: Participants were evenly distributed among genders (male, 52%) and mode of transmission (perinatal, 54.9%) with a mean age of 20. Most participants were heterosexual (60.3%) and African American (67.9%). On the BEHKA-HIV Action subtest, 76.5% of participants indicated they take their medications under all conditions. Participants endorsed not taking their medication when the medications made them feel bad (13.7%), because they taste bad (9.8%), when they were feeling down or low (7.8%), because they were too tired (7.8%), and when they feel good (3.9%). On the Knowledge subtest, 44.1% gave the correct definition of CD4 count, 64.7% correctly defined viral load, 67.6% correctly named their medications, and 75.5% and 82.4% knew whether CD4 count and viral load, respectively, should go up or down as a result of treatment. HL (Knowledge and Action) was significantly associated with CD4 count and viral load. Decreasing Action scores were statistically associated with an increased likelihood of having a detectable viral load.
Conclusions: In the current study there were deficits in HL among YLWH. Findings point to the need for better patient education and support the importance of HL in determining health outcomes. It is important to measure HL beyond that of a patient's ability to read health related words. Interventions need to be designed to improve HL and, ultimately, health outcomes, particularly for YLWH.

HIV complications and comorbidities in paediatric and adolescent populations

DTI-based tractographic alterations within functional networks in HIV infected children at age 7 years

J.S. Madzime[1], M. J. Holmes[1], M.F. Cotton[2], B. Laughton[2], A.J.W. van der Kouwe[1,3], E.M. Meintjes[1,4], M. Jankiewicz[1,4]
[1]University of Cape Town, MRC/UCT Medical Imaging Research Unit, Division of Biomedical Engineering, Department of Human Biology, Faculty of Health Sciences, Cape Town, South Africa, [2]Stellenbosch University, Family Clinical Research Unit, Dept. of Paediatrics and Child Health, Cape Town, South Africa, [3]Massachusetts General Hospital, Department of Radiology, Boston, United States, [4]University of Cape Town, Cape Universities Body Imaging Centre at UCT (CUBIC-UCT), Faculty of Health Sciences, Cape Town, South Africa

Background: Despite increased access to antiretroviral therapy (ART) and early ART in children born to HIV infected (HIV+) mothers, school aged HIV+ children may still have neurologic abnormalities as well as neurocognitive delays and deficits.
Two recent functional magnetic resonance imaging (fMRI) studies in paediatric HIV+ cohorts on ART find effects of HIV infection and disease severity on functional connectivity within the default mode network (DMN) and between different networks.
Tractography is a technique used to study structural connectivity using diffusion tensor imaging (DTI) data, allowing one to examine tracts between grey matter regions.
Previously, we reported regional white (WM) abnormalities (reduced fractional anisotropy (FA) and increased mean diffusivity (MD)) and reduced functional connectivity in the DMN in 7-year-old HIV+ children on early ART compared to uninfected children. To understand how WM abnormalities relate to specific functional networks, this study used tractography to examine the properties of the WM tracts connecting grey matter regions in 12 resting state functional networks. We hypothesized lower FA and higher MD in tracts between regions of the DMN.
Methods: MRI scans were performed on 105 Xhosa and Cape Coloured 7-year-old children in Cape Town, South Africa. The participants included 59 HIV+ (age 7.2±0.1 yrs (mean age±standard deviation), 31 females, 50 Xhosa) children on ART from the Children with HIV Early Antiretroviral (CHER) study and 46 uninfected control children (age 7.3±0.1 yrs, 21 females, 37 Xhosa).
Data were processed using TORTOISE (version 3.0) and FATCAT AFNI. A multivariate group analysis was done using FATMVM comparing HIV+ to controls, controlling for gender and ethnicity. Multiple comparison correction was performed in R using the false discovery rate method.
Results: Results are summarized in Table 1.

[WM tracts showing significant differences in mean FA and MD between control and HIV+ children]

Conclusions: As hypothesized, we found higher MD and lower FA values in HIV+ children in tracts connecting regions in the DMN suggesting that loss of white matter integrity is involved in reduced functional connectivity. The reduced structural connectivity in the somatosensory, auditory and basal ganglia networks was unexpected, and may relate to previously observed reduced connectivity between these networks.

THPEB135

Prevalence and associated factors of proximal renal tubular dysfunction among perinatally HIV-infected Thai adolescents

T. Sudjaritruk[1,2], S. Kanjanavanit[3], L. Aurpibul[2], T. Chotecharoentanan[2], S. Sarachai[2], K. Sintupat[2], R. Khampan[2], NEPHRO Study Group
[1]*Faculty of Medicine, Chiang Mai University, Department of Pediatrics, Chiang Mai, Thailand,* [2]*Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand,* [3]*Nakornping Hospital, Department of Pediatrics, Chiang Mai, Thailand*

Background: The information regarding renal tubular disorders among HIV-infected youth is limited. This study aimed to identify the prevalence and associated factors of proximal renal tubular dysfunction(PRTD) among perinatally HIV-infected Thai adolescents.

Methods: This was a sub-study of a multicenter, prospective cohort study evaluating kidney diseases among HIV-infected Thai adolescents. Participants with (1) perinatally acquired HIV infection, (2) aged 10-25 years, and (3) were on combination antiretroviral treatment (cART) for ≥12 months, together with their age- and sex-matched healthy controls were enrolled (ratio2:1). HIV-infected participants were categorized as tenofovir disoproxil fumarate (TDF) users *versus* non-TDF users, according to their current cART regimens. At enrollment, proximal renal tubular function parameters, including urine 2-microglobulin to creatinine ratio (U2M/UCr), tubular reabsorption of phosphate (TRP), fractional excretion of uric acid (FEUa), and fasting urine glucose levels were measured and calculated. PRTD was defined as the presence of ≥1 abnormalities in the following criteria:

(1) 2-microglobulinuria (tubular proteinuria): U2M/UCr>1,000 mcg/g Cr;
(2) phosphaturia: TRP< 80%;
(3) uricosuria: FEUa>15%; or
(4) normoglycemic glycosuria: fasting urine glucose>25 mg/dL, while fasting plasma glucose <100 mg/dL.

Logistic regression analysis was conducted to identify factors associated with PRTD among our HIV-infected adolescents.

Results: During December 2016 to June 2017, 210 participants (140 HIV-infected and 70 healthy), with a median age of 18(IQR:15-21) years, were enrolled. Half of them(50%) were male. Among HIV-infected adolescents, almost all (99%) had World Health Organization (WHO) clinical stage 1-2, 70 (50%) were TDF users (35 were concurrently receiving protease inhibitors [PI]-based regimens), and 116 (83%) had HIV RNA<50 copies/mL at enrollment. Overall, PRTD was identified in 18 participants (9%), which was significantly higher among TDF users (*n*=13; 19%) compared with non-TDF users (*n*=4; 6%) and healthy controls (*n*=1; 1%) (*P*=0.001) (Table 1). Focusing on TDF users, the prevalence of PRTD was not different between those concurrently receiving PI-based(*n*=7; 20%) *versus* non-nucleoside reverse transcriptase inhibitor-based regimens (*n*=6; 17%) (*P*=0.76). In the multivariable analysis among HIV-infected adolescents, TDF use (adjusted odds ratio: 3.6; 95%CI:1.1-12.1) was associated with PRTD, controlling for current WHO clinical stage, immunologic status, and virologic status.

Conclusions: PRTD is relatively common among our perinatally HIV-infected adolescents. TDF use is strongly associated with this condition. Routine evaluation of renal tubular function, particularly among TDF users, is necessary to promptly identify the abnormalities.

Renal tubular abnormalities*	HIV-infected adolescents (n = 140) TDF users (n = 70)	HIV-infected adolescents (n = 140) Non-TDF users (n = 70)	Healthy adolescents (n = 70)	P-value
Proximal renal tubular dysfunction (presence of ≥1 abnormalities: β2-microglobulinuria, phosphaturia, uricosuria, or normoglycemic glycosuria)	13 (18.6%) 95% CI: 10.3-29.7%	4 (5.7%) 95% CI: 1.6-14.0%	1 (1.4%) 95% CI: 0.04-7.7%	0.001
β2-microglobulinuria (Uβ2M/UCr >1,000 mcg/g Cr)	10 (14.3%) 95% CI: 7.1-24.7%	4 (5.7%) 95% CI: 1.6-14.0%	1 (1.4%) 95% CI: 0.04-7.7%	0.01
Phosphaturia (TRP <80%)	1 (1.4%) 95% CI: 0.04-7.7%	0 (0)	0 (0)	0.37

Normoglycemic glycosuria (fasting urine glucose >25 mg/dL while fasting plasma glucose <100 mg/dL)	1 (1.4%) 95% CI: 0.04-7.7%	0 (0)	0 (0)	0.37

Abbreviations: FEUa, fractional excretion of uric acid; TDF, tenofovir disoproxil fumarate; TRP, tubular reabsorption of phosphate; Uβ2M/UCr, urine β2-microglobulin to creatinine ratio; 95% CI, 95% confidence interval.
*Data were presented as number (%).

[Table 1. Prevalence of proximal renal tubular dysfunction, β2-microglobulinuria, phosphaturia, uricosuria, and normoglycemic glycosuria among perinatally HIV-infected Thai adolescents and healthy controls]

THPEB136

Early clinical outcomes among Tanzanian children with HIV and severe acute malnutrition: A comparison between those starting ART and those starting anti-TB treatment first

J. Gwimile[1], M. Chimwanda[1], T. Roche[1], E. Batungi[1], M. Mgawe[1], A. Salum[1], S. Shea[1,2], J. Cataldi[1,2], M. Minde[1,2], L. Mwita[1,2]
[1]*Baylor College of Medicine Children's Foundation-Tanzania, Mwanza, Tanzania, United Republic of,* [2]*Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States*

Background: Children with severe acute malnutrition (SAM) and HIV have high morbidity and mortality and are at high risk of co-infection with tuberculosis (TB). This study compares clinical outcomes of children with SAM and HIV at the time of enrollment between children initiating anti-TB treatment (ATT) prior to anti-retroviral treatment (ART) and those starting ART first.

Methods: Retrospective chart review was performed to identify HIV-infected children with SAM at enrollment at the Baylor clinic in Mwanza, Tanzania from August 2011 to December 2016. Baseline nutritional status, TB risk factors, dates of ART and ATT initiation, and 6-month nutritional status and clinical outcomes were collected.
Results: One-hundred forty-seven children with HIV and SAM were identified. Eight were excluded from analysis for early transfer of care (n=2) or loss to follow-up [(LTFU) 4] or death (2) prior to starting any ART or ATT. Seventy-five percent (104/139) were < 5 years old and 48% (67) were male. Nine percent (13) had a documented TB contact and 76% (120) had at least one symptom of TB (cough, fever, weight loss, or localizing symptoms for extra-pulmonary TB). Fifty-nine percent (82) of children started treatment for TB prior to ART, and 71% (98) received inpatient care at enrollment. After six months, 9% (12) were LTFU and 17% (23) had died, with no difference in these outcomes between those starting ART or ATT first. Children starting ATT before ART had mean weight gain of 3.8kg and those starting ART first had mean weight gain of 4.2kg in the first 6 months (p=0.17).

	ART first, n=57	ATT first, n=82	Total, n=139	p-value
	n=57	n=82	n=139	chi-square test, unless indicated
Lost to follow-up	9% (5)	9% (7)	9% (12)	1.00
Died	18% (10)	16% (13)	17% (23)	0.76
Mean weight gain at 6 months in kg [SD]	3.8 [2.5]	4.5 [2.8]	4.2 [2.6]	0.17*
*t-test comparison of means				

[Clinical outcomes at six-months for children with HIV and SAM: comparison between those starting ART vs ATT first]

Conclusions: Confirming the findings of other studies, we found that children with HIV and SAM have a high risk of early mortality after enrollment in care. Diagnosis of TB in the setting of HIV/SAM co-morbidity remains challenging. Additional study is needed to define the relationship between timing of ART and ATT treatment, nutritional outcomes, and mortality among HIV-infected children with SAM.

THPEB137

Antiretroviral prophylaxis for infants of drug-resistant perinatally HIV infected (PHIV) women

M.J. Trahan[1], M.E. Metras[2], S. Valois[3], C. Renaud[4], V. Lamarre[5], F. Kakkar[5]
[1]McGill University, Obstetrics and Gynaecology, Montreal, Canada, [2]CHU Sainte-Justine, Pharmacology, Montreal, Canada, [3]Centre Maternel et Infantile sur le SIDA, Montreal, Canada, [4]CHU Sainte-Justine, University of Montreal, Microbiology and Immunology, Montreal, Canada, [5]CHU Sainte-Justine, University of Montreal, Infectious Diseases, Montreal, Canada

Background: Due to a lifetime of antiretroviral (ART) exposure and often difficulties with adherence, PHIV women may be multidrug-resistant once of child-bearing age. However, there are no guidelines for the ART prophylaxis of infants born to drug-resistant mothers. The objective of this study was to describe the ART resistance profiles of PHIV women, and specifically to the drugs recommended for prophylaxis for HIV-exposed newborns.
Methods: Clinic records from the Centre Maternel et Infantile sur le SIDA mother-child cohort in Montreal, Canada, were reviewed to identify all pregnancies among PHIV women previously followed as children at two tertiary care centers in Montreal, Quebec. Drug resistance was identified using cumulative HIV-1 mutations (extracted for all available on record) by Virco Type HIV-1 Virtual phenotype, and classified according to the HIV-resistance interpretation algorithm (Agence nationale de recherche sur le SIDA) consensus technique.
Results: There were 23 pregnancies among 12 PHIV women, resulting in 17 live births (5 terminations and 1 miscarriage.) At the first prenatal visit, 71% had a detectable viral load (range 933 - 201250 copies/ml), 53% were on ART, and 35% were immunosuppressed (absolute CD4 count < 200 cells/mm^3). While all were prescribed ART during pregnancy, at the time of delivery, 41% continued to have a detectable viral load (range 148-55 000 copies/ml), and 29% remained immunosuppressed. Cumulative drug resistance profiles were available for 10/12 women. All carried mutations conferring resistance to zidovudine (ZDV) and lamivudine (3TC), 8/10 were also resistant to Nevirapine (NVP), and 4/10 harbored mutations to protease inhibitors. In the 7 cases determined to be at high-risk of transmission due to detectable viral load at delivery, combination ART (empiric HIV therapy) was used for prophylaxis in all but one case. Specific combinations included ZDV and 3TC (1), in combination with raltegravir (3), nelfinavir (1), lopinavir/ritonavir (1) or NVP (1). None of the infants were infected.
Conclusions: The majority (80%) of PHIV women in our cohort were resistant to the standard drugs given for neonatal prophylaxis. These results suggest that for infants of PHIV women with detectable viral load prior to delivery, alternatives to the currently recommended regimens for newborns may be necessary.

THPEB138

HIV-infected patients in Shenzhen, China: Trends in mortality and cause of death from 2005 to 2017

P. Qiaoli[1], T. Xian[1], Z. Yang[1], X. Liumei[1], Z. Lukun[1], Z. Jin[2], C. Lin[2], Y. Zhengrong[2], T. Wei[2], C. Zhiwei[3], W. Hui[1]
[1]Shenzhen Third People's Hospital, Shenzhen, China, [2]Shenzhen Center for Disease Control and Prevention, Shenzhen, China, [3]University of Hong Kong, Hongkong, China

Background: The AIDS epidemic has reached its peak with an over 20% raise per year since 2010 in Shenzhen, China. Trends in mortality and cause of death in HIV-infected patients in this region have not been reported.
Methods: To study the mortality trend, causes of death and associated risk factors in a 13-year retrospective analysis among HIV-infected patients in Shenzhen, China. HIV-infected patients were followed up from January 2005 until December 2017. All deaths that occurred in Shenzhen were classified according to the Coding Causes of Death in HIV (CoDe) protocol (Version 2.3).
Results: During the past 13 years, a total of 18007 persons were tested HIV-positive in Shenzhen. 358 deaths were reported, with the crude mortality rate of 19.06%. Shenzhen has achieved the first "90%" since 2012 with the number of reported HIV infections nearly equal to the epidemic estimates in the past five years. The rate of the antiretroviral treatment coverage increased from 4.0% in 2005 to 57.2% in 2017 with viral inhibition rate more than 96%. In the mean time, the annual death rate decreased from 10.7 in 2005 to 1.7 per 1000 person-year in 2017. The death rate was 2.28 times higher in treated persons than non-treated persons. Of the 358 patients who died, 63.4% were aware of their HIV status (within 6 months before death) and only 35.8% had received HAART with viral inhibition rate at 34.4%. The median CD4 cell count at the time of death was 19 cells /mm^3. The most frequent cause of death was AIDS-related (269 deaths, 75.1%). Viral hepatitis (233 deaths, 9.2%) was the main cause of non-AIDS-related death. Cardiovascular disease (CVD) was the second most common cause of death for HAART-treated patients.
Conclusions: The mortality rate among HIV-infected individuals significantly decreased since 2005. AIDS-related causes remained the strongest factor associated with mortality in the era of HAART because of late diagnosis and treatment even when two "90%" goals have been achieved in Shenzhen. The prevention of HBV/HCV co-infection and HAART-induced cardiovascular disease are important for the control of non-AIDS related death.

THPEB139

Catch-up growth after ART initiation for late-diagnosed perinatally-infected children and adolescents

V. Simms[1], G. McHugh[2], T. Bandason[2], E. Dauya[2], S. Munyati[2], H. Mujuru[3], H.A. Weiss[1], R.A. Ferrand[2,4]
[1]London School of Hygiene and Tropical Medicine, MRC Tropical Epidemiology Group, London, United Kingdom, [2]Biomedical Research and Training Institute, Harare, Zimbabwe, [3]University of Zimbabwe, Department of Paediatrics, Harare, Zimbabwe, [4]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom

Background: Perinatal HIV infections inhibits growth through multiple pathways. Children who initiate ART before age 5 subsequently have improved height and weight z-scores but it is not known whether older children can also experience catch-up growth from ART initiation. We investigated the effect of ART initiation on growth outcomes in a cohort of late-diagnosed perinatally-infected children and adolescents in Zimbabwe.
Methods: This prospective cohort study was nested within the ZENITH randomised controlled trial. Trial participants who initiated ART during follow-up and had at least two height and weight measurements including one at ART initiation, were included. Growth measures were height-for-age, weight-for-age and body mass index (BMI), with z-scores calculated using the UK reference population. We used multilevel mixed-effects linear regression with a piecewise four-knot restricted cubic spline for time since ART initiation, and random intercept and slope. Fixed effects were age at initiation, sex and CD4 count at initiation as fixed effects, with an interaction between baseline growth measure and time. Baseline growth was categorised as below -3 z-scores; -3 to < -2; -2 to < -1; and -1 and above.
Results: The 282 participants had a mean 6.8 observations each (range 1-14) over a median 498 days follow-up (range 14-940 days). At ART initiation, the mean height-for-age z-score was -1.6 (SD 1.1) and mean weight-for-age was -1.6 (SD 1.2), both slightly lower for boys than girls. The major predictor of growth outcomes over time was z-score at ART initiation. There was no evidence of change in height-for-age or weight-for-age z-score over time, within any category of baseline growth level. For BMI, children with a baseline z-score below -2, and especially below -3, gained weight-for-height over time while those with a higher initial BMI z-score had no change (interacton term p< 0.001).
Conclusions: Children aged 6 to 15 do not recover height or weight for age when initiated on ART. Children with severe wasting gain weight-for-height in the first 12 months. These results support WHO guidelines of immediate ART initiation of perinatally-infected children, as the catch-up growth characteristic of children under 5 does not occur at older ages.

HIV-associated co-infections and malignancies in paediatric and adolescent populations

THPEB140

Characteristics and outcomes of children, adolescents, and young adults with Kaposi sarcoma treated in a comprehensive care program in Mbeya, Tanzania

L. Campbell[1,2,3], J. Slone[2,4], P.S. Mehta[2,4], N. El-Mallawany[2,4], J. Bacha[1,2,3]
[1]Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States, [2]Baylor College of Medicine, Houston, United States, [3]Baylor College of Medicine Children's Foundation - Tanzania, Pediatrics, Mbeya, Tanzania, United Republic of, [4]Texas Children's Cancer and Hematology Centers, Houston, United States

Background: Despite increasing availability of antiretroviral therapy (ART), Kaposi sarcoma (KS) remains an important HIV related malignancy in regions with high human herpes virus 8 seroprevalence, such as Tanzania. To address the needs of pediatric, adolescent and young adult (AYA) patients with KS, a comprehensive care program was established in Mbeya, Tanzania in 2011.
Methods: A retrospective chart review was conducted to describe characteristics and outcomes of patients diagnosed with KS between 1 March 2011 and 31 Dec 2017. Services provided included chemotherapy, ART, nutrition and psychosocial support.
Results: The cohort included 60 patients: 58% (35/60) male, median age 12.8 years (2.2-22.1). Clinical diagnosis was supported by histopathology in 36% (22/60). At diagnosis, 35% (21/60) had lymphadenopathic KS, 28% (17/60) had woody edema KS, 26% (16/60) had visceral and/or disseminated KS and 10% (6/60) had moderate cutaneous/oral KS. Severe anemia (Hgb < 8g/dL) was present in 28% (17/60) and severe thrombocytopenia (platelets < 50,000/mm³) was present in 22% (13/60). 97% (58/60) were HIV +, of those, 78% (45/58) were on ART for a median of 11 months (2 days -120 months). IRIS occurred in 24% (11/45). CD4 data was available for 95% (55/58), of whom 64% (35/55) met criteria for WHO severe immunosuppression. 45% (27/60) patients had severe acute malnutrition (SAM).
95% (57/60) patients were treated with chemotherapy; 3 patients died before treatment initiation. 52% (30/57) were treated with bleomycin and vincristine (BV); doxorubicin was added for 39% (22/57). Paclitaxel was given to 21% (12/57) who failed to achieve complete clinical remission (CCR) with BV or BV + doxorubicin; 1 patient was initially treated with paclitaxel. 96% (56/58) of HIV + patients were given ART. At the end of study period, 72% (43/60) patients were alive. No patients were lost to follow up; 7 transferred out. Of living patients, 67% (29/43) achieved CCR. Median follow up for living patients was 25 months (2-78) from diagnosis to end of study.
Conclusions: Despite the resource limitations that exist in southwestern Tanzania, pediatric and AYA patients with KS can be successfully treated with the majority of patients in our clinical oncology program achieving positive outcomes.

THPEB141

Prevalence and risk factors for TB/HIV co-infection in children with severe acute malnutrition (SAM) in Uganda

V. Namale ssonko[1], E. Mupere[2], J. Orikiriiza[3]
[1]Kampala International University, Peadiatrics, Kampala, Uganda, [2]Makerere University, College of Health Sciences, Pediatrics, Kampala, Uganda, [3]Infectious Disease Institute, College of Health Sciences, Peadiatrics, Kampala, Uganda

Background: Tuberculosis and Human Immunodeficiency Virus (TB/HIV) co-infection is very high in Africa with a prevalence of 30% - 50%. The diagnosis of paediatric TB remains very difficult especially in the presence of HIV and severe acute malnutrition (SAM).
There is paucity of information on burden of TB/HIV in children with SAM. We aimed to study the prevalence and factors associated with TB/HIV co-infection among SAM children in Mulago Hospital, Kampala-Uganda.
Methods: This was a cross sectional study that consecutively enrolled children aged 1-5 years fulfilling study criteria between November 2016 and March 2017. A questionnaire, appropriate HIV test, *Mycobacterium tuberculosis* rifampicin (MTB RIF) gene x-pert on early morning gastric aspirates, a tuberculin skin test (TST), anthropometric measurements and chest x-ray were performed on all children. HIV positive children who fulfilled criteria for TB diagnosis were considered to have TB/HIV co-infection.
Results: A total of 173 children were then enrolled with male to female ratio of 1.3. Prevalence of TB/HIV co-infection was 20.2% (35/173) with overall HIV prevalence of 32.9% (57/173) and only 53% (30/57) were on ART at time of enrolment despite 83% (47/57) having been diagnosed prior to enrolment. TB diagnosis was made in 33.5% (58/173) with clinical diagnosis contributing 86% (50/58) and only 12% (7/58) having positive gene x-pert. Only 21% (6/27) of the children with a positive history of contact had been started on Isoniazid prophylaxis therapy (IPT). Of the 35 children diagnosed with TB/HIV co-infection, 31% had consolidation and 28% had hilar lymphadenopathy on chest x-ray.

Risk factors associated with TB/HIV co-infection included history of positive TB contact AOR 10.7, (95% CI: 3.9-34.9), hypothermia AOR 10.7, (95% CI: 1.5-51.6), lymphadenopathy AOR 11.3, (95% CI: 2.1-39), hepatomegaly AOR 6.2 (95% CI: 1.5-14.5) and a chest x-ray showing miliary TB AOR 2.81,(95% CI: 3.07-550).
Conclusions: Prevalence of TB/HIV co-infection is still very high among SAM children with most delaying to initiate HIV treatment. Clinicians should strengthen implementation of the existing guidelines and have a high index of suspicion for co-infection among malnourished HIV positive children.

Behavioural health outcomes in paediatric and adolescent populations

THPEB142

To study the status of HIV disclosure in children and adolescents

A. Hemal, R. Meena, S. Ppal
PGIMER, Dr RML Hospital, New Delhi, India

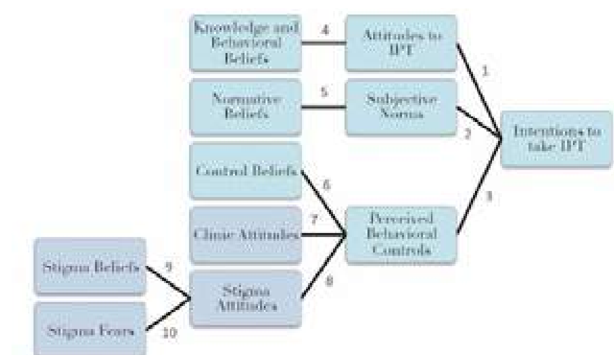
Background: Disclosure to HIV-infected children regarding their diagnosis is important as expanding numbers of HIV-infected children attain adolescence and may become sexually active. HIV disclosure is an important step towards long-term disease management and necessary for the transition from paediatric care into adolescent and adult care settings.
Methods: This was a cross sectional study carried out in 144 caregivers of Children and adolescents aged between 6 to 16 years of age attending the pediatric ART clinic. The subjects were enrolled consecutively and were interviewed using a structured questionnaire after taking written informed consent. The questionnaire included information on the demographic details, the disclosure status of HIV infection in children and perceptions about disclosure of status to the child.
Results: The mean age of children was 11.40 ± 2.86 years. Although 93.8% of caregivers believed children should know their HIV status, the prevalence of disclosure to the child was only 33.3%. Disclosure had been done primarily by caregivers (72.9%). Caregivers reported that (22.9%) children self-disclosed. Majority of caregivers felt 10-12 years as the appropriate age for disclosing the HIV infection status. Most of children 89.6% acquired HIV through vertical transmission. Majority of care givers 83.3% believed that care givers are most suitable person for disclosure. Furthermore, in our study 66.7 % children were unaware of this HIV status and most common reason (92.7%) for their non disclosure was child does not understand about illness and others to be 82.3% did not disclose as child may tell secret to others and 66.7 % child is too young to understand the disease. There was increase in drug compliance 47.9% and improvement in behaviour 12.5 % noticed in children.
Conclusions: In our study prevalence of HIV disclosure was 33.3 % there was increase in drug compliance, improvement in behaviour, school performance and attendance. Most common reason for their non disclosure was child does not understand illness and child may tell secret to others.

THPEB143

Toward improved IPT implementation for adolescents living with HIV in Swaziland: Elucidating the barriers through the theory of planned behavior

A. Kay[1,2], N. Thivalapill[3], S. Donald[4], P. Fuentes[2,5], N. Dlamini[1,6], P. Ustero[1,2], L. Adams[7], A. Mandalakas[1]
[1]Baylor College of Medicine and Texas Children's Hospital, Global Tuberculosis Program, Houston, United States, [2]Baylor Children's Foundation-Swaziland, Mbabane, Swaziland, [3]Columbia University, New York City, United States, [4]Human Sciences Research Council of South Africa, Pretoria, South Africa, [5]Baylor College of Medicine and Texas Children's Hospital, Global Tuberculosis Program, Pediatrics, Houston, United States, [6]Baylor Children's Foundation-Swaziland, Mbabane, Swaziland, [7]Dartmouth College, Geisel School od Medicine, Hanover, United States

Background: Global uptake of isoniazid preventive therapy (IPT) in adolescents with HIV is poor. IPT implementation is impacted by features of health systems and patient perceptions. This study identified factors that influenced adolescent intentions toward IPT to guide behavioral interventions.
Methods: 52 adolescents living with HIV were surveyed at the time of IPT prescription at an HIV clinic in Swaziland. The survey was designed according to the Theory of Planned Behavior (TPB), which models intention toward a behavior as a product of attitudes, subjective norms, and perceived behavioral controls. Stigma and clinic access were evaluated in a modified TPB model. Relationships between TPB variables were analyzed using Spearman's rank order correlation and linear regression. The overall goodness of fit of the traditional and modified model was tested using coefficients of determination and comparative fit indices.



Model Fit	Model Classification	Relationship	R^2, p value
CFI = 0.459 RMSEA = 0.243 AIC = 1273.015 CD = 0.213	Original Theory of Planned Behavior Model	1	0.2988 p < 0.0001
		2	0.1306 p = 0.0085
		3	0.1900 p = 0.0012
		4	0.0006 p = 0.8686
		5	0.1686 p = 0.0025
		6	0.0528 p = 0.1012
CFI = 0.649 RMSEA = 0.159 AIC = 2211.271 CD = 0.620	Modified Model with Considerations for Clinic Attitudes and Stigma	7	0.0969 p = 0.0247
		8	0.1347 p = 0.0075
		9	0.4807 p < 0.0001
		10	0.1545 p = 0.0039
		Multivariate Regression (1,2,3)	0.3783 p < 0.0001
CFI = Comparative Fit Index, RMSEA = Root Mean Square Error of Approximation, Akaike Information Criterion, CD = Coefficient of Determination			

[Flow diagram of original (light blue) and modified (dark blue) Theory of Planned Behavior with linear regression analyses and model fit statistics]

Results: Adolescents were knowledgeable about IPT but did not feel supported by their community; 48%(25/52) believed their neighbors would not support them, 40%(21/52) thought they would be verbally abused due to their taking IPT and 46%(24/52) worried their neighbors would think they had HIV. Multivariate linear regression indicated that traditional TPB variables predicted intention to take IPT (r^2=0.3783, p< 0.0001, Figure 1). On bivariate regression, intention was strongly predicted by attitudes to IPT (r^2=0.2988, p< 0.0001), but knowledge about IPT did not predict a more favorable attitude. Attitudes to IPT were positively correlated with external support measured by subjective norms (=0.50, p=0.0002) and negatively correlated with stigma beliefs (=-0.28, p=0.0482). Clinic access and stigma attitudes were both predictive of

perceived behavioral controls. The addition of stigma and clinical access variables improved the model's coefficient of determination from r^2 =0.213 to 0.620.

Conclusions: The addition of stigma and clinical access to the TPB model improved the model fit, indicating the important role these factors play in shaping adolescent decisions toward IPT. Stigma and community support were correlated with attitudes about IPT, a major predictor of intention, but attitudes were not modified by IPT knowledge. Interventions to reduce stigma, improve community support and reduce behavioral barriers may improve HIV+ adolescent acceptance of IPT more effectively than patient education alone.

THPEB144

It´s like having a case manager in your pocket!: Mobile application with coach, key to addressing barriers to HIV and preventive care

R. Arrington-Sanders[1], J. Iyer[2], D. Brooks[3], A. Wirtz[4], A. Morgan[4], N. Dowshen[5], C. Trexler[6], D. Celentano[4]
[1]Johns Hopkins School of Medicine & Public Health, Departments of Pediatrics & Health, Behavior & Society, Baltimore, United States, [2]Johns Hopkins School of Public Health, Baltimore, United States, [3]Johns Hopkins School of Medicine & Public Health, Departments of Pediatrics & Epidemiology, Baltimore, United States, [4]Johns Hopkins School of Public Health, Epidemiology, Baltimore, United States, [5]Children's Hospital of Philadelphia, Division of Adolescent Medicine, Philadelphia, United States, [6]Children's National Medical Center, Washington, United States

Background: HIV disproportionately affects young Black and Latino gay and bisexual men (YBLGBM) and transgender women (YBLTW). Earlier engagement in the HIV and preventive care cascade are key strategies, but YBLGBM and YBLTW disproportionately fall out of the treatment and prevention cascade. Mobile phone applications (apps) can engage youth in HIV treatment and prevention cascade. We sought to explore barriers in treatment and prevention and potential bidirectional mobile app components that could address those barriers.

Methods: 17 YBLGBM and YBLTW service providers and youth aged 18-26 from Baltimore, MD, Philadelphia, PA, and Washington, DC were recruited to complete a 45-minute key informant interview about barriers to care and mobile app needs to address barriers. Participants were identified through service agencies as being members who provided community support or who were key opinion leaders in the community. Two independent researchers coded the transcribed interviews using categorical and contextualizing analytic methods until agreement between coders (Kappa >0.80). Inductive open coding was used so emergent concepts were connected across interviews to develop major themes.

Results: Mean age, 22 years (SD=2.56). Most participants (n=10) provided services to youth or described having received HIV or preventive services at sites. Informants identified individual and system-level barriers preventing youth from engaging in HIV and preventive care. Individual: fear of diagnosis/illness, stigma with HIV/preventive services, lack of knowledge and support with HIV, and other priorities (housing, survival) superseding desire for care. System: difficulty navigating and lack of appropriate resources for youth with multiple intersecting identities. Key app components: bilingual resources, pill reminders/medication alarms, security and ability to make appointments directly on one's phone. Participants described wanting to confidentially video chat with a live person (or a coach) 24 hours a day via the mobile app. "*Because...it would make me feel good that someone´s helping me and keeping me on track, if I can´t do it by myself..but someone always needs that extra push and that extra help.*"

Conclusions: Barriers to HIV and preventive care continue to impede access for YBLGBM and YBLTW. A mobile application with a coach or peer would effectively address barriers and help youth access care.

Mental health and neuro-cognition in paediatric and adolescent populations

THPEB145

Loss of associations between basal ganglia volumes and neuropsychological scores in HIV-infected children at 5 years

A. Ibrahim[1], S.R. Randall[2], M.F. Cotton[3], B. Laughton[3], F. Little[4], A.J.W. van der Kouwe[5], E.M. Meintjes[1], M.J. Holmes[1]
[1]University of Cape Town, MRC/UCT Medical Imaging Research Unit, Division of Biomedical Engineering, Department of Human Biology, Faculty of Health Sciences, Cape Town, South Africa, [2]University of Cape Town, Department of Human Biology, Faculty of Health Sciences, Cape Town, South Africa, [3]Stellenbosch University, Family Clinical Research Unit, Department of Paediatrics and Child Health and Tygerberg Children's Hospital, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [4]University of Cape Town, Department of Statistical Sciences, Cape Town, South Africa, [5]Massachusetts General Hospital, Department of Radiology, Boston, United States

Background: Neurodevelopmental delay and cognitive impairments are reported even in HIV-infected (HIV+) children starting early antiretroviral therapy (ART). Structural magnetic resonance imaging (MRI) is used to study developing structure of the brain. Neuropsychological assessments measure various aspects of cognitive development in children. However, studies combining measures of both in the same cohort are uncommon.

In a recently published paper, we reported increased basal ganglia (nucleus accumbens (NA), putamen (Pu) and globus pallidus (GP)) and decreased corpus callosum (CC) volumes in 5-year-old HIV+ compared to HIV-uninfected (Ctl) children. To explore the possible cognitive implications of these volumetric abnormalities, we present an analysis of associations between volumes and neuropsychological performance at 5 years in these children.

Methods: Seventy-one children (39 Female; mean age±sd 5.4±0.3; 11 Cape Coloured/60 Xhosa; 46 HIV+/25 Ctl) received high-resolution T1 weighted imaging on a 3T Allegra Scanner (Siemens, Erlangen, Germany) as part of an ongoing longitudinal study being conducted in Cape Town, South Africa. The HIV+ children were part of the Children with HIV early antiretroviral therapy (CHER) trial sub-study; the control children were age and sociodemographically matched from a parallel vaccine study.

Select structures - caudate head, NA, GP, Pu and CC - were manually traced using MultiTracer software. Children were assessed on the Griffiths Mental Developmental Scales - Extended Revised version (GMDS). A linear regression model was used to examine group differences and the relationship between GMDS scales and volumes; ethnicity, sex, handedness, total intracranial volume (ICV), age at neuropsychological testing and time between scan and neuropsychological testing were included as confounders in R.

Results: GMDS subtest scores were similar between groups, apart from Personal-Social.

Larger right NA and left Pu were associated with poorer eye-hand coordination (Table 1, Fig1), and larger left Pu with lower scores on the Performance subtest (=-0.068(SE=0.003), p = 0.05). Associations with eye-hand coordination were not evident in the HIV+ group.

Conclusions: Even though no group difference is observed in eye-hand coordination, larger right NA and left Pu relate to poorer scores in uninfected children *only*. The bilateral NA and Pu increases in HIV+ children may be responsible for the altered relationship with subtest scores.

Subcortical volumes	Groups	Eye-Hand Coordination subtest β(std error), p-value
Right NA	All	-0.020 (0.010), p = 0.050
Right NA	Ctl	-0.008 (0.004), p = 0.007
Right NA	HIV+	-0.008 (0.011), p = 0.500
Left Pu	All	-0.005 (0.002), p = 0.050
Left Pu	Ctl	-0.050 (0.018), p = 0.050
Left Pu	HIV+	-0.004 (0.003), p = 0.200

[Associations of right NA and left Pu with Eye-Hand Coordination across groups and within each group separately]

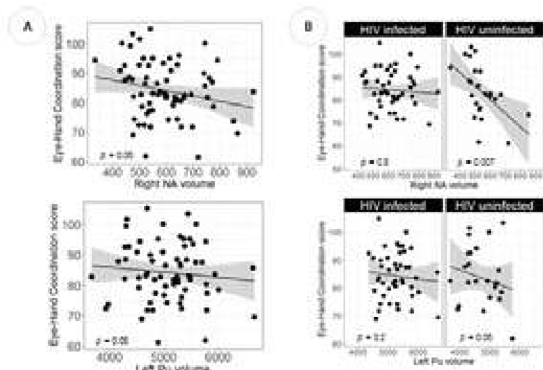


Figure 1. (A) Plots showing significant relationship between Eye-Hand Coordination score and subcortical volumes (NA and Pu) across all children. (B) Plots showing relationship between Eye-Hand coordination score and subcortical volumes (NA and Pu) in HIV-infected and uninfected children separately.

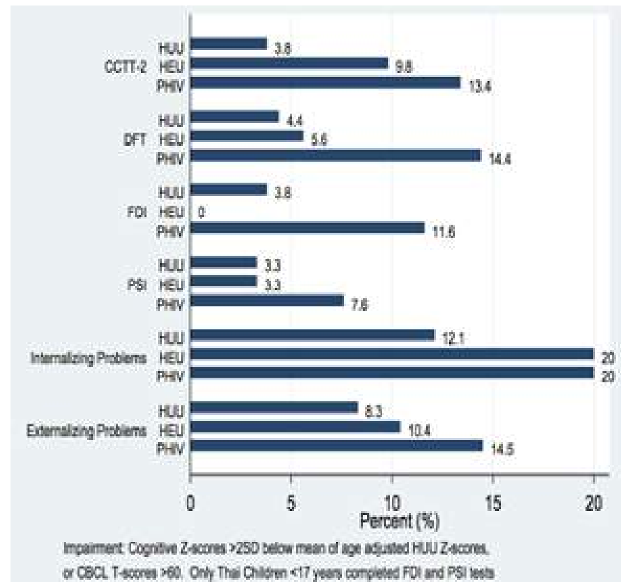
Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [15]Department of Global Health, University of Amsterdam, Amsterdam, Netherlands, [16]HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute, and Columbia University, New York, United States

Background: Large numbers of perinatally HIV-infected children (PHIV) are aging into adolescence, a time of increased behavioral risk. We examined cognitive and behavioral outcomes in one of few longitudinal cohort studies of Asian adolescents, in whom brain development is not confounded by in-utero drug or alcohol exposure.

Methods: We enrolled 231 PHIV, 125 HIV-exposed, uninfected (HEU), and 138 HIV-unexposed uninfected (HUU) adolescents (aged ≥10 years), matched by age/sex, in Thailand and Cambodia. Executive function was assessed with Children's Color Trails Test-2 (CCTT-2) and DKEFS Design Fluency test (DFT; Weeks 0 and 48). Working memory (Freedom from Distractibility index [FDI]) and Processing Speed ([PSI], week 0) was assessed with the WISC-III. Internalizing and Externalizing behavioral problems were assessed with the Child Behaviour Checklist (CBCL, Weeks 0 and 48). Generalised estimating equations examined adjusted odds ratios (aOR) of executive impairment (Z scores ≥2 SD below age-adjusted means of HUU group) and CBCL T-scores in the borderline-clinical range (T-Scores ≥60) in PHIV and HEU versus HUU. Linear regression examined adjusted mean differences in FDI and PSI between HIV-exposure groups. Adjustment was made for age, sex, ethnicity, household income, and caregiver characteristics.

Results: Median (IQR) age at enrolment was 14.0 (12.0-16.2); participants were 58% female and 64% Thai, with >86% virological suppression. PHIV were more likely than HUU to have impairment on CCTT-2 (aOR 4.43 (95% CI 1.8-11.0); p=0.001) and DFT (aOR 3.6 (95% CI 1.1-11.6); p=0.03). In PHIV versus HUU, the adjusted mean difference in FDI and PSI was -7.1 (95% CI -12.6 to -1.6); p=0.01) and -6.7 (-13.0 to -0.4); p=0.04), respectively. Results were similar between HEU and HUU groups.
Compared to HUU, PHIV (aOR 3.6 (95% CI 1.9-7.0); p< 0.001) and HEU (aOR 2.5 (95% CI 1.3-4.9); p=0.009) had higher odds of Internalizing problems but PHIV only had higher odds of Externalizing problems (aOR 2.5 (95% CI 1.2-5.5); p=0.02). Figure 1 shows prevalence estimates at enrolment.

Conclusions: Asian adolescents with PHIV remain at risk for cognitive and mental health problems despite HIV treatment. HEU youth are also at increased risk for mental health problems that require interventions.



[Figure 1. Prevalence of impaired cognitive scores or behavioral problems at Week 0]

Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [11]University of Amsterdam, Department of Global Health, Amsterdam, Netherlands, [12]Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand

Background: HIV-related stigma could undermine quality of life and self-esteem of people living with HIV. In youth, stigma may result in social distancing from friends, teachers, and other family members and may contribute to risk for depression. We determined HIV-related stigma and depressive symptoms among HIV-infected youths in Thailand and Cambodia.

Methods: Perinatally-infected youths living with HIV (YLWH), aged 10-24 years, had long-term follow-up in a clinical trial among 8 sites in Thailand and Cambodia. YLWH and their caregivers responded to dichotomous response questions asking about enacted stigma, defined as lifetime experiences of social abuse and problems with neighbors, schools, and other family members due to their HIV status. Depressive symptoms were assessed using the Child Depression Inventory (CDI) for those < 15 years of age and the Center for Epidemiologic Studies Depression Scales (CES-D) for those > 15 years; the cut-off scores were >15(CDI), or >22(CES-D).
Results: Two hundred and thirty-one YLWH (131 Thai /100 Cambodian) were included; 137(59%) were female. The median age at HIV diagnosis and at this assessment were 5.9 years (interquartile range, IQR 2.4-7.6), and 14.9 years (IQR 12.7-16.7), respectively. Caregivers were biological parent(s), relatives, and orphanage home in 154(67%), 40(17%), and 36(16%), respectively. Eighty-six percent knew their HIV status at the median age of 10 years (IQR 8-12).
Overall prevalence of HIV-related stigma reported by either YLWH or caregivers was 35% (80/229), with good agreement (Kappa=0.88). There was no significant difference in prevalence of stigma among Thai and Cambodian YLWH (25 vs. 35%, p=0.14). Among 56 YLWH with stigma experiences, being treated badly by friends or teachers (26%), problems with neighbors (7%), and school problems due to HIV infection (4%) were reported. The prevalence of high depressive symptom scores among YLWH was 29% (Thai 28%, Cambodia 30%). YLWH aged >15 years who experienced stigma were more likely to report high depressive symptom scores compared to those without (31 vs. 14%, respectively, p=0.04).

	YLWH with stigma (N=56)	YLWH without stigma (N=173)	p-value
High depressive symptoms score, n (%)	16 (29%)	29 (17%)	0.05
Age < 15 years (n=107)	N=24	N=83	
CDI score	12 (8-16)	11 (7-15)	0.69
Score > 15, n (%)	6 (25%)	16 (19%)	0.38
Age > 15 years (n=122)	N=32	N=90	
CES-D score	15 (8-24)	12 (8-18)	0.54
Score > 22, n (%)	10 (31%)	13 (14%)	0.04
CDI > 15, or CES-D >22 were defined as high depressive symptom scores			

[Table 1. Comparison of depressive symptom scores between youths living with HIV (YLWH) with and without HIV-related stigma]

Conclusions: One-third of YLWH had HIV-related enacted stigma, which was associated with depressive symptoms in older youth. Internalized stigma should be explored to learn how youth manage such experiences and to inform appropriate prevention/intervention efforts.

THPEB148

The impact of depression in HIV positive mothers on child development in Zimbabwe

R. Chingono[1,2], H. Mebrahtu[1], V. Simms[3], A. Rehman[3], Z. Mupambireyi[2], P. Ndlovu[4], R. Malaba[4], L. Sherr[1], F. Cowan[2,5]
[1]University College London, London, United Kingdom, [2]CeSHHAR Zimbabwe, Harare, Zimbabwe, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]World Education Inc., Harare, Zimbabwe, [5]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Background: Child cognitive development can be negatively impacted by depressive symptoms in primary caregivers. HIV positive women of childbearing age are at risk of depression, often unrecognized and untreated in low- and middle-income countries. We explored the relationship between maternal depression and child cognitive development to determine how poor maternal mental health influence child development.
Methods: Biological mothers of 0-24 month old infants enrolled in the CHIDO cluster-randomised trial (n=562) were assessed on mental health using the Edinburgh Postnatal Depression Scale (EPND), and a locally validated measure - the Shona Symptom Questionnaire (SSQ8). Infant development was assessed using the age-adjusted Mullen T-scales.
We used linear regression to compare Mullen overall and subscale scores across 4 groups defined by the mental health scale cut offs, adjusted for infant's sex, age (0 to < 3m, 3 to < 6m, 6 to < 12m, 12 to < 18m and 18 to 24m), HIV status and socio-economic status generated from principal components analysis. We used robust standard errors to account for clustering.
Results: There were 186/562 (33.1%) who were assessed as having depression above the cut off on both scales. Maternal depression was associated with lower overall child development (mean difference -7.5 (95% CI: -10.6, -4.4)) and with lower scores on the subscales expressive language (-2.5 (95% CI:-4.1, -1.0)), fine motor (-4.2 (95% CI: -6.5, -1.9)), receptive language (-3.5 (95% CI: -5.4, -1.6) and visual reception (-5.6 (95% CI: -8.2, -3.1)) (Wald p-value< 0.03).
Conclusions: Prevalence of depression assessed using two locally validated screening scales was very high in this population of HIV positive post-partum women in Zimbabwe. Depression in mothers was significantly associated with low cognitive development in infant children. Addressing poor maternal mental health is important for improving child development outcomes.

THPEB149

Validation of an HIV/AIDS stigma measure for children living with HIV and their families

R. Vreeman[1,2,3], M. Scanlon[2,4], W. Tu[5], J. Slaven[5], C. McAteer[1,2], J. Aluoch[2], S. Ayaya[2,3], W. Nyandiko[2,3]
[1]Indiana University School of Medicine, Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indianapolis, United States, [2]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [3]College of Health Science, Moi University, Department of Child Health and Paediatrics, Eldoret, Kenya, [4]University of Massachusetts Boston, John W McCormack Graduate School of Policy and Global Studies, Boston, United States, [5]Indiana University School of Medicine, Department of Biostatistics, Indianapolis, United States

Background: There are few validated tools to measure HIV-related stigma and its impact for children living with HIV, particularly in sub-Saharan Africa. We assessed the validity of a novel questionnaire to measure HIV stigma among children living with HIV and their families in Kenya.
Methods: This validation study was nested within a larger study following child-caregiver dyads (children ages 10 to 15 years) for two years at eight clinics in western Kenya within the Academic Model Providing Access to Healthcare (AMPATH). Construction of the 13-item stigma questionnaire involved literature review and qualitative inquiry, followed by cognitive interviewing to assess face validity, acceptability, and cross-cultural adaptation of the questionnaire. We administered the instrument to both children and their caregivers at two study evaluations, 6 months apart. The primary endpoint was construct validity assessed by comparison to criterion constructs. Criterion constructs (and measures) were: quality of life (GHAC QoL), behavioral health (SDQ), depression (PHQ-9), antiretroviral adherence (MEMS® electronic dose monitoring) and clinical characteristics.
Results: Among 240 child-caregiver dyads, child mean age was 12.3 years and 52% were female. The majority of caregivers (54%) were the biological mother. Adherence by MEMSÒ was 70% of doses taken. The stigma questionnaire had good face validity and acceptability in cognitive interviewing. Using the questionnaire, caregivers reported experiencing higher levels of HIV stigma than their children; for example, 10% of caregivers reported being discriminated against in their neighborhood versus 2% of children. A substantial percentage of children (9%) and caregivers (14%) reported that HIV stigma made them feel stressed, anxious, or depressed. Several child and caregiver stigma questionnaire items had good construct validity in terms of associations with outcome variables (emotional and behavioral outcomes on the SDQ and GHAC QoL.) The stigma items most highly correlated with feelings of anxiety, depression, negative future outlook, and losing social support due to HIV.
Conclusions: These findings suggest that the stigma questionnaire generated valid and useful reports of HIV-related stigma for both children living with HIV and their caregivers, though reliance on child-report only may underestimate stigma experiences. This questionnaire may be suitable as a family stigma screening tool.

THPEB150

Initiation of ART after 2 years of age affects CNS white matter microstrusture in adolescents living with HIV

J. Hoare[1], S. Heany[1], J.-P. Fouche[1], N. Phillips[1], L. Myers[2], H. Zar[3], D. Stein[1]
[1]University of Cape Town, Department of Psychiatry, Groote Schuur Hospital, Cape Town, South Africa, [2]University of Cape Town, Public Health, Cape Twon, South Africa, [3]Universtiy of Cape Town, Pediatrics, Cape Twon, South Africa

Background: Updated guidelines advise that all children receive ART irrespective of their age, clinical stage or immunological status. However context-specific differences in treatment guidelines and access to ART over the past two decades have resulted in great variability in exposure to ART among adolescents living with HIV. The corresponding central nervous system (CNS) white matter (WM) microstructure signature and neurocognitive effects of ART initiation after 2 years of age is poorly understood.

Methods: Forty-six adolescents who initiated ART before the age of 2 years (< 2yrs), and 79 adolescents who initiated ART after the age of 2 years (>2yrs), with perinatally acquired HIV (mean age 10 years; mean age of initiation of ART 3.41years; mean CD4 953) were enrolled within the Cape Town Adolescent Antiretroviral Cohort (CTAAC). Adolescents completed a detailed neurocognitive battery testing a number of cognitive domains. Diffusion tensor imaging was done to determine fractional anisotropy (FA), mean diffusivity (MD), axial diffusion (AD) and radial diffusion (RD) in a region of interest analysis examining the corona radiata, cingulum, cerebral peduncle, internal capsule, external capsule, fronto-occipital fasciculus and corpus callosum.

Results: Neurocognitive performance was similar between adolescsnts who initiated ART < 2yrs and >2yrs. There was a trend towards attention (p=0.066) and working memory (p=0.053) being poorer in the group who initiated ART >2yrs. FA was reduced in the >2yrs group, in the superior corona radiata (p=0.046), posterior corona radiata (p=0.004) and the external capsule (p=0.03), suggesting an increased risk of WM alterations in this group. MD was increased in the >2yrs group in the cerebral peduncle (p=0.003), the interapsule (p=0.03), the superior corona radiata (p=0.014) and the superior fronto-occipital fasciculus (p=0.007) suggesting increased inflammation in these structures. Differences in AD and RD were also found between the two groups.

Conclusions: These findings suggest that initiation of ART >2yrs increases the risk of WM alterations in the CNS. The similar perfomance in neurocognitive domains suggests that initiation of ART within the first 2 years of life, but not at birth is not sufficient to protect adolescents from neurocognitive impairment observed in pediatric neuroAIDS.

THPEB151

Neurocognitive outcomes among perinatally-HIV infected young adults

R. Robbins[1], A. Bucek[1], J. Raymond[1], N. Nguyen[1], C. Dolezal[1], E. Abrams[2], A. Wiznia[3], C.S. Leu[1], C.A. Mellins[1]
[1]New York State Psychiatric Institute & Columbia University, Division of Gender, Sexuality, & Health, HIV Center, New York, United States, [2]Mailman School of Public Health, Columbia University, International Center for AIDS Care and Treatment Program, New York, United States, [3]Albert Einstein College of Medicine, Pediatric Allergy & Immunology, New York, United States

Background: Poor neurocognition is a barrier to perinatally HIV-infected (PHIV+) young adult (YA) health outcomes. Few studies longitudinally examine key domains of neurocognition (i.e., processing speed [PS], working memory [WM], and executive functions [EF]) among PHIV+ and perinatally HIV-exposed, uninfected (PHEU) YA. We examined:
1) differences in PS, WM, and EF between PHIV+ and PHEU YA at and across three time-points, and 2) associations between viral load (VL) over time and neurocognitive outcomes among PHIV+YA.

Methods: CASAH is an ongoing NYC-based, longitudinal cohort study of PHIV+ and PHEU YA recruited at ages 9-16 (2003-2008) and followed at 12-18 month intervals. Tests of WM (Digit Span), PS (Trail Making Test, Part A), and EF (Trail Making Test, Part B) were administered at follow-up interviews FU 5, 6 and 7 (7 still ongoing). We compared neurocognitive test performance by HIV status at three time-points, and used generalized estimating equations (GEE) to calculate mean differences across all tests and follow-ups. Among PHIV+, we used GEE to examine the association between the proportion of VL test results >400 copies/ml across the three time-points and neurocognition.

Results: Participants at FU5 (N=249) were: 18-28 years old (mean=21.90; SD=2.68); 53% female; 56% African-American/Black; 40% Latino. PHIV+ YA had significantly slower PS scores compared to the PHEU YA at all follow-ups; significantly lower WM than PHEU YA at FU5 and FU6 (FU7 was at the trend level); and significantly worse EF scores compared to the PHEU YA at FU7. HIV status was related to PS performance across all follow-ups; HIV status was not related to WM performance across all follow-ups; and HIV status was related to EF performance across all follow-ups (not significant). The proportion of viral load tests >400 only predicted PS.

Conclusions: While PHIV+ YA performed worse at most follow-ups on tests of WM, PS, and EF than PHEU YA, HIV may not be the driving factor in their lower performance WM and EF tests. Neurocognition must continue to be monitored among PHIV+ YA and interventions developed to address poor performance. Continued research is needed to identify non-HIV related contributors to poor neurocognition among PHIV+ YA.

[Neurocognitive Test Performance across Follow-Ups by HIV Status]

THPEB152

Effect of caregiver training on the neurocognition of school-age siblings of preschool HIV-exposed uninfected target children: A Ugandan cluster randomized controlled trial

M.J. Boivin[1,2], J. Augustinavicius[3], I. Familiar-Lopez[4], A. Sikorskii[5], S.M. Murray[3], C. Shohet[6], D. Givon[6], T. Mendelson[3], N. Nakasujja[7], J.K. Bass[3]
[1]Michigan State University, Psychiatry and Neurology & Ophthalmology, East Lansing, United States, [2]University of Michigan, Psychiatry, Ann Arbor, United States, [3]Johns Hopkins University Bloomberg School of Public Health, Global Mental Health, Baltimore, United States, [4]Michigan State University, Psychiatry, East Lansing, United States, [5]Michigan State University, Psychiatry and Statistics & Probability, East Lansing, United States, [6]Bar Ilan University, Early Childhood Education, Ramat Gan, Israel, [7]Makerere University, Psychiatry, Kampala, Uganda

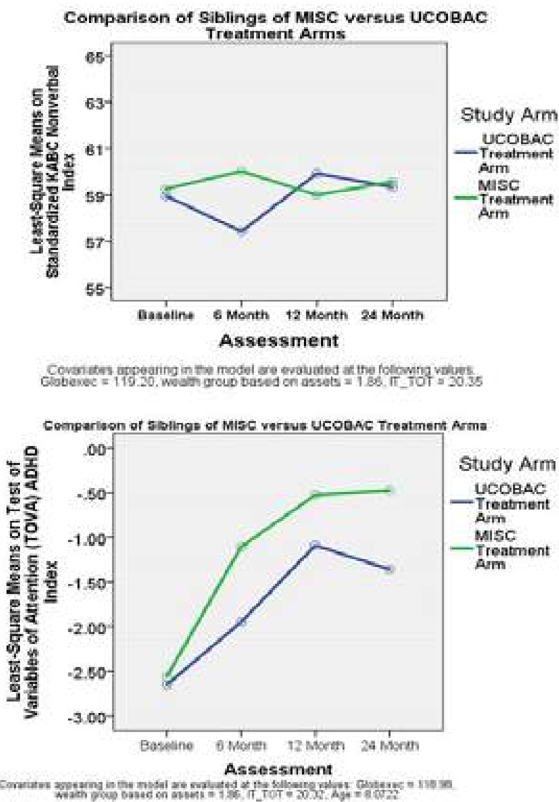
Background: Early childhood development (ECD) programs typically combine healthy nutrition and cognitive stimulation in an integrated model. We separately delivered these two components in a clinical trial to evaluate their comparative effectiveness. This is the first study to evaluate whether older siblings of preschool target children benefit from training intervention for their HIV-infected mothers.

Methods: 210 school-age siblings (5-12 years old) in ECD intervention households with target children 2-3 years of age were evaluated on neurocognitive outcomes using the Kaufman Assessment Battery for Children (KABC), computerized Tests of Variables of Attention (TOVA), the Behavior Rating Inventory for Executive Function (BRIEF; parent) and an ADHD-R-IV questionnaire completed by the mother. Households from 18 geographic clusters in eastern Uganda were cluster-randomized to biweekly individualized sessions of either: 1) Mediational Intervention for Sensitizing Caregivers (MISC) training emphasizing cognitive stimulation/enrichment; or 2) health/nutrition/development (UCOBAC) program. Siblings were evaluated at baseline, six months (mid-intervention), one year (post-intervention), and one-year after completing intervention.

Results: Adjusting for baseline value of each outcome, SES, and care-giving quality (HOME scale) a linear mixed-effects model resulted in significantly better MISC-arm performance on the KABC non-verbal index (NVI) (global performance) at 6 months, with the UCOBAC arm significantly below MISC by -2.87 points, 95% CI (-5.08, -0.65; p=0.01) (Table 1). However, by 12 and 24 months the two arms were similar (Figure 1). TOVA ADHD index favored the MISC children at six (p=0.06) and 24 months (p=0.05) but not at the completion of caregiver training at 12 months (p=0.43) (Figure 1). MISC caregivers scored their children with significantly more BRIEF (p< 0.01) and ADHD-RS-IV (p< 0.01) problems than the UCOBAC mothers at all time points, perhaps because of the MISC training emphasis on children's behavior.

Outcome	Time Points (Months)	UCOBAC, LS Mean (SE)	MISC, LS Mean (SE)	P-value for the arm difference, 95% CI
KABC Nonverbal Index	6	57.53 (0.78)	60.40 (0.85)	0.01, (-5.08, -0.65)
	12	58.89 (0.79)	59.29 (0.84)	0.59, (-1.61, 2.81)
	24	59.22 (0.79)	59.98 (0.83)	0.50, (-2.98, 1.45)
TOVA ADHD Index	6	-2.40 (0.30)	-1.23 (0.33)	0.06, (-1.66, 0.03)
	12	-1.04 (0.30)	-0.70 (0.32)	0.43, (-1.18, 0.51)
	24	-1.39 (0.30)	-0.56 (0.32)	0.05 (-1.68, 0.00)
BRIEF Behavior Regulation Index	6	41.85 (0.94)	46.67 (1.04)	<0.01 (-7.51, -2.13)
	12	41.83 (0.95)	46.11 (1.03)	<0.01 (-6.97, -1.58)
	24	39.13 (0.96)	45.05 (1.03)	<0.01 (-8.62, -3.23)

[Table 1. Comparison of KABC, TOVA, and BRIEF for MISC and UCOBAC treatment arms]



[Figure 1. Comparison of MISC and UCOBAC treatment arms for KABC and TOVA outcomes]

Conclusions: MISC caregiver training results in more immediate neuro-cognitive performance benefits for household school-age children while sensitizing the moms to behavior problems. However, by the end of the year-long training and at 1-year post-training follow-up, there is no appreciable difference on cognitive outcomes for an intervention focusing on cognitive enrichment/learning versus one favoring health/nutrition/social development. Both programs are effective for household children and should be integrated in ECD training.

THPEB153

Neurodevelopmental and behavioral outcomes in perinatally HIV infected children who initiated antiretroviral therapy within 3 months of age

W. Jantrabenjakul[1,2,3], J. Srisamer[2], T. Theerawit[2], J. Sophonphan[2], M. Veeravigom[1], W. Chonchaiya[1], T. Puthanakit[1,2], J. Anantaworanich[4,5], N. Jahanshad[6], P.M. Thompson[6], K. Malee[7], C. Pancharoen[1,2],
The DOET Study
[1]Chulalongkorn University, Pediatrics, Faculty of Medicine, Bangkok, Thailand, [2]Chulalongkorn University, Center of Excellence for Pediatric Infectious Diseases and Vaccine, Bangkok, Thailand, [3]King Chulalongkorn Memorial Hospital, Emerging Infectious Diseases Clinical Center, Bangkok, Thailand, [4]The Thai Red Cross AIDS Research Center (TRCARC), SEARCH, Bangkok, Thailand, [5]Henry M. Jackson Foundation for the Advancement of Military Medicine, Maryland, United States, [6]Keck School of Medicine of USC, Imaging Genetics Center, Stevens Neuroimaging and Informatics Institute, Marina del Rey, United States, [7]University Feinberg School of Medicine, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, United States

Background: Data regarding neurodevelopmental and behavioral outcomes among children who initiated antiretroviral therapy (ART) within 3 months old are limited. This study compares neurodevelopmental and behavioral outcomes among children with perinatally-acquired HIV infection (PHIV) and perinatally HIV-exposed uninfected children (PHEU).
Methods: This is an observational study of children aged 12-56 months. PHIV children with 2 positive HIV DNA PCR were classified as early PHIV if they commenced ART within 3 months old, and late PHIV if ART began between 3 and 12 months. Age-matched PHEU children had negative HIV DNA PCR at age > 4 months or anti-HIV negative at age > 12 months. Neurodevelopmental outcomes were assessed with the Mullen Scale of Early Learning (MSEL). Behavioral outcomes were evaluated by Child Behavioral Checklist (CBCL). Global developmental impairment was defined by MSEL Early Learning Composite (ELC) Score of < 70. Prevalence of development impairment and behavioral problems were compared by Chi-square test. Predictors of ELC scores were analyzed by multiple linear regression models.
Results: From 2016 to 2017,150 children were enrolled (27 early PHIV,23 late PHIV and 100 PHEU children). Median (IQR) age was 28 (19-41) months. 37/50 (74%) of PHIV children had undetectable HIV- RNA.
Prevalence of global developmental impairment was 26% in late PHIV, 7.4% in early PHIV, and 8% in PHEU, p=0.047. Mean (SD) ELC scores were 80 (18) in late PHIV, 83 (11) in early PHIV, and 90 (16) in PHEU,p =0.005. Late PHIV had significantly lower scores in gross motor and visual reception domains, p < 0.05. Predictors of ELC score were ART initiation after 3 months old [mean difference -8.6, 95% CI (-16.3) - (-0.9) p=0.03] and no nursery school attendance [mean difference -5.9, 95% CI (-11.4) - (-0.3) p=0.04].
No significant differences were observed in CBCL internalizing, externalizing or total behavioral problems. Among individual behavioral problems, somatic complaints were reported more often in late PHIV (64% in late ART, 48% in early ART and 33% in PHEU, p=0.02).
Conclusions: Late PHIV had higher rate of developmental impairment when compare to early PHIV and PHEU. Early initiation ART and nursery school attendance mitigated neurodevelopmental scores in PHIV children.

THPEB154

Prevalence and cross-sectional correlates of cognitive difficulties among HIV-positive adolescents in South Africa

H.P. Mbaziira Natukunda[1,2,3], L. Cluver[1,4], E. Toska[5], Mzantsi Wakho Adolescent Study Team
[1]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [2]MRC/UVRI Uganda Unit on AIDS, Mental Health Research, Entebbe, Uganda, [3]Medical Research Council, Pathology Department, Oxford, United Kingdom, [4]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [5]University of Cape Town, Centre for Social Science Research, AIDS and Society Research Unit, Cape Town, South Africa

Background: This study examined the baseline prevalence of cognitive difficulties and its correlates in a large community-based sample of South African adolescents.
Methods: A total of 1059 cART-initiated 10-19-years-old adolescents and 467 community controls attending 53 public health facilities in the Eastern Cape were interviewed in 2014-15. Cognitive difficulties were assessed as adolescent self-reports of past 6-months difficulties remembering things, following a story or conversation or < 60% immediate recall on a memory task or caregiver/school reports of an adolescent being a ´slow-learner´ or attending a special needs schools. Data on clinical and psychosocial variables associated with cognitive impairment were also gathered. Analyses were disaggregated by gender, HIV-status.To assess the correlates of cognitive difficulties, analyses used multivariable logistic regressions in Stata 14.
Results: The overall prevalence of cognitive difficulties was 64.4% (95% CI: 61.9-66.7). Cognitive difficulties were significantly higher among boys than girls (68.0% vs. 61.6%, *p* =.010). These findings were different for the different HIV groups, indicating that the observed relationship between gender and cognitive difficulties was moderated by HIV status i.e. (61.8% vs. 59.2%, *p* =.576) and (70.4% vs. 62.8%, *p* =.009) for the community controls (apparently HIV-negative) and HIV-positive adolescents respectively. HIV-positive adolescents had higher rates of cognitive difficulties than community controls (risk difference 6%, *p* =.024). HIV-positive adolescents were also less likely to be in an age-appropriate grade than community controls (46.2% vs. 56.8%, *p*< .001). The prevalence of cognitive difficulties among adolescents for whom ART data were available was 63.7% (CI: 59.4-67.7). Factors associated with cognitive difficulties among HIV-positive adolescents were age (aOR: 1.19, CI: 1.07-1.34), being in primary school (aOR: 1.99, CI: 1.10-3.62), physical disability complaints e.g. unable to self-care (aOR: 1.89, CI: 1.13-3.17), ADHD score (aOR: 1.21, CI: 1.07-1.37), and having opportunistic infections (aOR: 1.65, CI: 1.10-2.48). Stavudine-based regimens at baseline were associated with a lower likelihood of cognitive difficulties (aOR: 0.26, CI: 0.10-0.70). Other HIV treatment regimens were not associated with cognitive difficulties in our sample.
Conclusions: Cognitive difficulties were high among South African adolescents. Interventions to address cognitive impairment are urgently needed to prevent early onset dementia and help affected adolescents reach their full potential.

HIV-exposed uninfected children

THPEB155

A population-based study of health outcomes of HIV-exposed uninfected children using Ontario's administrative health databases

J. Brophy[1], S. Chen[2], R. Ng[3], J. Bowes[1], T. Antoniou[4,5]
[1]Children's Hospital of Eastern Ontario, Infectious Diseases, Ottawa, Canada, [2]Institute for Clinical Evaluative Sciences (ICES), Central, Mental Health & Addictions Research Program, Toronto, Canada, [3]Institute for Clinical Evaluative Sciences (ICES), Central, Data & Analytic Services Group, Toronto, Canada, [4]Institute of Clinical Evaluative Sciences (ICES), Central, Primary Care & Population Health Research Program, Toronto, Canada, [5]Saint Michael's Hospital, Department of Family and Community Medicine, Toronto, Canada

Background: Maternal treatment with combination antiretroviral therapy in pregnancy has led to a generation of HIV-exposed uninfected children (HEUs) globally and in Canada. Some data suggests increased immunologic, infectious and neurodevelopmental morbidities in HEUs. We utilized Ontario's administrative health databases to estimate rates of these morbidities in Ontario-born HEUs.
Methods: A retrospective population-based study was conducted comparing diagnoses among children of women living with HIV to matched HIV-unexposed children born between 01-04-2002 and 31-12-2015. Each HEU was matched with up to 5 non-HEU children based on: year of birth, maternal age, calendar quarter of birth, neighbourhood income quintile, local health integrative network, and urban/rural residence. Child health outcomes included: all-cause and infection-related hospitalizations from 3-24 months of age, and autism or other developmental disabilities diagnosed from 2-10 years of age. Crude rates of outcomes were calculated and regression analyses adjusted for maternal risk factors/comorbidities, pregnancy syndromes and infant characteristics were conducted to determine whether HEUs were at greater risk of negative health outcomes.
Results: A total of 993 HEUs and 4953 matched non-HEU children were included in the analysis. All-cause (53.35 per 1000 person-years [PYs]) and infection-related hospitalizations (7.66 per 1000 PYs) among HEUs were higher than in matched non-HEUs (37.81 and 5.26 per 1000 PYs, respectively), with unadjusted hazard ratios [HR] (95%CI) of 1.433 (1.126-1.824) and 1.465 (0.789-2.720), respectively. Adjusted hazard ratios [aHR] were 1.142 (0.856-1.048) and 0.481 (0.181-1.280), respectively. Rates of autism alone and autism plus other developmental disabilities were each 3.12 per 1000 PYs, higher than those for non-HEUs (2.29 and 2.60 per 1000 PYs, respectively. The HR for autism among HEUs was 1.392 (0.875-2.217) and for autism/developmental disabilities was 1.213 (0.767-1.919); aHR for these diagnoses in HEUs were 1.232 (0.699-2.173) and 1.143 (0.652-2.002), respectively.
Conclusions: HEUs had higher rates of all-cause and infection-related hospitalizations and developmental disabilities than matched controls, although adjusted hazard ratios showed no elevated risk of these outcomes compared to non-HEUs. This suggests a strong contributing role of maternal factors to the increased rates of outcomes, and warrants further investigation in this growing vulnerable population.

THPEB156

24-month incidence of hiv infection, loss to follow-up and mortality among exposed infants at referral hospitals in Uganda

M. Kwikiriza[1], H. Alima[1], P. Elyanu[2], G. Tugume[1]
[1]University Research Co LLC, Kampala, Uganda, [2]University of Texas Health Sciences Center at Houston, School of Public Health, Texas, United States

Background: Uganda has implemented Option B+ since 2012, but there is limited data on 24-months outcomes of HIV exposed infants. We examined the 24-month cumulative incidence of HIV-Infection, loss to follow-up and death among HIV exposed infants at regional referral hospitals in Uganda. We also determined the factors associated with mother to child HIV transmission (MTCT).

Author Index

Methods: We respectively reviewed clinical charts of HIV exposed infants (HEI) recruited in care between October 2012 and September 2013 at 11 regional referral hospitals in Uganda. The 24-month cumulative incidence of HIV, LTFU, and death was calculated using competing risks analysis, and predictors of MTCT determined using sub-distributional hazard regression analysis.

Results: .Of 2959 HEI, 83 (2.8%) were excluded for missing date of birth and 2776 were included in the analysis. Of these 2776, the median age at 1st HIV test was 7 weeks [interquartile range: 6.4-12]. The 24-month cumulative of HIV infection, LTFU and death was 7.5% (95%CI: 6.6%, 8.5%), 31.7% (95%CI: 30%, 33.5%) and 0.9% (95%CI: 0.6%, 1.4%) respectively. The factors associated with MTCT were: mother or infant not receiving ARV's for PMTCT Subdistributional Hazard ratio (sHR) 2.2(95% CI: 1.5, 3.2) and sHR 1.7(95%CI: 1.1, 2.6) respectively; Testing at age 2-6 month [sHR 2.1(95%CI: 1.3, 3.4)] or age >7month [sHR 2.8(95%CI: 1.5, 5.1)] compared to testing 2 months of age.

Other factors were mixed feeding, complementary feeding or no-longer breastfeeding at the time of first HIV test compared to those who were exclusively breastfed *see table 1.*

Conclusions: MTCT rate and loss to follow-up of HEI from care at regional referral hospitals in Uganda are high. Factors to prevent MTCT are maternal and infant ARV use, early care entry and testing, and exclusive breastfeeding. Loss to follow-up should be addressed.

Predictors*	Total	% infected	Univariable analysis Crude SHR (95%CI) P-Value	Multivariable analysis aSHR (95% CI) p-Value

Role of infant nutritional status (stunting) on early cognitive development: Cross sectional study in Zimbabwe

H. Mebrahtu[1], A.M. Rehman[2], R. Chingono[1,3], V. Simms[2], P. Ndlovu[4], F.M. Cowan[3,5], L. Sherr[1]

[1]UCL, Global Health, London, United Kingdom, [2]London School of Hygiene & Tropical Medicine, MRC Tropical Epidemiology Group, London, United Kingdom, [3]Center for Sexual Health HIV/AIDS Research Zimbabwe, Harare, Zimbabwe, [4]World Education, Harare, Zimbabwe, [5]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Background: Nutrient deficiencies during early childhood may have long-term and irreversible effects on brain development of infants exposed to HIV.

Methods: Study participants were recruited from the Child Health Intervention for Developmental Outcomes trial in Zimbabwe and consisted of infants aged 0-24 months born to women living with HIV. Child anthropometric measurements included height, weight, and head circumference. Child development outcomes were assessed using the Mullen Scale of Early Learning which measures five cognitive domains (visual reception, fine motor, gross motor, receptive language, and expressive language). Regression models were built to assess the association between stunting and infant cognitive scores, adjusting for infant's age, birth weight and growth rate. Data were adjusted for clustering by clinic.

Results: 571/574 infants recruited had their anthropometric measurements provided. The mean age of infants was 12.0 months (SD 6.5), 282 (49%) were male and 18 (4%) were HIV positive. Mean birth weight was 3.0 (SD 0.4), 265 (47%) of the infants had a normal growth rate, with 87 (15%) underweight.

Stunted infants (n=207) were older than non-stunted (14.4 vs. 10.6; p< 0.01), more likely to be male (55% vs. 46%; p=0.04), had lower mean birth weight (2.8 vs. 3.0; p< 0.01) and more likely to be underweight (33% vs. 5%; p< 0.01).

In adjusted multivariate regression models, stunting was significantly associated with lower scores across the developmental domains. Stunted infants scored significantly lower in the overall composite score (adjusted mean difference (aMD)=-5.23; 95%CI: -7.88 to -2.59; p< 0.01), expressive (aMD=-3.11; 95%CI: -4.74 to -1.48; p< 0.01) and receptive (aMD=-3.07; 95%CI: -4.96 to -1.17; p< 0.01) language, and gross motor development (aMD=-2.53; 95%CI: -4.51 to -0.56; p< 0.01).

Conclusions: High levels of child stunting in an HIV affected population is associated with lower child cognitive outcomes. Early interventions should combine child stimulation with nutrition programmes for effective long-term gains and optimal child development.

THPEB158

HIV-exposure without infection impacts early language development: Outcomes from a South African birth cohort study

C.J. Wedderburn[1,2], S. Yeung[1], W. Barnett[2,3], R.T. Nhapi[2], A.M. Rehman[4], D.M. Gibb[5], H.J. Zar[2,3], D.J. Stein[6,7], K.A. Donald[2]

[1]London School of Hygiene & Tropical Medicine, Department of Clinical Research, London, United Kingdom, [2]University of Cape Town, Department of Paediatrics and Child Health, Cape Town, South Africa, [3]South African Medical Research Council (SAMRC), Unit on Child & Adolescent Health, Cape Town, South Africa, [4]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [5]University College London, MRC Clinical Trials Unit, London, United Kingdom, [6]University of Cape Town, Department of Psychiatry & Mental Health, Cape Town, South Africa, [7]SAMRC, Unit on Risk and Resilience in Mental Disorders, Cape Town, South Africa

Background: Sub-Saharan Africa, where HIV is most prevalent, has the highest proportion of children at risk of not reaching their neurodevelopmental potential. Whereas HIV infection is a known risk factor for developmental delay, effects of HIV and antiretroviral therapy (ART) in exposed HIV-uninfected (HEU) children remain unclear. We compared neurodevelopmental outcomes in HEU and HIV-unexposed uninfected (HUU) children during their first 2 years.

Methods: The Drakenstein Child Health Study is a population-based birth-cohort in the Western Cape, South Africa. Women were enrolled antenatally from two clinics between 2012-2015. Mothers and children from these two communities received HIV testing and treatment as per the Western Cape prevention of mother-to-child transmission guidelines at the time. Developmental assessments were conducted by trained assessors blinded to HIV/ART status, using the Bayley-III Scales of Infant and Toddler Development (BSID-III) at 6 and 24 months.

Results: A subgroup of 260 children (61 HEU, 199 HUU) had a BSID-III assessment at 6 months and 732 children (168 HEU, 564 HUU) at 24 months. Mean scaled scores of all subscales were within normal range (BSID-III standardised mean 10, SD 3) at 6 months with no differences between HEU and HUU (p>0.1). However, at 24 months, HEU scores were significantly lower than HUU in cognitive mean (SD) [6.80(1.88) vs.7.14(1.84), p=0.049]; receptive [6.62(1.82)vs.7.25(1.97), p=0.001] and expressive language [6.94(2.29)vs.7.57(2.30), p=0.028]; in contrast, fine and

gross motor domains were similar (p=0.93 and p=0.53 respectively). HEU had higher risk of delay (>2 SD below the mean) than HUU children in receptive (13.9%vs.7.2%, odds ratio [OR] 2.09, 95%CI 1.21-3.61) and expressive language (11.4%vs.5.7%, OR 2.12, 95%CI 1.15-3.90) but not in the cognitive scale (10.8%vs.9.3%, OR 1.18, 95%CI 0.67-2.09). After adjusting for age, sex, clinic and maternal education, the effect remained for receptive (OR 2.23, 95%CI 1.16-4.30) but not expressive language (OR 1.74, 95%CI 0.86-3.54).
Conclusions: These initial analyses suggest receptive language is impaired in HEU children. Ongoing analyses will focus on disaggregating effects of in-utero exposure to HIV and ART. Given the global focus on child development and the critical importance of language in society, further work is needed to monitor and address the long-term clinical outcomes of HEU children.

Transition of adolescents into adult care

THPEB159

Post transition outcomes in young adults living with HIV: '90':99:80

C. Foster[1], S. Chhabra[2], S. Ayers[1], G. Frize[1], S. Macdonald[1], S. Filder[2]
[1]*Imperial College NHS Trust, 900 Clinic, HIV/GUM, London, United Kingdom,* [2]*Imperial College, 900 Clinic, HIV/GUM, London, United Kingdom*

Background: Adolescence is the only age group where HIV associated mortality is rising, with poorer outcomes at all stages of the care cascade compared to adults; many cohorts report < 25% retained on suppressive antiretroviral therapy (ART) post transition to adult care. We examined the post transition outcomes for young adults (YA) with perinatal HIV (PaHIV).
Methods: Retrospective cohort analysis PaHIVYA attending a specialist service between 01.01.06 and 31.12.17, assessing retention, mortality, morbidity and viral load (VL) suppression. Incidence rates (IR) are compared to aged matched UK population data.
Results: 180 PaHIVYA contributed 921 person-years of follow-up within adult services. Over the study period, 14 (7.8%) transferred care, 4 (2.2%) were lost to follow-up (LTFU) and 4 (2.2%) died; median age 20 years (range 19-27); end-stage HIV/poor ART adherence (3), HIV/HBV hepatocellular carcinoma (HCC). All-cause mortality rate 4.3/1000 person-years (95% CI 1.2 - 11.1), 10-fold the age-matched general population (incidence rate ratio (IRR) 11.6 (95% CI 3.2 - 29.8), p< 0.0001). Post transition, 17/180 (9.4%) had 1 or more new AIDS diagnoses, IR 18.5/1000 person-years (95% CI 10.8 - 29.6). Four (2.2%) new malignancy diagnoses; lymphoma (3), HCC (1); IR 4.3/1000 person-years (95% CI 1.2 - 11.1), twelve times the age-matched population (IRR 12.6 (95% CI 3.4 - 32.3), p< 0.0001). Nine new onset psychosis IR 9.8/1000 person-years (95% CI 4.5 - 18.6), IRR to ethnically matched UK adults 50.3 (95% CI 22.6 - 97.9), p< 0.0001. Of 158 in current follow up, median age 22.9 years (IQR 20.3-25.4), 56% are female, 85% Black African. 157 (99.4%) have ever received ART. At latest follow up; median CD4 count 626 cells/ul (IQR 441-820) and 127/158 (80.4%) have a VL < 200 c/ml. 66/158 (42%) have resistance mutations; 23 (15%) mono, 33(21%) dual and 10 (6.3%) triple/quadruple class. Post transition, 33/158 (20.9%) have had anxiety and/or depression, 3 attempted suicide and a further 4 self harmed.
Conclusions: Post transition retention in care with access to ART far exceeded 90:90:90 targets in this highly complex cohort. Whilst LTFU and mortality combined was < 5% over a decade, a fifth struggle with adherence and mental health issues prevail.

THPEB160

Increasing age predicts viral suppression in adolescents transitioning to adult HIV care

N. Lin[1], L. Phung Khanh[2], S. Fidler[3], C. Foster[4]
[1]*London North West Healthcare NHS Trust, London, United Kingdom,* [2]*Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam,* [3]*Imperial College London, London, United Kingdom,* [4]*Imperial College Healthcare NHS Trust, London, United Kingdom*

Background: Retention in care on antiretroviral therapy (ART) is key to long-term survival in people living with HIV. Perinatally-acquired HIV positive (PaHIV+) adolescents and young adults (AYA) face particular challenges when negotiating transition from paediatric to adult settings. Clinical data in HIV+ adolescents are limited despite a global population numbering two million. This retrospective, single-centre UK cohort analysis examines predictors of viral suppression in PaHIV+ AYA following transition to a specialist AYA service.
Methods: 147 PaHIV+ AYA with > 1 year ART experience were included. HIV viral load (VL) data were collected from first AYA clinic visit onwards. Two annual viral suppression outcomes were identified: ´intermittently suppressed´ (any VL < 400 c/ml in 1 year) or ´suppressed´ (all VL < 400 c/ml in 1 year). Marginal logistic regression models using generalised estimating equations and independence working correlation structure were employed to explore sex, age at diagnosis, age and VL at first AYA clinic visit and increasing age as independent predictors of each outcome. Sensitivity analysis was conducted to examine the effect of drop out and missing data.
Results: 54% of patients were female and 82% Black African. Median age at first AYA clinic was 18yr (IQR17-19). Four patients were lost to follow up and 4 patients died during the data collection period. Amongst individuals with detectable VL at transition (≥400c/ml, 36%), odds of having ´intermittently suppressed´ or ´suppressed´ VL increased with yearly increment in age (OR 1.64 [1.45, 1.85] p < 0.001, OR 1.47 [1.27, 1.69] p < 0.001). This relationship was preserved in individuals with at least 3 years of clinic data (OR 1.51 [1.14, 2.00] p = 0.004, OR 2.51 [1.71, 3.69] p < 0.001). An inverse relationship between increasing age/log10VL was also observed when VL was analysed as a continuous variable with imputations to account for missing data. Age at diagnosis and at first AYA clinic and gender were not significantly associated with VL at first AYA visit or annual VL status.
Conclusions: Viral suppression rates improved as AYA matured. With support, PaHIV+ AYA who are viraemic at transition can remain in care and achieve viral suppression.

THPEB161

Impact of a formal transition of care process on young adults living with HIV attending who are moving from a pediatric to adult clinic in Mwanza, Tanzania

S. Msonga[1], T. Roche[1], W. Elimwaria[1], S. Shea[1,2], V. Kweka[1], J. Cataldi[1,2], B. Desderius[3], M. Minde[1,2], L. Mwita[1,2]
[1]*Baylor College of Medicine Children's Foundation- Tanzania, Mwanza, Tanzania, United Republic of,* [2]*Baylor College of Medicine International Pediatric AIDS Initiative At Texas Children's Hospital, Houston, United States,* [3]*Bugando Medical Centre, Mwanza, Tanzania, United Republic of*

Background: Adolescents and young adults living with HIV represent the only age group with increasing HIV prevalence and mortality worldwide. HIV-infected adolescents and young adults face many challenges to long term anti-retroviral treatment (ART) including peer pressure, risky behaviors, poor adherence, and missed appointments. To counter the potential risks these challenges pose for adolescents as they move from pediatric to adult care, the Baylor College of Medicine Center of Excellence - Mwanza,Tanzania (COE) has established a formal transition process. Adolescents complete 2 sessions between ages 15 and 17 prior to transfer to adult care. Through transition, they receive encouragement to take responsibility for their healthcare needs while learning more about their disease process and how to live positively with HIV.
Methods: To assess the impact of this transition process, we conducted a retrospective chart review of clients ages 18-24 years enrolling at Bugando Medical Centre (BMC) adult HIV clinic from January 2015 to May

Tuesday 24 July

2016. Clients on ART transferred from Baylor after completing transition were compared with clients on ART enrolled directly at BMC or transferred from a non-Baylor clinic. The last five visits through May 2017 were reviewed for ART regimen, good adherence (pill count adherence 95-105% at ≥4 visits), good attendance (no missed visits), and most recent viral load.
Results: Sixty-four young adults who completed transition and 50 non-transitioned young adults were enrolled at BMC during the study period. Clinical and behavioral characteristics are presented in the accompanying table. Compared with non-transitioned clients, more transitioned clients had good adherence (89% vs 64%, p< 0.01) and good clinical attendance (92% vs 60%, p< 0.01). There were no pregnancies among the transitioned clients and one pregnancy among the non-transitioned clients. There was no difference in viral load results between the two groups.
Conclusions: Young adults completing a formal transition program had better attendance and adherence to ART. A transition process bridges the gap between pediatric and adult services and represents an effective strategy to ensure long term ART adherence for adolescents. Additional study is needed to determine the impact of transition programs on clinical indicators including viral load and treatment failure.

Indicators	Transitioned Clients, n=64 (n=38 for Viral Load)	Non-Transitioned Clients, n=50 (n=22 for Viral Load)	p-value* (chi-square test)
2nd Line ART Regimen	18 (28%)	5 (10%)	0.02
Good Clinical Attendance	59 (92%)	30 (60%)	<0.01
Missed Appointments	1 (2%)	14 (28%)	<0.01
Lost to Follow-Up	4 (6%)	6 (12%)	<0.01
Good Adherence	57 (89%)	32 (64%)	<0.01
Viral Load <1000**	7 (18%)	2 (9%)	0.61
Viral Load >1000**	7 (18%)	4 (18%)	0.61
Undetectable Viral Load**	24 (63%)	16 (73%)	0.61
*p<0.01 is significant based on alpha=0.05 using Bonferroni correction for multiple comparisons; **Viral load results not available for 26 transitioned and 28 non-transitioned clients.			

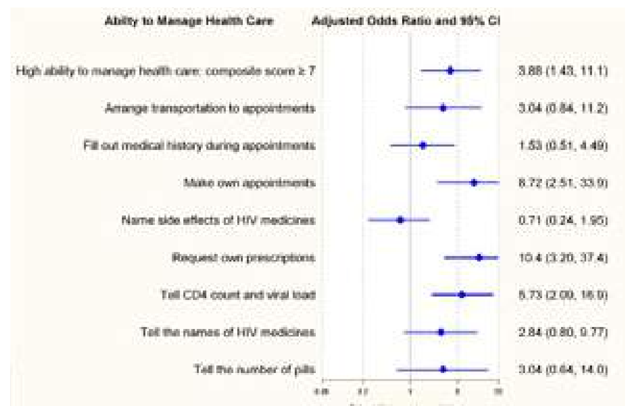
[Behavioral and clinical indicators among young adults living with HIV compared based on participation in a formal transition program]

THPEB162

Ability to manage health after transition to adult care is associated with retention in care among young adults with perinatal HIV infection

K. Tassiopoulos[1], Y. Huo[2], K. Patel[1], S. Nichols[3], D. Kacanek[2], S. Allison[4], M. Paul[5], S. Siminski[6], C. Mellins[7], The Pediatric HIV/AIDS Cohort Study (PHACS)
[1]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [2]Harvard T.H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [3]University of California San Diego, Department of Neurosciences, La Jolla, United States, [4]National Institute of Mental Health, Division of AIDS Research, Bethesda, United States, [5]Baylor College of Medicine, Pediatrics, Houston, United States, [6]Frontier Science & Technology Research, Amherst, United States, [7]Columbia University, Psychiatry and Sociomedical Sciences, New York, United States

Background: Perinatally HIV-infected (PHIV) adolescents are reaching adulthood and transitioning from pediatric to adult health care in increasing numbers. Yet there is little research on satisfaction with and retention in care after this transition.
Methods: The PHACS (Pediatric HIV/AIDS Cohort Study) AMP Up protocol is enrolling PHIV adults 18 years and older (including targeted enrollment of mothers) for long-term study of clinical and behavioral health. Participants complete an annual online survey on sociodemographics, behaviors, quality of life, and health care, including 8 questions on the ability to manage different aspects of one's own health. This analysis of entry visit data focused on the 124 out of 455 AMP Up participants (27%) enrolled to-date who had completed the transition to adult care. Multivariable logistic regression models evaluated associations of several factors with satisfaction with adult care provider/clinic (very satisfied/satisfied vs. dissatisfied/very dissatisfied) and retention in care (having had a health care visit within past 6 months).
Results: The average age at study entry was 26.6 years; 52% are Black or African-American, 46% Hispanic, and 71% female. The average age at transition was 21.7 years (range=15.9, 27.4). Older age at transition was associated with greater satisfaction with adult care provider (per year increase in age, OR =1.36, 95% C.I.=1.03, 1.84; p-value=0.04) and clinic (OR=1.30, 95% C.I.=0.98, 1.78; p-value=0.08). Young adults who reported greater ability to manage their care (yes to ≥7 of 8 questions) were more likely to have had a recent health care visit. Several individual indicators of health care self-management (ability to make their own appointments, fill prescriptions, and state their CD4 or viral load measures) were strongly associated with having a recent health care visit (Figure). Other factors (involvement in choosing adult care provider, depression, availability of supportive services at clinic) were not associated with the outcomes.
Conclusions: Young PHIV adults with greater ability to manage their health after their transition to adult care are more likely to have had a recent health care visit. This finding suggests that providers can assist their patients' successful transition by helping them develop skills to manage their health prior to this transition.



[Associations between Ability to Manage Health Care and Visit to Adult Care Clinic]

Adolescent to Adult Patient-centered HIV Transition (ADAPT) study: Adolescents' perspectives about transition from pediatric to adult HIV care setting in northern Nigeria - findings from a qualitative study

V. Tepper[1], C. Edokwe[2], C. Isah[2], A. Shutt[3], M. Charurat[3], F. Hassan-Hanga[4], B. Ismail[5], M. Essen[6], E. Audu[7], A. Okechukwu[8], H. Onyegbutulem[9], E. Ekong[2,3]
[1]University of Maryland School of Medicine, Pediatrics, Baltimore, United States, [2]Institute of Human Virology-Nigeria, Abuja, Nigeria, [3]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [4]Aminu Kano Teaching Hospital, Kano, Nigeria, [5]General Hospital Katsina, Katsina, Nigeria, [6]Federal Medical Centre, Keffi, Nigeria, [7]Dalhatu-Araf Specialist Hospital, Lafia, Nigeria, [8]University of Abuja Teaching Hospital, Abuja, Nigeria, [9]Asokoro District Hospital, Abuja, Nigeria

Background: One of the challenges faced by emerging adults living with HIV is the transition of care from their long-term pediatric HIV providers to treatment within an adult HIV program. Unsuccessful transition can be difficult and catastrophic. Limited studies have been conducted in sub-Saharan Africa incorporating the voices of youth in the design, implementation and interpretation of interventions to assist ALHIV in their transition to the adult HIV care system. This qualitative study explored ALHIV perspectives on the process of transition.
Methods: Eighteen Focus Group Discussions (FGDs) were conducted for 15-19 years old ALHIV across 6 healthcare facilities in Northern Nigeria May-July 2017. To be included in the study, ALHIV knew their HIV status and were enrolled in ART clinic for ≥12 months. Participants were interviewed by a researcher using a script containing a series of open-ended questions in key domains: experience of having the health care provider introduce the concept of transition, AHLIV readiness for and importance

of transition, advantages and disadvantages of transition, and what constitutes a successful transition. All participants provided written informed consent prior to FGD. Discussions were audio-recorded. FGDs in English were transcribed verbatim, those in Hausa were translated to English after transcription. Thematic analysis was performed using the MAXQDA software; common themes were extracted.
Results: A total of 150 ALHIV participated; 56 preparing for transition, 53 with successful transition, and 41 unsuccessful transition; 57% were female, 79% perinatally-infected, and 46% Muslim. Several themes emerged related to the experience of learning about transition; ALHIV reported feeling unhappy, anxious, confused, and uncomfortable when their health care provider introduced the idea of transition. Consistent themes emerged among all participants related to AHLIV definition of transition readiness: age, maturity/sense of responsibility, and ownership of care. Participants identified the following themes when describing transition success: improved state of their health and physical growth.
Conclusions: The voices of ALHIV are essential to the development of interventions to support their transition from pediatric to adult HIV care. Findings from this study will be presented to inform strategies for the development of transition services in resource-limited settings.

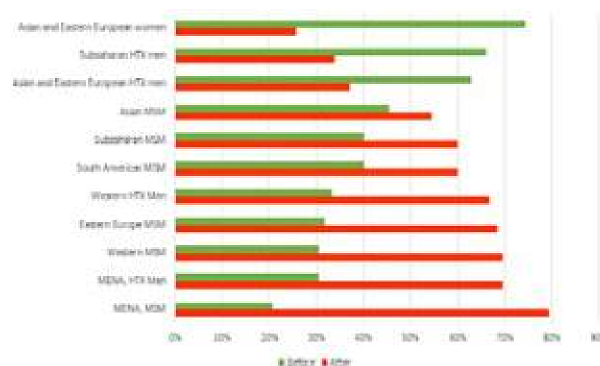
Surveillance in key population groups

THPEC164

Do migrants acquire HIV before or after migration to Denmark? And can we determine the groups most in need of prevention?

S.A. Cowan, A.H. Christiansen
Statens Serum Institut, Department of Epidemiology, Copenhagen, Denmark

Background: Since the start of HIV-surveillance it has been assumed that most HIV-positive migrants were infected before arrival to Denmark. European research has revealed that the majority of migrants in Europe acquire HIV post-migration. The aim of this study was to determine what proportion of migrants in Denmark acquire HIV post-migration and to analyze the underlying demographic factors.
Methods: Using national surveillance data for 2005-2017 including date of migration, CD4-cell count, confirmed HIV-negative tests, acute HIV-infection or AIDS at diagnosis, we modelled pre-/post-migration HIV-acquisition among migrants who were newly HIV-diagnosed in Denmark. We grouped the migrants after region of origin, gender, and mode of infection. Tourists (160) and undocumented migrants (91), who are not given a unique personal identifier, were excluded.
Results: For 912 (98%) out of 928 migrants, 15 years or older at migration, it was possible to estimate time of infection as pre- or post-migration using the model. We included 860 migrants who were registered as sexually infected, 596/ 69% heterosexually (HTX) and 264/31% homosexually (MSM). 34 infected by intravenous drug-use and 18 with unknown transmission-route were excluded. According to the model, 41% were infected post-migration, whether in Denmark or traveling/visiting relatives. There were large differences between women, HTX men and MSM, and between region of origin. Figure 1 shows the most likely and the least likely groups to become infected after migration to Denmark. Groups with less than 10 HIV-positive were omitted as was persons from Greenland as they were all infected in Denmark regardless of group.
Conclusions: Among HIV-positive migrant-women regardless of origin, and HTX men from Asia, Eastern Europe and Sub-Saharan Africa the vast majority (63-80%) of transmissions had occurred pre-migration. The opposite was true for Middle-eastern and North-African men and Eastern- and Western-European MSM. Among those groups 67%-79% were infected post-migration. Asian, Sub-Saharan and South American MSM were infected post-migration in just over half the cases (55%-60%). This large difference in risk of post-migration HIV-acquisition enables prevention-policies to focus on both openly gay men from MENA and Europe, and on men from MENA and Western Europe who seem to be MSM, but register as HTX because of stigma.



[% HIV infected before or after migration to Denmark, by origin and sexual orientation]

THPEC165

Changing motives to test for HIV and for not using condoms - an analysis of pre-test questionnaires from clients of community-based voluntary testing sites in three large German cities, 2015-2017

U. Marcus, S.B. Schink, German Checkpoint Collaborative Group
Robert Koch-Institut, Infectious Disease Epidemiology, Berlin, Germany

Background: Since 2015 the estimated HIV incidence among men having sex with men (MSM) residing in Germany has decreased. Due to a significant price cut, HIV pre-exposure prophylaxis (HIV-PrEP) became more widely affordable by late 2017.
We analysed data collected by pre-test questionnaires from 7 community-based voluntary counselling and testing sites (CBVCT) from 2015 through 2017 in the three largest German cities to monitor changes in the motives for HIV testing and for not using condoms amongst MSM and non-MSM clients.
Methods: CBVCT clients filled-in self-administered pre-test questionnaires. Data collected included motives for HIV testing and motives for not having used condoms during the last sexual risk situation. Clients were asked to indicate all reasons that applied. No unique identifiers to detect repeat testers were used.
Changes in the frequency of motives of MSM and non-MSM CBVCT clients from 2015 through 2017 were analysed using logistic regression (with Stata 14).
Results: Data from 28,654 client visits (MSM: 18,936; non-MSM: 9,718) could be evaluated. Reasons for testing were given by 15,492 MSM and 7,850 non-MSM, reasons for not using condoms by 7,949; 4,629 respectively.
Figure 1 shows changes of the frequency of responses from MSM and non-MSM clients comparing 2016 and 2017with 2015. Amongst both groups, routine testing increased, while testing when entering a new partnership decreased. Having had an (unsuspected) HIV-positive partner decreased amongst MSM as reason for testing.
Amongst both groups, assuming the partner was HIV-negative decreased as reason for not having used condoms, while desire for condomless sex increased. Amongst MSM, sex partner having undetectable viral load increased, as did sex partner demanding condomless sex. Loss of control due to substance use decreased.
Conclusions: Promotion of routine sexual health checks at CBVCT is successful and appears to partly replace testing when entering a new partnership. Testing due to unprotected sex with an unsuspected HIV-discordant partner decreases, and viral sorting (condomless sex with effectively treated partners) increases among MSM, suggesting increased serostatus awareness.
Demand for condomless sex is increasing, which may be a consequence of increased serostatus awareness and may also reflect increasing discussion and awareness of HIV-PrEP as an additional prevention tool.

Surveillance surveys of behavior with biological linkage in Haitian and Dominican-Haitian construction workers living in Santo Domingo, Dominican Republic

T. Contrera Charpentier
Socio-Cultural Movement for Haitian Workers (MOSCTHA), Health, Santo Domingo, D.N., Dominican Republic

Background: It is estimated that 7% of the population of the Dominican Republic is Haitian or of Haitian descent (UNFPA 2013). However, uncertainty has persisted about the burden of HIV and the degree of risk behavior between people who migrate from Haiti and people born Dominican of Haitian descent. The degree to which their risk derives from factors related to internal and external migration, their livelihood while in the Dominican Republic, their behavior, their access to health services and the effect of a higher overall prevalence of HIV compared with the The Dominican Republic has not been measured.

Methods: Sampling of construction workers was carried out at the construction sites using a local-based cluster sampling design (VBCS). We start with a mapping phase to create a sample frame of construction sites, including the number of workers in each location. We divided a map of Santo Domingo and its surroundings into five geographic areas: Distrito Nacional, Santo Domingo Este, Santo Domingo Oeste, Santo Domingo Norte and Boca Chica.

Results: A large percentage of the participants reported having had unprotected sex at some time (44.1%) with their last partner. 56.5% of the population believed that a person who looked healthy could not be HIV positive. This study calculated the prevalence of HIV among Haitian and Dominican-Haitian construction workers in Santo Domingo at 4.6%. That is, one in every 22 Haitian or Dominican-Haitian men who work in construction in Santo Domingo in 2014 was infected with HIV. The prevalence of syphilis among Haitian and Dominican-Haitian construction workers in Santo Domingo was 7.9%; that is, about one in every 13 workers was infected with syphilis in 2014.

Conclusions: Relatively high prevalence of HIV. In this sample, HIV prevalence was 4.6%, much higher than the national prevalence of 0.7% in the Dominican Republic and 2% in Haiti. The prevalence is close to 5%, a threshold considered as a definition of a key population that merits special resources for the prevention and care of HIV. The study corroborates the fundamental hypothesis that mobile men in many parts of the world carry a disproportionate burden of infection.

THPEC167

Presentation with advanced HIV disease in a Southern US State, 1996-2013

S. Nduaguba, K. Ford, J. Wilson, K. Lawson
University of Texas at Austin, College of Pharmacy, Austin, United States

Background: Late presentation with HIV is associated with poor response to treatment and high risk of mortality and remains a major issue in all settings affected by HIV. In the US, national and state-level HIV testing programs have been initiated to enhance early diagnosis and link infected individuals to care. The objective of this study was to assess whether these programmatic efforts have improved the timing of presentation with advanced HIV disease (AHD) by examining presentation trends in a Southern US state.

Methods: This was a retrospective study of individuals aged 18 to 89 years who were diagnosed with HIV in Texas from 1996 to 2013. Eligible cases were identified using surveillance data from Texas Department of State Health Services. The proportion of individuals presenting with AHD, defined as having an AIDS diagnosis within 365 days of HIV diagnosis, was determined and compared for each year from 1996 to 2013 stratified by gender, race/ethnicity, and risk transmission group using frequencies and Wald tests.

Results: Of the 77,844 individuals included in the cohort, 78% were male and 27%, 38%, and 31% were Whites, Blacks, and Hispanics, respectively. Overall, 30,573 individuals (39%) presented with AHD. Sixty-five percent, 63.3%, and 60.2% of individuals diagnosed with HIV respectively presented with AHD in 1996, 1997, and 1998. The proportion presenting with AHD fell sharply to 38.3% in 1999 and then gradually declined to 29.3% in 2013. The percentage drop from 1996 to 2013 was greater among men (40%, 95% confidence interval=38%-42%) than women (18%, 14%-23%), greater among Whites (42%, 39%-46%) than Blacks (34%, 31%-38%) and Hispanics (35%, 31%-38%), and greater among males who have sex with males (41%, 39%-44%) than heterosexuals (22%, 17%-26%) and injecting drug users (32%, 24%-41%) (p< 0.001 in each case).

Conclusions: In Texas, the timing of presentation with AHD has improved. The sharp drop in 1999 may reflect the introduction of highly active antiretroviral therapy allowing for uptake and adoption in clinical practice. Close to 30% presented with AHD in 2013, indicating that there are still opportunities for early diagnosis and consequent improvement of health outcomes for people living with HIV.

THPEC168

HIV, HCV and syphilis prevalence among MSM in Tajikistan are stabilized

T. Sherkhonov[1], M. Kasianchuk[2], S. Khuvaydo[3], U. Rahmatjonov[4]
[1]National AIDS Center, M&E, Dushanbe, Tajikistan, [2]Eurasian Coalition on Male Health (ECOM), Tallinn, Estonia, [3]UNDP, Dushanbe, Tajikistan, [4]National AIDS Center, Dushanbe, Tajikistan

Background: Men having sex with men (MSM) remain one of the most HIV vulnerable groups of population in developed countries. There is very limited data on HIV epidemics among MSM in Central Asia region, especially in Tajikistan, primarily due to the hidden character of the group. The surveillance studies conducted earlier (2011 and 2015) showed alarming HIV prevalence among MSM (4.1% in Dushanbe and 2.7% in the whole country, 2015).

Methods: A cross-sectional integrated bio-behavioral survey was conducted among MSM by UN Development Program in Tajikistan and National AIDS Center from November to December, 2017. A total respondent-driving sample was 700 MSM (350 in Dushanbe).

Results: MSM in Dushanbe were 28 y. o. in average; 44% had secondary and 33% tertiary education; 38% are living with women; last 6 months, they had sex with 3 men in average; last year, no one was an injection drug user; 72.9% (CI: 68.2-78.0) used a condom at last anal intercourse with man; 8.5% (5.7-11.7) were HIV tested and knew their result during last 12 months.

In 2017, the prevalence of HIV among MSM in Dushanbe was 2.4% (CI: 0.9-4.3), HCV 4.3% (2.1-6.8) and syphilis 4.9% (2.7-7.2). In 2015 and 2011, HIV prevalence was 4.1% (2.1-6.2), 1.5% (0.2-3.2) respectively, HCV prevalence was 2.3% (0.9-4.0) and 3.9% (1.2-7.3), syphilis prevalence 9.3% (6.4-12.4) and 5.1% (2.7-8.8).

Conclusions: The analysis of the collected data shows that HIV, HCV and syphilis prevalence among MSM in Tajikistan are stabilized (compared to 2015). This is one of the major positive impacts of prevention programs among MSM in the country. For further progress in the prophylaxis of these infections among MSM prevention programs should be continued and strengthened.

THPEC169

Tuberculosis and HIV co-infection in the European Union: Epidemiology and tuberculosis treatment outcomes

M. van der Werf, C. Ködmön
European Centre for Disease Prevention and Control, Stockholm, Sweden

Background: Tuberculosis (TB) is a common disease in people living with HIV. To implement adequate activities for the prevention and control of TB/HIV co-infection robust and timely information is essential. European Union (EU) and European Economic Area (EEA) countries report their TB cases annually to the European Surveillance System (TESSy). We analysed trend data on the epidemiology of TB-HIV co-infection and TB treatment outcomes of co-infected people in order to provide up-to-date information to guide TB control efforts.

Methods: We analysed case-based information on HIV status of TB cases for the years 2012 to 2016. We assessed reporting completeness, trends in co-infection, and TB treatment outcomes 12 months after diagnosis.

Results: In the years 2012 to 2016, 14 to 21 of the 31 EU/EEA countries reported on HIV status of TB cases and in the countries reporting, the completeness was on average 65.3% (range between 2.2 and 100.0%). In the analysis period, the percentage TB-HIV co-infected cases varied between 3.1 and 3.3% in the EU/EEA. Of the countries reporting HIV status of > 20 TB cases in 2016, Malta reported the highest percentage of co-infected cases (16.0%), whereas Bulgaria, Cyprus, and Slovakia reported no co-infected cases. Four countries reported >10% of the TB cases co-infected with HIV in any of the years included in the analysis. Of the total of 5119 co-infected cases 1413 (27.6%) were in women and 24 (0.5%) in children < 15 years. For TB-HIV co-infected cases diagnosed in 2015 TB treatment outcomes were reported by 14 countries. Of 779 co-infected cases 438 (56.2%) were successfully treated. The percentage of cases successfully treated was similar in other years.

Conclusions: There are gaps in the surveillance of TB-HIV co-infection in the EU/EEA with about 65% of the countries reporting case-based HIV-status data. The observed co-infection percentage of around 3% if significantly lower than the 10% estimated at global level. An important point of attention are the treatment outcome results for co-infected cases which are worse than the overall treatment success rate of 71.5% in the EU/EEA and far from the 85% target.

THPEC170

Measuring late diagnosis in an era of frequent testing: Correcting for CD4 at seroconversion

P.D. Kirwan[1], A. Aghaizu[1], J. Tosswill[2], G. Murphy[2], A. Brown[1], V. Delpech[1]
[1]Public Health England, HIV & STI Surveillance, London, United Kingdom, [2]Public Health England, Virus Reference Department, London, United Kingdom

Background: For public health purposes, persons diagnosed with a CD4< 350 are classified as "late presenters". However, people can experience a transient dip in CD4 during seroconversion or may experience rapid progression of HIV and expedited CD4 decline, resulting in misclassification. We present a novel algorithm to measure late diagnosis using tests for recent infection (TRI) and evidence of recent negative tests.

Methods: All persons diagnosed in England, Wales and Northern Ireland between 2011-2016 with baseline CD4 within 91 days were included (83% completion) and linked to TRI results and STI clinic data for testing history. Those with viral load < 200 indicated recent treatment initiation and were excluded. Patients with TRI LAg results< 1.5 and CD4 ≥50 suggested likely recent infection and those with negative HIV tests within 2 years (LN) were classified as "not-late". A correction factor (CF) was defined as the percentage change applied to the original figure to adjust for serocoversion (CF=unadjusted/adjusted*100).

Results: Of 27,652 eligible people, 43% (11,935) had CD4< 350 (unadjusted late diagnosis figure), 55% (15,324) had a TRI and 20% (5,516) had a LN test. No difference by age, ethnicity or country of birth was observed between those with/without CD4 or TRI information.

Among those with CD4< 350, 7% (480/6,655) had a TRI suggesting recent HIV acquisition and a further 9% (567/6,175) had a LN test. Reclassification of these cases resulted in a late diagnosis rate of 37% (5,608/15,324) among those with complete information and 38% (10,479/27,652) for the whole study group; equating to a CF of 16%.

The CF increased over time (from 11% in 2011 to 19% in 2016) and was larger among gay and bisexual men (27%) than heterosexual men and women (both 8%) (table 1).

	Proportion diagnosed late	Revised proportion diagnosed late	Correction factor
Total population, all years	43%	37%	16%
2011	47%	42%	11%
2012	49%	42%	14%
2013	42%	36%	14%
2014	40%	34%	17%
2015	39%	30%	21%
2016	44%	36%	19%
Gay and bisexual men	32%	24%	27%
Heterosexual men and women	59%	55%	8%

[Proportion diagnosed late and correction factor, by year and exposure route]

Conclusions: Incorporating TRI and HIV testing history into the late diagnosis algorithm reduced the late diagnosis rate up to 21%. People are increasingly diagnosed at earlier stages of infection due to increased HIV testing (especially gay/bisexual men). These results suggest that increasing numbers are being misclassified as late presenters.

Despite this reclassification, a third of diagnoses over the past 6 years were diagnosed late.

THPEC171

Complex health issues experienced by people accessing HIV care in England

P.D. Kirwan, M. Kall, A. Brown, V. Delpech
Public Health England, HIV & STI Surveillance, London, United Kingdom

Background: As people with HIV are living longer, an increasing number may experience complex health issues. Using national HIV cohort data we examine the demographic characteristics of patients with co-morbidities, co-infection and persistent viraemia accessing HIV care in England.

Methods: We used attendance-based data on adults (aged 15+) attending specialist HIV clinics in 2016. Clinics submitting all 4 quarters (167/183; 91%) of data were included and attendances linked across quarters. We analysed demographic characteristics of patients with and without a comorbidity or coinfection reported at one or more attendances in 2016 including: tuberculosis, an AIDS-defining illness, HIV-associated end organ disease, cancer (on treatment) care, chronic viral liver disease (receiving treatment) and under psychiatric care, and those with persistent viraemia (>2 viral loads ≥200 copies/mL after >6 months on ART). A suppressed viral load was defined as a viral load < 200 copies/mL.

Results: Of 68,697 adults included in the study, 12% (8,306/68,697) had at least one co-infection, co-morbidity or persistent viraemia reported in 2016 with 2% (1,102/68,697) experiencing two or more conditions. Demographic characteristics differed by condition (table 1) with co-morbidities disproportionately affecting older persons and those living in more deprived areas of England. Among people with any co-morbidity, co-infection or persistent viraemia, 41% were aged 50 years or over and 6% were aged 65 years or over, this compared to 36% and 5% for those without these conditions. 72% of people with a co-morbidity or co-infection were men, compared to 67% without. Regardless of co-infection or co-morbidity, >92% of people on HIV treatment attained viral suppression.

Condition	% of study population	% aged over 50 years	% living in most deprived quintile	% on treatment with suppressed viral load
Tuberculosis treatment	0.7%	31%	42%	94%
AIDS-defining illness	2.3%	48%	41%	94%
Chronic viral liver disease	2.0%	43%	37%	96%
Cancer treatment	1.1%	58%	35%	96%
End organ disease	3.1%	60%	39%	96%
Under psychiatric care	3.3%	35%	39%	92%
Persistent viraemia	1.5%	25%	43%	N/A
None	87.9%	36%	35%	97%

[Prevalence and key demographics of co-morbidities, co-infections and persistent viraemia]

Conclusions: A significant proportion of people living with HIV experience complex health issues, with the prevalence of certain conditions increasing with age. We anticipate that the economic impact of such conditions will intensify as people continue to live longer with HIV.
Complex health issues were more common among people living in deprived areas which may suggest inequity of access to appropriate healthcare services. Reassuringly, the presence of a co-infection or co-morbidity did not have a significant adverse effect on virological suppression, suggesting effective management of HIV by clinicians in spite of co-morbidity and co-infection.

THPEC172

Vulnerability, risk and HIV, Syphilis and other infections among female sex workers in Agadir, Casablanca, Fes, Marrakesh, Rabat and Tangier, Morocco 2016

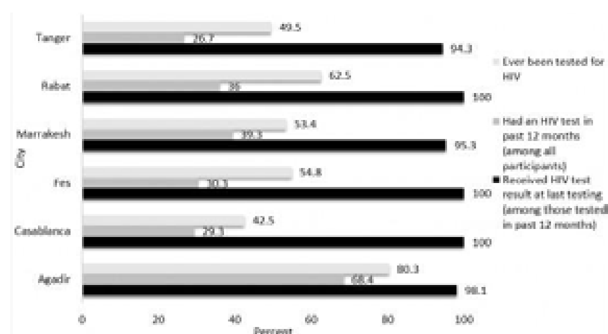
L. Johnston[1], A. Bennani[2], H. El Rhilani[3], L. Ghargui[2], K. Alami[3], B. El Omari[4], A. Maaroufi[2]
[1]*Independent Consultant, Valencia, Spain,* [2]*Ministry of Health, Rabat, Morocco,* [3]*UNIADS, Rabat, Morocco,* [4]*Global Fund to Fight AIDS, Tuberculosis and Malaria, Rabat, Morocco*

Background: An HIV bio-behavioral survey using respondent-driven sampling was conducted in 2016 among 256 female sex workers (FSW) in Agadir, 276 in Casablanca, 253 in Fes, 254 in Marrakesh, 250 in Rabat and 261 in Tangier.

Methods: Eligible females were ≥18 years, reported exchanging penetrative sex for money with > one male client in the past six months, having Moroccan nationality and working in the study location. Respondents completed an interview and provided blood specimens for HIV and syphilis. These findings are compared to a 2011-2012 survey.

Results: As in 2011-2012, almost half of FSW in all cities reported ever attending school and most reported having been married but currently being either separated or divorced and financially supported other adults or children. The percentage of Agadir FSW reporting always using condoms in the past 30 days increased significantly, by almost 30%, between 2011-2012 and 2016 whereas in Fes, Rabat and Tangier percentages were unchanged or declined. Between 27% in Tangier and 68% in Agadir reported having an HIV test in past 12 months, among which all or almost all received their results (Table). There were substantial increases in ever having an HIV test in Agadir, Fes, Rabat and Tangier between the 2011-2012 and 2016 surveys. Agadir FSW had the highest HIV prevalence and Tangier FSW had the highest active syphilis prevalence. Overall, HIV prevalence was >2.5% and syphilis prevalence was >25%. Between 2011-2012 and 2016, there were non-significant decreases in HIV prevalence in Agadir (5.1%-2.3%) and increases in Tangier (1.4%-1.8%) and a significant decrease in Fes (1.8%-0.2%). No one was positive for HIV in Rabat in 2011-2012 and only one person was positive in 2016 (0.4%). In Agadir, active syphilis prevalence was 21.2%, in Casablanca 15.7%, in Fes 21.7%, in Marrakesh 22.9%, in Rabat 4.7% and in Tangier 24.8%. Although there was no change in Syphilis prevalence in Agadir (21.4%) and Fes (18.8%) did not change significantly between 2011-2012 and 2016, there was a significant increase in Tangier (13.3%) and decrease in Rabat (13.9%).

Conclusions: Findings show improvements in HIV testing but also identify the need to expand programs targeting FSW in Morocco.



[HIV testing among FSW in Agadir, Casablanca, Fes, Marrakesh, Rabat, and Tangier, Morocco, 2016]

THPEC173

Persistent high burden of advanced HIV disease in South African children and adolescents at entry into care: Data from a longitudinal nationwide laboratory cohort

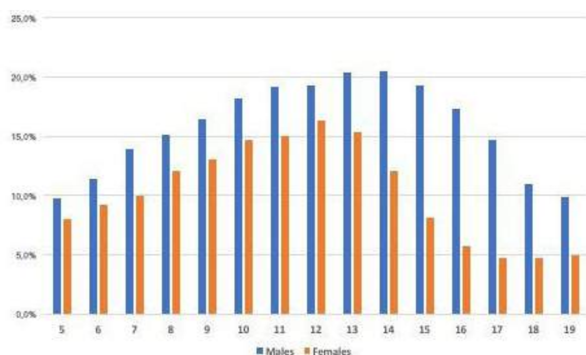
S. Carmona[1,2], M. Maskew[3,4], G. Sherman[5,6], J. Bor[3,7,8], M. Penazzato[9], M. Fox[3,7,8], N. Ford[9], W. Macleod[3,8]
[1]University of the Witwatersrand, Molecular Medicine and Haematology, Johannesburg, South Africa, [2]National Health Laboratory Service, Johannesburg, South Africa, [3]Health Economics and Epidemiology Research Office (HE2RO), Johannesburg, South Africa, [4]University of the Witwatersrand, Johannesburg, South Africa, [5]University of the Witwatersrand, Paediatrics and Child Health, Johannesburg, South Africa, [6]National Institute for Communicable Diseases, Centre for HIV and STI, Johannesburg, South Africa, [7]Boston University, Department of Epidemiology, Boston, United States, [8]Boston University, Department of Global Health, Boston, United States, [9]World Health Organization, HIV/AIDS, Geneva, Switzerland

Background: The South African National PMTCT programme has made remarkable progress in reducing vertical transmission and increasing coverage of antiretroviral therapy (ART) over the last decade. However, delayed ART initiation in children and adolescents persists due to delays in identification and limited availability of age-appropriate formulations and services delivery models. Using a linked National HIV Cohort, we assessed the proportion of children and adolescents entering care with advanced HIV disease (CD4 < 200 cells/mm³) over time.

Methods: We constructed a cohort of children and adolescents aged 5-19 years utilizing nationwide laboratory records of CD4 counts from 2005-2016. Using probabilistic linkage methods, we determined first CD4 cell count at entry to care. Numbers and proportions of patients with first CD4 < 200 cells/mm³ by age and sex were calculated.

Results: From 2005-2016, 587,316 children and adolescents had a first CD4 count test and 18.0% had CD4 count < 200 cells/mm³. The proportion of children and adolescents entering into care with advanced disease declined from 22.6 to 15.9% from early to later years (Table 1). However, from 2011 onwards the proportion entering ART care with low CD4 counts has remained relatively unchanged at 15-16%. While the absolute number of girls entering care with advanced disease was near twice the number of boys, the proportion of boys entering care with advanced HIV disease was greater than that of girls (risk ratio: 1.63; 95% CI: 1.61—1.65). The gender distribution of advanced disease varied by age; the proportion of girls with advanced disease peaked at 12 years and then declined sharply, levelling off at 17 years of age whereas boys peaked at 14 years of age and declined steadily thereafter (Figure 1).

Conclusions: The proportion of children and adolescents presenting with advanced HIV disease remains consistently high despite ART scale up. Testing campaigns focused on early HIV-diagnosis and linking patients to ART care should be prioritised, particularly among adolescent boys. CD4 testing to identify advanced disease, provide screening and prophylaxis for opportunistic infections and rapidly initiate ART remains critical.



[Figure 1. Proportion of children and adolescents presenting with advanced disease by Age and Sex (2005-2016)]

	Females		Males		Total

HIV dynamics in migrants from Central, Eastern and Western Europe in the Europe Union/Economic Area (EU/EEA)

J. Del Amo[1], I. Jarrín[1], V. Hernando[1], B. Alejos[1], T. Noori[2], A. Pharris[2]
[1]Institute of Health Carlos III, National Center for Epidemiology, Madrid, Spain, [2]European Centre for Diseases Prevention and Control, Stockholm, Sweden

Background: We aim to quantify the contribution of migrants from Central (CE), Eastern (EE) and Western European (WE) origin to HIV reports in EU/EEA, describe trends by transmission category and examine median CD4 count at diagnosis.

Methods: HIV reports to the European Surveillance System (TESSy) from 30 EU/EEA countries from 2004 till 2015 pooled in December 2016 were analysed. To minimize artificial declines due to reporting delay, 2015 was excluded when appropriate. Cases from Europe were divided into three European UN sub-regions. Differences in CD4-counts at HIV diagnosis over time for each sub-region were modelled using median regression adjusting for transmission category, age and sex.

Results: Of 375,743 cases reported in 2004-2015, 26,600 (7%) were European migrants; 48% from WE, 31% from CE and 21% from EE. Overall, 74% and 57% of HIV reports in WE and CE migrants were men who have sex with men (MSM) and 34% of HIV diagnoses in EE migrants were persons who inject drugs (PID). From 2004 to 2014, absolute (+833) and relative (+139%) increases in HIV diagnoses in MSM from all three sub-regions were observed, although increases were more noticeable in CE (+405, 431%) and EE (+81, 238%) than in WE (+347, 74%). For heterosexually transmitted cases, absolute (+429) and relative (+257%) increases from CE and EE and stable trends from WE were reported. For PID, absolute (-63) and relative (-52%) declines in WE migrants and absolute (+54, +47) and relative (+357%, +62%) increases in HIV diagnoses in CE and EE migrants, respectively, were observed. Median CD4-counts were consistently higher among women, MSM and people under 30 years from all regions. Sensitivity analyses from 2008 onwards (more stable CD4-count reporting) revealed increases overtime for CE migrants and no change in those from EE.

Conclusions: The current HIV epidemic in European migrants within EU/EEA is driven by on-going transmission among MSM from WE, CE and EE, who consistently show higher CD4 counts at diagnosis. These infections are likely to be acquired HIV post-migration and require enhanced preventive interventions. HIV infections in heterosexuals and PID from CE and EE are increasing, calling for enhanced focus on these populations.

THPEC175

An innovative vending machine-based HIV testing and intervention service: Anonymous urine collection kits distributed at universities in China

X. He, Y. Jiang
National HIV/HCV Reference Laboratory, National Center for AIDS/STD Control and Prevention, China CDC, Beijing, China

Background: Vending machines have recently been evaluated as a feasible delivery mode for HIV tests. In this study, we for the first time, assessed an innovative HIV vending machine and internet-based anonymous urine test at seven universities in four provinces of China in 2016.
Methods: The students anonymously and voluntarily purchased the urine collection kits from vending machines after publicity campaigns which were launched by university student organizations on campuses. Students collected their own urine samples in private and returned them to vending machine return slot. Urine samples were transported to the laboratory for testing within seven days using urine HIV-1 antibody ELISA kits. Uploaded the results to a special website where participants could receive their test results. Provided testing instructions on the results search page and a confidentiality notification for participants to receive post-test support services. Finally, retrieved and analyzed the data from the positioning and online data management systems.
Results: In total, we dispensed 957 HIV urine collection kits through vending machines sales and free as part of an education campaign, a total of 378 (39.5%) urine samples were returned and 376 (99.5%) of them were qualified to be tested for HIV antibody in a local professional laboratory, 7 (1.86%) urine samples were HIV antibody positive. 67.8% (255/376) participants searched for their test results using the internet. The percentages of participants testing HIV antibody positive and negative who searched for their results were 100% (7/7) and 67.2% (248/376). Finally, 1 of 7 HIV antibody-positive participants voluntarily accepted support services and was referred to a hospital for antiviral treatment.
Conclusions: The results showed the acceptability, feasibility, and effectiveness of this innovative HIV testing service based on vending machines. This service can play an important role in HIV education and intervention.

THPEC176

Disparities in timely ART initiation among persons newly diagnosed with HIV in San Francisco, California, USA 2011-2016

L. Hsu, S. Schwarcz, S. Scheer, A. Hughes
San Francisco Department of Public Health, San Francisco, United States

Background: In 2010 the San Francisco Department of Public Health recommended universal antiretroviral therapy (ART) for all persons with HIV regardless of CD4 count and in 2015 implemented the rapid ART initiation initiative. We used the San Francisco HIV surveillance registry data to examine trends and characteristics of persons with timely ART initiation and reasons for not initiating ART.
Methods: Data were obtained from mandatory HIV reporting from laboratories and physicians, and from medical chart review that included dates of HIV diagnosis and ART initiation and when noted in the chart, reasons for not initiating ART. Persons aged 13 years and older who were diagnosed with HIV in 2011-2016 and resided in San Francisco at time of diagnosis were included. Differences in socio-demographic and risk characteristics between those who initiated ART within one month of diagnosis and those who did not, were assessed using the Chi-Square test. Logistic regression was used to identify factors independently associated with timely ART initiation.
Results: The population was predominately male (90%), white (46%), men who have sex with men (MSM) (74%), aged less than 40 years (59%), born in the United States (57%), housed (90%), and had CD4 count ≥ 200 cells/mm³ at diagnosis (78%). The number of persons newly diagnosed with HIV increased from 2011 to 2012 and then declined through 2016. Overall 50% of the 2083 persons diagnosed in 2011-2016 initiated ART within one month of diagnosis, increasing from 36% in 2011 to 72% in 2016 ($p < 0.0001$). In the multivariate analysis, females, trans females, African Americans, MSM who inject drugs, and persons without health insurance were less likely to initiate ART within one month of diagnosis (all $p < 0.05$). Of the 203 persons not known to have started ART, 51% were not in care and 7% of patients refused ART. Other less frequently documented reasons included perception of non-adherence and homelessness.
Conclusions: While rapid initiation of ART has become significantly more likely in recent years in San Francisco, improved timely ART initiation has not benefited all persons equally. Efforts to address barriers to timely ART initiation should focus on vulnerable populations.

THPEC177

High HIV and STI diagnosis rates in people without health insurance in community based HIV/STI testing services in large cities across Germany, 2015-2017

S.B. Schink[1,2], U. Marcus[1], German Checkpoint Collaborative Group
[1]*Robert Koch Institute, Infectious Disease Epidemiology, Berlin, Germany,*
[2]*Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: Universal health insurance was mandated in Germany in January 2009 requiring everybody to have public or private healthcare coverage. Nevertheless, people report that they lack health insurance. We analysed health outcome data from community-based voluntary counselling and testing (CBVCT) with regard to insurance status in Germany from 2015 through 2017.
Methods: CBVCT clients filled in self-administered pre-test questionnaires. Data collected included sexual orientation, migration, hepatitis A vaccination and health insurance status. We matched questionnaire data to laboratory results for HIV, gonorrhea and chlamydia. We used bivariate analysis and multivariate logistic regression (MLR) analysis with stratification by self-declared gender/sexual orientation (women, heterosexual men, men having sex with men (MSM)) in Stata© 14.
Results: Data from 27,439 CBVCT visits were evaluated; 4.3% (1,190) reported no valid health insurance. Compared to women, heterosexual men were 1.5 times (odds ratio (OR) = 1.5, 95% confidence interval (95%CI): 1.1-1.9) and MSM more than twice (OR=2.4, 95%CI: 1.9-3.1) as likely to be uninsured. Compared to nationals, we found no difference to people with a parental migration history, however clients born abroad were almost 15 times more likely to be uninsured (OR=14.9, 95%CI: 12.3-17.8). [Table 1]
A new HIV diagnosis was 3.5 times (OR=3.5, 95%CI: 2.5-5.1) more likely in visits by uninsured people compared to insured people. For MSM without healthcare coverage, MLR showed that MSM were twice (OR=2.0, 95%CI: 1.6-2.5) as likely not to be vaccinated against hepatitis A virus infection, 1.4 times (OR=1.4, 95%CI: 1.1-1.9) more likely to test positive for gonorrhea and/or chlamydia and 2.9 times (OR=2.9, 95%CI: 1.6-5.4) more likely to be newly diagnosed with HIV infection.
Conclusions: In spite of mandatory health insurance, 4.3% of CBVCT visits are by people who are uninsured. Uptake of recommended preventative services like HAV vaccination is lower while infection rates with gonorrhea and chlamydia are higher in uninsured MSM. Infection rates for HIV are higher among women, heterosexual men and MSM alike. Since CBVCT welcome uninsured people at risk for HIV and other infections, we recommend that either referral services for treatment complement CVBCT screening or CBVCTs are strengthened to provide treatment to those without access to care.

	Odds Ratio	p-Value	95% Confidence Interval

Recent HIV infection among newly diagnosed individuals in the Eastern European country of Georgia, 2015-2016

N. Dvali[1], N. Chkhartishvili[2], M. Karchava[1], M. Ghvaberidze[3], T. Tsertsvadze[2,4]
[1]*Infectious Diseases, AIDS and Clinical Immunology Research Center, Virology and Molecular Medicine, Tbilisi, Georgia,* [2]*Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia,* [3]*Infectious Diseases, AIDS and Clinical Immunology Research Center, Laboratory of HIV Diagnostics, Tbilisi, Georgia,* [4]*Ivane Javakhishvili Tbilisi State Univeristy, Tbilisi, Georgia*

Background: Surveillance of recent infection can help to better understand patterns of HIV transmission and identify populations at most risk of infection. Initially injection drug use driven HIV epidemic in Georgia had been shifting to predominance of sexual transmission. Objective of this study was to identify recent infections and associated factors among newly diagnosed persons.

Methods: Recent HIV infections were identified using recent infection testing algorithm (RITA) combining laboratory assay for recent infection and clinical data on immune status and disease stage. Limited antigen avidity (LAg) enzyme immunoassay (EIA) was used on frozen remnant HIV diagnostic specimens. Data on CD4 cell count, presence of AIDS defining illness and viral load was extracted from the national AIDS health information system. HIV infection was defined as recent if individual had LAg EIA and did not have evidence of longstanding infection. Study included 1132 adult persons newly diagnosed in 2015-2016 (80% of new diagnoses made).

Results: Among 1132 persons included 547 (48.3%) were infected in 2015 and 585 (51.7%) in 2016; 853 (75.4%) were men and 279 (24.6%) women; 599 (52.9%) were infected through heterosexual contact, 324 (28.6%) - through injection drug use (IDU) and 192 (17.0%) through sex between men. Overall 136 (12.0%) persons were classified as recently infected with similar proportions identified in 2015 and 2016 (13.0% vs. 11.1%, p=0.33). Men who have sex with men (MSM) had highest proportion of recent infections (27.6%) and the difference was statistically significant compared to all other transmission categories. In addition to MSM, age category of 18-25 years was also significantly associated with recent infection.

Conclusions: High rate of recent infection among MSM indicates active ongoing transmission of HIV in this population. Scale-up of combination prevention including PrEP for MSM is urgently needed to halt the spread of the virus.

THPEC179

An explosive epidemic of HIV infection among men who have sex with men (MSM) in the Philippines

J.D. Rosadiño[1], R.V. Pagtakhan[1], C. Lagman[1], J.W. de Lind van Wijngaarden[2], R. Ditangco[3], Y.R. Lo[4], F. van Griensven[5]
[1]*LoveYourself Foundation, Manila, Philippines,* [2]*Burapha University, Bang Saen, Thailand,* [3]*Research Institute of Tropical Medicine, Manila, Philippines,* [4]*World Health Organization, Regional Office for the Western Pacific, Manila, Philippines,* [5]*Thai Red Cross AIDS Research Center and UCSF Department of Epidemiology and Biostatistics, Bangkok, Thailand*

Background: In most countries in Asia-Pacific, HIV epidemics in MSM have been trailing those in persons who inject drugs (PWID's) and heterosexuals. The Philippines however, never experienced a heterosexual HIV epidemic and the prevalence of infection in the Filipino general population has remained low (< 0.1%). Despite the absence of a heterosexual pre-cursor epidemic, the spread of HIV infection is believed to be growing rapidly in the country's MSM population.

Methods: The Philippine Department of Health maintains a unique and well-functioning HIV case reporting system, mandated by law. The consistency of this system over the past three decades allows monitoring of long-term epidemic trends in the general population and in specific transmission categories. Here we present and analyze the reported number of newly diagnosed cases of HIV infection in the Philippines from 1984 to 2017.

Results: Since January 1984, 49,733 newly diagnosed cases were reported, of which 41,369 (83.2%) from 2012 to the present and 10,111 (20.3%) during the first 11 months of 2017 alone. Of the latter, 9,625 (95.2%) were in males and 8,485 (91.0%) in MSM. During the first ten years of the registry (1984-1993) only 476 cases were reported, the majority (51.4%) in heterosexuals and a minority (18.3%) in MSM. This pattern reversed towards during 2009-10, when MSM began to outnumber heterosexuals. Since that time, newly diagnosed HIV cases in MSM have been doubling every 1.5 to 2 years (figure). Such increases were not seen in heterosexuals and PWID's, where the yearly number of cases increased from 480 to 1293 and from 175 to 236 between 2012 and present, respectively. The average number of reported newly diagnosed cases of HIV infection in the Philippines increased from < 1 before 2008, to four in 2010, 17 in 2014 and to 31 in 2017 (figure). Of the latter, 90% are in MSM, mostly from the National Capital Region and adjacent provinces.

Conclusions: After years of incremental increases among heterosexuals and PWID's, HIV is now spreading rapidly among MSM in the Philippines. Effective behavioral and biomedical interventions, such as HIV pre-exposure prophylaxis, are urgently needed to stop the transmission of HIV in this population.

Trends in HIV and HCV seroprevalence among inmates entering the NYS department of corrections and community supervision system, 1988-2015

B.J. Anderson[1], L. Wang[1], B. Zhu[1], D.D. Akinleye[1], A. Gallucci[1], M. Parker[2], J. Tesoriero[3], K. Koenigsmann[4]
[1]*New York State Department of Health, AIDS Institute Bureau of HIV/AIDS Epidemiology, Albany, United States,* [2]*New York State Department of Health, Wadsworth Center, Albany, United States,* [3]*New York State Department of Health, AIDS Insitute, Division of HIV/STD Epidemiology, Evaluation, and Partner Services, Albany, United States,* [4]*New York State Department of Corrections and Community Supervision, Albany, United States*

Background: HIV and HCV are serious health issues for correctional facilities and their incarcerated populations. Rates of diagnosed HIV infection among persons incarcerated in US prisons are more than five times higher compared to those not incarcerated; estimates of HCV prevalence range from 10-17 times higher. This analysis monitors trends in HIV and HCV seroprevalence among persons entering custody of the New York State (NYS) prison system over three decades.

Methods: Since 1988, NYS' Department of Health and Department of Corrections and Community Supervision have conducted biennial crosssectional anonymous HIV seroprevalance surveys among persons entering the NYS prison system; HCV testing was introduced in 2000. Self- reported demographic and risk data are collected during medical intake, and remnant blood is tested for HIV and HCV antibodies. Females are oversampled.

Results: 43,051 persons are included in the study. The 2015 cohort includes 4,239 newly incarcerated persons, who are predominately male (80%) and racially diverse (42% black; 32% white; 21% Hispanic). Median age is 34 years. Self-reported HIV and HCV risk includes history of injection drug use (15.5%), sex partner of person who injects drugs (11.4%), history of exchange sex (4.1%), and male to male sexual contact (1.5%). The 2015 cohort has the highest proportion self-reporting injection drug use since the 1992 (15.9%) and 1988 (27.6%) study cohorts.

Between 1988 and 2015, HIV seroprevalence decreased significantly for both male and female incoming inmates (17.6% to 1.9% males; 18.8% to 2.8% females). HCV seroprevalence was relatively stable over time for males. Among females entering prison, 2015 marked a reversal in the historical decline in HCV seroprevalence since the 2003 high, with 24.2% sepositivity. Between 2012 and 2015, HCV seropositivity increased 65.8% among females. Overall HIV-HCV coinfection rates are low in 2015 (0.63%), though 31% of HIV seropositive inmates were also HCV seropositive.

Conclusions: This study is the longest and largest HIV and HCV seroprevalance study of an incoming population to a state prison system. The study highlights the increasing HCV burden to correctional health and the opportunities related to addressing HCV and HIV treatment needs, both during and after incarceration.

Definitions of homelessness - surveillance-based housing status compared to self-reported housing status, San Francisco, California, USA, 2012-2016

C. Kazbour, S. Scheer, A. Hughes
San Francisco Department of Public Health, Applied Research, Community Health Epidemiology, and Surveillance, San Francisco, United States

Background: Unstable housing and homelessness have been shown to be risk factors for HIV seroconversion and strong predictors of suboptimal health outcomes among people living with HIV (PLWH). We sought to compare housing status among PLWH in the San Francisco (SF) surveillance case registry (eHARS) with self-reported housing status from interview during the Medical Monitoring Project (MMP) to assess concordance.

Methods: In SF, housing status and address is collected at time of diagnosis and updated through medical chart abstraction and from HIV-related laboratory reports. PLWH are defined as homeless in eHARS if their medical record states they are homeless or not housed or their address is a known homeless shelter or free postal address not connected to a residence. Persons living in a single room occupancy hotel (SRO) or other transitional housing situation are considered housed.

MMP is a supplemental surveillance project collecting information on HIV care via interview that defines homelessness as living on the streets, a shelter, a SRO or a car 12 months prior to interview.

We compared housing status reported during MMP interviews between 2012-2016 with eHARS data and a Kappa score was calculated to estimated agreement between the two data sources. For persons with multiple addresses, the address with date closest before and after the MMP interview was selected (N=1030).

Results: Twenty-seven percent of MMP participants who self-reported as homeless were also classified as homeless in eHARS and 97.6% of MMP participants classified as housed were classified as housed in eHARS (Table). The Kappa coefficient showed fair agreement by housing status between data sources (k= 0.3162, 95% CI 0.2327 - 0.3998, p< .0001). Ninety-two of the homeless MMP participants reported living in a SRO. If these 92 were reclassified as housed in MMP, the concordance between self-reported homelessness in MMP and eHARS would increase to 30.6% and decrease between participants classified as housed to 96.5%.

Conclusions: The strict definition of homelessness used by surveillance significantly underestimated self-reported homelessness and unstable housing among PLWH.

Going forward, surveillance-based definitions of homelessness should be considered conservative and may benefit from including of other types of unstable housing including living in a SRO.

	Self-reported data				
	Homeless		Housed		
Surveillance data	N	Col.%	N	Col.%	Total
Homeless	41	26.6%	21	2.4%	62
Housed	113	73.4%	855	97.6%	968
Total	154	100%	876	100%	1030

[Homelessness by data source - comparing matched self-reported Medical Monitoring Project data with surveillance-based eHARS data]

THPEC182

Misclassification of the male-to-male sexual mode of HIV transmission in HIV case reporting data in Ukraine

O. Varetska[1], K. Dumchev[2], C. Vitek[3]
[1]*Alliance for Public Health, M&E Team, Kyiv, Ukraine,* [2]*Ukrainian Institute on Public Health Policy, Kyiv, Ukraine,* [3]*Ukraine Country Office, Division of Global HIV/TB, Centers for Disease Control and Prevention, Kyiv, Ukraine*

Background: The literature suggests that stigmatization of men who have sex with men (MSM) leads to underreporting of male to male sexual transmission of HIV in Ukraine. As of December 31, 2015, 1,368 HIV cases were registered with male to male sexual mode of transmission in Ukraine out of a total of 126,604 registered cases (1.1%). Recent integrated bio-behavioral surveillance (IBBS) data suggest HIV prevalence among MSM is 19% in certain cities, and a minimum of 14,000 MSM live with HIV infection nationwide.

Reluctance by clinicians to assess sexual behavior risks and hesitation by patients to self-report stigmatized risk behaviors may lead to misclassification or non-reporting of transmission risk.

The purpose of this study is to evaluate the probable misclassification of male to male sexual mode of transmission in Ukrainian HIV case reporting.

Methods: The study included 2,096 randomly selected HIV-positive males enrolled into care in 7 regions of Ukraine during Q4 (October - December) of 2013, 2014 and 2015. Results of patient interviews about potential exposure to HIV and presence of risk behavior in the past 10 years (to capture all potential risks prior to transmission) were compared to the patient registration data used for the Ukrainian case-reporting system. McNemar's test was used to test the difference between paired measures.

Results: Of 2,096 study participants, 1,240 participated in the interview. Out of these, 59 (4.7% (95%CI 3.5%-5.9%)) had male to male sexual mode of transmission recorded in the medical record. 130 (10.6% (8.9%-12.3%)) reported male-to-male anal sex in past 10 years during the interview, and 96 of them (7.7% of total (6.3%-9.3%)) denied injecting drug use, thus likely they acquired HIV through MSM contact. Therefore, the true proportion of MSM transmission among newly registered cases may be at least 1.7 times higher than currently reported 4.7% (p< 0.001).

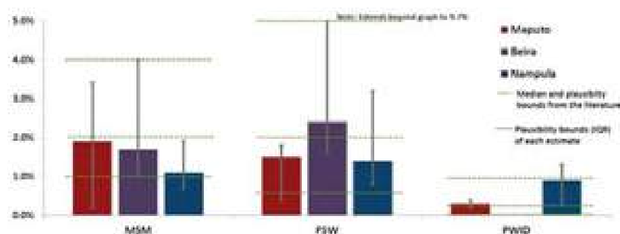
Conclusions: This study provides evidence of misclassification of the male-to-male sexual mode of HIV transmission in HIV case reporting data in Ukraine. Improvements in ascertaining risk-factor information from patients are important to monitor the epidemic and to provide relevant HIV clinical care.

THPEC183

Estimating the number of men who have sex with men (MSM) and female sex workers (FSW) in Mozambique using a multiple methods approach

I. Sathane[1], R. Horth[2], M. Boothe[3], N. Chicuecue[4], H.F. Raymond[2]
[1]Global Programs for Research and Training, Maputo, Mozambique, [2]University of California, San Francisco (UCSF), San Francisco, United States, [3]University of California, San Francisco (UCSF), Maputo, United States, [4]National Institute of Health (INS), Maputo, Mozambique

Background: Mathematical modelling demonstrates that the greatest reduction in HIV incidence can be achieved through prioritization of resources to key populations. Evidence is needed about the number of men who have sex with men (MSM) and female sex workers (FSW) in order to measure their contribution to the HIV epidemic and appropriately allocate prevention and treatment efforts. Mozambique conducted the first Biobehavioral Survey (BBS) survey in three urban areas Maputo, Beira and Nampula among MSM and FSW in 2012. This analysis presents size estimations for MSM and FSW.
Methods: We used multiple methods to generate best estimates of MSM and FSW living in major cities in Mozambique: unique object, unique event and service multipliers with sequential sampling. Multiplier methods rely on two independent data sources from the same target group. Sequential sampling is a relatively new Bayesian approach for estimating population size using data from Respondent Driven Sampling (RDS) survey methodology. The median used different estimators to establish best estimates for each city-population. while the interquartile range of the different estimates served as plausibility bounds. Our best estimate was then compared to plausibility bounds found in the literature.
Results: BBS survey were conducted among MSM [Maputo (n=496); Beira (n=583), Nampula (n=353)] and FSW [Maputo (n=400); Beira (n=411); Nampula (n=429)]. The numbers of MSM were estimated at 10,070 (1.9% of adult male population) in Maputo, 2,129 (1.7%) in Beira and 1,608 (1.1%) in Nampula. Among FSW, population size was estimated at 8,603 (1.5% of the adult female population), 2,936 (2.4%) and 2,033 (1.4%), respectively. Using these population size estimates, we estimate that there are 951MSM in Maputo, 179 in Beira, 45 in Nampula and 1,851 FSW in Maputo, 619 in Beira and 328 in Nampula living with undiagnosed HIV.
Conclusions: Our results demonstrate the feasibility of using multiple methods to generate population sizes, falling within the estimates produced in other sub-Saharan countries. This provides essential information for optimal resource allocation and contributes to the literature about key populations in the region.



[Size Estimation of FSW and MSM in Mozambique]

THPEC184

Results of a third round of HIV surveillance amongst female sex workers in Hargeisa, Somaliland

K. Kriitmaa[1], N. Fara[2], I. Hussein[3], A. Ismail Omar[3], A. Abdow[1], Z. Dominkovic[4], C. Ito[1], C. Maskia[5]
[1]International Organization for Migration, Migration Health Division, Nairobi, Kenya, [2]Somaliland National AIIDS Commission, Hargeisa, Somalia, [3]International Organization for Migration, Migration Health Division, Hargeisa, Somalia, [4]University of Zagreb, WHO Collaborating Centre for HIV Surveillance, School of Medicine, Zagreb, Croatia, [5]Independent Research Consultant, Nairobi, Kenya

Background: Research in Somaliland indicates a concentrated HIV epidemic, including two previous rounds of HIV surveillance in Hargeisa, Somaliland in 2008 and 2014, showing an HIV prevalence amongst female sex workers (FSW) of 5.2% and 4.8%. A third round of surveillance was conducted in 2017.
Methods: A cross-sectional integrated biological and behavioural surveillance survey among FSW was undertaken between April and June 2017. A total of 238 FSW participated in the study. A face-to-face, structured interview using electronic data collection was completed and blood samples collected for serological testing. All three surveillance surveys used respondent driven sampling and data was analysed using RDS Analyst for comparing results.
Results: The 2017 IBBS survey showed a steady decline in HIV prevalence in Somaliland from 5.1% in 2008 to 4.8% in 2014, and 3.6% in 2017. On the contrary, prevalence for active syphilis decreased from 3.4% in 2008 to 2.4% in 2014, and rose again to 3.3% in 2017. Condom use with last client has steadily improved across the three surveys - 25.6% in 2008, 31.5% in 2014, and 37.9% in 2017. Similarly, the proportion of vulnerable women who know their HIV status from an HIV test 12 months prior to this survey shows an upward trend - 2.4%, 21.3% and 36.6%, in 2008, 2014 and 2017, respectively.
Similarly, improvement on knowledge has improved significantly, with 48.9% of FSW in 2017 correctly identifying ways of preventing sexual transmission of HIV and rejecting major misconceptions, in comparison with 10.4% in 2014 and 6.4% in 2008.
However, key indicators around stigma and discrimination remain sub-optimal, 30.7% of FSW avoid accessing services because of stigma and prevention programmes are only reaching 23.1% of the population, two indicators which were added to the survey in 2017.
Conclusions: HIV prevalence among FSW remains five times higher than in the general population, emphasizing the need for targeted prevention, care and treatment services. While improvements have been shown in condom usage, HIV testing and knowledge around HIV, high stigma and discrimination of FSWs persist, affecting access to services and ultimately impacting effectiveness of prevention and treatment programmes.

THPEC185

The impact of childhood sexual abuse on the HIV epidemic among men who have sex with men on a Western State in the U.S.

E.R. Orellana[1], S. Schafer[2], A. Bhattarai[1], B. McArdle[1], L. Fisher[1], J. Ramirez[1]
[1]Portland State University, Portland, United States, [2]Oregon Health Authority, Portland, United States

Background: Men who have sex with men (MSM) continue to carry the burden of HIV in many parts of the world. Histories of trauma, including childhood sexual abuse (CSA) have been associated with high HIV risks among different populations. This study examined the association between CSA, HIV serostatus, and risky behaviors among a sample of MSM.
Methods: Data were obtained from the Portland, Oregon arm of the 2017 National HIV Behavioral Surveillance system, a cross-sectional survey conducted in 22 cities in the United States. Interviews and HIV tests were completed by 424 MSM. We used correlational and logistic regression analysis to test associations between experiences of CSA and HIV serostatus, and other high-risk behaviors.

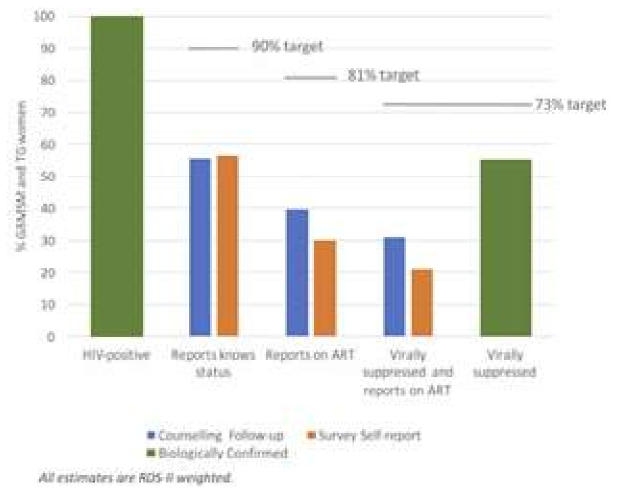
Results: An estimated 33% percent of the sample reported experiences of CSA, and 16.5% tested, or had previously tested, positive for HIV. Thirty-four percent of men identified as African American, Latino or other non-white ethnicity, while the rest identified as white (66%). All participants were adults, with 65% between the ages of 18 to 39 (65%). MSM with a history of CSA were significantly more likely to report unprotected casual sex in past 12 months (Odds Ratio [OR]: 1.7 CI: 1.1-2.6); mental health problems (OR: 1.7; CI: 1.0-2.8); and HIV positive serostatus (OR: 2.0; CI: 1.1-3.5).
Conclusions: For decades, childhood sexual abuse has been at epidemic levels among different populations throughout the globe. CSA among MSM in this part of the United States was alarmingly high, and appeared to increase the vulnerability of men to high risk behaviors such as condomless casual sex, and increased prevalence of mental health problems. This study highlights the continued need for combination prevention strategies that take into account the consequences of childhood trauma, especially CSA, among men at higher risk for HIV and sexually transmitted infections.

THPEC186

A population-based assessment of the HIV care cascade among gay, bisexual and other men who have sex with men and transgender women (MSM/TG) in Johannesburg

E. Fearon[1], S. Tenza[2], K. Moodley[2], C. Mokeona[2], A.D. Smith[3], A. Bourne[4], P. Weatherburn[1], T. Palanee-Phillips[2], TRANSFORM Study Group
[1]London School of Hygiene and Tropical Medicine, Department of Public Health, Environments and Society, London, United Kingdom, [2]Wits Reproductive Health Institute, Johannesburg, South Africa, [3]University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom, [4]La Trobe University, Australian Research Centre in Sex, Health & Society, Melbourne, Australia

Background: To track HIV care, treatment adherence and onwards transmission, UNAIDS has set the 90:90:90 targets. Despite the high HIV burden experienced by MSM/TG, population-based assessments of progress towards these targets among MSM/TG in sub-Saharan Africa are lacking. This study estimated the HIV care cascade among a representative sample of MSM/TG in Johannesburg, and investigates factors associated with viral suppression.
Methods: In 2017, we recruited 301 MSM/TG via respondent-driven sampling in Johannesburg (birth/current male gender, sex with a man in previous 12 months). Participants gave a blood sample for HIV rapid-testing, ELISA-confirmed if positive (Alere Combo and Advanced Quality HIV tests, back-up Alere Determine), and viral load-testing if HIV-positive (GeneXpert). Participants completed a self-administered survey detailing socio-demographics, sexual behaviour, HIV testing history and engagement in care. We compared survey responses to the HIV counsellor report for those who tested HIV-positive and were virally suppressed (< 40 copies/ml) but did not report being on ART, as this would be improbable in large numbers. To inform gaps in care and potential patterns of onwards transmission, multivariate logistic regression sought to identify factors associated with viral suppression among participants who tested HIV-positive. Proportions and analyses were RDS-II weighted.
Results: There were 118/300 MSM/TG who tested HIV-positive (37.5%, 95% CI 28.2-46.9%), of whom 55 were virally suppressed (55.5%, 95% CI 39.6-70.4%), Figure 1. One participant refused testing. There were 29 of these 55 virally suppressed HIV-positive participants who reported no current ART usage. The 90:90:90 using survey data was estimated to be 57% (n=76/118):53% (n=39/76):70% (n=27/39), and using HIV testing counsellor-reported data, 56% (n=78/118):72% (n=55/78):78% (n=43/55). Viral suppression among HIV-positive GBMSM varied by neighbourhood (p=0.023), but lacked substantial evidence for a difference by age, education, employment, birth place or sexual or gender identity, nor sexual behaviours after adjustment by neighbourhood.
Conclusions: The proportion of HIV-positive MSM/TG who are virally suppressed falls well short of the UNAIDS targets. As in other surveys, we have found discrepancies between self-reported cascade indicators and biologically-measured viral load that could indicate misunderstanding or social desirability biases. The study does indicate gaps in testing and/or ART adherence, and a high potential for ongoing transmission.



[Figure 1: The HIV Care Cascade among gay bisexual and other MSM and trandgender women in Johannesburg, n=118 HIV-positive individuals]

THPEC187

HIV prevalence and sexual behavior among transgender in Paraguay, 2017

G. Aguilar[1,2], W. McFarland[3], A. Kawabata[1], T. Samudio[4], G. Lopez[4], I. Prado[5]
[1]National HIV Program, Strategic Information and Surveillance, Asuncion, Paraguay, [2]National University of Caaguazu, Research Directorate General, Caaguazu, Paraguay, [3]University of California San Francisco, San Francisco, United States, [4]National HIV Program, Asuncion, Paraguay, [5]University of California San Francisco, Center for AIDS Prevention Studies, San Francisco, United States

Background: Trans women may be the population most vulnerable to HIV in the world, with prevalence in Latin America ranging from 18-38%. In Paraguay too, HIV prevalence (26%) was higher among trans women than among men who have sex with men (MSM) and female sex workers (FSW) when first measured in 2014. A high level of vigilance is warranted for trans women to track HIV and behavioral causes of infection for this marginalized and disproportionately affected population who have been left out of previous surveillance data. We therefore conducted a bio-behavioral survey among trans women in Paraguay in 2017, incorporating novel methods in the design to increase inclusion.
Methods: We conducted a cross-sectional survey with transgender women in Paraguay in 2017. To maximize efficiency in reaching diverse trans women, we used a hybrid method ("Starfish Sampling") that combines venue recruitment, a random sample of clients, and short-chain peer referral. The study began with mapping places of sex work and where trans women congregate. A random selection of trans women clients was also conducted. Further, trans women referred peers to the study. Participants complete a questionnaire on demographic characteristics and behavior, and blood samples were drawn for HIV antibody testing. Participants provided written informed consent.
Results: A total of 304 trans women were enrolled. Participants were young, with 55.9% in their 20s. The majority had secondary education or less (74.5%). HIV prevalence was 25.6% (95% confidence interval 19.3-31.9%). Trans women reported a mean of 22.5 casual partners in the last 6 months, with whom condom use was 73.0%.The proportion of trans women who had sex for the first time under age 14 years was 58.6%. The majority of trans women (82.6%) reported selling sex.
Conclusions: Our bio-behavioral survey found the prevalence of HIV consistently high among trans women in Paraguay, confirming this population remains the most severely affected. The young age of the population, the young age of sexual debut, the high partner number, and inconsistent condom use point to high potential for continuing transmission. New strategies are necessary to improve education on reducing acquisition risk among transgender women.

THPEC188

Recent infection and repeat testing among MSM newly diagnosed with HIV at STI clinics

F. van Aar[1], B. van Benthem[1], H. Götz[2], T. Heijman[3], C. Kampman[4], T. van de Laar[5], E. Op de Coul[1], RITA Surveillance Network of STI Clinics
[1]National Institute for Public Health and the Environment (RIVM), Centre for Infectious Disease Control, Bilthoven, Netherlands, [2]Municipal Public Health Service, Department of Infectious Disease Control, Rotterdam, Netherlands, [3]Public Health Service (GGD) Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, [4]Public Health Service Twente, Enschede, Netherlands, [5]Sanquin Blood Supply, Virus Diagnostic Services, Amsterdam, Netherlands

Background: To detect HIV infections early, Dutch STI clinics advise men who have sex with men (MSM) to test 3- or 6- monthly, dependent on risk behaviour. Previous studies showed that repeat testing increased, but consistent 6-monthly testing among MSM was low. Recent HIV infection (RHI) surveillance facilitates the understanding of transmission patterns. We explored proportions of recent HIV infections (RHI) and repeat testing among MSM newly diagnosed with HIV at STI clinics between January 2016 and September 2017.
Methods: Samples from MSM newly diagnosed with HIV at participating STI clinics (n=12/24) were tested with an avidity assay. Cut-off values for Avidity Index (AI) were AI≤0.75 for RHI (≤6 months), AI between 0.76-0.84 for dubious result, and AI≥0.85 for established infection (>6 months). The results were merged with STI clinic surveillance data. Repeat testing was based on a self-reported date of last negative HIV test or on information from previous consultations as identified by a unique client number. Dubious and negative results were reclassified to RHI if within the six months prior to diagnosis an HIV-negative test result was available.
Results: In total, 270 samples were tested for RHI. Of these, 121/270 (44.8%) were categorized as having RHI; 53 based on an AI ≤0.75 plus a recent negative HIV-test, 40 based on an AI≤0.75 only and 28 based on a recent negative test result despite an AI>0.75. Among those who had RHI, 2.5% tested for the first time, 66.1% tested negative 6 months previously, 21.5% tested negative more than 6 months previously (median 10.5 months (IQR): (8-20) and 9.9% tested negative previously but the date was unknown. Among those not recently infected, 25.5% tested for the first time, 43.6% tested negative previously (median time since last negative test: 20 months; IQR: 12-27) and 30.9% tested previously but the test date was unknown.
Conclusions: The proportion of RHI was high among MSM diagnosed with HIV at STI clinics and the majority had tested HIV-negative within the 6 months prior to diagnosis. Repeat testing among MSM at high risk for HIV should be further encouraged to increase early diagnosis of HIV.

THPEC189

Complacency is the new problem: Comparative analysis of recent outbreaks of HIV among persons who inject drugs in Europe and North America

D. Des Jarlais[1], V. Sypsa[2], L. Wiessing[3], A.-O. Abagiu[4], V. Arendt[5], D. Broz[6], C. Devaux[7], J.M. Duwve[8], C. Ferbineaunu[9], M. Fitzgerald[10], D.J. Goldberg[11], A. Hatzakis[2], D. Igoe[10], A. McAuley[11]
[1]Icahn School of Medicine at Mount Sinai, Psychiatry & Preventive Medicine, New York, United States, [2]University of Athens, Athens, Greece, [3]European Monitoring Center for Drugs and Drug Abuse, Lisboa, Portugal, [4]National Institute for Infectious Diseases, Bucharest, Romania, [5]CHL, Luxembourg, Luxembourg, [6]Centers for Disease Control and Prevention, Atlanta, United States, [7]Luxembourg Institute of Health, Luxembourg, Luxembourg, [8]University of Indiana, Bloomington, United States, [9]Romanian Association Against AIDS, Bucharest, Romania, [10]Health Services Executive, Limerick, Ireland, [11]NHS National Services Scotland, Glasgow, United Kingdom

Background: Despite the effectiveness of "combined prevention," outbreaks of rapid HIV transmission have recently occurred in Europe and North America. Understanding how/why these outbreaks occurred should contribute to avoiding future outbreaks.
Methods: A research group among persons interested in outbreaks was formed by the EMCDDA to conduct a systematic review/comparison of the outbreaks. Publications and conference presentations on the outbreaks were compiled and a standardized template was constructed for structured comparisons. A mixed quantitative/qualitative synthesis was developed through successive rounds of data analyses and interpretation among members of the group.
Results: Outbreaks occurred among PWID in Athens, Greece; Bucharest, Romania, Dublin, Ireland; Glasgow, Scotland; Luxembourg; and Scott County, Indiana, United States. There was substantial variation in the size of the outbreaks from under 100 (Dublin, Luxembourg) to over 1100 (Athens, Bucharest) new HIV infections. Outbreaks occurred in areas that had not implemented large-scale combined prevention programming (Athens, Indiana) or where funding was interrupted (Bucharest) but also in areas where combined prevention had been implemented but changes in patterns of drug use (increased use of cocaine or novel psychoactive substances (NPS)) may have led to high rates of injection risk behavior (Bucharest, Dublin, Glasgow, Luxembourg). HCV infection increased rapidly and/or was at very high prevalence prior to several outbreaks (Athens, Bucharest, Glasgow, Indiana, Luxembourg). Community economic problems preceded the outbreaks in Athens, Dublin and Indiana and homeless/economically disadvantaged PWID were particularly vulnerable in all outbreaks. Public health responses included introduction (Indiana) or expansion of standard prevention interventions (syringe service programs, medication-assisted treatment and antiretroviral treatment) but coverage of interventions varied. HIV transmission among PWID has continued in all outbreak locations. Despite substantial decreases in some settings (Athens, Indiana, Dublin), the number of reported cases has not yet been reduced to pre-outbreak levels in any sites.
Conclusions: Complacency for HIV prevention is emerging as an important threat to the success of combined HIV prevention for PWID. Successful HIV prevention for PWID needs to be conceptualized as implementing and maintaining high coverage prevention programs and adapting to changes in patterns of drug use. Particular attention should be paid to NPS, communities undergoing economic difficulties, and homeless PWID.

THPEC190

Size estimation of FSW population in Ulaanbaatar, Mongolia via mapping and quantitative survey: Lessons and program recommendations

B. Aumakhan[1], J. Schue[2], A. Delegchoimbol[3], S. Munkhbaatar[1], S. Baral[2]
[1]Global Fund Supported HIV Program, Ministry of Health, Ulaanbaatar, Mongolia, [2]Johns Hopkins University, Baltimore, United States, [3]UNAIDS Mongolia, Ulaanbaatar, Mongolia

Background: An accurate estimation of the size of FSW in Mongolia is challenging due to hidden nature, generalized stigma and outreach limitations by community-based organizations (CBO) and targeted programs. Previous size estimation attempts used rapid assessment and survey built-in multiplier methods and produced varying estimates noted for methodological limitations.
Description: A modified Priorities Locations for AIDS Control Efforts (PLACE) method was used to characterize venues where FSW meet sexual partners, recruit FSW into a quantitative survey, and conduct size estimation of FSW population in Ulaanbaatar, Mongolia between August 2015 and May 2016. The survey conducted verification of 134 venues and recruited 293 FSW. The size estimation methods employed were the wisdom of the masses, multipliers, and capture-recapture. The multipliers were derived using a broad range of data sources, including
1) research or survey-based data,
2) FSW-targeted programs and
3) police records on FSW detentions.
After validation, the mean of point size estimates was calculated to arrive at the final estimate. The range was constructed using the lowest and highest point size estimate values.
The final FSW population size estimate was 1,293 (range: 549-2,860) which corresponds to proportions in the female population age 15-49 in Ulaanbaatar of 0.33% (range: 0.14%-0.74%). These proportions fall within the range of the similar estimates in countries of Asia-Pacific region. Mapping showed that venues frequented by FSW are widely distributed across the city. Street-based FSW comprised approximately 60% of surveyed participants.

Author Index

Lessons learned: Data from community-based programs had unknown validity and accuracy issues. Recruitment of FSW was hindered by frequent police raids as well as difficulties in identifying and approaching FSW inside the hotels, bars and/or clubs. Recommendations have been put to improve program data quality, conduct periodic mapping and size estimation and improve the legal environment that is supportive of HIV prevention and sexual health needs of FSW.
Conclusions/Next steps: The use of multiple estimation methods and triangulation of different data sources ameliorated biases and produced final estimate consistent with the previous local and regional estimates. These estimates can be used in national HIV/STI prevention, treatment and care planning.

THPEC191

The first HIV and hepatitis C prevalence and behavioral survey among crsytal methamphetamine *(Sabu)* users in Indonesia

I. Praptoraharjo[1], L. Nevendorff[2], A. Widihastuti[2], M. Mediestya[2], M. Busz[3], N. Veldwijk[3], M. Handulle[3]
[1]*AIDS Research Center Atma Jaya University, DI Yogyakarta, Indonesia,* [2]*AIDS Research Center Atma Jaya University, Jakarta, Indonesia,* [3]*Mainline, Amsterdam, Netherlands*

Background: The National Narcotics Board (NNB) estimated that *crystalline methamphetamine or sabu* users in Indonesia has reached up to 760,795 individuals in 2015. Previous research show that methamphemtamine use is significantly associated with the higher risks of HIV transmission and HIV infection. This study aims to estimate the HIV and HCV serology and associated risk behaviors among *Sabu* users in order to provide an evidence for developing an HIV prevention program targeting sabu users.
Methods: The study was conducted in 2017 as a cross-sectional survey using the respondent-driven sampling (RDS) method in six cities (Makassar, Denpasar, Jakarta, Bandung, Batam and Medan). Through 3-4 seeds in each city, a total of 1498 crystal meth users consisting of 85% male and 15% female were recruited to participate in the study. Data analysis was conducted using RDSA to produce population estimate and STATA to assess the characteristics of social and sexual network of sabu users.
Results: HIV and HCV prevalences were 10.15% and 14.23% respectively. Based on ASSIST scale, 92.5% of the respondents reported to have drug problems at medium level and 7% at high level. One fifth of *Sabu* users have had experience in injecting drugs, but only 2% reported injecting *Sabu.* Only 60% *Sabu* users were unmarried, the majority of them (84%) were sexually active in the last one year. *Sabu* users reported to have heterosexual, homosexual and bisexual as their sexual behaviors. Condom use during the last sexual encounter was reported to be 34% and only 17% has reported consistency in the last 30 days. Three quarter of *Sabu* users do not have comprehensive knowledge on HIV. Only 2% of them accessed drug treatment last year.
Conclusions: This survey shows that sabu users are at the higher risk of being exposed to HIV and HCV through risky sexual behaviors. This population has been overlooked by HIV response in Indonesia. As the second largest number of drug user in Indonesia, Sabu users has to be included in the existing HIV prevention and treatment in order to achieve national target of the triple 90s.

THPEC192

Changes in HIV and syphilis prevalence among female sex workers (FSW) in Brazil from 2009 to 2016

C. Landmann Szwarcwald[1], P.R. Borges de Souza JJunior[1], G. Nogueira Damacena[1], O. Ferreira Junior[2]
[1]*Oswaldo Cruz Foundation, ICICT, Rio de Janeiro, Brazil,* [2]*Federal University of Rio de Janeiro, Institute of biology, Rio de Janeiro, Brazil*

Background: In the context of introducing PrEP in Brazil, the present study aims at establishing the main predictors of HIV prevalence increase from 2009 to 2016 among Female Sex Workers (FSW).
Methods: The baseline RDS study among FSW was carried out in 2009 and recruited 2523 women in 10 Brazilian cities. The second RDS survey was carried out in 2016 and recruited 4245 FSW in 12 Brazilian cities. Both surveys aimed at estimating prevalence of HIV and syphilis and establishing knowledge, attitudes, and risky practices related to HIV infection. In this study, we analyzed changes in HIV and syphilis prevalence based on the comparison of 95% confidence intervals for each estimate. We used Poisson regression models to estimate prevalence ratios (PR) and to establish the main factors associated to HIV prevalence increase between 2009 and 2016. The analyses took into account the dependence among observations resulting from the recruitment chains, and the unequal probabilities of selection, resulting from the different network sizes.
Results: HIV prevalence was 4.8% (95% CI 3.4-6.1%), in 2009, and 5.3% (4.4-6.2%), in 2016, with no significant difference. In contrast, syphilis prevalence was found to be more than three times higher in 2016 (8.4%; 95% CI 7.3-9.2%) than in 2009 (2.5%; 95% CI 1.7-3.4%). Among FSW diagnosed with syphilis, HIV prevalence significantly increased from 11.5 to 14.1% ($p< 1\%$). Although the 5% level was sustained for the total sample, significant PR ($p< 1\%$) were found for: FSW who work at street points (PR=1.33); are aged 35 years or over (PR=1.10); did not complete elementary school (PR=1.30); are low-paying FSW (PR=1.17); and use crack or cocaine more than once a month (PR=1.39). Older street FSW with low educational level and crack/cocaine users showed the highest HIV prevalence increase, from 7.6 to 18.6% (PR= 2.45, $p< 0.0001$).
Conclusions: The results emphasize the need of introducing PrEP among those FSW most-at-risk for HIV. However, given the low educational level of these women and the significant syphilis prevalence increase, many challenges have to be faced to monitor the consistent uptake of medications as well as the use of condoms and other combined prevention methods.

THPEC193

Long-term trends of HIV-1 and HIV-2 prevalence in pregnant women in Guinea-Bissau, West Africa

J. Lopatko Lindman[1], A. Biai[2], Z. da Silva[2], H. Norrgren[1], F. Mansson[3], SWEGUB CORE Group
[1]*Lund University, Clinical Sciences, Division of Infection Medicine, Lund, Sweden,* [2]*National Public Health Laboratory, Bissau, Guinea-Bissau,* [3]*Lund University, Infectious Diseases, Dept of Translational Medicine, Malmo, Sweden*

Background: Guinea-Bissau had the global highest prevalence of HIV-2 in the late eighties when HIV surveillance started. However, in virtually all reports from Guinea-Bissau and West Africa, there has been decreasing prevalence of HIV-2 and increasing HIV-1 prevalence until the year 2000. We have previously published surveillance data until 2006 with similar trends. While PMTCT services started earlier, the national HIV treatment programme including triple therapy ART started in 2005 with possible selection of more HIV positive women to give birth at government structures.
Methods: Anonymous HIV surveillance of pregnant women giving birth at the National Simão Mendes Hospital in the capital Bissau from 1987 up until 2016. The surveillance has been performed every or every second year with the exception of a time gap in 2011-2013.
Results: As part of the surveillance, a total of 27948 women were HIV tested between 1987 and 2016. HIV-2 prevalence decreased from 8.3% in 1987 to 0.9 % in 2016. HIV-1 prevalence increased from 0% in 1987 to 5.2% in 1999 but thereafter levelled off to around 5% in the subsequent years. An increase was seen to 6.5% in 2008, corresponding in time to the rollout of the treatment programme indicating possible selection of HIV positive women to the maternity ward at the national hospital. However, in the following years the increase did not continue and HIV-1 prevalence stayed stable around 6%, being 6.4% in 2016.
Conclusions: HIV-1 prevalence increased sharply from 0% until 5.2% in 1999 but has thereafter only increased slowly to level off around 6%, while HIV-2 prevalence now is below 1% in pregnant women in Guinea-Bissau. The initiation of the national HIV treatment programme in 2005 with gradual expansion of coverage as well as gradual implementation of universal HIV screening at maternal health care centres may have contributed to the stabilization of the HIV-1 epidemic and continuous decrease of HIV-2 prevalence in Guinea-Bissau.

Determining the incidence of HIV

THPEC194

Community-level HIV incidence in a hyper-endemic epidemic region in KwaZulu-Natal, South Africa

A. Kharsany[1], C. Cawood[2], D. Khanyile[2], L. Lewis[1], A. Grobler[1], A. Puren[3], K. Govender[4], G. George[4], N. Samsunder[1], S. Madurai[5], Q. Abdool Karim[1]
[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [2]Epicentre AIDs Risk Management (Pty) Limited, Cape Town, South Africa, [3]Centre for HIV and STIs, National Institute for Communicable Diseases, National Health Laboratory Service, Johannesburg, South Africa, [4]Health Economics and HIV and AIDS Research Division (HEARD), University of KwaZulu-Natal., Durban, South Africa, [5]Global Clinical and Virology Laboratory, Amanzimtoti, South Africa

Background: In hyper-endemic epidemic settings, as prevention strategies are scaled-up to achieve epidemic control, timely reliable measurements of new HIV infections are critical elements of surveillance. However, measurement of new HIV infections is complex and challenging. We report on the measurement of HIV incidence from The HIV Incidence Provincial Surveillance System (HIPSS) in KwaZulu-Natal (KZN), South Africa.

Methods: We undertook a community representative, cross-sectional household survey enrolling men and women 15 to 49 years of age from rural to peri-urban areas of uMgungundlovu district in KZN. We measured HIV prevalence and HIV negative individuals between the ages of 15 and 35 years were followed-up approximately 12 months later to measure new HIV infections. HIV prevalence and incidence rates were adjusted allowing for multilevel sampling and to represent the population.

Results: Of the 9812 (15-49 years) individuals enrolled from June 2014 to June 2015, 3548 (15-35 years) were re-tested from June 2015 to February 2017. HIV prevalence was 36.3% [95% Confidence interval (CI) 34.8-37.8); 44·1% (95%CI 42.3-45.9) in women and 28·0% (95% CI 25.9-30.1) in men. Overall 163 seroconversions occurred, an HIV incidence rate of 2.31 [1.89-2.87) per 100 person-years of observation (pyo). HIV incidence was 3.44 (95%CI 2.76-4.36) per 100 pyo in women and 1.44 (95% CI 0.96-2.25) per 100 pyo in men. The highest HIV incidence was 4.34 (95% CI 3.37-5.69) per 100 pyo in women in the age group 15-24 years, whilst in men in the same age group it was 0.93 (95% CI 0.45-1.60) per 100 pyo. However, in men 25-35 years HIV incidence was 2.29 (95% CI 1.26-4.61) per 100 pyo whilst in women in the same age group it was 1.65 (95 % CI 0.67-2.92) per 100 pyo.

Conclusions: Our findings show the excessively high HIV incidence rates in men and women 15-35 years in this hyper-endemic epidemic setting of KwaZulu-Natal. The disproportionate rate of HIV acquisition in young women 15-24 years underscores the importance of strengthening and intensifying coverage of HIV prevention strategies to reduce transmission potential.

THPEC195

Estimating national HIV incidence, prevalence and the proportion diagnosed in Canada in 2016

C. Archibald, N. Khalil, Q. Yang, P. Yan
Public Health Agency of Canada, Ottawa, Canada

Background: Estimating HIV incidence, prevalence and proportion diagnosed at the national level is critical for tracking the leading edge of the epidemic, planning and evaluating HIV prevention and care programs, and improving the first of the UNAIDS 90-90-90 targets to reduce the onward transmission of the virus. We updated national estimates of HIV incidence, prevalence and the proportion diagnosed for Canada for 2016.

Methods: Estimated annual incidence was back-calculated from the time series of national HIV diagnostic data, based on assumptions about HIV testing and case reporting patterns and calibrated using detuned assay data which reflect recent infections. Deaths among HIV-infected persons were estimated using vital statistics data for HIV-related deaths and data from cohort studies for all-cause mortality among persons living with HIV. Prevalence was estimated by subtracting cumulative deaths from cumulative incidence. The number of living diagnosed cases was calculated as the cumulative number of diagnosed cases minus estimated mortality, and the proportion diagnosed as the number of living diagnosed individuals divided by the estimate of prevalence.

Results: An estimated 2,570 new HIV infections occurred in Canada in 2014, for an incidence rate of 7.2 per 100,000 population. Fifty-four percent of new infections were among men who have sex with men, 33% were attributed to the heterosexual exposure category, and 11% to injection drug use. Indigenous people and people from sub-Saharan Africa or Caribbean countries were over-represented. An estimated 11% of new infections were among Indigenous persons, who comprised 4.3% of the Canadian population. An estimated 14% of new infections were among persons in the heterosexual exposure category born in sub-Saharan Africa or the Caribbean, whereas people born in these countries represented 2.5% of the overall population. An estimated 65,040 persons were living with HIV in Canada, of whom an estimated 80% were diagnosed. Updated estimates for Canada for 2016 are being finalized and will be presented.

Conclusions: Estimated HIV incidence in Canada has declined since 2005, but may have levelled off in the past 5 years. Despite the great progress Canada has made in addressing HIV, there is still work to be done to reach the first 90-90-90 target by 2020.

THPEC196

Diverging trends in incidence of HIV-1 versus other sexually transmitted infections in HIV-negative men who have sex with men (MSM) in Amsterdam

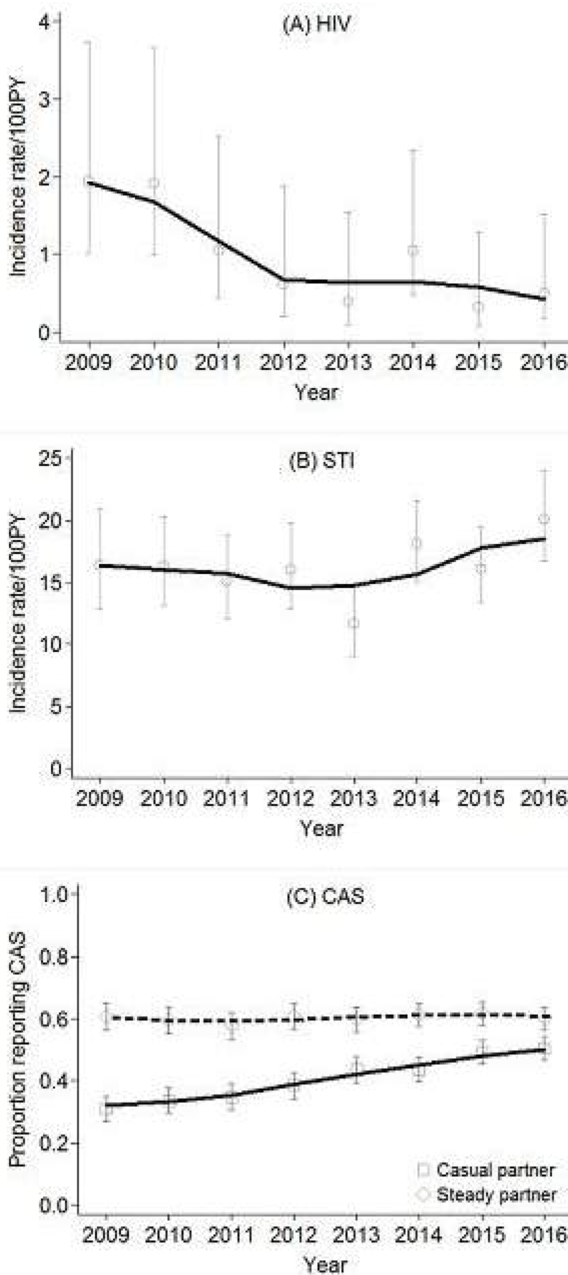
W.P.H. van Bilsen[1], A. Boyd[1,2], M.F. Schim van der Loeff[1,3], U. Davidovich[1], A. Hogewoning[1], L. van der Hoek[4], M. Prins[1,3], A. Matser[1]
[1]Public Health Service, Infectious Diseases Research, Amsterdam, Netherlands, [2]Sabonne Université, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Inserm, Paris, France, [3]Academic Medical Center, Department of Internal Medicine, Amsterdam Infection & Immunity Institute (AIII), Amsterdam, Netherlands, [4]Academic Medical Center, University of Amsterdam, Laboratory of Experimental Virology, Amsterdam, Netherlands

Background: The incidence of HIV-1 among men who have sex with men (MSM) in the Amsterdam Cohort Studies (ACS) slowly increased between 1996-2009. In the Netherlands, several new HIV prevention strategies were implemented thereafter. For this study, we investigated the incidence rates of HIV-1 and other sexually transmitted infections (STIs) among MSM in the ACS from 2009-2016. Moreover, we explored changes in condomless anal sex (CAS) over time.

Methods: We included all HIV-negative MSM participating in the ACS between 2009-2016. Participants completed a self-administered questionnaire on sexual behavior and were tested for HIV-1, syphilis, urethral and rectal chlamydia and gonorrhea, and pharyngeal gonorrhea every 3-6 months. Time trends in incidence rate were assessed using an exponential survival model with gamma-distributed shared frailty. Trends in CAS were evaluated using a non-parametric test for trend.

Results: Of 789 HIV-negative MSM, with a median age of 34 (IQR 28-41) years in 2009, 40 HIV seroconverted during follow-up. HIV-1 incidence rate was 1.9/100 person-years (PY) (95%-confidence interval(CI) 1.0-3.7) in 2009 and decreased non-significantly over time to 0.5/100 PY (95%-CI 0.2-1.5) in 2016 (p=0.4; *fig 1A*). Among 722 MSM with other STI testing during follow-up, 807 STI diagnoses were made, of which 334 were rectal STIs. STI incidence rate was 13.5/100 PY (95%-CI 10.2-17.8) in 2009 and significantly increased over time to 19.6/100 PY (95%-CI 16.2-23.7) in 2016 (p< 0.001; *fig 1B*). The incidence rate for rectal STIs significantly increased over time from 7.4/100 PY (95%-CI 5.1-10.8) in 2009 to 12.6/100 PY (95%-CI 10.0-16.0) in 2016 (p=0.002). In total, 30.9% reported CAS with casual partner(s) in 2009, compared to 50.5% in 2016 (p< 0.001; *fig 1C*). CAS with steady partner(s) remained stable over time (p=0.5; *fig 1C*).

Conclusions: Among MSM in Amsterdam, incidence rates of HIV-1 versus other STIs show diverging trends. The increase in STI incidence coincides with a decrease in condom use with casual partners. However, the decreasing trend in HIV-1 incidence despite the decrease in condom use, might suggest that other HIV prevention methods have been successful in lowering the transmission of HIV-1 among MSM, such as treatment as prevention or more recently, pre-exposure prophylaxis (PrEP).



[Figure 1. A. HIV-1 incidence rate, B. STI incidence rate and, C. reported condomless anal sex (CAS) with casual or steady partners(s) among HIV-1 negative MSM participating in the Amsterdam Cohort Studies 2009-2016]

Novel methods/algorithms for detecting acute and recent HIV infections

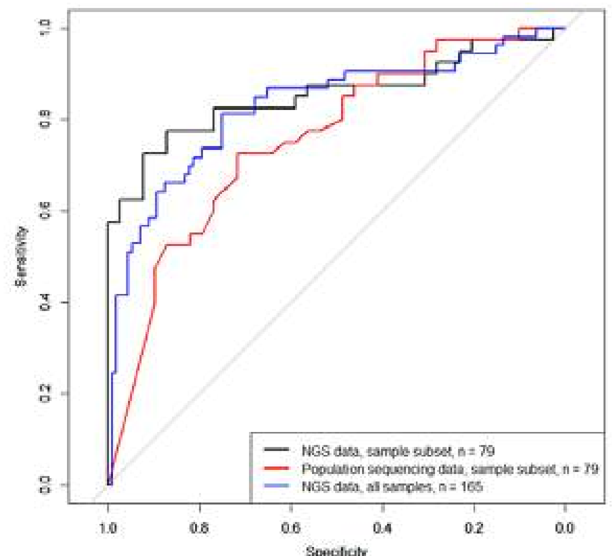
Estimating HIV-1 infection recency: Viral diversity from next-generation sequencing is more informative than the fraction of ambiguous nucleotides from population sequencing

L.A. Carlisle[1,2], T. Turk[1,2], K. Kusejko[1,2], K. Metzner[1,2], C. Leemann[1,2], N. Bachmann[1,2], S. Posada[3], N. Beerenwinkel[3], J. Böni[2], S. Yerly[4], M. Perreau[5], T. Klimkait[6], D. Braun[1], H. Günthard[1,2], R. Kouyos[1,2]
[1]University Hospital Zurich, Division of Infectious Diseases and Hospital Epidemiology, Zürich, Switzerland, [2]University of Zurich, Institute of Medical Virology, Zurich, Switzerland, [3]ETH Zurich, Department of Biosystems Science and Engineering, Zurich, Switzerland, [4]Geneva University Hospital, Laboratory of Virology, Geneva, Switzerland, [5]Lausanne University Hospital, Faculty of Biology and Medicine, Lausanne, Switzerland, [6]University of Basel, Molecular Virology, Department Biomedicine, Basel, Switzerland

Background: Viral genetic diversity within an HIV-1 infection increases over time and can be used to classify an infection as recent or chronic. We assess whether the diversity calculated from next-generation sequencing (NGS) correlates more strongly with time since infection, and offers a more accurate classification than the fraction of ambiguous nucleotides obtained by population sequencing (AN-PS), a previous proxy.
Methods: We considered 165 HIV-1 individuals from the Zurich Primary HIV Infection Study and Swiss HIV Cohort Study, for whom true time since infection (±12 months) could be determined by other methods, and NGS-derived nucleotide frequency data were available for over 50% of the 3rd codon positions in *pol*. A previously calculated fraction of ambiguous nucleotides from AN-PS data was available for 79/165 individuals. We calculated average pairwise diversity over *pol* 3rd codon positions using the NGS data, with a 1% error cut-off. A linear regression was performed against time since infection, and sensitivity and receiver operating characteristic (ROC) analyses were used to measure the ability to predict if a sample came from recent (< 1 year) or chronic infection. These measures were compared to values obtained using AN-PS data.
Results: Using NGS data, average pairwise diversity calculated over *pol* 3rd codon positions can classify an infection as recent with a sensitivity of 81.1% and specificity of 75.0% (ROC area under curve = 82.8%, n=165). When directly comparing the 79 samples to the AN-PS method, the NGS method has a lower sensitivity (77.5% vs 87.5%), but a higher specificity (87.2% vs 46.2%) and a higher ROC area under curve (85.3% vs 75.7%). Diversity calculated from NGS data correlates with time since infection (R^2 = 0.258), and for the sub-sample of 79 does so more strongly than the fraction of ambiguous nucleotides (R^2 = 0.358 vs 0.333).



[ROC curves, classifying infection as recent versus chronic]

Conclusions: Viral genetic diversity calculated using NGS data is a better predictor of recency of infection, and correlates more strongly with time since infection than using the fraction of ambiguous nucleotides from AN-PS data. This approach is therefore a promising method to estimate the time since an individual was infected with HIV-1.

THPEC198

Social network methods for HIV case-finding among people who inject drugs in Tajikistan

M. Kan[1], D. Garfinkel[2], O. Samoilova[1], R. Gray[2], K. Little[2]
[1]*Population Services International/Central Asian Branch, Almaty, Kazakhstan,* [2]*Population Services International, Washington, DC, United States*

Background: HIV testing programs have struggled to reach the most marginalized populations at risk for HIV. Social network methods such as respondent-driven sampling (RDS) and peer-based active case-finding (ACF) may be effective in overcoming barriers to reaching these populations. We compared the client characteristics, yield, and number of new cases found through two RDS strategies and an ACF approach to HIV case-finding among people who inject drugs (PWID) in Tajikistan.

Methods: Routine program data from adult PWID recruited to testing under the USAID Central Asia HIV Flagship Project in Tajikistan were analyzed to compare client demographic and clinical characteristics across the three approaches. We also compared the number of previously untested clients, the number of new HIV cases found, and the yield across the case-finding strategies, and evaluated predictors of new HIV diagnosis using fixed-effects logistic regression.

Results: Between October 24, 2016-June 30, 2017 Flagship tested 10,300 PWID for HIV, including 2,143 under RDS with unrestricted waves (RDS1, yield: 1.5%), 3,517 under restricted RDS (RDS2, yield: 2.6%), and 4,640 under ACF (started in January; yield: 1.5%). Clients recruited under ACF were significantly younger than those recruited through RDS (35.8 vs. 36.8, $p< 0.001$), more likely to be male (91.1% vs. 89.6%, $p=0.008$), and more likely to report being a first-time tester (85.1% vs. 68.3%, $p< 0.001$). After controlling for age, sex, previous testing history, and accounting for clustering at the site level, we found that clients tested under both RDS1 (aOR: 1.74, 95% CI: 1.04-2.90) and RDS2 (aOR: 1.54, 95% CI: 1.11-2.15) had significantly higher odds of testing newly positive for HIV relative to clients recruited through ACF. We did not find significant differences in the odds of new HIV infection between those recruited from RDS1 vs. RDS2 (aOR: 1.12, 95% CI: 0.67-1.86).

Conclusions: RDS-based interventions resulted in higher yields and overall case-finding, especially when recruitment was restricted. However, ACF identified a higher proportion of new testers and younger PWID, and recruited clients faster than RDS1. To find at least 90% of PWID living with HIV in Tajikistan, it may be necessary to implement multiple case-finding approaches concurrently to maximize testing coverage.

Interpreting diagnostic histories into HIV infection date estimates: An online tool

E. Grebe[1], S. Facente[2], R. Kassanjee[3], A. Powrie[4], J. Gerber[4], G. Priede[4], T. Chibawara[1], M. Busch[5,6], G. Murphy[7], C. Pilcher[6], A. Welte[1]
[1]*SACEMA, Stellenbosch University, Stellenbosch, South Africa,* [2]*Facente Consulting, San Francisco, United States,* [3]*University of Cape Town, Department of Statistical Sciences, Cape Town, South Africa,* [4]*Implicit Design, Cape Town, South Africa,* [5]*Blood Systems Research Institute, San Francisco, United States,* [6]*University of California, San Francisco, United States,* [7]*Public Health England, National Infection Service, London, United Kingdom*

Background: The ability to estimate the date of infection for people with HIV is useful for surveillance purposes, pathogenesis studies, and evaluation of novel diagnostics. For more than 15 years, the only widely referenced algorithm to estimate time-since-infection has been 'Fiebig staging,' which defines stages of early HIV infection through standard combinations of discordant results using diagnostic tests of different sensitivity; however, the tests used in these original calculations are no longer in use. We set out to develop a new, flexible infection dating algorithm to translate information from a subject's diagnostic testing history into an Estimated Date of Detectable Infection (EDDI), and to develop an open-source tool that would make this algorithm accessible to researchers.

Description: Every HIV assay has a 'diagnostic delay,' i.e. the number of days from infection during which the test will continue to produce a negative result. Estimating median diagnostic delays - accounting for inter-subject variability in assay performance - allows for calculation of an individual EDDI, using an algorithm to infer a time interval during which the date of detectable infection likely lies. Our team has curated estimates of diagnostic delays for approximately 70 assays currently or formerly in use, incorporating them into a new online tool that allows a user to employ these default estimates or specify their own preferred delays.

Lessons learned: This online tool synthesizes available assay data to allow for easy computation of individual EDDIs, provided that each individual has at least one negative and one positive HIV test result, and the dates of testing and assays used are known. To facilitate automated processing, the tool demands a simple dataset with four columns: Subject, Date, Test, and Result, with the result being 'positive' or 'negative' for each test. EDDIs, along with an 'earliest plausible' and 'latest plausible' date of infection are calculated for each subject. The tool is easily updated as new assays come into use worldwide.

Conclusions/Next steps: The whole code base for the tool (available at tools.incidence-estimation.org/idt) is available in a publicly-viewable repository on github. Anyone can deploy their own copy of the tool or make modifications.

Background: Tests for recent infection (TRI) distinguish recent HIV infection from non-recent infection using markers of antibody maturation. The LAg-Avidity enzyme immunoassay (LAg) is widely used together with HIV viral load (VL) in a recent infection testing algorithm (RITA) to estimate HIV incidence to inform epidemic monitoring. A new point-of-care recency test (POC-RT), Asante, can determine HIV serostatus and HIV recency within minutes on a single lateral flow device through visual or quantitative assessment. We conducted a field validation of the Asante POC-RT in routine HIV testing services for pregnant adolescent girls and young women (AGYW) attending antenatal clinics (ANC) in Malawi to inform prevention strategies.

Methods: We enrolled pregnant AGYW aged < 25 years testing HIV-positive at their first ANC visit from 94% of ANCs in Lilongwe and Blantyre. Consenting participants provided blood for recency testing using the LAg and Asante assays. Specimens with LAg normalized optical density (ODn) values ≤2.0 tested LAg-recent, else they tested LAg-non-recent. Asante results were determined based on: (1) visual assessment: presence of the "Long-term (LT) line" indicated non-recent infection and absence of the line indicated recent infection or (2) quantitative assessment: specimens with LT line reader values ≤3.0 were Asante-recent, else they were Asante-non-recent. VL was measured for specimens testing recent; those with VL>1,000 copies/mL were RITA-recent. We evaluated the performance of the Asante by calculating percent agreement and correlation between Asante-RITA and LAg-RITA results and by comparing Asante-visual (V) with Asante-quantitative (Q) results.

Author Index

Results: Between 11/6/2017-1/20/2018, 108 specimens were available for Asante validation; all confirmed HIV-positive on Asante POC-RT. Percent agreement was >90% between Asante-RITA and LAg-RITA and 96.3% between the Asante-quantitative and Asante-visual results (Table). Using LAg-RITA as reference standard, sensitivity was 53.3% (Asante-Q-RITA) and 46.7% (Asante-V-RITA); specificity was 98.9% (Asante-Q-RITA) and 97.8% (Asante-V-RITA). LAg ODn and Asante-Q values had strong correlation (Spearman Rho=0.654, p< 0.001; Figure). Of 7 LAg-RITA-recent cases discrepant on Asante-Q-RITA, 5 (71.4%) fell within 0.5 units of the Asante-RITA cut-off.

Conclusions: This was the first field validation of a POC-RT in sub-Saharan Africa. While POC-RT performance is promising, more data are needed for validating the test in this population.

Test comparison	Percent agreement % (95% Confidence Intervals)	Kappa
Asante-V-RITA vs. LAg-RITA	90.7 (83.6-95.5)	0.535
Asante-Q-RITA vs. LAg RITA	92.6 (85.9-96.8)	0.628
Asante-Q-RITA vs. Asante-V-RITA	96.3 (90.9-99.0)	0.758

Acute HIV infection among newly diagnosed patients in Santo André Aids Program, São Paulo, Brazil

E. Monteiro Matsuda[1], L. Portes Ozório Coelho[2], C. Mayumi Ahagon[2], G. de Faria Romero[2], G. Bastos Cabral[2], G. Ibete Silva Lòpez Lopes[2], I. Barros Campos[3], L.F. de Macedo Brigido[2], MIR - Monitoring Incident HIV Infection Working Group

[1]Programa de AIDS de Santo André, Ambulatório de Referência em Moléstias Infecciosas, Santo André, Brazil, [2]Instituto Adolfo Lutz, Centro de Virologia, São Paulo, Brazil, [3]Instituto Adolfo Lutz, Regional Santo André, Santo André, Brazil

Background: Identifying and incorporating acute HIV infection (AHI) into health system, with adequate viral suppression, may diminish secondary transmission as well as benefit patients, including by reducing HIV reservoirs, favoring future cure strategies. We evaluated newly diagnosed cases according to CDC2014 categories.

Methods: Patients newly diagnosed with HIV infections at our service (2012-2017) with blood collection for *pol* genotyping were included. Viral load (Abbott rtPCR), CD4 (BD, USA), antibodies avidity (CEPHIA protocol) and HIV partial *pol* sequences (nested RT-PCR followed by Big Dye, life, USA) were analyzed, with subtypes (REGA Subtyping tool), resistance mutations (CPR v.6.0 and GRI-HIVdb) and genetic ambiguity (Bioedit). Continuous variables are described as median and percentile 25th-75th (IQR).

Results: 204 new diagnoses were studied out of 1337 admissions at the study period. Patients' were mostly male young MSM. Table 1 shows demographic and laboratory characteristics according to CDC2014 classification. 194 started ART, 92% on treatment for 180+ days with viremia < 200copies/mL at last viral load measurement. Out of 25% cases at CDC2014_zero, 22% were Fiebig stage I-III. Most patients (63%) referred previous negative serological result, mostly by rapid diagnostic test (RDT). Recent infection surrogates as low avidity (< 40%) or ambiguity< 0.45 were observed in 30% and 58% of cases, respectively, with significant lower genomic ambiguity (p=0.002) and avidity index (p=0.0001) among cases at CDC_zero. A lower avidity and ambiguity also showed a significant association to previous HIV negative result (p=0.0003/ p=0.002). Heterosexual man was more likely than MSM to be at CDC_3 (35% versus 5.5%, p=0.0002) and less likely to refer previous HIV test (19% versus 70%, p< 0.0001).

Conclusions: Cases classified as recent infections (CDC2014_zero) tended to have laboratory surrogate markers of recent infection, which was also associated to previous negative HIV serological testing. The diagnosis of some cases might have been delayed by previous rapid testing during immunological window. Recommendation to prompt retesting and easier access to RNA tests and/or fourth generation when a serological window may be considered can improve AHI diagnosis, especially for the MSM population. Health policies aiming heterosexual man, as incentives to repeat testing, may improve earlier diagnosis.

Novel studies to measure HIV incidence

THPEC202

New methods of HIV incidence estimation indicate a second wave of infections in Brazil

T. Mangal[1], A.R. Pascom[2], J. Vesga[1], M.V. Meireles[2], A.S. Benzaken[2], T. Hallett[1]
[1]*Imperial College London, Infectious Disease Epidemiology, London, United Kingdom,* [2]*Ministry of Health, Department of STI, HIV/AIDS and Viral Hepatitis, Brasilia, Brazil*

Background: Emerging evidence has suggested that HIV incidence rates in Brazil, particularly among young men, may be rising. Brazil has a wealth of surveillance data, with integrated health systems documenting reported HIV/AIDS cases since the 1980s. Here we describe a mathematical model designed to reproduce the complex surveillance systems, providing estimates of HIV incidence, prevalence and linkage to care over time.

Methods: An age-structured deterministic model with a flexible B-spline was used to describe the natural history of HIV along with detection and treatment rates. Individual-level surveillance data (new detected cases, ART dispensations, CD4 counts and HIV/AIDS-related deaths) were used to calibrate the model using Bayesian inference.

Results: The estimated epidemic curve showed a second wave of infections occurring after 2001. The number of new infections in 2016 was 52,413 (95% CI 37,469 - 76,946), 37,292 (27,834 - 54,270) infections in men and 15,121 (9,635 - 22,676) in women. The prevalence by end-2016 was 876,582 (95% CI 708,002 - 1,137,555), with 115,603 (84,309 - 159,916) individuals infected and undiagnosed.

By end-2016, 78.5% (60.5 - 97.2%) of people living with HIV in Brazil were aware of their status. Women were more likely to be diagnosed and reported than men; 86.8% of infected women had been reported compared with 75.7% of men and the average time from infection to detection was 1.9 years in women and 2.9 years in men. Of those who had been reported, 482,854 (70.2%) were accessing ART, indicating an overall treatment coverage level of 55.1%.

Conclusions: The finding of a second wave of infections contradicts previous estimates and official positions on the HIV incidence trends in Brazil. There are persistent differences in the rates of accessing care between men and women. Nevertheless, the HIV program in Brazil has achieved high rates of detection and treatment initiation, making considerable progress over the past ten years.

THPEC203

Newly increasing HIV incidence among adults aged 50 years or older in Ukraine

Y. Rozanova[1], O. Zeziulin[2], I. Zaviriukha[2], T. Sosidko[3], O. Gvozdetska[3], V. Kurpita[4], T. Kiriazova[2], K. Gulati[5], F.L. Altice[1], S.V. Shenoi[1]
[1]*Yale University, Internal Medicine, New Haven, United States,* [2]*Ukrainian Institute on Public Health Policy, Kiev, Ukraine,* [3]*All-Ukrainian Network for People Living with HIV, Kiev, Ukraine,* [4]*Ukrainian Center for Public Health, Kiev, Ukraine,* [5]*University of Connecticut, Neuroscience, Storrs, United States*

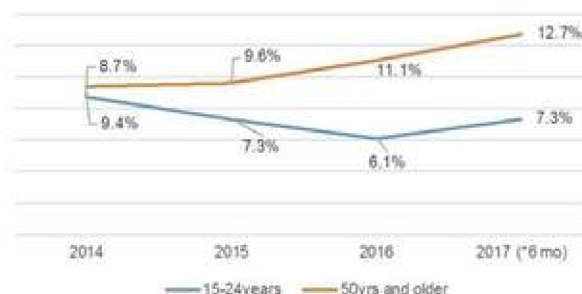
Background: Eastern Europe and Central Asia (EECA) is the only region globally where HIV incidence and mortality are still increasing. Ukraine has one of the most volatile HIV epidemics in the world (after Russia) with over 240,000 PLWH (~ 0.5%) and 17,066 new HIV diagnoses in 2016. While the 15-24 HIV risk group is a priority, there is a dearth of HIV prevention efforts for mature adults and HIV incidence in later life is understudied. We sought to explore and characterize the new trend in HIV epidemic in Ukraine.

Methods: We reviewed trends in aggregated national data from the All-Ukrainian Network for People Living with HIV 2014-2017 (1st 6 mo) and compared 1) ≥50yo 2) 25-49yo 3) 15-24yo. Bi-variate statistical analyses were performed using Chi-square test ($p < 0.05$). We defined CD4 ≤200 cells/ml as advanced HIV and mortality as annual number of deaths among people living with HIV (PLWH) diagnosed with HIV during that year.

Results: In 2014, those 15-24yo and ≥50yo constituted 9.4% and 8.7% of all new HIV diagnoses respectively. In 2015 however, new diagnoses among ≥50yo became more common, increasing 90% by 2017 (p=XXX), and overtook those 15-24yo (Figure 1).

Second, the majority (54.5%) of PLWH ≥50yo had advanced HIV at the time of diagnosis, and were significantly more likely to have advanced HIV at diagnosis than both 25-49yo (39.3%) and 15-24yo (17.2%) ($p< 0.001$). Third, in 2016-17, nearly 5% of PLWH ≥50yo died within the first year of HIV diagnosis; mortality was nearly double among those 15-49 yo ($p< 0.001$), and 17 times more likely than 15-24yo ($p< 0.001$).

Conclusions: This is the first report to identify a new epidemiological trend in the HIV epidemic in Ukraine. PLWH are increasingly comprised of an older population who are being diagnosed at late stage of HIV disease with high rates of mortality. While further exploration of this population is critical, HIV programs and public health efforts need to recognize this population by supporting routine screening of adults 50yo+ for HIV. These findings have potentially tremendous implications for public health policy and clinical HIV practice.



[Figure 1. HIV Incidence in Ukraine, 2014-2017]*

THPEC204

Incidence of HIV in sub-Saharan Africa: A systematic review with implications for surveillance and prevention planning

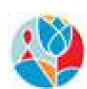
B. Samuel
Hôpital Général de Bukavu, Medical, Bukavu, Congo, Democratic Republic of the

Background: Population-based HIV incidence estimation and risk factor identification is increasingly being incorporated into routine HIV/AIDS surveillance activities. The US recently produced a national HIV incidence estimate of 0.022 per 100 person-years [PY] using the serologic testing algorithm for recent HIV seroconversion (STARHS) method via BED capture ELISA. We conducted a systematic review of estimates and risk factors for HIV incidence from sub-Saharan Africa, including the methods by which they were obtained.

Methods: We examined peer-reviewed articles, conference proceedings and technical reports published between 2010-2016. Incidence estimates were classified by country, year, population group, and estimation method (prospective study or STARHS).

Results: Our search yielded HIV incidence estimates for 15 of 44 sub-Saharan African countries, including 57 studies, for a total of 264 unique HIV incidence estimates. Of these, 239 (91%) were obtained via prospective studies (range: 0.6-16.5 infections/100PY), and 25 (9%) via the STARHS method (24 using BED) (range:1.8-17.0/100PY). Only 5 countries (Kenya, South Africa, Tanzania, Uganda, and Zimbabwe) reported national population-based estimates (range: 0.6-9.0/100 PY). STARHS use increased over time, comprising 20% of estimates since 2010. However, African studies that compared STARHS estimates with prospectively observed or modeled estimates often found concerning levels of disagreement. There was a high degree of correspondence between risk factors for HIV incidence versus prevalence in studies where both were measured.

Conclusions: Population-based HIV incidence estimates and associated risk factor information in sub-Saharan Africa remain scant but increasingly available, and are 1-2 orders of magnitude higher than the most recent national estimate in the US. However, data from some studies using the STARHS method in sub-Saharan Africa suggest a need for



further validation prior to widespread scale-up. In the meantime, prevalence and behavioral risk factor data remain an important mainstay for HIV prevention planning.

Measuring the epidemic through population-based surveys, including the undiagnosed fraction

90-90-90 targets in Malawian men using results from MPHIA

C. West[1], T. Kalua[2], M. Odo[3], N. Wadonda-Kabondo[4], M. Nzima[5], S. Kinchen[6], J. Cuervo-Rojas[7], H. Patel[6], R. Bray[7], G. Bello[2], D. Payne[4], A. Auld[4], MPHIA Study Team
[1]Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Lilongwe, Malawi, [2]Ministry of Health, Lilongwe, Malawi, [3]I-TECH, Lilongwe, Malawi, [4]Centers for Disease Control and Prevention, Lilongwe, Malawi, [5]UNAIDS, Lilongwe, Malawi, [6]Centers for Disease Control and Prevention, Atlanta, United States, [7]ICAP at Columbia University, New York, United States

Background: Men remain an important group for testing and treatment interventions in Malawi, as they represent a probable source of HIV transmission in the country. This analysis aimed at describing progress and associated factors in achieving UNAIDS 90-90-90 targets among adult men in Malawi.
Methods: The 2015-16 Malawi Population-Based HIV Impact Assessment (MPHIA) was a two-stage cluster survey of randomly selected households in Malawi. The survey included home-based HIV counseling and testing using the national rapid testing algorithm, followed by laboratory-based confirmation for positive results using Geenius™. HIV-1 viral load was measured using the Abbott m2000 System; viral load suppression (VLS) was defined as < 1,000 HIV RNA copies/mL. Antiretroviral therapy (ART) was determined by self-report or detection of antiretroviral drugs (ARVs; atazanavir, efavirenz, nevirapine, tenofovir) in blood. All analyses accounted for survey design.
Results: A total of 7,208 men aged 15-64 years were interviewed and tested; HIV prevalence was 8.5% (95% confidence intervals (CI): 7.8-9.2). Seventy-one percent (71.7%, 95%CI: 67.7-75.6) of men were aware of their HIV+ status. Among men who knew their HIV+ status, 88.7% (95%CI: 85.5-92.0) reported being on ART or had detectable ARVs in their blood. Of these, 89.8% (95%CI: 86.2-93.4) had achieved VLS. Among all HIV+ men, irrespective of awareness of HIV and ART status, 60.9% (95%CI: 56.8-65.0) had achieved VLS. Status towards 90-90-90 targets varied by age (Table 1). Younger HIV+ men aged 15-29 years were less likely to be aware of their status and be on treatment. Men in urban areas (65.7%, 95%CI: 59.3-72.1) compared to those in rural areas (73.8%, 95%CI: 69.0-78.6) were also less likely to be aware of their status (p< 0.05). Of men who were unaware of their status, 23.4% (95%CI: 16.3-30.6) reported two or more sexual partners in the last 12 months.
Conclusions: MPHIA results indicate that there is still progress to be made in reaching men for HIV testing and treatment in Malawi; 40% of all HIV+ men in Malawi are not virally suppressed, demonstrating gaps in achieving 90-90-90 targets. Strategies are needed to facilitate access to services for men, especially testing among younger men and those residing in urban areas.

	Aware of HIV-positive status		On ART among those aware of their HIV-positive status		Viral suppression among those on ART

Late diagnosis of HIV among adults in Zimbabwe, Malawi and Zambia: Risk factors and burden from three population-based HIV impact assessments (PHIAs)

E. Radin[1], S. Birhanu[2], A. Low[1], S. Saito[1], K. Sachathep[1], S. Balachandra[3], J. Manjengwa[1], Y. Duong[1], S. Jonnalagadda[2], G. Bello[4], A. Hakim[2], N. Ahmed[1], J. Cuervo-Rojas[1], A. Auld[5], H. Patel[2], B. Parekh[2], A. Voetsch[2], D. Williams[2], D. Barradas[6], D. Payne[5], O. Mugurungi[7], L. Mulenga[8], J. Justman[1]
[1]ICAP at Columbia University, New York, United States, [2]U.S. Centers for Disease Control & Prevention, Atlanta, United States, [3]U.S Centers for Disease Control & Prevention, Harare, Zimbabwe, [4]Ministry of Health, Government of Malawi, Lilongwe, Malawi, [5]U.S. Centers for Disease Control & Prevention, Lilongwe, Malawi, [6]U.S. Centers for Disease Control & Prevention, Lusaka, Zambia, [7]Ministry of Health & Child Care, Government of Zimbabwe, Harare, Zimbabwe, [8]Ministry of Health, Government of Zambia, Lusaka, Zambia

Background: Late diagnosis (LD) of HIV increases the risk of morbidity, mortality, and disease transmission. However, the group(s) at greatest risk for LD are not clearly identified in Zimbabwe, Malawi and Zambia. We describe the distribution, burden and correlates of LD among people living with HIV (PLHIV) using the 2015-16 PHIA household surveys.
Methods: The Zimbabwe, Malawi and Zambia PHIAs respectively recruited 20,577 adults aged 15-64, 17,187 adults aged 15-64 and 19,115 adults aged 15-59 for interviews and HIV rapid testing using each country's national algorithm. All HIV+ adults underwent CD4 count testing. HIV+ participants who reported being HIV- or unaware of their status were defined as undiagnosed. Undiagnosed PLHIV with CD4 cell count< 350 cells/μl were defined as meeting LD criteria. Correlates of LD were assessed using multivariate logistic regression. All analyses were weighted to account for the complex survey design of the PHIAs.
Results: Across countries, 26% of PLHIV were undiagnosed. Among undiagnosed PLHIV, 48% met LD criteria: 54% of men and 43% of women. This corresponds to 371,000 undiagnosed adults, 189,000 men and 182,000 women, meeting LD criteria in the total population. Among undiagnosed PLHIV aged 15-24, 35%, or 58,000 people, met LD criteria, while 49% of undiagnosed PLHIV aged 25-40, or 196,000 people, and 55% of undiagnosed PLHIV aged 41-64, or 116,000 people, met LD criteria.
In multivariate analysis, being male (Adjusted Odds Ratio (aOR) 1.54), being aged 25-40 (aOR 1.62), being aged 41-64 (aOR 1.89) and being widowed (aOR 1.76) were associated with LD. Wealth, education, country, urban residence, never having an HIV test and high-risk sexual behaviors (having multiple partners in 12 months, buying or selling sex, and having non-marital, non-cohabiting partners) were not associated with LD.

Characteristic	Proportion with CD4 cell count <350 cells/μl	Number in Total Adult Population w/ CD4 cell count <350 cells/μl	aOR (95% CI) *= p≤.05, **=p≤0.01, ***p≤0.001
Zimbabwe	50.3% (46.6%-54.1%)	157,000 (137,000-177,000)	ref
Malawi	47.1% (41.2%-53.1%)	93,000 (77,000-109,000	0.88 (0.66-1.19)
Zambia	45.1% (41.1%-49.1%)	121,000 (105,000-138,000)	0.86 (0.68-1.07)
Female	42.6% (39.6%-45.7%)	182,000 (164,000-202,000)	ref
Male	54.0% (49.9%-58.0%)	189,000 (167,000-210,000)	1.54 (1.25-1.90) ***
Age 15-24y	34.7% (29.6%-40.3%)	58,000 (47,000-70,000)	ref
Age 25-40y	49.2% (45.7%-52.7%)	196,000 (175,000-218,000)	1.62 (1.22-2.16) ***
Age 41-64y	55.2% (50.6%-59.7%)	116,000 (102,000-131,000)	1.89 (1.38-2.59) ***
Widowed	61.1% (52.3%-69.2%)	35,000 (27,000-43,000)	1.76 (1.18-2.64) **

[Table: Proportion, Number and Correlates of CD4 cell count <350 cells/μl among Undiagnosed PLHIV in Zimbabwe, Malawi and Zambia (N=1934)]

Conclusions: Timely diagnosis remains a challenge, particularly among men and PLHIV over 40 in Zimbabwe, Malawi and Zambia. In addition to increasing risk for morbidity, mortality and transmission, LD may compound difficulties faced by older adults in immune system recovery after treatment initiation. To improve patient outcomes and control the epidemic, it is critical to reach the large numbers of undiagnosed PLHIV with low CD4 counts in this African sub-region.

THPEC207

Who are the missing men? Characterizing men who have never tested for HIV from population-based surveys in six sub-Saharan African countries

C. Quinn[1], D.T. Kadengye[2], C. Johnson[1], R. Baggaley[1], S. Dalal[1]
[1]*World Health Organization, HIV/AIDS, Geneva, Switzerland,* [2]*School of Statistics and Planning, Makerere University, Kampala, Uganda*

Background: Attaining the first of the 90-90-90 global targets requires focused approaches to reach people with undiagnosed HIV. In 2014, men took only 30% of all HIV tests. We sought to characterize men who had never tested for HIV, understand factors associated with not testing, and measure survey HIV test uptake.

Methods: We analyzed nationally-representative Demographic and Health Surveys (DHS) from six Sub-Saharan countries: Malawi, Zimbabwe, Lesotho, Rwanda, Zambia, and Ethiopia. We included adult men and their corresponding HIV laboratory results for the most recent survey year. Eligible women were household residents or overnight visitors aged 15-49 years. Eligible men were 15-59 years in Lesotho, Rwanda, Zambia and Ethiopia; 15-54 years in Malawi and Zimbabwe. We analyzed self-reported questionnaire responses on HIV testing, known behavioral risk factors, and corresponding HIV test results. Survey results were weighted using country-specific sampling weights provided by DHS.

Results: Between 2,931-14,773 men and 6,621-24,562 women participated in each survey. Approximately double the proportion of men had never tested for HIV compared to women (Malawi: 30% vs. 17%, p=< 0.0001; Zimbabwe: 35% vs. 19%, p=< 0.0001; Lesotho: 34% vs. 15%, p=< 0.0001; Zambia: 36% vs. 20%, p=< 0.0001); although, less of a differential existed in Rwanda (19% vs. 14%, p=< 0.0001) and Ethiopia (60% vs. 61%, p=0.14). When offered a test during the survey, high proportions of sexually-active men who had never previously tested, did accept testing (Malawi: 90%, Zimbabwe: 85%, Rwanda: 99%, Lesotho: 93%, Zambia: 91%, Ethiopia: 92%). HIV positivity ranged from 1-14% (table 1). Across countries, factors associated with never having tested for HIV among men after adjusting for age, were never being married (adjusted odds ratios for countries [aOR] ranging from 1.47-8.70), not having children (aOR 1.36-3.51), having health insurance (aOR 1.04-3.49) and lower levels of education (aOR 1.87-4.45).

Conclusions: Although higher proportions of men than women had never tested for HIV, between 85-99% of men did test when offered during a survey. Finding opportunities to offer HIV testing to single men with lower levels of education may increase testing among men, and link those who test positive to treatment.

	Malawi (2015-16) N=1,465	Zimbabwe (2015) N=1,728	Lesotho (2014) N=804	Rwanda (2014) N=486	Zambia (2014-13) N=3,697	Ethiopia (2011) N=5,307

[Table 1: Survey testing results of sexually-active men who had never previously tested for HIV]

THPEC208

Reasons for not HIV testing among sexually active men and women who have never tested for HIV

D.T. Kadengye[1], C. Quinn[2], C. Johnson[2], R. Baggaley[2], S. Dalal[2]
[1]*School of Statistics and Planning, Makerere University, Kampala, Uganda,* [2]*World Health Organization, HIV/AIDS, Geneva, Switzerland*

Background: By 2016, 70% of people with HIV knew their status. To reach the UN 90-90-90 target for 90% of people with HIV to be diagnosed, HIV test uptake must increase. We aimed to quantify and compare reasons for not testing for HIV among sexually-active men and women who had never tested.

Methods: We analyzed Demographic and Health Surveys in Zambia and Lesotho. Respondents were household residents or overnight visitors aged 15-49 years for women and 15-59 years for men. We reported frequencies of sexually-active respondents who had never tested and answered „yes" to reasons why people do not test. Survey results were weighted using country-specific sampling weights.

Results: More men than women had never tested for HIV (Zambia: 68.7% vs. 31.3%, p< 0.0001; Lesotho: 64% vs. 36%, p< 0.0001). The most common reasons for not previously testing among men and women were fear of results (Zambia: 81.4% vs. 74.1%, p< 0.0001; Lesotho: 72.2% vs. 79.0%, p=0.051), fear of stigma (Zambia: 36.9% vs. 30.9%, p=0.003; Lesotho: 23.9% vs. 29.2%, p=0.113), and low perceived HIV risk (Zambia: 19.4% vs. 13.0%, p< 0.0001; Lesotho: 13.0% vs. 12.1%, p=0.692) (Table 1). After adjusting for age, for Zambia, statistically significant correlates for fear of results were being male (adjusted odds ratio [aOR] 1.29, 95% confidence interval [CI] 1.07 - 1.56), living in urban areas (aOR: 1.70, CI: 1.37 - 2.10) and having secondary education (aOR: 1.74, CI: 1.07 - 1.56) or higher (aOR: 1.29, CI: 1.07 - 1.56). Correlates for low perceived risk of HIV infection were being male (aOR: 1.54, CI: 1.24 - 1.92) and living in urban areas (aOR: 1.66, CI: 1.30 - 2.12). In Lesotho, having more than one lifetime sexual partner (aOR: 1.78, CI: 1.08 - 2.96) and primary (aOR: 2.43, CI: 1.46 - 4.02) or secondary education (aOR: 5.07, CI: 3.04 - 10.67) were significant correlates for fear of HIV-positive results.

Conclusions: Fear of positive results remains an overriding reason for not testing for HIV among both men and women. Outreach messages that aim to increase risk perception and emphasize treatment success may assist in reaching people who have never tested for HIV.

THPEC209

The continuum of HIV care and population viral load (PVL) among a representative sample of gay, bisexual and other men who have sex with men (MSM) in Nairobi, Kenya

A.D. Smith[1], R. Kabuti[2], M. Kung'u[2], E. Irungu[2], P. Muthoga[2], A. Mugambi[2], C. Nyamweya[2], P. Weatherburn[3], E. Fearon[3], A. Bourne[4], J. Kimani[2,5], TRANSFORM
[1]*University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom,* [2]*Partners for Health and Development, Nairobi, Kenya,* [3]*London School of Hygiene and Tropical Medicine, Department of Public Health, London, United Kingdom,* [4]*La Trobe University, Australian Research Centre in Sex, Health & Society, Melbourne, Australia,* [5]*University of Manitoba, Department of Medical Microbiology and Infectious Diseases, Winnipeg, Canada*

Background: The UNAIDS 90-90-90 is central to Kenya's National AIDS Control Strategy. MSM are a key population in Kenya yet criminalisation and discrimination present obstacles to care engagement. This study set out to assess for the first time the continuum of HIV care among a representative sample of MSM in Nairobi.

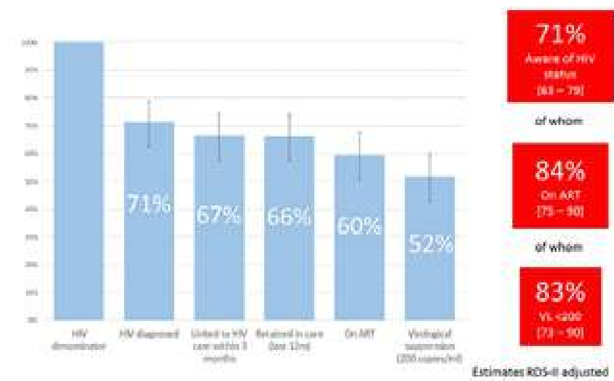
Methods: Respondent-driven sampling (RDS) was employed to recruit 618 MSM. Eligibility criteria were age 18+, male gender at birth or currently, Nairobi residence and consensual oral or anal intercourse with a male partner in the last 12 month. Consenting HIV-positive participants conducted a computer-assisted survey, which included HIV testing history, timing of diagnosis, care linkage within 3 months, retention in care

(12 months) and current ART use. HIV status was established using Determine® & First Response® HIV-1-2 and XPert® HIV-1 Qual. Viral load was quantified using Xpert® HIV-1 Viral Load (cut off 200 cells/mm³). All measures were adjusted for RDS sampling (RDS-II).

Results: 186/618 participants were HIV positive (28.7%[21.4-37.3]). In total 139 (71.3%[62.7-78.6]) were aware of their status, 116 (59.5%[50.7-67.7]) were on ART and 102 (51.7%[43.0-60.2]) had a viral load < 200 copies/ml. In relation to 90-90-90 targets, these data represent 71-83-83. Among men aware of their diagnosis, 118/129 (94.9%[88.7-97.8]) reported linkage to a care provider within 3 months of diagnosis and 76/111 (65.8%[54.3-75.8]) started ART within two weeks of diagnosis. 121/127 (94.9%[88.1-97.9]) reported attending clinical HIV services in the last year (public clinic (37.0%); private clinic (21.5%); MSM-specific services (41.2%)).

The geometric mean PVL among HIV positive MSM was 826[409-1668] copies/ml. The proportion of HIV positive MSM with viral loads >50,000 copies/ml was 21.0%[14.9-28.7] or 5.5%[3.9-7.9] of the MSM population as a whole.

Conclusions: These first population-based estimates of the care cascade and PVL among MSM in Kenya are highly encouraging. Engagement in care is remarkably high and compares favourably to continuum estimates among MSM in other settings and to the general adult population in Kenya. HIV diagnosis represents the weakest link in the current continuum of care for MSM in Nairobi, and approaches to increase testing access and uptake should be prioritised.



[HIV diagnosis, care and treatment engagement among MSM in Nairobi, Kenya (2017)]

THPEC210

Characterizing the prevalence and determinants of newly HIV diagnosed female sex workers in urban centers across Cameroon

A.L. Bowring[1], S. Ketende[1], I.N. Mfochive[1,2], A. Rao[1], G. Fako[2], U. Tamoufe[2], C. Lyons[1], G. Turpin[1], M. Decker[3], G. Fouda[4], F. Ndonko[4], D. Levitt[5], A. Bissek[6], O. Njoya[7], S.C. Billong[8], S. Baral[1]

[1]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Metabiota, Yaounde, Cameroon, [3]Johns Hopkins Bloomberg School of Public Health, Department of Population, Family, and Reproductive Health, Baltimore, United States, [4]CARE Cameroon, Yaounde, Cameroon, [5]CARE USA, New York, United States, [6]Ministry of Health, Department of Operational Research, Yaounde, Cameroon, [7]Yaounde University Hospital Centre, Department of Internal Medicine, Yaounde, Cameroon, [8]Groupe Technique Central (CNLS), Yaounde, Cameroon

Background: Female sex workers (FSW) are disproportionately affected by HIV in Cameroon with an estimated HIV prevalence of 23.6%. Although HIV incidence data are unavailable, here we assess the prevalence and determinants of new HIV diagnoses among FSW in Cameroon.

Methods: In 2016, FSW (sex work principal source of income in past year) were recruited through respondent-driven sampling for a bio-behavioural survey carried out in five urban centers in Cameroon. New diagnoses were defined as testing HIV positive when participant reported HIV-negative or unknown status; participants self-reporting to be living with HIV or with indeterminate test status were excluded from these analyses. A multivariable Poisson regression model was developed to assess determinants of new HIV infection using *a priori* determined individual, network and structural covariates, with manual backwards elimination and controlling for clustering by study site; adjusted prevalence ratios (aPR) are reported if significant(p< 0.05).

Results: Overall 2,255 FSW were recruited. Excluding participants who self-reported HIV positive (n=297) and indeterminate (n=7) test results, prevalence of newly diagnosed HIV was 13.3% (260/1,951).

Variables significantly associated with new HIV diagnosis were: older age (aPR: 1.05, 95%CI: 1.04-1.07); primary school education or less (aPR: 1.51; 95%CI: 1.07-2.14); sex with clients at brothels (aPR: 1.52, 95%CI: 1.10-2.11); unprotected sex with regular non-paying partners (aPR: 1.75, 95%CI: 1.17-2.60); knows safest lubricant is water-based (aPR: 1.52, 95%CI: 1.08-2.13); no HIV test in previous year (aPR: 1.58, 95%CI: 1.10-2.27); experienced STI symptoms in past year (aPR: 1.65, 95%CI: 1.19-2.29); and low social participation (aPR: 1.59, 95%CI: 1.11-2.28).

Conclusions: In the absence of HIV incidence data, these results provide insights into ongoing HIV acquisition risks among FSW across Cameroon. These data specifically suggest the need to understand HIV acquisition risks from non-paying partners, build social capital, and better integrate services such as PrEP and STI services into HIV programs to prevent new HIV infections.

Hidden epidemic in Akwa Ibom State: Findings from the first AIDS Indicator Survey (AIS) in Nigeria

T. Badru[1], C. Agbakwuru[1], O. Negedu-Momoh[1], E. Oladele[1], A. Chen-Carrington[2], E. James[2], P. Essiet[3], S. Raj Pandey[1], H. Khamofu[1]

[1]Family Health International (FHI 360), Abuja, Nigeria, [2]United States Agency for International Development (USAID), Abuja, Nigeria, [3]Akwa Ibom State Ministry of Health, Uyo, Nigeria

Background: HIV testing remains the gateway to achieving the ambitious UNAIDS 90-90-90 target. Undiagnosed HIV-infected individuals are more likely to transmit infection to others. We analyzed the prevalence of undiagnosed HIV and its correlates in Nigeria.

Methods: Akwa Ibom AIDS Indicator Survey (AKAIS), a USAID-funded population-based cross-sectional survey, was conducted between April and June, 2017. The survey was a collaborative effort between Akwa Ibom state government and USAID implementing partner FHI 360. Households were selected and household members were consented/enrolled through a two-stage probability sampling technique. A total of 15,609 eligible participants including children and adults were sampled. Tablet-based questionnaires were administered through face-to-face interviews. Participants were questioned about socio-demographics, history of HIV testing, and sexual behavior. Participants self-reported their sero-status. Consenting participants were tested for HIV according to national algorithm and confirmed with Bio-Rad Geenius HIV 1/2 Con-

firmatory Assay. Multivariable logistic regression analyses were done using Stata version 12 to assess correlates of undiagnosed HIV infection amongst adult participants who tested positive.

Results: A total of 8,963 adults aged 15 years and older participated in the study; 4,932 (55%) were females, median age was 34 years(IQR; 23-49), 4,223 (47%) had secondary education and 4,173 (47%) were married. Of the 8,306 (93%) participants who agreed to HIV testing, 394 (4.8%) were positive. 332 of those (84%) were undiagnosed prior to the survey, i.e. unaware of their HIV status. Correlates of undiagnosed HIV were being male (aOR 6.47, 95% CI 2.62-15.96), rural dweller (aOR 3.37, 1.63-6.96), never married compared to currently married (aOR 6.73, 95% CI (2.13 -21.28), having one partner compared to two or more partners (aOR 3.80, 95% CI 1.75 -8.25) and expressing a discriminatory attitude toward PLHIV (aOR 3.14, 95% CI 1.50-6.59).

Conclusions: This study demonstrates a substantial burden of undiagnosed HIV infection among males and adult rural dwellers. Findings underscore the importance of targeted community-based testing strategies in order to meet the UNAIDS target of diagnosing 90% of those living with HIV by 2020.

THPEC212

Knowledge of HIV-positive status among adult people living with HIV (PLHIV) in Swaziland: A population-based survey

M. Pasipamire[1], T.T. Ao[2], S. Mazibuko[2], F. Mhlanga[3], L. Dube[1], Z. Mnisi[4], H. Nuwagaba-Biribonwoha[5], C. Draghi[6], N.M. Philip[5], K. Brown[6]

[1]Ministry of Health, Swaziland National AIDS Programme, Mbabane, Swaziland, [2]Division of Global HIV and TB, Center for Global Health, CDC Swaziland, Mbabane, Swaziland, [3]Central Statistics Office, Government of the Kingdom of Swaziland, Mbabane, Swaziland, [4]Ministry of Health, Government of the Kingdom of Swaziland, Mbabane, Swaziland, [5]ICAP-Columbia University, New York, United States, [6]Division of Global HIV and TB, Centre for Global Health, CDC, Atlanta, United States

Background: HIV testing is the entry point to HIV prevention and treatment. The Joint United Nations Programme on HIV/AIDS set the 90-90-90 targets with the first-90 expecting 90% of PLHIV to know their status by 2020. Swaziland has 220,000 PLHIV but lacks a population-based first-90 estimate. Therefore, we used the 2016-17 Swaziland HIV Incidence Measurement Survey2 (SHIMS2) to describe and determine factors associated with knowledge of HIV-positive status (awareness/aware).

Methods: Completed in 2017, SHIMS2 was a cross-sectional, nationally representative, and population-based, two-stage randomized cluster-sampled household survey. Interviews and rapid HIV testing were conducted on adults aged ≥15 years. Using weighted Jackknife survey data in Stata 14, frequencies, weighted proportions, Chi-square and logistic regression analyses were conducted. Potential factors were analyzed in two blocks, namely socio-demographic and behavioral. Adjusted odds ratios (aORs) with 95% confidence intervals (CI) were reported.

Results: Of the 13,339 adults, 10,934 (81.97%) responded to the HIV-testing questionnaire, with 2,031 (32.51%) females and 972 (20.39%) males confirmed HIV sero-positive. Among those confirmed, 1,811 (88.56%) females and 776 (77.46%) males knew their HIV-positive status (p-value(p)< 0.001).

Awareness was less likely among those reporting no condom usage compared to those who used condoms at last sexual encounter within the preceding year in both females (aOR=0.48 (95% CI:[0.34-0.67]),p< 0.001) and males (aOR=0.33 [0.22-0.50],p< 0.001). Awareness was more likely in females (aOR=5.26 [2.75-10.05],p< 0.001) and males (aOR=2.65 [1.58-4.44],p< 0.001) reporting previous tuberculosis-clinic visits compared to those reporting no previous visits. Among females, awareness was more likely in those aged 25-49 years compared to those 15-24 (aOR=2.23 [1.53-3.26],p< 0.001), and those reporting previous antenatal-clinic visit (aOR=1.76 [1.20-2.58], p=0.004) compared to those reporting no previous visits. Awareness increased with increasing number of pregnancies (see Table). Among males, awareness was more likely among those aged 25-49 (aOR=2.16 [1.19-3.91], p=0.012) and 50+ (aOR=3.88 [1.75-8.57], p=0.001), compared to those aged 15-24 years. Awareness was more likely among married (aOR=2.09 [1.38-3.16], p=0.001) and divorced (aOR=2.32 [1.26-4.26], p=0.007) men compared to never married men.

[Table: Multivariate analysis of factors affecting awareness of HIV positive status among adults aged 15+]

Conclusions: In Swaziland, females are close to reaching the first-90 whilst males are >10% behind. Providing male-friendly, male-targeted services may unlock more testing opportunities required to bridge this gap.

THPEC213

Prevalence and correlates of active syphilis and HIV co-Infection among persons aged 15 - 59 in Zambia: Results from the Zambia population-based HIV impact assessment (ZAMPHIA) 2016

H. Solomon[1,2], A. Moraes[1,3], D.B. Williams[4], A.S. Fotso[5,6], C.B. Ndongmo[7], L. Mulenga[1,8,9], ZAMPHIA Project Team

[1]Ministry of Health Zambia, Lusaka, Zambia, [2]National Health Research Authority, Lusaka, Zambia, [3]Zambia National Public Health Institute, Lusaka, Zambia, [4]Centers for Disease Control and Prevention, Atlanta, United States, [5]ICAP at Columbia University, New York, United States, [6]DPS University of the Witwatersrand, Johannesburg, South Africa, [7]Centers for Disease Control and Prevention, Lusaka, Zambia, [8]University Teaching Hospital, Lusaka, Zambia, [9]University of Zambia, School of Medicine, Lusaka, Zambia

Background: Prior studies have suggested sexually transmitted infections, such as syphilis, are associated with an increased risk of transmission of the HIV virus. However, no study has measured the population-level prevalence and predictors of co-infection in Zambia.

Methods: We use data from the 2016 ZAMPHIA, a national household survey that included the DPP® Syphilis Screen & Confirm Assay (Chembio) for active syphilis and Alere Determine™ and Uni-Gold™ rapid HIV tests, per national algorithm. Bivariate and multivariate logistic regression models were developed to assess associations between co-infection and selected socio-demographic and sexual behavior variables.

For the multivariate analysis, those infected with both active syphilis and HIV were classified as co-infected, and the comparison group is those who had no infection.

Due to the complex survey design, all reported figures account for the survey design and are weighted.

Results: A total of 19,114 individuals aged 15-59 responded to the individual interview and had a valid syphilis and HIV test. Among this sample were 10, 972 females and 8, 142 males. The national prevalence of active syphilis was 3.0%. Prevalence of active syphilis was highest among females (3.4%), those ≥25 years of age (3.9%), and respondents who reported ≥2 sexual partners in the last 12 months (5.3%). Sexually active HIV-positive persons had a higher prevalence of active syphilis compared to those who were HIV-negative (9.6% vs. 2.1%). The national prevalence of HIV/syphilis co-infection was 1.3% (95% CI 1.1, 1.5).

Co-infection was higher among females living in urban areas (aOR =3.1, 95% CI=1.9, 5.0) and females who had an early sexual debut (before age 15 years) (aOR =1.7, 95% CI=1.0, 3.0). Co-infection was also high among both men and women who engaged in transactional sex in the past 12 months (aOR=2.3 (95% CI= 1.1, 5.2) and 4.1 (95% CI= 1.7, 9.8), respectively).

Author Index

Conclusions: These findings show high prevalence of HIV/syphilis co-infection in Zambia and the need for the scale up of syphilis screening and treatment, particularly among HIV-infected adults. Additionally, these results can be used by syphilis and HIV prevention programs to target populations most at risk for co-infection, specifically those engaging in transactional sex.

Variable	Category	% Active Syphilis Infection		% Active Syphilis and HIV coinfection		Males	Females

Prevalence and factors associated with HIV infection among pregnant women attending ANC in Tanzania Mainland: Results from a National ANC Sentinel Surveillance 2017

J. Mushi[1], G. Somi[1], A. Ramadhani[1], B. Jullu[2], A. Sabasaba[3], K. Mukurasi[4], B. Jani[5], E. Mwendo[6], G. Mgomella[7]
[1]Ministry of Health, Community Development, Gender, Elderly and Children, National AIDS Control Program, Dar es Salaam, Tanzania, United Republic of, [2]Saint Francis University College of Health and Allied Sciences, Microbiology, Morogoro, Tanzania, United Republic of, [3]Muhimbili University of Health and Allied Sciences, Epidemiology and Biostatistics, Dar es Salaam, Tanzania, United Republic of, [4]Muhimbili University of Health and Allied Sciences, Field Epidemiology, Dar es Salaam, Tanzania, United Republic of, [5]WHO, HIV, Dar es Salaam, Tanzania, United Republic of, [6]Zanzibar Intergated HIV,TB and Leprosy Program, Strategic Information, Zanzibar, Tanzania, United Republic of, [7]CDC, Surveillance, Dar es Salaam, Tanzania, United Republic of

Background: Globally, HIV and AIDS still a major public health problem. In Tanzania, it is estimated that 1.4 million people are living with HIV. Prevalence among pregnant women aged 15-49 years is 6.2%. This is above the National prevalence of 4.7%. Antenatal screening for HIV is important for early diagnosis as it is routinely offered to all pregnant women attending ANC. This study aimed at determining the prevalence of HIV infection and associated factors among pregnant women attending ANC in Tanzania mainland following a National survey in 2017.

Methods: A cross-sectional survey was conducted in all 26 regions in Tanzania mainland. Both urban, semi-urban and rural sites were included. All eligible and consented pregnant women were tested using National HIV testing algorithm. Data were analyzed using STATA. Logistic regression technique was used to establish factors associated with HIV infection.

Results: A total of 34,935 attendees were enrolled in the survey. HIV prevalence was found to be 6.1% (95% CI: 5.9-6.1). After adjustment for other covariates; increasing age, marital status and total number of previous pregnancies were found to have association with increased odds of HIV infection. Compared to women aged 15-19 years, those aged 20-24, 25-34 and 35-49 had aOR=1.90, (95%CI; 1.54-2.36), aOR=4.00 (95% CI; 3.21-4.97), aOR=5.89 95%CI; 4.59-7.56) higher odds of HIV infection respectively. Divorced/separated and widow women had nearly two times increased odds of HIV infection compared to married/cohabiting women (aOR1.58,95% CI;1.05-2.36) and (aOR1.90, 95% CI 1.12-3.22) respectively. Women with 3-4 previous pregnancies were at risk by 2.53 more-times of having HIV compared to those with zero pregnant history (aOR: 2.53 ;95% CI: 2.17-2.95). Increase in education level was associated with decreased odds of HIV infection; women who attained secondary and post-secondary education had 44% and 65% lower odds of HIV infection compared to those with no formal education (aOR: 0.56; 95% CI: 0.46-0.68) *and aOR* 0.35; 95% CI: 0.22-0.56).

Conclusions: HIV prevalence among pregnant women is still high in Tanzania. To achieve the goal of eliminating HIV, effective combination prevention strategies should be used with special emphasis on above risk factors.

Measuring the population impact of prevention and treatment interventions

THPEC215

Prevalence and correlates of PrEP awareness and use among Black bisexual men in the United States

M.R. Friedman[1], D. Matthews[2], J. Egan[3], C. Chandler[2], L. Eaton[4], L. Bukowski[2], H.F. Raymond[5], R. Stall[3]
[1]University of Pittsburgh, Infectious Diseases and Microbiology, Pittsburgh, United States, [2]University of Pittsburgh, Pittsburgh, United States, [3]University of Pittsburgh, Department of Behavioral and Community Health Sciences, Pittsburgh, United States, [4]University of Connecticut, Hartford, United States, [5]Rutgers University, Piscataway, United States

Background: In the United States, Black men who have sex with men (MSM) have the highest incidence and prevalence rates of HIV infection. Though men who have sex with men and women (MSMW) have been shown to experience lower HIV prevalence rates than men who have sex with men only (MSMO), they experience higher rates than the general male population. Pre-exposure prophylaxis (PrEP) is an efficacious tool to prevent HIV infection, but utilization among Black MSM remains low. Limited research exists on prevalence and correlates of PrEP awareness and use among Black MSMW.

Methods: We used time-location sampling to recruit Black MSM ≥ 18 years old attending Black Gay Pride events in six U.S. cities between 2014—2017. We conducted multivariable logistic regressions to assess correlates of self-reported PrEP awareness and utilization among serologically confirmed HIV-negative Black MSM (n=2398). Within-group analyses assessed predictors of PrEP awareness and current use among past-year MSMW (n=419). Analyses adjusted for year, city, Hispanic/Latino ethnicity, age, and income.

Results: Black MSMW were significantly less likely than Black MSMO to report being aware of PrEP (46.3% vs. 55.2%; aOR=0.74; 95% CI: 0.59, 0.92). However, among PrEP-aware Black MSM (n=1278), MSMW were significantly more likely than MSMO (20.8% vs. 13.6%) to report currently using PrEP (aOR=1.67; 95% CI: 1.12, 2.48). Within Black MSMW, those reporting any past-year sexually transmitted infection (STI) diagnosis (aOR=1.94; 95% CI: 1.16, 3.24) were more likely to be PrEP-aware, as were those who reported social support from the gay community (aOR=2.07; 95% CI: 1.25, 3.42). MSMW reporting any past-year STI diagnosis were significantly more likely to report current PrEP use (aOR=7.44; 95% CI: 3.50, 15.83), as were MSMW who reported three or more past-year STI diagnoses (aOR=10.57; 95% CI: 4.07, 27.50).

Outcome	Sub-sample	Main predictor	aOR (95% CI)
PrEP-aware	HIV-negative Black MSM (n=2398)	MSMW	0.74 (0.59, 0.92)
	HIV-negative Black MSMW (n=419)	Past-year STI diagnosis	1.94 (3.50, 15.83)
	HIV-negative Black MSMW (n=419)	Any gay community support	2.07 (1.25, 3.42)
Current PrEP use	HIV-negative, PrEP-aware Black MSM (n=1278)	MSMW	1.67 (1.12, 2.48)
	HIV-negative Black MSMW (n=419)	Past-year STI diagnosis	7.44 (3.50, 15.83)

[Predictors of PrEP awareness and use among Black MSMW: multivariable logistic regressions]

Conclusions: Low rates of PrEP awareness and utilization among Black MSM persist in the U.S., including among Black MSMW. Our data show that, if aware of PrEP, Black MSMW may be even more likely than other Black MSM to use it. PrEP awareness and linkage campaigns tailored for Black bisexual men, in conjunction with practitioner-based STI-to-PrEP interventions, will likely increase PrEP utilization in this group.

THPEC216

Impact of Option B+ and maternal HIV RNA viral load on mother-to-child HIV transmission: Findings from an 18-month prospective cohort of a nationally representative sample of mother-infant pairs, Zimbabwe 2016-2017

T.-H. Dinh[1], A. Mushavi[2], S. Balachandra[3], R.W. Shiraishi[1], J. Nyakura[4], E. Munemo[5], G. Shambira[4], O. Mugurungi[2], B. Tippett Barr[3], ZIM-PMTCTE Survey Team

[1]US Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV/TB, Atlanta, United States, [2]Ministry of Health & Child Care of Zimbabwe, AIDS & TB Department, Harare, Zimbabwe, [3]U.S. Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV/TB, Harare, Zimbabwe, [4]University of Zimbabwe, Department of Community Health, Harare, Zimbabwe, [5]National Microbiology Reference Laboratory of Zimbabwe, Harare, Zimbabwe

Background: Zimbabwe began implementing Option B+ nationwide in 2015, having achieved an 18-month cumulative mother-to-child HIV transmission (MTCT) risk of 7.0% in 2014 under Option A. We assessed the population level impact of Option B-plus and maternal viral load (VL) suppression (VLS, defined as < 1,000 copies/mL) on the cumulative MTCT risk during pregnancy and through 18 months post-delivery.

Methods: From February to May 2016, using a multistage stratified cluster sampling method, we consecutively recruited a nationally representative sample of 8,570 pairs of mothers and infants aged 4-12 weeks, from 151 immunization clinics. Of those, we identified 1,978 pairs with HIV-infected mothers using HIV-rapid tests or documented ART prescriptions at enrollment. We evaluated these pairs at baseline, and every three months until the child became HIV-infected, died, or reached age 18 months. Maternal VL was measured at 4-12 weeks, and 12 months post-delivery. We defined a mother with a durable VLS status if she had VLS at both time points. Findings were adjusted for study design and non-responses.

Results: Nationally, the observed 18-month cumulative MTCT risk was 3.3%, including 1.7% perinatal MTCT. Overall, 52.1% (95% Confidence Interval (CI): 49.0-55.2) of HIV-infected mothers initiated ART pre-conception, and another 44.9% (CI: 41.9-47.8) initiated during pregnancy. The population level VLS was 81.2% (CI: 79.4-83.1) and 85.2% (CI: 82.9-87.4) measured at 4-12 weeks and 12 months post-delivery, respectively, including 49.9% (CI: 46.1-52.8) of the mothers with a durable VLS status. Mothers with durable VLS status had an 18-month cumulative MTCT risk of 0.1%, a seven-fold decrease compared to the risk among mothers without durable VLS (0.7%). Of mothers with VLS at baseline, the perinatal MTCT risk was 0.3% (CI: 0.0-0.7) among mothers starting ART during pregnancy and 0.0% (CI: 0.0-0.3) in mothers starting ART pre-conception.

Conclusions: After one year of implementing Option B+ nationwide, Zimbabwe reduced the cumulative 18-month MTCT risk from 7.0% to 3.3%. Eliminating MTCT to zero may be feasible through the prioritization of ART for HIV-infected women planning to become pregnant coupled with intensified VL monitoring and ART adherence support during pregnancy and breastfeeding could increase the proportion of mothers with a durable VLS status.

THPEC217

Population-level effectiveness of anteritroviral therapy (ART) to prevent early mother to child transmission of HIV in Namibia

A. Agabu[1], A.L. Baughman[1], C. Fischer-Walker[1], M. De Klerk[1], N. Mutenda[2], F. Rusberg[2], D. Diergaardt[2], N. Pentikainen[3], S. Sawadogo[1], S. Agolory[1], T.-H. Dinh[4]

[1]US Centers for Disease Control & Prevention, Division of Global HIV/TB, Windhoek, Namibia, [2]Namibia Ministry of Health and Social Services, Windhoek, Namibia, [3]Namibia Institute of Pathology, Windhoek, Namibia, [4]US Centers for Disease Control and Prevention, Division of Global HIV/TB, Atlanta, United States

Background: Namibia introduced the prevention of mother to child HIV transmission (MTCT) program in 2002 and lifelong antiretroviral therapy (ART) for pregnant women (option B-plus) in 2013. We sought to quantify MTCT measured at 4-12 weeks post-delivery.

Methods: During Aug 2014-Feb 2015, using two stage sampling approach we recruited a nationally representative sample of 1040 pairs of mother and infant aged 4-12 weeks at routine immunizations in 60 public health clinics. Of these, 864 HIV exposed infants (HEI) had HIV test results available. We defined an HEI if born to an HIV-positive mother with documented status, or diagnosed at enrollment using rapid HIV tests. Dried Blood Spots samples from HEIs were tested for HIV. Interview data and laboratory results were collected on smartphones and uploaded to a central database. We measured MTCT risk at 4-12 weeks post-delivery and evaluated associations between infant HIV infection and maternal and infant characteristics including maternal treatment and infant prophylaxis. All statistical analyses accounted for the survey design.

Results: Nationally weighted early MTCT was 1.74% (95% CI: 1.00%-3.01%). Overall, 62% of mothers started ART before pregnancy, 33.6% during pregnancy, 1.2% post-delivery and 3.2% never received ART. Mothers who started ART before pregnancy and during pregnancy had low MTCT risk, 0.78% (95% CI: 0.31%-1.96%) and 0.98% (95% CI: 0.33%-2.91%), respectively. MTCT rose to 4.13% (95% CI: 0.54%-25.68%) when the mother initiated ART after delivery and 11.62% (95% CI: 4.07%-28.96%) when she never received ART. The lowest MTCT of 0.76% (95% CI: 0.36% - 1.61%) was achieved when mother received ART and ARV prophylaxis for infant and highest 22.32% (95%CI: 2.78% -74.25%) when neither mother nor infant received ARVs (RR=29.2, 95% CI: 4.47 - 190.7; p< 0.01). After adjusting for mother's age, no maternal ART (RR=10.2, p< 0.01) and no infant ARV prophylaxis (RR=3.24, p=0.05) remained strong predictors of HIV transmission.

Conclusions: As of 2015, Namibia achieved MTCT of 1.74%, measured at 4-12 weeks post-delivery. Women already on ART pre-conception had the lowest risk of MTCT emphasizing the importance of early HIV diagnosis and treatment initiation before pregnancy. Studies are needed to measure MTCT and maternal HIV seroconversion during breastfeeding.

THPEC218

Effectiveness of interventions for changing HIV related risk behaviours among key populations in low-income setting: A meta-analysis, 2001-2016

K. Deuba[1], U. Shrestha[1], B. Rawal[2], R. Khanal[1], R. Shrestha[3], B.D. Pandey[2], R.K. Bhattarai[4], A.M. Ekstrom[5]

[1]National Centre for AIDS and STD Control/ Global Fund Programs, Kathmandu, Nepal, [2]National Centre for AIDS and STD Control, Ministry of Health, Kathmandu, Nepal, [3]Public Health and Environment Research Centre, Lalitpur, Nepal, [4]Save the Children, Kathmandu, Nepal, [5]Karolinska Institutet, Department of Public Health Sciences, Stockholm, Sweden

Background: Lack of evaluation of interventions presents a hurdle in identifying what works best for reducing the HIV incidence in low-income countries. The aim is to conduct a meta-analysis to assess the effectiveness of behavioural interventions in reducing HIV related risk behaviours among key populations [people who inject drugs (PWID), female sex workers (FSW), men who have sex with men (MSM) and transgender (TG)] of Nepal.

Methods: Systematic searching of literature focusing on peer education interventions and HIV testing and counselling (HTC) services in Nepal was done using different electronic databases. Search was restricted to

the interventions (peer education in both formal and informal setting and HTC) targeted for FSW, PWID, MSM and TG and literature published from January 2001 to December 2016 from Nepal. We used random-effects models to calculate the pooled odds ratio (OR) for dichotomous outcomes (condom use in last sex or unsafe injection practices) including pooled HIV prevalence, subgroup analyses of age groups (aged 15-24 vs ≥25) and epidemic zones.

Results: Forty-three studies with 13,021 participants were included (PWID: 5180; MSM and TG: 2279; FSW: 5562). Pooled prevalence showed a higher occurrence of HIV among PWID (12%) followed by other key populations (< 5%). A significant increase in the odds of condom use among FSW (pooled OR=2.21, 95% confidence interval (CI): 1.65-2.95), MSM and TG (pooled OR=2.24, 95% CI: 1.77-2.83) who received peer education interventions in both informal and formal setting compared to who did not. Similarly, there was a significant increase in the odds of condom use among FSW, MSM and TG who received HTC compared to those who did not. However, none of these interventions were found to be effective in reducing unsafe injection practices among PWID. Subgroup analyses also proved the effectiveness of these interventions for both young and old FSW, MSM and TG and across all three epidemic zones.

Conclusions: Interventions being carried out in Nepal are effective at reducing risky behaviours among FSW, MSM and TG except for PWID. This demands continued implementation of existing efforts as well as modifying interventions modality as per the need of PWID to reduce their risky injection behaviours.

Couple Oriented Counselling improves male partner involvement in sexual and reproductive health of the couple: Evidence from the ANRS 12127/12236 PRENAHTEST Cohort in Cameroon

C. Kengne Nde[1,2,3], M.C. Tejiokem[1,4], J. Orne-Gliemann[5], B. Melingui[6], P. Koki Ndombo[7], A. Ngo Essounga[8], A.C. Bissek[9], S. Cauchemez[3,4], P. Tchendjou Tankam[1,4]
[1]*Centre Pasteur Cameroon, Epidemiology and Public Health Service, Member of the International Network of Pasteur Institutes, Yaounde, Cameroon,* [2]*Bordeaux School of Public Health, Bordeaux University, Bordeaux, France,* [3]*Mathematical Modeling of Infectious Diseases Unit, Pasteur Institute, Paris, France,* [4]*International Network of Pasteur Institutes, Paris, France,* [5]*INSERM U 897, Bordeaux School of Public Health, Bordeaux University, Bordeaux, France,* [6]*Centre Pasteur Cameroon, Hematology Laboratory, Yaounde, Cameroon,* [7]*Centre of Mother and Child, Chantal Biya Foundation, Yaounde, Cameroon,* [8]*Ministry of Scientific Research and Innovation, Yaounde, Cameroon,* [9]*Division of Operational Research, Ministry of Public Health, Yaounde, Cameroon*

Background: Male partner involvement (MPI) has been recognized as a priority area to be strengthened in prevention of Mother to Child Transmission (PMTCT) of HIV. Here, we explored the impact of Couple Oriented Counseling (COC) in MPI in sexual and reproductive health and associated factors.

Methods: From February 2009 to October 2011, pregnant women were enrolled at their first antenatal care visit (ANC-1) and followed up until 6 months after delivery in the Mother and Child Center of the Chantal Biya Foundation within the Prenahtest multicentric project (Figure 1A). MPI, a composite variable was defined using sexual and reproductive health behaviors variables by multiple correspondence analysis followed by mixed classification. Men were considered highly involved if they had shared their HIV test results with their partner, discussed on HIV or condom used, contributed financially to ANC, accompanied their wife to ANC or practiced safe sex. Factors associated to MPI were investigated by the logistic model with GEE estimation approach.

Results: A total of 484 pregnant women were enrolled at a median age of 27 years (IQR: 23-31). Among them, HIV prevalence was 11.9% (95% CI: 9.0 - 15.4), 55.23% had a gestational age greater than 16 weeks at ANC-1. The median duration of the women relationship with partner was 84 months (IQR: 48-120). MPI was significantly greater in COC group than SC group 6 months after delivery (14.8% vs 8,82%; p = 0,043; Figure 1B). The partners of the women who participated to COC were more likely to be involved during follow up (aOR = 1.45; 95% CI = 1.00 - 2.10) than others. Partners with no incoming activity (aOR = 2.90; 95% CI = 1.96 - 4.29), who did not used violence within the couple (aOR = 1.70; 95% CI = 1.07 - 2.68), and whose partner came early for ANC-1 (aOR = 1.37; 95% CI = 1.00 - 1.89) were more likely to be involved than others.

Conclusions: MPI remains low in stable couples and COC improves partner involvement. Our results also confirm that strengthening outreach towards „stable" couples and address barriers could go a long way to improve PMTCT in Cameroon.

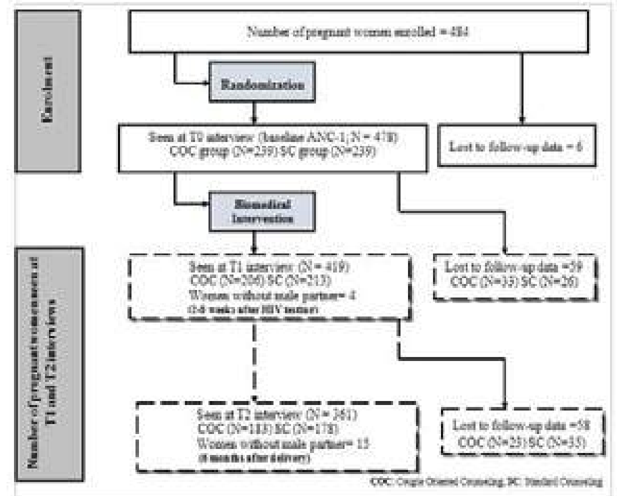

Figure1A: Flowchart describing enrolment and follow-up within the cohort of pregnant women in Yaounde, Cameroon. ANRS 12127-12236 Prenahtest Trial (2009-2011).

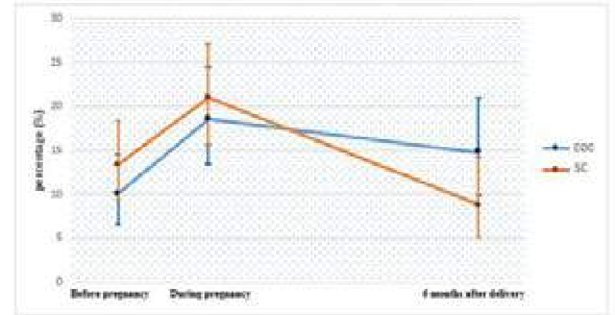

Figure 1B: Evolution of the proportion (%) of high involvement of male partner in sexual and reproductive health of the couple among pregnant women cohort, in Yaounde, Cameroon, ANRS 12127-12236 Prenahtest Trial (2009-2011) (N=478).

THPEC220

Application of goal 90-90-90 (ONU / UNAIDS) in an infectious-contagious disease hospital for adult patients in Belo Horizonte, Brazil

E. Barbosa Silva[1], R. Andrade Carmo[2], R. Cassia Santana do Amaral[3]
[1]*Hospital Eduardo de Menezes, Hospital-dia, Belo Horizonte, Brazil,* [2]*UFMG, DIP, BELO HORIZONTE, Brazil,* [3]*Medical specialization in medical practice, BELO HORIZONTE, Brazil*

Background: This survey is premised on the ambitious 90-90-90 goal launched by the ONU/UNAIDS and its member countries to overcome the AIDS epidemic by 2030. It consists of 90% of patients diagnosed, 90% in treatment and 90% with viral suppression by the year 2020. In the period from July 2016 to July 2017, all patients diagnosed with HIV / AIDS at Eduardo de Menezes / FHEMIG Hospital, a state reference in infectious-contagious diseases for adult patients were analysed.

Methods: The parameters gender, onset of ART and viral suppression (viral load below 50 copies / mm^3) were evaluated. Data were obtained through compulsory HIV / AIDS notifications from the HEM Epidemiology Center, the Laboratory Testing System of the National Network for CD4 + / CD8 + Lymphocyte Count and HIV Viral Load (SISCEL) and the National Service System Physician (SINAM).

Results: We evaluated 424 patients (through serology Elisa method and rapid testing), 78,5% of the patients were male and 21,5 % were female. The onset of HAART occurred in 100% of patients and the viral suppression rate was 84,4%. It is worth mentioning that, in Brazil, the initial HAART regimen is composed of a non-combined triple of drugs, one integrase inhibitor associated with 2 NNRTIs.
Conclusions: Among the patients diagnosed with HIV / AIDS, we noticed that the target of 90% in treatment was successfully achieved. A 90% with viral suppression was close to being achieved. Decreasing the number of pills would be important to reach this goa One way to help reach 90% of diagnosed patients would be easy access to the self-test (CROI / 2017), made available in Brazil from July 2017, when this survey had already ended. However, it is well known that most seropositive patients adhere to treatment in the first few years after diagnosis, but maintaining adherence is somewhat challenging. According to national studies, at least 1/3 will drop out of treatment at some point. In view of this, preventive and facilitative educational strategies are necessary for the end of the epidemic to take place in Brazil.

THPEC221

Closing the third 90 gap: Viral suppression in adults 15 years and older in Swaziland

S. Mazibuko[1], C. Draghi[2], T. Ao[2], Z. Mnisi[3], H. Nuwagaba-Biribonwoha[4], C. Ginindza[5], N. Philip[6], H. Patel[2], F. Ogollah[2], K. Sleeman[2], R. Sahabo[4], A. Voestsch[2], J. Justman[6], C. Ryan[7]
[1]CDC Swaziland, Care and Treatment, Mbabane, Swaziland, [2]Centers for Disease Control and Prevention, Atlanta, United States, [3]Ministry of Health, Government of the Kingdom of Swaziland, Mbabane, Swaziland, [4]ICAP at Columbia University, Mailman School of Public Health, Mbabane, Swaziland, [5]Central Statistical Office, Government of the Kingdom of Swaziland, Mbabane, Swaziland, [6]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [7]Centers for Disease Control and Prevention, Mbabane, Swaziland

Background: Viral load suppression (VLS) indicates the effectiveness of national HIV treatment programs. The Swaziland HIV Incidence Measurement Survey (SHIMS2, 2016) shows that Swaziland has achieved the third 90 target set by the United Nations Joint Programme on HIV/AISDS (UNAIDS). However, program data suggests that the third 90 has not been achieved for all sub-populations. We assessed correlates of VLS among HIV+ participants 15+ to identify remaining unsuppressed sub-populations.
Methods: SHIMS2 used a two-stage cluster randomized design to attain a nationally representative sample. The national testing algorithm was used to determine HIV status and VLS was defined as HIV RNA < 1000 copies/ml. Prevalence of VLS among HIV+ persons was calculated using weighted analyses to account for complex survey design. Logistic regression was conducted using Jackknife variance methods.
Results: Seventy-two (72%) of all PLHIV were virally suppressed. Among 15,628 surveyed adults, 10,934 agreed to HIV testing, of which 3,003 (27%, 95% Confidence Interval (CI):25.7, 28.3) were HIV+, of these 65.5% were female and the median age was 37 years (Interquartile range (IQR): 30-47). A majority (87.4%, CI: 85.8-89.1) reported current ART use. Among those reporting ART use: VLS among those who had never married (87.5%, 95% CI: 84.6-90.4) was significantly lower compared to ever married (93.9%, CI: 92.7-95.2, p<.001). PLHIV were progressively more likely to be VLS with increasing age; compared to 15-24 year olds odds ratio [OR]=2.9 p<0.001 for 25-34 years, OR=4.4, p<.001 for 35-44 years and OR=8.3, p<.001). No significant difference in VLS by sex, region or education was observed. In multivariate modelling, controlling for sex and marital status, older participants still had higher odds of being VLS compared to 15-24 year olds, adjusted odds ratio [aOR]=2.3, p=0.003 for 25-34 years; aOR=3.5, p<.001 for 35-44 years and aOR=6.7, p<.001 for 45+ years.
Conclusions: Young PLHIV have lower odds of having VLS compared to older age groups. Though many factors influence VLS, including ART adherence, age is the most significant. It is critical that programs understand the needs of 15-24 year olds in order to close the gap in VLS, since this population will expand as the youth bulge ages.

THPEC222

Antiretroviral therapy uptake among adults 15 years and older in Swaziland, 2016

S. Mazibuko[1], T. Ao[1], C. Draghi[2], Z. Mnisi[3], C. Ginindza<sup, J. Justman[4], H. Nuwagaba-Biribonwoha[5], H. Patel[2], S. Saito[2,2], Y. Pottinger[2], N. Philip[4], K. Brown[2], K. Brown[2], R. Sahabo[5], R. Sahabo[5], A. Voestsch[2], C. Ryan[1,1]
[1]Centers for Disease Control and Prevention, Mbabane, Swaziland, Mbabane, Swaziland, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, Centers for Disease Control and Prevention, Atlanta, GA, United States, United States, [3]Ministry of Health, Government of the Kingdom of Swaziland, Mbabane, Swaziland, Mbabane, Swaziland, [4]ICAP at Columbia University, Mailman School of Public Health, New York, NY, United States, New York, United States, [5]ICAP at Columbia University, Mailman School of Public Health, Mbabane, Swaziland, Mbabane, Swaziland

Background: As countries scale up anti-retroviral treatment (ART) to achieve epidemic control and end the global HIV pandemic by 2030, it is critical to understand factors associated with ART uptake to guide program modification and implementation. Data from the Swaziland HIV Incidence Measurement 2 (SHIMS2) included measurement of progress towards the UNAIDS three 90s i.e. HIV status awareness, ART uptake and viral load suppression. Although Swaziland has made significant progress, deeper analysis is required to understand which populations and geographic locations are not meeting ART coverage targets.
Methods: Using data from a nationally representative survey, we examined correlates of ART uptake, defined as either self-reporting being on ART and/or testing positive for one or more antiretrovirals in their blood. The survey used a two-stage cluster sampling design to attain a nationally representative sample. National testing algorithm was used to determine HIV status and a qualitative assay to test for efavirenz, nevirapine, and lopinavir. Prevalence and correlates of ART use were estimated using weighted multivariable logistic regression analyses with jackknife variance estimation methods accounting for the complex survey design.
Results: Of the 2,997 HIV+ participants, 87.0% were reported to be aware of their status with 88.8 % of those being on ART. ART uptake did not differ by sex. Compared to people residing in Lubombo (Eastern region), people residing in Hhohho (Adjusted odds ratio [aOR]: 1.83, p=0.0127) and Shiselweni (aOR: 1.92, p=0.0105) regions had higher odds of ART uptake. Those with lower than secondary education had higher odds of being on ART compared to those with secondary education or higher (aOR: 0.65, p=0.0096). Older participants (35-44 years, aOR: 1.70, p=0.0390; 45+ years, aOR: 1.81, p=0.0480) were more likely to be on ART compared to 15-24 year olds while those that had disclosed their HIV status were 92% more likely to be on ART compared to those who had to hide their status (aOR: 1.92, p=0.0034).
Conclusions: Disparities observed in ART uptake by region, level of education, age and disclosure status, emphasize the need to expand and modify existing interventions to reach specific sub-populations that currently have lower ART coverage as demonstrated in this analysis.

THPEC223

Earlier treatment initiation correlates with a decreased number of HIV-1 subtype A transmissions in Greece

Syngros Hospital of Dermatology and Venereology, HIV/AIDS Unit, Athens, Greece, [10]Hippokration GH, Medical School, National and Kapodistrian University of Athens, 2nd Department of Internal Medicine-HIV Unit, Athens, Greece, [11]Laikon GH, Medical School, National and Kapodistrian University of Athens, Pathophysiology Department-Infectious Diseases Unit, Athens, Greece, [12]Sismanogleion GH, 2nd Department of Internal Medicine, Athens, Greece, [13]University GH, Democritus University of Thrace, Department of Internal Medicine, Alexandroupolis, Greece

Background: Subtypes A1 and B are the most prevalent HIV-1 clades in Greece. The subtype A1 epidemic is highly monophyletic and corresponds to transmissions that occurred locally. UNAIDS has set a global target to eliminate the HIV pandemic in 2030 by reaching a 90-90-90 treatment cascade. We aimed to investigate the role of treatment as prevention (TasP) to prevent new HIV-1 transmissions.

Methods: Our analysis focused on the major subtype A1 local cluster that included 791 out of 916 (86.4%) sequences from treatment-naïve individuals sampled in Greece during 22/07/1997-02/06/2015. Estimation of infection dates was performed by molecular clock calculations using phylodynamic analysis based on birth-death models, as implemented in BEAST v1.8.0. We also estimated the time interval:

i) between the infection and sampling dates (*linkage to care window*), and;

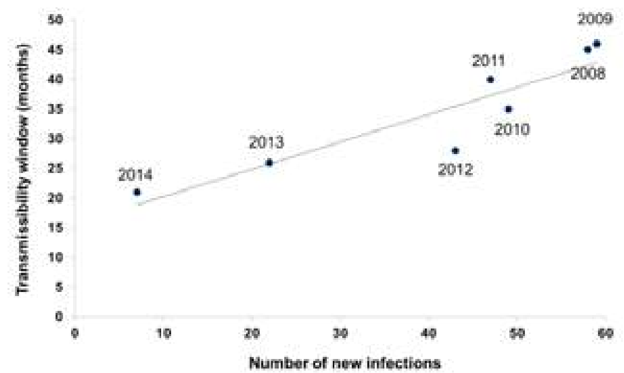
ii) between infection dates and antiretroviral therapy (ART) initiation (*transmissibility window*) for the study population.

Results: The number of new transmissions (incidence trend) decreased during the 2008-2014 period among subtype A1-infected individuals in Greece. A significant time trend for the transmissibility window was found. Similarly, the linkage to care window decreased significantly over time.

Infection year	New transmissions (n)	Transmissibility window (months)	Linkage to care window (months)
2006	40	79	68
2007	33	55	25
2008	58	45	32
2009	59	46	26
2010	49	35	23
2011	47	40	24
2012	43	28	15
2013	22	26	10
2014	7	21	4

[Description of new transmissions, transmissibility and linkage to care windows for subtype A infections over time]

We also found a significant positive correlation between the transmissibility window and the number of new infections for each time period (Spearman correlation coefficient R=0.91, p< 0.01). Specifically, the trend in new infections was correlated with the decrease in the transmissibility window. The longer the transmissibility period the greater the number of new infections.



[Correlation between the transmissibility window and the number of new subtype A infections for each time period.]

Conclusions: It has been demonstrated that molecular analysis can be used for accurate estimation of infection dates. Our findings, based on a large proportion of subtype A1 infections in Greece, showed that the linkage to care and transmissibility windows are decreasing over time, suggesting that a larger proportion of individuals are being diagnosed and treated closer to their infection dates, presumably due to improved diagnosis and updated treatment guidelines. Our study also provides evidence that earlier treatment is correlated with lower incidence among subtype A1 strains in Greece, thus documenting the benefits of early ART initiation to prevent ongoing HIV-1 transmission.

THPEC224

Trends in HIV diagnostic coverage & prevalence of undiagnosed infection in a high burden district with annual home-based HIV testing: Findings from the Chókwè Health Demographic Surveillance System, Mozambique, 2014-2017

R. Nelson[1], I. Casavant[2], R. Thompson[3], S. Pals[1], J. Bonzela[3], J. Cardoso[4], S. Mikusova[5], D. Ujamaa[1], I. Pathmanathan[1], V. Chivurre[6], S. Tamele[7], A. de Louvado[2], S. Wei[2], A. Vergara[2], D. Mackellar[1]
[1]Centers for Disease Control and Prevention, Atlanta, United States, [2]Centers for Disease Control and Prevention, Maputo, Mozambique, [3]Chókwè Health Research and Training Center, Chókwè, Mozambique, [4]Jhpiego, Maputo, Mozambique, [5]Elizabeth Glaser Pediatric AIDS Foundation, Maputo, Mozambique, [6]Provincial Directorate of Public Health, Xai-Xai, Mozambique, [7]District Directorate of Public Health, Chókwè, Mozambique

Background: Few communities in sub-Saharan Africa have achieved the UNAIDS goal of diagnosing >90% of HIV-infected residents (diagnostic coverage). Beginning in April 2014, periodic rounds of home-based HIV testing and counseling (HBHTC) were conducted in the Chókwè Health Demographic Surveillance System (CHDSS), located in a high-prevalence district in southern Mozambique. We describe uptake of HBHTC, and trends in diagnostic coverage and prevalence of undiagnosed HIV infection among CHDSS residents.

Methods: CHDSS conducts annual demographic surveillance of 95,000 residents. During each surveillance round, all households are visited and encountered residents aged 15-59 years are asked to participate in a brief survey on prior HIV testing and result of most recent test, and to test for HIV if not confirmed HIV-positive through CHDSS. Estimated diagnostic coverage and prevalence of undiagnosed infection (previously unaware of current HIV-positive test result) are weighted to the 2016 census.

Results: From 2014-2017, 76,620 tests were conducted, 40,272 (78%) of 51,878 residents aged 15-59 years tested at home at least once, and 3,957 were newly HIV diagnosed. In each round, 19,811-24,946 residents participated in the brief survey. Among participants with HIV, diagnostic coverage increased in all demographic groups, particularly among young adults, and in 2017, exceeded 90% among men, women, and persons aged 25-59 years. In 2015, 2016, and 2017, prevalence of undiagnosed (total) HIV infection was 5.0% (24.5%), 3.1% (26.1%), and 1.8% (25.6%), respectively. In 2017, prevalence of undiagnosed HIV infection was greater among males (2.0%) than females (1.6%), and greatest among

males 30-34 years (4.4%) and females 25-29 years (2.9%) (Figure). Applying estimated prevalence of undiagnosed HIV infection to the CHDSS census, we estimate that 934 HIV infected CHDSS residents were undiagnosed in 2017, 639 (69%) of whom were 15-34 years of age.

Conclusions: In a high HIV prevalence district in Mozambique with annual HBHTC, substantial progress has been made in achieving the UNAIDS goal of >90% diagnostic coverage and reducing the prevalence of undiagnosed infection in all demographic groups. In the CHDSS, focused efforts are now warranted on identifying methods to reach and test young adult men and women at high risk for undiagnosed infection.

Earlier HIV diagnosis among men who have sex with men in Amsterdam following interventions to increase awareness of early HIV infection

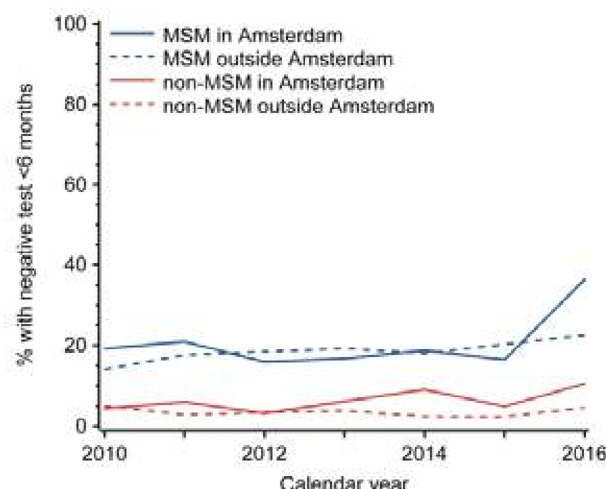
A. van Sighem[1], G. de Bree[2,3], U. Davidovich[4], W. Zuilhof[5], A. van Bijnen[5], F. Verdult[6], M. Dijkstra[4], T. Heijman[4], A. Hogewoning[4,7], E. Op de Coul[8], J. van Bergen[5,8,9], M. Schim van der Loeff[4], P. Reiss[1,2,3], HIV Elimination Amsterdam (H-TEAM) Initiative and the ATHENA National HIV Cohort
[1]Stichting HIV Monitoring, Amsterdam, Netherlands, [2]Academic Medical Centre of the University of Amsterdam, Department of Global Health and Division of Infectious Diseases, Amsterdam, Netherlands, [3]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, [4]Public Health Service Amsterdam, Amsterdam, Netherlands, [5]STI AIDS Netherlands, Amsterdam, Netherlands, [6]Dutch Association of People Living with HIV, Amsterdam, Netherlands, [7]Academic Medical Centre of the University of Amsterdam, Department of Dermatology, Amsterdam, Netherlands, [8]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [9]Academic Medical Centre of the University of Amsterdam, Department of General Practice, Division Clinical Methods and Public Health, Amsterdam, Netherlands

Background: The HIV Transmission Elimination AMsterdam (H-TEAM) initiative, a unique collaboration between all relevant stakeholders involved in HIV prevention and care in Amsterdam, implemented several interventions to increase awareness of early HIV infection, including a multi-media campaign targeting men who have sex with men (MSM), which was launched in August 2015 and repeated early 2016. We investigated the possible impact on early-diagnosed HIV infections in Amsterdam compared to the rest of the Netherlands.

Methods: Data on people diagnosed with HIV in 2010-2016 were retrieved from the ATHENA national HIV database. We studied changes over time in proportions of people with recent infection, defined as HIV diagnosis with a negative test ≤6 months before, and changes in CD4 cell counts at diagnosis. Differences between groups were compared with Pearson's chi-square test.

Results: 6,931 people were newly diagnosed in 2010-2016: 1,193 (17%) MSM and 370 (5%) other men and women in Amsterdam, and 3,476 (50%) MSM and 1,892 (27%) other men and women outside Amsterdam. The proportion of MSM with a recent infection was 18% (196/1,080) in 2010-2015 and increased ($p < 0.001$) to 36% (41/113) in 2016 in Amsterdam, compared to a more modest increase (from 18% to 22%, $p=0.03$) outside Amsterdam (Figure). Among other men and women, < 10% had a recent infection, both in and outside Amsterdam, without significant changes over time ($p>0.1$).

CD4 counts at diagnosis were available for 4,234 (91%) MSM and 1,988 (88%) other people. Among MSM, the proportion with ≥350 CD4 cells/mm³ increased from 62% (597/956) in 2010-2015 to 77% (85/111) in 2016 in Amsterdam ($p=0.003$), but did not change outside Amsterdam: 62% (1747/2816) in 2010-2015 and 58% (202/351) in 2016 ($p=0.1$). Among other men and women 39% (772/1,988) had ≥350 CD4 cells/mm³ at diagnosis with no differences by time period or residence.



[Annual proportion of new HIV diagnoses with a last negative test at most 6 months before diagnosis.]

Conclusions: MSM in Amsterdam are now being diagnosed earlier in their HIV infection than in the rest of the Netherlands. Although our findings need further confirmation with ongoing observation, they may be an early indicator of the effectiveness of H-TEAM's combined efforts to increase HIV testing and diagnosis at early stages of the infection.

Measuring the population-level impact of policy-level HIV interventions

THPEC226

Achieving >80% ART coverage in a high burden district with annual home-based HIV testing: Findings from the Chókwè Health Demographic Surveillance System (CHDSS), Mozambique, 2014-2017

A. De Louvado[1], I. Pathmanatan[2], R. Thompson[3], I. Casavant[1], R. Nelson[2], S. Pals[2], J. Bonzela[3], D. Ujamaa[2], V. Chivurre[4], Z. Languitone[4], S. Tamele[5], M. Simango[4], S. Uache[4], S. Mikusova[6], M. Bono[7], A. Auld[2], L. Nhalusse[4], M. Briggs-Hagen[1], D. Mackellar[2]
[1]US Centers for Disease Control and Prevention, Maputo, Mozambique, [2]US Centers for Disease Control and Prevention, Atlanta, United States, [3]Chokwe Health Research and Training Center, National Institute of Health, Chokwe, Mozambique, [4]Provincial Directorate of Public Health, Xai-Xai, Mozambique, [5]District Directorate of Public Health, Chokwe, Mozambique, [6]Elizabeth Glaser AIDS Foundation, Maputo, Mozambique, [7]Elizabeth Glaser AIDS Foundation, Xai-Xai, Mozambique

Background: Few communities in sub-Saharan Africa have achieved the UNAIDS goal of more than 80% of people living with HIV (PLHIV) on antiretroviral therapy (ART). In September 2016, the Government of Mozambique approved ART for all PLHIV (Test & Start, T&S), beginning with highest burden districts. We evaluate trends in ART coverage in a T&S district where home-based HIV testing and counseling (HBHTC) had been implemented since 2014.
Methods: The Chókwè Health and Demographic Surveillance System (CHDSS) conducts annual demographic surveillance of 95,000 residents in Chókwè District. During each round of surveillance, encountered residents aged 15-59 years in all CHDSS households are asked to participate in a brief survey on knowledge of HIV status and current ART use, and to test for HIV if not previously tested positive through CHDSS. For each round 2014-2017, we estimate ART coverage overall, and by sex and age group. All estimates are weighted to the 2016 census.
Results: Between 2014 and 2016, 37,766 (73%) of 51,878 adult residents (15-59 years of age) underwent home-based HIV counselling and testing (HBHTC) at least once, with 19,811-24,946 residents participating in each round of the survey. Among participants with HIV, ART coverage increased from 49% (95% confidence interval [CI] 47.7-50.6) in 2014 to 85% (95% CI: 83.7-86.0) in 2017 (Table); pill bottles were observed for ≥82% of ART reporters per round. ART coverage increased most among residents aged 15-24 years, from 28% (95% CI: 25-0-31.8) in 2014 to 73% (95% CI: 69.0-76.8) in 2017. In 2017, ART coverage exceeded 80% for women aged 25-59 years and men aged 35-59 years (Figure). The percentage of participants on ART in 2017 who were newly HIV-diagnosed at home in prior surveillance rounds was 29%, 21%, and 18% among participants aged 15-34, 35-45, and 45-59 years, respectively.
Conclusions: One year after approval of T&S, substantial progress has been made in achieving the UNAIDS goal for over 80% ART coverage among all demographic groups in a high burden district in Southern Mozambique. Improvements are still needed to expand this achievement to all sub-populations, particularly youth aged 15-34.

Improvements in the South African HIV care cascade: Findings on 90-90-90 targets from successive population-representative surveys

S.A. Lippman[1], A.M. El Ayadi[2], J.S. Grignon[3,4], A. Puren[5,6], T. Liegler[7], M.J. Ratlhagana[4], J. Moris[1], E. Naidoo[4], E. Agnew[1], S. Barnhart[3], S.B. Shade[1]
[1]University of California, Center for Aids Prevention Studies, Department of Medicine, San Francisco, United States, [2]University of California, Bixby Center for Global Reproductive Health, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, United States, [3]University of Washington, Department of Global Health, Seattle, United States, [4]International Training and Education Center for Health (I-TECH) South Africa, Pretoria, South Africa, [5]National Institute for Communicable Diseases/NHLS, Johannesburg, South Africa, [6]University of Witwatersrand, Johannesburg, South Africa, [7]University of California, HIV, Infectious Diseases and Global Medicine Division, Department of Medicine, San Francisco, United States

Background: South Africa began staged roll-out of fixed dose combination (FDC) antiretroviral therapy (ART) in April, 2013; expanded ART initiation from CD4< 350 to CD4< 500 in January, 2015; and instituted universal treatment in September, 2016. We assessed whether these changes facilitated meeting UNAIDS 90-90-90 targets by comparing population-representative surveys before and after expanded treatment policies were introduced.
Methods: Data were collected in January-March 2014 and August-November 2016 in Lekwa-Teemane and Greater Taung sub-Districts, Dr. Ruth Segomotsi Mompati District, North West Province. In both surveys, 46 enumeration areas (EA) were selected proportional to size, an average of 39 dwelling units (DU) per EA were randomly selected, with one DU resident 18-49 years old randomly selected for participation. Participants responded to a behavioral survey, were invited to undergo rapid antibody testing and provide dried blood spots (DBS) for HIV detection and viral load testing. Weighted analyses accounted for multi-stage sampling.
Results: For both surveys, over 90% of those eligible enrolled, resulting in 1044 participants in 2014 and 971 in 2016; approximately 70% underwent HIV testing. HIV prevalence was 23.1% (95% CI=19.1-27.2) in 2014 and 21.0% (95% CI=17.2-24.9) in 2016. The proportion of HIV-positive individuals with knowledge of their status remained constant at 65.8% (95% CI=58.1-72.7) in 2014 and 65.3% (95% CI=56.3-73.4) in 2016, despite increases in reported testing. Men were significantly less aware of their status than women in both surveys (Table 1). The proportion of HIV-positive individuals on ART increased significantly from 79.0% (95% CI=69.6-86.0) in 2014 to 91.3% (95% CI=84.3-95.4) in 2016. Among those on ART, viral suppression (< 5,000 DBS copies/ml) increased significantly from 55.6% (95% CI=40.0-71.1) in 2014 to 83.6% (95% CI=74.0-93.2) in 2016, with a particularly large increase for men.
Conclusions: Over two and a half years during which FDC was introduced and ART eligibility was expanded to universal access, the second 90-90-90 target was reached and the third is within reach in rural South Africa. No improvements were evident in the first 90 target, despite increases in reported HIV testing. Targeted and differentiated testing models to encourage uptake of HIV testing by people most at risk are required.

HIV incidence trends by marital status in mature HIV epidemics: Evidence from two community cohort studies in Uganda

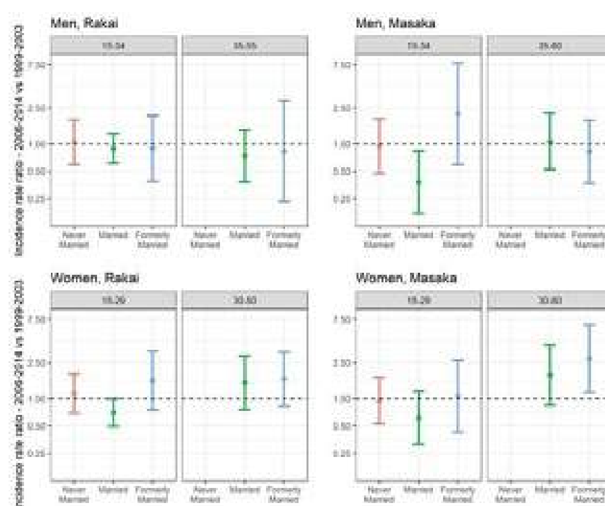
G. Reniers[1,2], K. Risher[1], E. Sully[3], E. Slaymaker[1], T. Lutalo[4], R. Newton[5,6], D. Nabukula[4], J. Seeley[6,7], B. Zaba[1]
[1]London School of Hygiene and Tropical Medicine, Department of Population Health, London, United Kingdom, [2]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [3]Guttmacher Institute, New York, United States, [4]Uganda Virus Research Institute, Rakai Health Sciences Program, Rakai, Uganda, [5]University of York, Department of Health Sciences, York, United Kingdom, [6]Medical Research Council / Uganda Virus Research Institute, Uganda Research Unit on AIDS, Entebbe, Uganda, [7]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom

Background: The association between marital status and HIV incidence has at times been heavily contested in the literature. In this study, we revisit the evidence against the background of increasingly expansive combination HIV prevention programmes, including medical male circumcision and antiretroviral treatment for prevention.

Methods: Data for this study come from two population-based HIV surveillance sites Uganda: the Kyamulibwa General Population Cohort in the Masaka District and the Rakai Community Cohort Study. Each of these have conducted repeated serological surveys, which allow for the direct measurement of HIV incidence. Our dataset spans the years 1999-2015 (to be updated by the time of the IAS conference), and is used to describe trends in HIV incidence rates and the distribution of seroconverters by marital status. Poisson regression is used to test for changes in the relationship between marital status and HIV incidence over time. All analyses are gender disaggregated and control for age.

Results: Known HIV negative adults (aged 15-50) in Rakai and Masaka respectively contribute 68,132 and 66,667 person-years of exposure to the analysis. HIV incidence rates are typically highest among never married or formerly married men and women, but married individuals still account for around 40% of new infections because Ugandans spend most of their sexually active lives in a formal union. We find evidence for a decline in HIV incidence rates in young married men in Kyamulibwa (Incidence Rate Ratio: 0.38, 95%-CI: 0.17-0.84) and young married women in Rakai (0.70, 95%-CI:0.49-0.99, Figure 1). There is no evidence of a decline in HIV incidence among married individuals above age 30, but their incidence rates have always been relatively low. HIV incidence among never married or formerly married men and women stagnated, or in the case of older women in Masaka, increased.

Conclusions: We find support for recent studies that documented declines in HIV incidence in the period that HIV prevention efforts expanded. However, the possible impact of these programs is confined to young married men and women. Other prevention efforts are needed to reach never or formerly married men and women.



[Figure 1: HIV incidence rate ratios 2006-'14/15 versus 1999-'03 by sex, study site, marital status and age]

THPEC229

Changes in time to ART initiation in adults with high CD4 count in Latin America, 2003-2016

B. Crabtree- Ramírez[1], Y. Caro-Vega[1], P.F. Belaunzarán- Zamudio[1], B.E. Shepherd[2], P.F. Reibeiro[3], V. Veloso[4], C. Cortes[5], D. Padgett[6], E. Gotuzzo[7], C. McGowan[3], J.G. Sierra- Madero[1], A.K. Person[3]
[1]Instituto Nacional de Ciencias Medicas y Nutricion, Salvador Zubiran, Infectious Diseases, HIV/ AIDS Clinic, Mexico City, Mexico, [2]Vanderbilt University, Biostatistics, Nashville, United States, [3]Vanderbilt University School of Medicine, Medicine, Division of Infectious Diseases and Epidemiology, Nashville, United States, [4]Instituto Nacional de Infectologia Evandro Chagas-Fiocruz, HIV, Rio de Janeiro, Brazil, [5]Universidad de Chile, Fundación Arriarán, Santiago, Chile, [6]Instituto Hondureño de Seguro Social and Hospital Escuela Universitario, Tegucigalpa, Honduras, [7]Instituto de Medicina Tropical Alexander von Humboldt, Lima, Peru

Background: In 2013 the World Health Organization (WHO) recommended initiating ART in all adults with HIV and CD4+ lymphocyte counts (CD4) < 500cells/mm³. In 2015, WHO updated this guidelines to recommend initiating ART in all patients with HIV, regardless of CD4 count. Implementation of these guidelines in real-world settings has not been evaluated in Latin America. To assess the impact of WHO guidelines on ART initiation during routine care, we estimated trends in time from enrollment in care to ART initiation in HIV-positive adults in the Caribbean, Central and South America network for HIV epidemiology (CCASAnet) during 2003-2016.

Methods: ART-naïve adults, with CD4 ≥350cells/mm³ at enrollment in five CCASAnet sites (Brazil, Chile, Honduras, Mexico and Peru) during 2003-2016, were included. We estimated time from enrollment to ART initiation by calendar year. Using a Cox model, we calculated adjusted hazard ratios (HR) and 95% confidence intervals (95%CI) for trends in ART initiation using splines for continuous variables accounting for age, sex, CD4 at enrollment, route of HIV transmission, and site.

Results: Among 3325 patients, 1720 (52%) had CD4 ≥500cells/mm³ at enrollment. Median time to ART initiation by year was 5.8 (interquartile range (IQR): 1.4, 21.9) weeks after 2013 (Fig.1A). Adjusted probability of ART initiation increased significantly in later years, in particular after 2015 (2013 vs. 2003: HR=5.70, 95%CI: 4.75-6.83 and 2015 vs. 2003: HR=12.62, 95%CI: 10.58-15.05) (Fig.1B). Older age (50 vs. 20 years: HR=1.24, 95%CI: 1.09-1.41) and receiving care in Honduras and Mexico (Honduras vs. Brazil: HR=1.45, 95%CI: 1.14-1.85; Mexico vs. Brazil: HR=1.19, 95%CI 1.02-1.37) were also associated with earlier initiation. Among 801 (24%) patients never initiating ART, 55% were enrolled before 2013, 49% were lost to follow-up, and 43 (5%) died after a median of 2.76 (IQR: 0.7, 4.9) years.

Conclusions: Time to ART initiation in patients with high CD4 cell counts decreased significantly following changes in WHO guidelines in this real-world setting in Latin America. Nonetheless, a sizeable portion of

Tuesday 24 July
Wednesday 25 July

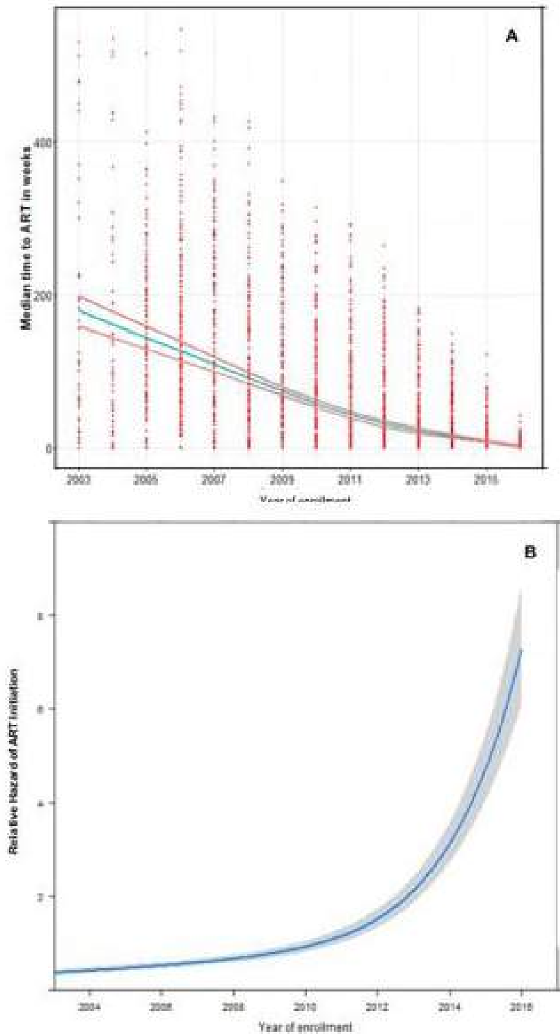
the cohort never started ART; half of these were lost to follow-up. Further efforts to reduce time to ART initiation are needed particularly for those at risk for loss to follow-up.



[Figure 1. A) Median time of starting ART by calendar year among all ART initiators. B) Relative Hazard of ART initiation by calendar year, adjusted for sex, age, CD4 at enrollment, route of HIV transmission, and site]

THPEC230

Trends and disparities in failure to achieve indicators of engagement in HIV care, San Francisco, CA, USA 2009-2014

S. Scheer[1], S.K. Schwarcz[1], L.C. Hsu[1], S. Pipkin[1], N. Hessol[2]
[1]*San Francisco Department of Public Health, HIV Epidemiology Section, San Francisco, United States,* [2]*University of California, Departments of Clinical Pharmacy and of Medicine, San Francisco, United States*

Background: Aggressive efforts are underway to reduce new HIV infections and improve health outcomes for persons living with HIV. We measured trends and factors associated with failure in the care continuum among persons newly diagnosed with HIV in San Francisco (SF).

Methods: Newly diagnosed (2009-2014) HIV/AIDS cases reported to the SF surveillance registry were analyzed to identify persons: who failed to

1) initiate care ≤ 3 months after diagnosis,
2) remain in care 6-12 months after entry into care,
3) achieve viral suppression ≤ 12 months after diagnosis, who
4) had AIDS ≤ 3 months after diagnosis, and
5) died ≤12 months after diagnosis. Multivariable Poisson logistic regression measured prevalence ratios and 95% confidence intervals of each outcome, adjusted for gender, race/ethnicity, age, transmission risk, homelessness, low income, and CD4 count.

Results: There were 2,530 persons analyzed. After adjusting for confounding, the risk of late entry into care and not achieving viral suppression by 12 months after diagnosis was significantly decreased in 2014 compared to all earlier years (Table). Rapid progression to AIDS was also significantly less likely in 2014 compared to 2009-2011 (Table). Risk for late initiation of care and for not remaining in care after initial linkage was significantly increased for persons with no reported risk of HIV (NRR) (PR=2.47, 95% CI 1.49-4.07) and (PR=1.84, 95% CI 1.22-2.76), respectively. For no early viral suppression, increased risk was observed for MSM who inject drugs (PR=1.39, 95% CI 1.13-1.71), persons with NNR (PR=1.57, 95% CI 1.03-2.40) and homeless persons (PR=1.30, 95% CI 1.00-1.72). For late HIV diagnosis, an increased risk was observed for older age (PR=1.34, 95% CI 1.24-1.44), other race (PR=1.32, 95% CI 1.03-1.69), and heterosexual HIV transmission (PR=1.89, 95% CI 1.32-2.69). Risk for death was increased for older persons (PR=1.79, 95% CI 1.41-2.26) and those with NRR (PR=3.99, 95% CI 1.59-10.05).

Conclusions: Temporal improvements in indicators support the beneficial impact of HIV care-related interventions, including rapid linkage to care and ART initiation, but targeted services are needed to reduce disparities. Public health surveillance provides a population-based data-driven approach to evaluate interventions and identify vulnerable populations in greatest need of assistance.

	No initiation of care <=3 months of diagnosis (n=2333)	Not retained in care 6-12 months after entering care, among those linked to care (n=2233)	No viral suppression <=12 months of diagnosis, among those with viral load tests (n=2193)	AIDS diagnosis <=3 months of HIV diagnosis (n=2333)	Died <=12 months of diagnosis (n=2333)

Who will be lost? A psychosocial review on loss to follow-up in people with HIV

P. Torres-Bertral[1,2], M.J. Ferrer Lasala[2], J.A. Muñoz-Moreno[2,3]
[1]*Institut Català d'Oncologia (ICO), Hospital Universitari Germans Trias i Pujol, Badalona, Spain,* [2]*Fundació Lluita contra la SIDA (FLS), Hospital Universitari Germans Trias i Pujol, Badalona, Spain,* [3]*Universitat Oberta de Catalunya (UOC), Facultat de Psicologia i Ciències de l'Educació, Barcelona, Spain*

Background: Although access to antiretroviral therapy and viral suppression may be available and achievable, retention in care is crucial to reach these and other successful goals in HIV clinical management. However, undesirable rates of loss to follow-up (LTFU) are still present today. We reviewed the literature with 2 primary aims:

1) to identify the correlates associated with LTFU, and
2) to categorize those factors involving psychological, social and cultural issues.

Methods: We developed a narrative review of studies in HIV infection in which variables concerning retention in care were investigated. We used Pubmed with a selection period from January 2010 to December

2017. Eligible studies met the following criteria: 1) English language, 2) published in a peer-reviewed journal, 3) including any step of the HIV care continuum, and 4) finding at least one of the following factors as relevant: psychological, social or cultural. We performed descriptive statistical analyses.

Results: We found 2325 citations investigating aspects related to retention in care. A total of 29 reports met the study criteria and were included in the review. The most common definition of LTFU was not attending the next scheduled clinical or medical appointment up to 180 days following the last clinical visit. The rate of LTFU ranged from 1% to 59%. The studies described up to 55 variables, which could be classified into 7 categories: anthropometric, demographic, institutional, physical complications, psychosocial, related to laboratory results, and therapeutic. Regarding psychosocial variables, 13 factors were detected in connection with LTFU (*Table 1*): the most important were depression (in 14% of the reports), low social support (14%), perceived stigma (14%), and HIV nondisclosure (10%).

Conclusions: Psychological, social and cultural factors influence not only health-related outcomes of people living with HIV, but also, importantly, retention in care. Risk factors such as depression, poor social support, highly perceived stigma, and difficulties for HIV disclosure lead to a greater likelihood of LTFU. Detection and assessment of psychosocial variables are strongly recommended in people living with HIV, in order to both predict a potential loss of retention in care, and propose and establish intervention programs to ensure and optimize linkage to care.

[Table 1. Psychosocial variables related to loss to follow-up.]

THPEC232

Risk factors for loss to follow-up, transfer or death among people living with HIV on first ART regimen in Mali

A. Baldé[1], L. Lièvre[1], A.I. Maiga[2], F. Diallo[3], I.A. Maiga[4], D. Costagliola[1], S. Abgrall[5]

[1]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France, [2]Unité d'Epidémiologie Moléculaire de la Résistance du VIH aux ARV du Centre de Recherche et de Formation sur le VIH/Sida et la Tuberculose (SEREFO), Université des Sciences, des Techniques et des Technologies de Bamako (USTTB), Bamako, Mali, [3]Association de Recherche, de Communication, d'Accompagnement à Domicile des Personnes Vivant avec le VIH (ARCAD-Sida), Bamako, Mali, [4]Ensemble pour une Solidarité Thérapeutique Hospitalière en Réseau (ESTHER), Bamako, Mali, [5]AP-HP, Hôpital Antoine Béclère, Service de Médecine Interne, Clamart, France

Background: Among 99 000 adults living with HIV in Mali in 2013, 27 000 were treated. Healthcare for people living with HIV (PLHIV) started in 1998 in Bamako (capital), extended to other regions from 2001 and became free from 2004. To assess the quality of follow-up according to the national programme (quarterly visits); risk factors for lost-to-follow-up (LTFU) were assessed using the ESOPE medical database from different outpatient clinics (care expertise level II) and hospitals (care expertise level III).

Methods: HIV-1 individuals, ≥18 years, starting ART in 2006-2013 and coming back for their 1 month visit were considered. LTFU was defined as had no visit in the 6 months previous to database endpoint. Risk factors for LTFU were assessed at 5 years on ART using Cox model, taking into account the competitive risks of transfer to another centre and death. Potential risk factors at start of ART were age, sex and pregnancy, WHO stage and CD4, period of ART, type of ART, marital status, education level, professional activity, and a variable combining region of care, care level and distance from home. We used multiple imputations to deal with missing values. Last database update was 31/03/2015.

Results: We included 9,307 PLHIV starting ART in 9 outpatient clinics and 7 hospitals (5+2 in Bamako and 4+5 in the Regions), 33% male, median (IQR) age 36 (29-43), CD4 count 157/µL (58-273) and duration (months) on ART 32 (13-61). At 5 years, 37.1%, 7.5% and 4.3% were LTFU, transferred or dead respectively. Compared to Bamako outpatient clinics, people in Bamako hospitals living >5 kilometers (kms) apart, in Regions hospitals, or in Regions outpatient clinics living < 5 kms apart were at higher risk for LTFU, whereas people in Regions outpatient clinics living 5-50 kms apart were at lower risk for LTFU. Other adjusted risk factors for being LTFU were male sex, recent periods, lower education, farmers/fishers and WHO stage 3-4 with lower immunity.

Conclusions: Care expertise level, distance to care and economic insecurity were associated with LTFU. Political crisis since 2012 have impacted the quality of follow-up. Stigmatization might play a role for low distances in the Regions.

THPEC233

Online MIS database to improve HIV case detection and case management tracking in Central Asia

M. Kan, R. Shaimerden, O. Samoilova

Population Services International/Central Asian Branch, Almaty, Kazakhstan

Background: PSI Central Asia (PSI/CA) previously used the MS Access database for project management. Although the tool was useful for management, it did not allow reviews until the end of a quarter, when partners sent their data. This hindered ongoing data quality checks and real-time data-driven decision-making.

Under USAID Central Asia HIV Flagship Project, PSI/CA decided to move to a web-based database that would eliminate these delays. This transition was intended to inform programmatic decision-making, and increase the use of high-quality HIV prevention, testing, and treatment services.

Description: PSI/CA engaged a local web developer. Prioritizing flexibility of design and responsiveness to project changes, PSI/CA management relied on the developer's ability to create a new database that would remain adaptable and help achieve all project goals. The database development was an iterative process with multiple meetings between M&E and program teams to refine the system features. The architecture of the database and improved usability have been developed within very strict time constraints. The regional nature of the project added to the complexity of the database design, as it covers three Central Asian countries.

Lessons learned: The new system has proved more robust and comprehensive - it accurately captures the complex case detection process following the RDS recruitment method. All necessary tracking of this method is built into the new system, including tracking of coupon distribution to initial contacts and recruitment management. The database generates coupons for recruitment, tracks the recruitment chains and has a sophisticated tool to manage the number of coupons and waves across chains. The system is extremely responsive to program design changes, and able track at individual client, target group, and NGO levels.

It also captures different variables of case management for PLHIV, including clients' socio-demographic information. This cascade starts with case detection, and follows clients through to enrollment in case management and linkage to care at AIDS Centers.

Conclusions/Next steps: In just a year, the database has enabled PSI/CA to conduct ongoing monitoring and evaluation of the project activities and provide improved, comprehensive support to clients. The next step is to roll-out the use of mobile devices for data collection.

THPEC234

Treatment for all, implementation for most: Heterogeneous roll out of test and treat by clinics near Agincourt, South Africa

N. Haber[1], M.-S. Kang Dufour[2], C. Kabudula[3], A. Julien[2,4,5], F.X. Gómez-Olivé[3], K. Kahn[3,6], S. Lippman[2,3], A. Pettifor[3,7]

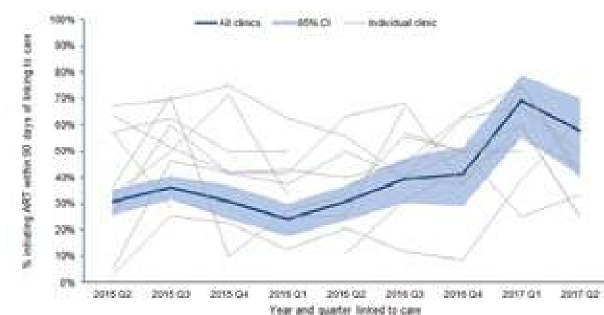
[1]University of North Carolina at Chapel Hill, Carolina Population Center, Chapel Hill, United States, [2]University of California, San Francisco, United States, [3]University of the Witwatersrand School of Public Health, Medical Research Council/Wits University Rural Public Health and Health Transitions Research Unit (Agincourt), Johannesburg, South Africa, [4]University of North Carolina, Chapel Hill, United States, [5]University of Antwerp, Antwerp, Belgium, [6]Umeå University, Umeå Centre for Global Health Research, Division of Epidemiology and Global Health, Department of Public Health and Clinical Medicine, Umeå, Sweden, [7]University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Chapel Hill, United States

Background: South Africa officially implemented universal access to antiretroviral therapy (ART) for all diagnosed with HIV, treatment for all (TFA), in September 2016. However, successful implementation of this policy may vary both across South Africa, and even within regions. We estimated heterogeneity in the time from linkage to care to ART initiation across clinics near rural Agincourt, South Africa.

Methods: We utilized data from the Agincourt health and socio-demographic surveillance system, which combines data from the annual population census and electronic clinical record systems for the 10 clinics with HIV services in the region. These data include the dates on which HIV-positive individuals entered the clinical system and first initiated ART. Kaplan-Meier (KM) survival curves were generated to estimate time from linkage to care (LTC), defined as first CD4, viral load test, or follow-up visit after diagnosis, to ART initiation, stratified by the quarter/year of LTC and by clinic, from Q2 of 2015 to Q2 of 2017, censored by end of data collection and/or out-migration. Heterogeneity of curves was measured using a log-rank test of survival functions. The proportion of participants initiating ART within 90 days of LTC was estimated for each quarter and clinic from the KM survival curves.

Results: Between Q2 of 2015 and Q2 of 2017, 1,169 individuals were recorded as having been linked to care for the first time in the Agincourt clinical dataset. The proportion of individuals who initiated ART within 90 days of linking to care changed from 31% (95% CI: 26%-36%) in Q2 of 2015, 31% (95% CI: 24%-37%) in Q2 of 2016, and 58% (95% CI: 41%-70%) in Q2 of 2017 over all 10 clinics. However, treatment initiation times appear to be highly heterogeneous, with highly significant log-rank heterogeneity test ($p < .001$) for all years, including for 2017.

Conclusions: TFA resulted in increased ART initiation once individuals entered into the clinical setting. However, successful implementation of this policy was highly heterogeneous between clinics, even within a single sub-district. Monitoring and additional assistance for clinics which have fallen behind on TFA implementation is needed to ensure the population has universal and immediate access to ART.



[Percentage initiating ART within 90 days of linking to care]

THPEC235

Service utilization along the prevention of mother-to-child transmission of HIV cascade and determinants of child HIV positivity in Nigeria

S. Yin[1], I. Jahun[2], S. Pals[3], T. Efuntoye[2], M. Bronson[3], M. Swaminathan[2], J. Gwamna[2], I. Dalhatu[2], I. Mgbakor[2], A. Abutu[3], D. Ogundehin[4], C. Onyenuobi[2], C. Nzelu[5]

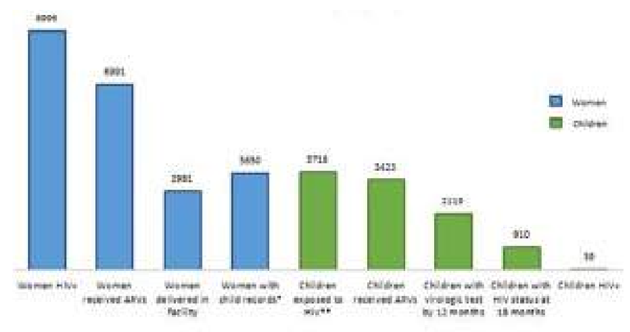
[1]Northrop Grumman (Centers for Disease Control and Prevention Contractor), Atlanta, United States, [2]Centers for Disease Control and Prevention, Abuja, Nigeria, [3]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [4]United States Agency for International Development, Abuja, Nigeria, [5]Federal Ministry of Health, Abuja, Nigeria

Background: Nigeria expanded its prevention of mother-to-child transmission of HIV (PMTCT) program threefold from 2012-2014. We examined the cascade of PMTCT services for HIV-positive women and their HIV-exposed infants (HEIs) post expansion to assess program effectiveness.

Methods: A retrospective study was conducted in a stratified cluster sample of HIV-positive women presenting for antenatal, delivery, and/or postpartum services in 2014-2015, followed through 2017. We randomly selected 114 facilities within 12 states (two high HIV prevalence states per region) and three levels of care. Weighted frequencies and 95% confidence intervals (CI) adjusted for within-facility correlation were calculated for steps along the cascade. Factors associated with child HIV positivity were determined using multiple logistic regression.

Results: Overall, 8,996 HIV-positive women were enrolled, of whom 6,991 (74.0%, 95% CI 68.2-79.7) received antiretroviral drugs (ARVs) for PMTCT and 2,981 (35.4%, 95% CI 30.6-40.3) delivered in facility. We found records for infants of 3,650 (40.4%, 95% CI 35.4-45.4) HIV-positive women. Including multiple births, 3,716 HEIs were identified, of whom 3,423 (91.7%, 95% CI 88.1-95.2) received ARVs. Final HIV status was defined by rapid test at 18 months or positive virologic test at any age. Of 910 (26.3%, 95% CI 16.3-36.3) HEIs with a final HIV status, 39 (3.8%, 95% CI 1.1-6.5) were positive. Children of women <25 years and primiparous women were less likely to be HIV-positive compared with children of women 25-34 and women who gave birth 2-3 times, respectively (adjusted odds ratio [AOR] 0.24, 95% CI 0.08-0.71; AOR 0.15, 95% CI 0.04-0.59). Children who did not receive ARVs after birth were more likely to be HIV-positive (AOR 4.88, 95% CI 1.27-18.71). Timing of women's HIV diagnosis was not significantly associated with child positivity.

Conclusions: One in four women eligible for PMTCT did not receive ARVs to reduce HIV transmission risk. Although 3.8% positivity among HEIs with final HIV status is within the elimination of mother-to-child transmission target of <5%, most HEIs did not have a final status due to tests not being done or documented. Poor linkage between mother and child highlights the need to improve recordkeeping and patient follow-up.



[Number of patients along the PMTCT cascade 114 facilities in 12 states, Nigeria, 2014-2015]

THPEC236

Progress towards UNAIDS goals by 2020 in Ukraine at 01.01.2017

L. Legkostup[1], I. Kuzin[1], L. Hetman[1], O. Mishchenko[1], I. Chybisova[2], O. Naduta-Skrynnyk[1]

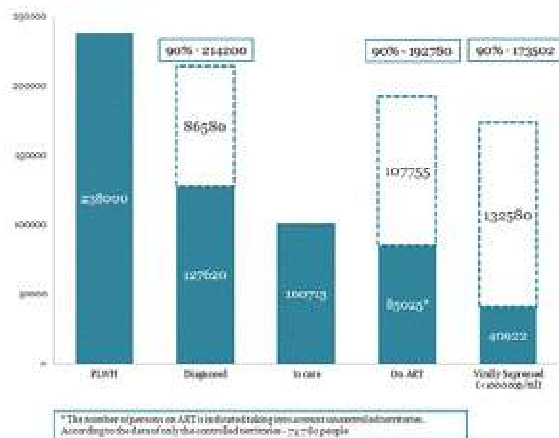
[1]State Institution 'Public Health Center of the Ministry of Health of Ukraine', Kyiv, Ukraine, [2]Ministry of Healthcare of Ukraine, Kyiv, Ukraine

Background: Ukraine has adopted the UNAIDS goals to achieve 90/90/90 by 2020, 90% of people living with HIV (PLWH) will be tested, 90% of those tested receive antiretroviral treatment (ART), 90% of ART-treated patients have viral suppression (VL). The cascade of HIV services plays a key role in achieving the goals. It is the crucial factor for assessing the progress in the implementation of national programs related to reducing the HIV incidence and mortality rate, as well as for tailoring the measures in place and planning for the future periods.

Methods: Estimated data as of January 1, 2017 was obtained with the aid of Spectrum software. Indicators for testing, treatment, and laboratory diagnostics of VL were provided by the national official statistical reporting from 25 regions of Ukraine, except for the non-government controlled area (Donbass region, the Autonomous Republic of Crimea, and the city of Sevastopol).

Results: As of January 1, 2017, the estimated number of PLWH in Ukraine was 238,000. 127,620 of HIV patients (54% of the PLWH) were under medical supervision. The ratio between estimated and actual data of the PLWH number is 1.86: 1, that is, each second HIV person in Ukraine was registered in medical records. Actively monitored PLWH - 100 713 (42% of the PLWH). 85,025 of HIV persons received ART (36% of the estimated number of PLWH). 40 922 PLHIV (17% of the estimated number of PLWH) reached HN < 40 RNA copies/ml. The virological efficacy of treatment from those receiving ART was 80.2%.

Conclusions: Cascade analysis reflects systemic failures in achieving all three 90%. The cascade demonstrates the gap between the coverage of HIV testing and the involvement of people with HIV in the ART programs. The proportion of people with VL remains low. Analysis data are used as arguments for resource allocation, in strategic decisions to strengthen preventive programs, medical services, as well as care and support services. Data also enable programs to be expanded further in those areas that are most in need in order to achieve UNAIDS goals.



[HIV Care Cascade in Ukraine, 01.01.2017]

THPEC237

Higher CD4 count at ART initiation predicts increased viral suppression during universal test and treat in a South African clinic

J. Dorward[1], P.K. Drain[2], F. Osman[1], T. Hong[2], J. Quame-Amaglo[2], K. Ramsaroop[1], F. Sayed[1], Y. Sookrajh[3], A. Olowolagba[3], N. Garrett[1,4]

[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [2]University of Washington, Departments of Global Health, Medicine and Epidemiology, Schools of Medicine and Public Health, Seattle, United States, [3]Prince Cyril Zulu Communicable Disease Center, Ethekwini Municipality, Durban, South Africa, [4]University of Kwazulu-Natal, Discipline of Public Health Medicine, School of Nursing and Public Health, Durban, South Africa

Background: In the context of universal test and treat (UTT) there is little data on viral outcomes amongst patients newly eligible for antiretroviral therapy (ART) at higher CD4 counts. We assessed the relationship between initiation CD4 count and subsequent viral load (VL) suppression, in a South African public sector clinic which implemented national UTT guidelines in September 2016.

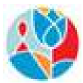
Methods: This was an analysis of baseline data at enrolment into a randomised trial of point-of-care VL testing. Eligible participants were non-pregnant, HIV-positive adults who were enrolled at six months after first-line ART initiation, at which point VL testing was performed. Association between a suppressed six month VL < 40 copies/ml and CD4 count at ART initiation, and potential sociodemographic and clinical confounders, were assessed using logistic regression, adjusted for study arm.

Results: Of 390 participants enrolled between February to August 2017, 60% were female and median age was 32 years [interquartile range (IQR) 27-38]. At ART initiation, median CD4 count was 366 cells/mm³ (IQR 204-546), and 30% had a CD4 >500 cells/mm³, with 99% receiving tenofovir, emtricitabine and efavirenz. Amongst 388 participants with VL available for analysis, 86% (95% confidence interval 83-89%) had a VL <40 copies/ml six months after ART initiation. In univariable analysis, age, gender, time from HIV diagnosis to ART initiation, previous ART exposure, intimate partner violence (women participants only), positive depression screen or alcohol use were not associated with VL results (p-values >0.1). An association between previous TB and a detectable VL was partially confounded by initiation CD4 count. In both univariable and multivariable analyses patients with initiation CD4 count >500 cells/mm³ had over 6 times higher odds of achieving VL suppression compared to those initiated at ≤200 cells/mm³ (Table).

Characteristic		VL < 40 copies/ml, n/N (%)	Odds ratio*	95% Confidence Interval	P-value	Adjusted odds ratio*†	95% Confidence Interval	P-value
Age (years)	18-35	219/249 (88)	1			1		
	> 35	116/139 (84)	0.69	0.38-1.24	0.216	0.79	0.42-1.49	0.391
Previous TB	No	291/329 (88)	1			1		
	Yes	44/59 (75)	0.35	0.17-0.69	0.003	0.45	0.21-0.95	0.037
Initiation CD4 count (cells/mm³)	≤ 200	67/92 (73)	1			1		
	201-350	72/88 (82)	1.54	0.75-3.16	0.243	1.29	0.61-2.71	0.509
	351-500	85/92 (92)	4.17	1.69-10.31	0.002	3.80	1.52-9.48	0.004
	>500	111/116 (96)	8.00	2.91-21.99	<0.001	6.84	2.45-19.09	<0.001

*[Table. Associations between age, previous TB, initiation CD4 count & VL <40 copies/ml, *adjusted for study arm, †and all other variables in table, N=388]*

Conclusions: After introduction of UTT in a South African clinic, less than 90% of patients achieved VL suppression after six months on ART. While VL suppression was high amongst those who initiated with greater CD4 counts, suppression rates were much lower amongst more immunocompromised patients and those with a history of TB. As UTT implementation continues, these patients may require increased VL monitoring and adherence support to achieve 90-90-90.



THPEC238

Evaluation of attrition between HIV testing and initiation of antiretroviral therapy among the newly diagnosed people living in the "test and treat" strategy

V. Chitiyo[1], K. Webb[1], T. Maphosa[1], P. Nesara[1], S. Page-Mtongwiza[1], P. Mawora[2], T. Moga[2], T.A. Tafuma[2], B. Engelsmann[1]
[1]*Organisation for Public Health Interventions and Development, Harare, Zimbabwe,* [2]*FHI 360, Harare, Zimbabwe*

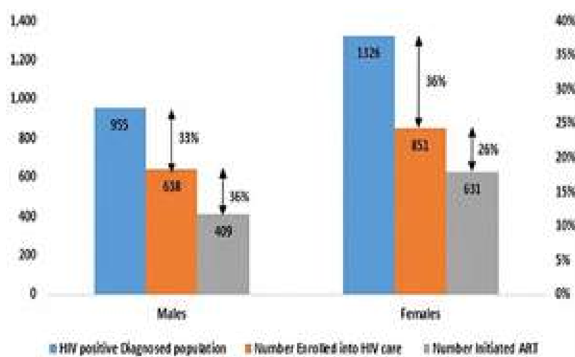
Background: 2015 WHO guidelines recommended immediate HIV treatment for individuals diagnosed HIV positive, "test and treat" strategy. These were widely adopted across countries aiming to reduce progression of disease and risk of HIV transmission.

Linking PLHIV to care and treatment is a key bottleneck to achieving desired outcomes. Attrition was often attributed to lengthy and complicated processes where treatment eligibility was based on specific thresholds of HIV disease progression, e.g. CD4< 350 cells/µl.

The objective of the assessment was to quantify attrition along the new HIV cascade of "test and treat" strategy.

Methods: Purposively sampled 13 health facilities in six districts through collaboration between facility-based and community-based Zimbabwe HIV Care and Treatment programs supporting MOHCC HIV care and treatment program. Secondary program data for newly diagnosed HIV positives between September-December 2016 in Manicaland and December 2016 to March 2017 in Midlands province when "test and treat" was adopted were abstracted and analysed. We examined documented access to HIV services at-least three months after positive diagnosis.

Results: 2297, PLHIV were newly diagnosed and comprised of 101 (4%) children < 15 years and 2183 (95%) adults 15+ years. Attrition was highest between testing and HIV care, 35% (798/2297) and 27% (403/1096) between HIV care services and ART initiation. While there was no significant difference in the losses of PLHIV from testing to enrolment into care by gender, a significantly higher proportion of men were lost between enrolment into care and ART initiation compared to women, 36% vs 26%, p=0.0007.



[Attrition along HIV care and treatment cascade of a Cohort of clients at 13 health facilities]

Conclusions: Although, the "test and treat" strategy simplified and shortened processes of getting HIV treatment, the evaluation demonstrated pervasive attrition along the HIV cascade. As HIV treatment program expands, it is imperative that linkages be strengthened specifically between testing and enrolment in care, as this initial step into HIV treatment is crucial for second and third 90s.

THPEC239

Progress in achievement 90-90-90 in Armenia

S. Grigoryan, A. Papoyan, T. Grigoryan
National Center for AIDS Prevention, Yerevan, Armenia

Background: Creation of prerequisites for achieving the UN 90-90-90s and ending the AIDS epidemic by 2030 are implied by the overall goal of the National AIDS Programme for 2017-2021. Existing level of outbound migration, gaps in reaching key populations by testing, late diagnosis of HIV remain significant challenges today. Calculation of HIV Treatment Cascade, comparative analysis of its changes occurred over the recent years allow assessing possible influence of the implemented activities at different stages of the treatment cascade, identifying weaknesses and gaps in the sequential steps starting from HIV-positive diagnosis to provision of effective ART.

Methods: The HIV treatment cascade was built using the data on estimated number of PLHIV, programmatic data on number of people with HIV knowing their status, on those linked to HIV care, those received ART and those achieved viral suppression. The cascade indicators for 2014-2016 were compared to show the trends.

Results: The treatment cascade analysis showed that percentage of PLHIV who know their status increased from 38.3% in 2014 to 60% in 2016, of those linked to HIV care - from 86.8% in 2014 to 91% in 2016, percentage of PLHIV on ART - from 48.4% in 2014 to 59.7% in 2016.

In 2016 number of PLHIV on ART increased sharply due to change in criteria of eligibility for ART initiating from CD4 count ≤350 cells/mm^3 to ≤500 cells/mm^3. Indicator of ART efficacy, viral load suppression, remained at high level, making up more than 80% in 2014-2016.

Conclusions: There is a significant increase in indicator of PLHIV who know their status, but for attaining the first 90s there is need to enlarging coverage of targeted testing, increasing number of those seeking HIV services, including extension of routinely offered HIV testing in health care facilities, as well as scaling up testing among outbound labour migrants and other key populations.

In July 2017 Armenia adopted new HIV/AIDS Treatment Guidelines comprising the «Treat All» strategy. However, prospective impact the outbound migration high level on treatment and adherence causes difficulties in reaching the UN 90-90-90 targets, which could be addressed by coordinated actions of host and originating countries.

THPEC240

Nepal's progress towards 90-90-90 targets by 2020: The case of HIV care cascade

K. Deuba[1,2], U. Shrestha[1], B. Rawal[3], R. Khanal[1], B.D. Pandey[3], R.K. Bhattarai[4], R. Shrestha[5], A.M. Ekstrom[2,6]
[1]*National Centre for AIDS and STD Control/ Global Fund Programs, Kathmandu, Nepal,* [2]*Karolinska Institutet, Department of Public Health Sciences, Stockholm, Sweden,* [3]*National Centre for AIDS and STD Control, Ministry of Health, Kathmandu, Nepal,* [4]*Save the Children, Kathmandu, Nepal,* [5]*Public Health and Environment Research Centre, Lalitpur, Nepal,* [6]*Karolinska University Hospital, Department of Infectious Diseases, Stockholm, Sweden*

Background: Measuring progress towards the HIV care cascade provides an opportunity for modifying the response to achieve UNAIDS 90-90-90 targets by 2020.

This study assesses progress in the HIV care cascade among people living with HIV (PLHIV) in Nepal and subgroups analyses by sex. We also conducted a cohort analysis of mortality, retention and loss to follow-up (LTFU) over time.

Methods: We estimated the number of PLHIV in the country using mathematical modelling (Estimation and Projection Package/Spectrum). Routine program data of 2016 from 68 antiretroviral therapy (ART) centres were used to calculate progress in different steps of the cascade.

For cohort analysis, we analysed data between 2012 and 2016. Retention in treatment was defined as the percentage of PLHIV alive and on ART at 12, 24, 36 and 60 months following ART initiation. LTFU was defined as those who have not visited the ART centre for at least 90 days.

Results: Of the total estimated number of PLHIV (32735) in 2016, 62% were men, and 38% were women. Almost 55% of the total estimated PLHIV [men: 56% (11241/20232) and women 55% (6889/12503)] were alive and linked to HIV care by the end of 2016. Only 40% PLHIV were on ART and significantly fewer men [34% (6790/20232) than women [50% (6289/12503)]. Of the total estimated PLHIV, only 19% had been tested for viral load, and 17% remained virologically suppressed. Retention on ART was 88%, 83%, 76% and 73% at 12, 24, 36 and 60 months respectively, and higher among women than among men (at 12 months: 90% vs 78% and at 60 months: 82% vs 66%). The LTFU rate increased from 5% at 12 months to 12% at 60 months. Similarly, the mortality rates sharply rose from 7% at 12 months to 15% at 60 months.

Conclusions: To achieve the 90-90-90 targets by 2020, more efforts are needed to identify PLHIV who are not aware of their status, linking them to treatment and improving access to viral load testing. Interventions to address gender differences in the engagement of the HIV care cascade, mortality rates and LTFU need to be prioritized and implemented in Nepal.

THPEC241

HIV treatment cascade among MSM in Brazil

I. Prado[1], C.R.d.S. Barros[2], I. Dourado[3], L. Magno[4], M.D.C. Guimarães[5], C. Kendall[6], L. Kerr[7], R.M.S. Mota[8,9], L. Fernando de Macedo Brigido[10], M.A. Veras[11], the Brazilian MSM Group
[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, Collective Health Department, São Paulo, Brazil, [2]Universidade Católica de Santos, Santos, Brazil, [3]Federal University of Bahia, Collective Health Institute, Salvador, Brazil, [4]Universidade do Estado da Bahia, Departamento de Ciências da Vida, Salvador, Brazil, [5]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [6]Tulane University, Global Community Health and Behavioral Sciences, New Orleans, United States, [7]Universidade Federal do Ceará, Departamento de Saúde Comunitária, Fortaleza, Brazil, [8]Universidade Federal do Ceará, Fortaleza, Brazil, [9]Universidade Estadual do Ceará, Fortaleza, Brazil, [10]Instituto Adolfo Lutz, São Paulo, Brazil, [11]Faculdade de Ciências Médicas da Santa Casa de São Paulo, São Paulo, Brazil

Background: Brazil ratified UNAIDS 2030 Agenda for Sustainable Development. However, data about HIV among MSM appear to be moving in the opposite direction, and it is imperative to identify gaps in the MSM HIV continuum of care. We analyzed the cascade among MSM in Brazil and estimated factors associated with two stages: previous diagnosis (HIV Awareness) and viral suppression.

Methods: Cross sectional study of 4,176 MSM, conducted in 12 Brazilian cities in 2016, using respondent driven sampling. Participants were interviewed and tested for HIV. The cascade was defined as:
1) diagnosis (HIV test results in the study, and self-reported HIV positive status),
2) self-reported ART use,
3) viral suppression (viral load ≤ 50 copies/mL).
Statistical analysis was carried out using complex sampling design procedures. Poisson regression was used to estimate factors associated with "HIV awareness" and "Viral Suppression". Prevalence rate ratio (PRR) with 95% confidence interval (CI) was calculated.

Results: Overall HIV prevalence was 18% and 44% of the participants were unaware of their positive serostatus before the study, representing the biggest gap in the care continuum. Only 18% of HIV positive young men (18-20 years) were previously diagnosed, while older MSM (51-67 years) had higher HIV infection awareness (87%), (PRR 1.9 [95%CI 1.1-3.4]). MSM self-identified as Black had the lowest HIV awareness (50%). Among the participants testing positive before the study, 98% were taking ART, and in this group the proportion of viral suppression was 74%. Only 8.6% of the participants with the lowest education level were virally suppressed, while 90% of those with college education had viral load < 50 copies/mL (PRR 8.6 [95%CI 1.4-50.9]).

Conclusions: The biggest challenge for the HIV continuum of care for MSM in Brazil was testing for HIV, suggesting deficits in promotion and potential barriers to access. In contrast, use of ART among HIV positive MSM and its effectiveness was high. The association between level of education and viral suppression may reflect the extreme inequalities prevailing in the country, emphasizing the importance of the structural interventions in UNAIDS Agenda to end the epidemic.

THPEC242

Patterns of retention of mothers and their children in an HIV/ART clinic in Southern Mozambique: Evidence to support a family-centered care model

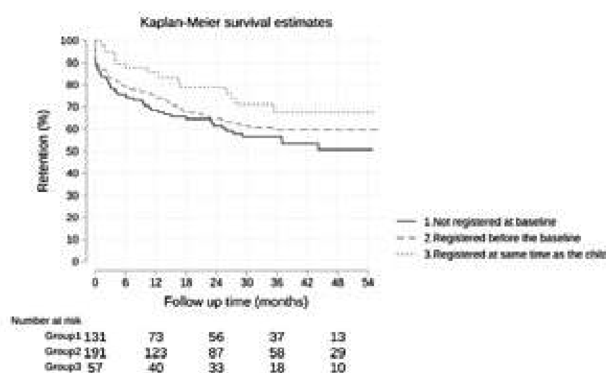
E. Lopez-Varela[1,2], T. Nhampossa[2], L. de la Fuente Soro[1], S. Maculuve[2], S. Fernandez[2], E. Bernanrdo[2], W.C. Buck[3], O. Augusto[2], D. Naniche[2]
[1]Barcelona Institute for Global Health, Barcelona, Mozambique, [2]Manhiça Health Research Center, Manhiça, Mozambique, [3]University of California, Department of Pediatrics, Los Angeles, United States

Background: For HIV infected children, adherence to care is determined largely by their caregivers. It is often assumed those children and their caregivers either stay in care together or abandon together, but few studies have actually evaluated this. We sought to describe the pattern of care among a cohort of HIV infected children and mothers enrolled in care at the Manhiça District Hospital (MDH), Southern Mozambique.

Methods: This was a retrospective review of routine HIV clinical data collected for children enrolled in an open prospective HIV cohort at the MDH. Children initiating HIV care from February 2013 to November 2015 who had been followed up for at least 12 months at the time of the study were included and their mother´s clinical data extracted. Retention in care was estimated 12 months after first consultation for children (baseline). We used Kaplan-Meier estimates and Fine and Grey competing risks models to estimate the effect of mother´s pattern of care in their child´s LTFU.

Results: A total of 395 children initiated HIV care during the study period. At baseline, 34.6% of the mothers had never enrolled in care, 15% had initiated care at the same time as their child and 50.4% had initiated care before their child, of whom 57% were lost to follow-up (LTFU). Fifty-four % children were female and the median age was 3.0 years (IQR:1.0-9.0). Median CD4 was lower for children born to mothers LTFU (676 cells/mm3) as compared to mothers retained or initiating at the same time (850 and 864, respectively p=0.034). One year after baseline, 77.1% of children were retained in care (95%CI 71.9-.81.5). LTFU was less likely among children of mothers initiating care at the same time as compared to children whose mothers had never initiated care (sub-distribution hazard ratio 0.57, 95% CI 0.33-0.99, p=0.045).

Conclusions: The overall low retention rates suggest the need for family-centered care models that facilitate enrollment and re-engagement in care of both mothers and children in order to improve their health outcomes.



[Figure: Cumulative incidence of children´s LTFU in the first 12 months of HIV care according to mother's engagement in care at baseline]

Second line ART switching in Mozambique: Coverage and time line

A. Torrens[1], J. Rodo[1], L. Molfino[1], C. da Silva[1], G. Ferrario[1], L. Haldna[2]
[1]Medecins Sans Frontieres, Maputo, Mozambique, [2]Medecins Sans Frontieres-Belgique, Maputo, Mozambique

Background: For HIV patients failing on first line treatment, switching to second line ART can be crucial for treatment success. In Mozambique, during the time of this study, all second line ART switching of suspected therapeutic failure cases had to be approved by the National or an autonomous Provincial ART Committee. The purpose of this analyzes is to determine the percentage of patients with virological failure (two viral loads ≥ 1000 cp/mL) who were submitted to the ART committee, approved to switch and that effectively switched to 2ndline ART, and the time it took for each one of these steps to occur.

Methods: A retrospective cohort study design with routine program data was used. The study was conducted between October 2013 and March 2016 in 18 MSF supported health centers of Maputo and Tete, including a referral center for HIV treatment - CRAM in Maputo, where routine VL was implemented. All eligible patients with 2 high viral loads (≥ 1000 cp/mL) were included in the study. Standard descriptive statistics were used to report all results.

Results: Among 1,934 ART patients with two high viral loads, only 37% were referred to the ART Committee. Of these, 96% were approved for switching to a 2nd line ART and 71% switched regimens. Effectively, 27% of all patients with virologic failure switched to 2nd line ART. The median of days between: the 2nd high VL sample collection date and referral to the ART Committee was 183 days; referral to the ART Committee and approval was 5 days and approval by the ART Committee and switch to 2nd line was 28 days. The whole cascade of 2nd line switch lasted a median of 216 days. Results differ between health centers of Maputo, Tete and CRAM.

Conclusions: These results highlight the complexity and delay in switching patients with 1st line treatment failure to 2nd line regimens. The referral of patients to the ART Committee is challenging and access to second-line ART is low. Factors contributing towards these values include a resistance of the clinician to switch patients, stock out of 2nd line drugs and lost to follow up, among others.

Estimating the need for ART and other clinical services

THPEC244

Occupational blood exposure (OBE), seroconversion and coinfection HIV/HBV in CAR

D. Mossoro-Kpinde[1], D.C. Mossoro-Kpinde[2], C.E. Gaunefet[3]
[1]Paediatrics Complex, Bangui, Health, Bangui, Central African Republic, [2]Laboratoire National de Biologie Clinique et de Santé Publique, Health, Bangui, Central African Republic, [3]Hôpital Communautaire de Bangui, Health, Bangui, Central African Republic

Background: CAR has been heavily affected by HIV (4.9%) hepatitis B (15%) and C (8%), but has not yet developed a prevention plan against OBE, even though its health care staff, already low in numbers, is overwhelmed by a massive patient load. This study aims to assess the current OBE situation and develop a national plan for the management of these accidents.

Methods: A study was conducted in 2017 amongst health care facilities groups in Bangui. The parameters being studied were collected using a standard form including serological status for HIV, HBV and HCV, vaccination against hepatitis B, incidents of OBE and their subsequent management.

Results: Three hundred members of the health care staff were included in the study. 18,4% had been vaccinated against hepatitis B. Thirty six percent (36%) had already been tested for HIV, with 7.3% of the tests performed within the last three months. Fifty four percent (54%) cited an incident of OBE within the last six months. Sixty eight percent (68%) of these were from accidental needle stick injuries. At the time of the accident, 39.9% knew their HIV serological status, and 22% their HBV status. Three percent had been vaccinated against hepatitis B. Three per cent (3%) of the accidents received subsequent care. The post-OBE care management did not cover hepatitis B. Among them one showed documented seroconversion for HIV despite post exposure treatment. The victim was a carrier of HBV before the accident, which placed her directly in the category of HBV-co-infected persons and HIV, which makes treatment more difficult.

Conclusions: There is a high prevalence of OBEs in the sites studied. The number of health care staff receiving subsequent care is low. Five years after the introduction of OBE surveil, we are facing the first documented seroconversion. How many other occupational seroconversions are ignored In addition, this observation highlights the protection of healthcare workers and the establishment of mechanisms for compensating and managing staff against OBE.

Expanding the HIV care cascade

THPEC245

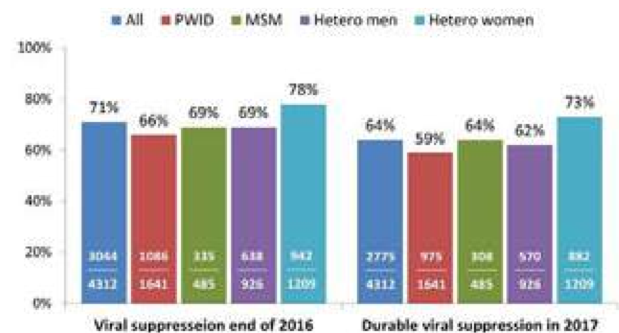
Durability of viral suppression in the Eastern European country of Georgia

N. Chkhartishvili[1], E. Karkashadze[1], O. Chokoshvili[1], N. Dvali[1], A. Abutidze[1], T. Tsertsvadze[1,2]
[1]Infectious Diseases, AIDS & Clinical Immunology Research Center, Tbilisi, Georgia, [2]Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia

Background: HIV care continuum provides cross-sectional snapshot of population level viral suppression and does not capture changes in viral load dynamics. Proportion of persons with viral suppression may substantially fluctuate even in short period of time. We assessed durability of viral suppression over one year period among persons diagnosed with HIV in the Eastern European country of Georgia.

Methods: Standard of HIV care in Georgia includes antiretroviral therapy (ART) regardless of CD4 cell count and 4-6-monthly viral load monitoring. We calculated number and percentage of persons with viral suppression from the end of 2016 through the end of 2017. Viral suppression was defined as viral load < 1000 copies/ml. Analysis included all adult (age ≥18 years) cases of HIV diagnosed through the end of 2016, who were known to be alive by the end of 2017. Data were extracted from the national AIDS health information system.

Results: Among 4312 persons with diagnosed HIV, 3044 (71%) had viral load suppressed at the end of 2016 and 3046 (71%) - at the end of 2017. Over 2017, 269 (6%) persons reverted from suppressed to detectable and 271 (6%) improved from undetectable to suppressed. A total of 2775 (64%) persons maintained viral suppression through the end of 2017 translating into 10% relative difference compared to a single viral load measure. Analysis by transmission categories showed that heterosexually infected women had the highest rates of viral suppression (figure). Of 1537 persons without durable viral suppression, 326 (21%) had at least one episode of viral suppression in 2017, 415 (27%) were in care, but did not achieve viral suppression in 2017 and 796 (52%) were fully disengaged from care.



[Proportion of diagnosed persons with viral suppression]

Conclusions: 91% of persons with initial viral suppression maintained it over 2017. Single viral load measure overestimated durable viral suppression by 10%. Majority of unsuppressed cases are due to disengagement from care. Efforts are needed to ensure high retention and treatment uptake.

THPEC246

The role of access to HIV services at opioid antagonist treatment sites in reaching 90-90-90 in people who inject drugs in Ukraine: Country-level data

A. Meteliuk[1], T. Prokhorova[1], S. Filippovych[1], O. Iakunchykova[2]
[1]Alliance for Public Health in Ukraine, Kyiv, Ukraine, [2]Public Health Center of Ministry of Health of Ukraine, Kyiv, Ukraine

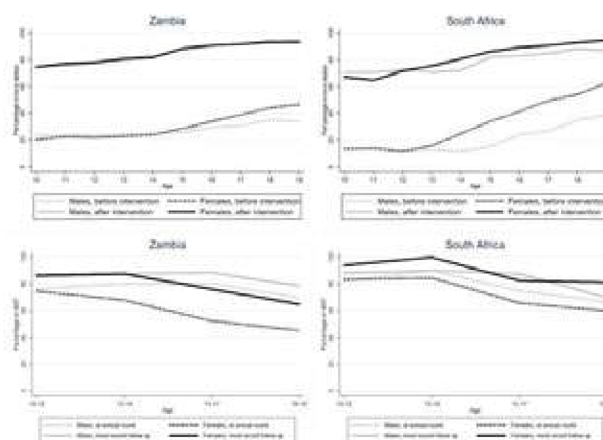
Background: Opioid antagonist treatment (OAT) is an effective means to prevent HIV transmission. Recently, Ukraine started integrating HIV services into OAT sites to improve PWID access to treatment.
Methods: National register of OAT patients (n=10,053) managed by the Alliance for Public Health was analyzed. These data are quarterly collected from all 179 OAT sites throughout Ukraine and entered into SYREX database. For building the cascade, HIV-positive OAT patients (n=4,084) were stratified into two categories: 'OAT alone site' (those who receive their OAT medication at one site and ART at different location, n=1,598) and 'integrated care site' (patients who receive both OAT medication and ART at one location, n=2,486) for comparison. The HIV cascade categories were: (1) proportion of HIV-positive OAT patients linked to HIV care; (2) proportion of them receiving ART; and (3) proportion of them virally suppressed (viral load< 75 copies) stratified by the type of site. Chi-square tests were performed to assess the associations between the variables.
Results: Majority of HIV-positive OAT patients in Ukraine are male (74.1%); mean age is 40 years old (range: 23-64); mean length of injecting before starting OAT-18 years (range:1-47); mean length on OAT 2.9 years (range: less than a year-12 years). Even though all of the HIV-positive OAT clients are aware of their HIV status, progress along the cascade was greater in the 'integrated care sites' stratum compared to the 'OAT alone site'. The proportion of HIV-positive clients who received ART was higher at an integrated care sites (84%) compared to 73% at OAT alone sites; and the distribution of viral suppression among those who receive ART across the strata were 79 and 59% for 'integrated care sites' and 'OAT only sites' respectively. The bivariate analysis showed statistically significant associations between all the variables of interest (p< 0.05).
Conclusions: The results of the analyses clearly demonstrate much better results in reaching the 90-90-90 goals among those OAT patients who receive integrated care services (both OAT and ART) at one site at each stage of HIV cascade, thus there is an urgent need in further expansion of integrating OAT and HIV services in Ukraine.

THPEC247

HIV care cascade among adolescents in a ´test and treat´ community based intervention in Zambia and South Africa: HPTN071 (PopART) for Youth study

K. Shanaube[1], D. Macleod[2], J. Mwate Chaila[1], G. Hoddinott[3], A. Schaap[1,2], S. Floyd[2], C. Mackworth-Young[1,2], P. Bock[3], R. Hayes[2], S. Fidler[4], H. Ayles[1,2], HPTN071 (PopART) Study Team
[1]Zambart, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Desmond Tutu TB Centre, Stellenbosch University, Pediatrics and Child Health, Cape Town, South Africa, [4]Imperial College, London, United Kingdom

Background: Adolescents have worse outcomes across the HIV care cascade compared to adults. Dropouts at each stage of the cascade lead to poor individual health outcomes and pose challenges for 'test and treat' efforts. The PopART for Youth (P-ART-Y) study is nested within the HPTN071 (PopART) trial, a 3-arm community randomized study in 21 communities in Zambia and South Africa (SA).
The P-ART-Y study aims to evaluate the acceptability and uptake of an HIV prevention package, including universal HIV testing and treatment (UTT), among young people. We report the HIV care cascade for adolescents aged 10-19 years from 7 Arm A intervention communities in Zambia and SA.
Methods: Using a door-to-door approach that included systematically visiting and re-visiting households, across entire communities, all adolescents enumerated were offered participation in the intervention and verbal consent was obtained. Data analysed were collected from September 2016 to December 2017, covering the third round (R3) of the PopART intervention.
Results: Overall, we enumerated 60,515 adolescents (Zambia: 45,271, SA: 15,244). Participation was lower among males. Of all offered HIV testing, 78.8% accepted in Zambia and 70.9% in SA. Knowledge of HIV status was associated with age and increased from 30.6% to 87.5% after the intervention in Zambia and from 29.5% to 81.6% in SA. The intervention closed the gap in HIV-status knowledge between males and females (figure 1). Overall, 774 adolescents were HIV-positive (222 new diagnoses and 552 self-reported), the majority of new diagnoses (144) being females aged 17-19 years. Among the 774 HIV-positives, 64.6% (62.7% in Zambia and 70.3% in SA) reported being on ART at the time they were first seen in R3. Among newly diagnosed and self-reported HIV-positive, median time to initiate ART was 5 months in Zambia and 3 months in SA. At the last follow-up, ART coverage had increased to 78.5% and 85.1% in Zambia and SA respectively, with differences observed by sex (figure 1). Self-reported ART retention was high (approximately 95%).
Conclusions: Despite increased attention to adolescent HIV, gaps remain in the HIV care cascade by age and sex. Differentiated models of care and UTT can help close identified gaps.



[Figure 1: Proportion of adolescents who know their HIV status pre and post intervention & proportion of known positives on ART stratified]

THPEC248

Prior incarceration associated with missed HIV care visits among young people living with HIV in the US

C. Ludema[1], C. Wilson[2], M.A. Lally[3], J.D. Fortenberry[4]
[1]Indiana University, Epidemiology and Biostatistics, Bloomington, United States, [2]University of Alabama Birmingham School of Medicine, Epidemiology, Birmingham, United States, [3]Lifespan Hospital Systems and Alpert Medical School of Brown University, Providence, United States, [4]Indiana University School of Medicine, Adolescent Medicine, Indianapolis, United States

Background: Maintenance in HIV care is important to achieve optimal personal health and HIV viral load suppression for young people living with HIV (PLWH). Prior studies have identified incarceration as a risk factor for poor long-term HIV outcomes. We assessed the relationship between incarceration and missed visits among young PLWH in the US.
Methods: Longitudinal data were collected on a cohort of PLWH (n=924), ages 12-24, from 14 adolescent trial network sites across the US. Incarceration histories were self-reported, missed HIV care appointments and viral load measurements were ascertained by records review. The time from study entry to missed visits was modeled using Cox proportional hazards models.

Results: The cohort was mostly male (78%) and African American (75%) with a median age of 22 (IQR: 20-23). Prior incarceration (i.e., being put in jail, prison, or juvenile detention, or held overnight after an arrest) had been experienced by 40% of the cohort, with a median number of times incarcerated of 2 (IQR: 1-3).
The hazard ratio for missed HIV care visits comparing those with incarceration histories to those without was 1.28 (95% CI: 1.06, 1.54). After adjustment for study site, age, gender, and race the hazard ratio was 1.46 (95% CI: 1.19, 1.79).
While time to re-connection to care after a missed visit did not differ between the two groups, HIV viral loads upon returning to care differed comparing those with incarceration history to those without (43% unsuppressed viral load (>200 copies/mL) versus 29%, p=0.03).

	With incarceration history	No incarceration history
VL ≥ 200 at enrollment*	105/289 (33%)	119/479 (25%)
Missed a scheduled visit	191/363 (53%)	257/561 (46%)
Returned to care	168/191 (88%)	222/257 (86%)
VL ≥ 200 on return to care*	45/105 (43%)	39/133 (29%)
*May not sum to total due to missing viral load measurements		

[Characteristics of cohort (n=924)]

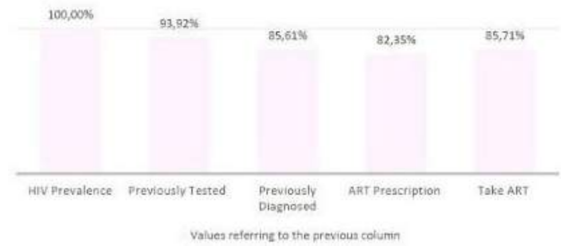
Conclusions: One mechanism by which incarceration may affect HIV viral load suppression is through missed HIV care visits. To achieve the goal of retaining young PLWH with incarceration histories in the HIV care cascade, programs to maintain regular HIV care through and following incarceration periods are needed.

THPEC249

HIV care cascade among transwomen living with HIV in São Paulo-Brazil

A. B M Rocha[1], E. C. Wilson[2], C. Turner[2], G. B. de Souza[1], I. Prado[1], M.A. M. Veras[1], Divas Project
[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, Public Health, São Paulo, Brazil, [2]San Francisco Department of Public Health, San Francisco, United States

Background: Transwomen bear a large burden of HIV worldwide and are a key population in the HIV epidemic whose prevention and care needs have largely been ignored. In Brazil, estimates suggest at least 30% of transwomen are living with HIV. Testing and treatment access are essential to reducing the impact of HIV on transwomen. This study was conducted to examine the HIV care cascade among transwomen in the most populous city in South America, São Paulo-Brazil.
Methods: Divas Project was a cross-sectional study conducted from November 2016 to May 2017 in São Paulo-City. Respondent driven sampling was used to recruit 386 transgender women (i.e., transwomen and travesits) who participated in a HIV risk survey and were tested for HIV. A multivariable Poisson regression model with robust variance was conducted to identify associations between socio-demographic factors (gender identity, race/ethnicity, education level, income, age, housing situation, health care service registration, and hormone use) and HIV treatment utilization.
Results: In total, 148 (38.34%) participants tested positive for HIV. Almost all had been previously tested for HIV (N=139/148,93.92%) and knew they were HIV positive at the time of the survey (N=119/148,85.61%). The majority of transwomen living with HIV had been prescribed ART (N=98,82.35%), of which 84(85.71%) took the medication. Those who were not registered in primary health care had a lower adjusted prevalence of being on ART compared to those who were registered (adjusted prevalence ratio, aPR:0.56,95%CI:0.32-0.98). Those who identified as transwomen had higher adjusted prevalence of being on ART compared to women (aPR:1.31,95%:1.02-1.68). Transwomen who were between 31-40 years old and those above 40 had a higher adjusted prevalence of being on ART (aPR:2.22,95%CI:1.23-4.00 and aPR:2.21,95%CI:1.22-3.98, respectively) compared to younger transwomen.
Conclusions: Over a third of transwomen in our sample were living with HIV, but most knew they were HIV-positive, were engaged in HIV care and taking ART. These data suggest successful testing and treatment policy implementation among transwomen in São Paulo-City. However, young transwomen and those not registered in health care service may benefit from multi-level efforts to engage this part of the population in care to improve HIV treatment and care outcomes.



[HIV Care Cascade Graph]

THPEC250

Community initiated treatment intervention (CITI) improves linkage to art for key populations

P. Smyrnov[1], I. Sazonova[2], K. Boiko[1], T. Mykhalchuk[2], O. Denisiuk[1]
[1]Alliance for Public Health, Kyiv, Ukraine, [2]Alliance for Public Health, Monitoring and Evaluation, Kyiv, Ukraine

Background: For many KPs knowing their HIV positive test result is not leading to ART initiation. Multiple barriers on personal and health system side delay life-saving treatment despite its availability.
Methods: Community initiated treatment intervention (CITI) facilitate immediate treatment access for active drug users and other KPs. This intervention is aimed to locate HIV positive clients, and their sexual partners and link them to HIV treatment using intensive need-based case management approach. CITI supports HIV positive clients up to 6 months into ART if no support was granted through other projects during CITI implementation (care and support, ST, integrated services). The case manager responsibilities include assessment of the clients' status, their needs and motivation; eliciting information on specific client's barriers to ART access; perform analysis of available resources and services; creating individual assistance plan; coordination of social and health services, representation of client's interests in health care institutions, monitoring of implementation of client progress through cascade. Program data are routinely collected for each HIV positive case on its progress through the cascade despite participation in the CITI. We have analyzed data from 2016 for 3,774 HIV positive cases detected in outreach. Out of them 2,034 received CITI support. We compared program data for clients who received CITI support and those who had standard referral to AIDS clinics.
Results: During 2016 out of all who received HIV positive test in outreach: 75% visited health facility, 53% have registered in care and 30% initiated ART. Participants who received CITI had significantly higher odds to visit health facility (OR=16.7, 95%CI:13.4 - 20.8), register in care (OR=5.4, 95%CI:4.7 - 6.2), initiate ART (OR=4.2, 95%CI:3.6 - 4.9). CITI group represented slightly older age group with mean age 37 (SD=7.7) in comparison with referral group mean age of 35 (SD=8.1). There was no difference between group in gender.
Conclusions: Based on program data CITI improves linkage to ART for HIV positive KPs and should be introduced as a standard practice to HIV programs among KPs to ensure 90-90-90 strategy.

THPEC251

Enhanced Peer Outreach Approach (EPOA): A quick way of reaching out to key populations, linkages project, Malawi

M. Ngulube, MSM Group
Center for the Development of the People, Lilongwe, Malawi

Background: The Centre for the Development of People (CEDEP), with support from FHI 360, has been implementing the USAID-funded LINKAGES project since 2015. In Malawi, the project reaches men who have sex with men (MSM) with HIV prevention, care, and treatment. At CEDEP, we noted that we were getting a lower HIV-positive yield than the na-

tional prevalence of 17.5% among MSM. We therefore sought to identify hard-to-reach MSM by piloting the Enhanced Peer Outreach Approach (EPOA).

Description: EPOA is a time-limited approach for improving access to HIV services for MSM never reached by the program. It uses existing social networks among MSM in the community, in which peers reach out to fellow MSM using coupons. Trained peer educators (PEs) identify other influential helpers called peer mobilizers (PMs), who facilitate the identification of fellow MSM and engage them to be tested for HIV and enroll in antiretroviral therapy (ART), if found HIV positive. Treatment defaulters are also brought in for ART. The peers identified by the PMs are requested to also become mobilizers, who help quickly expand reach to other eligible peers.

Lessons learned: Within two weeks of implementing EPOA, we broke into new MSM networks and identified more HIV-positive MSM. We distributed 881 coupons through 58 PMs, with 286 MSM returning their coupons and getting screened for eligibility. Ninety-three were tested for HIV for the first time; fourteen (15 percent) tested HIV positive and were linked to treatment (whereas the routine HIV-positive yield trend since the inception of the program has been between 4 and 6 percent). Among 180 repeat testers, three (1.7 percent) tested HIV positive. All recruited participants were also screened for STIs and gender-based violence. Previously, using the peer educators model, it was not possible to reach such a large number of MSM in a two-week period, except during social events. Additionally, MSM diagnosed HIV positive took much longer to be initiated on treatment.

Conclusions/Next steps: EPOA is playing a significant role in increasing the identification of new MSM, case detection, treatment initiation, STI screening, violence screening, and linkage to services.

THPEC252

Higher HIV testing yield and lower linkage to treatment among selected key populations compared to general population in mixed epidemics: Evidence from PEPFAR program data Oct 2016 - Sep 2017

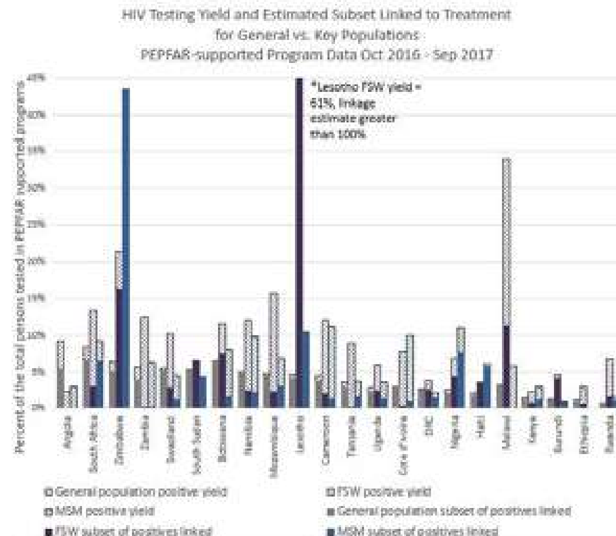
T. Lim[1], P. Vinayak[2], M. Au[3], S. Mital[1]
[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV & Tuberculosis, Atlanta, United States, [2]PricewaterhouseCoopers, Public Sector LLP, Washington, United States, [3]United States Agency for International Development, Office of HIV/AIDS, Washington, United States

Background: Mixed epidemics are the confluence of elevated HIV prevalence among key populations (KP), including female sex workers (FSW) and men who have sex with men (MSM), within a generalized HIV epidemic. HIV programs may disproportionately target the general population (GP), even if HIV prevalence and barriers to services are much higher among KP. The extent of this disparity in the HIV treatment and prevention cascade has not been globally quantified across KP. PEPFAR is the largest bilateral funder of HIV programs globally and began collecting KP-disaggregated testing and treatment data in October 2016.

Methods: Program data on HIV testing and treatment are reported on a quarterly basis as site-level totals by all PEPFAR-supported partners. Standardized program indicators for HIV tests performed, HIV positive test results returned, and treatment naïve patients newly initiated on ART, are each disaggregated by KP type. For each country with a GP prevalence ≥1% and prevalence ≥5% in at least one KP, we calculated HIV testing yield as total positive tests divided by total tests performed. We estimated linkage to treatment as new patients initiated on ART divided by total positive tests for each population.

Results: In the countries that met inclusion criteria (n=22), 31% of testing partners and 37% of treatment partners, respectively, reported KP type disaggregates. Median GP testing yield was 4.0%. FSW had higher HIV testing yield in 21/22 countries (median 4.8% absolute higher yield overall) and MSM in 16/20 countries (median 1.5% absolute higher yield overall). Median GP linkage was 86.7%. FSW had lower linkage to treatment in 16/22 countries (median linkage 39.6%) and MSM in in 15/18 countries (median linkage 57.0%).

Conclusions: The elevated HIV testing yield for KP is consistent with findings of higher prevalence among KP and highlights need for targeted testing strategies. The lower linkage to treatment in PEPFAR programs could be due to underreporting of KP status disaggregation in treatment results, at sites where stigma may discourage disclosure of KP status or treatment initiation altogether. PEPFAR should continue to improve reporting of KP-specific data to highlight and respond to service delivery gaps for KPs.



[Figure 1. HIV positive testing yield (hashed bars), and the subset of which are estimated to be linked to HIV treatment initiation (solid bars), across PEPFAR-supported countries with mixed HIV epidemics among the general population, female sex workers (purple), and/or men who have sex with men (blue)]

THPEC253

Data from large electronic medical record dataset reveal significant improvements and gaps in HIV treatment cascade in Ukraine

K. Dumchev[1], Y. Novak[2], O. Shestakovskyi[2], T. Saliuk[2]
[1]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [2]Alliance for Public Health, Kyiv, Ukraine

Background: Rapid expansion of ART, including implementation of 'Test-and-Start' approach, is a top priority for national HIV programs in Ukraine and globally. Key national stakeholders and international donors have set ambitious fast track goals to increase the number of patients from 88,270 on 01/01/2018 to 140,000 by the end of the year.

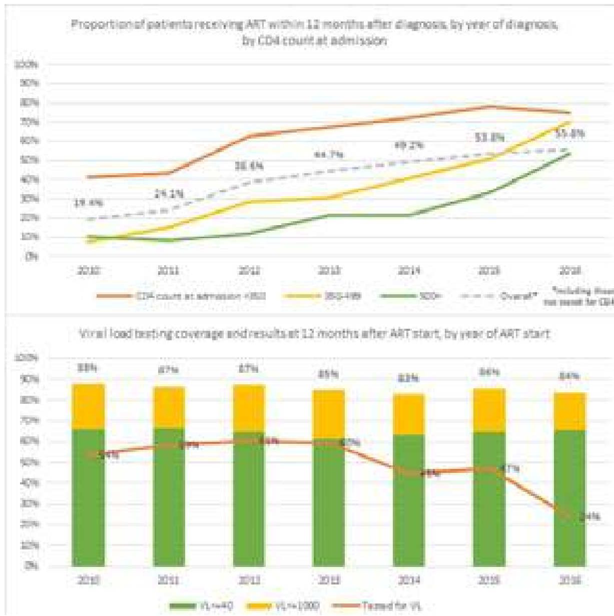
This study was commenced to obtain reliable data on key treatment quality indicators, contributing factors and trends to inform program planning.

Methods: Data from medical charts of all patients who received care at HIV facilities in 2010-2016 in 18 out of 27 regions of Ukraine were entered into an electronic medical record system. After verification of data quality, depersonalized datasets linked by unique patient code were extracted at each facility and merged for analysis. Entire dataset, excluding children younger than 15 at diagnosis, was analyzed using time-to-event methods, including Kaplan-Meier and log-rank test to assess difference between sub-groups.

Results: The cohort included 52,813 patients with HIV infection, approximately 40% of all patients receiving care in Ukraine in 2016. 46.5% were females. Median time from diagnosis to ART receipt decreased from 69 months (95%CI: 65.2-72.8) among patients diagnosed in 2010 to 3 months (95%CI: 2.6-3.4) in 2016 (p< 0.001). Proportion of patients who had received ART within 12 months after diagnosis increased from 19.4% to 55.8%, with most notable increase among patients with CD4>350, from 7.8% to 70.2% (see Figure; p< 0.001 for all strata).

Coverage with viral load testing within 12 months after ART initiation moderately increased from 53.8% in 2010 to 60.6% in 2012, then declined to 23.8% in 2016 (p< 0.001). Among those tested, proportion reaching viral suppression (< 1000 copies/ml) within 12 months after treatment initiation declined from 87.9% to 83.5% (p< 0.001).

Conclusions: First results of the analysis of the large national clinical dataset confirm rapid acceleration of ART uptake, especially among those with less severe immunosuppression, reflecting the change in national guidelines. On the other hand, access to viral load testing and level of suppression remains suboptimal, calling for urgent programmatic actions to improve clinical management of virologic failure and to ensure uninterrupted availability of laboratory services.



[ART coverage and viral suppression in Ukraine]

"A way of escaping": Exploring reasons for silently transferring between clinics among HIV-infected women enrolled in Option B+ in Malawi

A. Bengtson[1], W. Kumwenda[2], V. Go[3], A. Kutengule[2], M. Lurie[1], P. Simelane[2], W.C. Miller[4], M. Hosseinipour[2,3]
[1]Brown University, Providence, United States, [2]UNC Project, Lilongwe, Malawi, [3]University of North Carolina, Chapel Hill, Chapel Hill, United States, [4]Ohio State, Colombus, United States

Background: In order for Option B+ to improve HIV outcomes, women must remain engaged in HIV care. In Malawi, 25% of women default from Option B+ programs within 6 months. However, up to 30% of defaulting women may have unofficially or "silently" transferred to a new clinic and remain in care. Little is known about women's reasons for silently transferring and its impact on clinical care.
Methods: We conducted a qualitative study among HIV-infected pregnant women enrolling in Option B+ and healthcare workers (HCWs) at two large ART clinics in Lilongwe, Malawi between October and December 2017. We conducted focus groups (n=8) among women and HCWs and in-depth interviews (n=5) among HCWs to examine key drivers of silent transfers.
Results: Both women and HCWs reported a high degree of silent transfers between clinics. Silent transfers were often brought on by a specific trigger, such as seeing a friend at the clinic and fearing their HIV status would be disclosed, moving for a husband's job, or a marriage dissolving after a woman disclosed her status. Women described complex and ongoing considerations about disclosure to their partner, relatives, and neighbors as a key driver of where they sought care. In particular, anticipated or experienced stigma and being the subject of "gossip" among neighbors was a major reason for women to move clinics to avoid inadvertent disclosure. Giving false names and contact information to avoid being traced by HCWs to their communities was also common. To avoid disclosure to non-HIV HCWs, many women used two health passports (personal medical records); one for HIV visits and one for all other visits. HCWs reported that women silently transferring often presented as not knowing their HIV status and often repeated HIV testing and ART initiation procedures at the new clinic, leading to an inefficient use of resources and treatment disruptions.
Conclusions: Among women enrolled in Option B+ in Malawi, silent transfers were common and adversely affected clinical HIV care. More flexible systems that accommodate movement between clinics by monitoring engagement in care across clinics are urgently needed to streamline clinical care and optimize HIV treatment outcomes.

THPEC255

Syndemic factors and HIV risk among men who have sex with me in Taiwan

D.-M. Chuang[1,2,3]
[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [2]Asian Community AIDS Services, Toronto, Canada, [3]Committee for Accessible AIDS Treatment, Toronto, Canada

Background: Multiple health problems occurring in a population simultaneously experiencing poor physical and social conditions comprise a syndemic. The current study aimed to examine a possible syndemic and its association with HIV risk among Taiwanese men who have sex with men (MSM). Understanding the phenomenon of the syndemic necessitates comprehensive assessment in order to offer comprehensive community services and curtail the epidemic for this key population.
Methods: From July-September 2017, a cross-sectional, on-line survey was implemented among a convenience sample of MSM recruited from five LGBTQ community-based organizations across Taiwan. Survey items included socio-demographic characteristics, syndemic factors, including childhood abuse (CA), intimate partner violence (IPV), recreational drug use, and discriminatory experiences, and HIV risk index (total score, HIV status, and condom use). Multivariate logistic regression was conducted with HIV risk index as dependent variables, adjusting for socio-demographic characteristics.
Results: Among participants (n = 1000), 81.6% identified as gay; 92.2% had a university degree or more; 55.9% had a full-time job; 71.4% had a monthly income < $39,999 TWD ($1360 USD); 61.0% were single. Regarding syndemic factors, 41.4% experienced CA; 33.8% experienced IPV; 13.2% used recreational drugs, and 73.2% had discriminatory experiences toward their sexual orientation. In multivariate logistic regression, identified as gay (AOR=1.63, 95% CI=1.13-2.36) and experienced more than two syndemics (AOR=2.47, 95% CI=1.63-3.73) were associated with higher HIV risk (total score). Participants who experienced more than two syndemics (AOR=4.45, 95% CI=2.01-9.87) were associated with HIV seropositive; moreover, participants who experienced more than two syndemics (AOR=1.87, 95% CI=1.28-2.74) were associated with inconsistent condom use.
Conclusions: The results of this study provide evidence that syndemic factor on HIV risk among MSM in Taiwan. Multivariable analyses suggest that increased syndemic is associated with HIV risk in total and HIV serostatus. Social and behavioral research among MSM in diverse cultural settings may support the syndemic theory, which may facilitate service providers in applying a comprehensive biopsychosocial perspective in working with MSM.

Surveillance of drug resistance

THPEC256

Patterns of HIV-1 acquired drug resistance in children and adolescents from Argentina in the period 2006-2015

N. Lopez[1], S. Arazi[1], D. Mecikovsky[1], R. Bologna[1], A. Mangano[1,2,3], P. Aulicino[1,2,3]
[1]Hospital de Pediatría 'J.P Garrahan', Buenos Aires, Argentina, [2]Laboratorio de Biología Celular y Retrovirus, Buenos Aires, Argentina, [3]CONICET, Buenos Aires, Argentina

Background: HIV-1 infected children and adolescents have a higher risk of virologic failure and development of drug resistance than adults. In addition, subtype-specific variability can have implications for resistance monitoring, and for resistance development. Our aim was to investigate HIV-1 acquired drug resistance (ADR) in vertically infected children and adolescent from Argentina, and compare patterns of drug resistance mutations (DRMs) between the two major circulating subtypes (BF recombinants and subtype B).

Methods: DRMs and viral subtype were assessed in HIV-1 pol sequences obtained during routine genotypic testing of 247 children and adolescent with virologic failure between 2006 and 2015. Subtype along the PR-RT HIV-1 pol region was determined by phylogenetic inference and bootscanning analysis using Simplot. DRMs were identified according to the guidelines of the International AIDS Society-USA. Chi square test with Bonferroni correction was used for pairwise comparisons, and linear regression for the analysis of longitudinal trends.

Results: Of the 247 patients, more than 90% showed ≥ 1 DRM. The level of ADR was: 76,9% to NRTI, 93,1% to NNRTI and 80,2% to PIs. The frequency of NRTI and PI-associated DRMs decreased between 2006 and 2015, since to 2012 (73% to 19% for NRTIs, p:0,00007; 70% to 30% for PIs, p:0,0017). For NNRTI-DRMs, levels remained high, with a median of 65%.

BF recombinant were identified in 217 cases (87,8%), and subtype B in 30 (12,1%). More that 90% of BF recombinants showed 3 recombination breakpoints, defining subtype F regions between codons 36 to 54 of PR, and 87 to 131 of RT. In PR, I54V prevailed among BF recombinants (28,0% BF vs 6,0% B, p:0,0037), while in RT, K103S was more frequent in subtype B (12,0% B vs 4,0% BF, p:0,0482). DRMs to TAM1-NRTI profile (M41L, L210W, T215Y) were more frequent in the BF subtype (80% BF vs 61% B, p:0,0106).

Conclusions: In HIV-1 infected children and adolescents from Argentina, levels of ADR decreased significantly in association to the use of NRTIs and PIs, but not to NNRTIs. Specific selection of DRMs in regions defined as subtype F in most BF recombinants might have an impact on differential response to treatment among subtypes.

THPEC257

Increasing levels of pre-treatment HIV drug resistance in South Africa, 2000 - 2016

B. Chimukangara[1,2,3], R. Lessells[1], S.-Y. Rhee[4], J. Giandhari[1], K. Naidoo[2], S. Reshmi[5], A. Kharsany[2], A. Vandormael[1], B. Stray-Pedersen[6], M. Gordon[1], T. Makadzange[7], P. Kiepiela[8], G. Ramjee[8], U. Parikh[9], J. Mellors[10], J. Ledwaba[11], M. Kalimashe[11], L. Morris[11], G. Hunt[11], R. Shafer[4], D. Katzenstein[4], P. Moodley[3], R. Gupta[12,13], D. Pillay[12,13], S. Abdool Karim[2], T. de Oliveira[1,2]
[1]KwaZulu-Natal Research Innovation and Sequencing Platform (KRISP), Virology, Durban, South Africa, [2]CAPRISA, Durban, South Africa, [3]NHLS, Durban, South Africa, [4]Stanford University, Stanford, United States, [5]National Health Laboratory Service, Durban, South Africa, [6]University of Oslo, Oslo, Norway, [7]Ragon Institute of Massachusetts General Hospital, Cambridge, United States, [8]South Africa Medical Research Council, Durban, South Africa, [9]University of Pittsburgh, Pittsburgh, South Africa, [10]University of Pittsburgh, Pittsburgh, United States, [11]NICD, Johannesburg, South Africa, [12]University College London, London, United Kingdom, [13]Africa Health Research Institute (AHRI), Durban, South Africa

Background: South Africa has the largest HIV/AIDS treatment program globally. There are concerns over increasing levels of pre-treatment drug resistance (PDR) to levels of resistance ≥10%. To establish if there is a consistent increase in PDR with continued expansion of access to antiretroviral treatment (ART), we assessed studies on PDR from South Africa. This included two population-based studies: a longitudinal population-based HIV surveillance programme in northern KwaZulu-Natal (AHRI, 2013-2014) and a HIV Incidence Provincial Surveillance System in central KwaZulu-Natal (HIPSS, 2014-2015).

Methods: Trends in PDR were assessed through a meta-analysis of HIV-1 sequences from published and unpublished studies between 2000 and 2016. Pol gene sequences from studies on adult ART naïve patients were obtained from GenBank and corresponding authors. The sequences were analyzed for surveillance drug resistance mutations. Overall and drug class-specific trends of PDR were assessed using a generalized linear mixed effects regression model.

Results: We obtained 6880 pol gene sequences from published and publicly available data. From the analysis, an overall increase in PDR mutations was observed from low (< 5%) to moderate (5-15%) levels of resistance, with a 1.11-fold (95% CI: CI: 1·06-1·15) annual increase in PDR (p< 0.001). PDR was estimated as 11.3% (95% CI: 9.6-13·2) in 2014 and 11.9% (95% CI: 9.2-15.0) in 2015, and prevalence of non-nucleoside reverse-transcriptase inhibitor (NNRTI) PDR was 10.0% (95% CI 8.4-11.8) in 2014. Overall, the most prevalent mutation was the K103NS, observed in 278/6880 (4.0%) sequences. Mutations associated with reduced susceptibility to tenofovir (A62V, K65R, K70E and K70NT) were present at levels below 2%.

Conclusions: The high level NNRTI-PDR (≥10%) observed suggests a need to modify the standard first-line ART regimen, and to improve quality of HIV prevention, treatment and care. Although NRTI and NNRTI resistance have both increased, there is no evidence of increasing tenofovir resistance. There is need to consider replacing NNRTIs in first-line regimens with drugs that have a higher genetic barrier to resistance.

THPEC258

HIV pretreatment drug resistance surveillance in eight sub-regions of Mexico: Time to change to first-line regimens without NNRTI?

S. Ávila-Ríos[1], C. García-Morales[1], M. Valenzuela-Lara[2], D. Tapia-Trejo[1], M. Pérez-García[1], D.M. López-Sánchez[1], L.C. Maza-Sánchez[1], S.J. del Arenal-Sánchez[1], E.A. León-Juárez[2], C. Magis-Rodríguez[2], G. Reyes-Terán[1], for the Mexico HIVDR Surveillance Network.
[1]National Institute of Respiratory Diseases, Department of Research in Infectious Diseases, Mexico City, Mexico, [2]National Center for the Prevention and Control of HIV and AIDS (CENSIDA), Mexico City, Mexico

Background: HIV pretreatment drug resistance (PDR) to non-nucleoside reverse transcriptase inhibitors (NNRTI) in persons initiating antiretroviral therapy (ART) is increasing in Mexico. We present results of a large PDR survey carried out in 2017 with sub-regional representativeness, following WHO recommendations, in eight regions of Mexico, and discuss the option of a regionalized public health response to rising HIVDR levels.

Methods: A large PDR survey was implemented in Mexico in 2017 with sub-regional representativeness for eight regions of the country, previously defined by common socio-economic and cultural characteristics. All larger clinics providing ART to 90% of all initiators were included, allocating sample size per clinic using the probability-proportional-to-size method. HIV PDR levels were estimated from *pol* sequences according to WHO criteria, considering as resistant viruses with a Stanford score >15 to efavirenz, nevirapine, any NRTI, atazanavir, lopinavir or darunavir.

Results: From September to December 2017, 2182 participants were enrolled in 71 clinics. For all eight regions, PDR to NNRTI was higher than to other drug classes (p< 0.0001). We observed significantly higher levels of NNRTI PDR in the South-West region, including the three poorest states of Mexico, compared to the reference Centre-South region including Mexico City (p=0.03). NNRTI PDR was >10% in the Centre-North, North-West, East, South-East, and South-West, remaining under this threshold in the Centre-South, North-East and West regions. The proportion of persons re-initiating ART varied significantly by region from 4% to 16%, with higher prevalence in the North-East, West, East, and South-West (compared to the Centre-South, p< 0.01 in all cases). Nevertheless, the proportion of re-initiators did not correlate with NNRTI PDR level by region (r=0.3, p=0.5). As expected, PDR levels were significantly higher in re-initiators compared to ART-naïve individuals for all drug classes (p< 0.01 in all cases).

Conclusions: In large and complex countries such as Mexico, diversification of the public health response to HIVDR based on regional prevalence could be considered. Higher NNRTI PDR levels were associated with poorer regions, suggesting opportunities to strengthen local HIV programs. Price and licensing negotiations of drug regimens containing integrase inhibitors are warranted.

THPEC259

Emergence of the transmitted resistance of HIV-1 to antiretroviral drugs in Cuban patients during the period 2009-2016

L.Y. Machado[1], H.M. Díaz[2], M. Blanco[1], E. Noa Romero[3], M. Dubed[1], N. Ruiz[1], L. Martínez[2], E. Silva[4], L.S. López[1], D. Romay[1], N. Valdés[1], C. Nibot[1], J. Joanes[5], C.B. Rivero[1], I. Cancio[5], M. Rodríguez[1]
[1]AIDS Research Laboratory, San José de las Lajas, Mayabeque, Cuba, [2]Hermanos Ameijeiras Hospital, Havana, Cuba, [3]AIDS Research Laboratory, Mayabeque, Cuba, [4]Immunoassays Center, Havana, Cuba, [5]STI/HIV/AIDS Department, Ministery of Public Health, Havana, Cuba

Background: The emergence of antiretroviral-resistant HIV-1 variants compromises the first-line treatment regimens and the achievement of worldwide 90-90-90 UNAIDS target. Since 2009, the surveillance of HIV-1 transmitted resistance to antiretroviral drugs in newly diagnosed patients was introduced in Cuba. The aim of the present study is to evaluate the behavior of transmitted resistance of HIV-1 in Cuban patients of recent diagnosis and without antiretroviral treatment.
Methods: A cross-sectional descriptive and retrospective study was carried out that included 469 samples of HIV-1 Cuban patients diagnosed in the 2009-2016 period. The viral subtype was determined by phylogenetic analysis. Transmitted drug resistance was determined using the CPR tool v6.0. Some clinical and epidemiological variables were evaluated. A possible association of viral variants with sexual preference, disease progression and resistance to antiretroviral drugs was determined. For statistical analysis, the software package R was used.
Results: The predominant HIV-1 genetic variants were subtype B (27%), CRF 20, 23, 24_BG (23.5%) and CRF19_cpx (20.2%). An increase of the URF in the newly diagnosed patients was described in the period 2015-2016 (24.5%, $p < 0.05$). The most frequent URFs presented the combinations CRF19_cpx/B, BF1, BC, and CRF19_cpx/CRF18_cpx. Overall, 19% of the patients presented viruses with any mutation associated with the transmitted resistance of HIV-1 to ARVs (10.4% to NRTI, 12.8% to NNRTI, 2.8% to PI). The most frequent mutations were K103N/S and Y181C in the family of NNRTI, and M184V/I and D67N in the family of NRTI, which decrease the susceptibility to NVP, EFV and 3TC, AZT, respectively. The resistance to the NNRTI increased in the period 2015-2016 with respect to the 2009-2012 period (16.9% vs 11.9%). No significant differences were found between the genetic variants of HIV-1, the mutations associated with transmitted drug resistance, and the disease progression in the sample studied.
Conclusions: A high genetic diversity of HIV-1 and emergence of resistance transmitted to ARV in untreated population was described. These results demonstrate the need to continue epidemiological surveillance and search for new therapeutic strategies that contribute to accelerated compliance of worldwide 90-90-90 UNAIDS target.

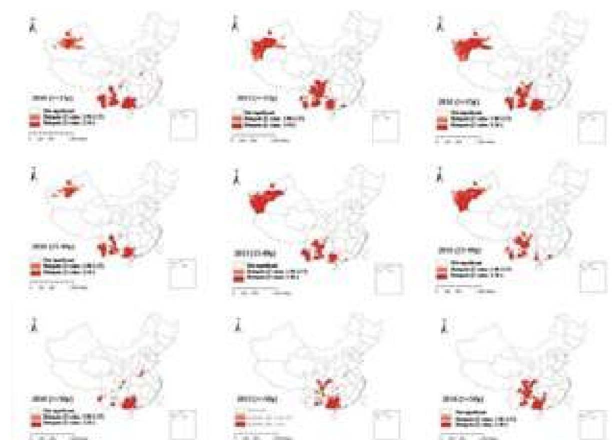
Describing the spread of HIV through geographical information systems

THPEC260

Trend and spatial analysis of the HIV epidemic among female adults in China, 2010 - 2016

F. Chen, W. Guo, Q. Qin, C. Cai, Y. Cui
National Center for AIDS/STD Control and Prevention, China CDC, Beijing, China

Background: Previous studies have shown an increasing burden of the HIV epidemic due to heterosexual transmission in China. Due to their biological susceptibility and social and cultural inequality, women are more likely to be infected than men. There are gaps in knowledge on the geographical distribution and evolution of the HIV epidemic among women in China. The purpose of this analysis was to identify epidemic clustering and temporal trends among HIV/AIDS cases in female adults in China through temporal and spatial analysis in order to inform intervention planning and optimization of resource allocation.
Methods: Data on newly identified HIV/AIDS cases among women aged >=15 years old from 2010 to 2016 were extracted from the HIV/AIDS Case Reporting System in China. Trends in demographic indicators were assessed using Cochran-Armitage trend tests. Spatial autocorrelation by year and age were evaluated to detect epidemic clustering at county level.
Results: From 2010 to 2016, 149,660 HIV/AIDS cases were identified among female adults in China (70.8% aged 15-49 years), which increased annually from 16,603 in 2010 to 26,196 in 2016. Differences in trends by age were detected with the proportion of cases among older women greatly increasing relative to decreasing cases among younger women (Z value=-56.21, P< 0.001). Spatial analysis demonstrated a county-level clustered distribution of HIV/AIDS cases among female adults across the country. Hotspots were concentrated in western and southern regions, including 6 provinces (Yunnan, Sichuan, Guizhou, Guangdong, Henan and Hunan), 2 autonomous regions (Guangxi, Xinjiang) and 1 municipality (Chongqing), with the trend of epidemic among younger women shifting towards western border and southern coastal provinces, and that of elderly women spreading northward from southwestern provinces.
Conclusions: Findings indicate an increasing clustering of the HIV epidemic among female adults in China, particularly in western and southern regions. Prevention and intervention strategies targeted to women by age, particularly in regions of increasing HIV epidemic, are urgently needed.



[Spatial clustering of newly identified HIV/AIDS cases among female adults in 2010,2013 and 2016 by age]

THPEC261

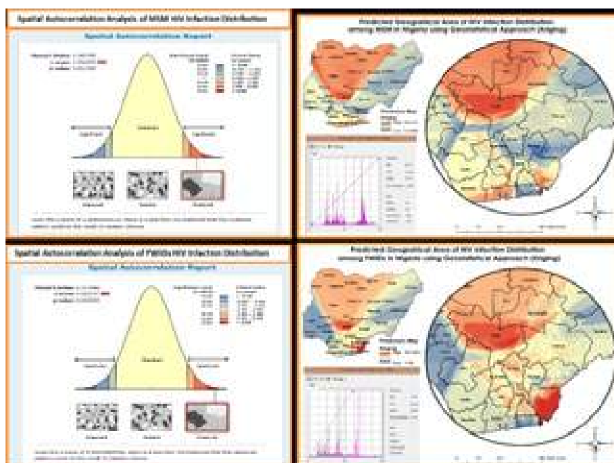
Geographical disparities in HIV seroprevalence among men who have sex with men and people who inject drugs in Nigeria: Mapping spatial clustering of HIV infection using GIS

A. Onovo[1], A. Kalaiwo[2], M. Katbi[2], P. Chen[1], U. Roxo[3], O. Keiser[4], G. Sarfaty[5], K. Badiane[6], H. Kang[6]
[1]U.S. Agency for International Development, Strategic Information, Office of HIV/AIDS & TB, Abuja, Nigeria, [2]U.S. Agency for International Development, Key Population, Office of HIV/AIDS & TB, Abuja, Nigeria, [3]U.S. Agency for International Development, Office of HIV/AIDS, Washington, DC, United States, [4]University of Geneva, Switzerland, Professor Epidemiologist, Head of Division, Institute of Global Health, Geneva, Switzerland, [5]U.S. Agency for International Development, Office of HIV/AIDS, Health Informatics Branch, Washington, DC, United States, [6]U.S. Agency for International Development, Office of HIV/AIDS & TB, Abuja, Nigeria

Background: Epidemiological assessment of geographical heterogeneity of HIV among men who have sex with men (MSM) and people who inject drugs (PWIDs) is necessary to inform targeted HIV prevention and care strategies in Nigeria. This study aimed to measure HIV seroprevalence, identify the spatial clustering of HIV infection among MSM and PWIDs and detect hotspots to prioritize program resources towards control efforts in Nigeria.

Methods: This was an ecological descriptive design conducted between Oct 1, 2016 and Sept 30, 2017. Study population were MSMs and PWIDs assessing HIV testing services across seven prioritized states (Lagos, Nasarawa, Akwa Ibom, Cross Rivers, Rivers, Benue and the FCT) in three geographic regions (NC, SS, SW**).** We georeferenced all HIV test results from 93 of 774 Local Government Areas (LGA). Seropositivity rate was calculated from data extracted from national testing registers. Global spatial autocorrelation techniques showed HIV infection distribution patterns and Hotspot analysis highlighted regions of significant clusters of HIV cases. Geostatistical approach using Ordinary Kriging predicted clusters of HIV infection in unmeasured program locations.

Results: Of the 40,423 MSMs and 20,336 PWIDs, 4,410 MSM (10.9%) and 1,761 (8.7%) PWIDs tested HIV positive. Global spatial autocorrelation Moran´s I statistics revealed a clustered distribution pattern of HIV infection among MSMs and PWIDs. Given the z-score of 2.29 [p< 0.021, Moran´s Index=0.162] for MSM and z-score of 4.03 [p< 0.000054, Moran's Index=0.317] for PWIDs, there is a less than 5% and less than 1% likelihood that this clustered pattern could be the result of random chance respectively. Getis-Ord-Gi* statistics indicated significant clusters of HIV infection among MSMs and PWIDs that were confined to LGAs in the NC and SS regions of the country. Kriging interpolation predicted cases of HIV infection to be similar among MSMs and PWIDs and confined to states in the NC and NW regions of Nigeria.



[Figure 1: Global Spatial Autocorrelation and Kriging Interpolation (Spatial Clustering of HIV Infection Distribution among MSM and PWIDs)]

OBJECTID/ LGA	Source ID	MSM (# HIV Positive)	Shape Length	Shape Area	GiZ Score	GiPvalue	GiBin
34	181	234	0.510309	0.011384	1.977624	0.047971	2
44	285	430	1.884064	0.145477	3.282569	0.001029	3
45	286	69	1.236706	0.075298	4.205538	0.000026	3
70	537	155	2.535182	0.216937	3.559387	0.000372	3
77	684	58	2.205402	0.073217	2.157567	0.030962	2
85	693	204	0.492685	0.008801	2.645243	0.008163	3

[Table 1: Hot Spot Analysis (Getis-Ord-Gi) Report of HIV Infection Distribution among MSM by Significant LGA]*

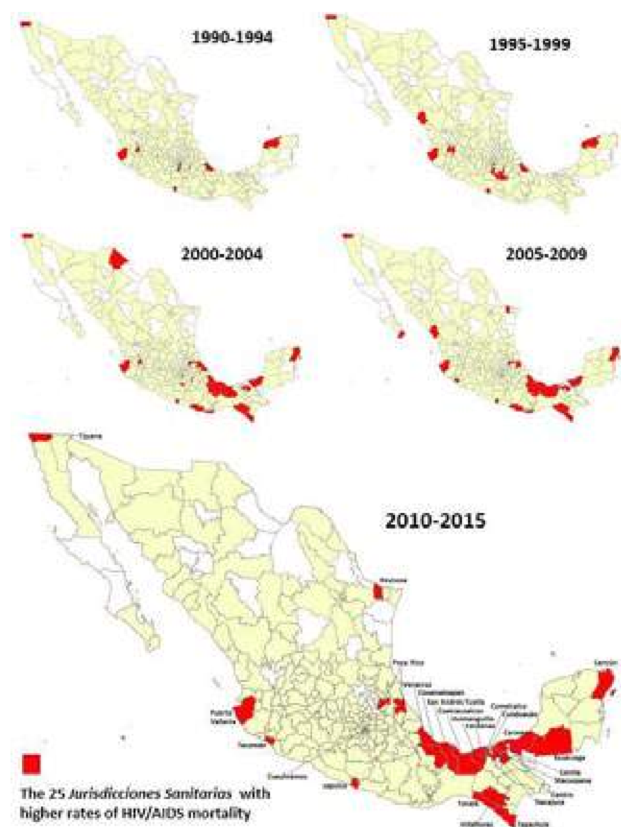
Conclusions: The study showed the north-central, north-west and southern regions of the country are most likely endemic cluster region. This study identified geographical areas to prioritize for control of HIV infection, thus demonstrating that geographical information system technology is a useful tool to inform interventions for epidemic control of HIV infection.

THPEC262

Where to strengthen the prevention and HIV/AIDS health services: Identifying critical areas to reduce HIV/AIDS mortality in Mexico

E. Bravo-García[1], C. Magis-Rodriguez[1], M. Palacios-Martínez[2], N. Guarneros-Soto[2]
[1]Censida, Mexico, Mexico, [2]INSP Tlalpan, Mexico, Mexico

Background: Free and universal access to HAART in Mexico became a public health policy since 2003. As a result, at the end of 2015, a total of 107,000 persons were receiving HAART. The HIV/AIDS mortality in Mexico declined 3% annually between 2008 and 2015. However, there are important differences between his distribution among the Mexican States, and inside them. The *Jurisdicciones Sanitarias* (**JS**) are geographics zones where the State Health Services that must coordinate the execution of the actions of prevention and control of HIV/AIDS.The aim was to analyzed the magnitude, distribution, and trends of HIV/AIDS mortality by **JS** in Mexico, from 1990 to 2015.



[The 25 Jurisdicciones Sanitarias with higher rates of HIV/AIDS mortality in Mexico from 1990 to 2015]

Tuesday 24 July

Author Index

Methods: Official vital statistics on mortality from *CONAPO*, and population estimates from *INEGI*, were used to calculate AIDS mortality standardized rates. HIV/AIDS mortality trends were analyzed by *JointPoint regression model*. *Mapa Digital de Mexico* (*GIS software*) were used to mapping.
Results: The 25 **JS** with higher rates of HIV/AIDS mortality has only 11% of the population of the country, but they account for 28.6% of the total deaths due to HIV/AIDS. They have a standardized mortality rate that is at least twice the national rate (3.7 per 100,000), and among them, seven **JS** have a rate three or more times higher. The highest average annual mortality rates, from 2010 to 2016, were observed in Tonalá, Chiapas (14.4 per 100,000 inhabitants), Veracruz, Veracruz (14.3 per 100,000), Carmen, Campeche (13.7 per 100,000), Centla, Tabasco (13.5 per 100,000 inhabitants), Cosamaloapan, Veracruz (13.3 per 100,000), Coatzacoalcos, Veracruz (13.3 per 100,000 inhabitants and Cárdenas, Tabasco (11.6 per 100,000 inhabitants). These 25 JS are located mainly in coastal areas, tourist sites, migration corridors or border areas of the country.
The most recent trend shows that HIV/AIDS mortality rates were increased in 9/25 **JS**; decreased in 8/25 **JS**; and has not changed in 8/25 **JS**.
Conclusions: The 25 geographic and operational areas (*JS*) were identified, where the prevention, and HIV/AIDS health care services should be focused. Otherwise, will be difficult to continue reducing the HIV/AIDS mortality in Mexico. It is the first study that analyzes a health problem (HIV/AIDS mortality) in all *JS* of Mexico.

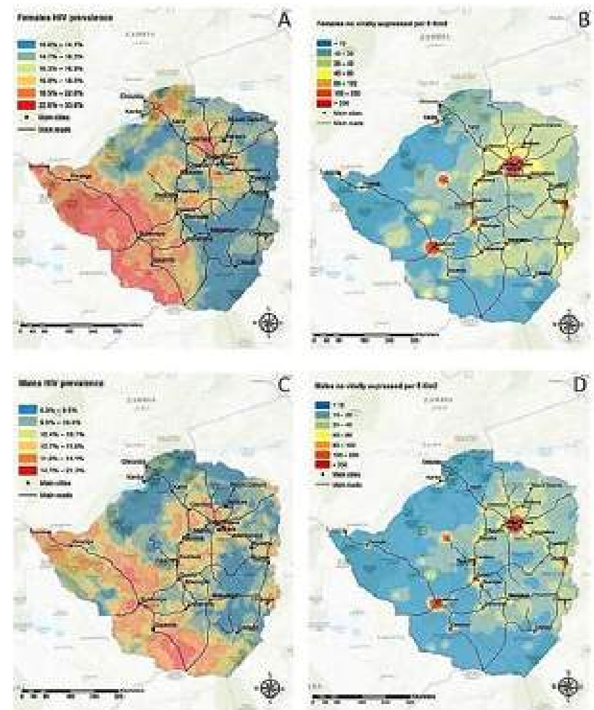
Towards UNAIDS 95-95-95 goal: Targeting priority geographic areas for HIV prevention and care in Zimbabwe

D. Cuadros[1], J. Li[1], Z. Mukandavire[2], G. Musuka[3], A. Branscum[4], B. Sartorius[5], F. Tanser[6]
[1]University of Cincinnati, Department of Geography and Geographic Information Science, Cincinnati, United States, [2]London School of Hygiene & Tropical Medicine, Department of Global Health and Development, London, United Kingdom, [3]ICAP-Columbia University, New York, United States, [4]Oregon State University, Biostatistics Program, Corvallis, United States, [5]University of KwaZulu-Natal, Department of Public Health Medicine, Durban, South Africa, [6]University of KwaZulu-Natal, Africa Health Research Institute, Durban, South Africa

Background: Zimbabwe has obtained substantial progress toward the UNAIDS targets of 95-95-95 by 2030, with 85% of PLHIV diagnosed, 87% of those diagnosed on antiretroviral therapy (ART), and 86% of those on ART virally suppressed. Despite this exceptional response, more effort is needed to completely achieve the UNAIDS targets and diminish the current HIV epidemic.
Here, we conducted a detailed spatial analysis of the geographical structure the HIV epidemic in Zimbabwe to include geographical prioritization as a key component of their overall HIV intervention strategy.
Methods: Data were obtained from Zimbabwe Demographic and Health Survey (ZDHS) conducted in 2015 as well as estimations from the Zimbabwe Population-Based HIV Impact Assessment (ZIMPHIA) 2016 report, and the maps for population density generated by the Worldpop project. Associations between covariates and HIV prevalence for males and females were assessed using non-spatial logistic regression models.
The prediction formula generated from the covariate analysis along with kriging interpolation techniques were used to produce high resolution continuous surface maps of HIV prevalence. Using these maps combined with the population density maps, we mapped HIV-infected, undiagnosed, and non-virally suppressed individuals.
Results: Behavioral and socio-economic factors such as lifetime number of sexual partners, age at first sex, and wealth index were associated with the spatial distribution of HIV prevalence for both males and females in Zimbabwe. HIV maps for both genders illustrated similar geographical variation of HIV prevalence within the country (Figure A, C). Maps of non-virally suppressed individuals localized areas where undiagnosed and not-currently on ART populations were concentrated, particularly in the main cities and urban settlements such as Bulawayo, Harare, Ruwa, and Chitungwiza (Figure B, D).

Conclusions: Our study showed an extensive local variation in HIV disease burden across Zimbabwe for both females and males. About 16% of the females, and 26% of the males in Zimbabwe are living in areas of intense HIV transmission. The high-resolution maps generated here identified the areas where high density of HIV-infected individuals that are still missing HIV care and treatment. These results suggest that there is need to tailor HIV programmes to address specific local needs to efficiently achieve epidemic control in Zimbabwe.



[Distribution of HIV prevalence in females (A) and males (C); Population density of females (B) and males (D) undiagnosed and not-currently on ART]

Optimizing vertical transmission prevention programs

THPEC264

Utilization of preconception care by HIV-infected women attending antenatal care in Kenyatta National Hospital

K. Mutai Kipyegon[1], E. Mundia Nyawira[1], K. Nyawira Gitahi[2], E. Sheila Juliet[1], L. Njagi[1], M. Njeri Mukunga[1], E. Yatich[3], O. Gachuno W[4]
[1]University of Nairobi, Centre of Excellence in HIV Management, Nairobi, Kenya, [2]LVCT Health, Nairobi, Kenya, [3]Kenyatta National Hospital, Nairobi, Kenya, [4]University of Nairobi, Obstetrics and Gynecology Department, Nairobi, Kenya

Background: Preconception care is fundamental for women planning to conceive and especially for those with chronic illnesses like HIV to optimize obstetric outcomes. There is little information on evaluation of preconception care implementation among HIV infected women in Kenya. This study described preconception care utilization by HIV-infected women with knowledge of their HIV status prior to pregnancy.
Methods: This was a cross-sectional study of 280 HIV positive pregnant women seeking antenatal care in Kenyatta National hospital between April 2015 to March 2016. Women who had tested sero-positive for HIV prior to conception were eligible for this study. Nurse counselors working in HIV care collected preconception care information from consenting women during routine antenatal care visits. Uptake of preconception care counseling was analyzed and presented as a percentage. The associated factors were tested using Chi square and Mann Whitney U tests. Statistical significance was set at a p value ≤ 0.05.

Results: The mean age of women was 30.7 years (SD 5.4 years), 62.5% had secondary or higher level of education and 43.1% were unemployed. Majority (85.7%) had sexual partners who had a lower unemployment rate (22.1%). HIV disclosure to the partner was at 91.3% and use of HAART before conception was at 89.3%. Pre-conception care counseling was reported among 35% (95% CI 28.9-40.7%) of the women. Those who sought preconception care counseling were those in employment, for women [OR 1.9 (95% CI 1.2-3.2), p=0.011] and their partners [OR 2.7 (95% CI 1.3-5.6), p=0.005], had disclosed their HIV status to the partner [OR 2.4 (95% CI 1.2-4.8), p=0.010] and had known their status for a longer duration (median of 75.5 months), p< 0.001.
Conclusions: There was low uptake of preconception care counseling services in HIV-infected women. Low socio-economic status is a likely barrier to access of the services. HIV disclosure has a positive influence on the preconception care uptake.

THPEC265

Sustained elimination of mother to child transmission of HIV and predictors of residual adverse outcomes at a large teaching and referral centre in Nairobi, Kenya

L.N. Njagi[1], C.O. Ojwang[1], K.K. Mutai[2], E.N. Kubo[1], S.C. Ilovi[1], R.C. Kenei[1], O.W. Gachuno[3], J.O. Mecha[1]
[1]*University of Nairobi, Clinical Medicine and Therapeutics, Nairobi, Kenya,* [2]*Kenyatta National Hospital, Nairobi, Kenya,* [3]*University of Nairobi, Obstetrics and Gynaecology, Nairobi, Kenya*

Background: Elimination of new pediatrics HIV infections is possible with existing public health and medical armamentarium. The global community has set as a target the virtual elimination of mother to child transmission (eMTCT) to < 5% in the breastfeeding and < 2% in the non-breastfeeding populations. We sought 1) to demonstrate that sustained virtual eMTCT to < 2% can be achieved in the breastfeeding populations, and 2) to explore the factors contributing to residual adverse outcomes; under programmatic conditions.
Methods: This was a retrospective cohort analysis of data on HIV exposed infants (HEI) and their mothers followed up at Kenyatta National Hospital, Nairobi Kenya from 2013 to 2015. We extracted data from the electronic medical database. Mothers were categorized as adolescent girls and young women (AGYW) 15-24.9 years and adults ≥25. We calculated the MTCT rates by birth cohort. Chi-square was used to determine association between attrition and maternal characteristics, and Kaplan-Meier analysis to estimate time to attrition by age group.
Results: Among 607 HIV infected women with singleton live born infants, the mean age was 34.8 years (standard deviation [SD] 5.4), 15 (2.5%) being AGYW. The infant outcomes were; 484 (79.7%) HEI discharged as HIV uninfected, 14 (2.3%) transferred out, 101(17%) lost to follow-up and 8 (1.3%) HIV infected. The MTCT rate remained < 2% during the follow-up period. Among the eight women with documented vertical transmission, the mean CD4 was 446 cells/ml (range 113-760), six (75%) had not attended antenatal care (ANC) and 5 (62%) were transfer-in postpartum. Women who were lost to follow-up were more likely to have a viral load >1,000 copies/ml (aOR = 5.011, CI = 1.02-15.49), be AGYW (aOR = 3.112, CI = 2.322-5.18) and be unmarried (aOR = 2.02, CI = 1.02-4.44). Attrition at 12 months was higher among AGYW compared to adults (p 0.0001).
Conclusions: Virtual eMTCT of HIV at < 2% can be achieved and sustained in the breastfeeding population. The likely factors for adverse outcomes such as delayed access to ANC and PMTCT interventions and attrition remarkably with AGYW are preventable through optimized and case-based facility and community level intervention.

THPEC266

Interactive Voice Response (IVR) messages and reminders increase completion of early infant diagnosis in a private sector PMTCT intervention in Southern India

L. Ramakrishnan[1], R. Gangula[2], J.S. Prashanth[2], A.R. Yeruva[2], R. Gill[3], A. Vuchelen[4], R. Rutten[4], K. Sen[5], V. Rasquinha[6], M.K. Suryadevara[2], S.K. Angappan[1], L. Ramakrishnan[1], S.S. Raghavan[5]
[1]*Solidarity and Action Against The HIV Infection in India (SAATHII), Chennai, India,* [2]*Solidarity and Action Against The HIV Infection in India (SAATHII), Hyderabad, India,* [3]*Jannsen Pharmaceutical Companies of Johnson and Johnson, London, United Kingdom,* [4]*Jannsen Pharmaceutical Companies of Johnson and Johnson, Antwerp, Belgium,* [5]*Solidarity and Action Against The HIV Infection in India (SAATHII), Delhi, India,* [6]*Mahiti Infotech, Bangalore, India*

Background: Effective PMTCT interventions require that pregnant women living with HIV (PPW) and Mother-Baby (MB) pairs be retained in the care cascade. India's national PMTCT program shows attrition at all stages, a problem exacerbated when women visit multiple sites (e.g. private sector for maternity services, public sector for HIV treatment and early infant diagnosis). SAATHII is currently implementing Svetana, a 22-state Global Fund-supported PMTCT initiative in the private sector. m-Maitri, an IVR initiative, was bundled with the intervention and piloted in Andhra Pradesh and Telangana, with support from Janssen Pharmaceutical Companies of Johnson and Johnson, and technology partner Mahiti.
Description: Over 250 IVR messages on maternal and child health, and HIV, are delivered to PPW and mothers of exposed infants via m-Maitri, an adaptation of the Connect for Life™ platform developed by Janssen. From June-Nov 2016, content was developed, vetted, translated into Telugu, the platform was developed and User Tested in parallel. Beginning December 2016, consenting women were enrolled in m-Maitri. They registered through a toll-free number, and received three health messages weekly on self-selected days and times. Additionally, m-Maitri sent reminders for immunization, early infant diagnosis and confirmation. As part of concurrent evaluation, timely completion of early infant diagnosis was compared between mothers receiving m-Maitri and outreach (intervention group) and the non-intervention group, which only received outreach visits. Quantitative results were supplemented with in-depth interviews of 50 women receiving m-Maitri messages.
Lessons learned: By end of Jan 2018, 672 of 753 eligible PPW mothers had registered, and 509 had received m-Maitri messages as well as outreach. Completion of early infant diagnosis was higher (P < 0.05) in the intervention group for six (OR 1.86), 12 (OR 1.68) and 18 months (OR 2.22). In-depth interviews indicated that m-Maitri messages and reminders motivated women to visit the doctor for timely antenatal consultations, prepare for institutional delivery, complete EID, and follow recommended infant feeding practices.
Conclusions/Next steps: The intervention is being scaled up with requisite adaptation of content to local contexts and languages across the country. Further work will examine the role of m-Maitri in enhancing other elements of retention such as maternal adherence to ART.

THPEC267

Formative research informs and guides intervention development for prevention of mother to child transmission of HIV: Barriers and strategies to improve adherence to Option B+ in urban and rural Uganda

R. King[1], J. Rujumba[2], J. Namale Matovu[3], P. Wavamunno[3], A. Amone[3], G. Gabagaya[3], P. Musoke[3]
[1]*University of California, San Francisco, Global Health Sciences, Entebbe, Uganda,* [2]*Makerere University, Kampala, Uganda,* [3]*Makerere University/ Johns Hopkins University Research Collaboration, Kampala, Uganda*

Background: Option B+ strategy is a recommendation by WHO to initiate all HIV-positive pregnant and breastfeeding women on antiretroviral therapy (ART) for life. Our aim was to conduct formative research to assess knowledge and attitudes regarding Option B+ among individual

HIV-positive PMTCT clients, community members and health workers and inform design of an enhanced group peer support intervention in a randomized controlled trial.

Methods: We conducted qualitative research at baseline using Focus Group Discussions (FGDs) to explore knowledge, beliefs, attitudes and challenges towards the Option B+ strategy for PMTCT among HIV infected pregnant and post-partum women enrolled on the Option B+ PMTCT programme (n=51 individuals). Key Informant Interviews (KIIs) were conducted with health workers, policy makers and community leaders to document their perceptions about the new PMTCT Option B+ strategy (n=14). FGDs and KIIs were conducted in Luganda or English using a pre-designed, semi-structured, IRB-approved guide. Topics explored included: PMTCT Option B+ understanding and benefits, program strategies, barriers and recommendations. We used content analysis to describe key emerging and existing themes and compared across participants using the social ecological framework to theoretically ground our analysis.

Results: Findings across both urban and rural sites indicated that participants had a good understanding of the benefits of the Option B+ program to the mother, baby, family and community including "*restoring hope for the future*". However, the barriers to adherence were clearly related to personal, relational and structural factors in a complex web of interactions. Key themes were: severe drug side effects both anticipated and experienced as well as non-disclosure at home and work and personal and community stigma. Structural drivers included health facility factors such as drug stock outs, human resource constraints, and nutritional limitations at home.

Conclusions: Our findings suggest that continuous education is needed on anticipated drug side effects, as well as ongoing psychosocial support at facility and community levels including use of peers, village health teams and political structures. Use of an innovative male involvement strategy (couple counseling and testing, home based testing), supply chain management to avoid stock outs, and ensuring that health workers are respectful to all clients are key.

THPEC268

Evaluating the vertical HIV transmission risks among South African female sex workers. Have we forgotten PMTCT in FSW HIV programming?

J.O. Twahirwa Rwema[1], S. Baral[2], N. Phaswana-Mafuya[3], A. Lambert[4], A. Rao[2], Z. Khose[3], H. Hausler[4], S. Schwartz[2]
[1]Johns Hopkins Bloomberg School of Public Health, Public Health, Kigali, Rwanda, [2]Johns Hopkins University, Epidemiology, Baltimore, United States, [3]Human Sciences Research Council, Port Elizabeth, South Africa, [4]TB/HIV Care Association, Cape Town, South Africa

Background: Female sex workers (FSW) have a greater HIV burden compared to other reproductive-aged women and experience high incidence of pregnancies. However, there are limited data on mother-to-child transmission of HIV in the context of sex work. This study assessed the uptake of prevention of mother-to-child transmission (PMTCT) services to understand the vertical HIV transmission risks among FSW in South Africa.

Methods: FSW ≥18 years were recruited into a cross-sectional study using respondent-driven sampling (RDS) between October 2014-April 2015 in Port Elizabeth, South Africa. An interviewer-administered questionnaire captured information on demographics, reproductive health histories, and HIV care, including engagement in PMTCT care and ART. HIV and pregnancy testing were biologically assessed. This analysis characterizes FSW engagement in HIV prevention and treatment cascades of the four prongs of PMTCT.

Results: Overall, 410 FSW were enrolled. The RDS-weighted HIV prevalence was 61.5% (95% bootstrapped confidence interval 54.1-68.0). A comprehensive assessment of the four PMTCT prongs showed gaps in cascades for each of the prongs. In Prongs 1 and 2, gaps of 42% in consistent condom use with clients among HIV-negative FSW and 43% in long-term high efficacy contraceptive method use among HIV-positive FSW were observed. The analyses for prongs three and four pertained to 192 women with children < 5 years; 101/192 knew their HIV diagnosis prior to the study, of which 85% (86/101) had their children tested for HIV after birth, but only 36% (31/86) of those who breastfed retested their children post-breastfeeding. A substantial proportion (35%, 42/120) of all HIV-positive women with children < 5 years of age were HIV-negative at their last delivery and seroconverted after delivery. Less than half (45%) of mothers with children < 5 years (45/101) were on ART and 12% (12/101) reported at least one child under five living with HIV.

Conclusions: These findings show significant gaps in engagement in the PMTCT cascades for FSW, evidenced by sub-optimal uptake of HIV prevention and treatment in the peri/post-natal periods and insufficient prevention of unintended pregnancies among FSW living with HIV. These gaps result in elevated risks for vertical transmission among FSW and the need for PMTCT services within FSW programs.

THPEC269

Virological suppression among pregnant and breastfeeding women in 105 clinics in Kinshasa: A baseline assessment for a data driven continuous quality improvement intervention trial

M. Yotebieng[1,2], C. Mpody[1], N.L.R. Ravelomanana[1,2], M. Tabala[2], F. Malongo[2], B. Kawende[2], P. Ntangu[3], P.W. Okitayemba[4], F. Behets[5], E. Okitolonda[2], OSU/UNC/KSPH PMTCT Team
[1]Ohio State University, College of Public Health, Columbus, United States, [2]University of Kinshasa, Kinshasa School of Public Health, Kinshasa, Congo, Democratic Republic of the, [3]National AIDS Program, Kinshasa's Provincial Coordination, Kinshasa, Congo, Democratic Republic of the, [4]National AIDS Program, Kinshasa, Congo, Democratic Republic of the, [5]University of North Carolina at Chapel Hill, Department of Social Medicine, Chapel Hill, United States

Background: Virological suppression is the central pillar of the UNAIDS strategy to end the AIDS epidemic. Despite being a priority population, limited attention has been given to viral load monitoring among pregnant and breastfeeding women.

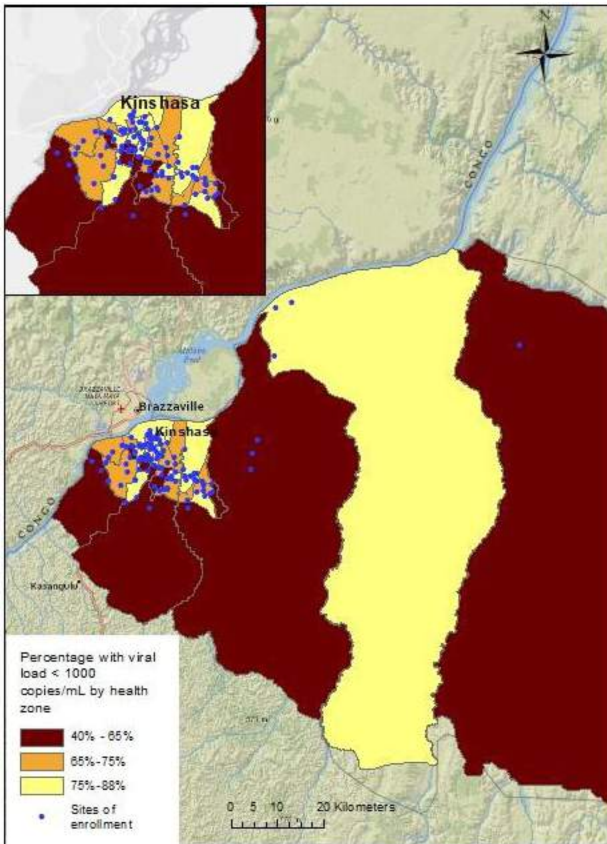
We assessed the prevalence of virological suppression (viral load < 1000 copies/mL) among pregnant and breastfeeding women in Kinshasa, Democratic Republic of Congo.

Methods: Data collection was done as part of a baseline assessment for an ongoing trial that will evaluate the use of data-driven continuous quality improvement to optimize PMTCT outcomes (NCT03048669).

From November 2016 to December 2017, in each of the 35 Kinshasa province health zones, study teams visited the top (by number served) three maternal and child health (MCH) clinics and enrolled all HIV-infected pregnant or breastfeeding women (< =1 year post-delivery). At enrollment, each participant provided a dry blood sample that was used for viral load testing at the national reference laboratory.

Results: At the end of December 2017, viral load results were available from 1160 (96%) of the 1214 women enrolled. Overall, 69% (803/1160) of participants were virologically suppressed including 71% (411/576), 62% (156/251), and 71% (236/333), of those tested respectively during pregnancy, at delivery, or in the postpartum period. 64% (304/473) of participants newly diagnosed during the current pregnancy were virologically suppressed as compared to 73% (465/634) among those diagnosed earlier (*P*=0.001). In multivariable logistic models stratified by time of HIV diagnosis, among participants diagnosed prior to current pregnancy, older age, being married, disclosure of HIV status to partner, receiving care in an urban health zone (figure) or one supported by PEPFAR were all strongly associated with higher odd of virological suppression (table). Participants enrolled at delivery or in the postpartum period were less likely to be virologically suppressed compared to those enrolled during pregnancy. Similar associations though attenuated, were observed among newly diagnosed.

Conclusions: Despite full implementation of option B+ in Kinshasa since 2015, the proportion of HIV-infected pregnant and breastfeeding women receiving care in MCH clinics, in Kinshasa, with virological suppression is far below the UNAIDS target of 90% even among those who were diagnosed prior to current pregnancy.



[Prevalence of viral load <1000 copies/ml among pregnant and breasfteeding women by health zone in Kinshasa]

	N	Virological suppressed: N (%)	Crude OR (95%CI)	adjusted OR (95%CI)
Age (25+ vs <=24 years)	55 vs 577	30 (55%) vs 434 (75%)	2.53 (1.44, 4.44)	2.36 (1.30,4.28)
PEPFAR support (Yes vs No)	395 vs 237	299 (76%) vs 164 (69%)	1.39 (0.97, 1.99)	1.48 (1.02, 2.17)
Location (Urban vs Rural)	580 vs 54	434 (75%) vs 31 (57%)	2.21 (1.25, 3.90)	2.30 (1.28, 4.22)
Testing time (Delivery vs pregnancy)	120 vs 332	79 (66%) vs 256 (77%)	0.57 (0.36, 0.90)	0.58 (0.40, 0.93)
Testing time (Postpartum vs pregnancy)	182 vs 332	130 (71%) vs (256 (77%)	0.74 (0.49, 1.12)	0.72 (0.46, 1.11)
HIV disclosure to partner (Yes vs No)	389 vs 236	299 (76%) vs 159 (67%)	1.61 (1.12, 2.31)	1.54 (1.06, 2.25)
Marital status (married/cohabing)	457 vs 176	349 (76%) vs 116 (66%)	1.68 (1.14, 2.44)	1.44 (0.96, 2.18)

*The data presented is only for 634 women who were diagnosed with HIV prior to the current pregnancy. Similar associations were found among 473 participants newly diagnosed (during the current pregnancy), but with attenuated strength. Odds ratios and their 95% confidence intervals were obtained using logistic regression models. #the delivery period includes the first 72 hours after delivery and prior to discharge from maternity. The postpartum period is anytime from 6 weeks to 12 months postpartum. Abbreviations: OR: Odds ratio, CI: confidence interval, PEPFAR: The US President's Emergency Plan for AIDS Relief.

[Associations of between socio-demographic and ecological factors and virological suppression (<1000 copies/mL) among pregnant and breastfeeding wome]

THPEC270

Pregnancy outcomes in women perinatally infected with HIV-1(PHIV) in Argentina: An emerging population

L. Guzzi[1,2], M. Barris[3], L. Figueras[3], S. Lauro[4], A. Cospito[4], V. Silenzi[5], A. Conesa[5], C. Zala[6]

[1]Instituto de Maternidad Santa Rosa, Servicio de Infectología, Vicente López, Argentina, [2]Clínica Olivos, Swiss Medical Group, Servicio de Infectología, Vicente López, Argentina, [3]Hospital Materno Infantil 'Dr. Carlos Gianantonio', Infectious Diseases, San Isidro, Argentina, [4]Instituto de Maternidad Santa Rosa, Social Work, Vicente Lopez, Argentina, [5]Hospital Central de San Isidro, Biochemistry, San Isidro, Argentina, [6]Hospital Central De San Isidro, Infectious Diseases, San Isidro, Argentina

Background: Widely available antiretroviral therapy has allowed for HIV infected girls to growth into women of reproductive age. However, concerns exist regarding the impact of long term HIV infection, co-morbidities and extensive drug exposure on pregnancy outcomes. In this context, limited information is available to guide counseling and care of this particular population.
We analyze the obstetric and clinical characteristics and the perinatal outcomes of pregnancies in women with PHIV and their exposed newborns.

Methods: Prospective observational study that included all pregnant women (PW) with PHIV at two hospitals in the northern area of Buenos Aires, from 1/1/2014 to present.

Results: Of a total of 41 pregnant women infected with HIV, 7 (17%) were PHIV, 2 of them continue in care and 1 was lost to follow-up at week 36. Median age at presentation was 18 years (range 17-20).5/7 (71%) had a history of one or more pregnancies, including one stillbirth. The median CD4 was 595 cells /uL (range 20-1030). All women were on ARVs at conception, 5 of them (71%) with irregular adherence. 3/7 (43%) had virological failure, with the K103N mutation in two and multidrug resistance in one. HIV viral load was < 50 copies/mL close to delivery in 40% and < 1000 copies/mL in 40% . Fifty percent had vaginal delivery. There was one preterm childbirth (week 35). All newborns remain alive and HIV negative at the time of this report. No mayor malformations were identified by clinical exam so far.

Patients	Age at conception	AIDS	Inicial HIV-1 RNA Viral Load (copy/mm3)	CD4 count (cells/mm3)	Sexual Transmitted diseases	HIV-1 RNA Viral Load (copy/mm3) at near delivery	Mode of Delivery	Infant Prophylaxis	HIV Vertical Transmission
1	17	NO	<50	1030	NO	<50	Elective cesarean section	Zidovudine	NO
2	20	NO	<50	700	NO	<50	Vaginal Delivery	Zidovudine	NO
3	17	YES	400.000	20	NO	200	Not Know	Not Know	Not Know
4	20	NO	32.400	Not Know	NO	Not Know	Elective cesarean section	Zidovudine Lamivudine Nevirapine	NO
5	18	NO	1600	345	NO	Ongoing Pregnant			
6	17	NO	483	840	NO	91	Vaginal Delivery	Zidovudine Lamivudine	NO
7	17	NO	<50	600	Herpes Simplex Virus	Ongoing Pregnant			

[Table 1 shows main characteristics from seven PW PHIV]

Conclusions: Pregnant women perinatally HIV-1 infected, seems to be able to carry a healthy pregnancy to term, despite long term HIV infection and massive exposure to antiretrovirals. Risk of lost to follow up and poor adherence resulting into ARV resistance is a serious concern. Further observations are needed to identify and to prevent potential complications in this particular population.

THPEC271

Combating the challenges of women with disabilities in the uptake of EMTCT services in Ekiti State, Nigeria

A. Ajumobi[1], R. Ajayi[2], B. Osuolale[3]
[1]Ekiti State AIDS Control Agency, Parnerships, Programme Planning and Community Mobilization, Ado Ekiti, Nigeria, [2]Ekiti State AIDS Control Agency, Community Mobilization, Ado Ekiti, Nigeria, [3]Ekiti State AIDS Control Agency, Partnerships and Programme Planning, Ado Ekiti, Nigeria

Background: An estimated 36% of women in sub-Saharan Africa have some form of disability. Identified factors such as susceptibility to sexual abuse, poor access to health care services and HIV prevention education, and discrimination related to the double burden of both gender and disability put them at increased risk of HIV. Despite policy and legal frameworks to support disability rights in Ekiti State, implementation of accessible PMTCT programs for women with disabilities remains limited. In 2014-2016, Ekiti State AIDS Control Agency designed and implemented HIV programmes targeting women with disabilities in the State.
Description: Baseline survey was conducted. 206 sign language experts were trained to implement "on-call" sign language interpretation in ANC clinics providing information on EMTCT to women and their partners who were hearing impaired. 522 health workers were trained on PWD targeted health care in a supportive environment to encourage access to HIV services and eliminate discrimination. EMTCT IEC materials were printed in braille and distributed to those who were visually impaired while bill boards and braille door signs were produced and strategically located within the communities and at health facilities/ANC clinics for easy access. Radio and TV jingles targeting pregnant women with disabilities were produced and aired. Trained health workers were engaged to provide home visits to the physically impaired HIV positive pregnant women while helplines were provided for ambulance services in case of emergencies. The trained sign language experts were also engaged during community outreaches to create demand for HTS and EMTCT services within the community of people with disabilities. Disabled persons were employed in ANC clinics for sustainability.
Lessons learned: Women with physical, hearing and visual disabilities who attended maternal/child health services increased from 8% to 46%, HTS service uptake increased from 37% to 66% and out of 24 HIV positive pregnant women with disability identified, 19 of them accessed EMTCT services while 16 infants had accessed EID services.
Conclusions/Next steps: Strategies and interventions targeted at addressing inequities in health care for women with disabilities is needed to achieve the goal of eliminating pediatric HIV by 2020 and improving the health and wellbeing of women.

THPEC272

Unintended pregnancy in women living with HIV in sub-Saharan Africa: A systematic review and meta-analysis

T. Feyissa[1], M. Harris[2], A. Sufa[1], D. Loxton[2]
[1]Wollega University, Public Health, Nekemte, Ethiopia, [2]University of Newcastle, Research Centre for Generational Health and Ageing, Newcastle, Australia

Background: In 2014, about 1.5 million pregnancies occurred among HIV-positive women in low and middle-income countries. Despite this, the magnitude of unintended pregnancies in women living with HIV is not well understood.
Methods: A systematic search of MEDLINE, PubMed, Embase, PsychINFO, Scopus, and CINAHL electronic databases was undertaken in November 2016. Only articles published from 2005 to November 2016 and written in English were included. Titles and abstracts were screened, and eligible articles reviewed. Two scholars with knowledge of the subject area independently extracted and appraised the quality of included papers. Data were summarized narratively and then random-effects meta-analysis was used to pool estimates.
Results: Eighteen studies from 12 countries were included for qualitative synthesis. The majority of studies (n=16) were conducted in health institutions. The studies covered a period from 2003 to 2014 with most publications concentrated after 2010. The magnitude of unintended pregnancy ranged from 37.2% in Nigeria to 75% in Malawi. Pooling the magnitude of unintended pregnancy reported by 15 studies yielded a crude summary prevalence of 55.5% (95% confidence interval (CI): 50%-60.9%). The magnitude of unwanted pregnancy in six studies ranged from 14% to 59%, while the magnitude of mistimed pregnancy ranged from 9% to 47.2%. Contraceptive failure was an important factor for many unintended pregnancies though a substantial number is related to unmet needs for family planning. The magnitude of unintended pregnancy was significantly higher in HIV-positive women than for HIV-negative women in three out of six studies.
Conclusions: Although robust prevalence studies for unintended pregnancy in women living with HIV are sparse, the available studies suggest that there is a high magnitude of unintended pregnancy. The existing data are insufficient to characterize unintended pregnancy (mistimed and unwanted) in women living with HIV in sub-Saharan Africa fully. Improving effective family planning utilization in women living with HIV is a priority to address unintended pregnancies and to prevent mother to child transmission of HIV.

THPEC273

Retention rate among pregnant women under Option B + and factors of the loss to follow up in 7 health institutions in Haiti

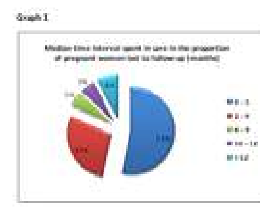
C. Beauharnais[1], N. Bertrand[2], G. Lapomarel[3], C. Sampin[4], E. Thoby[5]
[1]Catholic Medical Mission Board (CMMB), ALESIDA Technical Team, Port-au-Prince, Haiti, [2]Hôpital Alma Mater, HIV Project Coordination, Gros-Morne, Haiti, [3]Clinique Béthel, Monitoring & Evaluation, Aquin, Haiti, [4]Hôpital Saint François de Sale, PMTCT Service, Port-au-Prince, Haiti, [5]Hôpital Saint Jean, HIV Project Coordination, Limbé, Haiti

Background: Following WHO recommendations in 2013, the implementation of Option B +, the percentage of HIV+ pregnant women enrolled on life-long treatment increased from 40% to more than 90% between 2012 and 2014 in Haiti according to the National HIV / AIDS Program. However, the PMTCT program is confronted with a low retention of care among pregnant women infected with HIV. The treatment abandonment before delivery can compromise the health of the mothers and also causes many exposed children fail to be diagnosed to receive appropriate care. We proposed to quantify the number of HIV infected pregnant women receiving option B + lost to follow-up before delivery and to identify associated factors.
Methods: This is a cross-sectional descriptive survey. It was conducted at the cohort level of pregnant women enrolled in the PMTCT program and placed on ART from January 1, 2014 to June 30, 2017. Data were collected from 7 health institutions providing HIV testing, care and treatment services in 5 departments of the country. Data collection was done through the PMTCT registers, and electronic medical records. We defined as lost to follow up a patient who has not renewed her ARV prescription for 90 days after the date of her last missed appointment.

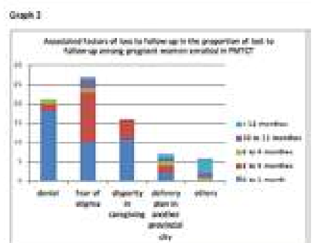
Table 1. - Characteristics of the 368 pregnant women enrolled in PMTCT program from January 2014 to June 2017

Table 2. - Proportion of lost to follow-up among PW enrolled in PMTCT

Graph 1



Graph 2



[Results]

Results: For the period evaluated, 368 new pregnant women were screened HIV + and placed under option B +. Nearly three quarters of pregnant women in the cohort are enrolled on ARV in WHO clinical stage I. The mean CD4 count at entry was 514 cells / µL (min: 15 max: 1337). The median day interval for enrollment of pregnant women under Option B + is 0-15 days. Before delivery, 20.9% of pregnant women diagnosed with HIV + and enrolled in the PMTCT program are lost to follow-up in the median time interval of 0 to 1 month. Associated factors identified include the denial (27%), fear of stigma (35%), mobility (29%).
Conclusions: The low retention rate among pregnant women is very worrying. We need to find immediate strategies to improve patient retention, taking into account the major factors associated with loss to follow up.

THPEC274

Stop Vertical Transmission (SVeT) Program as effective approach for Prevention of mother-to-child transmission (PMTCT)

A. Solovyeva[1,2], M. Dobkina[3], N. Zemlyanaya[4], A. Chernov[3], A. Yedilbayev[5]
[1]Partners In Health, Moscow, Russian Federation, [2]RUDN University, Department of Infectious Diseases with Courses of Epidemiology and Phthisiology, Moscow, Russian Federation, [3]Tomsk AIDS Center, Tomsk, Russian Federation, [4]Partners in Health, Tomsk, Russian Federation, [5]Partners in Health, Boston, United States

Background: The WHO determined a likelihood of HIV passing from a mother to a child as 15% to 45%. Antiretroviral therapy (ART) and other effective PMTCT interventions can reduce this risk below 5%. Success of PMTCT depends on adherence to the regimen. In 2014, a growth of HIV cases increased HIV rate in pregnant women in Tomsk, Russia. Some of them did not accept HIV diagnosis, refused taking ART, or did not visit AIDS center on time. In 2015, SVeT Program was implemented by Partners In Health (PIH) in collaboration with the Tomsk AIDS Center to reduce HIV mother-to-child transmission among women with poor ART adherence or refusal of PCTMT.
Methods: A multidisciplinary team was created at the Tomsk AIDS center. The project uses a patient-centered approach (PCA) to perform a set of comprehensive activities: searching for patients, building trustful patient-provider relationships, providing directly-observed ART for pregnant women and ARV prophylaxis in newborns. In addition, the SVeT team provided psychosocial support, counseling and patient education. Nutritional support and hygiene packages were used as incentives to improve compliance to PMTCT.
Results: During 2015-2016, 70 HIV-positive pregnant women were included in to SVeT Project. 42.8% (30) were not registered in AIDS Services before pregnancy and 75.7% (53) refused PMTCT. 15.7% (11) were diagnosed as intravenous drug users (IDU), 44.2% (31) had a history of being IDU, and 62.8% (44) were unemployed. 55 women completed PMTCT, 1 rejected and other were still on treatment. By the time of delivery, in 83.3% of women (45/54) viral load was undetectable. 55 children were born, 100% had negative PCR for HIV at birth. 48 of them were included into SVeT Project and 33 were followed up for 6 months and had three negative HIV PCR results.
Conclusions: The SVeT Project showed that a comprehensive PCA focused on daily DOT of ARV therapy, introduction of psychosocial support and building patient's ability to overcome medical and social barriers resulted in increase of favorable outcomes of PCTMT. Further scale up is possible in settings where burden of HIV epidemic is rising and resource-limited settings, especially in Eastern Europe and Central Asia.

Combination prevention strategies

THPEC275

Factors influencing the uptake of safe male circumcision among Makerere University undergraduate students, Kampala - Uganda

J. Nyamwiza[1], M.S. Kiwuwa[2], J. Mukisa[1], A. Bosco Bekiita[3], C. Karamagi[4]
[1]Makerere University, Clinical Epidemiology Unit, School of Medicine, College of Health Sciences, Kampala, Uganda, [2]Child Health Development Centre, Mulago National Referral Hospital, Kampala, Uganda, [3]Ministry of Health, National Disease Control, Kampala, Uganda, [4]Makerere University, College of Health Sciences, Paediatrics and Child Health, Kampala, Uganda

Background: Safe male circumcision (SMC) is currently recognized as a preventive strategy in reducing the risk of HIV; however, the prevalence of circumcised men in Uganda is still quite low at 26%. This study aimed to determine the uptake of SMC and associated factors among Makerere University undergraduate students, in Kampala Uganda.
Methods: We conducted a cross-sectional study in which we selected 602 participants with the multistage probability sampling strategy. Pretested semi-structured questionnaires and focus group discussions were used to collect data. Quantitative data were analyzed with Stata 12, where the prevalence ratio and *p*-values were calculated. Possible interactions and confounding variables were assessed with the Poisson regression model while qualitative data was analyzed with content analysis.
Results: The overall uptake of SMC among male undergraduates was 58.3% (95% CI: 54.37 - 62.24). Factors associated with SMC uptake included: safety of SMC procedure (PR = 1.13, 95% CI: 1.03 - 1.25) and friendly health workers (PR = 0.78, 95% CI: 0.74 - 0.83). The perceived benefits of SMC uptake included hygiene (86.5%, n = 521), reduced risk of HIV transmission (4.5%, n = 26) and reduced risk of penile cancer (45.7%, n = 275) while, the perceived barrier was pain (10.1%, n = 61). The general perception was that SMC recipient's first sexual partner post-procedure would not be his girlfriend.
Conclusions: The overall reported SMC success rate among participants was high, along with the safety of SMC services and friendly health workers as important factors among male students. There is a need for continuous sensitization campaigns and communication strategies to address beliefs about SMC, some related misconceptions, and barriers so as to increase its uptake.

THPEC276

Dramatic reductions in time to ART initiation among HIV+ individuals referred to HIV care following home-based testing services: Experiences from the HPTN071(PopART) trial between 2014 and 2017

S. Fidler[1], S. Floyd[2], B. Yang[3], M. Phiri[4], D. McLeod[2], A. Schaap[4], R. Sloot[3], K. Shanaube[4], S. Griffith[5], P. Bock[6], N. Beyers[3], H. Ayles[4], R. Hayes[2], on behalf of the HPTN071(PopART) Study Team
[1]Imperial College London, Medicine, London, United Kingdom, [2]LSHTM, London, United Kingdom, [3]University of Stellenbosch Desmond Tutu TB Centre, Cape Town, South Africa, [4]ZAMBART, Lusaka, Zambia, [5]FHI 360, North Carolina, United States, [6]University of Stellenbosch, Cape Town, South Africa

Background: To reach zero AIDS deaths and zero new HIV infections, antiretroviral therapy (ART) must be delivered to all people living with HIV. As HIV testing is decentralized and community testing and self-testing become more widely available, identifying and implementing strategies that facilitate linkage to HIV care (LTC) from the community to the clinic to start ART is crucial.
Methods: In seven urban communities in Zambia and South Africa, randomised to receive the universal-testing-and-treatment intervention (UTT) within the HPTN071(PopART) trial, Community HIV-care Providers (CHiPs) offer home-based HIV testing, referral to government clinic services for HIV-positive individuals, support for LTC, and ART initiation. CHiPs deliver the intervention in "rounds", during which they (re-)visit all

households in their community. Round 1 (R1) was November 2013-June 2015, R2 June 2015-September 2016, and R3 was September 2016-December 2017; 19 and 15 months respectively. CHiPs record data on electronic registers, including dates of referral, LTC and ART initiation, and conduct follow-up visits to support LTC and retention. From R2, with intensified efforts in R3, various strategies were implemented to facilitate LTC, including: targetted follow-up of individuals not yet LTC, extra counselling, more supervisory support to CHiPs, and increased coordination with the clinic. For each round, we estimated the time to ART initiation after first referral to care among individuals aged ≥15 years, using the Kaplan-Meier method and Cox regression for "time-to-event" analysis.

Results: In Zambia 6,197, 3,435, and 2,295, and in South Africa 1,375, 1,262 and 754 individuals were referred by CHiPs to HIV care in R1, R2, and R3 respectively (Table 1). The median time to ART initiation after CHiP referral to care was ~10 months, ~6 months, and ~3 months in R1, R2, and R3 respectively (Figure 1,p< 0.001), with a reduction overall and for both men and women (Table 1).

Conclusions: More rapid ART initiation for HIV-positive individuals after referral to HIV care was achieved over three rounds of community-wide intervention. We believe that improvements came from a combination of better targeted community and clinic activities, expanded national HIV treatment guidelines, increasing understanding of universal ART, and enhanced community acceptance of UTT.

Country	Referred to HIV care, and self-reported they were not on ART on the date of referral (N)	ART initiated, by months after referral (%) 3 months	ART initiated, by months after referral (%) 6 months	ART initiated, by months after referral (%) 12 months Estimates for % initiated ART by 12 months after referral are not given for individuals referred to care in R3, because as yet (as of Sep 30 2017) there is insufficient follow-up time during Round 3 to report reliable estimates for this time point; it will be possible to report such estimates (or at least up to 9 months after referral) after Dec 31 2017	Hazard ratios adjusted from Cox regression, adjusted for gender, age group, and community of residence
Zambia Overall	R1 6,197 R2 3,435 R3 2,296	32 % 39% 50%	42% 50% 64%	55% 67%	1 (Ref) (p<0.001) 1.37 [1.29-1.46] 2.13 [1.97-2.29]

THPEC277

Making combination prevention packages work for adolescent girls and young women through PEPFAR

J. Saul[1], N. Toiv[1], T. Beamon[1], C. Cooney[1], S. Allen[1], K. Sato[2], A. Achrekar[1], I. Zaidi[1]
[1]Office of the US Global AIDS Coordinator and Health Diplomacy, Washington, United States, [2]U.S. Peace Corps, Washington, United States

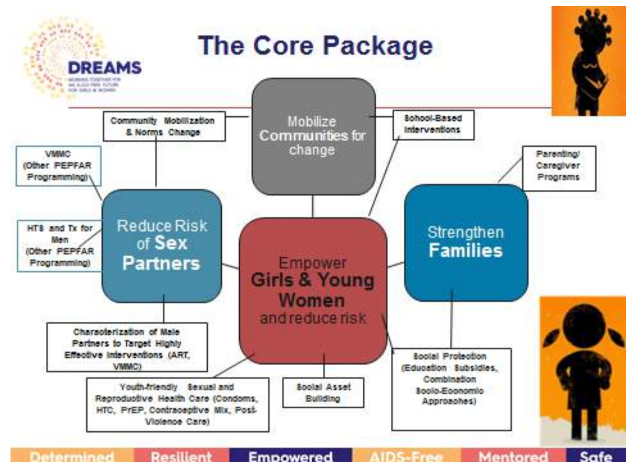
Background: In 2014, the U.S. President's Emergency Plan for AIDS Relief (PEPFAR) partnered with the Bill & Melinda Gates Foundation, Girl Effect, Gilead Sciences, Johnson & Johnson, and ViiV Healthcare to create the DREAMS Public-Private Partnership (Determined, Resilient, Empowered, AIDS-free, Mentored, and Safe). DREAMS was created to reduce the staggering rate of new HIV infections in adolescent girls and young women (AGYW) 15-24 in 10 high HIV burdened African countries.

Description: PEPFAR-supported DREAMS countries implemented a multi-faceted package of interventions in 63 high-burden districts to support AGYW, their families, and communities. DREAMS guidance examined contextual factors affecting HIV acquisition, such as sexual violence, limited access to education, and early pregnancy, and set out program requirements, including: engaging recipients and partners in conceptualization; recruiting the most vulnerable AGYW; utilizing evidence-based interventions; and ensuring layered programs so AGYW receive multiple interventions.

Lessons learned: DREAMS is a successful and vibrant public-private partnership. Since the launch of DREAMS, the DREAMS Innovation Challenge was created and country governments have embraced and expanded DREAMS. Given the deep inequalities AGYW experience in their communities, accessing the most vulnerable girls is challenging. Tools like The Girl Roster are pivotal in identifying them. Although combination prevention was emphasized in past PEPFAR programming, ensuring the practice and monitoring of layering has been challenging. In two years of DREAMS implementation, the five countries that have infrastructure to monitor layering provided three or more services to at least 50% of DREAMS-enrolled AGYW. Other DREAMS countries are developing systems to track layering.

Despite the challenges of such a massive effort, PEPFAR has reached over 2.5 million AGYW with comprehensive HIV prevention in DREAMS districts. In the 10 countries implementing DREAMS, a majority (65% or 41) of DREAMS districts achieved greater than a 25% decline in new diagnoses among AGYW 15-24 since 2015, including 14 districts that had a decline of greater than 40%. Importantly, new diagnoses declined in nearly all DREAMS districts.

Conclusions/Next steps: DREAMS showed the world a blueprint for evidence-based combination prevention among AGYW, and is showing success. Responding to lessons learned is critical to improve DREAMS and broader prevention programming for AGYW.



[The DREAMS Core Package]

THPEC278

Service workers in group (SWING): Addressing multi-level HIV risks associated with male sex workers through key population-Led comprehensive approach in Bangkok and Pattaya

S. Janyam[1], P. Srimanus[2], C. Phaengnongyang[1], S. Niamtanom[1], S. Sumalu[1], J. Jantarapakde[2], S. Pengnonyang[2], P. Rattakitvijun Na Nakorn[2], S. Charoenying[3], S. Mills[3], R. Vannakit[4], N. Phanuphak[2], P. Phanuphak[2]

[1]Service Workers in Group Foundation, Bangkok, Thailand, [2]The Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [3]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [4]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

Background: Criminalization and penalization of male sex workers (MSW) in Thailand often result in continuous exposure to violence and discrimination from the society, law enforcement officers and health care providers. In addition to biological risk from anal sex behavior, these multi-level social risks pose MSW at high level of vulnerability to HIV infection.

Description: Service Workers in Group (SWING) Foundation is the first MSW-led organization in Thailand. In order to address the multi-level risks of HIV among MSW, SWING uses a comprehensive approach which comprises i) Outreach through regular offline and online activities to empower MSW with HIV prevention and other life-saving skills; ii) Drop-in Centers (DiCs) in the heart of two major red-light districts in Bangkok and Pattaya to provide safe space for MSW; iii) HIV-related clinical services including HIV/STI testing and PrEP/PEP dispensing performed by trained community health workers who are members of MSW community, either at their DiCs or via a mobile clinic, as part of Key Population-Led Health Services (KPLHS) model; iv) Educational sessions for MSW including classes for non-formal education, English and other languages; and v) Human rights protection through legal consultation/assistance and serious engagement of police officers and business owners.

Lessons learned: From October 2015-December 2017, SWING reached 22,308 MSW (11,516 offline; 5 online) and tested 3,533 for HIV, with an overall HIV-positive yield of 12.6%. Among those tested positive, 47.3% were successfully linked to antiretroviral treatment (ART). Among HIV-negatives, 5.24% were provided with PrEP and there was no seroconversion among those who took PrEP continuously. Of 276 MSW who attended non-formal education at SWING, 97.8% graduated secondary education, 1.8% achieved their bachelor's degrees, and 0.36% master's degrees. Engagement of police officers and business owners has been crucial for SWING to be able to continue their outreach and clinical services activities during the periods of heightened enforcement of laws against human-trafficking in Thailand.

Conclusions/Next steps: SWING successfully implemented a comprehensive approach to address multi-level risks for HIV among MSW. KPLHS demonstrated high HIV-positive testing yield and successful linkage to ART and PrEP. Sustainability in the country would need strong policy support and clear financing mechanism.

THPEC279

Differential trends in biomedical HIV prevention among younger and older men who have sex with men in a treatment as prevention environment: A 5-year prospective cohort study

N.J. Lachowsky[1,2], L. Wang[1], N. Bacani[1], S. Chown[3], K.A. Closson[1], H.L. Armstrong[1,4], K.G. Card[5], G. Olarewaju[1], E.A. Roth[2], R.S. Hogg[1,5], D.M. Moore[1,4], Momentum Health Study

[1]British Columbia Centre for Excellence in HIV/AIDS, Division of Epidemiology & Population Health, Vancouver, Canada, [2]University of Victoria, Victoria, Canada, [3]YouthCO HIV & Hep C Society, Vancouver, Canada, [4]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [5]Simon Fraser University, Burnaby, Canada

Background: Post-exposure prophylaxis (PEP), pre-exposure prophylaxis (PrEP), and viral load sorting (VLS) provide novel combination prevention strategies for men who have sex with men (MSM). Despite promotion of Treatment as Prevention as policy since 2010, new HIV diagnoses among MSM in British Columbia remain unchanged (58.9% of all new diagnoses in 2015). Younger MSM are a key priority population locally and globally. We sought to evaluate and compare trends in awareness and use of biomedical HIV prevention (PEP, PrEP, and VLS) between younger and older MSM in Vancouver, Canada from 2012-2017.

Methods: The Momentum Health Study is a prospective cohort study of sexually-active MSM aged at least 16 years in Vancouver, recruited using respondent-driven sampling from 02/2012-02/2015. Follow-up visits occurred every 6 months with data included to 02/2017. Visits included a computer-assisted self-interview on sexual behaviour, HIV prevention practices, attitudes, and demographics. Three-level mixed effects models (RDS recruitment chain: participant: visit) addressed clustered longitudinal data. Multivariable trend analyses controlled for gender, sexual orientation, income, and HIV status ($P< 0.05$ considered significant). We compared trends using statistical interactions between calendar time (6-month periods) and age (younger versus older).

Results: Of 698 cohort participants, median follow-up was 3.42 years (n=3722 visits). At baseline, 257 (36.8%) participants were aged under 30 years and 201 (28.8%) were living with HIV. Overall, there were significant increasing trends in having heard of PEP (64.1% to 85.2%, $P< 0.001$), having heard of PrEP (29.3% to 81.0%, $P< 0.001$), having used PrEP (0% to 4.2%, $P=0.003$), higher HIV treatment optimism (50.0% to 82.1%, $P< 0.001$), and practicing VLS (15.5% to 25.3%, $P=0.006$). Two significant statistical interactions indicated differential trends for younger and older MSM. First, PrEP awareness (interaction $P< 0.001$) increased more for younger than older MSM. Second, VLS (interaction $P=0.004$) increased for younger MSM, but remained stable for older MSM. For both PrEP awareness and VLS, levels among younger MSM outstripped older MSM over time.

Conclusions: There have been marked increases in awareness and use of biomedical HIV prevention among MSM in this Treatment as Prevention environment. Differential trends by age group highlight particular success in health education among younger MSM.

THPEC280

School attendance and sexual behavior among adolescent girls and young women living in high-burden settings and receiving conditional cash transfer: Description of the MP3 youth cohort

S.O. Rao[1], I. Inwani[2], K. Agot[1], M.C. Cleland[3], J. Buttolph[4], M. Anam[1], J. Kinuthia[2], P. Cherutich[5], R. Nduati[2], A.E. Kurth[6]

[1]Impact Research and Development Organization, Research, Kisumu, Kenya, [2]University of Nairobi, Nairobi, Kenya, [3]Rory Meyers College of Nursing, New York University, New York, United States, [4]Interagency Collaboration for Program Improvement (ICPI), Atlanta, United States, [5]Ministry of Health, Nairobi, Kenya, [6]Yale University School of Nursing, Connecticut, United States

Background: Conditional cash transfer (CCT) can address some of the gender inequalities in school dropout rates and HIV risk perpetuated by poverty and economic dependence on older sexual partners. We assessed the effect of CCT on school attendance, sexual behavior and HIV incidence among school-going adolescent girls and young women (AGYW) in a high-burden setting of Homabay County, western Kenya.

Methods: Quarterly cash disbursements of $72 were offered to eligible HIV-negative school-going girls aged 15-24 years and their family as a component of gender-specific combination prevention packages in MP3 Youth study. The girls were required to attend school at least 80% of the time for her and family to receive the CCT. School attendance and sexual behavior was monitored every quarter for 12 months. Participants were retested for HIV after 12 months.

Results: We recruited 689 AGYW and enrolled 50 girls (mean age, 16.3 years) and their caregivers in the CCT cohort. During the intervention, 97.5% (195/200) of planned follow-ups were completed. In the first three quarters post-enrollment, 90% of the girls achieved the set mark (of at least 80%) for school attendance; however, only 60% of the girls maintained the required school attendance in the final quarter, with 24% of girls across follow-ups reporting missing school due to inability to pay school fees. In terms of sexual behavior, the change in the percentage of girls who were sexually active was insignificant at all follow ups, but

Tuesday 24 July

Wednesday 25 July

Thursday 26 July

Friday 27 July

Late Breaker Abstracts

Publication Only Abstracts

Author Index

the proportion having sex without a condom was higher at months 9 (3/6; 50%) and 12 (3/6; 50%) compared to month 3 (1/12; 14.3%). Receiving money or gifts in exchange for sex was rare
(< 10% of girls) at all follow-ups. Seven cases of pregnancy and 1 HIV seroconversion was reported.
Conclusions: Although overall school attendance was good in this cohort, a small proportion of girls missed school due to inability to pay fees, implying that either the amount was insufficient, or families did not prioritize using the funds to pay fees. Pregnancies and incident HIV suggest sexual risk remain for some girls despite CCT, which highlights the importance of combination prevention targeting AGYW in high-burden settings.

THPEC281

Mapping of key populations of Morocco: Empowering community

E.Z. Azza[1,2], Y. Yatine[2,3], M. Choukri[1,2], M. Lamouri[1,2], P. Huygens[4], L. Ghargui[5], A. Ben Moussa[1,2], L. Ouarsas[2,6], H. Himmich[1,2], M. Karkouri[1,2]
[1]ALCS, Casablanca, Morocco, [2]Laboratoire de Recherche Communautaire Coalition +, Casablanca, Morocco, [3]ALCS, Marrakech, Morocco, [4]Independent Consultant of the Global Fund, Brussels, Belgium, [5]Ministry of Health, Rabat, Morocco, [6]ALCS, Agadir, Morocco

Background: Since 2013, mapping of key populations (KPs) in areas with higher HIV prevalence has been part of the identification of "Corridors of vulnerability" in Morocco. In 2017, in order to gain better understanding about distribution of KPs and KP-friendly services in the country, the mapping of the Greater Casablanca was launched by the Ministry of Health supported by Global Fund and UNAIDS. Mapping of hotspots was conducted by community peer educators (PE) and outreach workers (OW) from the "Association de Lutte Contre le Sida" (ALCS).
Methods: A team of 56 PE, from Female sex Workers (FSWs) and men having sex with men (MSM) were mobilized and trained, beside 10 supervisors experienced in mapping.
The team received training on methodology and on using tools and smartphone Apps for GPS geolocation.
The mapping followed a four steps planning:
(1) sites and services identification,
(2) a census of MSMs and FSWs
(3) a first capture distributing tagging card to KPs included,
(4) a recapture counting all KPs met, as well as those who received the card during the first visit and those who refused contact.
Results: While performing the census the teams discovered many new KP-sites as compared to those initially identified. This led the program to realize that the needs for combined prevention are much higher than expected highlighting that the coverage has to be improved. Most hidden categories of FSWs and MSMs were also found thanks to enhanced mobilization by PE. Overall 519 FSWs' sites and 331 MSMs' sites were identified among which respectively 61% and 82% were unknown to prevention teams. Thanks to this enhanced peer-outreach work, a total of 8768 FSWs and 3032 MSM have been estimated for Casablanca.
Conclusions: Despite of the risk of violence during night exercises, the challenge of mapping of these KPs in a large city as Casablanca was met successfully. Thanks to mapping, peer-outreach work has been crucially enhanced. At the programmatic level, teams and KP were empowered as they have now the capacity to self-conduct mapping and to participate in the follow-up of strategic planning of comprehensive prevention over new corridors of vulnerability in the Country.

THPEC282

New South Wales HIV strategy 2016-2020: Working towards ending HIV transmission

C. Selvey[1], A. Grulich[2], J. Holden[3], P. Keen[2], M. Holt[4], C. Cooper[5], T. Duck[3], R. Guy[2], K. Price[6], B. Whittaker[7], B. Telfer[8]
[1]NSW Health, North Sydney, Australia, [2]The Kirby Institute, University of New South Wales, Kensington, Australia, [3]NSW Ministry of Health, North Sydney, Australia, [4]Centre for Social Research in Health, University of New South Wales, Kensington, Australia, [5]Positive Life NSW, Surry Hills, Australia, [6]ACON, Surry Hills, Australia, [7]NSW HIV Strategy Implementation Committee, NSW Ministry of Health, North Sydney, Australia, [8]Health Protection NSW, Sydney, Australia

Background: The HIV epidemic in New South Wales (NSW), Australia, is concentrated among gay and bisexual men (GBM). The second NSW HIV Strategy builds on our efforts to end HIV transmission by 2020 through improving: access to pre-exposure prophylaxis (PrEP); earlier diagnosis; and antiretroviral treatment (ART) coverage and early initiation.
Methods: Social media, gay press and broader community-based advertising was used to raise awareness of HIV testing, treatment as prevention and PrEP. Regular reporting of progress towards targets for increased HIV testing, higher ART coverage and earlier ART initiation was used to drive clinical redesign within NSW Health clinics. A large PrEP implementation trial began in March 2016 with the aim of rapidly increasing PrEP uptake. Progress is being monitored via testing data from laboratories and services, routine data on ART prescriptions, HIV surveillance and enhanced HIV surveillance undertaken six months after diagnosis.
Results: Between 2012 and 2017, HIV testing increased by 35% with increases among populations most at risk of HIV. In quarter 3 2017, 95% of HIV positive patients attending NSW Health HIV clinics and general practice clinics serving GBM had been prescribed ART. Seventy five percent of people newly diagnosed with HIV in January 2017 to March 2017 initiated ART within 6 weeks of diagnosis with a median time to treatment initiation of 28 days. Over 8,000 participants were enrolled in the PrEP trial by the end of 2017. The number of new diagnoses (166) among GBM in January 2017 to September 2017 was 24% lower than that for the previous six year average for same period (219). The number of Australian-born GBM diagnosed in 2017 with evidence of HIV acquisition within 12 or 3 months of diagnosis was the lowest seen in a decade. However, declines in recent infection were not seen in overseas-born GBM or heterosexual people.
Conclusions: Implementation of the NSW HIV Strategy is associated with a significant decline in HIV diagnoses with evidence of recent infection among Australian-born GBM. NSW is one of few jurisdictions that has taken a comprehensive approach to eliminating HIV transmission with positive progress so far.

THPEC283

HIV free testing services and distributions of incentives to indigent students in Orozo community, Nasarawa State Nigeria: Impact of incentives as a mobilization strategy

E.A. Bonderk, HIV/AIDS Medical CDS Team Group
National Agency for the Control of AIDS (NACA), Partnerships Coordination, FCT, Nigeria

Background: Nigeria has HIV prevalence of 3.4% and the second highest burden of HIV/AIDS globally. The National HIV & AIDS and Reproductive Health Survey, 2012, shows very low uptake of HIV testing in Nigeria. About 23% of males and 29% of females had tested in the year preceding of the survey. The desire to test for HIV was 77%, among adults. This prompted a push to increase the number of testing sites and improve on testing strategies. To complement this effort, community outreach was organized in the Orozo community to fast track effort in making more Nigerians' aware of their HIV status.
Description: The community testing model for HIV was adopted. A total of 6000 adults (4230 female-70.5% and 1770males- 29.5%) turned out for HIV testing service. Free note books and insecticide treated nets distributed to indigent students and parents. The mobilization efforts promot-

ed the availability of people tested. The incentives distributed only to those that took the test. The Rollback Malaria Programme, SFH provided the insecticide treated net used for the outreach, while IHVN provided the testing venue, testers, test kits and consumable, partnering private school provided the exercise books that were distributed.

Lessons learned: There was increased service uptake as a result of the incentives. Out of 6000 adults aged 18 and above that came out for the test, 5986 were tested and received their results. About 20% tested positive. The result of the outreach proves that incentives added to the call for HIV test uptake increases yield. The community members were eager to take up HIV testing despite stigma and fear of test outcome that have always hindered service uptake.

Conclusions/Next steps: HIV testing services should be routine for every Nigerian, Community based NGOs and other service providers should supplement HIV testing services with incentives to increase service uptake as this is the surest way to guarantee an HIV free generation. Due to increased number of people tested using this strategy, there is need to scale up to other communities to increase testing and general awareness on HIV/AIDS. Incentives can be leverage from other health implementing partners as a support for an intervention.

THPEC284

Combination Prevention among young people in key populations: A Brazilian experience through peer-to-peer education

D.A. Calixto, C.B.d. Sousa, L.P. Ribeiro, G.C.d. Silva, A.S. Benzaken
Ministry of Health of Brazil, Department of STI, HIV/AIDS and Viral Hepatitis, Brasilia, Brazil

Background: Young people represent 40% of new HIV infections worldwide. In Brazil, according to the 2017 Epidemiological Report, youngsters aged 15 to 19 accounted for 44.1% of new HIV cases. In order to understand the specific context of the HIV epidemics in this population, we need a focuses on their specificities and vulnerability contexts. Combination Prevention Workshop with the participation of young key populations (YKP) was marked by an assertive strategy through peer-to-peer education, emphasizing approaches to enhance sexual health through the exchange of experiences. The purpose of this study is to provide a snapshot of Combination Prevention among YKP, based on the information collected through this strategy.

Description: The Combination Prevention Workshop with YKP is an initiative launched by the Ministry of Health of Brazil in 2017. Six workshops have been conducted, qualifying 380 young people all over the national territory, to act as peer educators for Combination Prevention in their communities. In this strategy, the MoH, in partnership with local STIs and HIV/AIDS managers, carries out the workshops and activities with the purpose of promoting participation and building an atmosphere of empathy and belonging among these young people. This methodology has enabled the qualification of young peer educators while simultaneously strengthening the teams in charge of the strategy.

Lessons learned: This strategy has helped expanding knowledge and acceptance of Combination Prevention by YKP, paving the way for approaches that are coherent with their specificities and vulnerabilities. Besides sharing experiences, this strategy has also helped young people deconstructing biased ideas and discriminatory attitudes associated with sexual orientation, gender identity, use of alcohol and other drugs, sex work, skin color, race or culture, living with HIV, and people with disabilities, among others.

Conclusions/Next steps: Peer education has shown to improve quality of life of young people. Through this strategy, qualified youngsters have learned to use their knowledge on Combination Prevention and sexual health to develop interventions in their communities, take initiatives and commit themselves to their own health.

THPEC285

Depression and anxiety as risk factors for delayed care-seeking behavior in HIV positive individuals in South Africa

M. Rane[1], T. Hong[2], S. Govere[3], D. Ntshangase[3], H. Thulare[3], M. Yunus-Moosa[4], C. Celum[5], P. Drain[6]
[1]University of Washington, Department of Epidemiology, Seattle, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]AIDS Healthcare Foundation, Durban, South Africa, [4]University of KwaZulu-Natal, Department of Infectious Diseases, Durban, South Africa, [5]University of Washington, Department of Global Health, Department of Medicine, Seattle, United States, [6]University of Washington, Department of Epidemiology, Department of Global Health, Department of Medicine, Seattle, United States

Background: Clinic- and community-based efforts to improve HIV testing in sub-Saharan Africa may benefit from understanding how mental health influences HIV care-seeking behavior. We evaluated the associations of depression and anxiety with delayed presentation to care and late HIV testing in an HIV positive cohort in South Africa.

Methods: We conducted a cross-sectional study among adults presenting for voluntary HIV testing in the Umlazi township of South Africa. Prior to HIV testing, we measured depression using the Patient Health Questionnaire-9 (PHQ-9) scale and anxiety using the Generalized Anxiety Disorder-7 (GAD-7) scale. We categorized HIV care-seeking behavior using standardized definitions for *delayed presentation* (presenting to clinic >3 months after first HIV positive test regardless of CD4 count), *late testing* (presenting within 3 months of HIV diagnosis or at the time of enrollment with CD4 ≤200 cells/μ l), or neither (presenting within 3 months of HIV diagnosis or at enrollment with CD4 >200 cells/μl). We used multinomial logistic regression models adjusted for socio-demographic and behavioral characteristics to determine the effects of depression and anxiety on HIV care-seeking behavior.

Results: Among 1,483 HIV-infected adults, 59% were female, mean age was 33 years and 65% of the participants had been tested for HIV prior to study enrollment. The prevalence of depression in the cohort was 33% and that of anxiety was 9%. In adjusted models, HIV-infected adults with mild/moderate and severe depression had 2.5 greater odds [95% confidence interval (CI): 1.5, 4.3] and 4.8 greater odds (95% CI: 1.6, 13.6) of delayed presentation respectively, as compared to those without depression. Individuals with generalized anxiety had 3.3 greater odds (95% CI: 1.7, 6.2) of delayed presentation compared to those without anxiety. Depression was associated with late testing (OR: 1.4; 95% CI:1.05, 1.9), while anxiety was not (OR:1.3; 95%CI: 0.8, 2.1).

Conclusions: Depression was associated with delayed presentation and late testing, while anxiety was associated only with delayed presentation. This study underscores the influence of mental health on various types of HIV care-seeking behavior in a poor, South African township. Brief mental health screening at initial HIV testing and presentation may improve enrollment and linkage in HIV treatment programs.

THPEC286

HIV-positive women's perspectives on integrating a screening and brief intervention (SBI) for harmful alcohol use into HIV post-test counseling in Ugandan fishing villages: Assessing acceptability and barriers to implementation

A.P. Miller[1], G. Kigozi[2], E. Bonnevie[1], N. Nakyanjo[2], W. Ddaaki[2], C. Ssekyewa[2], J. Wagman[1]
[1]University of California San Diego, Medicine, La Jolla, United States, [2]Rakai Health Science Program, Kalisizo, Uganda

Background: Women who consume alcohol have increased risk for HIV infection and alcohol use among people living with HIV (PLHIV) is associated with numerous adverse health outcomes. Alcohol prevention research is a global priority, particularly in Uganda's fishing villages where HIV prevalence reaches 37% and more than half of women drinkers consume hazardous quantities. Evidence suggests reducing hazardous alcohol use can also reduce HIV risk behaviors and that integrating

alcohol screening and brief interventions (SBI) into health services (e.g. HIV testing and counseling services, HTC) is both effective and low-cost. This study examined women PLHIV's perceptions of:
(1) alcohol's role in HIV acquisition/transmission,
(2) how learning about HIV-positive status impacts drinking behaviors, and;
(3) the acceptability of integrating an alcohol reduction SBI into HTC among women in fishing communities in Uganda.
Methods: In-depth qualitative interviews were conducted in January 2017 with twenty female PLHIV
(15-49 years) from three Rakai fishing villages. Participants were drawn from a subset of Rakai Community Cohort Study respondents who requested an HIV test and post-test counseling. Interviews were conducted in Luganda by trained female researchers.
Results: Participants felt alcohol contributes to HIV infection by decreasing inhibitions and increasing HIV risk behaviors (e.g., condomless sex). Most felt receiving an HIV-positive diagnosis catalyzes people to change their alcohol behaviors but the direction of change varies, with some placing an increased emphasis on preserving their health and other feeling a diminished incentive to invest in their health. Most felt it was acceptable to intervene on harmful alcohol use at the time of HIV diagnosis and that it would be beneficial to include sex partner(s) in the intervention. Several considerations were flagged as areas to be addressed when designing the SBI (Table 1).

Thematic Area		Supporting Quotes from Interviews
Receiving an HIV+ diagnosis can serve as a catalyst for behavior change	Sometimes these changes are positive, to improve their life expectancy...	***"Normally people change their drinking patterns by drinking less in terms of the amount of alcohol they are used to drinking before because alcohol is like poison, when some is diagnosed HIV + they do not need to drink alcohol because alcohol reduces on CD4 count, and yet they struggle to increase on their CD4 count." [Female, 23 yrs, Ddimo]***
	Sometimes, the change is destructive...	***"There are those who can change. One says, ´I have been diagnosed with HIV let me reduce drinking alcohol.´ and there is one who decides to drink too much after being diagnosed with HIV. He says, ´Why not drink alcohol? After all I am going to die.´ So he starts drinking [more] than before the diagnosis to the extent of sleeping in bars. He says, ´Let me drink. I was diagnosed with HIV.´" [Female, 50 yrs, Namirembe]***
Assessing alcohol use at time of HIV diagnosis is appropriate	Because people are receptive to change after learning they have seroconverted...	***"I think its good time because you get to learn how to live your life well." [Female, 40 yrs, Namirembe]***
	And because drinking presents additional risks after diagnosis...	***"Yes. I think it would be good. If one has been going to the bar to drink, he or she can be counseled to stop drinking. A person may drink and then come back and swallow four tablets of ARVS instead on one or two tablets the health worker instructed him to swallow. He wrongly takes the medicine because of drinking alcohol. So I think it would be good for the counselor to talk about alcohol use during the time of diagnosis." [Female, 23 yrs, Malembo]***
Having HTC counselors implement the SBI is acceptable and culturally appropriate	Most respondents said discussing alcohol use with HTC counselors was appropriate and that they would have been willing to do so. Reasons provided for why it was not appropriate included...	***(1) Perceived Stigma around consuming alcohol "But about alcohol use, the counselor might feel that that is how you grew up. The person who drinks is taken to be in another group. I realized that when I drink they see me in a different image. Now that I no longer drink, I see myself in a different image and the people I associate with are respected compared to those I had before. I now sit with different people even though the other ones were my friends. People can now confide in me and tell me their secrets but before, they used to see me moving with people in groups. There are many things that I learnt and can compare them to when I used to drink and now that I am not drinking." [Female, 23 yrs, Malembo]***
		(2) Not feeling there was anything to gain from discussing their alcohol use with the counselors. NP: "No I would not feel uncomfortable because the advice I receive from [the] HTC counselor will be of much benefit, because it is about protecting my life so there is no need to discuss with the HCT counselor." [Female, 23 yrs, Ddimo]
Partners should be included in the alcohol intervention	So that both partners have access to the same information...	***"Because if they come and counsel me alone without counseling my partner, this will leave me informed when for him he is ignorant. If we are counseled together we all benefit together." [Female, 23 yrs, Malembo]***

[Table 1. Women PLHIV's (n=20) perceptions about an HTC-based alcohol SBI in their fishing village community]

Conclusions: Integrating an alcohol reduction SBI into HTC seems both acceptable and feasible in Rakai's fishing areas. Our next steps are to tailor the World Health Organization's alcohol risk reduction intervention, for scale up and evaluation - through a cluster randomized trial— in this setting. This combination prevention approach holds potential to improve the health of the population, the specific community members in fishing areas, and individuals in Rakai, Uganda.

THPEC287

High rates of linkage to care outside referral clinics in Botswana: Implications for accurate counting of PLHIV linked to care

P. Bachanas[1], M.G. Alwano[2], S. Behel[3], R. Lebelonyane[4], L. Block[5], W. Sento[6], W. Abrams[2], M. Pretorius-Holme[7], K. Manyake[8], S. Lockman[7,8,9], J. Moore[3]
[1]Centers for Disease Control and Prevention, Division of Global HIV/ AIDS, Atlanta, United States, [2]Centers for Disease Control - Botswana, Gaborone, Botswana, [3]Centers for Disease Control and Prevention, Division of Global HIV/AIDS, Care and Treatment, Atlanta, United States, [4]Ministry of Health and Wellness, Department of HIV, Gaborone, Botswana, [5]Intellectual Concepts, Atlanta, United States, [6]Tebelopele VCT, Gaborone, Botswana, [7]Harvard T. H. Chan School of Public Health, Boston, United States, [8]Botswana Harvard Partnership, Gaborone, Botswana, [9]Brigham and Women's Hospital, Boston, United States

Background: Evidence indicates that a substantial percentage of persons identified as HIV positive do not link to care. Emerging evidence suggests that many HIV-positive persons enroll in care in clinics outside their local communities; however, the data are often not captured in existing medical records thus artificially lowering linkage to care estimates. We were able to track patients referred through the Botswana Combination Prevention Project (BCPP) to determine the extent to which persons sought care at clinics outside their community of residence.
Methods: BCPP is a community-randomized trial evaluating the impact of a combination prevention package on population level HIV incidence in 30 communities. HIV testing in the 15 intervention communities included home-based and targeted mobile testing of residents age 16-64. Newly-identified and known HIV-positive persons not on ART were referred to the local clinic for HIV care and treatment; those who did not keep appointments were tracked and traced. Non-linkers were tracked through the national electronic medical record system and enrollment at outside clinics was verified by the nurse in that clinic.
Results: 13,434 HIV-positive persons were identified; of those, 3,635 (27%) were not on ART and were referred to their local clinic. Overall, 91% (3,311/3,635) of referrals linked to care and received an HIV service (e.g., consultation, labs); 76% (2,772/3,635) linked to their local clinic and 15% (539/3,635) linked to clinics outside their community. Only 9% of referrals did not link at all, with a higher proportion of youth than adult males or females never linking (X^2 =53.1, p< .0001).

	Linked to Referral Clinic	Linked to Outside Clinic	Never Linked
Women > 25	1,406 (79%)	275 (15%)	97 (5%)
Men > 25	991 (75%)	176 (13%)	154 (12%)
Youth (16-24)	375 (70%)	88 (16%)	73 (14%)
TOTAL	2,772 (76%)	539 (15%)	324 (9%)

[Table 1: Linked to Referral Clinic vs Outside Clinic by Age and Sex in BCPP Combination Prevention Communities 1-15]

Conclusions: A sizeable proportion of HIV-positive persons linked to clinics and received care and treatment outside their communities of residence. These data highlight the importance of tracking HIV-positive individuals referred for care beyond referral clinics, as estimates of linkage to care that do not account for linkage to outside clinics underestimate the number of PLHIV who enrolled in care. These findings also

emphasize the importance of a national data system with individual identifiers that can track patient data to all clinics so rates of both linkage and retention in care estimates are accurate.

THPEC288

Implementing World Health Organization (WHO) recommended Linkage services: Methods, outcomes, and costs of the Bukoba Tanzania combination prevention evaluation peer-delivered linkage case management program, 2014-2017

O.E. Rwabiyago[1], D. MacKellar'[2], H. Maruyama[3], C. Steiner[3], H. Cham[2], O. Msumi[3], G. Kundi[3], J. Byrd[4], E. Churi[3], R. Weber[5], S. Pals[2], C. Madevu-Matson[6], T. Mengistu[2], C. Suraratdecha[2], D. Mbilinyi[7], K. Kazaura[1], F. Morales[3], J. Justman[6], A. Rwebembera[8]
[1]Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [2]Centers for Disease Control and Prevention, Atlanta, Georgia, United States, [3]ICAP at Columbia University, Dar es Salaam, Tanzania, United Republic of, [4]ICF International, Atlanta, Georgia, United States, [5]Centers for Disease Control and Prevention, Yaounde, Cameroon, [6]ICAP at Columbia University, New York, Tanzania, United Republic of, [7]United Nations Children's Fund, Dar es Salaam, Tanzania, United Republic of, [8]National AIDS Control Program, MoHCDGEC, Dar es Salaam, Tanzania, United Republic of

Background: Despite improved access to antiretroviral therapy (ART), many people living with HIV (PLHIV) in sub-Saharan Africa, particularly those tested in community settings, continue to delay enrollment in care following HIV diagnosis. To enroll ≥90% of PLHIV within three months of diagnosis, we implemented a peer-delivered, linkage case-management (LCM) program providing WHO recommended linkage services.
Description: Conducted in Bukoba Municipality Tanzania (population: ~150,000) as part of a larger combination prevention evaluation, LCM was provided to clients who tested HIV-positive at 11 health facilities (facility clients), and at homes or community events in 14 urban and rural wards (community clients). LCM services were provided by HIV-positive, peer counselors for up to 90 days. During Test & Start, LCM was combined with same-day ART initiation for both facility and community clients.
Lessons learned: Of 4,805 eligible persons, 4,273 (89%) consented to LCM. Of 4,206 (98%) clients with complete indicator data, most received recommended services: counseling on early enrollment in care (100%); escort to HIV clinic (83%); treatment navigation (94%); telephone support (77%), and in two separate sessions, counseling on disclosure and partner/family testing (77%); and on real and perceived barriers to care (69%). Enrollment in HIV care and ART initiation within three months of diagnosis increased over time, exceeding 95% and 85% during Test & Start, respectively, for both facility and community clients (Table). During Test & Start, 98% and 97% of males (n=310) and females (n=442), and 96% and 98% of clients aged 15-24 (n=150) and 24-49 (n=535) years, respectively, enrolled in HIV care. Of 463 clients who participated in the last three months of the roll-out of Test & Start, 91% were initiated on ART. Per-client LCM service cost was $54 USD.

	All clients			Facility			Community		
	Total	Enrolled	ART	Total	Enrolled	ART	Total	Enrolled	ART
Client Characteristics	n	n (%)	n (%)	n	n (%)	n (%)	n	n (%)	n (%)
Total	4206	3918 (93)	2521 (60)	3538	3367 (95)	2247 (64)	668	551 (82)	274 (41)
ART-eligibility periods:									
Oct 2014 - Dec 2015 (CD4<350)	2233	2018 (90)	1057 (47)	1876	1738 (93)	971 (52)	357	280 (78)	86 (24)
Jan 2016 - Sep 2016 (CD4≤500)	1221	1168 (96)	815 (67)	1031	1013 (98)	732 (71)	190	155 (82)	83 (44)
Oct 2016 - Mar 2017 (Test & Start)	752	732 (97)	649 (86)	631	616 (98)	544 (86)	121	116 (96)	105 (87)

[Enrollment to HIV care and ART initiation in different ART-eligibility periods]

Conclusions/Next steps: WHO-recommended peer-delivered LCM services achieved early ART initiation for the majority of both facility and community clients in Tanzania at modest cost, and was more successful when combined with same-day ART. In Tanzania, peer-delivered LCM was approved by the Ministry of Health as a new service delivery model in 2017 and is being adopted for national implementation in 2018 by three PEPFAR-supported HIV-prevention and treatment organizations.

THPEC289

Achieving the first two UNAIDS 90-90-90 targets on completion of a three-year universal testing and treatment (UTT) intervention in the HPTN 071 (PopART) randomised trial in Zambia and South Africa

R.J. Hayes[1], S. Floyd[1], A. Schaap[1,2], K. Shanaube[2], B. Yang[3], S. Griffith[4], P. Bock[3], N. Beyers[3], H. Ayles[1,2], S. Fidler[5], HPTN 071 (PopART) Study Team
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Zambart, Lusaka, Zambia, [3]Desmond Tutu TB Centre, Western Cape, South Africa, [4]FHI360, Durham NC, United States, [5]Imperial College, London, United Kingdom

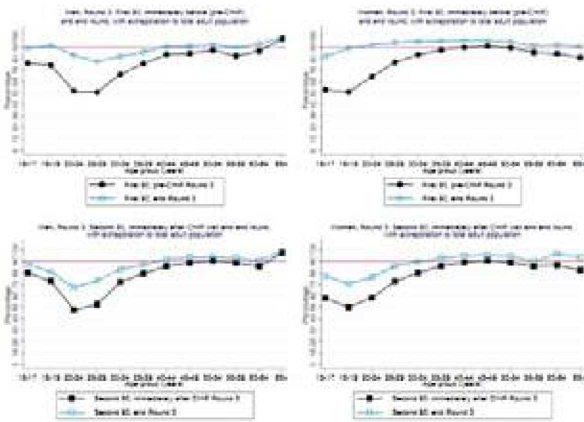
Background: The 90-90-90 targets aim to substantially decrease HIV transmission but it is unknown whether they can be achieved in urban communities with severe HIV epidemics. We report data from HPTN 071 (PopART), the largest programme delivering universal testing and treatment (UTT) in sub-Saharan Africa, to determine whether the targets have been reached after the three-year intervention.
Methods: PopART is a combination prevention intervention comprising annual rounds of home-based HIV testing delivered by Community HIV-care Providers (CHiPs) who also support linkage to care, ART retention and other HIV-related services. CHiP data from four communities in Zambia and three in South Africa receiving the full PopART intervention (including universal ART) were extrapolated to estimate the overall numbers of HIV-positive (HIV+) adults (15+) in these communities, the proportions who knew their HIV+ status (first-90) and the proportions of known HIV+ adults on ART (second-90), after the third annual round (R3:Sep 2016-Dec 2017) .
Results: By the end of R3, 75,472 (~100%) households had been visited by CHiPs, and 193,907 adult residents were enumerated of whom 139,951(72.2%) were contacted and consented to the intervention. Estimated total numbers of HIV+ adults (Table) were 9,332 men and 17,861 women, of whom 87% of men and 94% of women knew their HIV+ status following R3 (first-90) in Zambia, and 86% of men and 95% of women in South Africa.

	Estimated number of HIV+ individuals/Total population (%)	First 90: Immediately before R3 visit (%)	First 90: End of R3 (%)	Second 90: Immediately after R3 visit (%)	Second 90: End of R3 (%)
ZAMBIA: Adults who participated Men:	3,736/41,332 (9.0%)	78	97	73	85
Women:	9,395/56,345 (16.7%)	82	97	77	89
Extrapolated to total population Men:	6,244/64,704 (9.7%)	75	87	79	88
Women:	11,418/69,458 (16.4%)	82	94	79	89
S AFRICA: Individuals who participated Men:	1,557/17,813 (8.7%)	77	93	70	84
Women:	4.366/24,461 (17.8%)	88	97	82	92
Extrapolated to total population Men:	3,088/34,245 (9.0%)	77	86	77	85
Women	6,443/36,859 (17.5%)	88	95	84	92

[90-90 estimates before/after R3 among individuals (age 15+) who participated in intervention and extrapolated to total adult population]

Among these, 88% of men and 89% of women were estimated to be on ART (second-90) by the end of R3 in Zambia, and 85% of men and 92% of women in South Africa. Estimates displayed by gender and age (Figure; illustrated for Zambia) show that both indicators were achieved or exceeded in older adults, but gaps remained in men aged 18-34 years and women aged 15-29 years.

Conclusions: After three rounds of intervention in these urban communities with high mobility and migration, we estimated that the first and second 90 targets were reached overall among women and almost reached among men. Continuing efforts are needed to reach the remaining HIV+ adults not yet diagnosed or on ART, particularly among younger adults where important gaps remain.



[90-90 estimates before/after R3 extrapolated to total adult population, by age/gender (Zambian communities; data for S Africa will also be presented)]

THPEC290

Reaching men and young adults: Methods and outcomes of a 2.5 year comprehensive facility-and community-based HIV testing intervention in Bukoba Municipal Council, Tanzania, 2014-2017

O. Msumi[1], H.J. Cham[2], D. Mackellar[2], H. Maruyama[1], O.E. Rwabiyago[3], G. Kundi[1], C. Steiner[1], R. Weber[4], J. Byrd[5], E. Churi[1], S. Pals[2], C. Madevu-Matson[6], K. Kazaura[3], D. Mbilinyi[7], F. Morales[1], J. Justman[6], A. Rwebembera[8]
[1]ICAP at Columbia University, Dar es Salaam, Tanzania, United Republic of, [2]Centers for Disease Control and Prevention, Atlanta, United States, [3]Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [4]Centers for Disease Control and Prevention, Yaounde, Cameroon, [5]ICF International, Atlanta, United States, [6]ICAP at Columbia University, New York, United States, [7]United Nations Children's Fund, Dar es Salaam, Tanzania, United Republic of, [8]National AIDS Control Program, MoHCDGEC, Dar es Salaam, Tanzania, United Republic of

Background: Few communities in sub-Saharan Africa have achieved the UNAIDS goal of diagnosing ≥90% of people with HIV, particularly for men and persons aged 15-24 years (young adults). To increase diagnostic coverage in Bukoba, Tanzania (population: ~150,000), the Bukoba Combination Prevention Evaluation (BCPE) implemented a community-wide, enhanced provider-initiated (PITC), home- (HBHTC) and venue-based (VBHTC) HIV testing and counseling (HTC) strategy. We report methods and outcomes of our three HTC models implemented from Oct 2014 through March 2017.

Description: For all models, HTC was recommended for persons who were not in HIV care or had not previously tested in the prior 90 days. PITC was implemented in outpatient clinics in all eight public and three ministry-supported private health facilities in Bukoba. In each clinic, one of two lay counselors routinely screened patients in waiting areas and referred them for testing conducted by one dedicated nurse. In all 14 urban and rural wards of Bukoba, five-six teams, each with four lay counselors and one nurse, offered HTC to persons encountered at 31,293 home visits and 79 HTC events at male- and youth-frequented clubs, workplaces, and other venues.

Lessons learned: Of 138,259 client encounters during which HTC was recommended, 133,695 tests were conducted (66% PITC, 21% HBHTC, 13% VBHTC), including 56,304 and 43,247 tests among men and young adults, respectively. Compared with other HTC models, PITC had proportionally more female testers (65%), VBHTC had proportionally more male (69%) and young-adult (42%) testers, and HBHTC had proportionally more children testers (22%) (Table). Of 5,550 (4.2%) clients who tested HIV-positive, 4,143 (3.1% of all tests) were newly diagnosed, including 1,583 (2.8%) men and 881 (2.0%) young adults. Yielding more new HIV diagnoses than HBHTC and VBHTC in all sex and age groups, PITC accounted for 79% of new diagnoses.

Conclusions/Next steps: BCPE HTC models are promising interventions to help achieve ≥90% diagnostic coverage for all persons with HIV, including men and young adults. In Tanzania, BCPE PITC was approved by the Ministry of Health as a new service delivery model in 2017 and is being adopted for national implementation in 2018 by three PEPFAR-supported HIV-prevention organizations.

	HIV Tests (October 2014-March 2017)				New HIV Diagnoses (October 2014-March 2017)

THPEC291

Is it time to integrate innovative combination prevention approaches with conventional peer outreach to enhance HIV case-finding? An experience from India

D.R. Damara[1], P. Todankar[1], R.K. Bandi[1], N.M. K[1], J. Naga Dasu[1], A.K. Reddy[1], M.R. Parthasarathy[1], M. Doddamanne[1], M. Mathew[1], S. GS[1], B. George[1], J.J. Baishya[2]
[1]FHI360, LINKAGES, New Delhi, India, [2]USAID India, Project Management Specialist HIV/AIDS, New Delhi, India

Background: In India, the national HIV prevention program for key populations (KPs) is implemented through targeted interventions (TIs) run by non-governmental organizations**.** Program reviews document 0.11-0.66% HIV case detection, which is much lower than estimated HIV prevalence, pointing to the need to develop more efficient and effective approaches to engage unreached KPs. Hence, the USAID- and PEPFAR-supported LINKAGES project, led by FHI 360, sought to adapt and integrate surveillance-inspired strategies into outreach programming to reach and engage KPs.

Description: LINKAGES in India piloted enhanced peer outreach approach (EPOA), which adapts respondent-driven sampling from surveillance to reach hidden KP networks at high HIV risk. The referral chain starts with the primary seeds, who in turn refer the peers in their social and sexual networks to HIV testing services, through a coupon-based referral system. These clients, if willing, were recruited as peer mobilizers (PM) and were provided coupons with unique identifiers to refer their peers. In 2017, EPOA was rolled out among female sex workers (FSWs) and transgender women (TG) in Mumbai beginning in November; among people who inject drugs (PWID) in Krishna and Guntur districts beginning in October; and among men who have sex with men (MSM) and TG in Krishna District (JulyOctober).

Lessons learned: EPOA reached 737 KPs (170 PWID, 123 FSWs, 158 TGs, and 286 MSM) through 32 primary seeds. In Krishna, the coupon return ratio was 54.5% (648 coupons were distributed) while it was 34% in Mum-

bai (636 coupons were distributed). Overall, 101 participants were found positive, with HIV case finding rates of 8.9%, 11.4%, 19.2% and 10% among FSWs, TG, MSM and PWID, respectively. Of these 101 clients, 91% were linked to antiretroviral therapy (ART) centers, and 76% were initiated on ART.

Conclusions/Next steps: LINKAGES in India has demonstrated EPOA is effective at enhancing HIV case finding across geography and KP typologies. Complementing the EPOA with traditional peer outreach would further increase HIV case finding. LINKAGES will transfer the EPOA tools to the national program, ensuring sustainability of EPOA, and train TI outreach workers in reaching KPs outside traditional hot spots.

THPEC292

Community-based interventions as an entry point for men to access HIV testing services

A. Malima-Manana[1], T. Mmusi[2], L. Legoabe[1], S. Benyera[1], B. Pearce[1], E. Azibuike[3], L. Kamidzhi[4]

[1]Centre for Communication Impact, Community Responses Programme, Pretoria, South Africa, [2]Centre for Communication Impact, Community Responses Programme M&E, Pretoria, South Africa, [3]Project Support Association of Southern Africa, Monitoring and Evaluation, Bethel, South Africa, [4]Project Support Association of Southern Africa, Programmes, Bethel, South Africa

Background: According to a recent study by Sharma et al. 2017, in Sub-Saharan Africa, uptake of HIV testing services by men remains a challenge. HSRC 2017 shows HIV prevalence in South Africa was 21.17%. among female compared to men. Many men do not know their HIV status, and this lack of information hinders prevention efforts and attainment of the first 90 of the UNAIDS 90-90-90 strategy. The Community Responses (CR) programme is a USAID/PEPFAR funded community-based HIV prevention partnership with the South African government. It is implemented by the Centre for Communication Impact and Project Support Association of Southern Africa (PSASA).

Description: Using the participatory communication model for dialogue, reflection and action (DRA), we implemented the CR Programme in informal settlements in high burden sub-districts in Mpumalanga Province, South Africa. Community mobilizers and facilitators use evidence-based HIV Prevention and gender norms curriculum Stepping Stones and One-Man Can to engage both men and women to explore and address the drivers of HIV and Sexual and Gender-Based Violence (SGBV), challenge harmful gender norms in their community and to protect themselves from HIV. An added component is referral to and provision of HIC testing in collaboration with community-based partners outside or close to these sessions. This approach has led to an enabling environment for uptake of HTS by men.

Lessons learned: From June 2016 to December 2017, we reached 21,221 men with our sessions, of whom 8892 were referred (42%) and 8617 tested for HIV (96% of those referred). This shows that by bringing services closer, men are able to access HIV testing.

Conclusions/Next steps: Community-based interventions targeting men, can be used as an important platform to reach and mobilise men to access HIV testing services in the community and at health facilities.

THPEC293

Achieving HIV programming goals with male sex workers (MSW) and men who have sex with other men (MSM) through the innovative application of information, communication and technology platforms

P. Njoroge

Health Options For Young Men on HIV/AIDS/STIS, Communications, Nairobi, Kenya

Background: In Kenya, men who have sex with men and male sex workers are responsible for 18.2% of HIV prevalence against the 5.5% prevalence in the general population. Overall rates of HIV continue to decline within the general population while it continues to rapidly increase between MSM and MSW. Since 2015, the Health Options for Young Men on HIV/AIDS and STIs (HOYMAS) has taken advantage of the exponentially growing access to information and communication technology (ICT) to leverage its HIV and AIDS programming enabling it to achieve significant HIV and AIDS prevention and treatment health outcomes.

Description: HOYMAS uses ICT platforms such as Short Messaging Services (SMS), WhatsApp, Facebook, Twitter, and Website to mobilize MSMs and MSWs to access various HIV and AIDS prevention , care and treatment services. 300 SMS, 150 WhatsApp messages, targeted messages through HOYMAS Facebook and Twitter accounts with more than 5,000 followers. Messages are sent every week to MSM and MSWs based in Nairobi to visit HOYMAS community led clinic in order to access HIV services. In 2016/2017, HOYMAS reached 1,440 new MSM/MSW through ICT based mobilization and 75% of those mobilised visited the clinic for tests. Out of these 202 individuals received HIV positive results and 93% were put on treatment with a 95% adherence level. The PrEP service launched at the clinic has within one year achieved 69% of the two-year target period.

Lessons learned:

· The use of technology based interventions implementation is crucial in enabling key populations led organisations achieve quality health outcomes in HIV programming

· Combining the virtual with the physical while mobilizing MSM/MSW for HIV services is more effective than the use of ICT alone

· Privacy and confidentiality remain crucial issues but they are non-deterring concerns

Conclusions/Next steps:

· As an organisation, we will increase our monitoring and evaluation of our ICT based mobilization approaches.

· The evidence from our experience lay a strong emphasis on the utilization of ICT in better implementation of HIV services thus the need to expand it

· HOYMAS to champion for the inclusion of ICT platforms in HIV programming into the key national guidelines

THPEC294

Misunderstanding PrEP among rural Latino Immigrants: Likening PrEP to reproductive health strategies

C. Garcia[1], R. Melendez[2], S.J. Zepeda[3], I. Lozano-Verduzco[4], G. Alaniz[5]

[1]San Francisco State University, Sociology and Sexuality Studies, Burlingame, United States, [2]San Francisco State Univeristy, Sociology and Sexuality Studies, San Francisco, United States, [3]San Francisco AIDS Foundation, Latino Program, San Francisco, United States, [4]Universidad Pedagogica Nacional, Psychology, Mexico City, Mexico, [5]San Francisco State University, Sociology and Sexuality Studies, San Francisco, United States

Background: Research shows that HIV Pre-Exposure Prophylactics (PrEP) can lower HIV rates. However, PrEP may increase sexual risk behaviors and Sexually Transmitted Infections (STI). Recently, the United States (US) has experienced an increase in STI particularly among rural Latinos. Barriers such as language, migration patterns, poverty, and undocumented legal status makes it less likely for Latino immigrants to access PrEP and makes HIV prevention outreach more difficult. Insufficient and incorrect information about PrEP may lead to misunderstandings on the effectiveness of PrEP; likening it to a reproductive contraception, such as birth control and condoms.

Methods: We partnered with community-based organizations in three rural counties of California to inquire on PrEP knowledge and usage among Latino immigrants. The counties consist of largely migrant Latino communities. Participants were comprised of clients (n=56), many of whom identified as migratory agricultural workers, and health providers (n=29). In-depth interviews were conducted from February through March of 2017. Interviews were transcribed and coded.

Results: Many clients and providers used birth control analogies when discussing PrEP. Nearly 25% of health providers framed their understanding of PrEP and its effectiveness in terms of reproductive health, specifically birth control pills. One female provider noted, "It´s protecting yourself, like anybody on birth control. Whether it´ll be a condom, whether it´ll be...[an] IUD, whether it´s the shot, whether it's the pill..." Clients who likened PrEP to reproductive health, explicitly discussed it rela-

tive to contraception, "it´s like a contraceptive pill… take that pill before having sex but with the risk that… they are not going to catch infection, that is, they are preventing the infection." Each of the three gender-identity categories (male, female or trans-women) clients framed PrEP along birth control lines.

Conclusions: While birth control may be an efficient way of explaining PrEP to individuals, there is a risk that some may understand PrEP as a contraceptive pill rather than one that decreases chances of sero-converting. Strengthening health education on the effectiveness of PrEP may lead to more accurate dissemination of PrEP information. Carefully discerning between PrEP, birth control and STI prophylactics may decrease risky sexual behavior, STI rates, and unintended pregnancies.

THPEC295

Optimizing the HIV yield through targeted community-based HIV testing strategies: Experience of resources towards elimination of child vulnerability in Côte d'Ivoire

G. Abla Epse Semde[1], J. Tabler Mullis[2], A. Kouakoussui[3], S. Kanon[4], V. Noba[4], K. Ouattara[3]
[1]Save the Children, Program, Abidjan, Cote D'Ivoire, [2]Save the Children, Washington, United States, [3]Jhpiego, Abidjan, Cote D'Ivoire, [4]Save the Children, Abidjan, Cote D'Ivoire

Background: Community-based HIV testing is one of the flagship interventions of the PEPFAR/USAID funded project, Resources towards Elimination of Child Vulnerability (REVE) in Côte d´Ivoire. After 14 months of implementing HIV testing services (HTS), project data analysis in April 2017 revealed a yield of 0.6%. Although 20,731 individuals (4,913 adults and 15,818 children) were reached by the project with HTS and received their results (75% of the target), only 134 people including 96 adults and 38 children were found HIV positive. This low yield indicated that the project needed to revise the HTS strategy to reach the right people with HTS.

Description: The revision of the HTS strategy early in May 2017 led to a more aggressive approach in the search for sexual partners, and the development of new tools for identification of sexual partners and a HIV risk assessment tool for children, adolescents and adults. Community counselors (CCs) received intensive training on the revised HTS strategy followed by close mentoring and supervision of REVE staff in collaboration with health district officials.

Lessons learned: The deployment of the revised strategy led to the expansion of HIV testing service delivery in the community beyond beneficiary households through HIV screening of other households where sexual partners were found. Individuals identified using the new tools received counseling and testing by CCs. From July to September 2017, 1,254 individuals including 942 adults and 312 children were identified, tested and advised of their HIV status. Sexual partners accounted for 70% of those reached with HTS. Out of the 1,254 individuals tested, 591 (530 adults and 61 children) were found HIV positive recording 19.5% and 56.20% respectively for children and adults HIV yield. The project HIV yield increased from 0.6% to 3.2% by the end of fiscal year 17.

Conclusions/Next steps: As a result of the revised HTS strategy, REVE not only achieved a significant increase in the HIV yield, but also increased the number of individuals reached with HTS, from 75% of the target to 95% of the target.

THPEC296

HIV testing patterns in two community-based approaches to universal test and treat in the HPTN 071 (PopART) intervention in South Africa

B. Yang[1], R. Sloot[1,2], S. Floyd[3], F. Esau[1], J. Molaolwa[1], D. Awoniyi[1], Y. Saunders[1], P. Siboto[1], L. Gqiba-Tunywa[1], D. Myburgh[1], B. Cimi[1], S. Griffith[4], P. Bock[1], H. Ayles[5,6], S. Fidler[7], R. Hayes[3], N. Beyers[1], HPTN 071 (PopART) Study Team
[1]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [2]Amsterdam Institute of Global Health and Development, Amsterdam, Netherlands, [3]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [4]FHI360, Durham, South Africa, [5]Zambia AIDS Related Tuberculosis Project, University of Zambia, Lusaka, Zambia, [6]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [7]Imperial College, Department of Infectious Disease Epidemiology, London, United Kingdom

Background: HPTN 071 (PopART) is a community-randomised trial conducted in 21 communities in Zambia and South Africa (SA) with a population of over 1 million, to measure the impact of a combination HIV prevention intervention on population-level HIV incidence; delivered in annual rounds by Community HIV-care Providers (CHiPs), who provide home-based HIV testing services (HTS) door-to-door in the community. In response to a lower proportion of men being reached during home-based HTS (HBHTS), CHiPs offered HTS in tents in areas of high foot traffic.

We analysed HTS data to determine whether more men were tested through tent-HTS as compared to HBHTS, and compared other demographic characteristics between HBHTS and tent-HTS to understand HIV testing patterns.

Methods: During annual round three from April 2017-December 2017, when both HBHTS and tent-HTS were offered by CHiPs in six SA communities, tent-HTS was conducted at public transport hubs(4 days), shopping centres(13 days), schools/libraries(6 days), and a community event(1 day). 3-5 tent-HTS events were conducted in each community. HTS was offered through a finger-prick rapid test using the SA National HTS serial testing algorithm. CHiPs collected data on an electronic register. Multivariable logistic regression analysis was used to compare the population reached through HBHTS versus tent-HTS on gender, age, history of prior HIV testing, status as a presumptive TB case, and community.

	HIV test done		
	At home n (%)	In Tent n (%)	p-value[1]

SA6 (>77 km to the capital)	4,141 (13)	114 (28)	

[1] Chi-squared test
[2] Considered to be a presumptive TB case if an individual had any of the following signs and symptoms (coughing for more than two weeks, night sweats, weight loss of more than 1.5 kg) and/or in contact with an individual who has TB in the house or at work
[3] SA5 and SA6 are furthest from the capital (Cape Town) of the Western Cape Province, South Africa. They are also in areas of agriculture.

[Table 1. Characteristics of individuals tested for HIV by lay HIV counsellors at home and in tents in high traffic areas]

Results: 32,032 HIV tests were done through HBHTS and 402 during tent-HTS (Table 1 shows characteristics of the population tested). Those testing through tent-HTS were more likely than those testing through HBHTS to be men (aOR 1.9, 95%CI 1.5-2.3), more likely to be from the older age-groups of 25-29/30-39/40-49/50+ (p-values of all aOR's < 0.01), and more likely to be residents of communities SA5/SA6 (agricultural communities further from Cape Town). HIV positivity was slightly higher during HBHTS as compared to tent-HTS but was not significant (2.1%vs1.7%).

Conclusions: Tent-HTS in high traffic areas proved successful in reaching a higher proportion of men, although the absolute number of additional tests was relatively small. Tent-HTS was relatively more successful in agricultural areas. Studies with larger sample size are required to understand differences in HIV testing patterns between HBHTS and tent-HTS.

THPEC297

Integration of PrEP as combination prevention among lesbian, gay, bisexual, transgender and intersex (LGBTI) in public health facilities in Kenya. A case of Mombasa County

Z. Ahmed[1,2]
[1]County Government of Mombasa, Department of Health, Mombasa, Kenya, [2]LVCT Health, Health, Nairobi, Kenya

Background: High levels of self-stigma coupled with negative attitude, discrimination and lack of adequate skills among health care workers to handle LGBTI continue to be a hindrance to LGBTI in accessing HIV services. HIV services to LGBTI are predominantly offered by non-governmental organization in most part of Kenya. Since May 2017, LVCT Health a non-governmental organization has been implementing "Towards Universal Comprehensive Health services for LGBTI (TOUCH Plus)" project in collaboration with the County government of Mombasa to integrate HIV services for LGBTI in public health facilities. The main aim of this paper is to demonstrate integration and uptake of PrEP among LGBTI in public health facilities model in Kenya.

Description: A baseline need assessment was conducted targeting LGBTI community based organizations, peer educators and health care workers in public health facilities. Health care workers were trained on delivery of PrEP to the LGBTI. LGBTI peer educators were also trained as mobilizers and attached to the public health facilities. A mentorship, supervision and stakeholders engagement plan was developed and implemented. Data collection and reporting tools were piloted in the facilities from the national system.

Lessons learned: A total of 8 facilities were selected in phase 1 for integration of PrEP from May 2017-December 2017. A total of 67, 59 gay men, 8 bisexual male and female were initiated on PrEP. By December 50 (84.7%) of gay men were active on PrEP, and 5 (62.5%) of bisexual men and women. Cumulatively 55 (82.1%) were actively enrolled on PrEP program in public health facilities.

Conclusions/Next steps: Integration of PrEP in combination prevention for LGBTI is important to achieve the goal of zero new infections. There is need to for the public health care system to fully integrate PrEP in comprehensive HIV services for LGBTI through creating link with the community, capacity building of providers, provision of PrEP, and strengthening of national and county LGBTI health data management.

THPEC298

Reaching more key and vulnerable population with HIV services through combination prevention campaign

P. Urasa[1,2], A. Ramadhani[3], E. Matechi[4], B. Mpora[5], G.J.I. Lija[6,7], L. Subi[8]
[1]National AIDs Control Programme, Dar-es-Salaam, Tanzania, United Republic of, [2]Ministry Health, Prevention, Dar-es-Salaam, Tanzania, United Republic of, [3]Ministry of Health, Prevention, Dar-es-Salaam, Tanzania, United Republic of, [4]SMART RIDE, Dar-es-Salaam, Tanzania, United Republic of, [5]National AIDS Control Program (NACP), Ministry of Health, Community Development, Gender, Elderly and Children, Dar-es-Salaam, Tanzania, United Republic of, [6]Ministry of Health-, National AIDS Control Programme, Dar-es-Salaam, Tanzania, United Republic of, [7]Ministry of Health-, Dar-es-Salaam, Tanzania, United Republic of, [8]Ministry of Health-Tanzania, Dar-es-Salaam, Tanzania, United Republic of

Background: In Tanzania, ten regions with highest HIV prevalence covered 38% of the general population and constituted to 56% of HIV infections in the country. The nation recognized the need to target these regions with high impact prevention, care and treatment support interventions in order to achieve higher impact. The 2007 national HTC campaigns showed evidence of increased uptake of new testers. However, there was expressed need for other preventive services including VMMC, STI diagnosis and treatment, condoms and social behaviour change communication (SBCC).

Combination prevention is an evidence-based approach focusing on provision of structural, behavioural and biomedical interventions at once. We adopted this approach to target key and vulnerable populations, adolescents and youth.

Methods: To guide implementation of the combination campaign, standard operating guide was developed for ten diverse regions in 200 wards. The package was not a "one size that fits all" but an ideal menus tailored for specific behaviors within the targeted communities, regions, and risk categories/ drivers of the epidemic. Consideration were made to meet prevention needs of targeted population. A minimum package services included HTS, STI, SBCC, condom programming (public and social marketed), family planning services and provision of VMMC where applicable. Community leader's were involved from the planning including identification of hot spots wards and sensitization. The campaigns and follow up activities were implemented from July 2016 to December 2017.

Results: A significant Increased up-take of HIV testing to 739,944 first time testers (M- 374461 and F= 365483); HIV positive 4,736 (Male 2080 & Female 2656); 7,429 women screened for cancer; Family planning services offered to 2,654 women; TB screening 21,166; VMMC 3,594; STI services-727 and GBV 229. Other services offered were Prostate cancer screening 292. Formulation of 200 income- generating groups in each ward.

Conclusions: Community mobilization and empowerment during planning including identification of the drivers of the epidemic and location of the hotspots was crucial for a successful Campaign. Follow up activities post campaign promoted linkage and referral to other services.

THPEC299

HIV testing rates among young women aged 15 - 24 years in Nigeria: A situation analysis

R. Aguolu, G. Ashefor, K. Ogungbemi, J. Anenih
National Agency for the Control of AIDS, Abuja, Nigeria

Background: National data suggests that 4.2% of young people aged 15-24 years are living with HIV. (Nigeria GAPR 2015). Over the last few years, a number of prevention interventions aimed at improving access to HIV testing and care programmes have been implemented for these young people aged 15-24 years. The objective of this paper is to ascertain the HIV testing rates among young women aged 15-24 years in Nigeria, identify gaps in prevention interventions and proffer solutions.

Methods: Data used in this paper was derived from the nationally representative Multiple Indicator Cluster Survey conducted between September 2016 to January 2017, in the 6 geopolitical zones of Nigeria. A household pre-tested questionnaire was used to collect data in the field

which was captured electronically using Computer Assisted Personal Interviewing application 5.0. Data was analyzed using the Statistical package for Social Scientists (SPSS) software.

Results: Of the 12,637 young women aged 15-24 years interviewed, 81.8% had heard about HIV and AIDS. 54.4% of these young women knew where to get HIV test done while 23.1% had ever been tested for HIV and knew the result of their most recent test. 12.1% of these young women aged 15-24 years had been tested for HIV in the 12 months preceding the study and knew their results. The proportion of sexually active young women aged 15-24 years who had been tested for HIV in the 12 months preceding the study and knew their result was 16.7%.

Conclusions: HIV testing rates was significantly low among these young women aged 15-24 years, and barely half of the women interviewed knew where to get HIV test done. Hence, there is a dire need to design and implement targeted interventions aimed at improving access of young women aged 15-24 years to HIV testing and counseling services, so as to stem the tide of infections among them and the general population.

Innovative behavioural interventions

THPEC300

Sheroes: Feasibility and acceptability of a community-driven, group-level HIV intervention program for transgender women

J.M. Sevelius, T.B. Neilands, S. Dilworth, D. Castro, V. Warri, M.O. Johnson
University of California, Medicine, San Francisco, United States

Background: Transgender women, especially those of color, experience high risk of HIV acquisition and transmission. To meet the unique needs of transgender women with a focus on those of color and in close collaboration with community, we developed 'Sheroes,' a peer-led group-level intervention with 5 weekly sessions addressing the unifying lived experiences of HIV-positive, HIV-negative, and unknown status trans women.

Methods: We conducted a feasibility and acceptability pilot randomized controlled trial implementation of Sheroes. Participants in the intervention group received 5 weekly sessions of Sheroes; topics included healthy sexuality, communication, transition-related health information, and coping skills. Participants in the control group attended 5 weekly sessions of a group movie night (time and attention control). Preliminary outcome analyses were performed using generalized linear mixed models (GLLMs) stratified by HIV serostatus containing fixed effects for group (control, intervention), time (baseline, 3 month followup, 6 month followup), and their interaction. Pre-specified simple main effects compared outcomes on time points within each group.

Results: Participants were 45% Black/African-American, 10% Latina, 17% White, 19% Multiracial, 3% Native American, and 2% Asian/Pacific Islander. We found high levels of feasibility and acceptability; 82% of those randomized to intervention attended at least one session and 92% rated their overall experience with Sheroes as "excellent".

Regarding outcomes (see Table 1), for HIV-negative participants in Sheroes we observed reductions in the number of sex partners with whom participants had condomless intercourse and improved social support. For HIV-positive participants, both groups reduced their total number of sex partners; the change was sustained at the 6-month follow-up for the Sheroes group (p=.04), but not for the control group (p=.169) relative to baseline.

Conclusions: Sheroes was found to be highly feasible and acceptable to transgender women. Both groups reduced risky sexual behavior, which may indicate a high need for social support among transgender women, making even the control group therapeutic, though its beneficial effects may be more short-lived than those for Sheroes. Additional research with larger samples over a longer time horizon is needed to evaluate this innovative strategy for reducing sexual risk among transgender women at risk for acquisition or transmission of HIV.

THPEC301

Outcome evaluation of HIV prevention interventions for people who use drugs in Ukraine based on a bottom-up common factors approach

J. Owczarzak[1], T. Nguyen[2], A. Mazhnaya[1], O. Filippova[3], S. Phillips[4], T. Zub[3], P. Alpatova[3]
[1]Johns Hopkins School of Public Health, Health, Behavior and Society, Baltimore, United States, [2]Johns Hopkins School of Public Health, Mental Health, Baltimore, United States, [3]VN Karazin Kharkiv National University, Sociology, Kharkiv, Ukraine, [4]Indiana University, Anthropology, Bloomington, United States

Background: Current models of HIV prevention intervention dissemination involve packaging interventions developed in one context and training providers to implement that specific intervention with fidelity. Research shows that providers rarely implement these programs with fidelity due to perceived incompatibility, resource constraints, and preference for locally-generated solutions. In this study, we used the concept of "common factors," or broad constructs shared by most evidence-based HIV prevention interventions, to train service providers to develop their own programs. Our study examined whether the provider-developed and implemented interventions based on common factors of effective behavioral interventions led to reduction in drug-related HIV risk behavior.

Methods: This study took place in Ukraine between 2012 and 2016. We trained service providers from eight nongovernmental organizations (NGOs) to develop interventions based on a "common factors" approach. Four NGOs' interventions were selected for effectiveness evaluation. Each NGO conducted its intervention with at least N=130 participants (total N=520). Participants completed a baseline and a 90-day follow-up assessment. The assessment included sociodemographic characteristics and injection and sex-related risk behaviors. Our analysis focuses on injection-related HIV risk behaviors associated with drug acquisition (buying drugs in a preloaded syringe or giving one's syringe to someone to fill) and injection (common drug container, sharing drug preparation equipment, and front/backloading). We analyzed the prevalence of any risky behavior in drug acquisition and drug injection at baseline and 3-month follow-up.

Results: In three sites, prevalence of both any risk in drug acquisition and any risk in drug injection decreased. In the fourth site, the prevalence of any risk in drug injection decreased substantially, but the prevalence of any risk in drug acquisition did not change. Injection related risks decreased between 17 and 30 percent, with baseline prevalences ranging from 53 to 81 percent. Acquisition risks decreased between 14 and 35 percent, with baseline prevalences ranging from 50 to 89 percent.

Conclusions: Our findings suggest that a common factors approach may provide an alternative model to current intervention development and dissemination methods that aim to reduce HIV risk. However, more rigorous assessment is needed such as through a randomized controlled trial and with different target populations in other contexts.

THPEC303

Leveraging social networks and technology for HIV prevention and treatment with transgender women

I. Holloway[1], S. Jordan[1], S.L. Dunlap[2], C. Reback[3]
[1]University of California, Luskin School of Public Affairs, Los Angeles, United States, [2]University of California, Department of Social Welfare, Los Angeles, United States, [3]Friends Research Institute, Inc., Los Angeles, United States

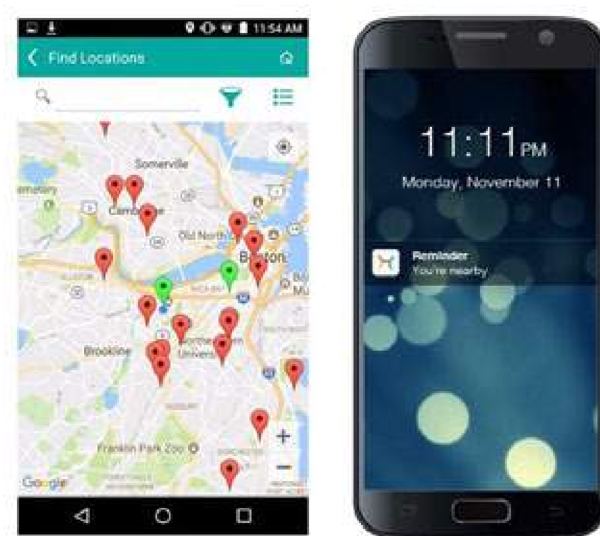
Background: In the United States, transgender ("trans") women are among the groups most disproportionately impacted by HIV/AIDS. Trans women use social networking sites (SNS) gain access to trans-specific resources and develop social networks. Five focus groups were conducted to better understand how trans women's social networks and technology-based networking platforms may be leveraged in developing health promotion strategies to prevent HIV acquisition and transmission.
Methods: Between January and February 2015, potential participants were recruited from community-based organizations, through street outreach, and through word-of-mouth (N=39). Each focus group lasted approximately 60 minutes and was audio recorded, transcribed verbatim and analyzed using Atlas.ti. Prior to the focus group, a brief assessment was administered to each participant to obtain sociodemographic and technology use data (i.e., age; race/ethnicity; sexual identity; HIV status; educational attainment; living situation; main source of income; and frequency of using technology, social network sites and apps). During the focus groups, open-ended questions focused on social network composition, and the use of technology for socialization, partner seeking, and health information.
Results: Participants were racially and ethnically diverse and ranged in age from 20 to 72 years old, with a mean age of 37; 28% were African American/Black, 28% Latina, 26% Caucasian/White, 5% API, and 13% mixed/other. Nearly three-quarters of participants owned a smartphone. The structure and composition of trans women's online networks were diverse with several participants describing robust and interconnected social networks comprised of many other trans people. Participants relied on technology to establish affiliations and support networks, find and exchange health information and advice, create and share media content, and connect with sexual partners and relationships. Many participants preferred trans-specific or inclusive SNS sites due to experiences of objectification and harassment on mainstream platforms.
Conclusions: In order to reduce risk for acquisition and transmission of HIV among low income trans women, culturally relevant prevention and intervention strategies are needed. The knowledge and expertise that trans women possess in establishing social networks, in using technology to organize resources, and to access to health care can be harnessed by practitioners and policymakers to inform HIV prevention and care interventions.

THPEC304

Repurposed technology: The process of integrating location-based alerts into an HIV testing app for young men who have sex with men

E. Marrow[1], K. Mayer[1,2,3], J. Dormitzer[1], L. Hightow-Weidman[4], P. Sullivan[5], K. Biello[1,6,7]
[1]Fenway Health, The Fenway Institute, Boston, United States, [2]Harvard Medical School/Beth Israel Deaconess Medical Center, Division of Infectious Disease, Boston, United States, [3]Harvard T. H. Chan School of Public Health, Global Health and Population, Boston, United States, [4]University of North Carolina-Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [5]Emory University, Rollins School of Public Health, Atlanta, United States, [6]Brown University School of Public Health, Behavioral & Social Sciences and Epidemiology, Providence, United States, [7]Brown University School of Public Health, Center for Health Equity Research, Providence, United States

Background: Location-based alerts that use real-time geo-data from a mobile device are commonly used in retail (e.g., Starbucks) and social/sexual networking apps to impact behavior, but have not been widely adopted for health promotion apps. We describe the development and integration of a location-based alert system for HIV testing into "MyChoices"—an app to increase HIV testing among young men who have sex with men (YMSM).
Methods: The location-based alert system for HIV testing evolved via an iterative development process with a multidisciplinary team of researchers, providers, app developers and youth. This included initial focus groups (n=6) with YMSM to obtain feedback on the concept, collaboration with the app developers to create and integrate the system, and additional focus groups (n=4) for feedback on the developed product.
Results: In initial focus groups with 33 YMSM in 3 U.S. cities, participants expressed interest in location-based alerts for HIV testing but wanted to be able to customize the alert frequency based on individual testing needs or preferences. Using available online resources, local expert consultation and calls to clinics and community-based organizations, we constructed a comprehensive database of HIV testing sites (including hours, cost, type of testing offered) in Boston, MA and Bronx, NY—our initial field-testing sites.
This database was integrated into the app along with a location-based alert system that "pings" users with a pop-up notification when geographically near (e.g. within ½ mile) an HIV testing site and due for a test based on their personalized, app-facilitated testing plan.
Focus groups were then conducted in Boston and Bronx to demonstrate the location-based alert system. YMSM (n=28) indicated that these alerts were acceptable, would facilitate testing as an immediate priority, and would increase long-term adherence to a test plan. Participants appreciated the ability to set alert frequencies and distance to the HIV testing site.



[Location-based alert screenshots from the MyChoices app]

Conclusions: Acceptability and efficacy testing of the MyChoices app and the location-based alert system is ongoing. If acceptable and efficacious, location-based alerts could be further customized (e.g., set "favorite" locations), expanded to include notification for other services (e.g., pharmacy refills, care appointments), and applied to a broad range of health promotion apps.

THPEC305

Acceptability and feasibility of m-health application for young MSM/TGs using real time data: Lessons from end line assessment of cohort population

L. Uppal, T. Khanna
MAMTA Health Institute for Mother and Child, Delhi, India

Background: India is third largest contributor to HIV in the world, epidemic being concentrated largely in adolescent key populations. Due to inequity in HIV policy and programming, young MSM and TGs have largely been excluded from national HIV response. To improve their equity in HIV access and prevention, mobile application (*Sabrang*) was de-

signed in consultation with community based organizations for improving their knowledge on safe sexual practices, HIV/AIDS prevention and linkages to HIV services.
Methods: We assessed the acceptability and feasibility and impact of application that provides knowledge (Q/A, games based, audio messages) and encourages access through doctors/professional counselors using peer led approach. A mix method pre-post study design was used along with real time data through dashboard. A cohort of 117 was retained at end line out of 167 participants (15-24 years) who used mobile application.
Results: Knowledge on all methods of HIV transmission increased from baseline (53%) to end line (65%) (p< 0.01). Misconceptions about HIV transmission was dispelled by 17 per cent point at end line significantly (p< 0.01). Chat with a doctor was found most useful feature for seeking health knowledge and counseling. Feasibility was demonstrated as participants who interacted with the doctor/counselor had correct knowledge on all methods of HIV transmission as compared to those who did not (p< 0.001). Around two-third respondents felt the ease of usage of app due to privacy and availability of GPS enabled health facility map (54%). Most respondents were satisfied as they received response within 24-hours and had interpersonal counseling. Qualitative investigation showed this application was accepted well since it provided safe and instant pocket information on safer-sex practices as well as 'near-by' access to health services.
Conclusions: m-Health tools designed in consultation with community through careful planning of the user interface, results in high acceptability. The application provided an opportunity to express sexual orientation or gender identity to many hidden community members, especially below 24 years. There are limited evidence based digital interventions focused on key populations in India due to policy implications, however, this application has shown to reach and impact the vulnerable community and link them to HIV services.

THPEC306

A qualitative study of perceived barriers and facilitators to the implementation of social network testing for HIV among MSM with a non-Western migration background

C. Den Daas[1], M. Geerken[2], M. Bal[3], J. de Wit[3], S. Bergh[2], R. Spijker[2], E. Op de Coul[4], PREVENT Study Group
[1]RIVM, STI/HIV, Bilthoven, Netherlands, [2]Soa Aids Nederland, Amsterdam, Netherlands, [3]Utrecht University, Utrecht, Netherlands, [4]RIVM, Bilthoven, Netherlands

Background: Peer-driven social network testing (SNT) for HIV is proposed as method to promote HIV testing in hard-to-reach populations. This qualitative study explored perceived barriers and facilitators to SNT for HIV among men having sex with men with a non-Western migration background (MSM-NW) in the Netherlands. How is SNT best implemented to reach this vulnerable population, while respecting cultural differences and minimizing any negative impacts?
Methods: Thirteen MSM-NW, recruited through STI clinics in Rotterdam and Amsterdam, were interviewed about SNT from the perspective as a peer providing HIV self-tests to network associates (NAs). The interviews were recorded, transcribed verbatim, and analysed by thematic content analysis.
Results: We identified four major barriers: fear, denial, time concerns, and being seen. For example, participants experienced fears that others will find out (either their HIV status or homosexuality), and although Prevent does not seem to be able to reduce fear, being able to test privately and get the result immediately seemed to alleviate some of the experienced fears. A major advantage of SNT is that it serves men who don't openly identify as homosexual, and those who are afraid of being seen at regular testing sites. For implementation, training of peers about HIV testing was also considered an important aspect of SNT, peers needed practical, informational, and emotional support. Finally, participants had very different opinions about sharing test results; while some saw it as an invasion of privacy, others considered it a natural consequence of SNT.
Conclusions: We expect that SNT will be most successful in networks with a certain level of trust between peers and NAs, because of the experienced barriers. Peers should be trained in how to start the conversation, how to deal with possible negative reactions, and how to support them after taking the test. Prevent does this by offering support via an e-tool and a peer-coordinator, a person who will personally answer questions and help where necessary. Although fear for the test result will remain, SNT can be tailored to the personal situation of individual friendships, and thus remove general barriers to testing, and facilitate HIV testing among hard-to-reach MSM-NW.

THPEC307

Addressing social support and social isolation in online interventions for young Black MSM and transgender women: Examining the role of peer-to-peer sharing

K.J. Marsh[1,2], S. LeGrand[3], Q. Wang[4], K. Muessig[5], K.J. Horvath[6], L. Hightow-Weidman[7]
[1]University of Minnesota, Division of Infectious Diseases and International Medicine, Minneapolis, United States, [2]University of Minnesota, Division of Pediatric Infectious Diseases and Immunology, Minneapolis, United States, [3]Duke University, Duke Global Health Institute, Durham, United States, [4]University of Minnesota, Clinical and Translational Science Institute, Minneapolis, United States, [5]University of North Carolina at Chapel Hill, Department of Health Behavior, Chapel Hill, United States, [6]University of Minnesota, Division of Epidemiology and Community Health, Minneapolis, United States, [7]University of North Carolina at Chapel Hill, Institute of Global Health and Infectious Diseases, Chapel Hill, United States

Background: Young black men who have sex with men and transgender women (YBMSM/TW) are disproportionately burdened by human immunodeficiency virus (HIV). Poor social support and social isolation are associated with decreased viral suppression and risky sexual behaviors, particularly for persons of color. Technology-based interventions that facilitate peer interaction through online forums may improve perception of social support and reduce isolation.
Methods: HealthMpowerment (HMP) was a randomized controlled trial of a mobile-optimized online intervention designed to reduce sexual risk behaviors through interactive features including a forum. 474 YBMSM/TW aged 18-30 (HIV-negative/status unknown [n=275] and HIV-positive [n=199]) enrolled and completed surveys at baseline, 3, 6, and 12 months. Items included sociodemographics, the Medical Outcomes Study Social Support Survey (MOS-SSS), and the Lubben Social Network Scale (for social isolation). Linear mixed models and generalized linear mixed models explored differences in change over time by intervention group, general HMP site use, number of forum posts, and HIV status.
Results: Mean age was 24.3 (SD 3.2). Baseline mean score for all participants of perceived total social support was low at 72.0 (SD 27.3) out of 100, and 30% were socially isolated (score < 12). At each time-point, there were no differences in social support or social isolation by intervention group, by overall HMP usage, or by use of the peer interaction features. HIV-positive participants had lower mean social support scores at baseline than HIV-negative participants (total social support p=0.02, emotional p=0.03, tangible p=0.05, interaction p=0.002) and reported more isolation (40% vs 23%, p< .001). Social support scores declined over time, for both HIV-negative and HIV-positive groups.
Conclusions: Perceived social support was low and social isolation was high in this sample of YBMSM/TW, especially among those living with HIV. Neither factor improved over time regardless of intervention group, intervention dosage, or use of HMP features that facilitated peer discussion. Future technology-based interventions that aim to impact these factors should consider how to optimize virtual spaces to foster peer-to-peer interactions. Additionally, measures that are more sensitive to changes in social support and isolation due to online intervention participation should be explored.

THPEC308

Coaching: Leveraging existing evidence-based interventions (EBI) to create a scalable, adaptable implementation model to increase uptake of the HIV prevention continuum among youth

D. Swendeman[1], E. Arnold[2], D.M. Harris[3], J. Fournier[4], M.J. Rotheram-Borus[3], S.E. Abdalian[4], Adolescent Medicine Trials Network (ATN) CARES Project
[1]David Geffen School of Medicine at UCLA, Department of Psychiatry & Biobehavioral Sciences, Semel Institute, Los Angeles, United States, [2]University of Central Florida, College of Health and Public Affairs, School of Social Work, Orlando, United States, [3]University of California, Department of Psychiatry & Biobehavioral Sciences, Semel Institute, Los Angeles, United States, [4]Tulane University, Department of Pediatrics / Adolescent Medicine, New Orleans, United States

Background: The U.S. CDC's portfolio of evidence-based interventions (EBI) has been broadly diffused with the intention to replicate intervention manuals with fidelity. Substantial evidence suggests that community and clinical agencies, even after extensive training, do not replicate these manuals. Coaching reflects an alternative strategy for synthesizing EBI into their shared theoretical model, foundational skills, common components, and targeted outcomes, and then training paraprofessionals to apply these to coaching young people to adhere to the HIV Prevention Continuum.
Methods: Ratings of five adolescent EBI for HIV and 800 child and family EBI for mental health have identified a common theory, set of skills and components, and a strategy for application to the HIV Prevention Continuum. Five B.A.-level coaches were recruited, each of whom had cultural similarities and sensitivities to youth at highest risk for HIV. After six weeks of training, 43 youth are receiving virtual/in-person coaching. Youth are 49% gay, bisexual, or transgender males (GBTM), 65% are African American, 15% Latino, 28% were previously hospitalized for mental health issues, 14% received substance abuse treatment, and 58% were formerly homeless. Coaches track each contact with youth, including the content areas discussed, skills employed and the goals established. Thus far, youth have been followed for an average of four months, but will be followed for 24 months.
Results: To date, Coaches have held an average of 2.5 coaching sessions per youth. Youth discussed problems related to daily living (housing, employment) most often (during 80% of sessions), with social relationships (48%), HIV-related behaviors (43%), substance abuse (25%) and mental health problems (31%) concurrently reviewed. Of the foundational skills that Coaches were trained to use, goal setting (61%), problem solving (62%), and praise (76%) were employed most often. Youth goals tended to focus on employment, school and transportation (about 15% each). Coaches provided referrals during 22% of sessions.
Conclusions: Coaching allows interventions to be customized to the risk profiles of youth; embraces diversity in the Coaches' ethnic, gender, language and cultural styles; and, includes strategies for ongoing monitoring of intervention delivery.

THPEC309

Dance for hope, dance to the light: A school-based multimodal approach to address HIV epidemic among youth in Pasig City, Philippines

R. Berba[1], J. Joaquin[2], M.J. Torres[3], C. Villa[3]
[1]The Medical City, I-REACT Clinic, Pasig City, Philippines, [2]University of the Philippines, Quezon City, Philippines, [3]The Medical City, Pasig City, Philippines

Background: The precipitous rise in new HIV cases in the Philippines is alarming! In August 2017, the UN announced that we are now the fastest-growing HIV/AIDS epidemic in Asia-Pacific. DOH reports that two of every three new HIV infections were 15-24 year-old men. Insufficient awareness about HIV continue to be cited as one of the main reasons behind this problem. Systematic reviews on HIV prevention have shown that school-based approaches were efficacious, cost-effective and can produce the largest impact in changing HIV-related behaviors. This report describes a multimodal school-based public-private partnership strategy on HIV/AIDS prevention for Grade 10 students of Pasig City.
Description: This TMC IREACT-initiated outreach project was completed in coordination with the Office of the Mayor, Departments of Health and Education, principals and parents.The target vulnerable population reached were 10122 Grade 10 students. We introduced a ***multimodal educational strategy*** with a 2-hour lecture on HIV/AIDS prevention; and an interschool Black Light dance competition on artistic interpretation of HIV prevention. The lecture was based on the UNICEF guidance for HIV in youth and the DepEd K-12 Curriculum Guide Grade 10 and was jointly made by Kalusugang Patrol(KP) of the City Government and TMC I-REACT. At the end of each lecture students were invited to join the challenge of an interschool
Black Light dance competition: Dance to the Light, Dance for Hope!
On January 2017, 4 schools with over 100 students competed in Black Light theater showing off their original creative works on HIV prevention at TMC auditorium.
Lessons learned: Teaching HIV to the youth requires extensive planning for efficient and effective execution. Teachers themselves must be comfortable to teach HIV and sensitive to the needs of their students. A creative approach to teach complex as HIV to youth is recommended. Volunteers from both private or public groups are valuable. The positive comments of the distinguished judges of the contest inspired the fighting spirits of the performing students, and affirmed the dedication of the coaches, teachers, organizers and parents.
Conclusions/Next steps: An innovative strategy to engage youth into getting interested, fully understand and use the information to change behavior and prevent HIV is badly needed.

[Trophies for Dance to the Light Dance for Hope HIV Prevention Dance Contest Winners]

THPEC310

Radio as a tool used by girls in Gulu and Gomba-Uganda to broadcast their own created programs around gender roles and HIV prevention

E. John Paul
Wizarts Foundation, Monitoring and Evaluation, Wakiso, Uganda

Background: Negative attitudes towards girl child education among rural communities of Uganda have led to high dropout rates in school among AGYW which has exposed them to the risk of contracting HIV . Observations from project work in Gulu and Gomba districts in Uganda indicate that when a girl has the opportunity to voice her thoughts, opinions, fears, experiences, dreams and aspirations on the radio there are two visible outcomes.
Her confidence and sense of self-worth grows. Secondly, when her teachers, friends, parents and neighbors listen to her on the radio they develop a sense of pride towards her and are positive and supportive.
Description: In year 1 of this project funded by PEPFAR through the DREAMS Innovation Challenge through a grant managed by JSI, 918 AGYW ages 15-24 from 10 secondary schools in Gulu and Gomba participated in school meetings to develop radio shows. 279 AGYW received

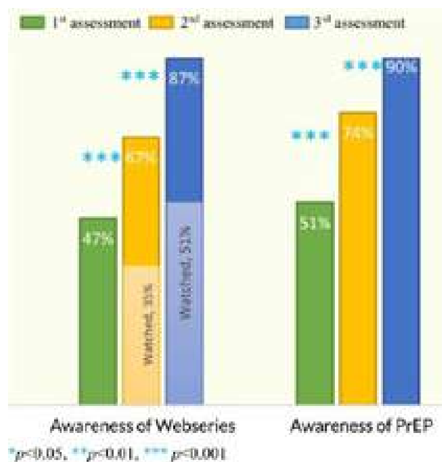
basic radio training and produced 85 shows and broadcast. 58 AGYW received have been recognized for their exceptional performance at community awards galas attended by 1566 boys, girls, parents, teachers and duty bearers.
Anecdotal evidence from Kyayi seed SS in Gomba district indicated that when a girl was heard speaking on radio by her father; it was impactful enough to reverse her fathers' decision to marry her off.
Lessons learned: Of the 918 AGYW enrolled into the program in year 1, 916 girls stayed in school at the end of the period, this is a 99.8% retention rate. 6 AGYW who had dropped out of school were re-enrolled in secondary school.
Conclusions/Next steps: More girls should have access to radios in their formed listener groups in school and in their communities. The schools can be assisted in acquiring laptops/desktops with supervised internet access and capacity building for AGYW to use internet and interact with a wider community on the Superwoman website. Year 1 has seen implementation covering all girls in some schools; therefore expansion/scale up of the intervention to other schools and districts is possible
in year 2.

THPEC311

GayOk Bangkok: Increasing PrEP awareness among young gay men in Bangkok with a scripted web series

S. Soeparna[1,2,3], R. Figueiredo[1], T. Guadamuz[4]
[1]APCOM, Bangkok, Thailand, [2]Elton John AIDS Foundation, London, United Kingdom, [3]FHI 360, Bangkok, Thailand, [4]Mahidol University, Bangkok, Thailand

Background: With support from EJAF and LINKAGES/Thailand—which is led by FHI 360 and funded by USAID and PEPFAR—TestBKK (APCOM's HIV testing campaign targeting young men who have sex with men [YMSM] in Bangkok) produced a scripted web series called GAYOK Bangkok (http://testbkk.org/GAYOKBangkok). GAYOK Bangkok follows fictional gay characters that represent different ages, body types, gender expression, and HIV status, and it provides a realistic and diverse portrayal of gay individuals of Bangkok. The sexual health messages, including PrEP, are threaded subtly into the storyline, which paints a picture of life drama among the characters. Partnering with Mahidol University of Thailand, APCOM conducted a study to assess the correlation between exposure to the web series and the trend of PrEP use among YMSM.
Methods: A serial cross-sectional survey was conducted with a closed cohort of 500 YMSM ages 1524 years who reside, work, or attend college/university in central or suburban Bangkok for a baseline evaluation (first assessment) before the release of the web series' first episode. The participants were then followed up for a second and third assessment at six-month intervals between September 2016 and April 2017. During that period, the web series had released five episodes for Season 1 and seven episodes for Season 2. The numbers of YMSM who participated in the second and third assessments are 270 and 207, respectively.
Results:



[Figure. Outcomes among 1st, 2nd and 3rd assessments]

Although the first assessment was done before the launch of the web series' pilot episode, awareness of the series among participants was caused by the pre-premiere promotional materials, such as the posters and teaser promoted through TestBKK's social media channels.
The study found that while the cohort's exposure to the series increased by 20% between the first and second assessments and between second and third assessments, the awareness of PrEP increased by 23% (between the first and second assessments) and by 16% (between the second and third assessments). All increases were statistically significant ($p < 0.001$).
Conclusions: Including PrEP into a plot of a scripted gay-themed web series increased the awareness of the medication among YMSM audiences, and therefore, should be considered as an additional strategy for online outreach to this demographic.

THPEC312

Factors related to lack of HIV-screening in people attending French adult erotic industry shows

P. Enel[1,2], M. Bonierbale[3], A. Alexandre[4], F. Brunel-Dalmas[5], K. Baumstarck[1,2]
[1]University Hospital Center, Assistance Publique - Hôpitaux de Marseille, Public Health Department, Marseille, France, [2]Aix Marseille University AMU, Center for Studies and Research on Health Services and Quality of Life EA 3279, Marseille, France, [3]University Interdisciplinary Association of Sexology, AIUS, Marseille, France, [4]Health Prevention National Association for Festive Venues, ENIPSE, Paris, France, [5]University Hospital of Edouart Herriot, Infectious Diseases Unit, Lyon, France

Background: The current aim of the fight against the HIV epidemic is to reduce the proportion of missed opportunities for HIV diagnosis. French regional adult erotic industry shows (ES) were thought to be good places to organize awareness campaigns and to propose HIV-RDT to people potentially at risk, with quite an appetite for sex and unsafe practices. This study aimed to document the individual factors associated with HIV screening test approach, sexual behaviors and the proportion of HIV-positive-RDT results.
Methods: A cross-sectional study was conducted in 2015 during 4 ES in which prevention booths were set up with confidential spaces to offer HIV-screening to individuals < =18 years volunteers for HIV-RDT and for respond to a validated anonymous questionnaire.
Results: We tested 943 people, mainly men (64%), young (mean age 30 years), living as a couple (63.7%). A very large majority (95.1%) reported having sexual intercourse over the last year, with 4.8 mean number of sexual partners and 68.6% with unprotected sex at least once; 37.5% had never been tested and had their first test during this campaign. Drugs (cannabis, 42.0%) and alcohol (64.4%) use were significant. We found 3 (0.32%) HIV-positive RDT results. In multivariate analysis, the 430 participants who reported no previous HIV-testing in the last 5 years compared to the 434 without previous HIV-test, more frequently declared heterosexual intercourse (OR: 2.31), being a man (OR: 1.82), transactional sex (OR: 1.92), living as a couple (OR: 1.67) and having fewer sexual partners (OR: 1.06).
Conclusions: These data showed for the first time the usefulness of HIV-screening and awareness campaigns, in new locations as fun and commercial backdrop events. We were able to find individuals never been HIV-tested and who had no intention of doing so before this campaign. This innovative and original intervention in ES had also enhanced the mobilization of local screening services, both health professionals and associations, who gave HIV informations and talked about sexuality and sexual risk behaviors. However this new model of additional intervention did not prove to be more valuable but complementary of the previous existing HIV screening services in approaching at-risk individuals for targeted intervention.

THPEC313

Improvement in HIV care continuum outcomes among young Black men who have sex with men: Results from forum engagement in in the HealthMPowerment intervention

J. Bauermeister[1], K. Muessig[2], S. LeGrand[3], S.K. Choi[2], L. Hightow-Weidman[2]
[1]University of Pennsylvania, Family & Community Health, Philadelphia, United States, [2]University of North Carolina, Gillings School of Global Public Health, Chapel Hill, United States, [3]Duke University, Global Health Institute, Durham, United States

Background: HIV-related stigma impedes HIV prevention and care. HealthMpowerment.org (HMP) is an interactive online HIV prevention and care intervention for young Black men who have sex with men (YBMSM) in the United States. HMP included three forums where participants shared experiences. We explored whether engaging in stigma-related discussions was associated with changes in HIV-positive YBMSM care-related outcomes.

Methods: HIV-positive YBMSM (ages 18-30; N=107) in HMP completed surveys at baseline, three-
(end of intervention) and six- (3 month post intervention) months that included HIV care continuum items (e.g. retention in care, disclosure to partners). We also coded instances when HIV-positive YBMSM posted HIV-related stigma content on the site. We employed growth curve modeling to examine whether changes in HIV-positive YBMSM's care-related outcomes were associated with stigma-related discussions in the site.

Results: Twenty percent of HIV-positive YBMSM (N=21; 19.6%) composed posts with HIV-related stigma content. HIV-positive YBMSM whose posts challenged HIV stigma were more likely over the 6-month follow-up to report greater provider communication (Cohen's d=.51; p< .01), serostatus disclosure to partners (Cohen's d=.38; p< .05), easier access to antiretroviral therapy (ART) (Cohen's d=.42; p< .05), and more likely to be in care (Hazard Rate=2.92 [1.25,6.83]; p< .01). Conversely, participants whose posts reflected anticipated HIV stigma were less likely to be in care (Hazard Rate =.05 [.01, .20];
p< .001) and to have a viral load test in the prior 3 months (Hazard Rate =.05 [.01, .040]; p< .01). Participants whose posts reinforced HIV stigmatizing norms were less likely to report disclosing their serostatus to recent sexual partners over time (Cohen's d=-.39; p< .05). Participants who shared experiences of HIV stigma were more likely to report lower ART adherence over time
(Cohen's d=-.67; p< .001).

Conclusions: Developing online strategies to combat stigma remains a key priority. HMP created a space where YBMSM could discuss HIV-related stigma. These discussions were associated with changes in the sample's HIV care continuum outcomes over time. Online interventions (e.g., social media, apps) should consider the inclusion of forums to address stigma, including resources to overcome anticipated stigma and leverage online peer support within their sites to improve YBMSM's HIV care outcomes.

THPEC314

A mobile app improves anti-retroviral therapy adherence in HIV-positive stimulant-using men who have sex with men

K. Horvath[1], S. Lammert[1], R. Maclehose[1], T. Danh[1], A. Carrico[2], J. Baker[3]
[1]University of Minnesota, Epidemiology and Community Health, Minneapolis, MN, United States, [2]University of Miami, Department of Public Health Sciences, Miami, United States, [3]University of Minnesota, Infectious Disease, School of Medicine, Minneapolis, United States

Background: Among HIV-positive men who have sex with men (MSM), the use of stimulants such as methamphetamine is associated with elevated HIV viral load and amplified risk of onward HIV transmission. The aim of this study is to assess the feasibility, acceptability, and preliminary efficacy of a mobile app intervention (called "APP+") on anti-retroviral therapy (ART) adherence among stimulant-using MSM (SUMSM).

Methods: We enrolled 90 HIV-positive SUMSM on ART and randomized them to either the APP+ intervention (n=45) or a no treatment control (n=45). Grounded in the IMB model, APP+ intervention components included HIV/ART information, adherence motivational content, and adherence strategies and self-monitoring to improve behavioral skills. Participants randomized to the APP+ intervention were given access to the intervention for an average of 108 days (i.e., 3.5 months; range=80-120 days). Study assessments occurred every 2 months over a 6-month period, including time in which men no longer had access to the intervention. Data collected were the percentage of men retained, the System Usability Scale (SUS) to assess intervention acceptability, and self-reported percentage ART adherence in the past 30 days.

Results: Participants were a mean age of 37 years (sd=9.9) and living with HIV for 8 years (sd=7.1). Most (56%) men identified as a racial/ethnic minority, 82.2% reported recent stimulant use, and 71% reported condomless anal sex (< 2 months). Retention at the 6-month assessment point was 81%. The mean SUS score was 68 (sd=19.6), which is considered average acceptability. Adjusting for baseline 30-day adherence, the APP+ intervention resulted in a 5.3 unit-increase in percent 30-day adherence over the 6-month follow-up period (p< .05; see Figure). Greatest differences were found at month 4, with higher 30-day adherence scores reported among intervention (89%) than control (77%; p< .05) participants. These improvements were not sustained once men lost access to the intervention.

Conclusions: Results provide proof of concept that a scalable mobile application can improve ART adherence in HIV-positive SUMSM. Findings support the need for a Phase II efficacy trial to examine the efficacy of APP+ for optimizing the benefits of HIV treatment as prevention with this high priority population of HIV-positive SUMSM.

Structural interventions

THPEC315

Impact of third party supports on increased access to condoms and outreach services amongst a community-based cohort of sex workers in Canada (2010-2016): Implications for HIV prevention and policy reform

B. McBride, S.M. Goldenberg, A. Murphy, S. Wu, M. Braschel, A. Krüsi, K. Shannon, AESHA Study Team
BC Centre for Excellence in HIV/AIDS, Gender and Sexual Health Initiative, Vancouver, Canada

Background: Despite growing evidence of the harms associated with criminalization, many countries continue to criminalize all/most aspects of the sex industry, including third party actors (e.g., receptionists, security), in large part due to misconceptions that assume third parties to be inherently exploitative (e.g., ´pimps´). Given limited epidemiological research on how third party involvement shapes access to health and HIV/STI prevention, we draw on longitudinal community-based research to examine the impact of third parties supports on access to HIV prevention and community-led services amongst sex workers in a Canadian setting.

Methods: Prospective data (2010-2016) were drawn from AESHA, a community-based open cohort of 900+ cis and trans women sex workers working across diverse indoor, outdoor, and online spaces in Metro

Vancouver. Women with lived experience (sex workers) are represented across interviewer, nursing and coordinator teams. Women are invited through mobile outreach and complete interviewer-administered questionnaires on a semi-annual basis. Bivariate and multivariable logistic regression with generalized estimating equations were used to 1) examine factors correlated with accessing administrative or security third party support, and 2) evaluate the impact of third party supports on HIV prevention and community-led services access, using time-updated measures.

Results: Of 816 cis and trans women sex workers, 29.5% (n=241) accessed any administrative or security third party supports over the six-year study. In multivariable GEE analyses, sex workers who were im/migrants (adjusted odds ratio[AOR] 2.32, 95% confidence interval[CI] 1.35-3.98), worked in in-call establishments (e.g., massage parlours) (AOR 3.41, 95%CI 1.89-6.15) and who experienced recent physical/sexual violence from clients (AOR 2.07, 95%CI 1.41-3.04) had higher odds of accessing third party supports. In separate multivariable GEE confounder models, accessing third party support was independently correlated with accessing condoms through mobile outreach (AOR 1.84, 95%CI 1.47-2.31) and accessing sex worker-specific/community-led services (AOR 1.61, 95%CI 1.15-2.24).

Conclusions: This research suggests that access to third party supports increases sex workers' access to HIV/STI prevention and community-led outreach services. Given continued criminalization of third parties in Canada and globally, this evidence suggests health and safety needs for policy reforms to fully decriminalize sex work to ensure sex workers´ labour rights and protections, including access to third party supports.

'Community Squad' a vehicle to address violence against female of sex workers (FSWs)

S. Sultana[1], K. Tarique[2], M. Imran[3], F. Karim[4], M. Omar Faruque[5], S. Begum[2]
[1]Save the Children, Health, Nutration and HIV/AIDS, Dhaka, Bangladesh, [2]Light House, Dhaka, Bangladesh, [3]Save the Children US, Washington, United States, [4]Save the Children, HIV Program, Dhaka, Bangladesh, [5]Save the Children, Dhaka, Bangladesh

Background: Violence against women is very high in Bangladesh. A recent government survey revealed violence in any means against married women from common walk is very high (80%). [Bangladesh Bureau of Statistics, 2015]. This situation is worse for 102,206 (Mapping Estimates, 2015) FSW's in Bangladesh. These population is highly stigmatized and subjected to many forms of discrimination in the society and at the government facilities. Police and administrative entities also harass them.

Description: Save the Children provides HIV prevention services to 17300 FSWs in 11 districts through Light House (LH) Consortium and maintains 27 drop in centers for them. To address the violence against this population with an approach of 'community for the community', in July 2015, LH created a central 'Community Squad' with senior FSWs & their leaders and members of community based organization (CBOs). This team is available for 24 hours to respond to any harassment cases. A dedicated hot number has been assigned. Lawyers, journalist, relevant NGOs and service providers are intervened by the community squad to resolve the cases for FSWs.

Lessons learned: During July 2016 - November 2017, community squad got huge responses from the FSWs community under the coverage. 519 cases of different merits were addressed by them. Analyzing the addressed cases 242 were violence victims 227 cases were discriminated. Victims were referred for treatment at public health facility and was linked for legal aid support. Different measures for gender sensitization and empowerment have been communicated by the Squad and the case studies have been documented for future references.

Conclusions/Next steps: Community squad for FSWs has been proved as a sustainable services to address violence against FSWs. It helps to see the scale of violence in different tires of the society and raise voice of the community. Presently the squad is operating only in the capital, Dhaka city, but soon the arena will be widened countrywide.

THPEC317

Preventing HIV in Botswana through support networks of young women

D. Loutfi[1], S. Law[2], L. Kgakole[3], N. Andersson[1], A. Cockcroft[1]
[1]McGill University, Family Medicine, Montreal, Canada, [2]Trillium Health Partners, Toronto, Canada, [3]CIET Botswana, Gaborone, Botswana

Background: One fifth of the population in Botswana is infected with HIV, and most new cases occur in young women. Poverty, poor education, and gender-based violence mean that many rely on transactional sex to provide for themselves and families. The INSTRUCT trial is a structural intervention that aims to help marginalized young women access existing government support programs to find work or return to education. The challenge is to figure out how to reach marginalized young women to include them in the intervention and ensure we are reaching those who will benefit most.

Methods: We carried out a social network analysis with 307 young women (16-29) not in work and not in school in 4 communities in Moshupa, Botswana in 2017. In a cross-sectional survey, we asked about their support networks, including who they turn to when socializing, for emotional support, and for information about jobs or school. Qualitative focus groups allowed for a contextualization of our findings. Our participatory approach involved community members, including young women, in recruitment and dissemination of results.

Results: Sociometric analysis found that marginalized young women were more connected to each other in rural rather than urban settings (see attached image). Participants sought a diversity of young women for support (in terms of age, education, and others), though the poorest young women were rarely the most central. Ego-centric analysis allowed us to explore the broader support networks of young women. When seeking information about work or about returning to school, they tended to seek support from family members (67%), rather than friends, and they turned to women (86%) more often than men. Multivariate analysis showed that the least educated participants were more likely to seek information from others that were poorly educated (OR = 2.36 (1.63-3.41)), or that lived in the same community (OR = 1.89 (1.28-2.78)), findings that were corroborated during the focus groups.

Conclusions: Studying social networks can provide insight into reaching marginalized populations with interventions. Targeted outreach of the poorest and least educated young women may be necessary and outreach through young women´s networks seems more feasible in rural settings.

Measuring and enhancing retention and adherence in HIV prevention programs

THPEC318

Increasing trends in PrEP use in young men who have sex with men from 2014 - 2016: Interim findings from the P18 cohort study

F. Kapadia[1,2], P. Halkitis[3,4], R. Greene[5]
[1]New York University, College of Global Public Health, Department of Epidemiology, New York, United States, [2]New York University, School of Medicine, Department of Population Health, New York, United States, [3]Rutgers University, Department of Biostatistics, East Brunswick, United States, [4]Rutgers University, Department of Social and Behavioral Health Sciences, East Brunswick, United States, [5]New York University School of Medicine, Bellevue Adult Primary Care Center, New York, United States

Background: There is substantial evidence supporting the use of pre-exposure prophylaxis (PrEP) to prevent HIV seroconversion in adult men who have sex with men (MSM). While awareness of PrEP has increased among both older adult and young/emerging adult MSM, information on PrEP uptake among young men who have sex with men (YMSM) is limited.
Methods: The P18 Study is on-going, prospective cohort study of young men who have sex with men residing in the New York City metropolitan area. The cohort study was initially launched in 2009 with enrollment re-opened in 2014; all participants were between the ages of 23-24 at re-enrollment. Participants were recruited via community- and venue-based recruitment efforts. All participants took part in semi-annual visits that included audio-computer based behavioral assessments.
Results: In this sample of n=665 YMSM (25.1% White, 27.4% Black, 32.2% Hispanic/Latino, 7.7% Asian Pacific Islander, and 7.7% Multi-Ethnic or Other), n=274 were retained from the original cohort and n=391 were newly recruited. At baseline, 8.9% of participants reported ever using PrEP with increases in PrEP use across 4 waves of semi-annual visits (wave 2: 10.7%, wave 3: 12.8%, wave 4: 13.7%; p(trend) < 0.05). There were no racial/ethnic differences in PrEP uptake across all study waves. In multivariable logistic regression analysis, ever use of PrEP was associated with an increased odds of condomless anal insertive sex in the last 30 days (OR=2.27, 95% CI 1.29, 3.98) and use of gamma hydroxybutyrate (GHB) in the last 30 days (OR=10.93, 95% CI 2.78, 43.02).
Conclusions: These interim findings suggest that, between 2014 - 2016, PrEP use increased among YMSM residing in the NYC metropolitan area. Also, based on these data, these increases in PrEP use did not differ by race/ethnicity. However, since engagement in sexual and drug use behaviors that may increase risk for HIV acquisition persist in this sample of YMSM, efforts to continue providing PrEP information and promoting PrEP uptake should be maintained. Targeted efforts to inform providers serving YMSM are warranted as well.

THPEC319

Attrition of HIV-exposed infants from early infant diagnosis services in low- and middle-income countries: A systematic review and meta-analysis

J. Carlucci[1], Y. Liu[2], H. Friedman[3], B. Pelayo[4], K. Robelin[4], E. Sheldon[5], K. Clouse[5], S. Vermund[6]
[1]Vanderbilt University Medical Center, Pediatric Infectious Diseases, Nashville, United States, [2]University of Rochester, Department of Public Health Sciences, Rochester, United States, [3]College of Charleston, Charleston, United States, [4]Meharry Medical College, Nashville, United States, [5]Vanderbilt Institute for Global Health, Nashville, United States, [6]Yale School of Public Health, New Haven, United States

Background: Identification and retention of HIV-exposed infants in early infant diagnosis (EID) services helps ensure optimal health outcomes. This systematic review and meta-analysis examines the magnitude of attrition from EID services in low- and middle-income countries (LMICs).
Methods: We performed a comprehensive database search through April 2016 following PRISMA guidelines (PROSPERO#: CRD42016034180). We included original studies reporting retention/attrition data for HIV-exposed infants in LMICs. Outcomes included loss to follow-up (LTFU), death, and overall attrition (LTFU + death) at time points along the continuum of EID services. At least two authors determined study eligibility, performed data extraction, and made quality assessments. We used fixed- or random-effect meta-analytic methods to aggregate effect sizes and perform meta-regression analyses.
Results: We identified 3279 unique studies, of which 92 met eligibility criteria and were included in the quantitative synthesis. The included studies represent data from 110,805 HIV-exposed infants, the majority of whom were from Africa (77%). LTFU definitions varied widely, and there was significant variability in outcomes across studies. The bulk of attrition occurred in the first six months of follow-up, with additional losses over time. Overall, 39% of HIV-exposed infants were no longer in care at 18 months and, when restricted to non-intervention studies, 43% were not retained at 18 months.
Conclusions: These findings underscore the high attrition of HIV-exposed infants from EID services in LMICs and the urgent need for implementation research and resources to improve retention among this vulnerable population.

THPEC320

Daily or event-driven PrEP? Interim results of “Be-PrEP-ared”, a PrEP demonstration project among men who have sex with men in Belgium

B. Vuylsteke[1], T. Reyniers[1], I. De Baetselier[2], K. Wouters[2], C. Nöstlinger[1,3], J. Buyze[2], M. Laga[1]
[1]Institute of Tropical Medicine, Public Health, Antwerp, Belgium, [2]Institute of Tropical Medicine, Clinical Sciences, Antwerp, Belgium, [3]University of Vienna, Faculty of Psychology, Vienna, Austria

Background: ‘Be-PrEP-ared’ aims to assess uptake, acceptability and feasibility of daily and event-driven Pre-Exposure Prophylaxis (PrEP) regimens among men who have sex with men (MSM) and transgender women at high risk for HIV. We present findings of regimen choices, sexual behaviour and adherence of the first 12 months of follow-up (FU).
Methods: In this prospective cohort study, participants choose between daily or event-driven Truvada (TDF/FTC). They are allowed to switch, discontinue or restart regimens at three-monthly visits. At each visit, participants receive preventive counselling, fill in a behavioural questionnaire, and provide samples for STI testing. Daily sexual behaviour and PrEP use are self-reported using a web-based diary. We performed an interim analysis on data from baseline (M0) to month 12 (M12).
Results: From 09/2015 - 12/2016, 197 MSM and 3 transgender women were enrolled in the study. Their median age was 38 years (range 22 - 70 yrs).
Initially, 76.5% chose daily and 23.5% event-driven PrEP. Feeling able to anticipate HIV risk was the most frequent reason for preferring event-driven PrEP. During 12 months FU, 28 participants (14%) switched regimen and five discontinued PrEP. Main reasons for switching included changes of life/partner situations, frequency of sexual contacts, simplicity, travel and side effects of Truvada. Adherence, measured as the proportion of participants reporting 100 % high risk sex acts covered by PrEP, was 77.7%, 80.5%, 85.6% and 79.8% at respectively M3, M6, M9 and M12. The reported median number of sexual partners in the past 3 months was 12, 6 and 3 for all, anonymous and occasional partners respectively. These numbers remained steady over the FU period of 12 months and were consistently higher when comparing daily with event-driven users. In total, 54.7% of the participants reported less condom use during receptive anal intercourse with occasional partners at M12 as compared with the baseline. The incidence of bacterial STI was 75% Persons-Years, but no new HIV infections were observed.
Conclusions: Event-driven PrEP was chosen by 23% of the participants and adherence to PrEP was high. Despite high rates of receptive condomless sexual intercourse and STI during FU, no new HIV infections were observed.

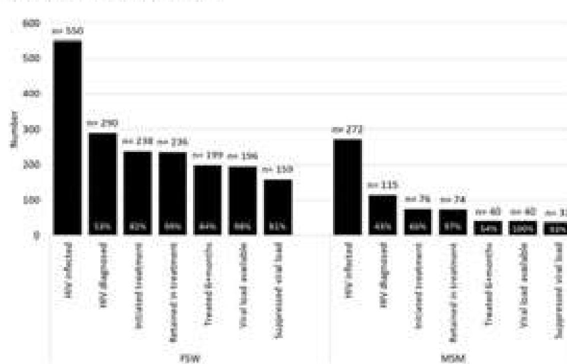
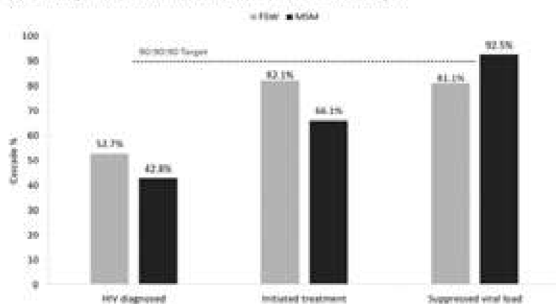
HIV treatment outcomes among female sex workers and men who have sex with men in Cameroon

A.L. Bowring[1], S. Zadrozny[2], I.N. Mfochive[1,3], G. Fako[3], A. Rao[1], S. Ketende[1], G. Turpin[1], C. Lyons[1], U. Tamoufe[3], G. Fouda[4], F. Ndonko[4], D. Levitt[5], A. Bissek[6], O. Njoya[7], S.C. Billong[8], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [2]University of North Carolina, Chapel Hill, United States, [3]Metabiota, Yaounde, Cameroon, [4]CARE Cameroon, Yaounde, Cameroon, [5]CARE USA, New York, United States, [6]Ministry of Health, Department of Operational Research, Yaounde, Cameroon, [7]Yaounde University Hospital Centre, Department of Internal Medicine, Yaounde, Cameroon, [8]Groupe Technique Central (CNLS), Yaounde, Cameroon

Background: In Cameroon, there are significant numbers of female sex workers (FSW) and men who have sex with men (MSM) living with HIV. Specific strategies to diagnose and initiate treatment are integral to optimize health outcomes and decrease onward HIV transmission.
Methods: In 2016, FSW (sex work as principal source of income in past year) and MSM (anal sex with man in past year) aged 18+ years were recruited via respondent-driven sampling from five cities of Cameroon for a biobehavioral survey including HIV and viral load (VL) testing. Among participants living with HIV, indicators of the HIV treatment cascade were compared between FSW and MSM using ²-test-of-proportions(< 0.05 significance); viral suppression (VS) was defined as < 1000 copies/ml. Association between population and VS was assessed using Poisson regression, controlling for clustering by site and time since diagnosis.
Results: Overall, 2,255 FSW (median age:28; IQR:23-36) and 1,322 MSM (median age:23; IQR:21-26) were recruited. Prior HIV testing was reported by 2,029(90.1%) FSW and 958(72.5%) MSM (p< 0.01), and in the past year by 1,329(59.1%) FSW and 728(55.1%) MSM (p=0.02). Unadjusted-HIV prevalence was 24.5% among FSW and 20.7% among MSM (p=0.01); 290(52.7%) FSW and 115(42.8%) MSM were previously diagnosed (p< 0.01). Of these, 238(82.1%) FSW and 76(66.1%) MSM reported initiating antiretroviral therapy (ART) (p< 0.01).





[Development and overview of the HIV treatment cascade among FSW and MSM in Cameroon, 2016]

The median time since initiating ART was 51.5 months (IQR:15.7-98.4) among FSW and 8.0 months (IQR:3.9-27.9) among MSM. After initiation, 37(15.6%) FSW and 21(28.0%) MSM reported any treatment interruption (p=0.02), but the majority (99%) self-reported currently on ART. Among individuals who had initiated ART at least 6-months prior to survey and with VL result available, 159(81.1%) FSW and 37(92.5%) MSM were virally suppressed (p=0.08). When controlling for years since diagnosis, MSM were marginally more likely to be virally suppressed than FSW (RR 1.13; 95%CI:1.00-1.26; p=0.04).
Conclusions: Once diagnosed and enrolled into treatment services, both populations reported engaging in sustained treatment, but there were notable gaps and disparities in testing/treatment uptake. There is evident need to rapidly expand testing modalities-including HIV self-testing, consider novel strategies for ART delivery, and evaluate PrEP as a means of reducing new diagnoses among key populations in Cameroon.

THPEC322

Dapivirine vaginal ring-004: Male partner perceptions and experiences

M. Malherbe, M. Isaacs, A. Nel
International Partnership for Microbicides, Clinical Affairs, Paarl, South Africa

Background: The dapivirine vaginal ring (DVR) demonstrated to be safe and effective in preventing HIV-1 infection in a Phase III trial (IPM 027/The Ring Study). Adherence to ring use may be influenced by multiple factors, including the perceptions and experiences of male sex partners.
Methods: The Ring Study was a phase III, randomized, double-blind, placebo-controlled trial using DVR; inserted monthly in healthy, sexually active HIV-negative women, 18 to 45 years of age. The trial was conducted at seven research centers in Sub Saharan Africa over 104 weeks.
Results: 1958/1959 women enrolled used the ring. The majority of those enrolled had a main sex partner (1924/1959, 98.2%). Results are provided according to the number of women who completed a questionnaire. Most women reported that their male partner knew they participated in the trial (1295/1913, 67.7%). Some participants reported concern that their partner might not like the ring (278/1820, 15.3%). At each post-enrollment assessment, >95% of participants self-reported they were ≥90% adherent to ring use. After 24 weeks, most women reported that their partner did not feel the ring during sex (1419/1709, 83.0%). Of those who reported that it was felt by the partner (289/1709, 16.9%), most partners did not mind the way it felt (189/288, 65.6%). After 104 weeks, most reported that their partner knew they were in the trial (686/813, 84.4%) and that their partner knew they were wearing the ring (654/686, 95.3%). By 104 weeks, few women were worried about their partner not liking the ring (3/819, 0.4%). Most participants reported that they could not imagine wearing the ring without telling their partner (472/808, 58.4%). HIV-1 risk reduction was higher when the participant reported that her partner was aware of ring use (53.8%, 95% CI: 21.15 - 73.02) than when not aware (4.1%, 95% CI: 57.54 - 41.62). Degrees of partner support differed, and partner resistance or lack of support was more common among young women.
Conclusions: Social and behavioral data from this trial suggest that partner perceptions and support could affect ring use. Male engagement in future trials should be considered.

THPEC323

Retention on ART within the HPTN 071 (PopART) universal testing and treatment programme in Zambia and South Africa

D. Macleod[1], B. Yang[2], S. Floyd[1], A. Schaap[3], S. Griffith[4], K. Shanaube[3], M. Phiri[3], R. Sloot[2], P. Bock[2], N. Beyers[2], H. Ayles[3,5], S. Fidler[6], R. Hayes[1]
[1]London School of Hygiene and Tropical Medicine, Dept. of Infectious Disease Epidemiology, London, United Kingdom, [2]Stellenbosch University, Desmond Tutu TB Centre, Cape Town, South Africa, [3]University of Zambia, Zambia AIDS Related Tuberculosis Project, Lusaka, Zambia, [4]FHI 360, Durham, United States, [5]London School of Hygiene and Tropical Medicine, Dept. of Clinical Research, London, United Kingdom, [6]Imperial College, Dept. of Infectious Disease Epidemiology, London, United Kingdom

Background: HPTN 071 (PopART) is a community-randomised trial of the impact of a combination HIV prevention intervention on population-level HIV incidence, conducted in Zambia and South Africa (SA). The PopART intervention is delivered in three annual rounds (R1-R3) by Community HIV-care Providers (CHiPs) who provide home-based HIV testing services, referral for HIV care and antiretroviral therapy (ART), and follow up HIV+ clients to provide adherence and retention support. The aim of this analysis was to provide estimates of retention on ART among individuals in seven communities randomised to receive the PopART intervention, where routine viral load testing was not readily available.
Methods: The analysis included individuals aged 18+ from R3 (September 2016-December 2017) known to the CHiPs as HIV+ and had self-reported ever taking ART. A cross-sectional measure of retention during R3 was defined as the proportion who, on the date of the R3 visit, self-reported taking ART within the last month and had not missed pills in the last three days. Retention at 6/12 months was defined using an individual's self-reported ART start date and the CHiP visit closest to 6/12 months after this date.
Results: In the four Zambian communities, on the date of the R3 visit 95.9% (9,491/9,902) adults were retained on ART. Restricting to those who initiated ART after the start of the PopART intervention in 2014, 94.1% (4,882/5,186) were retained on ART. Corresponding proportions in the three SA communities were 94.6% (4,339/4,651) and 93.5% (2,270/2,427) (table 1).
In Zambia retention in care 6/12 months following ART start was 93.9%/95.4% compared with 90.9%/91.1% in SA. A difference was observed whether an individual first participated in the PopART intervention in R3 or had participated previously in R1 and/or R2. Those participating previously had a lower proportion retained than those participating for the first time (e.g. 6 month retention in Zambia was 92.6% in previous participants compared to 98.5% in first time participants, with 89.4% vs. 96.0% in SA).
Conclusions: Overall self-reported retention was high. Estimates from individuals who participated in R1 and/or R2 are considered more reliable, as they use a history of CHiP follow-visits rather than a single self-report during R3.

ART initiation timing		Started ART anytime	Started ART pre-2014	Started ART in 2014 or later		
Time at which retention was measured		At time of R3 visit	At time of R3 visit	At time of R3 visit	6 Months after ART start date	12 months after ART start date

THPEC324

On feasibility and effect of extended Integrated next step counseling on subjects' adherence to HIV pre-exposure prophylaxis in the Senegal PreP demonstration project

E. Tousset[1], S. Mboup[2], D. Gueye[2], M. Sarr[3], A. Mboup[4,5], M. Mane[4], R. Paiva[1], G. Gottlieb[6], M. Aikenhead[7], J. Presley[7], T. Blaschke[7], P. Salif Sow[7]
[1]Westrock Healthcare, VISE, Belgium, [2]RARS, Dakar, Senegal, [3]Westat, Rockville, United States, [4]IRESSEF, Dakar, Senegal, [5]Universite Laval, Québec, Canada, [6]University of Washington, Seattle, United States, [7]BMGF, Seattle, United States

Background: Prophylactic use of antiretroviral drugs among individuals at high risk of HIV infection constitutes a cornerstone for HIV eradication programs. The effectiveness of orally administered PrEP is however dependent on subjects' adherence to the once daily dosing regimen. Demonstration projects in Senegal, Kenya and Nigeria have been implemented to test the feasibility, scalability and effect of measurement-guided adherence-enhancing interventions in resource-limited settings. This abstract focuses on the project conducted in Senegal.
Methods: The program has been conducted among female sex workers in 4 Ministry of Health (MoH)-run clinics in Dakar, Senegal. An Integrated Next Step Counseling (iNSC) was used for adherence counseling to optimize exposure to prophylaxis. The iNSC is a strengths-based discussion focused on PrEP adherence needs and tailored strategies to support individuals. The iNSC has been extended to rely on reliable and precise measure of medication adherence using Medication Event Monitoring System (MEMS). MEMS timestamped each opening of a medication package, providing a sound proxy for medication intake. Resulting dosing history data were used as individual feedback during the adherence counseling. The effect of this adherence-enhancing intervention is quantified and tested using longitudinal logistic regression models.
Results: Between July and November 2015, 350 individuals were identified, 321 (91.7%) were preliminarily eligible, and 267 (83.1%) were enrolled for up to 12-months of PrEP. 181 subjects were electronically monitored and entitled to receive extended iNSC counseling sessions.
According to MEMS data, an estimated 63% of the subjects took their medication daily as prescribed during the month preceding the first intervention, with large disparities between centers ranging from 51% to 76%.
The odds of taking the drug daily as prescribed after intervention was twice the odds pre-intervention (Odds Ratio 2.06, 95% CI 1.57-2.70; $p < 0.001$). Therefore, daily, the proportion of subject adherent to the prophylaxis was 17% higher after receiving extended iNSC counseling.
Conclusions: These results suggest the feasibility of adherence counseling sessions using adherence data as feedback in resource-limited settings. They also show the effect of the extended iNSC intervention on adherence to PrEP prophylaxis. Further analyses on the effect of recurrent interventions and their effect over time are ongoing.

THPEC325

Bi-directional communication in a text-messaging intervention with pregnant and postpartum women living with HIV in Kenya

M. Manwari[1], T. Odwar[1], I. Wanga[1], K. Owuor[1], T. Odeny[1,2], M. Onono[1,3], A. Helova[4], P. Musoke[4], E. Akama[1], P. Oyaro[1], E.A. Bukusi[1], L.L. Abuogi[5], J.M. Turan[4], MOTIVATE!
[1]Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya, [2]University of Missouri-Kansas City, Department of Medicine, Kansas City, United States, [3]The University of California, San Francisco, Department of Global Health, San Francisco, United States, [4]University of Alabama at Birmingham, Health Care Organization and Policy, Birmingham, United States, [5]University of Colorado Denver, Department of Pediatrics, Denver, United States

Background: Text-messaging interventions can be an effective method for enhancing antiretroviral therapy (ART) adherence and retention in care. An important component of text-messaging interventions is a bi-directional aspect, in which recipients of messages can communicate with healthcare providers for additional information and support.

Methods: The MOTIVATE! Study (R01HD0808477) is a cluster-randomized trial of interventions to support adherence and retention in care among pregnant/postpartum women living with HIV in southwestern Kenya. Women in two arms of the study receive weekly text messages starting in pregnancy, up to 12 months postpartum. Calls from participants to the free call-back number are recorded in a log, including date, type of contact (SMS or call), caller, content of the call, and response made. Content analysis methods were used to code the log and multivariate logistic regression analysis was utilized to examine which types of participants were more likely to utilize this service.
Results: From May 2016-Nov 2017, out of 670 participants at text-messaging sites, 225 calls/messages were received from 202 participants (30.2%). Around half of calls (49.8%) were made during pregnancy. Content of calls included: asking help regarding a health problem (32.9%), asking for health-related information (17.8%), updating the study team (11.0%), general support requests (4.5%), questions/complaints about health services (12.9%), and questions/acknowledgement about text messages (11.0%).
Types of health problems reported included maternal symptoms during pregnancy, delivery, or postpartum; infant illnesses; and ART side effects. Health-related information requested included infant feeding options, risks of mother-to-child transmission, family planning choices, and labor/delivery preparations.
Between June-November 2017, effects of the national nurse's strike were also reflected in the calls, with participants asking about the availability of basic health services. In multivariate analyses adjusted for study arm and parity, women who had been on ART for less than 24 months were 1.8 times more likely to use the bi-directional service, as compared to women who had been on ART longer (95% CI: 1.4-2.5).
Conclusions: The opportunity for bi-directional communication is well utilized by participants in this text-messaging study, especially by women with less time on ART. Bi-directional communication may help explain the effectiveness of text-messaging interventions.

THPEC326

Randomized controlled trial of daily text messages to support adherence to pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) and transgender women (TGW): PrEP Brasil pilot substudy

L.M.S. Marins[1], T.S. Torres[1], R.I. Moreira[1], I. Costa Leite[2], B. Hoagland[1], J.V. Madruga[3], E.G. Kallas[4], P.L. Anderson[5], A.Y. Liu[6], B. Grinsztejn[1], V. Veloso[1], PrEP Brasil Study Team
[1]Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, [2]Fundação Oswaldo Cruz, Escola Nacional de Saúde Pública, Rio de Janeiro, Brazil, [3]Centro de Referência e Treinamento em DST/AIDS, São Paulo, Brazil, [4]Universidade de São Paulo, School of Medicine, São Paulo, Brazil, [5]University of Colorado, Skaggs School of Pharmacy and Pharmaceutical Sciences, Denver, United States, [6]San Francisco Department of Public Health, Bridge HIV, San Francisco, United States

Background: Short-text-messaging (SMS) has emerged as an important communication tool in the health arena and may improve adherence to treatment. We evaluated the effectiveness of SMS in improving adherence to daily emtricitabine/tenofovir (FTC/TDF) for PrEP among MSM and TGW.
Methods: PrEP Brasil was a prospective, multicentre, open-label demonstration project assessing PrEP delivery in the context of the Brazilian Public Health System. A pilot sub-study of interactive SMS was offered to all participants at the screening visit. Individuals who agreed to participate were randomized 1:1 to intervention (SMS) or standard-of-care (SoC), which included adherence counseling. SMS was launched weekly to participants at a pre-determined time. Retention at week 48 was evaluated, as well as adherence, evaluated by tenofovir-diphosphate (TFV-DP) concentrations measured using LC-MS/MS. Adequate and optimal adherences were defined as TFV-DP≥700fmol/punch and ≥1250fmol/punch, respectively. Medication-possession-rate (MPR)≥1 at week 48 was used to verify if participants had enough pills for daily PrEP since the last pharmacy refill. Chi-square test was used to compare study arms. Logistic regression was used to evaluate factors associated with MPR≥1.
Results: From 450 participants included on PrEP Brasil, 417(92.7%) were randomized to SMS or SoC; 6.9%(31/450) refused to participate, 0.4%(2/450) were ineligible. Median age was 30 years(IQR: 25-35); 246(59.0%)were from São Paulo, 102(24.5%) aged 18-24 years, 25(6.0%) TGW, 188(45.4%) non-white and 110(26.4%) had < 12 years of education. A total of 347(83.2%) participants were retained at week 48, and there was no difference between arms. No difference between arms was observed either for adequate and optimal adherence. Conversely, a greater proportion of participants in the SMS arm had a MPR≥1 (Table 1). In an analysis adjusted by site location, SMS appeared to be a predictor of MPR>=1, as the association was borderline significant (AOR=1.57;CI 95%:0.98-2.51).
Conclusions: SMS-intervention had no impact on optimal and adequate adherence as measured by TFV-DP concentrations. Conversely, the SMS-intervention improved durability of PrEP coverage as measured by MPR. As individuals can make PrEP decisions based on perceived risk of HIV infection and having FTC/TDF is a necessary condition for high rates of adherence, SMS can be a useful method to improve drug coverage and prevent poor adherence.

	SMS n=207 (49.6%)	SoC n=210 (50.4%)	Total n=417	p-value (chi-square)
Retention at week 48	177(85.5)	170(81.0)	347(83.2)	0.21
Adequate adherence (≥4doses/week)	133(75.1)	125(73.5)	258(74.3)	0.73
Optimal adherence (≥7doses/week)	44(26.9)	52(30.6)	96(27.7)	0.23
MPR≥1	134(75.7)	113(66.5)	247(71.2)	0.06

[Table 1. Retention, adherence and MPR at week-48]

THPEC327

Retention-in-care after implementation of a phone-call tracing strategy, in HIV-infected individuals on antiretroviral treatment in Guinea

C. Quagliani[1], S. Boutouba-Combe[1], R.E. Harrison[1], Y.D. Ilale[1], A. Diallo[1], I. Adjaho[1], O. Tiemtore[1], M. Sesay[1], E. Casas[2], P. Isaakidis[2], D. Naniche[3]
[1]Medecins Sans Frontieres-Belgique, Conakry, Guinea, [2]Medecins Sans Frontieres, Cape Town, South Africa, [3]ISGlobal, Barcelona, Spain

Background: Retention in care at 12 months remains below 90% in HIV cohorts followed by MSF in Conakry, Guinea. MSF has implemented differentiated-models-of-care to serve the needs of people leaving with HIV/AIDS; among them the phone-call tracing strategy directed at patients who missed a follow-up visit. We describe the impact of this strategy on long-term retention in care.
Methods: This is a retrospective study based on routinely collected MSF program data. The eligible population was HIV patients on ART enrolled at Matam clinic, who missed a scheduled appointment between 2014-16. Cox proportional hazards models were used to assess the association between the phone call strategy and attrition from care following missed visit after adjusting for other demographic and clinical factors.
Results: 2153 patients with a median of 3.7 years (IQR 1.4 - 5.9) on ARVs among those with a contact on file and 2.8 years (IQR 0.6 -5.7) among those without a phone contact, with a total of 3261 missed appointments were included in the analysis. In 37% (n=1203) of the missed appointments the patient was successfully reached by telephone. Amongst the other 63% (n=2058) missed appointments, 41% (n=1342) could not be reached because there was no contact number in the patients file. 33% (n=718) patients returned to care after being telephoned. Thirty-nine percent (n=864) of patients had 6 month spacing between visits.
As compared to individuals reached by telephone, the risk of attrition was significantly higher amongst those that could not be telephoned, but had a telephone (HR=2.05, 95%CI: 1.45-2.91 / AHR=1.86, 95%CI: 1.31-2.64), and those that had no available contact details (HR=1.40, 95%CI: 1.02-1.93/AHR=1.34, 95%CI: 0.97-1.84). Those that did not have 6 month spacing between appointments, had the highest risk of attrition after a missed appointment (HR=3.28, 95%CI: 2.29-4.68 / AHR=3.55, 95%CI:2.61-4.83).
Conclusions: Contacting patients via telephone and implementing six-month visit spacing for stable patients, both elements of differentiated care, are associated with decreased attrition from care. Nevertheless,

in order to maximize efficiency, it is important to ensure contact details are updated in the patient file regularly. Additional understanding of the profiles of patients needing more attention will help contextualize such interventions.

THPEC328

Acceptability of a mobile health intervention to improve retention in care among young adults living with HIV in Peru: A mixed-methods evaluation

M. Prochazka[1], L. Otero[1,2], D.S. Batey[3], J. Dionne-Odom[4], J.M. Rodriguez[4], E. Gonzalez[1,2], A. Zinski[5]
[1]Universidad Peruana Cayetano Heredia, Instituto de Medicina Tropical Alexander von Humboldt, Lima, Peru, [2]Universidad Peruana Cayetano Heredia, School of Medicine, Lima, Peru, [3]University of Alabama at Birmingham, Department of Social Work, College of Arts & Sciences, Birmingham, United States, [4]University of Alabama at Birmingham, Division of Infectious Diseases, School of Medicine, Birmingham, United States, [5]University of Alabama at Birmingham, Department of Medical Education, School of Medicine, Birmingham, United States

Background: Effective interventions tailored to meet the needs of young adults living with HIV are essential to meet UNAIDS' 90-90-90 targets. Mobile Health (mHealth) interventions, including reminder and motivational short message services (SMS), are associated with improved attendance to health facilities. For this reason, we implemented a single-arm pilot mHealth intervention aimed towards improved retention in a public hospital in Peru, and conducted a mixed-methods evaluation of its acceptability among young adults.
Methods: For six months (November 2016-August 2017), young adults (18-29 years) with HIV received
(i) SMS reminders prior to their scheduled visits;
(ii) motivational SMS after each visit; and
(iii) phone call after missed visits.
End-of-study acceptability surveys included Likert scales to assess perceived clarity, utility and privacy, and open fields on positive and negative characteristics of the intervention. Participants were invited to focus group discussions (FGD) to share thoughts and experiences with the intervention, including suggestions for improvement. We analyzed qualitative data thematically to provide supplementary explanatory value to quantitative survey data.
Results: Among 80 intervention participants, 64 (80%) completed end-of-study surveys. Participants agreed that SMS messages were clear (100%), helped to remember appointments (100%), and motivated them towards continued attendance (94%). Participants agreed that privacy was maintained in messages (99%) and phone calls (95%). Reported positive characteristics of the intervention in open fields were effective reminders (n=40), feeling supported (n=32), and respect for their privacy (n=16). Negative characteristics included discomfort due to phone calls (n=7) and SMS being unidirectional (n=2). All participants agreed that they would recommend the intervention to others (100%). Eleven participants joined in three FGD; several reported receiving emotional and instrumental support from the intervention, including a perceived sense of care and timely reminders about visits. Suggestions for improvement included implementing a two-way messaging platform, as well as potentially using chat-based mobile applications.
Conclusions: A mHealth intervention to improve retention in HIV care was shown to be acceptable among young adults in Peru. As SMS may promote retention via discreet reminder prompts and supportive motivational messages, further interventions of this type may be a crucial component to meeting UNAIDS goals.

THPEC329

Sports betting centres and mobile health engagement: How to find, link, and retain men for HIV prevention or treatment

J. Bwanika[1], A. Kiragga[2], D. Musinguzi[1], W. Lubega[1], L.H. Kamulegeya[1], Y. Manabe[3]
[1]Medical Concierge Group Limited, Kampala, Uganda, [2]Infectious Diseases Institute Limited, Kampala, Uganda, [3]Johns Hopkins University, Baltimore, United States

Background: Finding men at high risk for Human Immunodeficiency Virus (HIV) infection is a top priority in sub-Saharan Africa. Mobile phone use offers new avenues for health information dissemination, long term engagement and mobile money reimbursements. We assessed the feasibility of using mobile platforms for HIV prevention messaging, participant reimbursement using mobile money and preliminary pilot assessment of impact on linkage to treatment.
Methods: Men at five sports betting and gaming centers in Uganda were consented for on-site HIV and syphilis tests between May and September 2017. Information on condom use, number of sexual partners, commercial sex and alcohol intake was collected using a structured questionnaire on the REDCap platform. Men were also consented to join a two-year mobile phone follow-up cohort using Short Message Service (SMS). Reimbursement for research participation was done using mobile money payment within seven days of their sign-up.
Results: We enrolled 516 men into the study; the median age was 28 years (Interquartile range: 24, 34), 52.6% were married, and 89.3% were employed with an average monthly income of USD 120. A majority (96%) owned at least one mobile phone and everyone consented to mobile money reimbursement and two-year mobile health engagement. During the first sixty days of the study, 2,919 SMS messages were sent out with either service linkage information for those who were HIV/syphilis positive or prevention content for those with a negative test result. Although the number of patients that tested positive for HIV (4) and syphilis (18) was small, 25% of those that tested positive for HIV and 26% of those with syphilis sought treatment at a health facility within seven days. This increased to 50% at end of twenty eight days, with the rest promising to do so within the second month.
Conclusions: Mobile health engagement coupled with mobile money reimbursement is a feasible way to maintain contact with men for HIV prevention messaging and/or linkage to treatment. Additional qualitative work is needed to improve the impact on linkage to HIV care and behavioral messaging for HIV prevention practices.

THPEC330

Pre-exposure prophylaxis (PrEP) adherence in Black men who have sex with men (MSM) and transgender women (TGW) in a community setting in Harlem

P. Colson[1], F.S. Winterhalter[1], Y. Wu[1], J. Franks[1], Y. Hirsch-Moverman[1,2], H. Ortega[1], J. Knox[2], W. El-Sadr[1,2]
[1]ICAP, Columbia University, New York, United States, [2]Mailman School of Public Health, Dept Epidemiology, New York, United States

Background: PrEP is efficacious for HIV prevention; however, effectiveness needs to be evaluated in community settings and populations most vulnerable to HIV, including black MSM and TGW in the United States (US). We compared the effectiveness of enhanced PrEP (EPrEP) adherence support to standard of care (SOC) PrEP among black MSM and TGW attending a community clinic in New York City.
Methods: EPrEP included behavioral interventions (peer navigation, live and online support groups, and SMS text messages). Interviews at baseline and 6-months assessed potential correlates of adherence including depressive symptoms, substance use, and homelessness. Self-reported adherence over previous 30 days was collected using a validated, structured questionnaire. The sample was divided into quartiles; the top quartile (≥87% adherence) was considered 'adherent.' Those in other quartiles were considered non-adherent, along with those who missed interviews. Adherence was analyzed using intent-to-treat (ITT) and as-treated (AT) methods. Crude and adjusted analyses examined factors associated with being adherent.

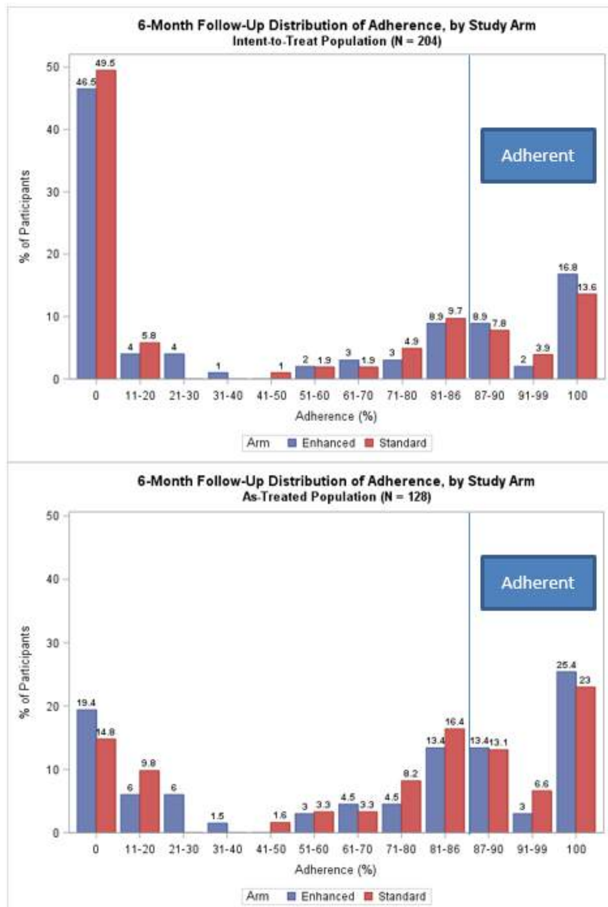
[Table. Associations between baseline demographic and psychosocial factors and PrEP adherence at 6 months (Intent-to-Treat population - N=204)]



[Figure 1. 6-Month Follow-Up Distribution of Adherence, by Study Arm]

Results: 204 participants (194 MSM and 10 TGW) were enrolled and randomized to EPrEP or SOC PrEP. Figure 1 shows the adherence distribution by study arm using ITT and AT analyses. Of 204 participants, 76 (37.3%) did not complete the 6-month interview and were assigned 0% adherence; there was no difference by study arm (p=.29). Of the EPrEP group, 28 (27.7%) were adherent, compared to 26 (25.3%) in the SOC PrEP group (p=.69). In the AT analysis, 28 (41.8%) in the EPrEP group were adherent, compared to 26 (42.7%) in the SOC group (p=.92).
As shown in Table 1, variables predicting lower non-adherence in the unadjusted analysis include lower educational attainment, not working, having Medicaid/Medicare, and having marginal housing. Study arm was not a significant factor. In multivariable analysis, only education remained significant.
Conclusions: A substantial proportion of participants were lost to follow-up and no difference was noted in adherence between EPrEP and SOC PrEP arms. Structural factors including education and employment impacted adherence. Findings suggest the need to develop and test interventions targeting multi-level factors associated with PrEP retention and adherence among groups most impacted by HIV, including black MSM and TGW in the US.

THPEC331

Predictors of PrEP continuation among young men who have sex with men (YMSM) in the U.S. that participated in the EPIC study

K. Bojan[1], R. Jackson[1], E. Vittinghoff[2], P. Serrano[1], P. Vonfelton[3], I. Ortiz-Estes[1], J. Brothers[4], K.R. Amico[5], L.M. Henry- Reid[1], J. Rooney[6], S. Hosek[4], J. Fuchs[3], A. Liu[3]
[1]Ruth M. Rothstein CORE Center/John H. Stroger Jr. Hospital of Cook County, Department of Pediatrics, Division of Adolescent Medicine, Chicago, United States, [2]University of California, San Francisco, United States, [3]San Francisco Department of Public Health, San Francisco, United States, [4]John H. Stroger Jr. Hospital of Cook County, Department of Psychiatry, Chicago, United States, [5]University of Michigan, Department of Health Behavior and Health Education, Ann Arbor, United States, [6]Gilead Sciences, Foster City, United States

Background: While PrEP has demonstrated efficacy, uptake and persistent use have been low among YMSM. Demographic and psychosocial variables that may predict continued PrEP use were explored among YMSM who had participated in a randomized clinical trial of a text messaging PrEP adherence intervention.
Methods: HIV-uninfected YMSM aged 18-29 initiating PrEP within Chicago's safety-net system were offered enrollment in the Enhancing PrEP in Community (EPIC) Study, which included provision of 36 weeks of free PrEP and randomization (2:1) to receive standard of care (counseling by health educator) only or standard of care plus PrEPmate (weekly text check-ins and daily reminders).
All participants were counseled about options to continue PrEP post-study. Participants were assessed up to 4 weeks post-study to assess barriers and facilitators to accessing PrEP via computer-assisted self-interview (CASI). Open-ended questions assessing self-reported barriers and facilitators to PrEP access post-study were reviewed by members of the study team and collapsed into thematic categories through consensus.
Results: A total of 79 participants completed the week 36/40 interviews (mean age = 24.2; 33% black, 38% Latino, 17% white). 80% had education beyond high school, and 72% were insured. Almost all respondents were very (85%) or somewhat (10%) interested in continuing PrEP after study completion, and 73.4% of participants reported taking PrEP since the end of the study.
Participants with education beyond high school were significantly more likely to report taking PrEP post-study (p≤0.05). Participants who were Black or unable to find a health care provider to prescribe PrEP were significantly less likely to have taken PrEP post-study (p≤0.05).
Reported barriers to continuing PrEP included lack of insurance (67%), no PrEP access/availability (23%), no PrEP-supportive provider (9%), and lack of self-motivation (7%). Facilitators to continuing PrEP included insurance or having financial resources (45%), more accessible clinic hours/locations (20%), PrEP-supportive provider (13%) and reminders (16%).

Conclusions: Shortly after completing a clinical PrEP trial, use of PrEP persisted for most participants. However, disparities in race and health care access are evident and will continue to inhibit the true potential of PrEP as an HIV prevention strategy for YMSM. Interventions addressing structural-level and provider-level barriers are urgently needed.

THPEC332

High postpartum retention in treatment among HIV positive women who were aware of their HIV status during pregnancy: Results from the Malawi population-based HIV Impact Assessment 2015-16

S. Jonnalagadda[1], E. Radin[2], D. Payne[3], R. Bray[2], T. Kalua[4], G. Bello[4], H. Patel[1], K. Sleeman[1], C. West[3], N. Ahmed[2], A. Voetsch[1], M. Nzima[5], E. Kim[3], MPHIA Study Team
[1]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [2]ICAP at Columbia University, New York, United States, [3]Centers for Disease Control and Prevention, Lilongwe, Malawi, [4]Ministry of Health, Government of Malawi, Lilongwe, Malawi, [5]UNAIDS, Lilongwe, Malawi

Background: Postpartum retention of women in HIV care is challenging but critical for achieving HIV epidemic control. We used 2015-16 Malawi population-based HIV Impact Assessment (MPHIA) survey data to describe postpartum viral suppression, as a measure of treatment retention, in HIV positive (HIV+) women.
Methods: Women who provided consent for participation in MPHIA were interviewed and tested for HIV using the national rapid test algorithm; positives were confirmed by Geenius™ (Bio-Rad). HIV RNA viral load suppression was defined as < 1,000 copies/mL. Current antiretroviral treatment (ART) use was defined as self-reported or detectable ART in blood. HIV+ women aged 15-49 years who delivered in the 36 months prior to the survey, were included in this analysis. We used weighted percentages to describe current viral suppression by self-reported HIV status and ART use during the most recent pregnancy in the 36 months prior to the survey.
Results: Of the 369 women who tested HIV+ in MPHIA and delivered in the last 36 months, 72.2% (95% confidence intervals (CI): 66.8% - 77.6%) self-reported being HIV+, 19.8% (95% CI: 14.8% - 24.8%) self-reported testing HIV negative (HIV-) and 6.7% (95% CI: 3.9% - 9.5%) self-reported being unaware of their HIV status during pregnancy. Of the 369 HIV+ women, 75.9% (95% CI: 70.5%-81.3%) were virally suppressed (VS).
Among women who self-reported being HIV+, testing HIV- or being unaware of their HIV status during pregnancy, 87.7%, 47.4% and 33.2%, respectively, were VS as measured in MPHIA. Among women who reported being HIV+ during pregnancy, 98.5% (95% CI: 97.1-99.9%) received ART during pregnancy; 95.5% were currently on ART, of whom, 90.8% were VS. Among women who reported testing HIV- during pregnancy, 39.0% were currently on ART, of whom 93.6% were VS. Among women who were unaware of their HIV status during pregnancy, 32.2% were currently on ART, of whom 89.8% were VS (Table).

Self-reported HIV status during most recent pregnancy in the 36 months prior to the survey	N (unweighted denominator)	Overall viral suppression in women who tested HIV+ in MPHIA (weighted percent)	95% confidence interval	Current ART use (Weighted percent)	95% confidence interval	Viral suppression among women currently on ART (weighted percent)	95% confidence interval
Self-reported HIV positive	276	87.7	82.7 - 92.7	95.5	91.7 - 99.3	90.8	86.6 - 94.9
Self-reported HIV negative	68	47.4	33.6 - 61.3	39.0	26.0 - 52.0	93.6	85.7 - 100.0
Self-reported unaware of HIV status	21	33.2	12.3 - 54.1	32.2	13.5 - 50.8	89.8	66.9 - 100.0

[Current ART use and viral suppression in HIV+ women, by self-reported awareness status during last pregnancy in the 36 months prior to the survey]

Conclusions: Viral suppression was high in women who received ART during pregnancy, indicating high retention on treatment. Our results indicate need to strengthen postpartum engagement in care for women who were unaware of their HIV status during pregnancy or were infected postpartum, through regular screening and re-testing.

THPEC333

Determinants of early retention in HIV care for newly diagnosed HIV-positive pregnant and lactating women in Uganda

A. Watsemba[1], F. Kasajja[2], R. M Flueckiger[3], J. Hayuni[1], B. Wandera[2], A. Mitchell Le Few[3], M. Lopez[4], E. Tanga[2]
[1]RTI International, USAID/Uganda HIV and Health Initiatives in Workplaces Activity, Kampala, Uganda, [2]World Vision Uganda, USAID/Uganda HIV and Health Initiatives in Workplaces Activity, Kampala, Uganda, [3]RTI International, Research Triangle Park, North Carolina, United States, [4]World Vision, Inc., Federal Way, WA, United States

Background: Mother-to-child transmission of HIV accounts for approximately 18% of all new infections in Uganda. According to the World Health Organization, prompt diagnosis, early enrollment and initiation on antiretroviral therapy (ART), and retention in care of HIV-positive women and HIV-exposed infants has the potential to reduce mother-to-child transmission of HIV to less than 2% in the non-breastfeeding population and to less than 5% in the breastfeeding population. The study assessed the retention in HIV care of newly diagnosed HIV-positive pregnant and lactating women after three months of enrollment in care.
Methods: A rapid retrospective assessment was conducted, reviewing all records of HIV positive pregnant women enrolled October 2015 to July 2017 in nine health facilities implementing the Prevention of Mother-to-Child Transmission of HIV Program in Uganda. A total of 191 records were reviewed. Early retention was computed as the proportion of newly ART-enrolled HIV-positive pregnant and lactating women active in care three months post-initial enrollment. Association between background characteristics and retention were tested using Pearson's chi-squared tests and odds ratios.
Results: The study found a 70% retention rate at three-months. Retention was associated with age groups (p< 0.05), parity (p< 0.001), marital status (p< 0.05), and HIV status of spouse (p< 0.001). Women 20-24 years old were 3.1 times more likely to be retained in care than those 15-19 years old (p< 0.05), while those 25-29 years old and 30-40 years old were 2.1 times and 2.8 times more likely to be retained in care, respectively. Women with one or two children were 2.8 times more likely to be retained in care, while those with three children were 3.1 times more likely to be retained in care compared to those with no children.
Conclusions: The study findings indicate sub-optimal retention of pregnant and lactating HIV-positive women newly enrolled in care. For elimination of mother-to-child transmission of HIV, there is a need for strategies to improve retention to at least 90%, with emphasis on young women 15-19 years old, women with no children, and married women.

A qualitative evaluation of women's experience receiving drug feedback in MTN-025/HOPE - an HIV prevention open-label trial of the dapivirine vaginal ring

A. van der Straten[1], A. Katz[2], I. Balan[3], K. Reddy[4], J. Etima[5], K. Woeber[6], T. Tauya[7], M. Atujuna[8], R. Scheckter[9], K. Ngure[10], L. Soto-Torres[11], N. Mgodi[7], T. Palanee-Phillips[4], J. Baeten[12], MTN-025/HOPE Study Group
[1]RTI International, WGHI Program/Center for Global Health, Kensington, United States, [2]RTI International, San Francisco, United States, [3]Columbia University, New York, United States, [4]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [5]Makerere University - Johns Hopkins University Research Collaboration, Kampala, Uganda, [6]Medical Research Council, Durban, South Africa, [7]University of Zimbabwe College of Health Sciences Clinical Trials Unit, Harare, Zimbabwe, [8]Desmond Tutu AIDS Foundation, University of Cape Town, Cape Town, South Africa, [9]FHI 360, Durham, United States, [10]Jomo Kenyatta University of Agriculture and Technology, Juja, Kenya, [11]NIH/NIAID, Bethesda, United States, [12]University of Washington, Seattle, United States

Background: Adherence to HIV prophylaxis is challenging. Real-time adherence feedback is a potential strategy to promote consistent product use. In MTN-025/HOPE, participants could choose to use the dapivirine ring or not. If yes, they received returned ring residual drug level (RDL) information during feedback adherence counseling.

Methods: The HOPE qualitative component took place at six sub-Saharan African sites. In-depth-Interviews (IDIs) were conducted with a subset of participants who, at enrollment, chose to use the ring. Interviews, conducted in local languages using semi-structured guides, were summarized in reports for rapid thematic analysis. RDL scores were calculated dividing residual dapivirine in ring by ring coverage period. RDL was discussed with participants approximately 2-3 months after the ring was returned. Counseling messages framed RDL adherence results in terms of HIV protection, from no protection (poor adherence; score=0) to high protection (high adherence; score=3).

Results: Among the 50 women interviewed (Malawi n=9; South Africa n=21; Uganda n=9; Zimbabwe n=11), reactions to RDL were often emotional. Participants with scores indicative of high protection usually responded with relief and happiness. However, for some, even a score of 2 created significant distress. Participants with lower scores who insistently reported high adherence often appeared upset, blaming laboratory errors or dysfunctional rings. However, many accepted their results and subsequently reported practices that could explain lower scores. Some participants remained perplexed by low scores in the context of consistent use. Test accuracy was often debated and most participants requested quicker RDL feedback. Participants acknowledged counselors' instrumental role in affecting their post-feedback behaviors and feelings: dominant themes were enhanced motivation to maintain consistent use (those with score=3), or persistence and striving for improvement (those with lower scores). A minor theme was "wait and see" if future scores improve or else choose another prevention approach (e.g. condoms only).

Conclusions: Participants valued the monitoring of protection level against HIV, but RDL was at times challenging and evoked strong reactions. Client-centered counseling helped to channel emotions and behavioral reactions positively. Emphasis on protection minimized confrontational interactions and facilitated alternative, but at times implausible, explanations. Participants recommended improved test accuracy to more precisely reflect product use.

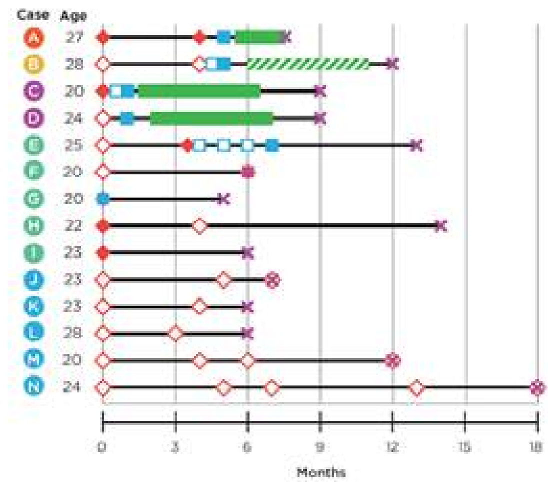
Beyond the biomedical: PrEP failures in a cohort of young Black men who have sex with men in Atlanta, GA

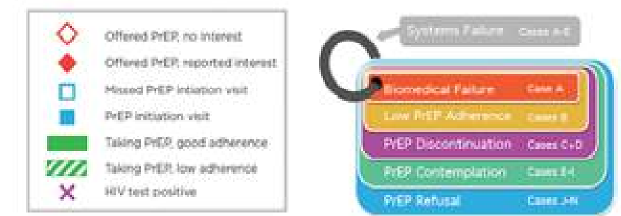
D.P. Serota[1], E.S. Rosenberg[2], A.M. Lockard[3], C.-P.M. Rolle[4], C. Del Rio[1,5], N. Luisi[3], S. Cutro[6], A.J. Siegler[3], T.H. Sanchez[3], P.S. Sullivan[3], C.F. Kelley[1]
[1]*Emory University School of Medicine, Department of Medicine, Division of Infectious Diseases, Atlanta, United States,* [2]*University of Albany School of Public Health, SUNY, Department of Epidemiology and Biostatistics, Rennselaer, United States,* [3]*Emory University Rollins School of Public Health, Department of Epidemiology, Atlanta, United States,* [4]*Orlando Immunology Center, Orlando, United States,* [5]*Emory University Rollins School of Public Health, Hubert Department of Global Health, Atlanta, United States,* [6]*Kaiser Permanente, Department of Infectious Diseases, Atlanta, United States*

Background: HIV pre-exposure prophylaxis (PrEP) has high biomedical efficacy; however, awareness, uptake, and persistence on therapy remain low among black men who have sex with men (BMSM), who are at highest risk for HIV transmission in the US. We implemented an optional PrEP program as standard of HIV prevention care within a cohort of young BMSM; nonetheless, high HIV incidence continues to be observed.

Description: The EleMENt study is a prospective observational cohort of 300 young (aged 16-29), HIV-negative BMSM in Atlanta, USA. At each study visit over 24 months of follow-up, participants complete questionnaires and undergo HIV/STI testing and risk-reduction counseling. We offer non-incentivized PrEP to all participants and provide physician and laboratory services and assistance from a PrEP navigator to obtain the medication at low/no cost. Most studies to date have framed PrEP failure as a rare event of seroconversion despite adequate PrEP adherence (biomedical failure); however, a much larger number of seroconversions will likely occur among those with access to PrEP who either do not initiate or persist in care.

Lessons learned: PrEP was offered to all 300 men, and as of December 2017, 53% (158/300) started PrEP. Over the first half of the study, 14 participants acquired HIV. We identified four additional typologies of 'PrEP failure' that expand beyond traditional biomedical failure: low PrEP adherence, PrEP discontinuation, PrEP contemplation, and PrEP refusal. Among the HIV seroconversion cases, 5 participants reported no interest in PrEP (PrEP refusal), 5 expressed interest but never started PrEP (PrEP contemplation), and 4 took PrEP at some time before seroconversion (PrEP discontinuation and low PrEP adherence). Only 1 participant could be considered a biomedical PrEP failure.





[Timelines of Seroconversions with Respect to PrEP]

Conclusions/Next steps: The majority of PrEP failures resulting in HIV seroconversion in our study, where barriers to PrEP access are minimized, were not due to biomedical failure or lack of adherence, but due to not initiating PrEP. To fully realize PrEP effectiveness for high-risk populations, such as BMSM, a broader understanding of PrEP failure and solutions need to be developed. Using these lessons learned we are optimizing PrEP delivery in our study to avoid additional PrEP failures.

THPEC336

Predictors of self-reported adherence to pre-exposure prophylaxis (PrEP), including barriers and facilitators, among men who have sex with men (MSM) and transgender women (TGW): PrEP Brasil Demonstration Study

T.S. Torres[1], L.M.S. Marins[1], P.M. Luz[1], R.I. Moreira[1], I.D. Costa Leite[2], B. Hoagland[1], E.G. Kallas[3], J.V. Madruga[4], A.Y. Liu[5], B. Grinsztejn[1], V.G. Veloso[1], PrEP Brasil Study Group
[1]*Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil,* [2]*Fundação Oswaldo Cruz, Escola Nacional de Saúde Pública, Rio de Janeiro, Brazil,* [3]*Universidade de São Paulo, School of Medicine, São Paulo, Brazil,* [4]*Centro de Referência e Treinamento em DST/AIDS, São Paulo, Brazil,* [5]*San Francisco Department of Public Health, Bridge HIV, San Francisco, United States*

Background: Adherence is a critical factor for efficacy of emtricitabine/tenofovir (FTC/TDF) for PrEP. Strategies for improving, supporting, motivating and sustaining adherence to PrEP are of great importance in maximizing the impact of PrEP in high-risk populations. We evaluated self-reported PrEP adherence and its perceived barriers and facilitators among MSM and TGW retained though 48 weeks in the PrEP Brasil study.

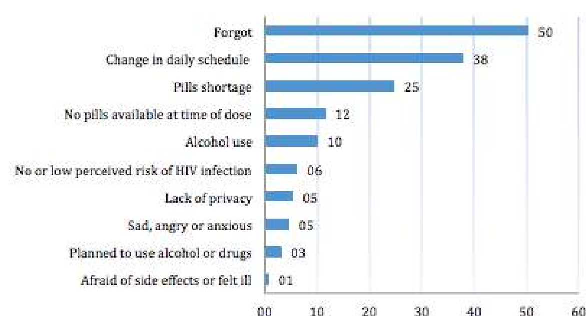
Methods: PrEP Brasil was a prospective, open-label demonstration project with HIV-uninfected MSM and TGW from 3 referral centers in Rio de Janeiro (RJ) and São Paulo (SP). Participants were followed-up for 48

weeks and daily FTC/TDF was provided. PrEP adherence (30-days recall), facilitators and barriers were assessed by the pharmacist using a questionnaire upon study completion (week 48). Logistic regression was used to evaluate predictors for optimal (=100%) adherence in the past 30-days.

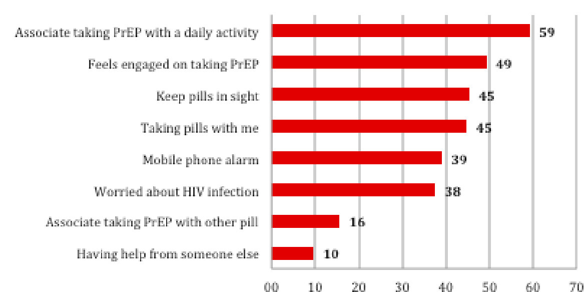
Results: From April/2014 to July/2016, 450 participants initiated PrEP, 375(83.3%) participants were followed through 48 weeks. Of these, 354(94.4%) were dispensed FTC/TDF in the previous 3 months and 338 (90.1%) answered the questionnaire. Median age was 30 years (IQR: 25-35). A total of 27(8.0%), 51(15.1%) and 53(15.7%) reported not missing any dose of FTC/TDF in the past week, 1-2 weeks and 3-4 weeks, respectively. Median adherence in the past 30-days was 100%(IQR:96-100); 60.6% of participants (205/338) reported optimal adherence. The majority (82.2%; 278/338) of participants reported not having difficulty with taking FTC/TDF and 81.3% (274/338) reported excellent or very good capacity to take FTC/TDF in the past 30-days. Perceived barriers and facilitators were reported by 38.2%(129/338) and 98.5%(333/338), respectively; main reasons reported by these participants are depicted in Figure 1. In multivariate analysis, being from RJ, TGW, stimulant use and having perceived barriers to adherence were associated with decreased odds of optimal adherence.

		Number of participants N=338	Optimal adherence (=100%) N=205 (60.6%)	OR (95%CI) (adjusted for site only)	p-value	AOR (95%CI)	p-value
Site Location	RJ (vs. SP)	118 (34.9)	55 (46.6)	0.41 (0.26-0.64)	0.0001	0.38 (0.20-0.73)	0.004
Gender	Transwomen (vs. male)	18 (5.3)	6 (33.3)	0.41 (0.14-1.14)	0.09	0.22 (0.07-0.73)	0.01
Sex with HIV positive partners	Yes (vs. no)	140 (41.4)	93 (66.4)	1.46 (0.92-2.32)	0.10	0.90 (0.48-1.70)	0.75
Stimulants in last 3 months	Yes (vs. no)	73 (21.6)	40 (54.8)	0.58 (0.33-1.00)	0.05	0.40 (0.20-0.80)	0.01
Depression PHQ score	PHQ-2 score ≥ 3 (vs. PHQ-2 score < 3)	20 (5.9)	8 (40.0)	0.39 (0.15-1.01)	0.05	0.41 (0.14-1.22)	0.11
GI symptoms	Yes (vs. no)	140 (41.4)	83 (59.3)	0.64 (0.39-1.05)	0.08	1.02 (0.54-1.93)	0.95
Perceived barriers	Yes (vs. no)	129 (38.2)	35 (27.1)	0.09 (0.05-0.15)	<.0001	0.12 (0.07-0.23)	<.0001

[Table 1. Unadjusted and adjusted odds ratios and 95% confidence interval for factors associated with optimal self-reported adherence at week 48.]



[Perceived barriers to adherence (n = 129; %)]



[Perceived facilitators to adherence (n = 333; %)]

Conclusions: High levels of self-reported adherence were reported among those retained through 48 weeks in the PrEP Brasil study. Our findings provide information for elaboration, reinforcement and/or update of strategies to improve adherence, especially among TGW and stimulant users, and for developing the best practices to promote PrEP adherence in our context. Interventions to reduce patient forgetfulness may be beneficial.

THPEC337

Predictors of loss to follow-up among HIV-infected children in rural Kenya: A retrospective cohort analysis

W.M. Saumu[1], E. Obimbo[2], G. Irimu[2], C. Gichuhi[3], R. Kumar[2]
[1]Ministry of Health, Government of Kenya, Paediatrics and Child Health, Chuka, Kenya, [2]University of Nairobi, Paediatrics and Child Health, Nairobi, Kenya, [3]University of Nairobi, Clinical Medicine and Therapeutics, Nairobi, Kenya

Background: Over the past decade, significant gains have been made in enrolment and care of HIV-infected children in Kenya. Their long-term survival depends on lifetime adherence to antiretroviral therapy. African studies have reported high rates of Loss to Follow up (LTFU) among children in HIV care and treatment centres. Factors associated with LTFU may vary across populations and countries. Few studies have been conducted among HIV infected children in care in rural areas of Kenya.

Methods: This was a retrospective cohort study involving children aged less than 15 years on follow up at Kangundo Level 4 Hospital HIV clinic from January 2010 to December 2015. We obtained sociodemographic and clinical information from patient files and electronic databases. We calculated period prevalence and incidence of LTFU over the 6 year period before and after physical tracing of those LTFU. Univariate and multivariate regression analyses were conducted to identify factors predictive of LTFU.

Results: 261 HIV-infected children were followed up (51.3% males). The mean age was 10.0 years and median CD4 count of 582. By December 2015, 171 children (65.5%) remained in active care, 32 (12.3%) transferred out, 13 (5%) died, while 45 (17.2%) were classified as LTFU giving a period prevalence of LTFU as 17.2% and incidence rate 44.9 per 1000 child years. Out of the 45 children presumed as LTFU, we successfully traced 44 out of the 45 children (98%), and found that their actual current status was as follows: 33 of the 44 children (75.0%) had dropped out of care, hence fulfilled the criteria for true LTFU.

Factors strongly predictive of LTFU included low caregiver level of education (HR 2.3, 1.9-3.9, P =0.001), WHO stage I and II at enrolment (HR 1.6, 1.4-2.1, P =0.05) and children not on ART at last contact with hospital (HR 4.7, 4.4-6.0, p=0.03).

Conclusions: Over the 6 year period, LTFU of HIV infected children was common with a true incidence of 32.9 per 1000 child years and occurred early in treatment and risk factors included poverty, low caregiver education, male child, early HIV disease stage and not being on ART.

THPEC338

Missed clinic appointments in the first six months of care and long term retention of HIV positive adults at a large Urban HIV clinic in Uganda

F. Mubiru, R. Kuteesa Bisaso, B. Castelnuovo, J. Mawejje, A. Kiragga
Infectious Diseases Institute, Research Department, Kampala, Uganda

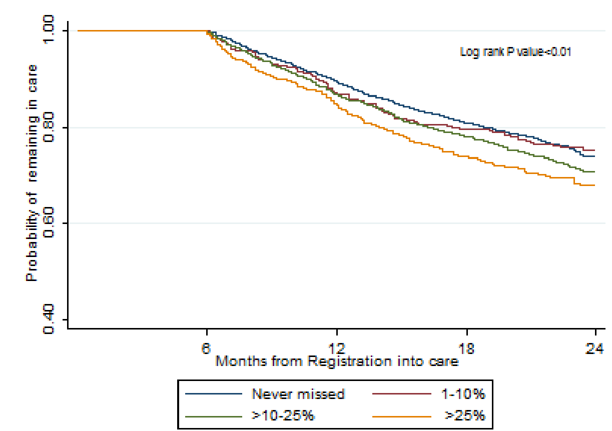
Background: In sub- Saharan Africa, patients started on ART are usually seen monthly during the first year to ensure close clinical and adherence monitoring. However, many patients miss scheduled visits in their first months of treatment. We hypothesize that missed appointments early in HIV care are an indicator of low long term retention. We aim to describe the patterns of missed visit appointments in the first six months, and examine their association with long term retention in HIV care.

Methods: We included HIV positive patients registered into HIV care from January 2008 to December 2014 at the Infectious Diseases Institute clinic in Kampala, Uganda. Data included: age, gender, WHO stage, and CD4 count. A missed appointment was defined as no visit to the clinic within 3 days of the scheduled appointment. Missed visits were classified as: Ever missed(yes/no); categorical (0, 1-2, >2); and Percentage of all scheduled visits missed (0%, 1-10%, >10-25%, >25%). Long term retention

was being active in care at 24 months. We used a Cox Proportional Hazards model to investigate whether missed visits were associated with long term retention.

Results: The study included 9,374 patients, 5,876(62.7%) were female, median age 33 years(IQR:27-40), 1809(19.3%) were young adults(16-<25years), 3,180(33.9%) in WHO stage 3&4, median CD4 count 268(IQR:100-489) cells/µL. 7112/9374(75.9%) were retained at month 6 and 5211/9374(55.6%) at month 24. Figure1 shows the probability of remaining in care by proportions of missed visits in the first 6 months of care. In the multivariable analysis, patients with: higher proportions (>10-25%) of missed visits (HR=1.20, 95%CI:1.11-1.36, P=0.003) compared to no missed visits and higher baseline CD4 count (200-300, >300: HR=1.30(1.22-1.60, p< 0.01, HR=1.23(1.10-1.40, p=0.002 respectively) compared to < 200 cells/µL, had higher risk of non-retention in HIV care.

Conclusions: Tracking missed visits in the first 6 months of ART can be a useful tool to identify patients at risk of low retention in order to target appropriate interventions. In the era of "treat all" our data also re-emphasizes the need for intervention for retaining healthier patients starting ART at high CD4 counts.



[Figure 1: Probability of remaining in care by proportions of visits missed in the first 6 months in HIV care]

THPEC339

Why they get lost: Results of tracing of children lost to follow-up from an HIV programme in lower Eastern Kenya

P.B. Karau[1], W.M. Saumu[2], E. Obimbo[3], G. Irimu[3], C. Gichuhi[4], R. Kuma[3]
[1]*Kenya Methodist University, Internal Medicine and Therapeutics, Meru, Kenya,* [2]*Chuka Level 4 Hospital, Chuka, Kenya,* [3]*University of Nairobi, Paediatrics and Child Health, Nairobi, Kenya,* [4]*University of Nairobi, Clinical Medicine and Therapeutics, Nairobi, Kenya*

Background: Loss to follow-up (LTFU) remains a major obstacle to the success of many HIV care programmes in Africa. Whereas many studies have focused on factors predictive of loss to follow-up, only a few have traced the children or their caregivers and elucidated the real reasons for dropping out of care. This aspect is important in tailoring interventions to increase retention in care.

Methods: A retrospective cohort study was conducted involving all children on follow up at Kangundo Hospital HIV clinic from 2010 to 2015. For those who satisfied the definition of LTFU, an attempt was made to trace the caregivers by phone calls. Those who responded to the calls were informed about the study and requested to come to the hospital or allow a home visit. For those with no phone contacts, physical tracing was conducted. Data was collected from the caregivers by administration of a structured pre- tested questionnaire. The status of the patient follow up was then reclassified as transfer out, dead or true LTFU.

Results: During the study period, 261 children we enrolled, with a mean age of 10 years. 45 children (17.2%) were lost to follow-up. Out of the 45 children who met the criteria for LTFU, 44 caregivers were successfully traced. 33 (75.0%) of the 44 had dropped out of care (True loss to follow up), while 6 (13.6%) were dead, and 5 (11.4%) had transferred to other facilities without referral. The true period prevalence of LTFU over the study period was found to be 12.6% (n= 261). The true Incidence of Loss to Follow- up was 32.9 per 1000 child years.The mean age of the caregivers was 48.5 years, with 29 (87.9%) of them being females. The mean approximate distance from home to Kangundo Level 4 Hospital was 11.8km. Fear of disclosure, stigma, adolescent children rebellion, death of primary caregivers and poverty were the main reasons for LTFU.

Conclusions: This study sheds light on the reasons for LTFU. Health care workers should trace children who don't honour clinic appointments. Interventions to reduce LTFU should focus on social, economic and healthcare related factors associated with LTFU.

THPEC340

Predictors of 1-month retention on PrEP for the general population in the public sector: A longitudinal study in routine care in Swaziland

A. Hughey[1], A. Hettema[1], C. Oldenburg[2], S. Kohler[3], S. McMahon[3], C. Lejeune[1], S. Matse[4], T. Barnighausen[3]
[1]*Clinton Health Access Initiative, Mbabane, Swaziland,* [2]*University of California, San Francisco, United States,* [3]*Heidelberg University, Heidelberg, Germany,* [4]*Swaziland Ministry of Health, Swaziland National AIDS Programme, Mbabane, Swaziland*

Background: Daily oral HIV pre-exposure prophylaxis (PrEP) can dramatically reduce HIV infection among HIV-negative individuals. Therefore, PrEP holds great promise to help end the HIV epidemic but the success of PrEP is contingent upon retention while at risk for HIV. It is thus important to understand predictors of retention among existing PrEP clients for targeting and to inform future designs of PrEP promotion and supporting interventions.

Methods: A PrEP demonstration study for the general population began on 1 August 2017 in Swaziland to assess the operationalization of PrEP as an additional HIV prevention method provided through the country's public-sector primary-care clinics for all clients ≥16 years at risk for HIV infection. Data were collected electronically from clinic-based client records. An analysis of 6-month baseline data through 31 January 2018 is presented. The primary outcome was retention at 1-month after PrEP initiation defined as continued PrEP use during the first month and attendance at the clinic within 7 days of the scheduled one-month follow-up appointment. A total of 217 clients, including 167 (77%) females and 50 (23%) males who initiated PrEP were analyzed for predictors of retention using a generalized linear model with a binomial distribution family and log link function, controlling for clustering of outcomes at the clinic level.

Variable	N (%)	RR	95% CI	P-value
Sex

No	44 (20.3)	--	--	--
Pregnant or Lactating (females only)				
Yes	65 (38.9)	0.99	(0.79, 1.24)	0.925
No	75 (44.9)	--	--	--
Missing	27 (16.2)			

[Table. Univariate regression results for predictors of retention at 1 month following PrEP initiation]

Results: Overall, 129 (59%) clients were retained at 1-month after PrEP initiation. Gender, pregnancy/lactation status and visiting the clinic specifically for PrEP services did not significantly predict retention. Clients with very high self-perceived risk of HIV infection (p<0.001), clients in middle age (p<0.05) and clients with a partner known to be living with HIV (p=0.024) were significantly more likely to be retained at 1-month after initiation than comparison groups (Table).

Conclusions: Women and men have approximately equal need for PrEP retention-supporting interventions. Interventions for PrEP retention should specifically target clients whose self-perceived HIV infection risk is relatively low, despite clear indications of high objective HIV acquisition risk. Increased support for risk self-assessment and enhanced PrEP counseling may have potential for improving PrEP retention. Younger clients and clients who do not know their partners' HIV status may need additional retention support.

THPEC341

Factors associated with loss to follow up among HIV patients with unsuppressed viral load in primary healthcare clinics

J. Kiwanuka[1], M. Muhindo Kahungu[1], J. Baligobye[1,2], M. Ssemakadde[3]
[1]AIDS Healthcare Foundation, Kampala, Uganda, [2]Makerere University, School of Public Health, Kampala, Uganda, [3]IeDEA Masaka Regional Referral Hospital, Masaka, Uganda

Background: Retention of patients initiated on antiretroviral therapy (ART) and ensuring good adherence remain cornerstone to long term viral suppression. Patients with un-suppressed viral load are presumed to have poor adherence, hence, are taken through intensive adherence counseling before switching treatment. However, how well such patients remain connected to care after unsuppressed viral load is an important metric in the HIV care cascade but hasn't been fully explored. We set out to determine loss to follow up (LTFU) and associated factors in patients with un-suppressed viral load in primary healthcare clinics.

Methods: We drew a sample of patients initiated on ART from January 2012 to December 2016 from two primary healthcare clinics. We analysed data for patients who had spent at least six months on ART, had viral load test results and presented with a most recent un-suppressed viral load. We defined LTFU as failure of a patient to return to the HIV clinic for at least 90 days from the date of their last appointment. We excluded deaths and transfers to other health facilities. We determined the proportion of patients LTFU and used logistic regression to assess factors associated with LTFU.

Results: We included 744 patients in our sample, with 55.7% females and median age at starting ART of 31.5(IQR= 22.5-38.5) years. The median CD4 cell count and weight at starting ART were 277 (IQR= 124-492.5) and 51kgs (IQR=42-58) respectively whereas 22.9% were in WHO stage 3 or 4 at baseline. Overall, 5.7% were LFTU. At bivariate analysis, there was no difference in LTFU between men and women (Female cOR=0.99, 95% CI=0.53-1.84). Compared to patients with a CD4 cell count of < 350, those with CD4 cell count of 350-500 (cOR=0.75, 95% CI=0.30-1.84) and >500 (cOR=0.50, 95% CI=0.20-1.22) were less likely to get LTFU. After adjusting for age, sex and baseline CD4, WHO stage 3 or 4 (aOR=2.1, 95% CI=1.1-4.2) was the only independent factor associated with LTFU.

Conclusions: Patients with a baseline WHO stage 3 or 4 had a higher likelihood of getting LTFU. This strengthens evidence for better treatment outcomes for initiating HIV positive patients in the infancy of disease progression.

THPEC342

Viral load outcomes in a cohort of alcohol consuming PLHIV receiving ART in Mumbai, India

A. Sarna[1], R.J. Singh[2], J.J. Schensul[3], B.B. Mahapatra[2], T. Huu Ha[4], S.L. Schensul[4]
[1]Population Council, HIV and AIDS, New Delhi, India, [2]Population Council, HIV and AIDS, Delhi, India, [3]Institute for Community Research, HIV and AIDS, Hartford, United States, [4]U Connecticut School of Medicine, HIV and AIDS, Farmington, United States

Background: Alcohol consumption among HIV-positive people on ART has been identified as a factor in sexual risk behaviour, poor immunological status and non-adherence to ART. However, less is known about its impact on viral load. We examined the association between alcohol consumption, adherence and viral load (VL) among HIV-positive men receiving ART in Mumbai.

Methods: We analysed enrolment data from a randomised controlled study evaluating the effect of three different counseling interventions to promote adherence and reduce alcohol use, in a cohort of 940 alcohol-consuming, HIV-positive men receiving treatment at government ART centers. Viral load testing was conducted as part of the study protocol. Alcohol consumption was assessed using AUDIT. Nonadherence was defined as self-reported, missed doses over the last 4 days >5%, and virological failure as VL>200 copies/ml.

Results: Mean duration of ART was 54.05 months. In terms of adherence, 16.7% of the participants had missed ≥1 doses in the last 4 days and 17.6% reported ≥1 treatment interruption in the last 12 months.
Of the total sample, 60.8% of the participants consumed alcohol ≥2 times/month, 62.8% consumed ≥3 drinks/typical day and 11.5% reported binge drinking ≥1 times/month. Binge drinking was associated with nonadherence (OR=2.38; 95%CI: 1.70-3.32) and treatment interruption (OR=2.99; 95%CI: 2.11-4.22).
Overall, 76.4% of the participants had VL< 200 copies/ml. On multivariate logistic regression, higher adherence (AOR: 0.98; 95%CI: 0.98-0.99) and better self-assessment of health (AOR: 0.98; 95%CI: 0.97-0.99) predicted a lower risk of virological failure, while treatment interruptions (AOR: 2.1; 95%CI: 1.39-3.16) and HIV symptoms (AOR: 1.06; 95%CI: 1.0-1.13) predicted a higher risk.
Higher alcohol consumption was associated with nonadherence (OR: 1.21, 95%CI: 1.12-1.31) and treatment interruptions (OR: 1.21; 95%CI:1.12-1.31). We found no direct association between alcohol use and VL. However, there was a significant interaction effect of alcohol use and nonadherence on virological failure (AOR: 1.23; 95%CI:1.03-1.47) implying that alcohol negatively impacts VL outcomes but mediated through adherence.

Conclusions: Alcohol consumption plays a significant role in the health status and behavior for HIV-positive men on ART. The study highlights the need for routine alcohol screening and follow up counseling for problem drinkers as an integral component of HIV care.

THPEC343

Understanding the uptake and retention patterns of PrEP users in Zimbabwe by sub population

E. Gwavava
Population Services International Zimbabwe, Social Franchising, Harare, Zimbabwe

Background: PSI Zimbabwe has been offering PrEP using TDF 300mg/FTC 200mg FDC tablets as an additional HIV prevention method at *New Start* centers in 6 districts in Zimbabwe - Mutare, Bulawayo, Chipinge, and Gweru, Masvingo and Harare - since August 2016. The *New Start* PrEP program is one of the demonstration projects that will help inform the MOHCC national PrEP implementation plan to introduce PrEP nationwide as a new HIV prevention strategy. The primary target populations include AGYW aged 15-24 years, FSWs, MSM, and serodiscordant couples.

Description: Programme data since programme inception in August 2016 to December 2017 was analysed for trends. Data for 2,275 clients enrolled on PrEP was analysed for uptake and retention trends by sub-population - AGYW, FSWs, MSM, transgender, serodiscordant couple, and other clients on PrEP.

Lessons learned: Data by subpopulation was analysed to determine the proportion of clients screening high risk and eligible for PrEP, the acceptance rate of PrEP and average retention by subpopulation. Clients with the highest proportions of clients at high risk include discordant male partner (99.2%), MSM and discordant female partner (98.3%); the lowest proportion at high risk were non-KP males (2.4%) and non-KP females (6.8%). The highest acceptance of PrEP was seen among non-KP females (95.2%) and discordant female partner (84.8%). The lowest acceptance rate was seen among MSM (37.2%) and non-KP males (39%). The highest average retention of 4.16 months was seen in female discordant partners.
Conclusions/Next steps: Understanding the various risk profiles by subpopulation of clients at substantial risk of HIV is important to help clients determine how long they need to be on PrEP whilst working on a risk reduction plan. Clients gave various reasons for not accepting PrEP, including the fear of perceived stigma that they are actually HIV-positive and taking ARVs for treatment rather than prevention of HIV. Clients who clearly understood their risk were more likely to stay on PrEP for longer.

THPEC344

Which MSM are most at risk of becoming HIV-infected in West Africa? (CohMSM ANRS 12324 - Expertise France)

P.-J. Coulaud[1,2], L. Sagaon-Teyssier[1,2], B. M'madi Mrenda[1,2], G. Maradan[1,2], M. Mora[1,2], M. Bourrelly[1,2], B. Dembélé Keita[3], A.A. Keita[3], C. Anoma[4], S.-A. Babo Yoro[4], T.T.E. Dah[5,6], C. Coulibaly[5], E. Mensah[7], S. Agbomadji[7], A. Bernier[8], C. Couderc[9], C. Laurent[9], B. Spire[1,2], The CohMSM Study Group
[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France, [2]ORS PACA, Observatoire Régional de la santé Provence-Alpes-Côte d'Azur, Marseille, France, [3]ARCAD-SIDA, Bamako, Mali, [4]Espace Confiance, Abidjan, Cote D'Ivoire, [5]Association African Solidarité, Ouagadougou, Burkina Faso, [6]Centre Muraz, Bobo-Dioulasso, Burkina Faso, [7]Espoir Vie Togo, Lomé, Togo, [8]Coalition PLUS, Pantin, France, [9]IRD, INSERM, Univ Montpellier, TransVIHMI, Montpellier, France

Background: Understanding the dynamics of HIV infection in men who have sex with men (MSM) can help improve the efficiency of existing prevention strategies. We aimed to describe the sexual behaviour evolutions of MSM most at risk of HIV infection in West Africa.
Methods: The community-based cohort CohMSM has recruited HIV-negative MSM in four West-African countries since 2015 (Mali, Cote d´Ivoire, Burkina Faso, Togo). MSM are followed quarterly for HIV testing and prevention. Socio-behavioural data are collected every 6 months using standardised face-to-face questionnaires. This sub-study used a baseline, 6- and 12-month data cluster analysis to determine sexual behavioural profiles from data on risky sexual practices over the previous 6 months: condom use during anal and oral sex (systematic versus non-systematic); position during anal intercourse (exclusively insertive versus receptive or both); multiple partners (< 2 versus ≥2). The number of HIV seroconversions over the first 12 months of follow-up was recorded for each profile. Factors associated with these profiles were estimated using a country-adjusted mixed-effects logistic regression.
Results: For the 550 MSM included, two sexual behavioural profiles were identified: high-risk exposure (HRE) (61%) and moderate-risk exposure (MRE) (39%). HRE-MSM (versus MRE-MSM) reported greater non-systematic condom use during anal (55% versus 41%) and oral sex (85% versus 42%), receptive anal intercourse (94% versus 9%) and more multiple partners (64% versus 59%). Of the 34 seroconverted MSM in the first 12 months, 91% were HRE-MSM. HRE-MSM were more likely to be younger (adjusted Odds Ratio (aOR) [95% Confidence Interval]: 0.92 [0.88-0.97] per 1-year increase), to report financial difficulties (aOR: 2.06 [1.04-4.06]) and to have experienced stigma in the previous 6 months (aOR: 1.29 [1.09-1.52]). Compared to MSM with at least one female partner and attracted to both sexes, those with no female partner and either attracted only to men (aOR: 7.25 [4.04-12.98]) or to both sexes (aOR: 3.22 [1.66-6.28]), and those with a female partner but only attracted to men (aOR: 2.53 [1.36-4.70]) were more likely to be HRE-MSM.
Conclusions: HIV prevention services tailored to MSM should take into account age, financial difficulties, experienced stigmatisation and sexual attraction.

THPEC345

Health Messaging from by the people or FOR the people? A comparative visual content analysis of crowdsourced and government HIV posters

M.K. Smith[1], B. Cao[2], R. Fu[3], Y. Zhao[4], C. Liu[5], M. Tangthanasup[6], A.J. Lazard[7], J.D. Tucker[8]
[1]University of North Carolina, School of Public Health, Chapel Hill, United States, [2]Shenzhen University, School of Media and Communication, Shenzhen, China, [3]Guangzhou Center for Disease Control, HIV/AIDS Prevention and Control Division, Guangzhou, China, [4]Guangzhou No. 8 Renmin Hospital, Infectious Disease Department, Guangzhou, China, [5]University of California San Diego, Department of Sociology, San Diego, United States, [6]UNC Project China, Social Entrepreneurship for Sexual Health, Guangzhou, China, [7]University of North Carolina Chapel Hill, School of Media and Journalism, Chapel Hill, United States, [8]University of North Carolina Chapel Hill, School of Medicine, Chapel Hill, United States

Background: Visual mass media including posters have been shown to increase HIV testing, but suboptimal global HIV testing rates underscore the need for novel content and messaging. Crowdsourcing, or the outsourcing of tasks to a large group, has been shown by a randomized control trial to induce more HIV testing in audiences exposed to them as compared to conventional images. To better understand the key visual differences between these two types of images, we compared crowdsourced HIV testing posters to those created by local disease control centers (CDC) in China.
Methods: Crowdsourced posters included finalist submissions from a series of nationwide contests in China held between 2014 and 2016 in which teams competed for cash and other prizes. CDC posters were sampled from an online database of health promotional materials related to HIV testing maintained by the Chinese National Center for AIDS. Posters were triple coded according to established visual content criteria, summary measures of which were compared across poster type by assessing 95% confidence intervals (CI) overlap.
Results: CDC posters were more likely to use positive facial expressions (65% [95% CI, 40.9-83.7] versus 12.5% [95% CI, 2.2-4%]) and to employ an educational messaging style (85% [95% CI, 61.1-96%] versus 31.3% [95% CI, 12.1-58.5]). Crowdsourced posters were more likely to exhibit qualities of strong craftsmanship (design simplicity, image diversity, color choice,

design quality, and moderate text use) and use visual metaphors as part of their messaging strategy (56.3% [95% CI, 30.6-79.2] versus 5% [95% CI, 0.2-26.9%]).No differences in visual complexity were found across poster types.
Conclusions: Crowdsourced posters exhibited better craftsmanship than CDC posters, possibly due to diversity of design input of this strategy. CDC posters' use of positive visual reinforcement (smiling faces) and an educational messaging style may be a relic of modern Chinese visual traditions rooted in Socialist ideals of optimism and national well-being. Crowdsourcing posters' use of visual metaphors highlights their potential to embed coded references resonant with key hidden populations, a key factor in models of persuasion process. Further research is planned to assess the impact of CDC versus crowdsourced posters on motivational thoughts on HIV testing in target populations.

[Examples of HIV testing posters designed by Chinese health authorities (left) and by crowdsourcing contestants (right).]

THPEC346

Social contexts as mediators of risks in Rwandan men who have sex with men (MSM): Implications for HIV infection and other STIs

A. Adedimeji[1], J.D. Sinayobye[2], B. Asiimwe-Kateera[3], G. Murenzi[2], V.V. Patel[4], P.E. Castle[1], L. Mutesa[5], J. Palefsky[6], K. Anastos[1,4]
[1]Albert Einstein College of Medicine/Montefiore Medical Center, Epidemiology and Population Health, Bronx, United States, [2]Rwanda Military Hospital, Kigali, Rwanda, [3]AIDS Healthcare Foundation, Kigali, Rwanda, [4]Albert Einstein College of Medicine/Montefiore Medical Center, Division of General Internal Medicine, Bronx, United States, [5]University of Rwanda, Kigali, Rwanda, [6]University of California, San Francisco, United States

Background: Men who have sex with men (MSM) are disproportionately impacted by HIV/AIDS resulting from risky sexual behaviors. Social and contextual factors are known mediators of risk behaviors, but there is limited information regarding the dynamics between practices that increase risk of Rwandan MSM and concomitant socio-contextual determinants. This makes it difficult to assess social determinants that are critical in reducing the vulnerability to HIV/STI transmission in this key population.
Methods: As part of an ongoing mixed methods study, we obtained qualitative data on the socio-contextual determinants of, and prevalence of risk behaviors for HIV/ STIs transmission and preventive measures/coping strategies used by MSM to improve health and wellbeing. Thirty Kigali-based MSM recruited through respondent-driven sampling provided data through individual in-depth interviews. Data were analyzed using standard qualitative data analysis procedures.
Results: Respondents' were 18-40 years old; all had completed primary education and were mostly low-socioeconomic status. Risky sexual practices were common but differed by individual and socio-contextual factors in which MSM live. Older respondents reported long-term relationships with women with whom they have sexual relations to avoid suspicion and stigma. Younger respondents' were more likely to engage in transactional sex that was considered a necessity and mediated by the need for social acceptance and support from a strong peer network. Knowledge of HIV/STIs was poor, but prevalence was high. The perceived options for improving sexual wellbeing were limited and mostly clandestine.
Conclusions: Pervasive stigma, concern for personal safety, social isolation, conservative culture, lack of access to health services and perception of public policies appear to mediate behaviors that increase risk among Rwanda MSM and are barriers to obtaining health-promoting information and services. Effective interventions that address individual and socio-contextual determinants of risk and access to health services are urgently needed to facilitate attainment of Rwanda's national HIV strategic goals for key populations.

THPEC347

Micro-planning, an effective tool for building the bridge and breaking barriers in HIV programming for female sex worker - Ekiti State experience

A. Ajumobi[1,2], K. Green[3,4], R. Ajayi[4]
[1]Ekiti State AIDS Control Agency, Monitoring and Evaluation, Ado Ekiti, Nigeria, [2]Environmental Development and Family Health Organization, Monitoring and Evaluation, Ado Ekiti, Nigeria, [3]University of Manitoba, Country Office, Abuja, Nigeria, [4]Ekiti State AIDS Control Agency, Community Mobilization, Ado Ekiti, Nigeria

Background: Sex workers face stigma,discrimination and violence across the globe hence, effective strategies towards sustainable delivery of Minimum Prevention Package Intervention (MPPI) to key populations in Ekiti State has been a challenge."Micro-planning" is a process that decentralizes programme planning to grassroots-level workers for decisions on how to best reach the maximum number of community members. It is low cost, simple but effective approach for use in Community Based Interventions. In 2015, the project engaged 4 CSOs for a 2 year HIV prevention programme for Female Sex Workers (FSW) using micro-planning tools in 6 Local Governments Areas of the State.
Description: CSOs recruited and trained 420 FSWs as peer educators (PEs) to provide MPPI using micro-planning tools. Peer led mapping were used to validate and define 32 hotspots and 64 geographic clusters. Profiling of the identified hotspot/clusters informed the interventions and components of HIV prevention service delivered at the site, peer social network analyses were used to list all FSWs known to each PE within the cluster/hotspot, the PEs decided on who takes responsibility for what i.e outreach, education and monitoring of each individual FSWs. Other relevant local service providers were identified and engaged. Micro planning tools were utilized to plan and monitor service delivery.
Lessons learned: 9,334 FSWs were reached with MPPI;2,020 brothel based FSW attended peer sessions, while 7,314 were provided with prevention education using interpersonal communication. 49 of them were HIV positive out of which 18 of them were previously known. 31 had a co infection of HIV and different forms of STI and were referred for care while 3,312 were treated for other forms of STI. 36,396,100 pieces of condoms were distributed to the FSWs.
Conclusions/Next steps: Clearly defined area of operation for each PE, improved data collection and reporting by tracking each individual FSW at a site and providing dashboard metrics,shifted the program from merely service delivery (push) by increasing demand generation for services from the community (pull) and created community ownership. It serves as a holistic and sustainable approach to effective service delivery to FSWs in Ekiti State and should be considered for programming for MARPs at national and global levels.

THPEC348

Social media for HIV/AIDS education among men who have sex with men with hearing impairment in Osogbo, Nigeria

A. Adelekan, P. Omoregie, F. Oyelami, A. Fakunle, O. Olaleye
Blue Gate Public Health Promotion Initiative, Ibadan, Nigeria

Background: Possession of accurate knowledge about HIV/AIDS is critical in limiting the spread of the infection. Various studies have shown that hearing impaired individuals lack access to HIV/AIDS information due to problems of communication. Globally, men who have sex with men (MSM) are 24 times more likely to be living with HIV than the general population and homosexual acts are illegal in more than a third of countries, preventing MSM from accessing *HIV* services. This social media intervention was therefore designed to prevent HIV/AIDS among MSM with hearing impairment in Osogbo, Nigeria.

Description: This intervention was carried out among 65 MSM with hearing impairment who are registered users of at least one social media. Participants' were selected at the community level using snowball sampling technique. Semi-structured questionnaire was used to obtained baseline information and HIV/AIDS education, importance of HIV counselling and testing (HCT) and messages on risky sexual behaviour reduction were discussed with participants through Facebook, Twitter, BBM and Whatsapp. Participants' were followed up for a year and the intervention was evaluated at 6 and 12 months. Data were analysed using descriptive statistics, Chi-square and t-test.

Lessons learned: Mean age of participants was 23.9 ± 8.9 years and 43.9% had secondary education. Almost all (97.5%) have a Facebook account, Twitter (56.9%), BBM (65.8%) and Whatsapp (98.1%). Respondents' knowledge of HIV/AIDS increased from 5.8% to 38.5% within 6 months and 86.9% after 12 months. Utilization of HCT services increased from 5.8% to 29.7% within 6 months and 76.9% after 12 months. At baseline, 78.9% of the participants considered themselves at risk of contracting HIV infection and after 12 months only 12.8% considered themselves at risk of HIV. Respondents' consistent use of condom for sexual intercourse increased from 5.8% to 43.3% within 6 months and 87.2% after 12 months.

Conclusions/Next steps: Social media was effective in educating hearing impaired people but internet subscription cost was a major barrier reported during this intervention. The study therefore recommends that service providers should, as their contribution to national development, reduce the cost of access to enable more people to register with and use social media.

THPEC349

Ensuring Linkage to care among key populations in high HIV burden townships in Myanmar

Y.T. Nu Oo[1], K.Y. Yu Hlaing[2], M.K. Lwin[2], L.L. Win[1], C.L. Oo[2], A.P. Phyo[1], H.N. Oo[3]
[1]Ministry of Health and Sports, Department of Medical Research, Lower Myanmar, Yangon, Myanmar, [2]Save the Children International, Global Fund PR, Yangon, Myanmar, [3]Ministry of Health and Sports, Department of Public Health, Yangon, Myanmar

Background: Myanmar implements HIV prevention programs in unison with non-government organizations (NGOs) with the aim of achieving UNAIDS's Fast Track Strategy 90-90-90 targets by 2020. Decentralization of HIV testing is a key component of this strategy, however this may increase the risk of loss-to-follow up in the HIV cascade. This study assesses the factors influencing effective linkage to care after diagnosis.

Methods: Nine NGOs supporting HIV testing in mobile and drop-in centers without HIV care and treatment services across six high HIV burden townships were involved in this study. The study population included HIV cases newly diagnosed in the four months prior to study implementation in 2016. The study sample was drawn proportionally across townships. Secondary data from testing and ART sites were used in this study. Variables included age, gender, geographic location, population type, referral type, and enrollment in care; analyses were completed using SPSS.

Results: A total of 690 PLHIV were included in this study. Males accounted for 66.2%, and females 33.8%. The average age was 31.0 years. Key populations (KP; men who have sex with men (MSM), female sex workers (FSW), and people who inject drugs (PWID)) accounted for 62.8%, and general population (GP) 37.2%.

Overall, 81.0% of PLHIV reached ART centers and were enrolled in care after referral. KP were equally likely to be linked to care as GP. Linkage success rates differed among KPs (MSM 83.8%, FSW 90.4%, and PWID 65.9%) and among townships (from 58.3% to 96.8%).

Gender was not associated with linkage to care, but older age was significantly associated (p=0.001). More accompanied referrals (87.8%) were linked to care than unaccompanied referrals (74.7%) (p< 0.001). The median number of days from diagnosis to enrollment in care was less than one for KP and nine for GP.

Conclusions: This study indicates that the referral system of PLHIV in Myanmar is reasonably effective. Improvements are necessary, however, particularly to increase PWID linkage rates and generally to improve the overall rates toward achievement of the 90-90-90 targets.

Further studies are required to explore the factors that facilitate linkage processes and to achieve the goals of Myanmar National Strategic Plan.

THPEC350

Towards increasing domestic financing for civil society organizations in the HIV response: Accreditation of HIV clinical services provided by key populations

D. Linjongrat[1], P. Srimanus[2], P. Panpet[1], N. Mahachokchai[1], P. Yokchawee[3], D. Kalayanamitr[3], J. Jantarapakde[2], S. Pengnonyang[2], P. Rattakitvijun Na Nakorn[2], S. Charoenying[4], S. Mills[4], M. Kim[5], M. Sanguankwamdee[5], P. Phanuphak[2], N. Phanuphak[2]
[1]Rainbow Sky Association of Thailand, Bangkok, Thailand, [2]The Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Songkhla, Thailand, [4]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [5]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

Background: To address the low uptake of HIV services among men who have sex with men (MSM) and transgender women (TGW), the key populations (KP) with the highest HIV prevalence and incidence in Thailand, the Key Population-Led Health Services (KPLHS) model was introduced in 2015. Under KPLHS, KP leadership ensures that service packages to address HIV and related health issues in their communities are needs-based, demand-driven, and client-centered.

Description: Rainbow Sky Association of Thailand (RSAT), the largest KP-led organization working with MSM and TGW in Thailand, set up its community health centers to conduct KPLHS in Bangkok and Songkhla in 2015. RSAT's KPLHS model built on its large-scale outreach workers network and trust among MSM and TGW communities from its long-standing advocacy for LGBT rights in these areas. Strong partnership between RSAT and local public health sectors was established to assure that clinical services, including HIV/STI testing and PrEP/PEP dispensing, provided by trained health workers who are members of MSM and TGW communities were of high-quality.

Lessons learned: During October 2015-December 2017, RSAT reached 52,891 MSM and 5,607 TGW through online and offline enhanced peer mobilizer method and tested 9,627MSM and 1,009 TGW for HIV. HIV prevalence was 10.9% among MSM and 8.03% among TGW. Linkage to antiretroviral therapy (ART) was successful among 64.1% of HIV-positive MSM and 66.7% TGW. Among HIV-negatives, 5.59% received PrEP. RSAT was well-recognized by Songkhla Provincial Health Office as key HIV testing site, contributing to 60.0% of new HIV cases diagnosed in the province among MSM and TGW. Regular quality assessment and quality improvement by Songkla public health sectors demonstrated high-quality of KPLHS provided by RSAT's health workers, leading to the first formal accreditation of community health center by the Thai Medical Technologist Council in Thailand.

Conclusions/Next steps: KPLHS implemented by RSAT demonstrated high HIV-positive testing yield, high linkage to ART, and substantial uptake of PrEP. Strong partnership between KP-led organizations and public health sectors was key to secure public sector's endorsement of KPLHS.

To end the AIDS epidemic, accreditation, legalization, and financing mechanisms are urgently needed for scale-up and sustainability of KPL-HS and KP-led organizations.

THPEC351

Mobile testing, ART enrollment and prescription refill may be linked to higher linkage to care and retention for men who have sex with men in Nigeria

T.A. Alamu[1], C. Trout[2], A. Kalaiwo[3], B. Ochonye[4], J. Stapleton[5], O. Ugege[4], G. Emmanuel[4], A. Ojemeire[4], O. Irinoye[4]
[1]Heartland Alliance International, Strategic Information and Knowledge Management, FCT, Nigeria, [2]Heartland Alliance International, HIV/AIDS, Chicago, United States, [3]USAID, HIV/AIDS for Key Population, FCT, Nigeria, [4]Heartland Alliance International, FCT, Nigeria, [5]Heartland Alliance International, Chicago, United States

Background: Globally, men who have sex with men (MSM) are under-served by HIV testing services (HTS) and antiretroviral therapy (ART) compared to the general population: an estimated 51% of MSM did not have access to HTS and only 14% enrolled in ART in 2015. For nine years, Heartland Alliance International (HAI) has implemented large-scale programming offering the continuum of HIV prevention, care and treatment to MSM in Nigeria.
Description: From October 1, 2016 to September 31, 2017, HAI fixed-site "One Stop Shops" (OSS) provided comprehensive HIV medical and community services. Mobile teams also offered testing, ART initiation and prescription refill in some field locations. HAI ensures that MSM are not lost to follow-up through active follow-up and data collection and analysis at every cascade step. Mobile teams were scaled up during the period in four states: Rivers, Akwa Ibom, Lagos and Cross Rivers but not in the Federal Capital (FCT), Nasarawa, and Benue.
Lessons learned: Out of the 3,295 MSM who tested HIV positive, 2,627 (79.7%) were enrolled in care either in the field or at the OSS while 668 (20.3%) declined because they were not prepared to commence ART.
All 2,627 enrolled MSM (100%) commenced ART. Of these, 90 (3%) were transferred out to continue ART elsewhere due to relocation, and seven (7) (0.3%) died. Confirmed transferred out and deaths were removed from and patients who transferred in (13) were added to the denominator when calculating retention. At the end of October 2017, 280 MSM (10.7%) who started treatment during the year were lost to follow-up, while 2,263 were still on ART, leaving a retention rate (0-12 months) of 89%
However, achievement varied by state. The percentage linked to care was below 80% in FCT (52% n=220), Nasarawa (53% n=136) and Benue (66% n=247) and Lagos (77.2% n=233); 0-12-month retention was below 90% in Benue (51.6% n=126) and Lagos (64.6% n=137).
Conclusions/Next steps: The poorer linkage and retention results occurred in the states which had not scaled up mobile services, suggesting that the mobile approach is crucial for these steps. During the next program year, HAI will scale up this approach to the remaining states.

THPEC352

Effectiveness of key population led HIV programmes in achieving the 90-90-90 for most-at-risk-populations in Nigeria

N. Ogbonna[1], O. Olukayode[1], B. Ochonye[2], E. Godwin[3], P. Umoh[1], A. Kalaiwo[4], A. Ojemeiri[5], A. Yusuf[1], O. Tewobola[2]
[1]Heartland Alliance International, Programs, Abuja, Nigeria, [2]Heartland Alliance International, Abuja, Nigeria, [3]Heartland Alliance International, Clinical Department, Abuja, Nigeria, [4]United States Agency for International Development, Programs, Abuja, Nigeria, [5]Heartland Alliance International, Nigeria, Monitoring and Evaluation, Abuja, Nigeria

Background: Female sex workers, men who have sex with men, people who inject drugs and Transgender persons are among key populations in Nigeria. Laws that criminalize their behaviors plus fear of harassment from the public and legal agencies debar them from accessing health-care from public facilities; those that do refuse to revisit due to stigmatizing attitudes of staff. These sustain high HIV prevalence among KPs, like MSM with rate from 13.5% (2007) to 17.2% (2010) and 22.9% (2014) according to Nigeria's Integrated Biological and Behavioral Surveillance Survey (IBBSS) 2014. It therefore became necessary to deliver rights-based and sustainable programs for KPs, within safe spaces, using members of their social/sexual networks.
Description: Heartland Alliance International's Integrated MARPS HIV Prevention Programme (IMHIPP) objective is to establish KP-led Community Based Organizations whose capacities would be built to provide HIV services to their groups with mentoring and support by HAI. Through green-housing, the CBOs gain technical capacity to function effectively and independently. Their trained personnel provide comprehensive HIV services (prevention messages, HIV testing services, condoms/lubricants distribution, STI screening/treatment, PEP, and referral of positive KPs to HAI's ART clinics) to other KPs within safe spaces. HAI's community ART team also enrolls positive clients into care within their milieu, thus, promoting Test and Treat. IMHIPP is implemented in seven high-burden states of Nigeria from September 2009 to October 2018.
Lessons learned:
HIV programmes are effective when beneficiaries occupy the forefront of implementation. This makes KPs active programme participants than passive beneficiaries. Across the IMHIPP states, the nascent organizations have reached the following KPs with HIV related services:

Type of services rendered/Results	Number of program participants reached				
	FSW	HRM	PWID	Transgender	Total
Prevention	188, 767	41, 701	14, 030	457	244, 955
HTS	123, 458	36, 131	16, 200	457	176, 246
HTS Positive	9, 467	4, 078	1, 292	52	14, 889
KPs linked and retained in care as at January 2018	6, 736	3, 624	1, 098	31	11, 489

[Number of persons reached by KP group and type of service received from inception of HTS in October 2015 to September 2017]

Green-housing, as best practice, showed that KPs have capabilities which, when developed, can deliver outstanding results. Following capacities developed, IMHIPP CBOs are now able to access and implement donor grants independently and credibly.
Conclusions/Next steps: Meaningful involvement of KPs in KP programming is vital for increasing service uptake. As IMHIPP outcomes, more KPs now present for HIV testing services; more also practice safer sex. Treatment retention is 77% and viral suppression 82%. These contribute towards meeting 90-90-90 for Nigeria. Heartland Alliance plans to extend IMHIPP strategies to other states to multiply impact.

THPEC353

Low awareness of pre-exposure prophylaxis (PrEP) for protection against HIV transmission among HIV-infected women in HIV-serodiscordant couples in Kenya: Results from a nationwide survey

J. Pintye[1], P. Oluoch[2], D. Achwoka[2], A. Langat[2], B. Singa[3], J. Kinuthia[1,4], A. Katana[2], L. Nganga[2], C. McGrath[1], G. John-Stewart[5], A. Drake[1]
[1]University of Washington, Department of Global Health, Seattle, United States, [2]Centers for Disease Control and Prevention, Nairobi, Kenya, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Kenyatta National Hospital, Nairobi, Kenya, [5]University of Washington, Departments of Global Health, Epidemiology and Medicine, Seattle, United States

Background: PrEP for HIV-serodiscordant couples is being scaled-up through HIV care programs in high burden settings. HIV-infected partners' awareness of PrEP as a method for protection against transmission will influence effective PrEP utilization among HIV-uninfected partners. We evaluated PrEP awareness among HIV-infected women in HIV treatment programs in Kenya.
Methods: Data from a cross-sectional survey of HIV-infected women enrolled at 109 HIV care programs with ≥1000 antiretroviral therapy (ART) clients across Kenya were analyzed to evaluate PrEP awareness. Data were collected from June-September 2016 by mobile teams. Participants were aged 15-49 years, not currently pregnant and had vaginal intercourse within the last 6 months. Clinical characteristics and male partner status were determined by women's self-report. PrEP awareness

was ascertained by asking participants to list methods they had heard of to protect their HIV-uninfected partners from acquiring HIV. Correlates of PrEP awareness were determined by logistic regression analysis adjusted for facility-level clustering.
Results: Among 4805 HIV-infected women surveyed, 938 (28%) had a known HIV-uninfected male partner. Of these 938 women in HIV-serodiscordant couples, 67% were married, median age was 34 years (interquartile range, IQR [29-40]), and median education was 9 years (IQR 8-12). Overall, 96% of HIV-infected women in HIV-serodiscordant couples were on ART for a median of 5 years (IQR 2-8). Most (96%) had disclosed their HIV status to their partner and 29% reported inconsistent condom use within the last month. Only 6% were aware of PrEP as a method for protecting HIV-uninfected partners from acquiring HIV. Compared to women unaware of PrEP, women with PrEP awareness were more likely to have completed >12 years of education (odds ratio [OR]=4.45, 95% CI 2.36-8.41, p< 0.001); there were no differences in age or employment between groups. Few (< 1%) women reported that their HIV-uninfected partners had ever used PrEP, though 51% believed their partner could take a daily pill to prevent HIV, if available.
Conclusions: PrEP awareness was low in this large survey of HIV-infected women in HIV-serodiscordant couples, but belief that partners could use PrEP was high. Sensitizing HIV-care clients in HIV-serodiscordant couples about PrEP may enhance awareness and utilization in this high-risk population.

THPEC354

Harm Reduction Community Client Model (HRCCM) for follow up, recruit test and treatment of positive living People Who Inject Drugs (PWIDs)

D. Katende[1], A. Mukanza[2]
[1]Uganda Harm Reduction Network (UHRN), Research and Documentation Officer, Kampala, Uganda, [2]Uganda Harm Reduction Network, Clinical, Kampala, Uganda

Background: In Uganda, the HIV prevalence among key populations is much higher than the national average of 6.2% (MoH & ICAP, 2017). Among PWIDs, the HIV prevalence has remained steadily high ranging between 30-40% (Muhangi et al (2017). Uganda Harm Reduction (UHRN) program data especially the community health outreach data targeting PWIDs shows a much higher figure up to 46% high HIV prevalence among PWIDs drugs in Uganda. Although there was a high prevalence of HIV among PWIDs, only 350 PWIDs had tested for HIV and among those tested positive, only 16%% were enrolled on ART (UHRN programs data from January to December 2016), yet PWIDs have the lowest levels of uptake to HIV services and have the highest dropout rate for HIV treatment standing at 33% according to UHRN program data. The low adherence rate for HIV treatment among PWIDs has been as a result of stigma that adversely affects how and when PWIDs should access HIV services.
Description: UHRN has adopted **HRCCM** Model, a model that is used to link and distribute essential HIV services to PWIDs. The model uses fellow PWID peers and HIV positive living to track their fellow positive living PWIDs who have not attained HIV testing and ART. These PWID peers are trained as community health workers and representatives from different drug use hotspots. It is an, innovative and efficient strategies for delivering HIV and prevention, care, and treatment services.
Lessons learned: The model has increased adherence rate for PWIDs on ART from 33% to 49%, enrolment rate on ART from 16% to 21% , number of PWIDs seeking HIV testing from 350 to 831, number of referrals on ART for PWID from 250 to 450 (UHRN program data January - December 2017).
Conclusions/Next steps: In Uganda health facilities are overcrowded leading to delay in service deliver, this discourages PWIDs from access to ART. Since the implementation of **HRCCM,** Uganda Harm Reduction Network has realized an increase in the adherence rate for PWIDs on ART, an increase enrolment rate for PWID on ART, an increase in a number of PWIDs seeking HIV testing.

THPEC355

Escorted referral by peer navigators improved linkage to HIV care and treatment services for FSW in Mzuzu, Malawi

A. Simwanza[1], B. Kapenuka[2], M. Msiska[3], M. Mkandawire[3], G. Kumwenda[4], S. Sikwese[4], E. Mpunga[5], G. Kamanga[5], M. Ruberintwari[5], C. Akolo[6]
[1]Pakachere IHDC, Lilongwe, Malawi, [2]Pakache IHDC, Blantyre, Malawi, [3]Pakachere IHDC, Mzuzu, Malawi, [4]Pakachere IHDC, Blantyre, Malawi, [5]FHI 360, Lilongwe, Malawi, [6]FHI 360, Washington DC, United States

Background: Since October 2015, FHI 360 has been implementing the PEPFAR-/USAID-funded LINKAGES project for key populations (KP) in six districts in Malawi. The project focuses on HIV prevention, care, and treatment for female sex workers (FSW), men who have sex with men (MSM), and transgender people.
Description: To achieve the project goal, FSW are being reached with HIV prevention messages and tested for HIV. Those who test HIV positive are followed and initiated on treatment. Initially, there was a problem linking FSW who tested HIV positive to treatment. In September 2016, peer navigators (fellow HIV-positive FSW), along with HIV testing providers, were recruited and trained to assist with escorted referral to health facilities. We implemented the escorted referrals from October 2016 through June 2017.
Lessons learned: During this period, 905 FSW were tested for HIV, 144 newly tested HIV positive, of whom 141 (97.9 percent) were initiated on treatment, in addition to 115 FSW known to be HIV positive when reached. The project also returned to treatment 20 FSWs who had defaulted on treatment in other programs. Prior to implementation of escorted referrals (October 2015 to September 2016); 575 FSW were tested for HIV, 193 were HIV positive, only 74 (38 percent) were started on ART, and one treatment defaulter was brought back to treatment.
Conclusions/Next steps: Deployment of peer navigators to assist with referral for ART initiation resulted in a significant increase in identification of HIV-positive FSW for ART initiation. Introduction of escorted referrals by both peer navigators and HIV testing providers has had a great impact on follow-up of HIV positives to link them to antiretroviral treatment. LINKAGES plans to scale up peer navigation across its districts. The project will put in place ongoing mentorship for peer navigators to scale up the escorted referrals as the number of FSWs being reached and tested increases.

THPEC356

HIV prevention and linkage to care among female sex workers in Malawi: Results and lessons learned from the MSF Corridor Project

E. Orban[1], J. Jung[1], A. Shigayeva[1], P. Mangochi[1], R. Piringu[2], L. O'Connel[3], T. Ellman[3], R. Ortuno[1]
[1]Médecins Sans Frontières (MSF), Malawi, Blantyre, Malawi, [2]Zomba District Health Office, Zomba, Malawi, [3]Southern Africa Medical Unit (SAMU), Médecins Sans Frontières, Cape Town, South Africa

Background: Mobile populations, especially sex workers (SWs), are particularly vulnerable and at high risk for HIV infection. The aim of the MSF Corridor project is to reduce HIV/AIDS and TB related morbidity, mortality and incidence among female SWs in Malawi by providing adapted models of care including prevention, access and continuity of integrated HIV, TB, and SRH care through tailored services targeting this key population.
Description: The project is set in three sites along the transport corridors from the Mozambican border into Malawi. SWs are enrolled into the program by peer educators during community outreach activities. HIV prevention, testing, and counselling are offered on-site, including Syphilis and pregnancy testing, STI and TB screening, and referrals for ART treatment and SRH services. Data on the outreach activities and ART information is collected via paper-based forms. By the end of 2017, 3103 SWs were enrolled. Of those, 50% were HIV positive. HIV positivity rate was 22.8% amongst 9-18 years old SWs and 54.2% for those older 18-66 years. The active cohort (seen in outreach visit during the last 6 months)

by end of 2017 comprised 1282 (41.3%). Of the HIV positive active cohort, 81.8% (493/603) were on ART and of those newly diagnosed or not on ART at enrolment, 51.1% (115/225) were initiated in the sites.Of the HIV negative SWs, 59% were seen and tested only once, 22% had two, 10% had three and only few had five or more tests. 32 SWs sero-converted during their follow up with an overall incidence of 5.9 (95% CI 4.2-8.3) per 100 person years - for SWs 9-18 years 9.3 (5.0-17.3) and for women who were 18-66 years 5.0 (3.2-7.6) respectively.
Lessons learned: The program has succeeded in reaching and enrolling a large number of beneficiaries interested in the offered services. The high HIV prevalence and incidence demonstrate the extreme risk among this group and the importance of community strategies to improve access to re-/testing, treatment and prevention, including oral HIV self-testing and PREP.
Conclusions/Next steps: Innovative strategies and further efforts are needed to reach this highly mobile population to enable access to prevention and retention in care.

THPEC357

Does knowledge of HIV status affect sexual behaviors? A longitudinal analysis of female sex workers in Uganda and Zambia

K. Ortblad[1], D. Kibuuka Musoke[2], M. Chanda[3], T. Ngabirano[4], J. Salomon[1,5], J. Haberer[6], M. McConnell[1], C. Oldenburg[7], T. Bärnighausen[1,8,9]
[1]The Harvard T.H. Chan School of Public Health, Department of Global Health and Population, Boston, United States, [2]International Research Consortium, Kampala, Uganda, [3]John Snow, Inc., Lusaka, Zambia, [4]Uganda Health Marketing Group, Kampala, Uganda, [5]Stanford University, Department of Medicine, Stanford, United States, [6]Massachusetts General Hospital, Department of General Internal Medicine, Boston, United States, [7]University of California, San Francisco, Department of Ophthalmology, San Francisco, United States, [8]Heidelberg University, Heidelberg Institute of Public Health, Heidelberg, Germany, [9]Africa Health Research Insitute, Mtubatuba, South Africa

Background: Routine HIV testing campaigns rely on the assumption that knowledge of HIV status, acquired through testing, affects individuals' behaviors in ways that reduce HIV transmission. Female sex workers (FSWs) have strong economic incentives for having multiple sexual partners and providing condomless sex, behaviors associated with increased risk of HIV transmission. We measure the effect of knowledge of HIV status on FSWs' sexual behaviors with clients in Uganda and Zambia.
Methods: We used longitudinal data from two FSWs cohorts; one in Kampala, Uganda, and one in three Zambian transit towns. The cohorts were formed as a part of two cluster-randomized HIV self-testing trials. Participants in the cohorts had ample opportunity for HIV testing, using HIV self-tests and standard HIV testing services. We assessed knowledge of HIV status and sexual behavior outcomes at baseline, one month and four months. We used linear regression models with individual-level fixed effects to measure the effect of knowledge of HIV status on FSWs' sexual behaviors.
Results: The majority of the 1925 FSWs enrolled in the two cohorts tested for HIV (95% of 960 in Uganda, 96% of 965 in Zambia) and experienced changes in knowledge of HIV status (71% in Uganda, 79% in Zambia). Knowledge of HIV status did not significantly affect FSWs' the number of clients, but knowledge of HIV-negative status significantly increased the probability that FSWs' consistently used condoms in sex acts with clients: by 9.5 percentage points in Uganda (95%CI 5.2 to 13.5, $p< 0.001$) and 8.4 percentage points in Zambia (95%CI 3.0 to 13.9, $p=0.003$). Knowledge of HIV-positive status did not significantly affect FSWs' condom use with clients.
Conclusions: In both Uganda and Zambia, FSWs engage in safer sex with clients when they know they are not living with HIV. Even in communities with very high HIV prevalence, the majority of the population will be HIV-negative. Our results imply that expansion of HIV testing programs leading to increased knowledge of HIV status can serve as an HIV prevention measure among FSWs.

THPEC358

Differentiated service delivery models for HIV testing among female sex workers: Lessons from the LINKAGES project in Blantyre, Malawi

M. Kamtimaleka[1], B. Matola[1], F. Kamtumbiza[2], G. Kumwenda[2], S. Sikwese[2], E. Mpunga[3], G. Kamanga[3], M. Ruberintwari[3], C. Akolo[4]
[1]Pakachere IHDC, Blantyre, Malawi, [2]Pakachere IHDC, LINKAGES, Blantyre, Malawi, [3]FHI 360, LINKAGES, Lilongwe, Malawi, [4]FHI 360, LINKAGES, Washington DC, United States

Background: In Blantyre, Malawi, Pakachere Institute for Health and Development Communication is implementing the PEPFAR-/USAID-supported LINKAGES project, which aims to reduce HIV transmission among key populations (KPs), including female sex workers (FSW), men who have sex with men, and transgender people, and extend the lives of those who are HIV positive. Using the HIV cascade framework, Pakachere identifies FSWs, enrolls them in the program, and offers HIV testing and other HIV-related services. The project uses a differentiated service delivery (DSD) model for HIV testing services, which includes testing at drop-in centers (DICs), and moonlight and daylight outreach to complement services offered in traditional public health facilities.
Description: During the design phase of the project, a KP needs assessment was conducted to understand the service needs of FSWs. An intervention was then designed to address FSW preferences for the place, time, and process of accessing HIV testing services. Three DICs were set up in Blantyre, and their catchment areas were mapped and defined based on hot spot mapping. A referral system was established to link FSW who are in need of specialized services and live far from DICs to preferred public facilities. A mobile/outreach clinic plan was also developed based on preferred times to access services, the distance from hot spots to static facilities, and KP needs.
Lessons learned: From October 2016 to September 2017, 1,178 FSW were tested in the program through the three HIV testing services models: 636 (54 percent) at DICs, 339 (28.5 percent) through outreach, and 203 (17.5 percent) at public health facilities. Of the total tested, 370 (31 percent) tested HIV positive, and all were linked to antiretroviral therapy. The DSD model also enabled provision of other services at the outreach and DIC levels. A total of 2,910 FSWs accessed sexually transmitted infection screening services, of whom 1,106 (38 percent) were diagnosed and treated. Sixteen FSWs were linked to prevention of mother-to-child transmission services, and 11 FSW accessed post-GBV services.
Conclusions/Next steps: The DSD model provides an opportunity for maximum linkage to treatment for difficult-to-serve populations such as FSWs because it offers convenience to service access.

THPEC359

Factors associated with HIV non-testing among female sex workers in India: A roadmap to achieve the UNAIDS first 90-90-90 target

S. Mukherjee, D. Bidhubhusan Mahapatra, D.S.k. Patel
Population Council, HIV/AIDS Program, New Delhi, India

Background: Evidence shows that timely diagnosis and effective linkages to care are critical to reduce the HIV risk burden. India's national HIV prevention guideline require Female Sex Workers (FSWs) to test for HIV in every six months. Given the UNAIDS call to achieve, 90-90-90 by 2020, this study examines the HIV testing scenario (first 90) among FSWs in India and identify characteristics associated with non-testing of HIV in last six months.
Methods: Data from a cross-sectional survey conducted among 3589 FSWs using a three-stage cluster sampling approach during Nov-Dec 2017 in five states of India were used. Question on whether FSWs have taken HIV test in last two years and time when they took last HIV test was asked to all FSWs. Bivariate and multiple regression analyses were conducted to find the predictors of HIV non-testing in last six months.
Results: FSWs were, on average, 35 years old, 65% were currently married and 40% were soliciting from homes. Almost all FSWs underwent HIV testing in past two years. More than half (54%) of FSWs had not tested for HIV in past six months. FSWs not going for HIV test in past

Tuesday 24 July

six months was more among young (< 25 year old) than those aged 25 years or older (60% vs 45%, Adjusted Odds Ratio (AOR): 1.55, 95% CI: 1.13 -2.13), currently married than never married (55% vs 47%, AOR (95% CI) 1.93 (1.41-2.65)), soliciting from homes (60% vs 44%, AOR (95% CI): 1.53 (1.28-1.83)), and dependent on sex work than those having alternative income source (62% vs 43%, AOR (95% CI): 1.71 (1.45-2.02)). FSWs using condoms inconsistently with clients were more likely not to go for HIV test than others (75% vs 46%, AOR (95% CI): 3.93 (3.24-4.77)).
Conclusions: While majority of FSWs were ever tested, more than half are not going for HIV testing as per national guideline. Given FSWs are at the core of HIV prevention program in India, efforts for HIV testing of all FSWs in every six months needs to be done in focussed way. FSWs who are home based, young and currently married should be targeted.

THPEC360

Female sex workers as peer educators in HIV prevention program in Ibadan, Nigeria, foundation for family health experience

J. Ojeikere[1], T. Ogunlade[2], T. Daniel[3], A. Tina[4]
[1]Foundation for Family Health, Monitoring and Evaluation Unit, Ibadan, Nigeria, [2]Family Counseling Center, Training, Ibadan, Nigeria, [3]Family Counseling Center, Programs, Ibadan, Nigeria, [4]Family Health, Programs, Ibadan, Nigeria

Background: HIV transmission in the context of sex work plays a significant role in the expansion of HIV epidemics in many countries around the world. Nigeria has a large population of female sex workers with extensive differences between and within states. Brothel -based female sex workers (FSWs) HIV prevalence rate is as high as 27.4%. It is imperative that an effective HIV prevention strategy must be in place. The aim of this study was to establish continuous HIV prevention messages through FSW peer educators.
Description: The program took place between November 2016 and March 2017, in 10 brothels in Ibadan, Nigeria. Brothels were selected using population of sex workers and 50 female sex workers (FSWs) were selected using a structured criteria. Capacity building was carried out on HIV prevention packages and peer education. Selected FSWs mobilized and conducted HIV testing and promoted condom use. Community gatekeepers were sensitized for improved access to the brothels. HIV positive identified were referred, condoms was distributed and FSW with sexually transmission were also referred. The peer educators had six refresher (interactive) meetings. They registered 525 sex workers for HIV counseling and testing and screened all the FSW for other sexually transmitted infected using a screening checklist.
Lessons learned: At the end of the six month activity, out of 525 sex workers that registered, 99.6% had HIV counseling and testing. A total of 9 FSW were found to be positive, they were linked and accessed antiretroviral therapy (ART). 30% of FSW had other sexually transmitted infections which they were referred.
Female sex workers were willing to have HIV test done as encouraged by their peers. Other prevention packages such as use of condoms was promoted by peers and acceptable by 80% of the sex workers.
Conclusions/Next steps: It appears that FSW may increase uptake of prevention programs. Future research with a comparison group is need and much time is needed to evaluate the sustainability of the program with the FSW.

THPEC361

Creating collaborative, client-friendly health services for key populations in Zambia: Overcoming stigma, discrimination, and HIV with sensitivity training for health workers

J.P. Mthoniswa[1], I. Jurkevich[2], K. Utan[2]
[1]American International Health Alliance, Lusaka, Zambia, [2]American International Health Alliance, Washington, United States

Background: In 2016 about 1.2 million people were living with HIV in Zambia, 65% of whom were accessing antiretroviral therapy. Zambia's National AIDS Strategic Framework acknowledges that female sex workers (FSW) and men who have sex with men (MSM) are key populations (KPs) driving the country's HIV epidemic and that more effort to engage these and other vulnerable populations and provide access to non-judgmental, client-friendly health and psychosocial support services.
Description: In 2016, American International Health Alliance (AIHA) established a partnership linking Chreso Ministries with the University of South Carolina to address the increased risk of HIV infection and significant barriers to care and treatment services faced by FSWs, MSMs, and other KPs in Zambia. The overarching goal of the project was to mitigate the impact of HIV/AIDS on KPs by reducing stigma and discrimination and improving access to crucial health and allied services. Activities focused on strengthening the capacity of health workers at Chreso Ministries clinics in Lusaka, Livingstone, and Kabwe, and increasing provider awareness and understanding of the special needs of KPs. The AIHA project team, with support from President's Emergency Plan for AIDS Relief (PEPFAR), developed a sensitivity training package for healthcare, training a total of 86 across the 3 pilot sites and establishing community advisory boards to provide input and feedback.
Lessons learned: Trainings enhanced health worker knowledge, skills, and attitudes toward KPs in general, and specifically the provision of inclusive HIV-related treatment and care. Members of KPs reported increased access to healthcare services and willingness to seek care when needed. In Livingstone, for example, 120 KPs were brought into care.
Conclusions/Next steps: Partnering with facility- and community-based health workers and KP communities is critical for mitigating the impact of HIV on vulnerable populations and attaining the global 90-90-90 targets. Health workers can harbour the same misconceptions that increase stigma and discrimination against KPs as the general population, so sensitivity training is a crucial first step toward developing more welcoming, inclusive healthcare services and achieving epidemic control.

THPEC362

PrEP implementation among gay and bisexual men in a policy vacuum: The power of cross-sector collaboration in New Zealand

J.G. Rich[1], E. Coughlan[2], M. Giola[3], J. Myers[1]
[1]New Zealand AIDS Foundation, Auckland, New Zealand, [2]Canterbury District Health Board, Christchurch, New Zealand, [3]Bay of Plenty District Health Board, Tauranga, New Zealand

Background: In 2016 New Zealand recorded the fifth consecutive increase - and highest number since records began - in HIV diagnoses among gay, bisexual and other men who have sex with men (GBM). Expanded HIV prevention options are urgently needed, yet the national HIV strategy has not been updated since 2003 and there is no policy on HIV pre-exposure prophylaxis (PrEP). Rising awareness of PrEP among GBM, regulatory approval, and improved availability of low-cost generics has increased demand and access. However, the absence of policy places communities and prescribers at risk of using PrEP unsafely and ineffectively.
PrEP is a sexual health programme not just a prescription. Concerns about improper use, workforce readiness and community knowledge prompted the GBM-led New Zealand AIDS Foundation (NZAF) to partner with clinical and community stakeholders to improve knowledge and access to 'grey market' PrEP, while advocating for publicly funded access.

Description: We devised a patient consent form to overcome medicolegal risks that clinicians faced in relation to prescribing for personal importation. We collaborated with clinicians to develop an online PrEP training module for general practitioners (GPs) and shared PrEP prescriber resources at conferences targeting GPs. Community education resources were developed and distributed to clinics and educational events targeting GBM were hosted in four key cities.

Lessons learned: In the absence of policy, cross-sector collaboration can empower communities and workforce to use new technologies safely. From 0 in 2016 there are now 25 providers across ten cities listed on endinghiv.org.nz as being knowledgeable about PrEP and prescribing for personal importation. Between November 2016 and August 2017, self-reported PrEP use among GBM increased from 0.7% to 3.1% and awareness from 40% to 65%.

Conclusions/Next steps: For PrEP to play an effective role in New Zealand's HIV response among GBM it must be implemented at scale and supported by Government policy. PHARMAC, the national drug buying agency, has announced public funding of PrEP for individuals at high risk of HIV from March 2018. This will further accelerate supply, yet there is still no policy or strategy to support its use. Without urgent action, there is continued risk of PrEP being used sub-optimally.

Public-private partnerships

THPEC363

Driving innovation at the community level: How leveraging human resources for health in the private health sector can help scale and sustain HIV/AIDS prevention and treatment

S. Dominis[1], E. Golub[1], S. Callahan[1], L. Weir[2]
[1]Abt Associates, Bethesda, United States, [2]Abt Associates, Rockville, United States

Background: National HIV responses in many countries are constrained by human resources for health (HRH) shortages. In order to accelerate and increase the provision of quality HIV and AIDS services in these settings, it is important to leverage private HRH, which is a significant source of non-HIV services for clients of all income levels. The Sustaining Health Outcomes through the Private Sector (SHOPS) Plus project, funded by USAID through PEPFAR, conducted a qualitative study to identify effective strategies and tools used by private providers to grow and retain HRH and incorporate community-based prevention and outreach activities; and to consider how private providers can be better engaged to support an effective health workforce for HIV.

Methods: The assessment consisted of a global literature review and case studies of private organizations in South Africa and India. In-depth interviews and site visits were conducted with 18 private service delivery organizations (9 per country) that had viable, innovative, sustainable service delivery models.

Results: Private service delivery organizations in India and South Africa are driving innovations that could increase access to comprehensive HIV prevention and treatment services at the community level. These innovations include integrating prevention and care services; maximizing the efficiency of care models and patient flow; implementing scalable and gender-specific staffing models to empower, retain, and increase HRH; and adopting new technologies, such as artificial intelligence and tablet-based information systems, that increase access to services, enhance CHWs' impact, and enable rapid access to patient data. However, their willingness to apply these innovative models to address HIV depends on the regulatory environment, financial incentives, and the organizations' own perceptions about their role in the national HIV response.

Conclusions: The private health workforce is critical to addressing HRH shortages and expanding access to HIV services. To maximize private providers' contribution to national HIV responses, donors and governments need to consider how their programs and policies directly and indirectly incentivize private organizations to scale up HIV service delivery or crowd them out.

THPEC364

Social franchising of community-based HIV testing and linkage to care services: An evaluation of a pilot study in Tshwane, South Africa

S. Shamu[1], T. Farirai[1], L. Mlambo[1], J. Slabbert[1], G. Guloba[1], N. Nkhwashu[1], N. Masihleho[2], J. Kamera[2], S. Johnson[1], V. Wong[3]
[1]Foundation for Professional Development, Pretoria, South Africa, [2]USAID/Southern Africa, Pretoria, South Africa, [3]USAID, Washington DC, United States

Background: In order to meet the 90 90 90 United Nations HIV targets in South Africa, the Foundation for Professional Development (FPD) implemented a Community based HIV counseling and testing (CBCT) programme to complement facility based HIV counselling and testing (HCT). FPD implemented an employee-managed and social franchisee (SFHCT)-managed pilot project. We evaluated the effectiveness of the SFHCT pilot project compared to the traditional CBCT teams.

Description: The goal of social franchising was to design, implement and test a SFHTC model which organizes local entrepreneurs to deliver standards-based HTC services to increase coverage and effectiveness through the use of a commercial relationship between the franchisor (FPD) and franchisees (local entrepreneurs). The pilot was implemented in high HIV prevalent communities in Tshwane district between October 2016 and September 2017. FPD selected unemployed, formally employed or own business individuals as franchisees and engaged, trained, provided branded materials, deployed and gave them minimal support to deliver HCT services under a common brand. FPD provided quality assurance and a remuneration for each test with larger payments for successfully linking HIV positive clients to care. FPD's traditional CBCT was remunerated through its employee's payroll and received similar training and observed similar standards as in the SFHCT.

Lessons learned: The SFHCT had 19 HIV counsellors while FPD employed 25. A combined total of 84556 clients were tested during the period. The SFHCT tested 42697 clients (54% females), while FPD tested 41859 clients (48% females). Overall 8% tested positive with more clients testing positive in the SFHCT (10.2%) than FPD teams (5.9%). In the SFHCT 11% females and 9% males tested positive while in FPD HCT 7% females and 5% males tested positive. In the SFHCT 22% were first time testers of which 9.6% were positive tests while 29% were first time testers with 9% positive tests in FPD's HCT. Linkage to care was 60% in SF and 62.5% in FPD HCT.

Conclusions/Next steps: SFHCT was effective in identifying more HIV positive people and women but slightly less effective in identifying first time testers and linking clients to care than FPD HCT. FPD is now demonstrating the SFHCT programme in more districts.

THPEC365

Same-same but different: Expanding HIV testing and PrEP to new MSM subpopulations through the private-sector Pulse Clinic in Thailand

N. Yaemin[1], M. Avery[2], B. Yaemim[1], R. Vannakit[3]
[1]Pulse Clinic, Bangkok, Thailand, [2]LINKAGES/Thailand, FHI 360, Bangkok, Thailand, [3]United States Agency for International Development Regional Development Asia, Bangkok, Thailand

Background: Men who have sex with men (MSM) account for more than 50% of new HIV infections in Thailand; however, only 1/5 of these individuals is aware of his HIV status. Some MSM reject public-sector facilities due to concerns about stigma and discrimination, while community-based service delivery partners have limited space, human resources, and capacity. Additional and sustainable service delivery models are required.

Description: To expand service delivery options and reach clients not covered by community-based testing services, Pulse Clinic and LINKAGES/Thailand—supported by USAID and PEPFAR and led by FHI 360—collaborated with a gay-operated, for-profit HIV testing clinic (Pulse) in a high-traffic area of Bangkok. LINKAGES supported clinic promotion and standardization of clinic procedures. HIV testing was subsidized for members of the target population while HIV pre-exposure prophylaxis

(PrEP) and antiretroviral treatment (ART) were paid for by patients. Data on client demographics and risk behaviors were collected via real-time mobile data collection.
Lessons learned: Over 15 months, Pulse provided HIV testing and counseling for 7,511 clients; during the same period two community-based service providers served 4,795 and 2,128 clients. Only 1% of clients overlapped. Pulse clients were on average older than community-based clients (34.3 versus 27.7 years), and more likely to have tested for HIV previously (90.1% versus 37.2%). As a consequence of being English-speaking and a clientele that can afford to pay for services, Pulse clients were also much more likely to be non-Thai (60.1% versus 5.2%) and to be MSM as opposed to other key populations (KPs). HIV testing yield was lower among Pulse clients compared with the community-based service providers (7.7% versus 11.3%); however, 26.1% of clients who tested HIV negative at Pulse accessed PrEP, compared with 8.4% of negative clients at community-based centers.
Conclusions/Next steps: Financial and technical support allowed Pulse to expand and standardize services for KPs, and demonstrated that private-sector partners complement, rather than cannibalize, service delivery for KPs by extending the HIV services cascade to other MSM subpopulations. However, development-sector support to for-profit service providers should be progressively reduced as providers and communities are able to sustainably bear the associated costs.

THPEC366

Working with financial institutions to integrate sexual reproductive health promotion and HIV prevention into financial literacy

R. Isabirye[1], A. Nattembo[2]
[1]*Straight Talk Foundation, Training and Development, Kampala, Uganda,* [2]*Straight Talk Foundation, Advocacy, Kampala, Uganda*

Background: Straight Talk Foundation (STF) is a health and development communications Non-Governmental Organization that is implementing The Youth Enterprise Model (YEM) with funding from UNFPA with the objective of integrating sexual reproductive health (SRH) promotion and HIV prevention into young people's business environments. The project engages 50 Small and Medium Enterprises (SMEs) and 23 Vocational Training Institutes (VTIs) in Mubende and Kampala districts.
Description: According to the Uganda AIDS Commission, it is estimated that 567 young people aged between 15-24 years get infected with HIV every week and of these 363 are girls! Uganda has a predominately young population with young people constituting 24.3% of the population. In an effort to prevent HIV among this population, STF partnered with financial institutions that included a community SACCO, banks and micro finance institutions to provide integrated SRH and financial literacy to young people as part of their corporate social responsibility. 39 officials from 5 financial institutions were trained by STF on how to integrate SRH into business using a manual developed by the financial institutions and relevant Ministries. 30 outreaches targeting young people from the 50 SMEs and 23 VTIs with over 480 members were organised. In these outreaches, officials from financial institutions gave financial literacy talks carefully integrating SRH information.
Lessons learned: From a recent survey conducted by the YEM project, 86% of young people talked to had HIV knowledge while 92% were aware of HIV transmission from mother to baby during pregnancy, delivery and breastfeeding. 5,044 young people accessed HIV counseling and testing. This shows the effectiveness of using financial systems to help in demand creation of HIV prevention services. Engaging financial institutions in SRH integration has contributed to increase in financial discipline among young people. This has led to a reduction in the procurement of risk among this population thus contributing to HIV prevention.
Conclusions/Next steps: With identified success using this strategy in just two districts, STF with support from UNFPA is considering scaling up this model to other districts to reach more young people in business to improve their financial discipline as well as their knowledge and access to SRH services including HIV prevention.

Awareness, information, and risk perception regarding HIV transmission and prevention

THPED367

Making police officers allies in HIV prevention for adolescents using drugs in Kharkiv, Ukraine

O. Mohylka[1], V. Kazus[2], A. Shebardina[3], O. Voskresenska[3]
[1]*NGO 'Charitable Foundation 'Blago', Kharkiv, Ukraine,* [2]*NGO 'Charitable Foundation 'Blago', Kyiv, Ukraine,* [3]*ICF 'AIDS Foundation East-West' (AFEW-Ukraine), Kyiv, Ukraine*

Background: The fear of being arrested and stigmatized by the police is one barrier to accessing HIV prevention and treatment services by adolescents using drugs (AUDs). Current law-enforcement reform in Ukraine puts greater emphasis on crime prevention and refrains from exclusively punitive functions in work with AUDs. Programme "Bridging the Gaps: Health and Rights for Key Populations" implemented in Ukraine since 2012 aims to improve access to services of drug users aged 14-19.
Description: The NGO „Blago" works closely with police to support their involvement in services for youth. The most interesting form is joint prevention activities of police, youth and NGO staff through trainings, urban quests and visits to police departments. One event was held in the form of an urban quest where adolescents together with police officers formed teams and used police cars to find locations/service points in a game format. Trainings of police on human rights and specifics of working with AUDs help to combat stigma and attract more young people to services. As a result police officers motivate ADUs to seek HIV prevention, and actively participate in advocacy (drug policy development and enhancing service delivery to AUDs).
Lessons learned: The police is interested in cooperation with NGOs as one of their tasks is to prevent crimes and risky behaviors. Police officers do not have enough skills and tools for working with youth and appreciate any support from NGOs' experts. Building trustful relationships between young drug users and police contributed to the creation of citywide referral system and increased number of visits to the center for HIV testing and counseling at least by 20%. Adolescents feel more confident in communication with police and are ready to defend their rights in case of detention.
Conclusions/Next steps: Many AUDs have negative experiences with police that make them afraid to request help from any other service providers. Ongoing education of policemen, joint events, including police officers in service delivery team makes interaction between adolescents and policeman constructive, minimizing the punitive component. The timely solution of problems related to delinquency and its prevention help to avoid imprisonment in future, and thereby reduce possible health risks.

THPED368

Barriers to condom use among young men who have sex with men in Lebanon

K. Ghosn
Arab Foundation for Freedoms and Equality, Tayf, Mount Lebanon, Lebanon

Background: In Lebanon, the number of new HIV infections is increasing specifically among YMSM.
One of the reasons is the absence of condoms during sexual intercourse. Understanding the reasons standing behind this behavior was crucial in creating HIV and safer sex related programming.
Description: Sexual health and HIV prevention workshop titled "below the belt" is a fun meeting that where YMSM discuss issues related to dating, sexual health, usage of condoms and peer influence.
During the session, various types of information is being circulated and many questions such as the barriers to condom-use are brought up with the group.
This session has been conducted with a total of more than 100 YMSM in 7 months.

Lessons learned: While many YMSM are aware of the importance of condoms, there were many socio-political reasons to why some would not use:

- Non-availability of the condoms or the cost of buying condoms
- The thoughts of reduced pleasures when using condoms
- Fear of being rejected by their sexual partners or boyfriend for suggesting condoms implying poor negotiation skills for condom use
- Being high on substance such as drugs or alcohol reduces the ability to request or negotiate condoms
- Trusting their partner is HIV negative solely on word of mouth
- For many YMSM who live with their parents buying and storing condoms represents a problem
- Power and Age dynamics specifically when meeting with older MSM
- Lack of school sexual education which plants the idea of condom use early on.

Conclusions/Next steps: During our program we discovered the importance of explaining the benefits of condom use in preventing HIV infection and other STIs. YMSM seem to be more convinced on condom used when pleasure is discussed in addition to prevention. New prevention methods such as Prep, Pep and Undetectable seem to gain more welcome among YMSM as alternatives to condoms. Recommendations around availability of condoms in bars and bathrooms and increased distribution by NGOS. Empowerment around condom negotiations is vital in spreading the culture of safety. Increase HIV testing rates by explaining and promoting MSM friendly spaces.

THPED369

Men's beliefs about likelihood of HIV seroconcordance in couples with an HIV-positive female partner: Evidence from rural Uganda

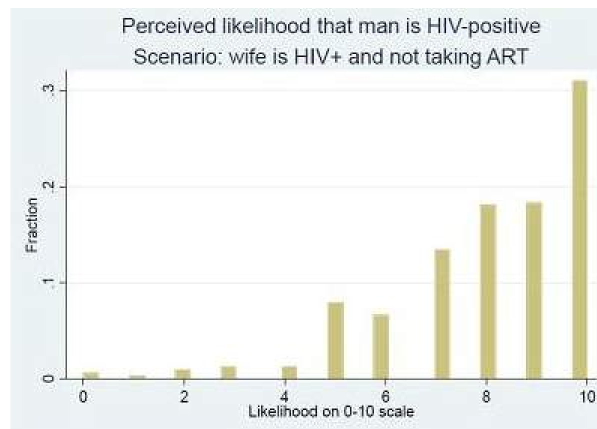
A. Ndyabakira[1], G. Chamie[2], D. Emperador[2], K. Marson[2], M. Kamya[3], D. Havlir[2], D. Kwarisiima[4], H. Thirumurthy[5]
[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of Calfornia, Division of HIV, Infectious Diseases & Global Medicine, San Fransisco, United States, [3]Makerere University College of Health Sciences, School of Medicine, Kampala, Uganda, [4]Makerere University, Joint AIDS Program, Kampala, Uganda, [5]University of Pennsylvania, Philadelphia, United States

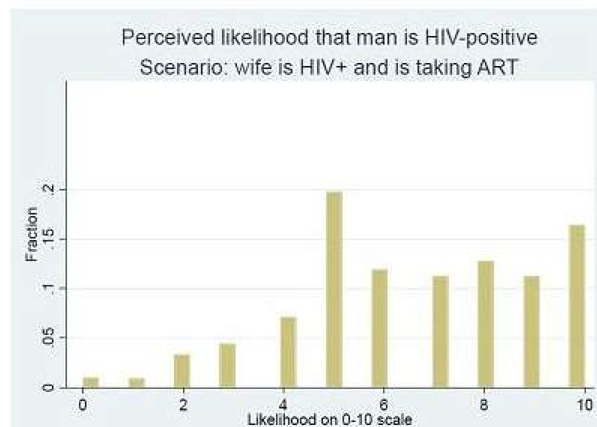
Background: Men's beliefs about the likelihood of serodiscordance in relationships and how it is affected by antiretroviral therapy (ART) may influence their decisions to uptake HIV prevention. However, few studies have assessed men's beliefs in sub-Saharan Africa.

Methods: In 2016, men from four rural parishes in Uganda were enrolled in an HIV testing trial (NCT02890459) and administered a baseline questionnaire that elicited their beliefs about the likelihood of a man being HIV-positive in two hypothetical scenarios: one in which the man's wife is HIV-positive and not on ART and another in which she is on ART. Beliefs were measured using a probabilistic scale from 0-10 (0=no chance of seroconcordance, 10=100% chance of seroconcordance). We assessed participants' responses in each scenario and calculated the difference in responses between scenarios as an indication of beliefs about the preventive effect of ART. Logistic regressions were estimated to explore associations between beliefs and health behaviors.

Results: Of 2,532 men enrolled, 2,386 (94%) had full data and mean age was 38 years. In the scenario in which a man's wife is HIV-positive and not taking ART, participants believed the man was very likely to be HIV-positive (mean seroconcordance likelihood=8.1 on 0-10 scale, standard deviation, sd, 2.0). In the scenario in which a man's wife is HIV-positive and on ART, participants believed the man was somewhat less likely to be HIV-positive (mean seroconcordance likelihood 6.6, sd 2.4). The distribution of responses (Figure) indicated a substantial proportion believed seroconcordance was 100% likely in both scenarios (0.31 and 0.16, respectively). Comparing within-participant differences between scenarios, 57% (N=1,348) reported >0% reduction in seroconcordance likelihood with ART but few reported large reductions. Logistic regressions suggested these beliefs are associated with health behaviors, with those reporting a 100% seroconcordance likelihood even with ART being less likely to seek medical male circumcision (adjusted odds ratio 0.75, 95% CI 0.62-0.91).

Conclusions: Men in rural Ugandan communities over-estimated the likelihood of seroconcordance in couples with an HIV-positive wife and under-estimated the prevention benefits of ART. These incorrect beliefs suggest a need for further education about treatment as prevention and may partially explain men's lower uptake of prevention interventions.





[Figure. Men's beliefs about likelihood of seroconcordance under different scenarios]

Evaluating the reach of a prevention campaign for men who have sex with men in Quebec, Canada

I. Robichaud[1], M. Fortin[1,2], R. Légaré[1,2]
[1]COCQ-SIDA, Montreal, Canada, [2]Coalition PLUS Community-Based Research Laboratory, Paris, France

Background: In June 2016, COCQ-SIDA launched "Sex on the Menu", a social marketing campaign aimed at preventing the transmission of HIV and other STIs among men who have sex with men (MSM) in the province of Quebec, Canada. Created by an advisory committee of gay men and other MSM, the campaign sought to inform MSM about different prevention options and encourage them to visit pretpourlaction.com, a sexual health information website. The following year, an evaluation protocol was developed and implemented to assess the reach of the campaign.

Methods: An online survey was developed to measure the proportion of the target population who: a) remembered seeing the campaign; b) were aware of its key message; and c) intended to learn more about the prevention methods. LGBT and HIV community-based organizations (CBO), research groups, and other stakeholders promoted the survey on social media for 10 weeks. Descriptive analyses of proportions were generated from survey responses. Two focus groups (N=12) were held to gather qualitative data that was analyzed thematically.

Results: A total of 123 participants responded to the survey with a completion rate of 68%. Nearly one quarter (24.3%) of respondents recalled seeing the campaign after being shown one of the visuals from the campaign. Of these, 60% were aware it was a prevention campaign, 38.7%

Tuesday 24 July

Publication Only Abstracts
Author Index

agreed that it had led them to learn more about or to use one or more prevention methods, and 20% had visited pretpourlaction.com after seeing the campaign. Focus group results suggest that MSM are exposed to many informational campaigns that deal with HIV or STIs. Participants could remember seeing these campaigns but had difficulty recalling the specifics of a particular campaign. Campaigns that they were able to recall in more detail were highly promoted on television for an extended period and were not related to sexual health.

Conclusions: Despite limited financial resources, "Sex on the menu" seems to have met its objectives: participants who saw the campaign remembered it, understood its message, and learned more about prevention options. To increase reach, CBOs should consider extending the longevity of prevention campaigns and tailoring promotional efforts to maximize visibility.

THPED371

Engaging youth in digital discussions about HIV and discrimination: How the initiative #UNAIDSChallenge caused a buzz in Brazil

D. De Castro[1], C. De Lima[2], M. Mayara[1]
[1]UNAIDS, Communications, Brasilia, Brazil, [2]UNAIDS, Community Mobilization and Networking, Brasilia, Brazil

Background: The growth of AIDS cases among young people aged 15-29 in the past decade remains a major concern in Brazil. Recent indicators show that young people living with HIV present lower adherence to treatment and consequently a lower proportion of them achieve viral suppression. The #UNAIDSChallenge aimed to:
(i) mobilize youtubers and digital influencers from different backgrounds and outreach capacity to use their creativity and promote new ways to debate HIV among their followers;
(ii) translate technical and formal language into messages relatable to young audiences;
(iii) provoke reflection on how society, especially young people, is debating HIV-related issues on the internet.

[#UNAIDSChallenge in Brazil with youtubers and digital influencers]

Description: The #UNAIDSChallenge was conceived as a social media informative game to raise awareness on AIDS-related issues. Over 30 digital influencers voluntarily accepted the challenge, and committed to publish their videos on YouTube and Facebook. Fifty of the most frequently asked questions about HIV were taken from the Internet and 15 of them were randomly sent to YouTubers as part of a special game box also containing tokens to skip and google questions, and even consult a specialist through a telephone-style headset. An online platform with quick guides, tips, videos, and all the answers was built to support them during the challenge.

Lessons learned: Altogether, the videos reached more than 1 million organic views, nearly 180,000 tweets and thousands of comments in a one-month period, rekindling an important debate on HIV and discrimination on social media, especially among young people. Mobilization was made on a voluntary basis, proving that young influencers are open to this kind of dialogue and that their followers welcome this kind of initiative. Social media monitoring tools have shown that acceptance and positive evaluation were at 100%.

Conclusions/Next steps: Innovative approaches to break down barriers in the promotion of the dialogue about HIV with young people are feasible and possible when tailor-made strategies are built with and for youth. Although intergenerational dialogue on HIV will continue to be a challenge, young people have proven to be open to the debate as long as it happens according to their preferences, languages and perspectives.

Gaps in delivery and uptake of patient-centered HIV testing: Provider and community leader perspectives on HIV testing in fishing and non-fishing villages around Lake Victoria, Kenya

K.R. Amico[1], N. Nguyen[2], Z. Simpson[2], E. Bennett[2], T. Navalta[2], J.E. Mantell[3], Z. Kwena[4], K. Ngure[4], E. Bukusi[4], B. Young[5], T.B. Masvaure[2,6], P. Ochwal[4,7], D. Ochola[2], P. Ryland[2], P. Valente[2], J. Wall[2], E. Stacey[5], J. Zuniga[5], R. Remien[8]
[1]University of Michigan, School of Public Health, Health Behavior and Health Education, Brighton, United States, [2]HIV Center for Clinical and Behavioral Studies at the New York State Psychiatric Institute, New York, United States, [3]HIV Center for Clinical and Behavioral Studies at the New York State Psychiatric Institute, Psychiatry, New York, United States, [4]Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya, [5]International Association of Providers of AIDS Care, Washington, United States, [6]College of the Holy Cross, Department of Sociology and Anthropology, Worcester, United States, [7]Impact-IRDO, Nairobi, Kenya, [8]HIV Center for Clinical & Behavioral Studies, NYS Psychiatric Institute and Columbia University, Psychiatry, New York, United States

Background: Wide-scale delivery and uptake of HIV Testing in high-prevalence communities around Lake Victoria is critical to controlling the HIV epidemic in Kenya. Engaging young women, men who have sex with men, and heterosexual men in HIV testing remains a challenge. We sought to better understand barriers to uptake and delivery of HIV testing in general, and high-quality patient-centered care specifically, from the perspective of those providing HIV testing and related community services in Homa Bay, Kisumu and Siaya.

Methods: We conducted 16 focus groups (11 with HIV testing and care providers, 5 with community leaders) with a total of 172 individuals. Semi-structured focus group guides focused on multilevel factors influencing the HIV care continuum. Transcripts were double coded and themes extracted inductively.

Results: Factors thought to influence uptake of HIV-testing were generally consistent across regions and focus groups, with main concerns (Figure 1) falling within the areas of lack of **trust** in services, **stigma**, problems in **delivering** high-quality patient-centered **care, fears** of negative consequences of **testing positive** (largely social in nature), entrenched **gender(ed) norms**, and **HIV testing policies**. Gender disparities included lower uptake of testing among men and men using the results of their female partners to determine their own HIV status. Participants recommended, as solutions, extending clinic hours, venue specific in-community testing, creation of welcoming environments that respect patient

dignity, time, privacy and confidentiality, providing incentives/tokens for testing, using peers and improving the counseling surrounding testing, and community-level efforts to reduce stigma and disseminate better information about HIV.
Conclusions: Despite considerable progress in HIV testing in high prevalence areas in Kenya, a number of barriers remain. Providers of HIV testing and care and community leaders offered a number of innovative strategies that should be seriously considered. Bringing opportunities to test into venues commonly accessed by at-risk groups, flexing clinic hours and creating inclusive clinic environments may help to improve current programs. Further research is needed to investigate if and how current policies (e.g., testing pregnant women) may reinforce existing gender disparities in HIV uptake
(e.g., men wait for their partners to test rather than test themselves).

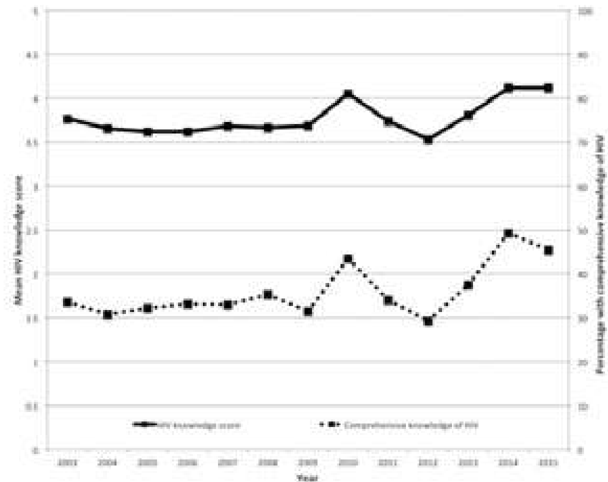
[Barriers to HIV Testing in Fishing and Non-Fishing Communities around Lake Victoria: Perspectives of Health Care Providers and Community Leaders]

THPED373

HIV knowledge trends during an era of rapid antiretroviral therapy scale-up: An analysis of 35 sub-Saharan African countries

B. Chan[1], A. Tsai[2]
[1]Brigham and Women's Hospital, Infectious Diseases, Boston, United States, [2]Massachusetts General Hospital, MGH Global Health, Boston, United States

Background: Population-level improvements in knowledge about HIV may reduce the stigma attached to HIV and ensure maximal uptake of HIV prevention initiatives. It is unknown to what extent levels of HIV knowledge in the general population of sub-Saharan Africa have changed in the current era of antiretroviral therapy (ART) scale-up.
Methods: Data on HIV knowledge in the general population were drawn from the 2003-2015 Demographic and Health Surveys (DHS) and AIDS Indicator Surveys (AIS) of 35 countries in sub-Saharan Africa. The DHS/AIS contain five questions on HIV prevention and transmission that have been used by UNAIDS as a core indicator of HIV knowledge. We created a composite HIV knowledge variable equal to the number of correct responses to these five questions; a participant was considered to have comprehensive knowledge of HIV (yes/no) if he/she answered all five questions correctly. We fitted negative binomial regression models with cluster-correlated robust standard errors and country fixed effects, adjusted for socio-demographic variables, specifying HIV knowledge as the dependent variable and year as the explanatory variable. As an alternative parameterization, we also fitted a multivariable linear probability model with cluster-correlated robust standard errors and country fixed effects specifying comprehensive knowledge of HIV as the dependent variable.
Results: 791,186 women and 395,891 men participating in 75 DHS/AIS were included in the analyses. The mean HIV knowledge score was 3.7 among women and 3.9 among men ($p < 0.001$). Only 35% of women and 41% of men ($p < 0.001$) had a comprehensive knowledge of HIV. We estimated a modest but statistically significant positive association between year of DHS/AIS and HIV knowledge (adjusted $b = 0.005$; 95% Confidence Interval [CI], 0.001-0.009). Similarly, we estimated a statistically significant positive association between year of DHS/AIS and comprehensive knowledge of HIV (adjusted $b = 0.011$; 95% CI, 0.005-0.017), suggesting an approximately 1% relative increase per year in the percentage of the general population who possess a comprehensive knowledge of HIV.
Conclusions: There have been only modest improvements over time in HIV knowledge across sub-Saharan Africa.



[HIV knowledge in 35 sub-Saharan African countries, by year, 2003-2015]

THPED374

Trends of people's HIV/AIDS knowledge and attitude in 42 sub-Saharan African countries

X. Dai, H. Wang, IHME HIV/AIDS Social Determinants Team
Institute for Health Metrics and Evaluation, University of Washington, Department of Global Health, Seattle, United States

Background: People's knowledge and attitude on HIV/AIDS are key determinants of HIV/AIDS epidemics and are crucial contributors to the success of HIV/AIDS interventions as well. However, evidence on country-level HIV/AIDS knowledge and attitude is still scarce and unbalanced across SSA countries. To fill in the gap, this study estimates national trends of HIV/AIDS knowledge and attitude from 1990 to 2016 across 42 SSA countries by using state-of-the-art techniques to borrow information across time and space.
Methods: To find all relevant data, the author searches in IHME's GHDx repository to identify all national surveys that have data on HIV/AIDS knowledge and attitude in the 42 SSA countries. After identifying all relevant surveys, individual level data on HIV/AIDS knowledge and attitude are extracted in a systematic and consistent way. Then, the individual level date are collapsed into country level estimates and multi-level multiple imputation is used to impute missing indicators on country level to make sure that all surveys have all the national indicators of interest. Lastly, spatial-temporal Gaussian process regression (ST-GPR) is used to synthesize all country level estimates and make trends estimation for each indicator in each country.
Results: From 1990 to 2016, across all countries, having heard of aids (**heard_aids**), knowing that having one partner reduces risk of HIV infection (**kw_one_partner**) and healthy looking person can have HIV/AIDS (**kw_look**) slightly increased from 93.7% to 95.0%, from 79.8% to 82.7% and from 67.4% to 75.7%, respectively. However, knowing that condom (**kw_condom**) reducing risk of HIV infection decreased from 77.9% to 73.8%. Regarding attitude, willing to frequent HIV+ vendor (**att_veg**), willing to take care of HIV+ family members in the house (**att_care**) and believing HIV+ teacher should continue to work (**att_teacher**) all increased from 28.4% to 62.7%, from 77.3% to 88.8% and from 47.6% to 69.3% respectively. Country specific trends vary greatly across countries.

Conclusions: Attitude towards people living with HIV has been improved significantly across all countries. However, improvement in knowledge is moderate and knowledge of condom use reducing HIV risk even decreases slightly, suggesting that health education on HIV/AIDS and condom use needs to be not only continued but also strengthened.

THPED375

Longitudinal studies of HIV risk perception and sexual risk behaviour in east Zimbabwe 2003-2013

R. Schaefer[1], S. Gregson[1,2], R. Thomas[1], C. Nyamukapa[1,2]
[1]Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom, [2]Biomedical Research and Training Institute, Harare, Zimbabwe

Background: Risk perception is central to behaviour change theories that informed HIV prevention interventions, but mixed evidence exists on associations between risk perception and sexual behaviour. This may be because risk perception is essentially a bi-directional longitudinal concept which is difficult to capture in cross-sectional studies. We use longitudinal data to examine whether changes in sexual behaviour lead to changes in risk perception, and whether changes in risk perception lead to changes in protective behaviour.

Methods: Data on HIV-negative adults (15-54 years) participating in ≥2 of 4 surveys (2003-2013) in a general-population open-cohort study in Zimbabwe were analysed. Individuals not reporting risk perception in the first of two surveys were examined regarding whether changes in sexual risk (having multiple, casual, or concurrent sexual partnerships) between surveys were associated with risk perception at follow-up. Individuals not reporting condom use during last sex in the first survey were examined regarding whether developing risk perception between surveys was associated with condom use at follow-up. Data were analysed as panel and logistic regressions were adjusted for socio-demographic characteristics.

Results: Among respondents not reporting HIV risk perception in the first of two surveys (n=5259/N=10089), increasing sexual risk between surveys was associated with developing risk perception (odds ratio [OR]=1.56, 95% confidence interval=1.09-2.24) (Table). Despite this higher relative risk among those increasing sexual risk, 86.0% of all developing risk perception (993/1155) did not change their sexual risk. Among respondents not using condoms in the first survey (n=7234), developing risk perception was associated with starting condom use (OR=1.52 [1.19-1.94]), controlling for changes in sexual risk, marital status, and other socio-demographic factors (Table). 63.5% of all starting to use condoms (374/590) did not change their risk perception.

Changes in sexual risk between surveys and risk perception at follow-up among those not perceiving a risk in the first survey.				Changes in HIV risk perception between surveys and condom use during last sex at follow-up among those not reporting condom use in the first survey.			
Outcome: Risk perception	**All (N=5180)**	**Males (N=2359)**	**Females (N=2821)**	***Outcome: Condom use***	**All (N=7059)**	**Males (N=2112)**	**Females (N=4947)**
	aOR (95% CI)	aOR (95% CI)	aOR (95% CI)		aOR (95% CI)	aOR (95% CI)	aOR (95% CI)
Sexual risk: No change	1 (Reference)	1 (Reference)	1 (Reference)	Risk perception: No change	1 (Reference)	1 (Reference)	1 (Reference)
Sexual risk: Increased risk	1.56 (1.09-2.24)	1.59 (1.03-2.44)	1.34 (0.73-2.44)	Risk perception: Increase	1.52 (1.19-1.94)	1.89 (1.12-3.19)	1.41 (1.01-1.98)
Sexual risk: Decreased risk	0.67 (0.46-0.99)	0.71 (0.45-1.13)	0.67 (0.37-1.20)	Risk perception: Decrease	1.24 (0.98-1.56)	1.51 (0.92-2.47)	1.16 (0.88-1.50)
Values are adjusted odds ratios (aOR), 95% confidence intervals (CI), and sample sizes (N). The sexual risk variable was based on reported multiple partners in the past 12 months, having at least one casual partners in the past 3 years, or having more than one sexual relationship at the time of the survey. A change in sexual risk was from having none of these risk factors to any of these (increase) or from any of these to none (decrease). Data were restricted to those not reporting risk perception in the first survey. The outcome was HIV risk perception at follow-up. Further covariates: Age, sex, change in marital status, change in condom use, survey round, and study site.				Values are adjusted odds ratios (aOR), 95% confidence intervals (CI), and sample sizes (N). A change in risk perception was defined as reporting risk perception at follow-up but not baseline (increase) or reporting risk perception at baseline but not at follow-up (decrease). Data were restricted to those not using a condom during last sex in the first survey. The outcome was condom use during last sex at follow-up. Further covariates: Age, sex, change in marital status, change in sexual risk, survey round, and study site.			

[Changes in sexual risk and risk perception, and changes in risk perception and condom use]

Conclusions: This is the first longitudinal study confirming expected associations between changes in sexual behaviour and HIV risk perception, and between changes in risk perception and protective behaviour. The results support prevention programmes to educate about risky behaviour and increase risk perception. However, only a small proportion of changes in condom use could be attributed to changes in risk perception, underlining the importance of other factors that determine HIV prevention behaviour, including factors beyond individual control.

THPED376

HIV intervention using interactive voice response (IVR) for key populations

S. Sokhan[1], S. Seng[2], V. Lan[3], S. Tep[3], R. Sopha[4], T. Eang[5], S. Kong[6], K. So[7]
[1]FHI 360, Prevention, Phnom Penh, Cambodia, [2]FHI 360, LINKAGES, Phnom Penh, Cambodia, [3]National Center for HIV/AIDS, Dermatology and STD, SBCC, Phnom Penh, Cambodia, [4]KHANA, Phnom Penh, Cambodia, [5]Cambodian Women for Peace and Development (CWPD), SBCC, Phnom Penh, Cambodia, [6]Men's Health Social Service (MHSS), Prevention, Phnom Penh, Cambodia, [7]KHANA, Flagship, Phnom Penh, Cambodia

Background: Physical outreach has been the main prevention approach for key populations (KP) in HIV programs, but is often costly and limited in its capacity to reach geographically dispersed, criminalized, stigmatized, or otherwise "hidden" KP. The use of mobile and internet technologies is a promising approach for young tech-savvy users with internet access. However, the conduct of virtual outreach among KP with low literacy or limited social media or Internet access remains challenging. The use of telephone-based Interactive Voice Response (IVR) systems may help overcome these barriers by supporting keypad-based interactions that require no advance knowledge on the part of end-users and can be accessed by mobile phone virtually anywhere.

Description: A four-digit, easy to remember, free of charge call number (1295), was linked to the VerboiceÒ free and open-source IVR and was promoted through leaflets and social media targeting KPs. A variety of services are available to callers via self-guided menu items, including health information via quizzes and short messages; edutainment using mini-dramas, songs, and testimonials; and, online live counseling. The system also provided an option for callers to register to receive HIV-related voice-message reminders monthly.

Lessons learned: Between September 2015 and November 2017, 55,877 calls were received from 8,027 unique telephone numbers registered. These included 22,809 calls where users opted to receive content relevant to entertainment workers (EW) (40.82%); 17,704 calls selecting content relevant to men who have sex with men (MSM) (31.68%); and 15,364 calls selecting content relevant to transgender (TG) people (27.50%). Edutainment was the most popular service selected, accessed 34,043 times or (60.92%) of the total calls. Approximately 13,204 users chose health information (23.63%), and online-counseling was accessed by 8,630 (15.44%). During the same period, 145,075 reminder messages were sent to numbers registered under the EW option; 132,520 for MSM; and, 29,415 for TG.

Conclusions/Next steps: IVR systems are a viable approach to providing KP with essential HIV-related information and bridging the digital divide. However, in adopting IVR it is also essential to establish online-to-offline referral systems to facilitate and document the connections to HIV testing and treatment services needed to accelerate epidemic control.

THPED377

Promoting HIV risk awareness among key population through tablet-based outreach risk screening in Cambodia

S. Sokhan[1], V. Lan[2], S. Tep[2], S. Seng[3], T. Eang[4], K. So[5], R. Sopha[6]
[1]FHI 360, Prevention, Phnom Penh, Cambodia, [2]National Center for HIV/AIDS, Dermatology and STD, SBCC, Phnom Penh, Cambodia, [3]FHI 360, LINKAGES, Phnom Penh, Cambodia, [4]Cambodian Women for Peace and Development (CWPD), SBCC, Phnom Penh, Cambodia, [5]KHANA, Prevention, Phnom Penh, Cambodia, [6]Khana, Flagship, Phnom Penh, Cambodia

Background: To support the National Center for HIV/AIDS, Dermatology and STD (NCHADS) in improving the effectiveness and reducing the costs of HIV programming, tools are needed to differentiate and prioritize the prevention and treatment response on the basis of individuals' risks and preferences. Persistent stigma, discrimination, and criminalization of key populations (KP) facing the greatest HIV risks prevent many KP from feeling comfortable disclosing their risks through face-to-face interaction. Confidential, self-administered, electronic risk screening tools may provide viable and preferred alternatives for eliciting personal risk information.

Description: We introduced a Tablet-based Outreach Risk Screening (TORS) as an electronic tool used during outreach to determine an individual's risk (high, medium or low) of HIV acquisition or onward transmission. It was piloted by the USAID Flagship project in Siem Reap province between April and July of 2015 and was then implemented more widely in four provinces from January 2016 through October 2017. Individuals categorized as "high-risk" included those reporting multiple partners or unprotected anal/vaginal sex. Following the risk screening, all those identified at risk (high and medium) were invited to participate in a finger-prick HIV screening test. A nine-digit unique identification number (UIC) was used to identify individuals participating in screening and finger prick testing.

Lessons learned: In total between January 2016 and October 2017, 16,424 EW, 7,171 MSM, and 1,318 TG had been screened. Among that 6,618 (40%) EW, 3,860 (53%) MSM, and 834 (63%) TG were identified as "High Risk". 5,465 (33%) EW, 1,344 (19%) MSM, and 114 (0.8%) TG were "Medium Risk". For finger prick testing, 4,767 (39%) EW, 1,829 (35%) MSM, and 186 (20%) TG of all "High Risk" and "At Risk" individual had taken the test; and 36 (0.8%) EW, 4 (0.2%) MSM, and 5 (3%) TG were reactive to the test.

KPs	Reached	Screened	High-Risk	HIV Test	At-Risk	HIV Test	Low-Risk	HIV Test	Total HIV+
EW	19,174	16,424	6,618	3,210	5,465	1,557	4,327	563	36
MSM	9,015	7,171	3,860	1,531	1,344	298	1,967	137	4
TG	1,377	1318	834	184	114	2	370	3	5

[Table 1]

Conclusions/Next steps: Tablet-based risk-screening can produce useful answers to risk assessment questions and promote HIV risk awareness among KPs by letting them know their risk status and behaviors. By knowing the individual risk behaviors, the outreach workers can provide more specific HIV and STI educational messages, and reduce unnecessary HIV testing among those with low risk.

THPED378

Predicting sexual assertiveness among Black women

S. Lewis-Keith, A. Prehn, W.-H. Kuo
Walden University, Maine, United States

Background: Despite the high HIV prevalence rate for Black women in Virginia, few studies have examined how potential protective factors against HIV vary within this group. The purpose of this study was to determine if four aspects of sexual assertiveness differed across demographic categories and were associated with self-esteem in a diversified group of Black women living in Virginia.

Methods: A cross-sectional survey was conducted with a community-based sample of 117 adult Black women. The women provided information on their age group, income level, highest level of education, sexual orientation, and relationship status. Self-esteem was measured using the Single-item Self-esteem Scale (SISES). The Sexual Assertiveness Scale(SAS) was used to measure four types of sexual assertiveness: (a) initiation of sexual interactions, (b) refusal of sexual activity, (c) HIV/AIDS/STD communication, and (d) contraception/STD prevention. ANOVAs determined differences in means of the four SAS subscales across the demographic categories. Pearson bivariate correlations were conducted between the SISES and the four measures of sexual assertiveness.

Results: HIV, AIDS, and STD communication assertiveness mean scores were significantly higher among higher- versus lower-income Black women (p_{adj}=.016) and Black women with a college versus a high school degree (p_{adj}=.047). Homosexual Black women had a significantly higher communication assertiveness mean score in comparison to heterosexual and bisexual Black women (p=.002). Similar results were found for contraception and STD prevention assertiveness. Moreover, self-esteem was significantly positively associated with all but one measure of sexual assertiveness in the sample of 117 Black women. No significant differences in sexual initiation or sexual refusal assertiveness scores were found across demographic groups.

Conclusions: Sexual assertiveness scores around HIV/AIDS and STD prevention and communication were associated with level of income and education. In addition, as the study participants' self-esteem increased, so did their sexual assertiveness. The findings suggest that HIV/AIDS prevention and education initiatives focusing on educational attainment and building self-esteem would be beneficial in building sexual assertiveness attitudes and behaviors among Black women as an HIV/AIDS prevention method.

THPED379

Factors associated with HIV status disclosure to partners and its outcomes among HIV- positive women attending care and treatment clinics in Kilimanjaro region, Tanzania

D. Damian
Kilimanjaro Christian Medical Centre, Community Health Department, Moshi, Tanzania, United Republic of

Background: Sub Saharan Africa continues to be the epicenter of HIV with 70% of people living with HIV globally. Women form nearly 60% of those living with HIV. Studies have shown disclosure of one's HIV status is important in HIV prevention, in increasing partners who are tested and getting into care early as well as in improving retention in PMTCT and ART programs. This study aimed to determine the prevalence, factors and outcomes of HIV status disclosure to partners among HIV-positive women attending HIV care-and-treatment clinics (CTCs) at Kilimanjaro region, northern Tanzania.

Methods: A cross sectional study was conducted from January to June 2014 in 3 out of the 7 districts of Kilimanjaro region. The study population was HIV-positive women aged 15-49, who were attending for routine HIV care at 19 selected clinics. Face to face interviews were conducted with consenting women to collect necessary information.

Results: A total of 672 HIV-positive women in Moshi municipal, Hai and Mwanga districts were enrolled. Of the enrolled, 609 HIV-positive women reported to have a regular partner. Prevalence of HIV-serostatus disclosure to partners was 66%. Of the 400 who had disclosed; 56% did so within the first month of knowing their HIV status. In multiple logistic regression HIV-serostatus disclosure was higher among women who: were married/cohabiting, currently on ART, who reported condom use, and who reported had ever communicated with partners on number of children and contraceptives. Most of the women (81%) who disclosed their HIV status to did not reported negative outcomes.

Conclusions: In this setting still a third of the HIV-positive women (34%) fail to disclose their HIV- serostatus to partners. Interventions to impart skills in communication and negotiation between partners may help in improving disclosure of HIV. Efforts to involve men in general sexual and reproductive health including couple counseling and testing will contribute in improving disclosure and communication on HIV among partners.

THPED380

Impact of workplace HIV interventions on HIV knowledge and risky sexual practices among key and priority populations in Uganda

A. Watsemba[1], L. Ayebale[1], R. M Flueckiger[2], J. Hayuni[1], B. Wandera[3], A. Mitchell Le Few[2], M. Lopez[4], E. Tanga[3]
[1]RTI International, USAID/Uganda HIV and Health Initiatives in Workplaces Activity, Kampala, Uganda, [2]RTI International, Research Triangle Park, North Carolina, United States, [3]World Vision Uganda, USAID/Uganda HIV and Health Initiatives in Workplaces Activity, Kampala, Uganda, [4]World Vision, Inc., Federal Way, WA, United States

Background: The USAID Uganda HIV and Health Initiatives in Workplaces Activity (HIWA) disseminates information on how to reduce HIV transmission, protect oneself from HIV infection, and reduce risky behavior to the following priority populations: Uganda Police Force (UPF), Uganda Wild Life Authority (UWA), private security guards (PSGs), and hotel employees. HIWA disseminates messages through:
1) enlisting workplace HIV champions,
2) conducting peer-to-peer small group sessions,
3) holding workplace-based HIV/health wellness events, and
4) supporting a 24-hour mobile health platform.
This study assessed the impact of these interventions after 2 years of implementation.
Methods: Surveys were conducted comparing baseline (November 2015) and post-intervention (October 2017) data from a random sample of 1,185 and 654 employees, respectively. Comprehensive HIV knowledge was calculated in accordance with Uganda Demographic and Health Survey methodology (survey participants were asked to name recommended ways to prevent HIV infection and reject two common misconceptions about HIV transmission). A composite indicator of participants' risky sexual behavior was generated by analyzing transactional sex, cross-generation sex, multiple sex partners, non-condom use with non-regular partners, and consumption of alcohol before sex.
Results: All indicators were significant at the 5% level. The study identified a 14% (confidence interval [CI] 10-18%) increase in HIV knowledge, a 2% (CI 1-3%) increase in ability to identify HIV preventive measures, and a 16% (CI 13-19%) increase in ability to reject misconceptions in the intervention group. The largest knowledge increase was among UPF and hotel employees (17%, CI 10-24%), followed by UWA (10%, CI 8-12%) and PSGs (5%, CI 3-7%). Reported engagement in risky sexual practices declined overall by 12% (CI 8-16%), with the largest decline among UPF (26%, CI 21-31%). However, an increase in risky sexual practices of 23% (CI 17-29%) was observed among hotel employees.
Conclusions: The study suggests HIWA's interventions contributed to measurable increases in HIV knowledge, with less consistency on their impact on risky sexual behavior. The results contribute to program learning and adaptation of implementation strategies. Additional exploration of workplace setting situations is needed to determine where specific approaches are most appropriate.

THPED381

Should the permanent deferral for blood donation among MSM be revisited: A cross-sectional study in 3 metropolitan cities in China?

X. Meng[1], X. Wang[1], T. Jia[1], H. Yin[1], W. Chen[2], Z. Luo[2], S. Huang[3], Y. Ding[2], H. Zheng[3], B. Yang[3], A. Grulich[4], H. Zou[4,5], T2T Study Group
[1]Wuxi Municipal Centre for Disease Control and Prevention, Wuxi, China, [2]Nanshan District Centre for Chronic Disease Control and Prevention, Shenzhen, China, [3]Dermatology Hospital, Southern Medical University, Guangzhou, China, [4]Kirby Institute, University of New South Wales, Sydney, Australia, [5]School of Public Health (Shenzhen), Sun Yat-sen University, Shenzhen, China

Background: Many countries are evaluating the potential risks and benefits of relaxing deferral policies for blood donation among men who have sex with men (MSM). In China many MSM conceal their same-sex behaviors and donate blood in despite of the permanent deferral. This study aimed to assess the prevalence of and factors associated with blood donation among MSM in China.
Methods: Our observational study was conducted between January and August, 2017 in 3 metropolitan cities: Guangzhou, Shenzhen and Wuxi. Eligible participants were MSM (≥18 years old) who had either ≥2 male sex partners or unprotected anal sex with casual partners, or had been diagnosed with an STI, in the past 6 months. A self-completed tablet-based questionnaire was collected about blood donation history, socio-demographic characteristics, sexual behaviors and HIV testing history.
Results: A total of 603 MSM were enrolled in our study, with a mean age of 27.9 years (SD=7.8). Overall, 29.2% (176/425) reported a history of blood donation, namely 33.1% (100/302) in Guangzhou, 27.6% (42/152) in Shenzhen and 22.8% (34/149) in Wuxi (^{2}=6.421, P=0.093). While 83.0% donated blood out of altruism, only 11.4% did so to get tested for HIV. MSM who had ever used geosocial networking (GSN) mobile applications (apps) (OR=2.4, 95%CI: 1.2-4.8) or had ever tested for HIV ≥2 times in the past 12 months (OR=1.5, 95%CI: 1.1-2.3) were more likely to have donated blood. Some 3.3% (20/603) reported blood donation in the past 6 months, among whom one person was tested HIV-positive with CD4 of 145 copies/mm^3. One other individual donated blood knowing his HIV-positive status. Compared to non-donors, a higher proportion of donors had >10 male sex partners in lifetime (36.4% VS 26.0%, P=0.011). Among 582 men who had sex in the past 6 months, only 20 (3.4%) donated blood in the same period.
Conclusions: Blood donation was common among MSM in China. The great majority of MSM may comply with 6-months deferral which implies the necessity of reconsideration of deferral length. In the meantime HIV testing technologies that can substantially narrow the window period should be scaled-up in blood donation venues.

THPED382

#WhatWomenWant: HIV prevention that works for adolescent girls and young women. Results of a consultation with adolescent girls and young women to operationalise UNAIDS HIV prevention guidance

K. de Graaf[1], J. Stevenson[2], C. Nyambura[3], T. Crone[4], E. Johnson[5], T. Otieno[4]
[1]ATHENA Initiative, Calgary, Canada, [2]ATHENA Initiative, London, United Kingdom, [3]ATHENA Initiative, Nairobi, Kenya, [4]ATHENA Initiative, Seattle, United States, [5]ATHENA Initiative, Washington DC, United States

Background: Adolescent girls and young women (AGYW) are disproportionately affected by HIV, and prevention efforts need to be targeted to meet their specific needs and experiences. As part of the #WhatWomenWant campaign, a global movement to advance gender equality, ATHENA led a consultation to engage AGYW in the new UNAIDS prevention guidance: 'HIV prevention among adolescent girls and young women: Putting HIV prevention among adolescent girls and young women on the Fast-Track and engaging men and boys.'
Methods: We used WhatsApp, an accessible, cheap, low-data tool widely used by AGYW, to convene an extended focus group. AGYW were invited to join, using snowballing recruitment through existing list servs and virtual platforms. The focus group was moderated by an ATHENA team member, who added participants once eligibility had been confirmed. 185 AGYW participated, from at least eight different countries: Botswana, Kenya, Malawi, Namibia, South Africa, Swaziland, Uganda, and Zimbabwe. The focus group adopted a semi-structured approach, with participants asked to respond to a set of questions about each strategy in the guidance, shared as a one-page, accessible summary. The consultation took place over a period of weeks. Findings were analysed thematically using a framework process.
Results: AGYW identified barriers to accessing HIV prevention, including age of consent laws, discriminatory treatment by healthcare staff (based on age, sexuality, disability, HIV status), lack of appropriate services or information, and cost. Very few participants were familiar with PrEP, and many thought it was the same as PEP. Some felt PEP was a better or safer option as it involved more short-term use of antiretrovirals. Fears about resistance and side effects were common. Participants also described barriers to accessing contraceptives, safe abortion and condoms, including legal barriers, age restrictions, cost and health worker attitudes. AGYW called for action to address keeping girls in school, child marriage, and gender-based violence.

Conclusions: WhatsApp is an effective, accessible tool to reach and engage AGYW. Participation was high, and contributions meaningful and on-topic. The application of top-level guidance must be informed by local realities and lived experience, and the consultation provided rich insights into how this can be achieved.

THPED383

Substance use, adherence to antiretroviral therapy, and sexual risk behaviors among people living with HIV in Guangxi, China

Y. Mao[1], Q. Zhao[2], X. Li[1], S. Qiao[1], Z. Shen[3], Y. Zhou[3]
[1]University of South Carolina, Health Promotion, Education, and Behavior, Columbia, United States, [2]Nanjing University of Information Science and Technology, Nanjing, China, [3]Guangxi Center for Disease Prevention and Control, Nanning, China

Background: Sexual risk behaviors among people living with HIV (PLHIV) can have serious public health consequences. Adherence to antiretroviral therapy (ART) can be positively or negatively associated with engagement in sexual risk behaviors. The negative associations can be due to the confounding effect of some factors such as substance use, while the positive associations have sometimes been attributed to treatment optimism. Given a general lack of relevant research in China, this study aims to explore the associations among substance use, ART adherence, and sexual risk behaviors among PLHIV in Guangxi, China.
Methods: Cross-sectional data from 1,134 PLHIV (664 men and 470 women) in Guangxi, who reported having been sexually active and receiving ART were analyzed. Measures included demographics, drug use, alcohol use, smoking status, medication adherence, HIV viral load, and sexual risk behaviors (multiple sex partners and inconsistent condom use). Path analyses were performed using Mplus 7 to identify the associations of interest.
Results: In the first path analysis for testing treatment optimism hypothesis, the participants who reported lower ART adherence were more likely to have an unsuppressed HIV viral load (=.11, p = 0.023), have multiple partners (=-.12, p = 0.017) and have used condoms inconsistently (=-.08, p = 0.037). No associations between HIV viral load and sexual risk behaviors were identified. In the second path analysis for testing confounder hypothesis, alcohol use (=-.12, p < 0.001), smoking (=-.09, p = 0.003), and drug use (=-.19, p < 0.001) were separately associated with poorer ART adherence. Those who reported alcohol use (=.14, p = 0.005), and smoking (=-.19, p = 0.001) were more likely to have multiple partners. Drug use had an indirect effect on partner concurrency (=.02, p = 0.033), while alcohol use had an indirect effect on inconsistent condom use through ART adherence (=.01, p = 0.032).
Conclusions: The findings indicated substance use was a confounder, and ART adherence buffered the positive associations between substance use and sexual risk behaviors. Future interventions to reduce sexual risk behaviors among PLHIV in Guangxi are recommended to focus on reducing substance use, as well as promoting ART adherence.

THPED384

AHF Checkpoint Kyiv: Effective marketing to increase HIV testing

D. Godlevskiy[1], A. Zakowicz[1], Y. Kvasnevska[2], A. Davies[1], Y. Kalancha[2]
[1]AIDS Healthcare Foundation Europe, Amsterdam, Netherlands, [2]AIDS Healthcare Foundation Ukraine, Kyiv, Ukraine

Background: The estimated number of HIV-positive people in Ukraine is more than 230,000, with 132,945 patients in care. The availability of rapid testing in Ukraine is a priority, in line with the recently adopted "Test and treat" strategy. In Eastern Europe there is a lack of effective marketing campaigns to motivate and educate people to get tested. The objective of the intervention was to use creative marketing to motivate people to get tested at AHF Checkpoint Kyiv.
Description: AHF Checkpoint Kyiv is a testing facility, opened in July 2015 that provides free, low-threshold, walk-in HIV rapid testing, counselling and free condom provision. The data reviewed covers January 2016 -December 2017 when the marketing interventions were launched: 1. interactive website with locations of testing site and HIV facts (August 2016), 2. campaign "New love" targeting youth and MSM with 130 outdoor billboards in subway (August 2016) , 3. campaign "Knockout HIV" covering over 200 public transportation stops in Kyiv (June 2017).
Lessons learned: Overall in 2016 and 2017, 9,294 HIV rapid tests were performed at AHF Checkpoint Kyiv with 348 reactive cases and 3.7% positivity rate. During the period of both campaigns the number of visits to the new website exceeded 31,000 people, all of them spent over 2 minutes on the site focusing on testing site locations, condom use guide and HIV facts. With the launch of the campaigns the monthly average of tests performed doubled, from 169 (positivity rate 6,7%) to 399 tests (4.6%) after the first activation to 709 (2,4%) after second activation. 6,489 (70%) clients were first time testers. There were 266 (3.5%) positive results in this group. Young people (15-24 years of age) constituted 30% of all people who tested at the Checkpoint with 44 reactive cases (1.6%).

[AHF Checkpoint Kyiv testing results 01.16 - 12.17]

Conclusions/Next steps: Creative marketing has a potential to motivate people to get tested. The campaigns in Kyiv were effective in increasing numbers of people who test from key populations (MSM, IDUs) and general population including young people. Use of campaigns with positive and motivating messages could close the gap of undiagnosed in the region of EECA.

THPED385

Following the WHO new global guidance on the use of hormonal contraceptives among people at a high risk: What next for women at a substantial risk?

H. Nagadya
International Community of Women Living with HIV, Membership &Programs, Kampala, Uganda

Background: Women make up more than half of all people living with HIV worldwide, and they continue to bear the burden of new infections. Incidence rates vary by age and country. They are particularly high in adolescent girls and young women. The same women at risk of HIV need of a variety of reliable methods of contraception. In sub-Saharan Africa, fewer than 20 percent of women use a modern contraceptive method. A lot has been done to distribute condoms for dual protection against HIV and unwanted pregnancies, but many report inconsistency in condom use. Depo is widely used but there is possible risk of acquiring HIV when on it. Echo trials are on going to establish its safety. In March 2017 World Health Organization issued an updated guidance statement on its recommendations for the use of hormonal contraception by women at high risk of HIV. The new guidance upholds women´s right to informed choice when they access contraceptives.
Description: The International Community of Women Living with HIV Eastern Africa (ICWEA) organized a meeting with 30 sex workers between the age of 15-24 in Mukono District, Uganda aimed at sharing the new WHO recommendation on Depo for women at risk of acquiring HIV and Pre Exposure Prophlaxis (PrEP) as an HIV prevention method.
The sex workers were concerned that the results from the ECO trial to evaluate the impact of different family planning methods on HIV acquisition, may take long yet they have sex on a daily basis. They expressed need for PrEP because it is controlled by women.

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

Lessons learned: The demand for PrEP, in Uganda exceeds supply. Information on PrEP still remains scanty as only a few organizations focus on it. The WHO guidance is clear that women should have information as well as full access to the method of their choice, regardless of their HIV risk.
Conclusions/Next steps: Use of Hormonal Contraceptives in Uganda, especially Depo is high. Women therefore need to have full information on the possible risk of acquiring HIV when on Depo so they can make informed choice.

THPED386

Beliefs about HIV treatment-as-prevention among young adults in rural South Africa

J. Bor[1], J. Barofsky[2], D. Flanagan[3], T. Barnighausen[4]
[1]Boston University School of Public Health, Roxbury, United States, [2]Ideas42, New York, United States, [3]Boston University, Boston, United States, [4]University of Heidelberg, Heidelberg, Germany

Background: WHO recommends treating all HIV-infected people with antiretroviral therapy (ART) at diagnosis in order to reduce onward transmission of the virus. Yet uptake of ART among young adults is low, contributing to persistently high transmission rates. We hypothesized that young adults may not be aware of the prevention benefits of ART, leading to potentially sub-optimal uptake of ART.
Methods: We conducted a population-representative household survey of 425 young adults (ages 18-25) in rural KwaZulu-Natal, an area where one in three adults is HIV-infected. Using an innovative method to ascertain quantitative risk perceptions, we assessed young adults' beliefs about the HIV risk environment, including prevalence, survival, and infection risk. We asked about the risk of HIV transmission within a serodiscordant couple under different scenarios, and compared perceived transmission risks to objective risks in the literature.
Results: Young adults had largely accurate beliefs about HIV prevalence and the survival benefits of ART. However, they substantially underestimated the prevention benefits of ART. On average, young adults perceived an 82% annual incidence of HIV in serodiscordant couples where the HIV-infected partner was on virally-suppressive ART. Young adults perceived that consistent condom use would reduce infection risk by 71% relative to unprotected sex - close to published estimates. However, young adults perceived that ART would only reduce per annum incidence by 17%. Published estimates indicate >95% reduction in risk.
Conclusions: Young adults in rural South Africa are growing up in an HIV risk environment that differs dramatically from that faced by the previous generation. Treatment-as-prevention, in particular, offers an opportunity to substantially reduce HIV transmission. However, gaps in knowledge about the benefits of HIV treatment-as-prevention may limit the potential of policies aimed at increasing ART uptake. Further efforts are needed to disseminate this information.

THPED387

Beyond clinicians' recommendations: Understanding the underlying reasons for infant feeding choices among HIV-infected women in the Eastern Cape, South Africa

A. Ajayi[1], O. Adeniyi[2], M. Issah[1], O. Owolabi[1], D. Goon[1], S. Majambe[3], C. Carty[3], L. Sidloyi[3], J. Lambert[4], East London Prospective Study Group
[1]University of Fort Hare, East London, South Africa, [2]Walter Sisulu University, East London, South Africa, [3]Relevance Network, Johannesburg, South Africa, [4]University College, Dublin, Ireland

Background: Prevention of breast milk transmission is the next critical step in attaining the goal of elimination of mother-to-child transmission of HIV in South Africa. This study examines the feeding choices of peripartum women infected with HIV in the Eastern Cape, South Africa; and assesses the underlying reasons for their choices.
Methods: Drawing from the baseline data of the East London Prospective Cohort Study Database, 1709 mother-infant pairs enrolled across three large maternity facilities were interrogated on infant feeding choices in the Buffalo/Amathole districts. All HIV-infected women who gave birth between September 2015 - May 2016 with complete responses (N=1662) were included in the analysis. In addition, semi-structured interviews were conducted among 177 purposively selected participants to gain insights into the reasons for choosing their preferred infant feeding method. Descriptive and inferential statistics were used to summarise the quantitative data, while thematic analysis was performed on the qualitative data.
Results: The participants mean age was 29.63 (SD±6.2) years. Most participants were already diagnosed with HIV prior to the index pregnancy. The majority of the participants (80.3%) preferred to breastfeed their baby. There were no significant associations between demographic characteristics and infant feeding choices. Aside from clinicians' recommendations, perceived benefits of breastfeeding, fear of transmitting HIV to the baby, unaffordability of formula feeding, coercion, low milk supply/painful breast and need to return to work and school were the underlying reasons for infant feeding choices.
Conclusions: The majority of HIV-infected women chose to breastfeed their infants. Beside the clinicians' recommendations, the socio-economic and socio-cultural factors are the facilitators of breastfeeding among women in this setting. Retention and continuous engagement in care post-partum are crucial for elimination of breastfeeding transmission in the exposed infants.

THPED388

Shaping policy with science and stakeholders: Development and administration of a survey on U=U messaging in New York State

J. Morne[1], M. Brown[2], T. Hatton[2]
[1]New York State Department of Health, Director, AIDS Institute, Albany, United States, [2]New York State Department of Health, AIDS Institute, New York City, United States

Background: In September 2017, New York became the first state in the US to adopt the Prevention Access Campaign's Undetectable equals Untransmittable (U=U) consensus statement. The U=U concept, that PLWH with a sustained undetectable viral load cannot sexually transmit the virus to partners, provides a structure to advance positive messages that help to reduce stigma and reinforce retention in care strategies to end the HIV/AIDS epidemic in New York State. The New York State Department of Health AIDS Institute (NYSDOH AI) plans to initiate programmatic efforts and messaging to ensure the U=U concept becomes broadly known throughout the State.
Methods: The NYSDOH AI implemented a statewide online survey to assess knowledge and to guide development of U=U messaging among key stakeholders, including consumers, medical providers, advocates, health workers and others involved in HIV activities from all regions of New York. With 23 questions, the survey assessed awareness and attitudes regarding U=U, verbal and visual image preferences, and potential impact.
Results: Results from this U=U survey provide a framework for a successful policy initiative around HIV prevention and stigma reduction. There were 617 individual respondents, including 90 clinical providers. Responses indicated a high level of awareness and positive attitudes about U=U. Overall, most of the participants (84.4%) had heard of U=U before taking the survey, and over half (57.5%) were very confident in the U=U concept. There were clear preferences for certain messaging terms, visuals that include images of people, and a multifaceted outreach approach. Some regional and occupational variations emerged that indicate a need for targeted messaging as well as informational initiatives.
Conclusions: The survey results affirmed that Undetectable equals Untransmittable represents a social and scientific shift, with significant positive implications for PLWH, their service providers and communities. This key information will be used to develop a statewide U=U messaging campaign adapted to the cultural, geographic, and socioeconomic diversity of New York State. Results also support a possible 'diffusion curve' for accepting certain U=U concepts, and further investigations are needed to assess the ways medical providers discuss U=U with patients.

THPED389

Egocentric networks, HIV knowledge and status disclosure: Case of St. Petersburg

A. Suvorova[1,2], G. Syraeva[3], G. Uraeva[4], A. Sirotkin[2], R. Heimer[5]
[1]SPIIRAS, St.Petersburg, Russian Federation, [2]National Research University Higher School of Economics, St.Petersburg, Russian Federation, [3]St. Petersburg City AIDS Center Hospital, St. Petersburg, Russian Federation, [4]St. Petersburg State University, St.Petersburg, Russian Federation, [5]Yale University, New Haven, United States

Background: Russia is currently experiencing an increase in HIV incidence. St. Petersburg is one of the cities with the highest level of reported HIV prevalence, especially among the heterosexual population. Social context plays a key role in forming attitudes and behavior but there are few studies in Russia examining egocentric networks of people living with HIV (PLWH). This research aims to serve as a pilot study to examine associations between the different aspects of disclosure of HIV-positive status, sexual risk behaviors, and HIV-related knowledge among PLWH and members of their egocentric networks.
Methods: We conducted a cross-sectional study with 134 patients of St.Petersburg AIDS Center and 137 members of their egocentric networks. Each respondent could recruit up to three members of their networks but only 95 patients (71%) recruited at least one alter. All participants completed self-administered questionnaires. We compared patients with their alters separately for parents and peer alters (paired statistical tests).
Results: We identified that men were more likely to recruit friends, women recruited mainly family members. Patients who did not recruit anyone did not differ significantly from the rest part of the sample. Patients showed better knowledge of facts related to HIV-infection compared to their peers (median value of right answers 80% compared to 60% for the peers, Mann-Whitney U=914, p< 0.001) and compared to their parents (median value of right answers 70% compared to 60% for the parents, Mann-Whitney U=98.5, p=0.03). Patients had less casual sexual partners during the last 3 months (exact test p=0.03) than their peer alters. Those who disclosed their status to the parents had lower rates of risky sexual behaviors (0% vs 44% of not using condoms with casual partners, Fisher test p=0.03).
Conclusions: We found that peer alters had poorer HIV knowledge than patients and were more engaged in HIV risk behavior which could result in HIV transmission. These patterns could be related to stigma associated with HIV in Russia. Because network members share features with patients that put them at risk for HIV, it makes egocentric networks a focus for HIV prevention interventions.

HIV services in healthcare settings

THPED390

“I will give you medicine but your behavior is not worthy… …!” Exploring access to health services by transgender women, female sex workers and people who inject drugs in Malawi

V. Jumbe[1], G. Trapence[2], V. Gama[2], D. Kamba[2], L. Kapanda[3], A. Muula[3]
[1]University of Malawi, College of Medicine, Health Systems and Policy, Blantyre, Malawi, [2]CEDEP, Lilongwe, Malawi, [3]University of Malawi, College of Medicine, Public Health, Blantyre, Malawi

Background: Access to sexual and reproductive health services (SRHS) is the first critical step in achieving the triple 90s- an ambitious target by UNAIDS to have 90% of all people living with HIV know their status, 90% of all people diagnosed with HIV initiated on antiretroviral therapy (ART) and 90% of people on ART having viral suppression by 2020. However, access to SRHS is limited among key populations. The purpose of this study was to identify barriers and facilitators of access to SRHS among Transgender Women (TGWs), Female Sex Workers (FSW) and people who Inject Drugs (PIDs) in nine districts in Malawi. This is the first such study on PIDs ever conducted in Malawi.
Methods: This was a cross sectional qualitative study. Purposive and convenience sampling was used to recruit participants from Karonga, Mzuzu and Nkhatabay in the North; Mchinji, Lilongwe and Salima in the central and Mulanje, Blantyre and Mangochi districts in the south. Data analysis was done inductively following grounded theory procedures.
Results: A total of 49 in-depth interviews were conducted; 14 with PIDs, 18 with TGWs and 17 with FSWs. Across populations studied, structural factors such as criminalization (especially of drug use and same sex sexual practice), internal or experienced stigma and discrimination both in private and public settings including health care settings; unavailability or being unware of available health services; human rights violations were key barriers to accessing SRHS among key populations in this setting. Making SRHS available and change of negative attitudes among health care professionals were observed as key facilitators to access of services.
Conclusions: We suggest SRH issues focusing on key populations be introduced into curricula for health care professionals; training should be conducted with already working health care professionals on how to provide health care sensitive to the needs of key populations; mechanism to monitor the implementation of laws addressing social homophobia be implemented by Ministry of Health and key populations should be empowered by human rights focused NGOs to relentlessly pursue their right to health.

THPED391

Expanding access - saving the future: Taking HIV testing to village health facilities increased the access to pregnant women. Results from Global Fund supported AHANA project in 9 states of India

K. Biswas[1], R. KB[2], D. Nirwal[2], R. Mitra[3]
[1]Plan International (India Chapter), Monitoring & Evaluation, New Delhi, India, [2]Plan India, Monitoring & Evaluation, New Delhi, India, [3]Plan India, Programmes, New Delhi, India

Background: While India has made a significant progress in arresting and reversing the HIV epidemic, testing coverage for pregnant women remained very low. Evidence suggests access to HIV testing remained at 18% in the 218 priority districts of 9 identified states with an estimated annual pregnancies of 15 million per year. A strategy study carried out under Plan India's Ahana programme supported by The Global Fund to understand the access to HIV testing among pregnant women.
Description: A mixed method study was carried out in 29 districts of 9 states. 22 In-depth interviews and 58 FGDs were carried out with state and district level health officials and 888 pregnant women were interviewed through a structured interview schedule. Quantitative data was analysed using SPSS and qualitative data was analysed through a structured coding template.
Lessons learned: Findings from the study suggests that as the access to HIV testing has expanded to the district and village level population, HIV testing has increased from 18% to 69% among pregnant women during Oct, 15 to Oct, 17. There has been substantial increase in the public health facilities providing HIV testing services, in CHCs it has increased from 59% to 91%, in PHCs from 7% to 48% and in sub centre from 1% to 19%. Three fold approach; investing in the capacities of community health worker, procurement of Kits and managing supply chain of kits and consumables resulted in increasing coverage of pregnant women with HIV testing. PPTCT related knowledge remained at 98% among the community health workers and only 6% pregnant women concluded saying access of HIV testing is difficult.
Conclusions/Next steps: Increased access to HIV testing led to pregnant women accessing more HIV testing. As the testing services was made available in the peripheral public health units the HIV testing increased manifold. Plan India's Ahana project shows the pathway to how to rationalise the investment in the high load and priority districts with the measures of capacity enhancement and enhancing the supplies so that coverage increases from 18% to 69% within 24 months.

THPED392

Reasons for failed linkage to care across four facilities in Lusaka, Zambia

J. Pry[1,2], S. Gass[1], M. Herce[1,3], J. Chipungu[1], J. Kadota[1], C. Bolton[1,4], T. Savory[1]
[1]Centre for Infectious Disease Research Zambia, Lusaka, Zambia, [2]University of California Davis, Davis, United States, [3]University of North Carolina, School of Medicine, Chapel Hill, United States, [4]University of Alabama Birmingham, School of Medicine, Birmingham, United States

Background: The Centre for Infectious Disease Research Zambia (CIDRZ) routinely monitors progress toward 90/90/90 in 223 government health facilities across four Zambian provinces. HIV testing services (HTS) are provided through a number of entry points. Despite expanding access to HTS, recent estimates for linkage-to-care in Zambia are 50% at 12 months. To better describe the role of HTS entry point on ART initiation, reasons for incomplete linkage in Lusaka Province were analyzed.

Methods: A mixed methods approach was used to evaluate reasons for ART initiation refusal among a convenience sample of two urban and two rural ART clinics. All individuals with a HIV-positive test recorded 1 May—30 June, 2017 at the four clinics comprised the study population. Data was abstracted from hard copy HTS registers, with specific reasons for failed (within 60-90 days) linkage ascertained using a "Comment" field in the HTS register. Individuals were categorized as: 1) linked-to-care, with evidence of registration in the national HIV electronic medical record (SmartCare); 2) not linked-to-care, with no documented registration in SmartCare; and 3) refused care, in which care refusal was documented in the HTS register. Documented reasons for refusal were categorized by keyword(s).

Results: Of the 1,191 records reviewed, 583 (48.95%) were identified as linked-to-care, 487 (40.89%) as not linked-to-care, and 121 (10.16%) as refused care. Of those that refused, we identified seven reasons for care refusal (figure 1). Of the 99 who refused care and had complete documentation, the majority (68.5%) received HTS through unspecified provider-initiated testing and counseling (PITC). Unspecified PITC had the highest proportion of refusals across all entry points at 15.0% compared to 5.3% for those entering via voluntary counseling and testing and the maternal child health department. The most common reason for refused care included promising to return at a later time (12.4%) followed by needing to consult spouse (9.1%), cited mostly by women (91%).

Conclusions: A better understanding of the reasons for refusing treatment may inform efforts to reach 90/90/90 goals. Tracking linkage-to-care by testing entry point may provide insights for facility-level quality improvement and targeted interventions to promote ART acceptance and initiation.

Factor	Level	Linked, n (%)	Not Linked, n (%)	Refused, n (%)	p-value
Age, mean (SD)		31.85 (10.67)	30.71 (10.70)	30.59 (9.42)	0.23
Sex	Female	355 (61.60)	292 (60.00%)	72 (59.50	0.82
Sex	Male	221 (38.40)	195 (40.00)	49 (40.50)	0.82
Entry Point	VCT	170 (33.10)	136 (28.80)	17 (15.70)	<0.001
Entry Point	PITC	190 (37.00)	230 (48.60)	74 (68.50)	<0.001
Entry Point	Maternal Child Health	109 (21.20)	34 (7.20)	8 (7.40)	<0.001
Entry Point	Tuberculosis Clinic	9 (1.80)	9 (1.90)	0 (0.00)	<0.001
Entry Point	Other/Unspecified	36 (7.00)	64 (13.50)	9 (8.30)	<0.001

THPED393

Experiences of patients on the quality of service delivery influencing the uptake of antiretroviral treatment in South Africa

P.T. Simelane[1], A.Y. Amoateng[2]
[1]Northwest University, Demography and Population Studies, Durban, South Africa, [2]Northwest University, School of Research and Post Graduate Studies, Mafikeng, South Africa

Background: Patients' non-adherence to antiretroviral treatment (ART) is now being considered as one of the major obstacles facing public health institutions around the world. Service quality plays a vital role in ensuring patients adherence to ART. A worldwide survey of 59 ART clinics around the world by World Health Organization (WHO, 2016) discovered that poor service quality results into non-adherence to ART. The objective of this study is to ascertain the perspectives of patients on the quality of ART service delivery influencing the uptake of antiretroviral uptake in Piet Retief Wellness Centre, Mpumalanga Province, South Africa.

Methods: This qualitative study draws on 20 individuals, in-depth, face-to-face interviews with both males and females between the ages 15-49 years enrolled at Piet Retief Wellness Centre for ART between the period 2010 and 2014. The quasi-experimental design was utilised whereby both patients who defaulted (10 patients) treatment as well as who have not defaulted treatment (10 patients) formed part of the study. The interviews were 20 minutes on average. To analyse the data, interviews were audio-recorded, transcribed and analysed using thematic analysis and NVIVO 8 software.

Results: The results of the study highlights patients' experiences with regard to service quality influencing the uptake of ART services. Clear instructions from service providers and patients' knowledge about the benefits of ART adherence positively contributed to the uptake of ART. In addition to that, patients' adequate knowledge about the dangers of non-adherence to ART contributed positively to the uptake of ART. However, shortage of staff workers, negative attitude from health care providers as well as long waiting times negatively affected the uptake of ART thus resulting into ART poor service quality at Piet Retief Wellness Centre.

Conclusions: Although ART is readily available in health institutions around the country, poor service quality affect adherence to this life saving treatment. Interventions should aim to ensure that adequate staffing of health workers is put in place to limit long waiting times, psychosocial support should be provided to health workers on an on-going basis and long-term learning should be provided ART patients through community support groups (ART adherence groups).

THPED394

Healthy Mothers, safe babies: EMTCT through strengthening public health system: Result from plan India's Global fund supported Ahana project in 9 state of India

R. Kochukudiyil Balanpillai[1], K. Biswas[2], D. Nirwal[2], R. Mitra[2]
[1]Plan International (India Chapter), Monitoring and Evaluation, New Delhi, India, [2]Plan International (India Chapter), Programme Implementation, New Delhi, India

Background: An estimated 29 million pregnancies in India need to be annually screened for HIV so as to meet the goal for elimination of Mother to Child Transmission. The Government of India accord priority attention to EMTCT of HIV by 2020.The study showed that importance given for strengthening public health system and follow up for saving HIV exposed babies and healthy mothers. Plan International (India) implements Global Fund-supported PPTCT program (AHANA) in liaison with NHM and NACO in 218 priority districts of 9 Indian states to achieve the goal of eMTCT.

Methods: A mixed method study has been carried out to understand the state Level implementation strategies towards strengthening the health system and follow up. All together 888 pregnant women and 51 Positive Pregnant Women were interviewed, FGDs were carried out with ASHA and ANM. Detailed and desk research was carried out to understand the response system.

Results: Continuous capacity Building on PPTCT issues and methods of executing whole blood finger prick testing (WBFPT) provided to peripheral workers through AHANA for streamline HIV screening in periphery level. 32717 ANM got WBFPT training and 37267 ANM got training on PPTCT. Created awareness about PPTCT through Community Mobilization Meeting and Mid media activities There has been substantial scaling up of HIV testing facilities in the periphery level. 95% PPW linked to ART. Continuations follow up leads to safe delivery and timely service. As a result of multipronged strategy engaged by Plan India resulted in increased HIV coverage among pregnant women from 18% to 70%.
Conclusions: The study suggests that a continuous dialogue and collaboration resulted in increased capacities at the periphery level health worker, improved HIV kit supplies which sets the demand and supply equilibrium at a higher level. There has been increased awareness on the issues of PPTCT at the beneficiary and as well as at the service provider level, reduction in stigma observed with the outreach work carried out at the field with existing public health workers e.g. ASHA and ANM. As a result of continuous treatment mothers were healthy and continuous follow up till 18th months leads babies were negative.

THPED395

Improving pediatric HIV testing and counseling and linkage to care: A pilot in Uganda

J.K. Nabalonzi[1], G.T. Taasi[1], B.T. Tumwesigye[1], A. Kiyonga[2], E. Bitalakwate[2], J. Kose[3]
[1]Ministry of Health, AIDS Control Programme, Kampala, Uganda, [2]EGPAF, Clinical Services, Kampala, Uganda, [3]EGPAF, Research, Nairobi, Kenya

Background: In many facilities throughout Uganda, there is low uptake of pediatric HIV testing and counseling (HTC). Of those children who are tested and identified as HIV-infected at different entry points, linkage to care and treatment services is also often poor. Of those eligible for antiretroviral treatment (ART), only 57.6**%,** are currently receiving it.
Description: We conducted a pilot to enhance efforts to improve identification of HIV positive children through high-quality pediatric HTC services and the successful linkage of those children to care and treatment, while ensuring high quality of pediatric HTC services. It was implemented December 2014-July 2015, in 20 health facilities within in 5 districts targeting different levels of the health care system in Uganda. Key activities included: pediatric HTC aligning with the highest-risk populations, successful linkage to care and treatment services of those children who are tested and identified as HIV-infected, and use of Quality Improvement (QI) approach to ensure high quality services. The pilot process had 7 key steps namely; selection of the 5 districts and 20 sites; training health care providers; formation of QI teams at facility level, and monthly mentorship using QI approach.
Lessons learned: Comparing the 4 pilot districts performance access to paediatric HTS has generally improved from an average of 4.75% (at baseline - December 2014) to 47.2% as of June, 2015; with the highest district scoring 60% and the lowest 39%. All the 20 pilot health facilities have functional QI teams and actively QI running projects. Improved from 0% pediatric HTC QI projects to 100% (none of the HF had pediatric HTC projects prior to the pilot).
Conclusions/Next steps: Routine conducting of HTC among children at the different entry point of care like; Outpatient, Pediatrics inpatient, nutrition unit, Immunization Clinics; creates the opportunity to increase coverage of pediatrics HTC and has helped us identify all the positive children and linking them to care.

THPED396

Improved utilization of the national pediatric and adolescent HIV/AIDS/TB call center through targeted marketing: Lessons from Baylor-Uganda

F.F. Tendo[1], L. Engurat[2], J. Balungi Kanywa.[3], A. Kekitinwa[4]
[1]Baylor College of Medicine Children Foundation, Call Center, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Call Center, Kampala, Uganda, [3]Baylor College of Medicine Children's Foundation, Manager Medical Care, Kampala, Uganda, [4]Baylor College of Medicine Children's Foundation, Executive Director, Kampala, Uganda

Background: Real time consultation between health specialists and lower cadre health care providers who are front line workers in the communities through call centers can improve HIV/AIDS and TB clinical management skills to achieve the 90:90:90 goals especially in developing countries like Uganda. There is limited documentation on utilization of this approach and the strategies used to improve access by health workers in periphery health care facilities. We describe how the utilization of the National Pediatric and Adolescent Call Center at Baylor-Uganda by health workers was accelerated nationwide from 2015 to 2017.
Description: Following the Call Center inception in 2015, review of data showed that it was receiving about 20 calls per month from health workers. The marketing strategies used at that time were radio and television advertisements which fetched more calls from patients than the real intended audience of health workers. Using a continuous quality improvement approach, the call center team conducted targeted visits to the ART health facilities across the country. Onsite CMEs were conducted and individual weekly SMS reminders sent out to emphasize health workers' awareness. Monthly feedback on the calls was tracked through client satisfaction surveys using the Likert scale (0-10). Responses were categorized into promoters, passives and detractors after which, the Net promoter score (NPS) was calculated.
Lessons learned: Overall, the calls received from health workers increased from 20 to 400 per month from March 2016 to March 2017. The NPS improved from 60% in 2016 to 73.3% in 2017 from a sample of 187 feedback calls made.
The national call center coverage rose from 40% in September 2016 to 94% in September 2017 with calls from over 95 districts in Uganda. Knowledge gaps were identified from frequently asked questions and 47% of the calls indicated a gap in pediatric TB management.
Conclusions/Next steps: Utilization and awareness of the National Call Center for HIV/TB increased following innovative approaches like targeted health worker marketing and site team improvement strategies. The Call Center, as a tool, can identify knowledge gaps that can guide health implementing partners to prioritize key areas for training such as pediatric TB management.

THPED397

Understanding the experiences of adolescents living with HIV in the context of lay health worker service delivery in Swaziland

C. Ahmed[1], N.P. Dlamini[2], T.C. Dlamini[2], A. Nkambule[2], S. Nkambule[2], M. Calnan[2]
[1]Fulbright U.S. Student Program, Washington, DC, United States, [2]University Research Co, LLC, Mbabane, Swaziland

Background: There is a growing prevalence of adolescents living with HIV (ALHIV) and a rising dependence on lay health workers (LHWs) to deliver HIV services throughout sub-Saharan Africa (SSA). Hence, it is important to understand how ALHIV experience and perceive HIV services delivered by LHWs. Expert clients (ECs) are a cadre of LHWs who are living with HIV and are deployed through Swaziland's National Expert Client Program and are generally recognized for effectively engaging people living with HIV within the health care system. However, there have been no studies done to determine how ALHIV experience services delivered by ECs.
Methods: This study utilized a qualitative descriptive approach to:
1) understand the experience of receiving services from LHWs from the perspective of ALHIV and;

2) explore specific health care needs among ALHIV that are addressed through LHW service delivery in Swaziland. Four focus groups among ALHIV (ranging from age 10 and 20 years) and 21 semi-structured interviews among ECs and key informants were conducted in urban, rural, and peri-urban areas throughout Swaziland from April to May 2017.
Results: The semi-structured interviews and the focus groups reveal that ECs are a necessity for ALHIV because
1) ECs are people or adolescents who are also living with HIV,
2) ECs are role models and can share their health care experiences with ALHIV,
3) ALHIV feel comfortable around ECs because they are a trusted member of the community,
4) ECs encourage ALHIV to adhere to their medications through home visitations and peer support groups,
5) ECs play a crucial role in linking adolescents to HIV care and services,
6) ALHIV are able to interact with ALHIV outside of normal work hours,
7) ECs maintain strong relationships with ALHIV by providing psychosocial support,
8) ECs help health care providers improve clinical care,
9) ALHIV find that ECs are more approachable than are professional health workers, and
10) ECs work directly with professional health workers as well as the caregivers of ALHIV.
Conclusions: ECs are a valuable cadre in adolescent-specific HIV service delivery. Future research should focus on the impact that LHWs have on health outcomes among ALHIV in SSA.

THPED398

Preventing loss to follow up at health facilities during transitioning from pediatric to adult clinic by adolescents living with HIV

F. Umoh[1], O. Morolake[1], T. Oyedemi[2], A. Adegoke[1]
[1]Positive Action for Treatment Access (PATA), Program, Ikeja, Nigeria, [2]Positive Action for Treatment Access (PATA), Administration, Ikeja, Nigeria

Background: In Nigeria, children living with HIV are expected to transit to adult clinic at age 15 as most health facilities do not have adolescent specific clinics offering youth friendly services. This has resulted in loss to follow up of adolescents during the transition from paediatric to adult care. This abstract presents the effort of PATA to address this challenge and ensure retention in treatment for children moving to adult health facilities.
Description: This initiative involves intensive training for selected adolescents living with HIV as peer mentors and treatment educators. At the end of the training, they are supported over a designated period and placed in HIV clinics to provide transitioning treatment support who are transiting from pediatric to adult care. In partnership with treatment sites, clinic based adolescent support groups are also established to serves as platforms for team bonding, experience sharing and promotion of treatment adherence. During the monthly meetings of the support groups, sexuality education sessions are skills acquisition trainings are also carried out.
Lessons learned: Effective in reducing loss to follow up at facility level for adolescents living with HIV.. In just one year 725 adolescents were reached with adherence counseling and support services in 3 sites. Promotes engagement of young people in HIV response. Effective in sustaining clinic based support groups for adolescents 'as monthly meetings and sessions at support groups are coordinated by the adolescents. Reduces the time spent at clinics by the adolescents' who get prompt attention from their peers. Prevents facility based stigma and discrimination as the adolescents are attended to by their peers. Reduces the pressures of work on adult care givers
Conclusions/Next steps: Uptake of treatment services at facilities by adolescents is most successful with the active participation of the adolescents themselves. Adolescents living with HIV are willing to serve as peer mentors, treatment educators and stigma fighters for their peers. All they need is the strengthening of their capacity and creation of appropriate enabling environment.. We recommend active engagement of adolescents at the clinics to provide services for their peers.

THPED399

Identification of barriers and potential strategies to improve the performance of publicly-funded healthcare facilities for people living with HIV in Mexico: A mixed methods and user-centered approach

L. Chavira-Razo[1], L.F. Barraza-Araiza[1], A. Salas-Ortiz[1], G. La Hera-Fuentes[1], S. Bautista-Arredondo[1,2]
[1]National Institute of Public Health, Mexico, Health Economics, Cuernavaca, Mexico, [2]UC Berkeley, School of Public Health, Berkeley, United States

Background: Since 2003, Mexico offers universal access to free antiretroviral therapy (ART). However, only 34% of people living with HIV (PLWH) have an undetectable viral load. Most research to address this issue has focused on the individual determinants of poor health outcomes, yet little is known regarding the influence of the healthcare provision process in middle-income settings, where ART is available through a public network of health services.
Therefore, we aim to analyze the barriers that public HIV healthcare facilities face in Mexico, in order to identify key strategies to improve their performance.
Methods: From September to October 2017 we conducted 40 semi-structured interviews with healthcare providers in 12 Mexican cities. Additionally, we applied an online survey to 196 healthcare providers from a nationally representative sample. Interviews and surveys focused on the barriers that facilities face during the healthcare delivery process.
We used 'Design-thinking', a user-centered approach, to guide the identification of barriers and the building process of the strategies. Finally, we implemented a discourse analysis and triangulated it with the descriptive results of the surveys.
Results: We identified several barriers that the facilities face to provide optimal care, and categorized them into 4 levels of necessity:
1) Lack of basic resources, especially office supplies, human resources and medical equipment.
2) Need of resources to provide ART and clinical monitoring, such as transportation means for antiretroviral drugs and blood samples.
3) Lack of drugs and lab tests for comorbidities, including opportunistic infections. And
4) beyond the facility, mostly discrimination and rejection of patients at referral hospitals.
Finally, we identified two potential strategies to overcome these barriers: improving the communication channels between facilities and higher organizational levels in order to achieve a sustainable and effective resolution of needs; and strengthening the facilities' capacity to find local allies and enrich their networks, to temporarily overcome transportation and supply barriers.
Conclusions: Despite the immense advance in ART access in Mexico, several challenges in the healthcare provision process remain. In order to successfully address them, additionally to delving into the facilities' current obstacles, we need to further test and assess the feasibility and effectiveness of our proposed strategies.

THPED400

Healthcare providers' attitudes and willingness to prioritize HIV prevention and treatment for gay and transgender communities in Manila, Philippines: An opportunity for provider-focused interventions

A. Restar[1], R. Chan[1], P. Rodarte[1], S. Gomes[1], A. Adia[1], E. Yoshioka[1], L. Hernandez[2], D. Operario[1]
[1]Brown University, Department of Behavioral and Social Sciences, Providence, United States, [2]University of the Philippines, Manila, Philippines

Background: Gay and transgender youths who have sex with men (GTYSM, ages 18-29) are disproportionately impacted by the rising HIV epidemic in the Philippines, where HIV incidence has more than doubled in the past six years. In the UNAIDS' 2017 Global Report, 86% of new HIV cases are concentrated among GTYSM. However, little is known about healthcare provider's capacity to servicing these populations. We ex-

plored providers' attitudes and their perspectives on prioritizing delivery of HIV prevention and treatment services to GTYSM communities in Manila, Philippines.
Methods: Between July and August 2017, we conducted semi-structured qualitative interviews with healthcare providers (n=15) delivering HIV-related services in hospitals, clinics, and organizations in Manila. Using Dedoose qualitative software, interviews were transcribed and examined for attitudes and willingness in providing HIV-related services for GTYSM.
Results: Overall, healthcare providers displayed positive attitudes in welcoming GTYSM patients who are at-risk for or living with HIV in their practice. Most expressed treating every patient equally and providing services regardless of their patient's gender or sexual identity. However, many also expressed hesitancy in providing HIV-related services due to: little to no training in providing care specific to GTYSM, difficulty understanding the importance of being sensitive to patient's gender and sexuality when delivering services, and fear that targeted services with GTYSM's could lead to further stigmatization of these communities. Although most healthcare providers were unsure how to tailor and prioritize HIV-related services for GTYSM, some providers acknowledge the importance of engaging GTYSM communities in their practice, learning how to improve their services from GTYSM's perspectives, and expressed willingness for HIV-related trainings focused on providing gender affirmative and culturally sensitive care for GTYSM.
Conclusions: Healthcare providers are willing to deliver HIV-related services to GTYSM patients but unsure how to approach service delivery specifically and sensitively among these highly-impacted populations. Provider-focused interventions that train providers to improve their knowledge, skills, and attitudes on GTYSM' gender and sexual identities, as well as their familiarity and sensitivity with GTYSM's lived experiences and health needs, are likely to increase healthcare providers' engagement in delivering and prioritizing gender affirmative and culturally sensitive care for GTYSM in Manila.

THPED401

"There's More to HIV than a Pill": Operationalizing and measuring a harm reduction approach to HIV clinical care

M. Hawk[1], M.R. Friedman[2], R.W.S. Coulter[3], S. Creasy[1], J.E. Egan[1], S. Krier[2], S. Kinsky[4]
[1]University of Pittsburgh Graduate School of Public Health, Behavioral and Community Health Sciences, Pittsburgh, United States, [2]University of Pittsburgh Graduate School of Public Health, Infectious Diseases and Microbiology, Pittsburgh, United States, [3]University of Pittsburgh, School of Medicine, Pittsburgh, United States, [4]University of Pittsburgh Medical Center, Center for High Value Healthcare, Pittsburgh, United States

Background: Retention in care and adherence remain weak points in the HIV treatment continuum, especially among vulnerable and often-marginalized populations including those living in poverty. Harm reduction refers to interventions aimed at prioritizing the reduction of the negative effects of health behaviors without necessarily extinguishing or stigmatizing the problematic health behaviors. A harm reduction-informed approach to care may help to improve clinical outcomes among vulnerable patient populations.
Methods: To test associations between patient-perceived aspects of care and improved clinical outcomes we conducted a patient survey in an HIV clinic in a mid-sized city in the United States. We identified 3 items, assessed on a 5-point Likert scale, related to the harm reduction principles of humanism: respect; user-friendly, unhurried care; and clinic responsiveness. Multivariable linear regressions assessed differences in perceived clinic humanism by race, ethnicity, gender, and poverty status (n=177). Multivariable linear regressions controlling for sociodemographics assessed effects of perceived clinic humanism on
(a) medication adherence for participants using ART (n=154); and
(b) concurrent viral load result (n=177), via de-identified linkage to participants' electronic health records.
Structural equation models, adjusting for covariates, assessed total and indirect effects of perceived clinic humanism on relationships between poverty and ART adherence and poverty and viral load.
Results: Of sociodemographic predictors, only poverty status was associated with lower perceived clinic humanism (=0.65; $p< .05$). Lower perceived clinic humanism was significantly associated with lower ART adherence (= - 0.34; $p< .05$) and with higher viral load (=0.07; $p< .05$). Perceived clinic humanism significantly mediated the relationships between
(a) poverty and ART adherence ($p< .05$) and
(b) poverty and viral load ($p< .01$).
Building on these findings and on the extant literature, we developed a set of Harm Reduction Principles for Healthcare settings to operationalize this HIV care approach. These include humanism, pragmatism, individualism, autonomy, incrementalism, and accountability without termination.
Conclusions: We are currently developing two complementary scales to test patients' and providers' perceptions of the degree to which harm reduction-informed HIV care is delivered incorporating the full set of harm reduction principles. Additional research is needed to assess the impact of harm reduction-informed care on clinical outcomes of vulnerable PLWH.

THPED402

The effect of differentiated care interventions on the workload of facilities providing ART in Onandjokwe district in Northern Namibia

S. Geza[1], P. Kalimugogo[2], J. Mdala[2], P. McQuide[2], A. Nepela[3], R. Shipena[3], S. Omukongo[3], P. Kandume[4], F. Velishavo[2], A. Zegeye[5], N. Hamunime[3], G. Mazibuko[6], S. Mwinga[6], E. Sagwa[6]
[1]USAID HIV Clinical Services Technical Assistance Project, Windhoek, Namibia, [2]IntraHealth International, Windhoek, Namibia, [3]Ministry of Health and Social Services, Windhoek, Namibia, [4]IntraHealth Namibia, Windhoek, Namibia, [5]USAID, Windhoek, Namibia, [6]Management Sciences for Health, Windhoek, Namibia

Background: The Namibia Ministry of Health and Social Services (MOHSS) 2016 ART guidelines recommend implementing differentiated care models (DCM) for eligible stable clients. Stable clients required at least four clinical reviews per year, resulting in high workload and long waiting times at health facilities. In January 2018, IntraHealth International, with USAID funding, analyzed program data to ascertain the effects of implementing DCM on workload for district ART services.
Description: Onandjokwe district in northern Namibia has one hospital and 10 primary health care (PHC) facilities providing ART to over 11,000 clients. In June 2017 all facilities began planning for, or implementing, at least one of two DCM for eligible stable clients: fast-track ARV refills at facilities and community ARV refill groups (CARGs) that are linked to the nearest facility. In both models, clients receive ARV refills every three months and are seen semiannually. Data from January-December 2017 were sourced from facilities' electronic patient monitoring systems, electronic dispensing tools and facility reports and quantitatively analyzed in Excel.
Lessons learned: Seven of ten PHC facilities are providing ART to 4,605 clients of which 357 (7.8%) are in CARGs; two of these facilities are also providing fast-track ARV refills to 81 clients, which translates to 876 fewer visits per year. Onandjokwe hospital has 60 out of 6,107 clients (1%) in CARGs and 732 (12%) on fast-track ARV refills, together amounting to 1,584 fewer visits per year. A comparison of client visits in February and November 2017 revealed that six of the seven PHC facilities and the hospital saw 33% and 68% fewer clients, respectively, in November.
Conclusions/Next steps: Within six months of implementing DCM, Onandjokwe district is experiencing a reduction in ART-related workload. The hospital is experiencing faster decline because clients are also transferring to PHC facilities. The rate of CARGs enrollment and fast-track ARV refills is expected to intensify in 2018, resulting in significant further reductions in facilities' workloads. National HIV programs should continuously monitor and evaluate such interventions and use the findings to advocate for scale-up. Findings can be used to conduct workload analyses to support equitable distribution of scarce human resources.

HIV services in community settings

THPED403

Community-based HIV care and treatment: Differential care among stable key population positives in Ghana

S. Benefour[1], P. Tapsoba[1], T. Waimar[2], E. Adiibokah[1], A. Kodua Nyanor[3], E. Bruce[4], H. Nagai[3]
[1]Population Council, Accra, Ghana, [2]Population Council, New York, United States, [3]John Snow Inc., Accra, Ghana, [4]John Snoe Inc., Accra, Ghana

Background: ART delivery has essentially been concentrated in health care facilities in Ghana. The Ghana national ART guidelines, which is in line with the Treat All policy makes provision for all people living with HIV regardless of clinical and immunological status to initiate treatment. This shift calls for meeting diverse patient needs. Addressing the diverse needs of HIV positive key populations (KP) such as men who have sex with men (MSM) and female sex workers (FSWs) in care require proper segmentation to provide for the unique needs of KPs receiving ART for at least 1 year with no adverse drug reactions requiring regular monitoring, no current illnesses or pregnancy, a good understanding of lifelong adherence, and evidence of treatment success.
Description: The USAID Strengthening the Care Continuum project, implemented by JSI, aims to improve the Government of Ghana's capacity to provide quality and comprehensive HIV services for KPs and people living with HIV by improving their access to and use of HIV services while reducing stigma and discrimination in health settings. The project trained 61 Case Managers (CM) comprising 3.2% healthcare workers and 96.8% peer educators. CMs follow up on HIV positive persons who consent to be followed up. Feedback from peer review meetings and field visits reveal that stable patients prefer to do their refill at designated community spaces and CMs they trust instead of the clinic. At one Polyclinic in Accra, there are 48 HIV-positive MSM enrolled in care, 38 initiated on ART out of whom 30.0% collect their refill at home and designated community spaces.
Lessons learned:
- From the focus group discussions with HIV positive MSM and FSWs, 25% wanted their refill from CMs, 5% by family members, 50% by health care workers while 20% preferred clinicians.
- Stable patients doing their refill at designated community spaces help to decongest the clinics and allow providers to give more attention to patients with more complex conditions.

Conclusions/Next steps:
- Community-based distribution for stable patients can reduce clinic visits and improve adherence.
- HIV positive KPs facilitate the access of their stable peers to ART at homes and agreed upon community spaces.

THPED404

Outsiders, Insiders and Intermediaries: Village Health Teams' negotiation of roles to provide high quality HIV care in Nakaseke, Uganda

S. Perry[1], C. Fair[1], S. Burrowes[2], S.J. Holcombe[3], R. Kalyesubula[4]
[1]Elon University, Elon, United States, [2]Touro University, Vallejo, United States, [3]University of California, Berkeley, United States, [4]Makerere University School of Medicine, Kampala, Uganda

Background: In 2001, Uganda's Ministry of Health instituted Village Health Teams (VHTs) using community health workers, as a formal part of the health system to increase access to community-based care, including HIV prevention/treatment services. Tensions may emerge as VHTs navigate dual roles as community members and care providers, posing challenges for quality of care and VHT retention. This study explores the benefits and challenges experienced as VHTs' utilize dual roles to provide high-quality HIV care.
Methods: Twenty-five semi-structured interviews were conducted with one-third of the VHTs affiliated with a rural clinic in Nakaseke, Uganda in 2017. Interview questions focused on challenges VHTs face in providing services, and strategies for improving quality care. After translation from Luganda, the local language, and transcription, interviews were analyzed using grounded theory to identify emergent themes.
Results: The majority of VHTs were female (n=16), with a mean age of 45.5 years, and 11.1 mean years of VHT work. Three themes emerged around VHTs' perceptions of their roles: community insiders, professional outsiders, and intermediaries. All VHTs capitalized upon the duality of their position, shifting roles depending upon the challenges presented. A caregiver insider role facilitated their ability to build rapport and discuss sensitive issues such as HIV with clients. As community members, VHTs leveraged existing community structures to educate clients in familiar settings such as "drinking places", where they felt comfortable. However, this intimate role posed challenges as some clients hid their status, fearful that the VHT would break confidentiality. Occupying a professional outsider role offered some VHTs more respect. Their specialized knowledge allowed them to follow-up with patients - accompanying reluctant clients to testing, explaining medication, and ensuring ARV adherence. Some VHTs faced opposition, as patients were suspicious of their motives as government representatives. In balancing these two roles, the VHTs adopted a third as intermediaries, connecting the community to resources and services in the formalized health care system.
Conclusions: As countries continue to scale up HIV services in rural community settings using VHTs, supervision and training are critical so VHTs are prepared for the challenges of assuming multiple roles within their community. Ethical dilemma training is advised.

THPED405

Bridging the gap: Reaching men for HIV testing through religious congregations in rural South Africa

R.P.H. Peters[1,2,3], S. Khoza[1], R. Mbeng[4], G. Kerongo[4], N. Befula[4], N. Mbambazela[1], J. Railton[1], H.E. Struthers[1,5], P. Mabizela[4], J.A. McIntyre[1,6]
[1]Anova Health Institute, Johannesburg, South Africa, [2]University of Pretoria, Department of Medical Microbiology, Pretoria, South Africa, [3]Maastricht University Medical Centre, Department of Medical Microbiology, Maastricht, Netherlands, [4]International Network of Religious Leaders Living with or Personally Affected by HIV&AIDS (INERELA+), Johannesburg, South Africa, [5]University of Cape Town, Department of Medicine, Cape Town, South Africa, [6]University of Cape Town, School of Public Health & Family Medicine, Cape Town, South Africa

Background: Men are underrepresented in the HIV programmes in sub-Saharan Africa. In this region, religious congregations play an important role in daily life. Bridging the religious and health sectors could provide an opportunity to reach men who normally do not engage with health-care. We aim to determine the potential of reaching men for HIV testing through religious congregations.
Methods: We implemented an innovative model of building capacity in religious congregations to increase engagement with the HIV programme. Following training of religious leaders, a family-centred mobilisation approach was implemented with provision of general information about HIV during Church services and including specific male-focused messages. Following this mobilisation period, the programme was concluded on a designated Sunday when HIV testing services (HTS) were provided at the Church. In this cross-sectional study we collected gender/age-disaggregated operational data on uptake of HTS services among church attendants.
Results: To conclude the capacity building programme, we provided HTS at 27 religious congregations with an estimated attendant population of 5250 individuals over a 15-months period in rural Mopani District, South Africa. A total of 1971 individuals attended the Church service on designated HTS days; 1416 (72%) of the attendants were female and 555 (28%) were male, with a median age of 32 years. HTS uptake by men (52%) was significantly higher than by women (40%; $p < 0.001$). A large proportion of men (35%) reported testing for HIV for the first time; this was significantly higher than reported by women (18%; $p < 0.001$). HIV test positivity rate was in a similar range for men and women (2.1% vs. 3.7%; $p=0.21$). Men testing HIV-positive at the Church were all >40 years old (median 50 years; range 41-64 years).
Conclusions: This innovative approach was successful in reaching a relatively large group of (older) men with unknown HIV status that has not engaged with HIV testing services before. Male uptake of HIV test-

ing was good with an HIV positivity rate in similar range to that of other community-based testing activities in this region. We have demonstrated promise of connecting religious and health sectors to improve male engagement with the HIV programme in rural African settings.

THPED406

Using m-counseling to increase linkage into care among HIV positive men who self test. A TASO Masindi experience

M. Nanfuka[1], A. Choko[2], A. Kisembo[1], J. Birungi[1], S. Helleringer[3]
[1]The AIDS Support Organisation, Kampala, Uganda, [2]Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [3]Bloomberg School of Public Health, John Hopkins University, Baltimore, United States

Background: HIV self testing is a strategy that has been employed to increase the number of people who know their HIV status. However linkage of people who test positive following self testing still remains a big challenge towards the attainment of the second and the third UNAIDS 90s.
We used the peer to peer distribution of HIV self test kits among fishermen and m-counseling to improve on the linkage into care for those who tested HIV positive.
Methods: Through the TASO expert clients, we identified fishermen who were in care and those who had never for HIV in the last one year.
These men were trained on the usage of the kit, given basic HIV counseling skills and information. Each fisherman received 5 kits, instruction leaflet and a number for a counselor for distribution to their fellow fishermen. Participants who received the kits were encouraged to call the counselor in case they needed more information and counseling . On calling, the counselor provided online counseling and encouraged the participants to return the used kits to the health facility.
Results: 19 fishermen of whom 10 were HIV positive and in care and 9 hadn't tested in the last one year approached 115 fishermen and 95 accepted to self -test . 4 out of 95 men were HIV positive, of whom 3 first called the counselor immediately after testing and shared their results. All the three were counseled on phone and encouraged to go to the health facility for confirmatory testing and were all linked into care. 1 out of the 4 who tested positive already knew his HIV status and was already on ART and this information was provided to the counselor on phone who confirmed that he was already linked into care.
Conclusions: Through m-counseling HIV positive men were influenced to go to a nearby facility for confirmation of results and linkage into care. Therefore in self-testing programs m-counseling replaces the convention counseling and contributes to linkage of HIV positive persons into care.

THPED407

Index partner testing in the community key to identifying new people living with HIV (PLHIV)

C. Pheko, B. Mantu, G. Morineau, B. Segwabanyane, J.M. Irige, O. Sokwe, C. Lesedi
FHI 360 Botswana, Advancing Partners and Communities (APC), Gaborone, Botswana

Background: According to UNAIDS (2017), 85% of people living with HIV (PLHIV) in Botswana know their HIV status. The Advancing Partners and Communities (APC) project in Botswana, funded by PEPFAR through USAID, is implementing targeted HIV testing services (HTS) to identify the remaining PLHIV who are unaware of their status, placing emphasis on index partner testing to offer HIV testing to sexual contacts of PLHIV.
Description: HTS training was provided to lay HTS counsellors in collaboration with the Ministry of Health and Wellness. APC developed standard operating procedures on targeted HIV testing to guide HTS counselors on strategies to obtain contact information of sexual partners from PLHIV newly identified through community testing. HTS counsellors were provided mobile phones, data bundles and local transport fare to facilitate reaching index partners of newly identified PLHIV and PLHIV who were new on antiretroviral treatment for testing.
Lessons learned: All targeted testing modalities have potential to identify new PLHIV, however, HIV prevalence among those tested through index partner testing was substantially higher than among those tested through other strategies. From October 2016 to September 2017, the APC project tested 32,382 people for HIV and identified 2,012 PLHIV (6.2%). 3,365 people were tested through index partner testing,17% of whom tested HIV positive. Out of 17,574 clients tested through targeted in-home testing, 6% tested HIV positive. Three percent of people tested through targeted mobile and community based VCT tested positive among the 10,481 and 962 people tested, respectively. Index partner testing was resource-intensive and time-consuming; repeated visits are often required to obtain partners' information from newly identified PLHIV.
Conclusions/Next steps: Index partner testing is an effective strategy to identify new PLHIV. Index partner testing should be incorporated into the national strategy to identify undiagnosed PLHIV, link them to HIV care and treatment, and prevent further new HIV infections in Botswana. Advocacy at national level for resources allocation towards index partner testing will enable scaling-up index partner testing through the set-up of a partnership between community and health facility service providers.

THPED408

Food security and nutrition vulnerability assessment among people living with HIV in South Sudan

J. Mukisa[1], D. Nabiwemba-Bushara[2], R. Smith[3], D. Aburmishan[3], L.L. Lole[4], E. Letio[5]
[1]World Food Programme, Nutrition, Juba, South Sudan, [2]UNICEF, Nairobi, South Sudan, [3]World Food Programme, Juba, South Sudan, [4]South Sudan Network of People Living with HIV and AIDS, Juba, South Sudan, [5]Network of Positive Women United, Juba, South Sudan

Background: South Sudan ranks among top 30 countries in the world which account for 89% of new HIV infections. Households of People living with HIV (PLHIV) are among those most affected by the persistent conflict, displacements, poverty, food insecurity and malnutrition in the country. The United Nations World Food Programme (WFP) supports a nationwide institutional feeding programme (IFP) for PLHIV but there was no reliable information on their food security and nutrition situation. The vulnerability assessment was conducted to provide reliable national data on food security and nutrition among households affected by HIV in order to inform appropriate responses.
Methods: Qualitative and quantitative data was collected from 933 households of PLHIV (aged 15 years and above) in 7 of the 10 former states of South Sudan, using a two stage cluster sampling method. The Consolidated Approach to Reporting Indicators for food security (CARI) was used to measure the degree of food insecurity. The nutrition status of 942 PLHIV was assessed using Body Mass Index (BMI) and Mid Upper Arm Circumference (MUAC).
Results: Majority of the household heads (77.2%) were PLHIV, 45% were headed by women and 41% households were food insecure. A significant proportion of households (60%) relied on unsustainable sources of food including remittances, begging and the sale of natural resources and alcoholic beverages. One in three PLHIV households consumed less than the recommended four food groups. The factors affecting food security included: nutrition and health status of PLHIV, ability to engage in agriculture, stigma and discrimination. The prevalence of acute malnutrition among PLHIV based on BMI was 26.2% and 19.7% based on MUAC. The risk of malnutrition was significantly higher among female headed households, those hosting an orphan or with a lower wealth index.
Conclusions: The food security and nutrition situation of PLHIV in South Sudan is alarming. PLHIV headed households had an increased risk of food insecurity. Special consideration should be made to provide food and nutrition support for PLHIV on ART and those with limited workability. The findings triggered a revision of the WFP HIV/AIDS nutrition strategy which is now aligned with national and global policies.

THPED409

Improving referrals from health facilities to community based structures: Strategies used to improve referrals in the Rwenzori Region in Uganda

S. Amodot, A. Kekitiinwa, R. Kizito, A. Lutaaya
Baylor College of Medicine Children's Foundation-Uganda, Health, Kampala, Uganda

Background: Achieving the UNAIDS 90-90-90 targets calls for the adoption of innovative and efficient strategies for delivering HIV and prevention, care, and treatment services. Baylor-Uganda developed a referral and linkage strategy to improve access to comprehensive HIV/AIDS/TB services as well as other wrap around services. The strategy focuses on strengthening bi-directional referrals. While referrals from the community to the facility were high, the referrals from the health facilities remained low in the Rwenzori Region. Strategies were implemented with the aim of increasing the number of referrals from the health facilities to the communities.

Methods: We convened a District based re-orientation meeting to review jointly the strategy. The meeting was also an opportunity to discuss and understand why fewer referrals from the health facilities. Causes were identified and joint action plans developed jointly by community structures and health facilities mapped out in their catchment areas. Notable causes included health workers not aware of services to refer, poor documentation of referrals and lack of knowledge on the model. Strategies developed included pinning up referral services in the health facilities, CMEs, on-site mentorship, coaching, monthly review meetings, health facility focal persons to create demand and timely updating of the linkage and referral register.

Results: Referrals in October, 2016 were 851 with a completion rate of 67% and with the strategies there has been gradual improvement to 5,233 (92% completion) in December, 2017.

Community referrals have contributed to improved Retention rates of 91% for ART clients for eMTCT and reduced Loss to follow up from 6% to 4% attributed to functionality of the community health facility linkage and referral process.

Conclusions: Strengthening the referral and Linkage model is critical in attaining the 90:90:90 goal as well as increase demand and utilization of HIV services at community level.

THPED410

Improving linkages and retention for TB clients through community health workers: A case study of Rwenzori, Uganda

S. Amodot, A. Kekitiinwa, A. Mukuye, A. Lutaaya
Baylor College of Medicine Children's Foundation Uganda, Health, Kampala, Uganda

Background: Over all Tuber culosis (TB) prevalence is 253/100,000 approximately 87,000 new cases occurring every year (Uganda National Tuberculosis Prevalence survey, 2015). Despite the high prevalence, there is minimal integration of interventions delivered by community structures into the existing formal health system. Community health workers (CHWs) have been considered as a key pillar in attainment of the UNAIDS 90-90-90 targets as well as the STOP-TB strategy. Uganda has embraced the use of CHWs in improving health care service delivery. Baylor-Uganda within its community framework model has used CHWs to assess their role towards timely linkages and TB retention rates in health facilities with Rwenzori region, Uganda.

Description: In 2016, Baylor-Uganda initiated a community framework model in reaching the 90:90:90 target. 289 CHWs were selected in the community through the District Health office and trained in Comprehensive HIV Care for 6 days using a tailored curriculum. A follow on onsite mentorship was conducted.

Outcomes of interest include retention of clients undergoing the TB treatment for a period of 12 months and timely Linkage for referrals made from the community to the facility for presumptive TB cases.

The TB program within Baylor-uganda in Rwenzori, embraced and utilized the community framework model to improve referral, linkage and retention. Data collected was collected over a period of 12 months from October, 2016 to October, 2017 and data was descriptively analyzed using excel.

Lessons learned: Linkage of TB clients to Community health workers and emphasis on monthly reporting greatly led to improvement of TB loss to follow up. There was a notable drop in Loss To Follow Up Kyenjojo dropped from 21% to 3%; Kamwenge from 6% to 2% and Kabarole from 13% to 2% for the period December 2016 and September, 2017.

Conclusions/Next steps: Community health workers when fully engaged improve identification, linkage to health facility for TB diagnosis and retention in care for those tested positive.

THPED411

Pathway to improved health outcomes and graduation of orphans and vulnerable children in the context of a generalized HIV/AIDS epidemic. Experience from Swaziland Umliba Loya Embili project

D. Kisyombe[1], N. Miller[2], J. Volle[3], E. Kuhlik[3], B. Ginindza[1], L. Huang[4]
[1]Pact Inc., Monitoring and Evaluation, Mbabane, Swaziland, [2]Pact Inc, Program Delivery, Mbabane, Swaziland, [3]Pact Inc, Program Advancement, Washington DC, United States, [4]Georgetown University, Washington DC, United States

Background: Pact's USAID-funded REACH III (2015-2018) project is designed to respond to the HIV prevention and impact mitigation needs of vulnerable populations in Swaziland. In 2015, Pact conducted a vulnerability assessment of adolescents (10-19 years) to determine enrollment eligibility and service needs of orphans and vulnerable children (OVC). Based on the results of the vulnerability assessment REACH III tailors services to OVC in the areas of HIV/health, education, household economic strengthening, child protection, and psychological support. The assessment also acts as a mechanism for monitoring the level of OVC vulnerability and determining the appropriate time for graduation from the program.

Methods: The baseline and follow-up vulnerability assessments were conducted with a cohort of OVC (n=18,042) and their caregivers in 2016 and 2017. The assessment scores and ranks vulnerability into three categories: most vulnerable (qualified for OVC and HIV prevention and/or care and treatment services); at risk of becoming OVC (qualified for HIV prevention services); and good wellbeing. Descriptive analyses and the Stuart-Maxwell test were conducted in Stata to determine statistically significant differences between enrollment and reassessment. Cohen's kappa analyzed inter-rater reliability.

Results: The Stuart-Maxwell test yielded statistically significant (p=0.00) change in the OVC vulnerability, with 10.2% of OVC shifting from the "most vulnerable" category at enrollment up to "at risk" at follow-up. Fifty-five percent of OVC who did not disclose their HIV status at enrollment reported being HIV-negative at reassessment, and 15.7% of OVC remained HIV-negative at reassessment. Self-reported VMMC rates climbed 9.1% at reassessment.

The cohort also saw statistically significant improvements in OVC school enrollment, attendance, and progression, and household economic security at follow-up over baseline.

Conclusions: The results demonstrate that providing a tailored package of services to OVC based on a vulnerability assessment is associated with decreased vulnerabilities and improved social and health outcomes for OVC, which leads to OVC graduation from support programs. The results also suggest that OVC support services and demand creation services at the household level over time may lead to HIV status disclosure, as well as increased uptake of health and HIV services, including VMMC, HIV testing services and linkages to care and treatment services.

THPED412

Achieving viral load suppression for men who sell sex to men (MSM/MSW) in Nairobi: A community led and centered approach

P. Irungu[1], E. Ndunda[2], J. Mathenge[2], P. Angote[3]
[1]Health Options for Young Men on HIV/AIDS/STIs, Monitoring, Evaluation, Research, Advocacy and Learning, Nairobi, Kenya, [2]Health Options for Young Men on HIV/AIDS/STIs, Program Management, Nairobi, Kenya, [3]Health Options for Young Men on HIV/AIDS/STIs, Clinical Services Lead, Nairobi, Kenya

Background: HOYMAS is registered as a CBO in Nairobi which has contributed remarkably towards progressive improvements in the number of MSM/MSW accessing HIV and STI prevention services, treatment and care services through networking with government led clinics and the community led comprehensive services clinic to provide services to 4500MSM/MSW.
Description: Since 2015, HOYMAS runs the community led clinic where HIV/AIDS prevention, treatment, and care services are offered. Peer educators conduct outreach and community mobilization activities to bring HTC services closer to clients as well as refer others to the clinic.
In addition, the HOYMAS community drop in centre continues to attract positive MSM for services including:
Support groups and Encounter groups where positive MSM supported each other and developed messaging to reach out other positive peers who are not yet in care, share experiences with ARV medication, side effects, disclosure and sex work.
Other innovations that have ensured that MSM are retained on care include utilizing Social media, including WhatsApp and Facebook to keep engaging the positive MSM who join support groups, continuous Peer and sex education that is offered through IEC materials, daily health education forums in the drop in centre, continuous Phone reminders by the clinician and improving relationships with strategic partners who provide a referral point for viral load testing for our patients.
As a result these activities and establishment of the HOYMAS community led clinic, 84 MSM/MSW received VL testing with 79 achieving VL suppression in the year 2017 and an improvement in turnaround time in VL results (from 6months to 2 weeks) through working with strategic partners.
Lessons learned: Social media engagement is key in ensuring people understand the importance of adherence, building strategic partnerships is key for grass root organizations who cannot provide all services across the 90-90-90 continuum of care, letting the HIV+ KP design and lead their own support groups and sharing forums is instrumental in reaching and maintaining the 3rd 90%.
Conclusions/Next steps: Continue utilizing social media for complementing the physical support and encounter groups, enhance peer education through continuous community outreaches and create more strategic and referral partners with donors and government.

THPED413

Virtual outreach finds hard-to-reach HIV+ MSM in Cambodia

P. Sophat[1], L. vanSeng[2], T. Samnang[3], S. Sokhin[4], N. Bora[5], K. Sothy[6], K. Vichet[7], S. Sopheap[8], R. Sopha[9]
[1]FHI360, Prevention Innovation in MSM and TG, Phnom Penh, Cambodia, [2]National Center for HIV/AIDS, Dermatology and STD, HIV/AID Prevention, Phnom Penh, Cambodia, [3]NCHADS, Behavioral Communication Change, Phnom Penh, Cambodia, [4]MHSS, Prevention Innovation in MSM and TG, Phnom Penh, Cambodia, [5]National Center for HIV/AIDS, Dermatology and STD, Care and Treatment, Phnom Penh, Cambodia, [6]Men's Health Social Service, Virtual Outreach Online for HIV Testing, Phnom Penh, Cambodia, [7]Men's Health Cambodia, Virtual Outreach Online for HIV Testing, Phnom Penh, Cambodia, [8]FHI360, LINKAGES, Phnom Penh, Cambodia, [9]KHANA, Flagship, Phnom Penh, Cambodia

Background: HIV prevalence among men who have sex with men (MSM) in Cambodia is estimated at 2.3%, but this low prevalence belies substantial risk and potentially high HIV incidence in this population. Despite numerous and diverse peer outreach and web-based interventions, a majority of MSM report low intervention exposure and HIV testing rates. Finding high-risk MSM in conventional outreach has proven challenging. Of 5,610 MSM reached by conventional outreach in 2015, 3,674 agreed to testing but only 27 were found HIV positive (0.73%).
Description: To find men actively seeking sexual partners online and presumed to be at higher risk, LINKAGES recruited communicators among local MSM NGOs to conduct virtual outreach online. Communicators broadcast messages to potential MSM clients online in chat rooms and on MSM dating sites. Messages include HIV prevention themes, including consistent condom use, HIV/STI risk reduction, and the importance of early testing and treatment. MSM who had not been previously tested were encouraged to come to an NGO drop-in center (DIC) to meet a peer counselor who would do a finger-prick combined HIV and syphilis test. If reactive for HIV and/or syphilis, the counselor accompanied them for confirmatory testing at the local Chouk Sar KP friendly clinic.
Lessons learned: Between November 2016-December 2017, 1,750 MSM were reached by virtual outreach, of which 354 (20.2%) accepted screening at the DIC. Of these 354, 26 (7.35%) were found HIV reactive, 10 times the yield via conventional outreach. Of these 354, 20 (5.7%) were syphilis reactive. All who were HIV reactive were successfully referred for confirmatory HIV testing, and all were enrolled in pre-ART. Those who had positive syphilis serology or STI symptoms were successfully referred to treatment.
Conclusions/Next steps: This intervention showed a 10-fold increase in yield compared to conventional outreach, demonstrating that virtual outreach for MSM can be used to reach high-risk and hard-to-reach MSM not reached or tested by traditional outreach. Further strengthening of the online outreach counseling to increase the proportion of clients willing to participate in facility-based screening or self-testing should be pursued.

THPED414

What are socio-demographic characteristics associated with uncollected HIV test results among caregivers of orphaned and vulnerable children in Tanzania?

A. Exavery[1], A. Barankena[2], J. Charles[1]
[1]Pact/Tanzania, MERL, Dar es Salaam, Tanzania, United Republic of, [2]Pact/Tanzania, Programs, Dar es Salaam, Tanzania, United Republic of

Background: Realization of the ambitious 90-90-90 target to end the HIV epidemic depends hugely on the success of the first 90 that targets to have 90% of all people living with HIV knowing their HIV status by 2020. This analysis assesses the magnitude and characteristics of caregivers of orphaned and vulnerable children (OVC) who tested for HIV but never showed up to received their test results in Tanzania.
Methods: Data originate from a community-based, USAID-funded *Kizazi Kipya* Project that seeks to increase uptake of HIV/AIDS services by OVC and their caregivers in Tanzania. Caregivers who were served by the project during January-March 2017 in 18 regions of Tanzania with complete information on their HIV status, household socioeconomic status and socio-demographic characteristics were analyzed. HIV status was self-reported. Multilevel mixed-effects logistic regression was performed, with those that tested for HIV but did not receive test results forming the outcome.
Results: The analysis included 59,683 caregivers of OVC, 71.2% of whom were females and the rest males. Of this, 37.2% (n=22,186) reported that they tested for HIV but never waited to receive test results. The rest received their test results, whereby 44.6% and 18.2% were HIV negative and positive respectively. Multivariate analysis showed that fleeing HIV test results was significantly higher among males than females (OR=1.21, 95% CI 1.15-1.27), singles (OR=1.13, 95% CI 1.04-1.24) and widows/widowers (OR=1.12, 95% CI 1.07-1.18) than married, those without health insurance (OR=1.38, 95% CI 1.30-1.47) and age 61+ than 18-30 (OR=1.72, 95% CI 1.58-1.88). Better education and wealth status were protective factors ($P < 0.001$).
Conclusions: An outstanding number of caregivers who test for HIV flee test results, suggesting lack of confidence in unpleasant results, thus a missed opportunity for timely care and treatment services for those that may be infected. While better education, economic strengthening

and expanding health insurance coverage appear imperative aspects to improve uptake of HIV test results, an attention is needed for men, the unmarried and the elderly.

Sero-adaptive behaviours: preference, practice, and impact

THPED415

HIV serostatus disclosure to sexual partners and HIV sexual risk behavior among people living with HIV in Botswana: Population-based household survey

K.P.C. Manyake[1], K.E. Wirth[2], M. Pretorius Holme[2], E. Kadima[1], T. Sekoto[1], J. Leinder[3], K. Powis[1,2], K. Bennett[4], M. Mmalane[1], R. Lebelonyane[5], T. Gaolathe[1], J. Makhema[1,2], M. Essex[1,2], S. Lockman[1,2,6,7], S. Moyo[1,2]
[1]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]Goodtables Data Consulting, LLC, Norman, United States, [4]Bennett Statistical Consulting, Ballston Lake, United States, [5]Ministry of Health and Wellness, Gaborone, Botswana, [6]Harvard Medical School, Boston, United States, [7]Brigham and Women's Hospital, Department of Medicine, Division of Infectious Diseases, Boston, United States

Background: Disclosure of positive HIV status to sexual partners is essential for optimizing prevention, and has been associated with greater engagement in HIV care and treatment. We investigated the association between non-disclosure of HIV positive status and sexual risk behavior among sexually active participants in an ongoing HIV prevention study, the Botswana Combination Prevention Project (BCPP).

Methods: In BCPP, we enrolled a random, population-based sample of adults aged 16-64 years in 30 rural and peri-urban communities in a prospective study. At enrollment participants were administered structured questionnaires, including questions about HIV sero-status disclosure to sexual partners over the prior 12 months and sexual risk behavior [inconsistent condom use, alcohol use, multiple concurrent partnerships (MCP)].

We analyzed responses from participants who knew their positive HIV serostatus at the time of the initial survey, and who reported being sexually active during the prior 12 months. HIV sero-status non-disclosure was defined as non-disclosure to at least one sexual partner. We estimated prevalence ratios (PRs) and 95% confidence intervals (CIs) for demographic, HIV sexual risk, and clinical (ART use and viral suppression) factors associated with non-disclosure, adjusting for community clustering, age and gender.

Results: Among 2270 participants who reported being sexually active in the past 12 months and who already knew their positive HIV status, 2192 (96.6%) had available data on HIV disclosure to their sexual partner. The proportion of participants who reported not disclosing was 7.9% (95.0%CI:6.8-9.1). Individuals who reported non-disclosure were significantly younger, more likely to be single / never married (PR=5.4;95%CI:3.0-9.5) or divorced / widowed (PR=5.3;95%CI:2.7-10.5) and with tertiary education (PR=2.1; 95% CI:1.21-3.5).

Non-disclosure was associated with MCPs (PR=2.6;95%CI:1.9-3.5). Not yet initiating ART was associated with non-disclosure (PR=0.50; 95%CI:0.35-0.74). A long-term relationship was associated with lower rate of non-disclosure (PR=0.38;0.29-0.50).

Conclusions: Individuals who did not disclose their positive HIV status were younger, had higher education and non-long-term partners. Those at high risk of forward HIV transmission, including those engaging in MCPs and those not on ART were significantly less likely to disclose their HIV status to a sexual partner, highlighting the importance of programming that successfully results in behavior change in high-risk populations.

Tetanus toxoid vaccination-PrePex active surveillance cascade in Zambia

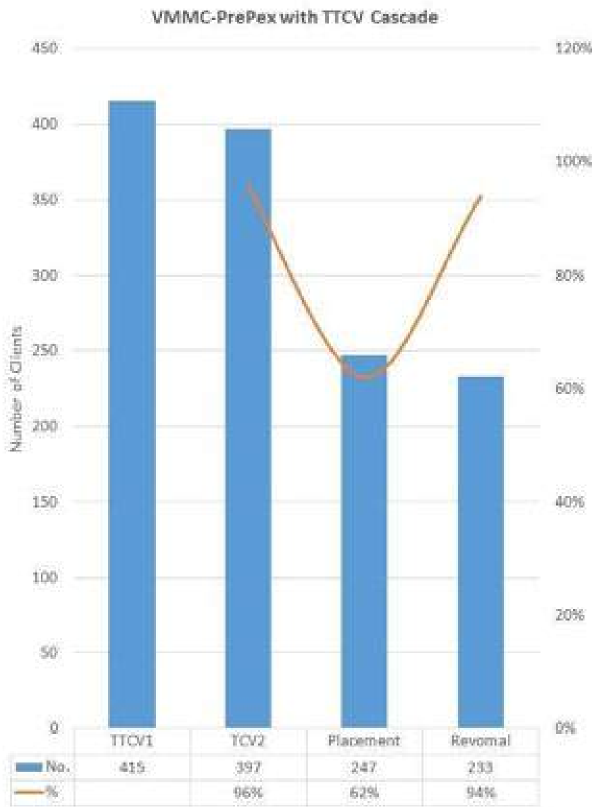
M. Namukoko[1], N. Nyirongo[1], O. Chituwo[2], H. Sichinga[1], J. Siachobe[1], J. Zulu[3], K. Asiedu[1], L. Aladesanmi[1], J. Banda[1], N. Zulu[1]
[1]Jhpiego, Lusaka, Zambia, [2]Centre for Disease Control, Lusaka, Zambia, [3]Ministry of Health Zambia, Lusaka, Zambia

Background: WHO prequalified the PrePex circumcision device in May 2013 for males 13 years and above. After a pilot in Zambia in 2014, active adverse event (AE) surveillance to further evaluate the device commenced in June 2016. However, it was halted in July based on WHO's recommendation of completed tetanus toxoid containing vaccine (TTCV) vaccination, at least 2 weeks prior to device placement. Active surveillance was restarted with TTCV in May 2017 by the Government of Zambia.

Description: Since April 2015, Jhpiego has been implementing a 5-year PEPFAR/CDC funded project that aims to increase male circumcision (MC) coverage to 80% in supported districts. In addition to MC provided by conventional surgical methods. Jhpiego is also supporting the Ministry of Health (MoH) to implement PrePex active AE surveillance.

Lessons learned:
Surveillance records from May 2017 to September 2017 were reviewed. 415 clients received the 1st TTCV vaccination, 397/415 (96%) received the 2nd dose, 247/397 (62%) had the device placed, 233/247 (94%) had the device successfully removed. The major point where clients discontinued was after the 2nd TTCV vaccination. Among reasons cited for deciding to forego PrePex circumcision after completing TTCV vaccination included testing HIV-positive as part of device placement screening or no longer wishing to wait for circumcision by the PrePex device method. In this cohort of clients there were no AEs.

Conclusions/Next steps: The completion rate observed is 56% (233/415) from first TTCV vaccination to device removal, with most clients lost to follow-up after the second TTCV dose. Demand generation activities are also being tailored with more TTCV specific communication to address these potential challenges, the project is also implementing additional follow up calls and visits after the second TTCV dose. In addition, the program has implemented a dual HIV testing process at first TTCV and just before placement.



[VMMC-PrePex with TTCV Cascade]

THPED417

The remaining 37%: How male circumcision (MC) in Zambia is contributing to the first 90

L. Aladesanmi[1], J. Banda[1], J. Zulu[2], O. Chituwo[3], K. Asiedu[1], M. Nyambe[1], C. Chiziba[1], H. Malombo[1], H. Shasulwe[1]
[1]Jhpiego, Lusaka, Zambia, [2]Ministry of Health, Lusaka, Zambia, [3]Centres for Disease Control, Lusaka, Zambia

Background: The 2016 Zambia Population-based HIV Impact Assessment (ZAMPHIA) revealed that 62.8% of men know their HIV status, whereas 70% of women know their status. Historically, care-seeking behavior among men is remarkably poorer than women. Men often await pregnancy related HIV test results from their partners before attempting to get tested. The MC service package provides HIV Testing Services (HTS) prior to circumcision and has been touted as a unique opportunity to reach men thus contributing towards the UNAIDS 90-90-90 goals.
Methods: Jhpiego is implementing a 5-year, CDC funded project under PEPFAR; providing MC services in Lusaka, Southern, Central, Copper belt and Western Provinces, from January 2016 to date 151 health facilities have been supported, clients in these sites also received HIV tests with positive clients referred to care and treatment subsequently. Jhpiego supports health facilities by providing equipment and medical-surgical supplies, building capacity of providers and deployment of multiple demand generation approaches.
Results: A retrospective analysis of routine data from January 2016 to October 2017 revealed that over 90% (N=99,929) of MC clients get an HIV test in Jhpiego supported sites (except in Lusaka Province where it was 83%)the yield here is quite low (0.4%) and linkage to care rates are sub-optimal (33%). Further analysis of facility-wide data from these provinces shows that 28% of HIV tests for men in health facilities are done at MC; with up to 37% in central province.
Conclusions: MC is still a unique opportunity to provide HTS for men, with over 90% of MC clients receiving HTS and a third of all tests for males done in MC service delivery points. The expectation however is to ensure positive clients receive treatment; with the low linkage rates seen here, the translation from the first to the second 90 is hindered. The project is implementing new strategies to improve linkage to care; building a client follow up continuum from demand creation through treatment initiation.

Provinces	# VMMC Clients	#Tested for HIV (%)	# HIV Positive (%)	% of Facility-Based Testing done in VMMC VMMC
Central	10,983	10,061 (91.6%)	88 (0.8%)	37.5%
Copperbelt	41,604	40,674 (98%)	190 (0.4%)	31.35
Lusaka	24,120	20,092 (83.3%)	42 (0.2%)	26.4%
Southern	20,532	19,219 (93.6%)	106 (0.5%)	23.8%
Western	2,690	2,683 (99.8%)	6 (0.2%)	20.7%
Total	99,929	92,729 (92.8%)	432 (0.4%)	28.3%

A public-private partnership approach to expand VMMC uptake in Khomas Region, Namibia

D.D. Pereko[1], L. Kahindi[1], A. Muganza[1], O. Mosisaotsile[2], C. Vejorerako[2], D. Mali[3], C. Thompson[4]
[1]Abt Associates, Inc., Windhoek, Namibia, [2]Ministry of Health and Social Services, Khomas Regional Team, Windhoek, Namibia, [3]United States Agency for International Development, Windoek, Namibia, [4]Abt Associates, Inc., International Development Division, Rockville, United States

Background: Namibia's Ministry of Health and Social Services (MOHSS) prioritizes voluntary medical male circumcision (VMMC) as a core intervention to avert new HIV infections. To achieve this goal, the country set out to conduct 330,218 procedures among men by 2021. Khomas Region, where the capital Windhoek is situated, has a population of 386,000 and a set VMMC target of 47,000. However, the region has only one public VMMC site. Uptake of VMMC services was therefore low, and innovative approaches to reach targets, including partnership with the private sector, were required.
The USAID-funded Strengthening High Impact for an AIDS-free Generation (AIDSFree) Project provides assistance to private for-profit health providers and stakeholders to increase access to and affordability and quality of HIV services, with an emphasis on VMMC.
Description: AIDSFree had a network of 32 private health facilities in Windhoek. These facilities were providing VMMC services only to clients with health insurance or those who could afford to pay out of pocket. To increase VMMC coverage in Windhoek, AIDSFree partnered with the Khomas VMMC regional team to pilot and introduce free VMMC services for uninsured males at private health facilities. The free services were introduced in October 2016 and are funded by USAID.
A service-level agreement was reached to reimburse facilities for the provision of the VMMC service package. Additionally, the facilities were supported with disposable kits, recordkeeping, and reporting. Finally, the Khomas regional VMMC team and AIDSFree undertook joint demand creation activities to encourage clients to access services.
Between October 2016 and September 2017, Khomas Region conducted 8,846 circumcisions; of these, 81% (7,172) were in private sector facilities.
Lessons learned:
· Private clinics reported providing more VMMCs to clients on the free program than to clients with insurance.
· The free VMMC program currently meets the needs of uninsured males.
· Engaging the private sector through a free VMMC program accelerates the achievement of national targets.
Conclusions/Next steps: Namibia has a well-developed, robust private health sector whose potential is not fully utilized. Private facilities are well-positioned to partner with the government to provide VMMC services beyond their regular health insurance clients.

THPED419

The factors that affect the low uptake of Voluntary Medical Male Circumcision amoung adult malea (20-39 years of age) in Gauteng Province, South Africa

E. Palmer
University of Fort Hare, Faculty of Health Sciences, East London, South Africa

Background: The South African government has been scaling-up VMMC services since 2010. However, South Africa has continued to miss its VMMC targets, indicating that more is needed in terms of understanding the slow uptake of VMMC services. The objective of this study is to determine the factors that contribute to low VMMC uptake with the aim of proposing strategies to improve VMMC demand creation for older adult males (20-39 years).
Methods: By employing a qualitative research methodology, the study explores the factors and barriers that contribute to the low VMMC uptake of adult males. A purposive sampling method was used to select 4 Program Managers from the National and Gauteng Provincial Department of Health. In addition, 20 uncircumcised males between the ages of 20 and 39 in Gauteng province were interviewed via focus group discussions.
Results: The main findings show that there are various contextual, individual and community factors contributing to the low VMMC uptake. Interviews with Program Managers revealed that:
1) there was no clear demand generation strategy in place,
2) no clear relationship between VMMC demand creation and actual uptake,
3) lack of human capital,
4) poor integration between VMMC and other prevention programs,
5) a lack of VMMC program leadership, and
6) a lack of resources.
Focus group discussions with uncircumcised males found several key deterrents to VMMC uptake, including:
1) fear of pain and adverse events,
2) a lack of confidence in the public health system,
3) the requirement of abstinence for 40 days after circumcision,
4) potential loss of income,
5) cultural and religious concerns,
6) HIV testing requirements,
7) peer pressure and
8) circumcision-related stigma.
Conclusions: There is a need to understand the lack of VMMC uptake both from the provider and the consumer perspectives. In many cases, the barriers to uptake identified by Program Managers were not identified as important by uncircumcised males, and vice versa. Among the uncircumcised males, barriers included a combination of real concerns, interspersed with myths, fears and false beliefs.

Antiretroviral therapy, including treatment as prevention

THPED420

Drug resistance mutations in patients enrolled in Rapid Start: Experiences from a New York City community health center

A. Radix, P. Carneiro, M. Egarr, R. Vail, S. Weiss, P. Meacher, L. Comstock, U. Belkind
Callen Lorde Community Health Center, New York, United States

Background: Same day HIV treatment initiation „rapid start" is feasible, well tolerated, acceptable to patients, reduces time to virologic suppression, lowers potential for HIV transmission and may improve 12-month retention and mortality compared with treatment as usual. Previous pilots have not documented ART modifications due to virologic failure or drug resistance mutations (DRMs). Callen-Lorde, a Community Health Center in New York City, implemented a multidisciplinary (medicine, nursing, case-management) Rapid Start program in August 2016. Preferred regimens were predominantly Integrase Strand Transfer Inhibitors (INSTI) based. We investigated regimen choice and switches due to tolerability or resistance.
Methods: A retrospective chart review was conducted of patients newly-diagnosed with HIV who accepted same-day ART initiation that investigated demographics, clinical data, treatment choice, switches, time to suppression and 6-month retention.
Results: Over 12 months 47 of 79 (59%) newly diagnosed patients opted to enroll in the Rapid Start program. Demographics: Patients opting in were predominantly MSM (92% MSM, 8% transgender women); ethnically diverse (23% Black, 23% Hispanic); 13% < 25 years; Many were uninsured at time of diagnosis (53%). After initiating ART 58% achieved viral suppression (< 200 copies/ml) within 30 days. Baseline results: mean eGFR 109 (76-148) mL/min, mean CD4 487 (12-947) cells/µL, all were HLA-B5701 negative. Initial regimens offered were INSTI or PI-based. Initially the majority (87%) of patients started elvitegravir/cobicistat/emtricitabine/tenofovir alafenamide after being presented with protocol ART options. Clinically significant resistance mutations occurred in 17%, including NNRTI (20%), NRTI (2.4%), Integrase (2.4%). 3 switches were due to DRMs but none for tolerability. The preferred INSTI regimen was changed from elvitegravir/cobicistat/emtricitabine/tenofovir alafenamide to dolutegravir plus emtricitabine/tenofovir alafenamide in 5/2017 due to one patient with a major primary resistance mutation (N155H) and 2 patients with major accessory resistance mutations (S230R, T97A).
Conclusions: Rapid start programs have evident individual and population level benefits however program scale-up requires close attention to baseline resistance testing and flexibility to change regimens. Prevalent DRMs should determine initial treatment regimens, and if possible, baseline INSTI resistance testing should be considered when these agents are used.

THPED421

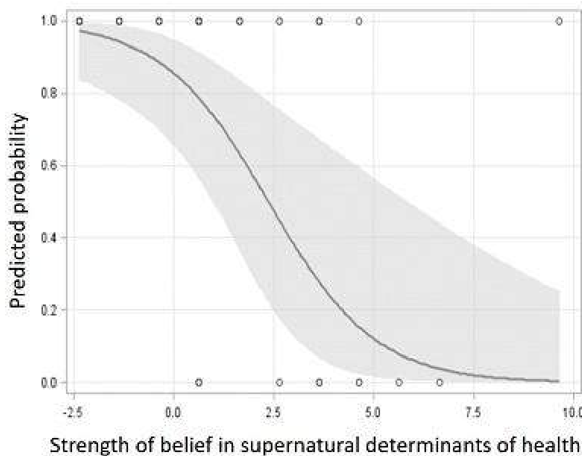
HIV testing and antiretroviral therapy usage are negatively associated with belief in supernatural determinants of health: A nationwide survey from China

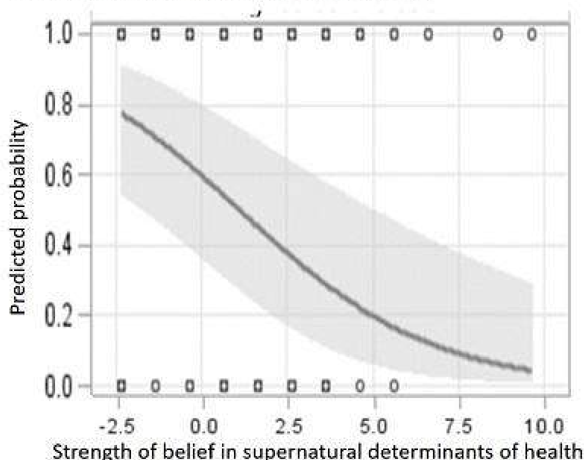
S.W. Pan[1,2,3], J.J. Ong[3,4], H. Fu[5], W. Tang[2,3,6], M.K. Smith[2,6], W. Huang[2,3], D. Wu[2,3], B. Cao[7], Z. Luo[8], J.D. Tucker[2,3,6]
[1]Xi'an Jiaotong-Liverpool University, Department of Public Health, Suzhou, China, [2]UNC Project China, Guangzhou, China, [3]Social Entrepreneurship to Spur Health, Guangzhou, China, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Eastern Virginia Medical School, Norfolk, United States, [6]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [7]Shenzhen University, School of Media and Communication, Shenzhen, China, [8]Shenzhen Nanshan Chronic Disease Hospital, Shenzhen, China

Background: Spiritual and religious beliefs in China are rapidly growing and may have profound impact on health behaviors related to the HIV cascade of care. We examined belief in supernatural determinants of health (degree of conviction that health is influenced by supernatural forces) and correlates with HIV-testing and antiretroviral therapy (ART) use among young men who have sex with men (MSM) in China, a key population with suboptimal testing and viral suppression.
Methods: Data were collected online in May 2017 by anonymous, self-administered, structured questionnaires. Participants were recruited via gay social networking platforms throughout China. Eligibility criteria: born male, ever had anal or oral sex with another man, seen a doctor in the past two years, and between 16 and 30 years old. Belief in supernatural determinants of health was assessed by a validated three-item continuous scale (range: 3-15 points; higher score = stronger belief). Adjusted measures of association (controlling for sociodemographics, religious affiliation, and sexual behavior) were estimated using logistic regression.
Results: 503 men participated in the survey and 72 (14.3%) had ever HIV tested. 14.5% reported ever testing positive for HIV (73/503), among whom 83.6% reported currently using ART (61/73). Overall, 37% (185/503) of participants expressed some belief in supernatural determinants of

health, and the mean score for beliefs in supernatural determinants of health was 5.37 (standard deviation = 2.47). Stronger belief in supernatural determinants of health was associated with lower odds of ever testing for HIV (adjusted odds ratio [AOR]: 0.84, 95% CI: 0.74-0.95) and currently using ART among participants living with HIV (AOR: 0.47; 95% CI: 0.29-0.77). Interaction analysis indicated that an inverse association between supernatural belief and HIV testing was only present among individuals with less than college education (p< 0.05) (Figure).

Conclusions: Many young online MSM in China appear to believe in supernatural determinants of health. Such beliefs may be inhibiting greater uptake of ART and HIV testing, particularly among men with lower educational attainment. Measuring patients' supernatural beliefs may help identify individuals at higher risk of stopping ART. Additional research on belief in supernatural determinants of health and use of HIV services is warranted.





[Figure: Predicted probabilities and 95% confidence intervals of HIV testing and antiretroviral therapy usage, by strength of supernatural beliefs]

'Treat All Policy' in Ghana: Unique approaches for HIV positivity and ART initiation among key population in fast tracking the 90/90/90 targets

I. Bonnah[1], S. Benefour[2], A. Kodua Nyanor[3], T. Waimar[4], P. Tapsoba[2], E. Bruce[3], H. Nagai[3]
[1]John Snow Inc, Accra, Ghana, [2]Population Council, Accra, Ghana, [3]John Snow Inc., Accra, Ghana, [4]Population Council, New York, United States

Background: Ghana's adoption of the WHO 'Treat All' Policy recommendation will see to the testing and treating of at least 90 percent of people living with HIV by 2020. Previously, Ghana adopted the WHO guidelines where only persons living with HIV with a CD4 count of 500 or lower were put on treatment. However, with the 'Treat All' Policy, every person who tests HIV positive will be put on treatment. However, ART prescribers require basic laboratory tests results including liver and kidney function tests and insists on adherence counselling. There are also issues related to costs of drugs, health insurance, stigma and discrimination and reliance on herbal medicines as cure for HIV.

Description: The USAID Strengthening the Care Continuum project, implemented by JSI, improves the Government of Ghana's capacity to provide quality and comprehensive HIV services for key populations and people living with HIV by improving access to and use of HIV services while reducing stigma and discrimination in health settings for key populations and people living with HIV. The project has trained 193 healthcare workers, strengthened capacity of community service organizations (CSOs) working with KPs to segment KPs into typologies with targeted HIV testing using innovative social media, social network testing and PLHIV partner testing from October 2016 to September 2017.

Lessons learned: HIV Positivity and Initiation) October 2016 to September 2017).

Quarters	Q1	Q2	Q3	Q4
Number of Positives	106	298	523	534
Number Initiated on Art	148	202	396	545

These numbers increased over the quarters because the project conducted increased supervision and hands on support to CSOs by adopting targeted testing using social media, social network testing, index case testing and partner notification. In some quarters, the numbers initiated were higher than positives identified because some positives from the previous quarters were still going through adherence counseling and looking for money to complete their lab tests.

Conclusions/Next steps:
- The decision to fast track treatment is based on the service providers' own assessments of the clients' conditions.
- Clients should be considered for ART initiation while the laboratory investigations go on.

THPED423

Mobile application for PLHIV

D. Kim
Public Fund, Program, Almaty, Kazakhstan

Background: There are estimated 26,000 people living with HIV in Kazakhstan. About 4,000 new HIV cases identified in 2017. Local AIDS centers cannot cope with such burden. Due to that, clients do not receive quality and timely services, necessary information, referral to other AIDS service organizations. Only 48% of PLHIV are adhered to ART. Old tools like tablets with timer and brochures are obsolete and irrelevant for the majority of PLHIV.

AFEW KZ within the HIV React Project funded by USAID has developed a mobile application named POZ.INFO, which combines necessary tools and intended to help people affected by HIV: increase awareness, adherence to treatment, improve quality of services for PLHIV.

Description: POZ.INFO is a free mobile application that helps PLHIV in taking ART, available for Android and iOS, does not require registration and does not collectstore personal data. It can be used onoffline.

POZ.INFO includes necessary information about HIV, medicine and per-

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

sonalized treatment regimen; reminder alarm clock; contacts and information of organizations that help PLHIV; question-and-answer forum and notes.
POZ.INFO allows entering: a personal regimen of ART independently or through immunoblot number previously entered by doctor; set up convenient time for taking medications; customize text of reminder to keep anonymity; get general information about HIV; find the nearest AIDS service organization; communicate with other PLHIV or specialists, make notes, such as test results or medical appointments.
POZ.INFO developed on data collected during focus groups with PLHIV and partners in Almaty, Ust-Kamenogorsk and Pavlodar. It was presented to international and local partners and supported by Republican AIDS Center - main governmental organization responsible for HIV prevention and treatment in Kazakhstan.
Lessons learned: Apply integrated approach to promote and disseminate application among PLHIV: through initiative groups, community-based NGOs and local AIDS Centers.
The application should be simple, user friendly, functional, available on/offline, anonymous, suitable for most smartphone models on most popular platforms in the region, information should be continuously updated.
Conclusions/Next steps: Further improvement of application based on clients' suggestions and comments.
Adoption of application on national level.
Provide application to partners for adaptation in other countries of the region.

Reasons for true loss to follow ups in patients on anti retro viral treatment in Maharashtra State, India

P. Murugesan[1], S. Seema[2], M. Ghate[2], M.B. Madane[3], B.D. Rajani[4], B. Shilpa[2], S.S. Sane[5], R. Gangakhedkar[6], T. Beena[1], N. Karikalan[1], C. Veeramani[1], P. Manoj[7], G. Archana[8], U. Medhe[9], D. Jathav[10], B. Bhalekar[11]
[1]National Institute for Research in Tuberculosis, Chennai, India, [2]National AIDS Research Institute, Pune, India, [3]National AIDS Research Institute-ICMR, Social and Behavioral Research, Pune, India, [4]National AIDS Research Institute, Social and Behavioral Research, Pune, India, [5]National AIDS Research Institute-ICMR, Epidemiology & Biostatistics, Pune, India, [6]National AIDS Research Institute, Clinical Sciences, Pune, India, [7]Network of Maharashtra by People Living with HIV/AIDS (NMP+), Pune, India, [8]Maharashtra State AIDS Control Society, Pune, India, [9]Yashwantrao Chavan Memorial Hospital, Pune, India, [10]Swamy Ramanand Teeth Rural Govt. Medical College, Ambajogai, India, [11]Sasson Hospital & BJ Government Medical College, Pune, India

Background: Adherence to Anti Retroviral treatment (ART) is influenced by multiple patient level and health system level factors .We interviewed True Loss to Follow Up (TLFU) patients onART to understand the reasons for ART discontinuation.
Methods: Between 2014 to 2017, 60 TLFU patients on ART (defined as those who were not keeping ART refill appointment for 90 days or longer, and being found alive but not on ART from any other source; or not being traceable to allow confirmation such as "dead or transferred-out") were traced back using phone calls and/or house visits by study investigators. Quantitative interviews were conducted among willing TLFU patients. The study was approved by the Institutional Ethics Committee of the National AIDS Research Institute and BJMC & Sasoon Hospital, Pune.
Results: Of the 34 TLFU patients interviewed, 52.9%(18) were male, 38.2%(13) were illiterate, 61.8%(21) were married and median age was 45. Only 64.7 %(22) of the TLFU patients were reportedly contacted over phone by ART staff during discontinuation period. Personally, side effects of drug and lack of money to visit ART center were major reasons for discontinuation said by 52.9%(18) and 26.5%(9) of TLFUs respectively. Lack of support from family, lack of care takers and stigma were cited as reasons for discontinuation by 5.9%(2) of TLFUs. Work related pressure was cited by 14.7%(5) of TLFUs. Long waiting time and long distance of ART center were program related reasons said by 20.6% (7) and 23.5%(8) of TLFUs. General financial assistance and specific for transport was needed by 90%(27) and 84.6%(22) of TLFUs. Drug collection on 2-3 month basis were expected by 81%(17) of TLFUs.
Conclusions: The findings highlight that side effect management, timely appointments and flexible drug dispensation schedules for patients at ART centers could help address facility level barriers for adherence. Financial assistance and counselling support for patients and their families could help address patient level barriers for adherence.

THPED425

Responding to ART non-adherence by strengthening youth resiliency in an under-resourced setting using TI_CTBTe youth leader model

C. Ingabire[1], M. Fabri[2], E. Remera[3], S. Nsanzimana[3], G. Donenberg[4], M. Cohen[5,6], KIP Study Group
[1]WE-ACTx For Hope, Research Department, Kigali, Rwanda, [2]WE-ACTx, Mental Health Department, Chinle, United States, [3]Rwanda Bio-Medical Center, HIV Division, Kigali, Rwanda, [4]University of Illinois at Chicago, School of Public Health, Chicago, United States, [5]Cook County Health & Hospitals System, Department of Medicine, Chicago, United States, [6]Rush University, Department of Medicine, Chicago, United States

Background: Rwanda, as a developing and recovering country from war and genocide consequences, is experiencing mental health human resource scarcity to respond to problems caused by war, genocide, and HIV. However, cost-effective initiatives to achieve multiple effect regardless the huge needs and little financial resources are possible. This abstract describes a Trauma Informed Cognitive Behavioural (TI-CBTe) Youth Leader Model and its effect on Youth Leader (YL) wellbeing and improvement in health outcome.
Methods: 14 YLs aged 21 to 24 were enrolled in the Kigali Imbereheza Project (KIP) in Rwanda which utilized cognitive behavioral strategies to improve mental health and adherence to antiretroviral therapy (ART) for youth. They were trained and delivered 9 6-session interventions over four years to groups of 10 14-21 year-old youth. YLs provided demographics and information on their behaviors, and treatment.
Data was collected using audio computer assisted technology at baseline, 6-months study visits. Using SPSS, we performed descriptive statistics to determine the mean and total score mean of different variables.
Results: The average age of Youth Leaders was 22.9 years, 57.1% male, only 7% [1] had both parents alive, 64% did not have any parents, they were all unmarried, and did not have any other source of income than KIP. At baseline, the mean viral load was 9420 copies/ml and was 171 copies/ml around 18-months after baseline. CD4 was 379 at baseline and 533 around 18-months post baseline. The Wilson Adherence total score was 84 at baseline and increased slightly to 86 at 6-month follow up. The Self Esteem total score also increased slightly from 22 at baseline to 24.7 at 6-month follow up. The cases of STIs were 0 during the first 6 months of intervention.
Conclusions: TI-CBTe led by YLs has promised decreasing viral load and increasing CD4, self esteem, and healthy behaviours.

THPED426

Factors associated with late presentation of paediatrics on anti-retro-viral therapy in Mashonaland East province, Zimbabwe

E. Muzulu[1], W. Dube Dr[2], G. Machacha[3], T. Magure Dr[4], E. Mugariri[1], A. Mpofu[5]
[1]National AIDS Council, Monitoring and Evaluation, Marondera, Zimbabwe, [2]National AIDS Council, Programmes, Marondera, Zimbabwe, [3]Ministry of Health and Child Care, Health Promotions, Marondera, Zimbabwe, [4]National AIDS Council, Chief Executive Officer, Harare, Zimbabwe, [5]National AIDS Council, Monitoring and Evaluation, Harare, Zimbabwe

Background: The provincial average of paediatric patients presenting late for ART rose from 23.33% in 2014 to 31.9% in 2016. Despite numerous interventions to improve early paediatric diagnosis and treatment of children below 14 years, they still present late for ART. Factors for such a trend needed to be identified to improve early diagnosis and initiation of paediatric patients on ART.

Methods: The study used an unmatched 1:1 case-control study design. Cases were defined as a paediatric patients who presented for ART initiation in WHO Clinical stage 3 or 4, and controls were defined as a paediatric patients who presented for ART initiation in WHO Clinical stage 1 or 2. Data was entered into Epi Info version 3.5.2. for analysis.Means, frequencies, proportions, odds ratios (OR), and their 95% confidence intervals (CI), were generated. Odds ratio (OR) that did not include the value 1 in the 95% confidence interval were considered statistically significant. Step wise multivariate analysis was carried out to estimate the measures of association while at the same time controlling for a number of confounding variables. All the variables that were significant at P-value< 0.025 in the Bivariate analysis were included in the logistic regression model. Variables that were not significant were eliminated until all the variables that were significant at 0.05 levels (95% CI) were added to the model.

Results: The results showed that children´s age on initiation on ART [AOR 4.18 (95% CI: 2.29, 7.63) p=0.0000] and travelling less than 5 kms to reach the clinic [AOR 0.496 (95% CI: 0.30, 0.82) p=0.0064] were independent factors associated with the likelihood of presenting late for paediatric ART. Children above the age of 5 years at time of ART initiation were 4 times more likely to present late for ART. Living within 5 km radius of a health facility was protective as the paediatric was 0.5 times less likely to present late for ART.

Conclusions: Children above the age of five years are most likely to present late for ART initiation. Living within five kilometres radius of health facilities is protective to the paediatrics as they are less likely to present late for ART.

THPED427

Why young African American MSM (YAAMSM) ages 18-29 who are living with HIV in the Southern region of the United States do or do not take HIV treatment regularly

S. Kegeles[1], G. Rebchook[1], L. Pollack[1], D. Huebner[2], S. Tebbetts[1], W. Vincent[1], J. Tan[1], B. Zovod[1], R. Williams[1], A. Leonard[3], J. Peterson[4]
[1]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [2]George Washington University, School of Public Health, Washington, DC, United States, [3]Legacy Community Health, Houston, United States, [4]Georgia State University, Department of Psychology, Atlanta, United States

Background: YAAMSM are disproportionately impacted by HIV, especially in the U.S. South. It has been estimated that 60% of AAMSM will be living with HIV by age 40. Adhering to HIV treatment so that men will become virally suppressed will not only reduce morbidity among this group, but will also reduce the transmission of HIV to others.

Methods: Long-chain peer recruitment was used to enroll YAAMSM in two large Texas cities. All men were tested for HIV, and HIV+ men were recruited into this study's cohort (N=333). Surveys were self-administered on iPads at project sites. Here we compare men currently taking ART who reported their 3-month medication adherence (N=189): missing doses once/week or more in the prior three months (35.4%) versus men who never or very rarely missed doses (64.5%).

Results: Cohort mean age was 24.5; 45% had high school degrees or less, and the other half had some college; few were college-graduates (6%). Bivariate analyses indicated that social issues were associated with adherence, including perceived social norms about adherence, support received about living with HIV, protecting sex partners, and friends talking with them about the importance of treatment. Experiencing greater societal oppression (through experiencing more homophobia, racism, and HIV stigma), internalizing the oppression (internalized heterosexism, HIV stigma) and depressive symptomology were also related to adherence. Medical mistrust and uncertainty about providers were marginally associated with medication adherence. There were no statistically significant differences in adherence by education, employment, income, poverty, incarceration history, conspiracy beliefs, or pride in being gay.

Conclusions: Increasing treatment adherence among YAAMSM living with HIV requires more than reminders. While some issues can be targeted at clinics (e.g., increasing HIV treatment literacy), other issues might be best met through efforts positioned in and focused on the YAAMSM community (e.g., changing social norms to support adherence; increasing supportive conversations from friends; decreasing internalized oppression). Multipronged approaches are needed to increase adherence to HIV treatment among YAAMSM that targets depression and important cultural issues, such as externally and internally experienced oppression, medical mistrust, resilience to adversity, agency about one's own health, and a desire to protect sex partners by becoming virally suppressed.

Item or Scale	Missed once/week or more	Missed less than once/week	p-value	Item or Scale	Missed once/week or more	Missed less than once/week	p-value
Experienced HIV stigma recently	38.81	34.35	.016	Supportive conversations from friends about treatment adherence	19.50	25.21	.001
Experienced HIV-related discrimination recently	36.81	31.02	.008	Feels responsible to protect sex partners	16.75	17.75	.053
Internalized HIV stigma	15.44	13.42	.044	Internalized heterosexism	7.25	5.94	.009
Mistrust of medical system	13.34	11.85	.061	Experienced homophobia recently	16.84	14.07	.008
Trust in provider competency	28.27	30.55	.069	Experienced racism recently	26.72	22.33	.025

THPED428

Poor rates of linkage to HIV care and treatment uptake after home-based HIV testing among 15-49 year-old men and women in a high HIV prevalence setting in South Africa

B. Maughan-Brown[1], S. Beckett[2], A.B.M. Kharsany[3], C. Cawood[4], D. Khanyile[4], L. Lewis[3], A. Venkataramani[5], G. George[2]
[1]Southern Africa Labour and Development Research Unit, University of Cape Town, Cape Town, South Africa, [2]Health Economics and HIV and AIDS Research Division, University of KwaZulu-Natal, Durban, South Africa, [3]Centre for the AIDS Programme of Research in South Africa, University of KwaZulu-Natal, Durban, South Africa, [4]Epicentre AIDS Risk Management (Pty) Limited, Paarl, South Africa, [5]University of Pennsylvania, Department of Medical Ethics and Health Policy, Perelman School of Medicine, Philadelphia, United States

Background: Early antiretroviral therapy (ART) initiation is essential to obtain the full therapeutic and prevention benefits from ART, but linkage to care following community-based testing services is often poor, and inadequately understood. This study examined demographic, socioeconomic and psychosocial factors influencing linkage to care following home-based HIV-testing services (HBHTS) in a hyper-endemic epidemic setting in South Africa.

Methods: HBHTS was offered to all participants (N=10,236) in the 2015-2016 cross-sectional survey of the HIV Incidence Provincial Surveillance System, KwaZulu-Natal, South Africa. Fieldworkers collected venous blood samples for health screening, including CD4 counts. Follow-up telephone surveys (N=194) collected data on clinic visits and ART initiation among individuals diagnosed HIV-positive through HBHTS. Factors associated with linkage to care (defined as a clinic visit within 12 weeks of receiving an HIV-positive diagnosis) were assessed using multivariable logistic regression models.

Results: Fifty-four percent of men and women linked to care, and 21% of ART-eligible participants started treatment within 12 weeks (men:25%, women:19%). The median CD4 count was 416 cells/µL (IQR:268-608) and 418 (IQR:254-612) among those that did, and did not, link to care respectively. Few men (11%) or women (13%) linked to care within 4 weeks. Linkage to care was less likely among participants who had doubted their HIV-diagnosis (aOR:0.54,95%CI:0.27-1.06, p=0.072), and who reported being unafraid of contracting HIV due to the effectiveness of ART (aOR:0.53,95%CI:0.28-1.01, p=0.054). Linkage to care was

more likely among participants who had disclosed their HIV status (aOR:2.28,95%CI:1.07-4.86, p=0.033), and who had recently engaged in an HIV-related activity (aOR:1.91,95%CI:0.93-3.94, p=0.079). Self-reported reasons for not linking to care included no time (men:75%, women:57%); only wanting to start treatment when sick (men:58%, women:39%); being afraid of side-effects (men:29%, women:35%); and not believing the HIV-diagnosis (men:4%, women:22%).

Conclusions: HBHTS needs to be paired with targeted interventions to facilitate early linkage to care. Interventions are required to counter denial of HIV status, and encourage early ART initiation among individuals inclined to delay treatment until falling ill. Further research is needed to better understand the interplay between perceptions of ART and HIV, and how perceptions of HIV affect the uptake of HIV care and treatment services.

THPED429

Changes in disclosure, adherence and patient experiences of communication following the 'Early access to ART for all' intervention in Swaziland

M. Molemans[1,2], E. Vernooij[3,4], N. Dlamini[3], F.S. Shabalala[3,5], S. Khan[6], F. van Leth[1,2], G.G. Gomez[2,7], R. Reis[3,8,9], MaxART Study Group
[1]University of Amsterdam, Department of Global Health, Academic Medical Center, Amsterdam, Netherlands, [2]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, [3]Amsterdam Institute for Social Science Research, University of Amsterdam, Amsterdam, Netherlands, [4]University of Edinburgh, Social Anthropology, School of Social and Political Science, Edinburgh, United Kingdom, [5]University of Swaziland, Department of Community Health Nursing Sciences, Faculty of Health Sciences, Mbabane, Swaziland, [6]Clinton Health Access Initiative (CHAI), Mbabane, Swaziland, [7]London School of Hygiene and Tropical Medicine, London, United Kingdom, [8]Leiden University Medical Centre, Department of Public Health and Primary Care, Leiden, Netherlands, [9]University of Cape Town, Children's Institute, School of Child and Adolescent Health, Cape Town, South Africa

Background: The WHO advises initiation of antiretroviral therapy (ART) on positive HIV diagnosis, regardless of CD4 count or WHO clinical stage. There are concerns whether immediate ART initiation affects HIV status disclosure and ART adherence. We assess changes in disclosure, adherence, patient experiences of HIV testing, ART initiation, and communication with healthcare workers following the introduction of 'Early access to ART for all' (EAAA), an immediate ART intervention in Swaziland.

Methods: We recruited two samples of participants between 2014 and 2017 from the MaxART study, which used a stepped-wedge design, where facilities transitioned from control (standard of care) to intervention (EAAA). One group was interviewed before the intervention was implemented (control); the second group was interviewed after the implementation of the intervention and six months thereafter (intervention). We present bivariable analyses comparing responses in the control and intervention groups, and comparing responses at start of intervention and six months later.

Results: All respondents reported high levels of disclosure to their partner (94% for control and intervention group) and family (controls: 78%, intervention: 79%), and high levels of adherence (15% missed a dose among the controls, and 16% in the intervention group). More respondents were worried about unintended disclosure during the intervention, compared with before (controls: 9%, intervention: 16%). Fewer respondents felt ill when they went for testing in the intervention group (controls: 36%, intervention: 28%). There were no changes in patient experiences of ART initiation (10% among the controls and 11% in the intervention group felt pressured). Overall, communication with healthcare workers improved following the intervention with more people having explained by healthcare workers that it was their choice to start ART (controls: 88%, intervention: 93%), being explained (controls: 15%, intervention: 49%) and receiving test results (controls: 13%, intervention: 46%).

Conclusions: Our results suggest that both reported adherence and disclosure levels continue to be high following the introduction of immediate ART in Swaziland. While we observe an improvement in the interactions with healthcare services, this might be due to the extensive training available at participating facilities and will be an important element for a successful roll-out of immediate ART.

THPED430

Factors affecting linkage to HIV care and ART initiation following referral for ART by a mobile health clinic in South Africa: Evidence from a mixed-methods study

B. Maughan-Brown[1], A. Harrison[2], O. Galárraga[3], C. Kuo[2], P. Smith[4], L.-G. Bekker[4], M. Lurie[5]
[1]Southern Africa Labour and Development Research Unit, University of Cape Town, Cape Town, South Africa, [2]Brown University School of Public Health, Department of Behavioral and Social Sciences, Providence, United States, [3]Brown University School of Public Health, Department of Health Services, Policy & Practice, Providence, United States, [4]The Desmond Tutu HIV Centre, Cape Town, South Africa, [5]Brown University School of Public Health, Department of Epidemiology, Cape Town, South Africa

Background: Community-based HIV-testing is effective at diagnosing asymptomatic people living with HIV, but subsequent linkage to care is often poor and inadequately understood. This mixed-methods study assessed factors that both improved and hindered linkage to care and antiretroviral therapy (ART) uptake following ART-referral by a mobile health clinic in Cape Town, South Africa.

Methods: From April 2015 to August 2016, longitudinal data were collected among individuals (N=86) referred for ART by a mobile health clinic: face-to-face survey data were collected immediately after ART referral, and data on subsequent clinic visits and ART initiation were obtained from clinic records. Multiple logistic regression analyses were used to assess factors associated with visiting a clinic within three months, and with ART-initiation within three months. Follow-up in-depth interviews (N=41) were conducted to examine challenges to, and factors motivating ART initiation.

Results: Among people living with HIV (N=86), 67% linked to care and 42% initiated ART within three months. Linkage to care was more likely among individuals expressing intentions to disclose their HIV-status (aOR: 2.99, 95%CI: 1.13-7.91), and among those who were classified as treatment ready (aOR: 2.97, 95%CI: 1.05-8.34); and less likely among individuals in good health (aOR: 0.35, 95%CI: 0.13-0.99), those who drank alcohol at least once weekly (aOR: 0.35, 95%CI: 0.12-0.98), and those reporting internalised stigma (aOR: 0.32, 95%CI: 0.11-0.91). ART initiation was more likely among individuals reporting greater treatment readiness (aOR: 3.20, 95%CI: 1.09- 9.39); and less likely among individuals who drank alcohol at least once weekly (aOR: 0.24, 95%CI: 0.08-0.73); who reported internalised stigma (aOR: 0.44, 95%CI: 0.17-1.12); and who reported any perceived stigma (aOR: 0.38, 95%CI: 0.14-1.02). In-depth interviews elucidated fears about ART side-effects, HIV-status denial, and lack of money for food as barriers to ART initiation. Factors motivating treatment uptake included awareness of a positive ART-effect, follow-up telephone counselling, familial ties and responsibilities, and maintaining health to avoid involuntary disclosure.

Conclusions: Results provide evidence that an array of interventions are required to encourage rapid ART initiation among individuals diagnosed HIV-positive by mobile health clinic HIV-testing services. This is especially the case among healthier populations.

THPED431

HIV-positive women's attitudes towards and willingness to use long-acting injectable antiretroviral therapy (ART): A qualitative study in San Francisco, New York and Chicago

M. Philbin[1], E. Kinnard[1], C. Parish[2], D. Feaster[3], M. Cohen[4], O. Sosanya[5], A. Adimora[6], J. Cocohoba[7], L. Goparaju[8], E. Golub[9], M. Fischl[2], L. Metsch[1]
[1]Columbia University Mailman School of Public Health, Sociomedical Sciences, New York, United States, [2]University of Miami, School of Medicine, Miami, United States, [3]University of Miami, Miami, United States, [4]Cook County Health and Hospitals System, Chicago, United States, [5]Montefiore Medical Center, Medicine, Bronx, United States, [6]University of North Carolina Chapel Hill, School of Medicine, Chapel Hill, United States, [7]University of California, Clinical Pharmacy, San Francisco, United States, [8]Georgetown University Medical Center, Medicine, Washington, United States, [9]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States

Background: Adherence to antiretroviral therapy (ART) is imperative for viral suppression and reducing further HIV transmission. Many HIV-positive individuals report difficultly sustaining long-term adherence and long-acting injectable (LAI) ART has the potential to transform HIV treatment and prevention. However, little LAI ART-related research has occurred among women.
Methods: We conducted 30 in-depth interviews with HIV-positive women at three sites (New York, Chicago, San Francisco) of the Women's Interagency HIV Study (WIHS), a national ongoing cohort study of HIV-positive and HIV-negative women. The majority were women of color (93%), not currently working (67%), and earned < $12,000/year (70%); median age was 53. Interviews were recorded, transcribed, and analyzed using thematic content analysis.
Results: The majority of women enthusiastically endorsed monthly ART injections and would prefer it over pills. Four primary reasons emerged for this preference: 1) convenience over daily pills ["*I'm tired of taking pills for years*"]; 2) increased privacy since there would be no pills to hide ["*everybody has nosey friends, people see things they don't need to see*"]; 3) not having daily reminders about being HIV-positive; and 4) believing that shots are more effective than pills ["*it goes right to the bloodstream*"]. Participants felt that LAI ART could be beneficial to all HIV-positive individuals, particularly those who are young, newly diagnosed, and female. Challenges remain, however, as some women expressed wariness about safety and effectiveness before they would try LAI ART: "*because there's not enough evidence of certainty.*" Women often took many daily pills (for HIV and other conditions), and differed on whether they would wait to switch until injectable ART could replace their entire HIV regimen. Some said any pill reduction was helpful and that they would want LAI ART ("*that's like six pills gone*"), while others expressed that "*If I'm taking one pill, I might as well take them all.*"
Conclusions: The majority of women would prefer monthly LAI ART over daily pills given its benefits for convenience, privacy, and perceived effectiveness. Future research should incorporate more women into LAI ART trials in order to better understand and align its development with user concerns and preferences in order to enhance uptake.

Pre-exposure prophylaxis

THPED432

Women's attitudes and perceived barriers towards long-acting injectable pre-exposure prophylaxis (PrEP) versus long-acting injectable antiretroviral therapy (ART): Results from a mixed-methods study in Chicago, New York and San Francisco

M. Philbin[1], E. Kinnard[1], C. Parish[2], M. Cohen[3], O. Sosanya[4], A. Adimora[5], J. Cocohoba[6], L. Goparaju[7], E. Golub[8], M. Fischl[2], L. Metsch[1]
[1]Columbia University Mailman School of Public Health, Sociomedical Sciences, New York, United States, [2]University of Miami, School of Medicine, Miami, United States, [3]Cook County Health and Hospitals System, Chicago, United States, [4]Montefiore Medical Center, Medicine, Bronx, United States, [5]University of North Carolina Chapel Hill, School of Medicine, Chapel Hill, United States, [6]University of California, Clinical Pharmacy, San Francisco, United States, [7]Georgetown University Medical Center, Medicine, Washington, United States, [8]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States

Background: Current HIV medication—for treatment and prevention—exists almost exclusively in oral formulations that require daily adherence. Long-acting injectable (LAI) antiretroviral therapy (ART) and LAI pre-exposure prophylaxis (PrEP) are therefore being developed to address such barriers.
Methods: We conducted 45 in-depth interviews with HIV-positive (n=30) and HIV-negative (n=15) women at three sites (New York, Chicago, San Francisco) of the Women's Interagency HIV Study (WIHS), a national ongoing cohort study of HIV-positive and HIV-negative women. The majority was women of color (93%), unemployed (64%), and earned < $12,000/year (71%); median age was 54. Interviews were recorded, transcribed, and analyzed using the constant comparative method.
Results: Half of the HIV-negative women had heard of PrEP and, once informed, the majority did not see it as useful for them regardless of formulation ["*I don't want to take another pill for another thing that...won't happen to me*") or viewed it as potentially harmful ["*I'm scared that if I take it I might get HIV*"). If asked to choose between formulations, 11/15(73%) would take bi-monthly shots over pills. HIV-positive women responded enthusiastically to monthly LAI ART ("*yes, lord, yes!*" and "*well shoot me up!*") and preferred monthly shots over pills (20/30;67%). While most HIV-negative women were somewhat/very concerned about potential pain at the injection site (8/15;53%), HIV-positive women were not (6/30;20%). LAI are currently administered in the buttocks; one-third of HIV-positive women and one-quarter of HIV-negative women said this would cause them to choose pills but *"if it's someplace else, I would do the shot."* All women were equally concerned about potential side-effects (12/15;80% and 21/30;70%) and expressed a desire to wait and talk to friends who use LAI ART and PrEP in order to ensure its safety and efficacy. Nearly all women (90%) said it would be somewhat/very easy to get to the clinic for injections.
Conclusions: While the majority of HIV-positive women expressed excitement about LAI ART, HIV-negative women were relatively indifferent toward PrEP for their own use, regardless of its formulation. Future research needs to address medical-related anxiety and injection site for ART and PrEP, with specific attention toward targeting women for whom PrEP is relevant.

Predictors of non-use of PrEP among gay and bisexual men

M.A. Hammoud[1], L. Maher[1], F. Jin[1], A. Bourne[2], S. Vaccher[1], L. Degenhardt[3], G. Prestage[1]
[1]The Kirby Institute, UNSW Australia, Medicine, Sydney, Australia, [2]Australian Research Centre in Sex, Health & Society, La Trobe University, Melbourne, Australia, [3]The National Drug and Alcohol Research Centre, UNSW, Sydney, Australia

Background: Australian eligibility criteria for being prescribed HIV pre-exposure prophylaxis (PrEP) among gay and bisexual men (GBM) include: having an HIV-positive partner with detectable viral load; receptive condomless anal intercourse with casual partners (CLAIC); methamphetamine use; or a recent rectal sexually transmissible infection. Although many GBM meet these eligibility criteria, most have not yet accessed PrEP since its approval.

Methods: By Dec 2017, 1258 Australian GBM who were not HIV-positive and were recruited through non-clinic settings completed 24 months follow-up in the FLUX online cohort study. We identified factors associated with not commencing PrEP among PrEP-eligible men.

Results: Of the 580 men (46.1%) who met the eligibility criteria, 52.8% were eligible at baseline and 49.7% at 24 months, with 26% eligible at both time points. About half those who were eligible at each survey round did not meet the eligibility criteria dusing the following round. By 24 months follow-up, 228 men had commenced PrEP.

Among PrEP-eligible men at each follow-up, ~45% of those not using PrEP reported five or fewer partners in the previous six months, compared to ~10% of those using PrEP (p< 0.001).

Men not commencing PrEP use were less likely to have been socially engaged with other gay men during prior survey rounds (aHR:0.94;95%CI:0.88-0.99), and less likely to have engaged in CLAIC during prior rounds (aHR:0.25;95%CI:0.06-0.99).

Conclusions: Although all PrEP-eligible men had engaged in high risk behaviours, those who did not initiate PrEP use were less sexually active and less 'risky' than those who did initiate PrEP. Some men met PrEP eligibility criteria at some survey rounds but not others. For men who did not initiate PrEP, they may assess their risk as insufficient relative to others to warrant using PrEP because they did not continue to engage in 'risky' behaviours, or did so less often.

Men not using PrEP were also less socially connected to gay community, which may have restricted access to information about PrEP, but men who are more or less socially engaged with gay community may also hold differing perceptions of social norms about or perceived acceptability of PrEP.

THPED434

Considering bias in the provision of PrEP: Reflections from early-adopting prescribers

S.K. Calabrese[1], M. Tekeste[1], K.H. Mayer[2,3], M. Magnus[4], A.I. Eldahan[5], D.S. Krakower[2,3], L.A. Gaston-Hawkins[6], K. Underhill[7], N.B. Hansen[8], T.S. Kershaw[9], J.R. Betancourt[3], J.F. Dovidio[9,10]
[1]George Washington University, Department of Psychology, Washington, United States, [2]The Fenway Institute, Fenway Health, Boston, United States, [3]Harvard Medical School, Boston, United States, [4]Milken Institute School of Public Health, George Washington University, Washington, United States, [5]Columbia School of Nursing, New York, United States, [6]University of Michigan Medical School, Ann Arbor, United States, [7]Columbia Law School, New York, United States, [8]College of Public Health, University of Georgia, Athens, United States, [9]Yale School of Public Health, New Haven, United States, [10]Yale University, Department of Psychology, New Haven, United States

Background: US retail pharmacy records suggest that HIV pre-exposure prophylaxis (PrEP) use is lower among Black Americans than White Americans despite their disproportionately high HIV risk. Efforts to identify and address factors contributing to social inequities in PrEP access are urgently needed. This qualitative study investigated early-adopting PrEP prescribers' beliefs about how bias may contribute to disparities in PrEP access and explored potential intervention strategies within the context of PrEP service delivery.

Methods: US-based PrEP prescribers were recruited via professional networks and referral by other participants (2014-2015). One-on-one, 90-minute interviews were conducted by phone or in person, transcribed, and thematically analyzed.

Results: Participants (n = 18) were primarily male (72%); White (39%) or Asian (33%); and heterosexual (56%). Most practiced in the Northeastern (67%) or Southern (22%) US; were physicians (94%); and specialized in HIV/infectious disease (89%). Participants described how structural and social biases may impede PrEP access at multiple levels within the healthcare system. The requirement that PrEP be accessed through a medical provider was recognized as a structural deterrent to PrEP uptake for Black Americans and other key populations for whom medical mistrust or low health literacy could deter engagement in medical services. Participants also acknowledged that policies and norms within medical practices, such as discussing PrEP only in response to patient requests, could favor privileged groups. In general, participants regarded themselves as having a high level of cultural competence compared to other healthcare providers. When probed about personal endorsement of social biases that may impact PrEP prescription, age-related stereotypes were the most readily acknowledged, including assumptions about older adults being sexually inactive and older adults being uncomfortable discussing sex. Participants criticized providers who chose not to prescribe PrEP within their clinical practice, particularly those whose decision reflected their personal values related to condomless sex or discomfort discussing sex with their patients. Suggested solutions to PrEP-related biases included standardizing PrEP service delivery and increasing provider cultural competence training.

Conclusions: Early-adopting PrEP prescribers perceived multiple structural and social biases operating within the healthcare system that could compromise PrEP access for key populations and illuminated practice standards and training as important points of intervention.

THPED435

Factors associated with condomless sex without PrEP among men who have sex with men enrolled in the ANRS-IPERGAY OLE

M. Di Ciaccio[1,2], L. Fressard[1], L. Sagaon-Teyssier[1], M. Suzan[1], L. Meyer[3], D. Rojas Castro[1,4,5], L. Cotte[6], E. Cua[7], M. Préau[1,2], B. Spire[1], J.-M. Molina[8], ANRS-IPERGAY Study Group
[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France, [2]Groupe de Recherche en Psychologie Sociale (GRePS), Université Lyon 2, Lyon, France, [3]INSERM SC 10 US 19, Villejuif, France, [4]AIDES (Mission Innovation Recherche Expérimentation), Pantin, France, [5]Coalition Internationale Sida, Pantin, France, [6]Hospital Croix Rousse, INSERM U 1052, Department of Infectious Diseases, Lyon, France, [7]Hospital Archet 1, Department of Infectious Diseases, University Hospital, Nice, France, [8]Hospital Saint-Louis, Department of Infectious Diseases, Assistance Publique Hôpitaux de Paris, University of Paris Diderot Paris 7, INSERM U 941, Paris, France

Background: The ANRS-IPERGAY trial showed the efficacy of on-demand PrEP whereby pills are taken before and after each sexual encounter. We investigated the proportion of sexual encounters without PrEP and associated factors among men who have sex with men (MSM) participating in the trial.

Methods: MSM were recruited in the open-label extension (OLE) study of ANRS-IPERGAY. During the OLE, participants were followed every two months (M0 to M18). They provided information on sexual behaviours, condom use and PrEP use through online questionnaires. Focusing on participants' most recent episode of anal intercourse, three specific behavioural groups were defined:

a) Anal sex with PrEP (behaviour A)
b) Anal sex with condoms without PrEP (behaviour B)
c) Condomless anal sex without PrEP (behaviour C)

Multinomial mixed logit models were performed to estimate the factors associated with these behaviours.

Results: A total of 296 participants (of the 361 included in the OLE study) were included in the present analysis, corresponding to 986 episodes of anal intercourse. Of these episodes, 76% were categorized as behaviour A, 5% behaviour B, and 19% behaviour C. Participants with behaviour C were more likely to have sexual encounters with HIV-negative partners

(aOR[95%CI]: 10,79[4.70,24.80]), with their main partner (3,41[1.91,6.10]), and with circumcised partners (2,11[1.06,4.22]) than participants with behaviour A. However, the probability of having behaviour C decreased with the number of sexual partners during the previous 2 months (0,98/ additional partner [0.96,0.99]).
MSM who met sexual partners in venues other than the internet (4,89[1.12,21.29]) were more likely to report behaviour B than participants with behaviour A.
Conclusions: MSM enrolled in the ANRS-IPERGAY trial reported a significant proportion of condomless sex without PrEP. Such sexual encounters were more likely to be with sexual partners who had a lower risk of HIV infection. The use of the combined prevention strategies - sex with circumcised partner, anal intercourse with HIV-negative partner, and sex with a main partner- suggest that MSM manage risk in a very reasoned fashion. PrEP uptake seems to be used for high-risk sexual intercourse encounters. Furthermore, the internet might facilitate anal sex with PrEP given that individuals can disclose online that they use PrEP.

THPED436

Experiences of pill-taking and attitudinal covariates of PrEP adherence among men who have sex with men - findings from the VicPrEP implementation project, Melbourne

J. de Wit[1,2], D. Murphy[2,3], L. Lal[4,5,6], J. Audsley[5,7], C.K. Fairley[8,9], M. Stoove[4,10], N. Roth[11], R. Moore[12], B.K. Tee[13], N. Puratmaja[6], R.M. Grant[14,15,16], E. Wright[4,5,6], The VicPrEP Study Team
[1]*Utrecht University, Department of Interdisciplinary Social Science, Utrecht, Netherlands, [2]UNSW Sydney, Centre for Social Research in Health, Sydney, Australia, [3]University of Sydney, Department of Gender and Cultural Studies, Sydney, Australia, [4]The Burnet Institute, Melbourne, Australia, [5]The Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia, [6]Monash University, Department of Infectious Diseases, Melbourne, Australia, [7]University of Melbourne, The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [8]Melbourne Sexual Health Centre, Melbourne, Australia, [9]Monash University, Central Clinical School, Melbourne, Australia, [10]Monash University, School of Population Health and Preventive Medicine, Melbourne, Australia, [11]Prahran Market Clinic, Melbourne, Australia, [12]Northside Clinic, Melbourne, Australia, [13]The Centre Clinic, Melbourne, Australia, [14]Gladstone Institutes, San Francisco, United States, [15]University of California-San Francisco, School of Medicine, San Francisco, United States, [16]San Francisco AIDS Foundation, San Francisco, United States*

Background: Oral pre-exposure prophylaxis (PrEP) has proven highly effective in preventing HIV infection, provided sufficient dosing levels are achieved. Insufficient adherence is an important explanation for differing outcomes of PrEP efficacy trials and a major concern regarding the implementation of PrEP in community settings. We previously reported continued high adherence over the first year of follow-up among participants in the VicPrEP community implementation project. Here we report an in-depth analysis of experiences of pill-taking and attitudes regarding HIV, PrEP and condoms which may contribute to informing adherence support.
Methods: Initiated in 2014, VicPrEP was a first PrEP demonstration project globally with no site in the US, undertaken through one sexual health clinic and three general practice clinics in Melbourne, Australia. A total of 115 participants were enrolled over one year, with daily dosing oral PrEP available for up to 30 months. Participants were provided baseline and 3-monthly self-report questionnaires during the first year of participation. Five-point rating scales were used to assess attitudes regarding HIV, PrEP and condoms (1 = low, 5 = high). Prospective data analysis was undertaking using Generalized Estimating Equations.
Results: At three months follow-up, nearly all participants (95.4%) indicated pill-taking around the same time each day, mostly early mornings (50.6%) or at night (22.2%). In the past 7, 30 and 90 days, 87.4%, 63.2% and 48.3%, respectively, reported missing no doses. Self-reported full adherence did not change significantly over 12 months follow-up, assessed for the past 7 days (Wald Chi^2 (df=4) = 1.741, p = 0.628), 30 days (Wald Chi^2 (df=4) = 5.272, p = 0.153) or 90 days (Wald Chi^2 (df=4) = 5.543, p = 0.136). Multivariable analysis found, controlling for socio-demographic characteristics, baseline motivation to take PrEP predicted 7, 30 and 90-day adherence over follow-up; no other attitudinal variables were significant.
Conclusions: Contrary concerns regarding PrEP adherence in community settings, findings from the VicPrEP study show high self-reported adherence, indicative of adequate protection. Self-reported adherence in this study was previously found to correspond well with objective indicators. Importantly, solely motivation to take PrEP predicted adherence over various intervals, underscoring the importance of appropriate motivational support for PrEP use.

THPED437

PrEP acceptability and preferences among a respondent-driven sample of MSM at high-risk in India: A discrete choice experiment

P.A. Newman[1], V. Chakrapani[2], M. Shunmugam[3], M. Cameron[4], S. Roungprakhon[5], S. Rawat[6], R. Nelson[3], R. Scarpa[4,7]
[1]*University of Toronto, Faculty of Social Work, Toronto, Canada, [2]Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India, [3]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [4]University of Waikato, Hamilton, New Zealand, [5]Rajamangala University of Technology Phra Nakhon, Science and Technology, Bangkok, Thailand, [6]The Humsafar Trust, Mumbai, India, [7]Durham University, Durham, United Kingdom*

Background: HIV prevalence among men who have sex with men (MSM) in India is 20-fold higher than general population prevalence. PrEP was recently approved in India after years of off-label ARV use among MSM who could afford it. To inform emerging government policy on PrEP implementation, we assessed PrEP acceptability and preferences among MSM.
Methods: From January-April 2017, we recruited HIV-negative MSM using respondent-driven sampling initiated in cruising areas and community-based organizations in Chennai and Mumbai. We programmed a tablet-administered survey interview (TASI), in Tamil and Hindi, including a discrete choice experiment (DCE) to assess PrEP preferences. Survey items assessed demographics, sexual risk behaviors and PrEP acceptability. The DCE used pictorial cards and a drag-and-drop technique on the tablet screen. Participants were presented with 8 double-rounds of best-worst choice sets of PrEP-scenario cards, each composed of 5 dichotomous attributes. To support DCE design, we obtained empirically-informed priors for model coefficients from a formative qualitative study and pilot DCE survey. We used logistic regression to identify demographic and behavioral correlates of acceptability. We modeled marginal willingness-to-pay (mWTP) for attributes of PrEP derived from a conditional logit model using the Krinsky-Robb procedure with 5,000 replications.
Results: Participants (n=200) (mean age=26.6y [SD=6.6]; 19.5% ≤high-school education; monthly income, mean=12,280 rupees [~US$192]; 19.5% heterosexually married), reported multiple (mean=6.0, SD=4.3) partners and 63.6% inconsistent condom use (past month). 77.0% would use PrEP immediately upon availability. PrEP acceptability was positively associated with perceived HIV-risk (AOR = 3.41, 95% CI: 1.07-10.84, p=.03), inconsistent condom use (AOR = 3.16, 95% CI: 1.03-9.70, p=.04), and inversely with being married (AOR = .25, 95% CI: .07-.80, p=.02). mWTP indicated highest estimates for (high) efficacy, no (vs. minor) side-effects, intermittent (vs. daily) dosing, with no preferences for government- vs. private-hospital access. 62.0% endorsed "PrEP would avoid the hassle of using condoms," associated with acceptability (^{2}=15.9, p< .001).
Conclusions: High PrEP acceptability among MSM in India indicates substantial opportunities to support combination prevention. Tailored interventions for heterosexually-married MSM, intermittent dosing options, and low-cost PrEP through government hospitals may support uptake. Possible reductions in condom use indicate the need for interventions addressing STI risks and supporting PrEP adherence.

THPED438

Bypassing policy inertia: How a collaborative, multi-channel advocacy campaign secured PrEP funding in New Zealand

J.G. Rich[1], S. Azariah[2], J. Myers[1], K. Macpherson[1], P. Saxton[3]
[1]New Zealand AIDS Foundation, Auckland, New Zealand, [2]Auckland District Health Board, Auckland, New Zealand, [3]University of Auckland, Auckland, New Zealand

Background: In 2016 New Zealand recorded the fifth consecutive annual increase in HIV diagnoses among gay, bisexual and other men who have sex with men (GBM) and expanded HIV prevention options are urgently needed. International guidelines have recommended HIV pre-exposure prophylaxis (PrEP) since 2015 but there is still no official policy in New Zealand. Increasing concern about the lack of Government strategy and action on PrEP, and HIV in general, prompted the New Zealand AIDS Foundation (NZAF), a non-government organisation, to collaborate with community, clinical and research stakeholders to advocate for publicly funded access.
Methods: We used a range of strategies to build the case for public funding of PrEP:
- A demonstration project, enrolling 150 GBM, was conducted in Auckland to ascertain the acceptability of PrEP among this most-at-risk group and how it can be delivered in local sexual health clinics;
- A national consensus statement on comprehensive HIV prevention was developed and signed by over 100 clinicians, community organisations and researchers calling for change (https://hivconsensus.org.nz/);
- An online learning course was developed for clinicians to support prescribing of PrEP for patients to import from overseas, resulting in 25 providers having sound experience in delivering PrEP and building health sector support;
- The presence of the Prime Minister and Leader of the Opposition at gay pride events was leveraged to secure high-level commitments to publicly fund PrEP;
- When pharmaceutical companies held off applying to New Zealand's medicines purchasing agency PHARMAC for PrEP funding, NZAF lodged its own community application;
- A petition was launched calling for an expedited decision on PrEP funding, receiving 2,289 signatures.

Results: When government and health departments fail to show leadership on HIV, collaborative and multi-channel non-government advocacy can raise awareness, build coalitions and articulate a credible case for change.
These efforts have successfully resulted in PHARMAC proposing to publicly fund PrEP in New Zealand for individuals at high risk of HIV acquisition, including GBM, from 1 March 2018.
Conclusions: Funded access to PrEP is an important milestone however there is no updated national HIV action plan to support implementation. Urgent actions include physician and community education and surveillance to monitor PrEP uptake.

THPED439

Preparing for PrEP: Community-level challenges on PrEP uptake and use among *Hijras* and transgender women in Mumbai, India

D. Baruah[1], S. Rawat[1], M. Shunmugam[2], V. Chakrapani[2], P.A. Newman[3], V.R. Anand[1]
[1]The Humsafar Trust, Research, Mumbai, India, [2]Center for Sexuality and Health Research and Policy (C-SHaRP), Research, Chennai, India, [3]Factor-Inwentash Faculty of Social Work, University of Toronto, Social Work, Toronto, Canada

Background: Pre-exposure Prophylaxis (PrEP) is recommended for HIV prevention for most-at-risk groups. Recent investigations have provided some understanding around PrEP acceptability among MSM; however, very little is known for *hijra* and other transgender communities. This qualitative study aimed at understanding PrEP acceptability and challenges for *hijra* and other transgender communities in Mumbai, India.
Methods: From March to June 2016, we conducted three focus group discussions (FGDs) with *hijras* and transgender women (n = 19) and four key informant interviews, including two with community leaders. Focus groups and interviews were transcribed, translated into English, and analyzed thematically.
Results: FGD Participants' mean age was 22.2 years and mean monthly income was INR 16000; 52% reported primary education. 32% participants reported inconsistent condom use, 90% reported no water-based lubricants use, and 63% reported sex work. Only one participant had heard of PrEP before and 47% reported PrEP as being their first choice new-prevention technique if made available. While added protection was seen as an advantage, the following were reported as challenges around PrEP use:
1) daily adherence;
2) perception by family as drug users;
3) long-term impact of PrEP use on appearance;
4) being perceived as HIV positive; and
5) risk compensation.
While adherence was perceived as a challenge, participants expressed that shorter PrEP regimens could improve adherence. Participants and community leaders alike highlighted the possibility of PrEP being used to compromise on condom use particularly among *hijra*/transgender women in sex work. They further anticipated consistent PrEP use to be a greater challenge among *hijra*/transgender women living with families due to lack of privacy. While participants were informed of potential side effects, misconceptions around PrEP having long terms effect on physical appearance (sunken cheek) was perceived as a challenge to PrEP uptake.
Conclusions: Despite the established effectiveness of PrEP among marginalized populations, PrEP-related knowledge among Indian transgender women is limited. Challenges identified in our study could be addressed with demonstration projects, education, and sensitization at the transgender community level. Operational research should be undertaken to understand effective ways to improve PrEP-related knowledge and assist *hijra*/transgender communities in making informed decisions in using PrEP.

THPED440

Is willingness enough? Exploring physician perspectives on pre-exposure prophylaxis for HIV prevention and discriminatory attitudes towards key affected populations in Ukraine

B. Gibson[1], R. Marcus[2], O. Zeziulin[3], I. Pykalo[3], M. Filippovych[3], A. Taroyants[3], T. Kiriazova[3], K. Dumchev[3], S. Dvoriak[3], F. Altice[2,4,5]
[1]Quinnipiac University, Frank H. Netter MD School of Medicine, North Haven, United States, [2]Yale School of Medicine, Department of Internal Medicine, Section of Infectious Diseases, AIDS Program, New Haven, United States, [3]Ukrainian Institute for Public Health Policy, Kyiv, Ukraine, [4]Yale School of Public Health, Epidemiology of Infectious Diseases, New Haven, United States, [5]University of Malaya, Center of Excellence for Research in AIDS, Kuala Lumpur, Malaysia

Background: Ukraine has one of the highest HIV prevalence rates in Europe, with a concerning rise in new infections among men who have sex with men (MSM). Pre-exposure prophylaxis (PrEP) is an emerging intervention using HIV medications in HIV-negative individuals to prevent infection. PrEP has been shown to greatly reduce the risk of HIV infection but requires prescription and careful monitoring by physicians. Research has shown that despite familiarity with PrEP, physicians present a major barrier to PrEP access when they are unwilling to prescribe it. Access to PrEP is further complicated by stigma in healthcare settings that prevents key affected populations (KAP) from seeking and adhering to prophylaxis.
Methods: We recruited 209 physicians from across Ukraine to participate in an online survey, disseminated by email, assessing knowledge of PrEP, willingness to prescribe PrEP, and stigma-related constructs towards people living with HIV/AIDS (PLWHA), MSM, and people who inject drugs (PWID).
Results: Fifty-five percent of participants had previously heard of PrEP and 7 participants had prescribed PrEP. Nearly 74% of physicians reported their willingness of prescribing PrEP as ³8 on a scale of 1-10 and

most would prescribe PrEP to high-risk patients, including persons with an HIV-positive sexual partner (95.7%), a patient who exchanges sex for money (95.7%), a man who has sex with multiple male sexual partners (94.2%), and a patient who injects drugs and is not on opioid agonist therapy (91.4%). Using a "feelings thermometer," physicians reported significantly more negative attitudes towards people living with HIV (p< 0.001), PWID (p< 0.001), and MSM (p< 0.001) compared to general patients. Infectious disease specialists had significantly more positive attitudes towards KAP than other providers from other specialties (p< 0.001). Bivariate analysis showed a positive correlation between reporting a high likelihood to prescribe PrEP (³8/10) and currently caring for HIV patients (p=0.035) and prescribing antiretrovirals in the last 12 months (p=0.044).
Conclusions: While nearly all physicians expressed willingness to prescribe PrEP, particularly for high-risk patients, discrimination towards KAP was high, especially in non-specialized settings. Lack of familiarity with HIV care and discriminatory attitudes may present a barrier to accessing PrEP and other services.

THPED441

Community preparedness for HIV Pre-Exposure Prophylaxis (PrEP) among transgender women (TGW) in India: A cross sectional survey

V. Arumugam[1], A. Aher[1], S. Shaikh[1], S. Kandaswamy[1], V. Chakrapani[2], U. Chawla[1], S. Mehta[1]
[1]India HIV/AIDS Alliance, Delhi, India, [2]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India

Background: High levels of HIV prevalence(7.5%) and inconsistent condom use (about 45%) among transgender wome(TGW) as per the National AIDS Control Organisation(NACO) annual report 2016 points out the need for additional HIV prevention methods in India. With PrEP emerging as a key addition to the combination HIV prevention approaches, India needs to fast track prevention. India HIV/AIDS Alliance conducted a study to examine PrEP awareness and willingness to use PrEP amongst TGW, including those in sex work, in 6 different states of India under Prayas project with the support of ViiV Health Care.
Methods: A concurrent triangulation mixed methods study design was used. The study conducted focus group discussions (FGD) with 57 TGs in 6 sites, and 7 key informant interviews(KII) were conducted among health care providers (physicians), TGW leaders and government officials. A structured questionnaire was provided to 355 TGs who were recruited through CBOs at the study sites. It assessed PrEP knowledge, condom use, attitudes towards PrEP (after a brief information on PrEP was provided to all), preferences in relation to PrEP regimens and access venues, and other factors influencing PrEP uptake.
Results: PrEP awareness among TGW was low at 17%,but after provision of brief information on PrEP,81% were willing to use PrEP. 96% agreed that PrEP could prevent HIV and 86% sensed PrEP could prevent HIV resulting from forced sex. TGW in sex work and those who had high scores on perceived benefits were significantly more likely to report that they would use PrEP(p< 0.05). Those who had reported discrimination experiences from health care providers and family members were significantly less likely to report that they would use PrEP, as others might then suspect them to be sexually promiscuous or HIV positive(p< 0.05).
Conclusions: Findings suggest that PrEP is urgently needed to reduce the disproportionate HIV burden among trans women in India. However, there is a bigger need of ensuring complete and correct education about PrEP. Given the high levels of HIV prevalence and inconsistent condom use among TGW in India, PrEP should be introduced as part of combination HIV prevention approaches, in addition to condom promotion and distribution.

THPED442

Limited PrEP awareness and use among young men who have sex with men and transgender women in Metro Detroit

D. Chittamuru[1], R. Weingarten[2], D. Connochie[1], R. Stephenson[3], J. Bauermeister[1]
[1]University of Pennsylvania, School of Nursing, Philadelphia, United States, [2]University of Pennsylvania, School of Social Policy and Practice, Philadelphia, United States, [3]University of Michigan, School of Nursing, Ann Arbor, United States

Background: Young men who have sex with men and transgender women (YMTW) are at a disproportionately higher risk for HIV infection. Pre-Exposure Prophylaxis (PrEP) can greatly reduce the risk of HIV infection, yet awareness and uptake has remained low in these key populations. We examined PrEP awareness and likelihood of use among a sample of YMTW in Metro Detroit participating in a pilot mHealth intervention (iCON 1.0).
Methods: We enrolled a sample of YMTW (N=158; 8.8% transgender) between the ages of 15 and 29 (Mean=23.5 years old) from Metro Detroit. Approximately 43% of participants identified as a racial or ethnic minority. Most (93.7%) had completed high school. Almost two-thirds had ever tested for HIV, with 6.3% identifying as HIV-positive. Focusing on the HIV-negative and HIV-unknown subsample (N=148), we explored the association between PrEP awareness—as well as likelihood of future use—and participants' sociodemographic characteristics (e.g., age, income, race and ethnicity, sexual identity), self-reported HIV risk behaviors (e.g., transactional sex, multiple sexual partners, HIV-testing), and recent alcohol and substance use.
Results: Two-thirds of participants (67%) had heard of PrEP, yet only 8.3% had ever used PrEP and even fewer (6.2%) were currently using PrEP. PrEP awareness was more likely among YMTW who were older (Odds Ratio=1.18, CI= [1.04, 1.34]) and had higher incomes (Odds Ratio=1.17, CI= [1.01, 1.36]). PrEP awareness was not associated with any additional sociodemographic characteristics, HIV risk behaviors, or alcohol and substance use behaviors. Two-thirds (66.7%) of YMTW who had not heard of PrEP expressed interest in PrEP after its efficacy was explained to them, with PrEP interest being greater among gay men (Odds Ratio=11.9, CI= [1.82, 77.88]) as compared to non-gay identified YMTW. No other association was observed between PrEP interest and participants' sociodemographic characteristics, HIV risk behaviors, and recent alcohol and drug use.
Conclusions: Disparities in PrEP knowledge and intention persist among YMTW. Five years after Truvada was approved in the United States, awareness and uptake of PrEP among YMTW remains limited. Interventions and policies focused on addressing age and income-related barriers to PrEP awareness and uptake are needed among YMTW communities.

THPED443

Community-led assessment of awareness and willingness to use HIV pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) in the Philippines

J.D. Rosadiño[1], R. Pagtakhan[1], K. Jonas[2], G.-M. Santos[3]
[1]LoveYourself, Inc., Mandaluyong, Philippines, [2]University of Maastricht, Maastricht, Netherlands, [3]University of California, San Francisco (UCSF), San Francisco, CA, United States

Background: Recent studies have demonstrated safety and efficacy of dual antiretroviral oral pre-exposure prophylaxis (PrEP) in preventing sexual and parenteral transmission of HIV infection. Philippines, a lower-middle income country, has a rapidly emerging HIV epidemic, especially amongst men who have sex with men (MSM). While HIV preventive behavior, including HIV testing, among Philippine MSM is being brought to scale, formative research and pilot studies evaluating the PrEP concept for wider implementation among Philippine MSM should begin. However, a better understanding for potential demand for PrEP needs to be assessed. This study assessed PrEP knowledge and willingness to inform future PrEP programs in the Philippines.

Methods: An online survey was conducted by LoveYourself (a community-based organization based in Manila, Philippines) among MSM and TGW in the Philippines, aged 18 years old and above. A total of 1,706 respondents answered the survey: 1,268 HIV-negative and 193 HIV-positive. A separate survey was conducted among 245 volunteers of LoveYourself.

Results: Out of 1,706 total respondents, 51.23% are aware of what PrEP is. 72.50% (1,023 out of 1,411) HIV-negative individuals are "probably" and "definitely" interested in using PrEP, while 75.99% (1,070 out of 1,408) are "probably" and "definitely" intending to use it when it becomes available in the Philippines.

Conclusions: This survey has determined that majority of HIV-negative individuals are interested to take PrEP should it become available in the Philippines. Further analysis of data, including their attitudes, and linking it to their sexual and drug taking behaviours should be conducted. Multi-stakeholder forums and focused group discussions should also be conducted to better understand client concerns, and provide qualitative data. Market analysis connecting PrEP use and demand can also be considered. Results of further studies and analyses could help future implementation of PrEP use in the Philippines.

THPED444

Acceptability of PrEP-based HIV prevention options among men who have sex with men in China

C. Wei[1], L.-E. Shi[2], J. Li[2], H. Yan[2], H.F. Raymond[3]

[1]Rutgers Univesity, Social & Behavioral Health Sciences, Piscataway, United States, [2]Jiangsu Provincial Centers for Disease Control and Prevention, Nanjing, China, [3]Rutgers University, Epidemiology, Piscataway, United States

Background: The HIV epidemic among Chinese men who have sex with men (MSM) continues to expand rapidly. Efficacious or potentially efficacious biomedical prevention strategies may reduce new HIV infections among this population. We assessed willingness to use PrEP-based prevention options (oral pill, lubricant, enema) among MSM in Jiangsu Province, China.

Methods: Participants in a longitudinal cohort study completed an online follow-up survey in January 2015. They were recruited through venue- and online-based sampling methods. Data on sociodemographics, sexual risk behaviors, practices of douching, and willingness to take PrEP pills and use PrEP-based lubricant or enema were collected. Multivariable logistic regression was conducted to identify independent correlates of acceptability.

Results: Participants were diverse in terms of sociodemographic characteristics. Of 316 participants who responded to questions on PrEP-based prevention options, 20.3% were willing to take 1 pill a day whenever exposure was possible, 59.8% would use lubricant every time for any anal sex, 6.3% would use enema, while 13.6% would not adopt any of these options. In a multivariable model, being employed fulltime or a student (AOR = 3.89, 95%CI: 1.43, 10.6) and having had condomless anal sex (AOR = 1.71, 95% CI: 1.03, 2.82) were significantly associated with willingness to use PrEP-based lubricant. Douching practice, number of casual male partners, and lifetime HIV testing were not significantly associated.

Conclusions: Acceptability of PrEP-based lubricant is relatively high among Chinese MSM. If proven efficacious, appropriate marketing strategies are needed to advertise it to the target audiences. Furthermore, in order to encourage uptake of oral PrEP, sociocultural concerns need to be taken into consideration including addressing drug toxicity and adverse effects.

THPED445

A missing perspective: Injectable pre-exposure prophylaxis (PrEP) for people who inject drugs

K. Biello[1,2,3], A. Edeza[4], P. Salhaney[2,4], D. Biancarelli[5], M. Mimiaga[1,2,3], M.-L. Drainoni[5,6,7], A. Bazzi[8]

[1]Brown University School of Public Health, Behavioral & Social Sciences and Epidemiology, Providence, United States, [2]Brown University, Center for Health Equity Research, Providence, United States, [3]Fenway Health, The Fenway Institute, Boston, United States, [4]Brown University School of Public Health, Behavioral & Social Sciences, Providence, United States, [5]Boston University School of Public Health, Department of Health Law, Policy & Management, Boston, United States, [6]Boston University School of Medicine, Section of Infectious Diseases, Department of Medicine, Boston, United States, [7]Boston University School of Public Health, Evans Center for Implementation and Improvement Sciences, Boston, United States, [8]Boston University School of Public Health, Department of Community Health Sciences, Boston, United States

Background: Large-scale clinical trials are now underway to test the efficacy of long-acting injectable Cabotegravir for HIV pre-exposure prophylaxis (PrEP) (LAIP) among at-risk cisgender men and transgender women who have sex with men, and at-risk cisgender women. However, these studies do not include people who inject drugs (PWID), a group experiencing overlapping sexual and injection-related HIV risk that could likely benefit from long-acting forms of PrEP.

Methods: We recruited HIV-uninfected PWID through community-based organizations (CBOs) in the U.S. Northeast where injection drug use is prevalent and an increasing public health concern. Qualitative interviews explored perspectives on HIV risk and PrEP. Thematic analysis identified key themes regarding LAIP acceptability, including perceived advantages and disadvantages of this modality.

Results: Among 33 PWID, 20 injected at least daily. Common drugs injected were heroin (n=31), cocaine (n=24), crack (n=13), and methamphetamine (n=11). Two-thirds reported recent sexual risk for HIV (i.e., condomless sex) (see additional sample characteristics in Table 1).

	n (%)
Age in years; median (interquartile range; IQR)	36 (31.5-48)

0	14 (42%)
1-2	13 (39%)
3+	6 (18%)
Had Heard of PrEP Prior to Study	12 (36%)

[Table 1. Sample Characteristics (n = 33)]

Most participants were enthusiastic about LAIP, and expressed greater interest in this modality than in daily oral PrEP. Participants perceived that appointments every 2 months would be more feasible and easier to remember than taking a daily pill, especially during drug "binges" or periods of frequent use when daily adherence would be challenging. Additionally, for many homeless and marginally-housed PWID, participants discussed the benefits of not needing to carry or store medications. Female participants compared the benefits of LAIP to injectable and im-

plantable contraceptives. A minority of participants expressed concerns regarding LAIP, including general mistrust of medical providers and the possibilities that injections could "affect their high" or be "triggering" for those entering recovery.

Conclusions: Overall, LAIP was highly acceptable in our sample of community-recruited PWID, with many participants perceiving adherence and logistical advantages over daily oral PrEP medications. These perspectives from PWID highlight the relevance of, need for and the moral obligation for representation of this marginalized, at-risk population in clinical trials of LAIP. Without this, a major opportunity will be missed.

THPED446

Comparative acceptability and preferences for oral, injectable, and ring-based PrEP: A project Shikamana mixed-methods study among Tanzanian female sex workers

S. Beckham[1], C. Shembilu[2], N. Galai[3,4], A. Mwampashi[2], S. Likindikoki[2], J. Mbwambo[2], D. Kerrigan[1,5]

[1]Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States, [2]Muhimbili University of Health and Allied Sciences, Psychiatry, Dar es Salaam, Tanzania, United Republic of, [3]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [4]University of Haifa, Tel Aviv, Israel, [5]American University, Sociology, Washington, DC, United States

Background: Pre-exposure prophylaxis (PrEP) is an efficacious though neglected tool for HIV prevention for female sex workers (FSW). PrEP options such as oral tablets, long-acting injectables, and cervical rings may differentially overcome issues with stigma and poor adherence. This research explored FSW's needs and preferences in order to inform strategies to improve uptake and adherence.

Methods: This was a sequential, explanatory, mixed-methods, secondary study of the Shikamana FSW cohort in Iringa, Tanzania. The quantitative phase involved a regression analysis of baseline survey participants who self-reported being HIV-negative (n=428) and thus asked PrEP-related questions. The qualitative phase involved in-depth interviews (n=10) and two focus group discussions (total n=20). Participants were selected purposively to represent a range of perspectives. Topics included perceptions, preferences, and dis/advantages of oral, injectable, and ring PrEP.

Results: Among participants, 59% (253/428) thought PrEP was acceptable ("personally worth taking"), and 82% (339/414) preferred injectable over oral PrEP. Factors associated with acceptability included age >30 (aOR 2.54 [95%CI:1.45-4.44]), recent self-reported sexually-transmitted infection (aOR 2.49 [95%CI:1.53-4.07]), and alcohol use during sex exchange (aOR 1.89 [95%CI1.25-2.86]). Predictors of preferring injectable vs. oral PrEP included younger age (aOR 1.88 [95%CI:1.10-3.20]) and non-local ethnicity (aOR 1.90 [95%CI:1.12-3.20]). In-depth interviews indicated positive perceptions of PrEP. The injectable was preferred because of the convenience of an injection bimonthly, especially given the mobility and spontaneity of their work. Women also highlighted the ability to hide use from others and its similarity to injectable contraception. Participants were willing to take the oral form, but feared people would assume it is HIV treatment, and may thus put them at risk of HIV stigma and violence from clients. They recommended different packaging to reduce resemblance to other antiretrovirals. Ring PrEP was the least preferred; women feared it may fall out, be discovered by clients, cause infertility, or be "pushed up into the body." Participants felt that any PrEP use would not reduce condom use, but rather protect them from HIV with clients who refused condoms anyway.

Conclusions: PrEP utilization may be optimized through providing multiple options, which will be enhanced by soliciting FSW's preferences and adapting roll-out to be sensitive to their needs.

THPED447

PrEP uptake among female sex workers in Kenya: Issues and challenges

M. Akolo[1], J. Kimani[2], L. Gelmon[2]

[1]Kenya Aids Control Project, Clinic, Nairobi, Kenya, [2]University of Manitoba, Nairobi, Kenya

Background: Sex workers outreach program of Kenya (SWOP-Kenya) is based in Nairobi and offers HIV treatment and prevention services to approximately 16,000 female sex workers (FSW). A PrEP uptake pilot study among FSW was done in one of the SWOP clinics; 75% of the target was reached/ screened of which 98% were eligible but only 58.5% enrolled .Among those enrolled 38.4 % remained active -the rest were either discontinued or lost to follow up. These results prompted the SWOP team to find out why the low uptake.

Methods: A qualitative crossectional study was carried out among the community members. Ten PrEP ambassadors were chosen purposively and recruited as research assistants (Those who were able to read, write, communicate and active on PrEP). They carried out one focused group discussion (FGD) each in their community hotspot units on challenges of taking PrEP; each group had 6-10 FSWs. The information was taped-transcribed and thematic analysis was done. Trained research assistants administered Key Informant interviews to 12 peer leaders (PE), five outreach workers (OW) and six staff who participated in implementation of the Pilot study. The ambassadors later addressed the issue raised.

Results: The FGDs showed 92% of population had low knowledge level on PrEP and reported many fears; 23% reported fear of liver maceration by the drugs that in-turn cause non-stop diarrhea, 92% reported loss of "marketing apparatus" (lipodistrophy of the breasts and the buttocks), close to 50% reported fear of infertility / reduced libido. The ones who had enrolled reported gender based violence from sex partners who accused them of wanting to infect them knowingly; others lost their drugs while running away from the police officers at night. Some had been stigmatized by fellow sex workers as being HIV positive on treatment-this caused them to loose clients. 98% of legible clients reported willingness to take PrEP after ambassadors' intervention.

Conclusions: Community involvement in all stages of PrEP implementation is very vital in Kenya, the significant barriers described by participants may need to be addressed through education to increase PrEP uptake.

THPED448

What would it be for? The potential impact of HIV prevention technologies on young people's sexual lives in environments of inhibited hope

S. Paparini[1], S. Bernays[2], N. Ngwenya[3], V. Dlamini[3], E. Tumwesigye[4], A. Asiimwe[4], J. Seeley[3,4,5]

[1]Graduate Institute of International and Development Studies, Anthropology and Sociology of Development, Geneve, Switzerland, [2]University of Sydney, School of Public Health, Sydney, Australia, [3]Africa Health Research Institute, Somkhele, South Africa, [4]MRC/UVRI Uganda Research Unit on AIDS, Social Science Programme, Entebbe, Uganda, [5]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom

Background: Proclamations about eliminating HIV are tantalising in their appeal, but the challenges in addressing the HIV incidence among youth as a key population in Sub-Saharan Africa are formidable and puncture the plausibility of such statements. The current epoch of HIV prevention is increasingly polarised between those contexts in which HIV prevention technologies hold unprecedented potential for reducing transmission amongst some populations, and those where complex structural drivers of HIV risk overwhelming narrow technological solutions. What can we learn from current qualitative work with young people about the possibilities for biomedical prevention interventions?

Methods: We draw on a series of multi-method, qualitative longitudinal studies with (160) young people affected by HIV (aged 12-24 years) in high prevalence settings in rural communities in Uganda and South Africa and, in light of thematic findings, reflect on global treatment as prevention (TasP) priorities of test-and-treat and pre-exposure prophylaxis (PrEP).

Results: Young people's social practices are moulded by community discussions which frame sexual risks as ubiquitous and where the consequences of acquiring HIV have been comparatively neutered by antiretroviral therapy. For young people, TasP remains not well understood and their engagement in test-and-treat is already fragile and undermined by multiple factors that would also impact on the feasibility of PrEP. The economic realities that young people are facing impede aspiration, encourage substance use and further disrupt the incentives to adhere to safe and protective behaviour. The future from where many of these young people are standing looks bleak.
Conclusions: TasP technologies need to be adapted and honed to interact with an array of broader prevention interventions that engage with the social (and highly gendered) realities of young people. Understanding the contexts, structures and economies which inhibit the hope necessary for young people to invest in sexual health is an urgent necessity in the era of TasP. In the enthusiastic pursuit of biomedical prevention technologies there is a risk that any limit to, or problems with, their effectiveness is interpreted as a failure of young people's behaviour, rather than as a reflection of their limited capacity to engage with the complexity of the contexts in which they intervene.

Risk compensation: conceptualisation, assessment, and mitigation

THPED449

Reality vs. perception: Differences in self-reported behavioral risk compensation between PrEP users and non-users in a large sample of American MSM

K. Biello[1,2,3], M. Mimiaga[1,2,3], K. Mayer[3,4,5]
[1]Brown University School of Public Health, Behavioral & Social Sciences and Epidemiology, Providence, United States, [2]Brown University School of Public Health, Center for Health Equity Research, Providence, United States, [3]Fenway Health, The Fenway Institute, Boston, United States, [4]Harvard Medical School/Beth Israel Deaconess Medical Center, Division of Infectious Disease, Boston, United States, [5]Harvard T. H. Chan School of Public Health, Global Health and Population, Boston, United States

Background: Pre-exposure prophylaxis (PrEP) is highly effective at preventing HIV acquisition among men who have sex with men (MSM). Some evidence suggests that PrEP use may increase rates of condomless anal sex (CAS) (i.e., risk compensation), thus increasing risk of STD transmission and HIV acquisition if adherence is suboptimal. This study aimed to examine risk factors for actual and perceived risk compensation when taking PrEP among high-risk HIV-uninfected MSM recruited via a large, national online sample.
Methods: Push notifications were sent daily to all active U.S. users of 2 MSM sexual networking mobile apps during March 2016 inviting them to participate in a brief, mobile-optimized survey. Multivariable logistic regressions were used to examine risk factors for perceived and actual risk compensation among PrEP non-users and PrEP users, respectively.
Results: Of the 4,638 respondents, 15% reported PrEP use. Of the 85% who never used PrEP, 30% reported that they thought they would increase their rate of CAS if they take PrEP in the future. Among those who had used PrEP, 43% reported that they had increased the rate of CAS when on PrEP. Among never users, being Black (OR=0.38, $p<0.0001$) and Latino (OR=0.65, $p=0.009$) (vs. White) was associated with lower odds of perceived risk compensation. Conversely, being older (OR=1.01, $p=0.005$) and having private insurance (OR=1.36, $p=0.05$) (vs. no insurance) and 2+ CAS acts (vs. no CAS) in the past 3 months (OR=2.9, $p<0.0001$) was associated with higher odds of perceived risk compensation. Among PrEP users, being Black (OR=0.52, $p=0.02$) was associated with lower odds, while reporting 2+ CAS acts in the past 3 months (OR=11.76, $p<0.0001$) was associated with higher odds, of reporting actual risk compensation.
Conclusions: Among this sample of risky MSM recruited online, PrEP users were more likely to report actual risk compensation when taking PrEP compared to perceived likelihood of risk compensation among never users, and risk factors differed between PrEP users and non-users. Differences in actual and perceived risk compensation should be considered in studies aiming to understand and reduce risk compensation in the future.

Combination HIV prevention

THPED450

Vaginal health and HIV prevention: Improving HIV programming for adolescent girls and young women by addressing vaginal practices

S. Leclerc-Madlala[1], N. Mazibuko-Ngidi[2]
[1]USAID, Office of HIV and AIDS, Washington, DC, United States, [2]Sol Plaatje University, Department of Anthropology, Kimberley, South Africa

Background: Social scientists have long suggested a possible association between vaginal practices and African women's risk of HIV acquisition. Research over several decades has explored behavioural motives and socio-cultural meanings, documented and classified particular substances and usage patterns, and estimated the prevalence of vaginal practices among various groups in HIV affected locales. Research in the context of microbicide development for HIV prevention has prompted a closer examination of practices in relation to their impact on vaginal ecology. More recently biomedical scientists have identified microbial factors that predict genital inflammation and suggest an association between inflammation and increased HIV susceptibility. We assess social and biomedical knowledge to date of vaginal practices in southern Africa and argue that there is a need to integrate vaginal health as a key protective issue for improving HIV prevention outcomes for adolescent girls and young women (AGYW) in high-burden countries.
Methods: This paper draws upon on-going ethnographic research commenced in June 2016 with women using *snuff* for sexual enhancement purposes in South Africa. We reviewed social science and biomedical studies of vaginal practices and vaginal ecology in southern Africa and situate our findings within this growing body of evidence.
Results: Vaginal practices are used for a range of purposes and hold various meanings for the women who use them. Most usage falls within three categories; for hygiene, health and wellness, and sexual enhancement purposes. Emerging evidence suggests some potentially harmful practices are increasing as women attempt to assert greater agency in sexual relationships with men and adopt behaviours associated with a more empowered femininity.
Conclusions: While still limited in terms of the precise biological mechanisms and pathways that might link particular vaginal practices to enhanced HIV susceptibility, we believe knowledge to date is sufficient to justify the immediate integration of education for vaginal health into HIV prevention for AGYW in high-burden countries. We identify some key lessons to inform the design of activities and the related pressures and cultural scripts that increase AGYW risk currently and likely in the future.

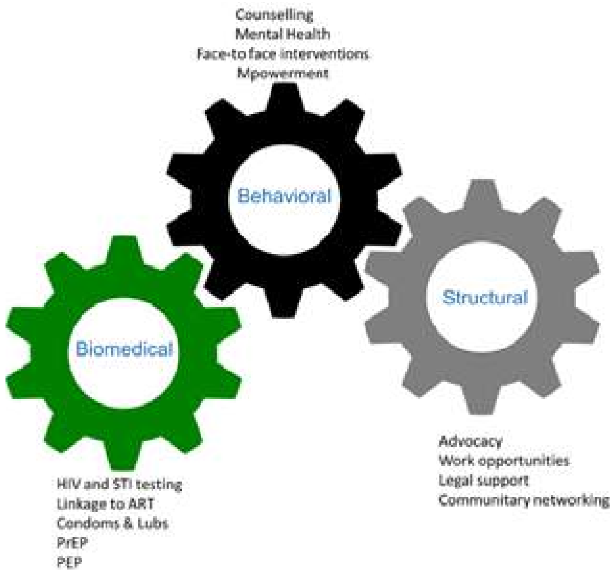
THPED451

Community based response to stop HIV in Guatemala: Combined prevention for and from the gay community in Guatemala city

R. Mendizabal-Burastero, C. Galindo-Arandi
Colectivo Amigos contra el Sida, Guatemala, Guatemala

Background: In Guatemala, MSM report the highest burden of HIV among key populations. Less than half had an HIV test done in the last 12 months and the coverage of prevention programs are less than 10% for them. Through different strategies based on the community, Colectivo Amigos contra el Sida (CAS) has implemented since July 2014, that including HIV and STI testing modalities, PrEP and PEP have reached nearly 50% of the MSM in Guatemala's department.

Description: First, we started a Saturday clinic opened, with an increase in coverage of three times with other similar services. Community testing was implemented since January 2015. To improve prevention, in October 2015 PrEP service was offered. In February 2016 we started a Monday-Friday night clinic, to improve access. In July 2016 we started PEP in case of sexual risk. We also implemented HIV testing with a mobile unit in 2016. We integrated mental health and legal services for MSM in 2017. We based our outreach in volunteer networks, but some of them were offered a job in our institution, part of a constant renovation process. Since 2016, we are also part of Ministry of Health (MoH) STI sentinel surveillance.



[CAS Combined Prevention Concept]

Lessons learned: Nearly 10,800 MSM accessed to HIV and STI services. 1 of every 3 MSM served had an STI, and a total of 642 HIV cases were diagnosed and linked 97% of them to HIV treatment services. 31 persons have been on PrEP and 30 on PEP, none HIV infection in both groups. We are currently an innovative service in Central America, as we are the only service to offer PrEP and PEP in the region, the first MSM-oriented mental health program and the biggest HIV testing service in Central America for MSM.
Conclusions/Next steps: Real combined prevention services by the gay community in a developing country are feasible, and our model can be easily replicated in other countries in Central America. Sustainability with the support of the MoH is a step needed, to ensure provision of prevention services for MSM. Integration of efforts between MoH and community is urgently needed to stop HIV in the region.

School-based sexual education, life skills and gender equality education

THPED452

How to develop effective comprehensive sex education? The 'Long Live Love' program - an example from the Netherlands

L. Schutte, S. Meijer
Sti Aids Netherlands, Youth, Amsterdam, Netherlands

Background: The Netherlands is often presented as an exemplary case for its pragmatic dealings with youth and sexuality. This is reflected in the lower numbers of teenage pregnancies, sti's and sexual coercion. Comprehensive sex education in the school-based setting contributes significantly to the positive sexual health of the Dutch youth. 'Long Live Love' (LLL) is by far the most successful , effective, evidence-based program in the field of sex education in the Netherlands. It has existed for over 27 years with the current program being the fourth generation. The systematic development of this program using the Intervention Mapping protocol is highlighted as an example for producing effective sex education programs. How can program developers optimize their current approach to a more systematic one? What are the benefits of systematic intervention development? How does this relate to the effectiveness of interventions? An example is provided with Long Live Love.
Description: Long Live Love is a school-based sex education program for secondary school students aged 13-15. It aims to assist youngsters in the healthy development of their emerging sexuality. It not only addresses knowledge but is also aimed at attitudes, skills and behavioural change. LLL is a teaching pack that consists of a student magazine, a DVD or online films, digital lessons and a teacher manual. LLL compromises six lessons , using a positive approach towards sexuality with attention for cultural-, gender- and sexual diversity . It targets unwanted teen pregnancy, sti's, assertiveness, communication, respecting and accepting boundaries, HIV/sti testing, managing relationships and dealing with sex on the internet. It was developed in close collaboration with students, teachers and Municipal health Service professionals using the Intervention Mapping protocol as a planning tool.
Lessons learned: The systematic and planned development of LLL has resulted in a proven effective program as shown in a national effect study. Over 550 schools have already ordered the program, with over 140,000 student magazines having been distributed.
Conclusions/Next steps: This systematic approach to intervention development serves as framework for sexual health promotion initiatives in other countries, with the highest potential for effectiveness.

[Long Live Love program]

Footprints of school based sexuality education in Uganda: Straight talk foundation's experience

R. Imakit[1], G. Walakira[2], I. Kato[2], D.O. Namukuza[2], S. Ajok[2]
[1]Straight Talk Foundation, Reserch and Evaluation, Kampala, Uganda,
[2]Straight Talk Foundation, Kampala, Uganda

Background: Sexual and Reproductive Health and Rights (SRHR) Alliance in Uganda is a consortium of 8 partner organizations (Straight Talk Foundation (STF) inclusive) implementing Get Up Speak Out (GUSO) for Young Rights program (GUSO 2016-2020). The program is funded by Dutch Ministry of Foreign Affairs and aimed at empowering young people to realize their SRHR in restrictive societies. The program is implemented in 2 Ugandan districts namely: Iganga and Bugiri. The two districts are chosen based on high teenage pregnancy rates standing at 30.1%.
Description: The GUSO program focuses on Sexuality Education by serving as mechanism to voice young people's rights among health, social policy and legal actors. STF uses a whole school approach (WSA)

in implementation which is based on the following principles: Ownership by the school; Involvement of all actors at schools; Participation and equity of all; a healthy, safe school environment; cooperation between the education sector and the health sector; Contextualization and embedding. To date; 60 schools are implementing sexuality education programs based on WSA in Bugiri and Iganga districts. Over 60,000 young people, 12,000 parents and 600 teachers have been reached utilizing this approach. Target schools have reported reduced risky sexual activity among young people, lower rates of child marriages and early unwanted pregnancy, lower rates of STIs including HIV/AIDS.

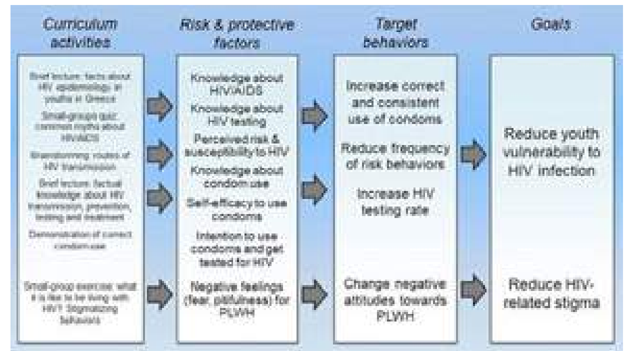
Lessons learned:
· There is improved school to school relationships and likelihood of more schools implementing sexuality education.
· Use of WSA ensures creation of safe, enabling environment to empower students, teachers and parents.
· Engagement of all stakeholders helped to curb the aggression of the community
· Having standard and uniform SRHR teaching materials led to improvement in accuracy and quality of sexuality education.
· Having well established youth corners in schools helps in managing menstruation, referrals and SRHR related problems and improved on retention of girl - child at school.
· Participation of School Management Committees and Parents Teachers Associations have created school ownership of the program.
· Integrating Income generating activities into SRHR intervention ensures self sustenance of the intervention in schools.
Conclusions/Next steps: Whole School Approach helps schools to implement sexuality education in a sustainable and scalable way.

THPED454

High school students' knowledge and attitudes towards HIV/AIDS: Baseline measures and the effectiveness of a nationwide, school-based program for HIV prevention and stigma reduction in Greece

A. Peltekis[1], P. Paranou - Lioliou[1], E. Pappa[2], K. Chatzimorakis[2], A. Kavouri[2]
[1]*Centre for Life, Thessaloniki, Greece,* [2]*Centre for Life, Athens, Greece*

Background: HIV prevalence is relatively high among youths in Greece with roughly 25% of new diagnoses concerning people aged 15-29 years (HCDCP, 2017). However, data on youths' knowledge of HIV/AIDS and attitudes towards PLWHA are lacking and no respective educational/prevention programs have been consistently implemented in Greece, nor tested for their effectiveness.
On September 2017, the NGO Centre for Life commenced the first nationwide, school-based HIV education program, authorized by the Greek Ministry of Education and scientifically edited by the National School of Public Health, aiming at raising high-school students' awareness of HIV/AIDS, promoting safe sexual behavior and reducing HIV-related stigma. 36,486 students have benefited until January 2018 (70,000 expected by May 2018 / 40% of the total population). The program applies a theory-driven logic model outlying its target variables and key interventions (Graph 1).
Methods: Adaptations of the HIV Knowledge Questionnaire (Carey & Schroder, 2002) and the HIV Stigma Scale (Visser et al., 2008) are used to assess baseline knowledge of HIV/AIDS and attitudes towards PLWHA in a stratified national sample of approximately 3,500 students, as well as the post-intervention effect on these variables in a subgroup of 1,200 students. Descriptive statistics and variance analysis are the main procedures used for data analysis. This is an ongoing study, the full dataset being expected by May 2018.
Results: Peers (73.8%) and the internet (56.1%) are the most common sources of students' information on sexuality issues, unlike school (17.7%), while 71.3% of students are unsatisfied from previous sexual education received by school. Results suggest a moderate baseline level of students' knowledge about HIV/AIDS (M=4.93/10, SD=2.54) and no significant gender difference, as well as relatively positive attitudes towards PLWH (M=7.29/10, SD=1.45) (n_1=1,246 [49.3% females]), with male students being more negatively biased towards PLWHA (r=.29). The intervention had significant (ps< .001) and large effects on both knowledge (r=.92) and attitudes (r=.83) (n_2= 548 [58.2% females], again with a significant gender x attitudes interaction (p=.003, r=.16).
Conclusions: Our findings clearly show the need for systematically applying sexual education programs within the school setting and that even brief interventions can induce large positive changes if certain conditions are met.



[Graph 1. Logic model developed for the HIV prevention and stigma reduction program]

The evidence on out of school Comprehensive Sexuality Education (CSE)

A. Irvin[1], I. Zhukov[2], M. Bakaroudis[3], M. Yamai[4]
[1]*Consultant, Bangkok, Thailand,* [2]*UNFPA, SRH Branch, New York, United States,* [3]*UNFPA, ESA Regional Office, Johanesbourg, South Africa,* [4]*UNFPA, New York, United States*

Background: UNFPA and its partners agreed to develop a guidance specifically on CSE delivered out of school. The literature review was conducted tosought evidence on the effectiveness and implementation of out of school CSE programs since 2008.
Methods: The initial search focused heavily on finding systematic reviews and randomized controlled trials using electronic databases. Systematic reviews were prioritized because they are based on extensive searches and synthesize the evidence from multiple randomized controlled trials and other types of studies, thereby providing time-efficient access to summarized findings. Randomized controlled studies were also searched for because they provide the highest quality evidence for the effectiveness of interventions, are the best way to assess the extent to which a program has its intended effect, and can provide specific examples of effective programs.
Results: Out of school CSE should preferably be embedded in multi-component, multi-level interventions. Emerging evidence indicates that CSE-related programs that directly address gender and power may have more impact on sexual and reproductive health and violence outcomes than those that do not. Clinic-based programs appear to be more effective in achieving their intended outcomes than other settings. Among the variety of delivery modalities of out of school CSE, parent-focused interventions and those that include parents appear to be more effective than family-based programs and programs delivered only to youth. Technology-based programs are still evolving and have yet to be tested in the "real world," but hold a lot of promise for reaching large numbers of young people cost-effectively. Peer education can increase knowledge and change attitudes but has not been found to consistently change behavior. However, programs that involve peers in outreach and education appear to be more effective in reaching hidden and stigmatized young people, such as young drug users and LGBTQ+ youth and are strongly preferred by Indigenous young people. Young key populations, LGBTQ+ people, people with disabilities, people in humanitarian crises, Indigenous people are neglected by current CSE programs.
Conclusions: Programs should involve young people from the group from the start, distinguish and address diversity within each group, treat them with respect and dignity.

THPED456

Finding them where they are: The potential of online social networking service for adolescent sexual health promotion

A. Nattembo[1], R. Imakit[2], S. Ajok[3]
[1]Straight Talk Foundation, Mass Media, Kampala, Uganda, [2]Straight Talk Foundation, Research and Evaluation, Kampala, Uganda, [3]Straight Talk Foundation, Management, Kampala, Uganda

Background: Population in Sub-Saharan African countries including Uganda is currently experiencing the increasing access to the Internet with the rapid prevalence of mobile phone ownership. Based on this background, sexual health promotions using Information and Communication Technology are taking place widely in those developing countries. However, sexual health interventions typified by text message services have not achieved long-term behavioral changes of adolescents who are at a great risk of sexually transmitted infections (STI) including HIV. Therefore, Social Networking Service (SNS) is drawing attention as an innovative alternative tool to impact on adolescent sexual health considering its increasing popularity.

Methods: A research study was conducted to explore the potential of online SNS for adolescent sexual health improvement in urban settings. The research adopted a mixed method consisting of questionnaire surveys and semi-structured interviews. The research participants received information regarding STI and HIV prevention on a Facebook group and their knowledge and attitude change was observed by a measurement tool. After the intervention, qualitative data on the participants' experiences were collected to specify what factors caused motivational change which could lead to sexual behavior change. 24 participants completed the whole research process.

Results: The results showed that the intervention had a certain degree of positive influence over sexual health knowledge and attitudes. The participants dominantly preferred education on SNS to other educational methods including text message services. The unique features to SNS such as the interaction with others, multimedia functions, compatibility and accessibility were discovered to make it easier for motivational changes towards target behaviors to happen.

On the other hand, it was revealed that behaviours related to cultural norms were difficult to change even by conducting sexual health promotion on SNS. The most interesting finding was that the participants found it easier to express their sexual values via online spaces than other occasions.

Conclusions: SNS could possibly be not only an instrumental sexual health promotion tool, but also a new educational opportunity. There is need to increase awareness of the available social media platforms so that more young people can access STI and HIV prevention information thus increasing their access to sexual reproductive health services.

THPED457

Access to comprehensive sexuality education and information by young people in schools and linkages to HIV/STI services

O. Corazon Ayoma, G. Ochieng
Family Health Options Kenya, Programs, Nairobi, Kenya

Background: Young people below the age of 25 constitute 66% of the total population in Kenya. Adolescents on the other hand make up 24% of the country's total population.

Young people (10-24) suffer from some of the worst SRHR outcomes . The causes of these poor outcomes include lack of correct and comprehensive information on SRHR issues including HIV and AIDS, barriers in accessing SRH services such as distance to health care centers, lack of access to youth friendly services and lack of knowledge on where to access SRHR services.

GUSO project is a four year project that sorts to empower all young people especially girls and women to realize their sexual reproductive health and rights in societies that are positive towards young people's sexuality. The program has three focus areas which include Advocacy, comprehensive sexuality education and integrated SRH/HIV services.

Description: The project is implemented in 4 counties in kenya. A needs assessment to map out schools with poor SRHR outcomes was conducted. A total of twelve schools primary and secondary were identified. As part of sustainability, the project identified young people in the selected schools and trained them as Trainer of trainers on provision of CSE.CSE in school is implemented in a structured way by the trained peer educators using FHOK CSE curriculum which has seven components. The components include sexuality Gender, SRHR and HIV, Sexual rights and sexual citizenship, Pleasure, Violence, Diversity and Relationships. Young people in schools are linked to nearby identified health centers for SRH/HIV services by trained peer providers.

Lessons learned: Training young people in school as peer educators to deliver CSE is a sustainability measure to ensure continuity and ownership even after project close out.

Lack of institutionalization of CSE curriculum in schools is a barrier to provision of CSE in school.

Results: 45844 (24755 F; 24755 M) young people were reached with CSE information and Education. Among these 6805(4682F;2123M) young people were reached with integrated HIV/SRHR services

Conclusions/Next steps: Conclusions/Next steps:

Advocate for inclusion of CSE in school curriculum

Continue to empower young people to exercise their SRHR rights

Involve parents in sex and sexuality dialogue

[Figure. Peer Educator facilitating on HIV/STI during Guidance and Counselling day]

THPED458

The whole school approach for sexuality education: A model for improving the implementation of school-based sexuality education?

I. Flink[1], A. Page[1], A. Schaapveld[1], T. Kruitbosch[1], V. Nyamongo[2], G. Walakira[3]
[1]Rutgers, Utrecht, Netherlands, [2]Center for the Study of Adolescence, Nairobi, Kenya, [3]Straight Talk Foundation, Training and Development, Kampala, Uganda

Background: Access to high-quality SRHR information and education is a key pillar to empowering young people to make safe and informed decisions regarding their SRHR. Governments around the world recognize this and are increasingly investing in school-based Sexuality Education (SE) programmes, also in Low and Middle Income Countries. Unfortunately, implementation challenges limit the sustainability, reach and effectiveness of such programmes. To address these challenges more systematically, Rutgers, the Centre for the Study of Adolescence in Kenya and the Straight Talk Foundation in Uganda are piloting a Whole School Approach for Sexuality Education (WSA for SE).

Description: The WSA for SE builds on the WHO health promoting schools framework and moves beyond classroom teaching of SE to address the whole school environment, including supportive school policies and school facilities, links with parents and the community and collaboration with health services. To follow the WSA implementation

closely, a pilot study which included an action research component was conducted between 2013 and 2015 among four schools in Western Kenya and eight schools in Eastern Uganda.
Lessons learned: The pilot demonstrated that by 2015, SE was more often timetabled and progress was made in reaching more students with SE (e.g. 48% increase in Uganda). By 2015, students reported more SRHR information sources within schools (e.g. through newly established links with SRH service providers). A focus on improving the school environment allowed schools to review their Codes of Conduct together with students and make changes to the physical environment (e.g. adding locks to toilets). Consequently, students reported feeling safer and absentee and dropout rates decreased. The pilot also demonstrated that by involving parents, the school management and government officials, more support is created for SE which, on the long run, is likely to lead to more sustainability and scalability of SE.
Conclusions/Next steps: This pilot shows that the WSA for SE has potential to reduce SE implementation challenges and improve ownership, sustainability and scalability of school-based SE. Given the short timeframe of the pilot study, it is necessary to follow schools for a longer period of time so that sustainability and scalability of the WSA for SE can be studied better.

Community-based approaches, including empowerment, outreach, and service delivery

THPED459

Supporting HIV treatment retention and adherence through community mobilization

M. Carrasco[1], E. Holman[2], R. Said[2], P. Poppe[2], M.E. Figueroa[2]
[1]USAID, Office of HIV/AIDS, Washington, United States, [2]Johns Hopkins Center for Communication Programs, Baltimore, United States

Background: Evidence points to the merits of community mobilization (CM) approaches for health promotion and HIV trials have examined impacts of community- and facility-based Antiretroviral Therapy (ART) care on adherence and retention. However, an in-depth analysis of the interplay of community factors promoted through CM approaches to support pro-ART attitudes and behaviors remains under-explored. This study analyzes these factors using end-line data from PACTO, a CM program implemented in Mozambique (2010-2016) to increase utilization of HIV services, strengthen the continuum of care, and promote HIV-supportive and gender-equitable social norms.
Methods: We used a qualitative subset of 22 interviews and 17 focus group discussions from the following PACTO participants: people living with HIV (PLHIV), community members, NGO staff, focal points linking communities with health facilities, and HIV health care providers. Thematic narrative analysis, using the collaborative web-based software Dedoose, identified community-level factors conditioning individual ART engagement behaviors and explored the role of CM in promoting these factors.
Results: With PACTO support, a critical mass of players with pro-ART attitudes was strengthened, providing an enabling environment for ART engagement. PACTO helped make cumulative acts of ART adherence and retention more valued and more visible, supporting ART use as normative. This was done through the formation of various community support groups, dissemination of information, community capacity building, and supporting community volunteers. In spite of increasingly supportive norms, internalized individual HIV stigma was still strong among many PLHIV, triggering a reluctance to seek care and risk public exposure. In those cases, a PACTO-supported multilayer net of community players including PLHIV, focal points, and NGO and health care staff brought patients back to ART through creative personalized approaches. This was made possible in an environment of community cohesion around the value of ART for broader community health. Results indicate that a supportive multilayer network, enabling social norms, community cohesion around health, and community agency to act were key community factors supporting ART access, retention, and adherence.
Conclusions: The results suggest that a CM program can precipitate community pro-ART attitudes and supportive behaviors that create an enabling environment to support ART access, retention, and adherence and make them sustainable.

THPED460

Developing the Y+ South Africa Network

T. Ngoato[1], H. Stevenson[2,3], T. Marshall[4], S. Jantjies[5], S. Brown[6], K. Moagi[7], T. Benge[8], T. Khuzwayo[9], S. Msomi[9], M. Dabaza[10], L. Nolusindiso[10], E. Dudula[8], N. Nelisiwe[11], V.R. Molapo[12], M.M. Modiba[12], M. Mokhothu[13]
[1]Y+ South Africa, Johannesburg, South Africa, [2]Y+ South Africa, Kimberly, South Africa, [3]Southern Africa AIDS Trust, Johannesburg, South Africa, [4]Y+ South Africa, Bloemfontein, South Africa, [5]Y+ South Africa, Bethel, South Africa, [6]Y+ South Africa, Mafikeng, South Africa, [7]Y+ South Africa, Rustenburg, South Africa, [8]Y+ South Africa, Cape Town, South Africa, [9]Y+ South Africa, Durban, South Africa, [10]Y+ South Africa, Port Elizabeth, South Africa, [11]Y+ South Africa, Malene, South Africa, [12]Y+ South Africa, Polokwane, South Africa, [13]Y+ South Africa, Blomfontein, South Africa

Background: Increasing evidence indicates that young people living with HIV (YPLHIV) are underserved by HIV services. Actively engaging YPLHIV is imperative to ensure that services are responsive and provide sustainable, appropriate solutions. Networks YPLHIV provide structured platforms for engagement, and for members to connect and advocate for change. Currently no formal networks exist in South Africa (SA) for YPLHIV. To develop a Y+ network in SA a youth-led community consultation was conducted.
We aimed to ensure that YPLHIV are meaningfully involved from the outset of developing the network and gain insights to inform the identity and strategy of the network.
Methods: Sixteen workshops, based on participatory learning and action approaches, were conducted in all nine provinces of SA. YPLHIV aged between 15 -24 years were invited through posters in clinics and social media posts. Conducted by 16 trained YPLHIV, the workshops followed standardised guides and reporting tools. The outcomes were analyzed using qualitative content analysis and the key themes identified were presented at a national network development meeting.
Results: In total 419 YPLHIV participated; 49% were 15-18 years old, 54% were female, 58% lived in rural or township areas, 32% had not disclosed their status and 68% were sexually active. Participants highlighted internal and external stigma, fear of rejections and judgement with many not wanting to disclose. Emotional distress including suicidal ideations were prominent especially when newly diagnosed. Accepting their status took time and was made possible with support especially from others YPLHIV. Poor access to and quality of services were noted with lack of information as a major barrier. Participants requested that the network be youth-led. That it provides information, builds skills, raises awareness and empowers them to live positively. They want a support systems, a safe space to be heard and listened too and a platform that connects them. Ultimately, they want a network that raises their voice, advocates on their behalf and fights for their rights.
Conclusions: A consultation process was imperative to ensure that Y+ SA is responsive to the needs and desires of YPLHIV in SA. The network's identity and work plan have been developed based on these outcomes.

THPED461

Capacity development for improved performance of organizations serving key populations with HIV services

E. Kuhlik, B. White, L. Stenberg, S. Ko
Pact, Washington, United States

Background: Pact's capacity development (CD) theory of change posits that organizational CD interventions improve internal systems, policies, processes, procedures, and networks, leading to increased organizational performance, translating into improved programmatic impact. Under LINKAGES—a USAID/PEPFAR-supported, FHI 360-led global mechanism that aims to reduce HIV transmission among key populations (KPs) and improve their enrollment and retention in care—Pact

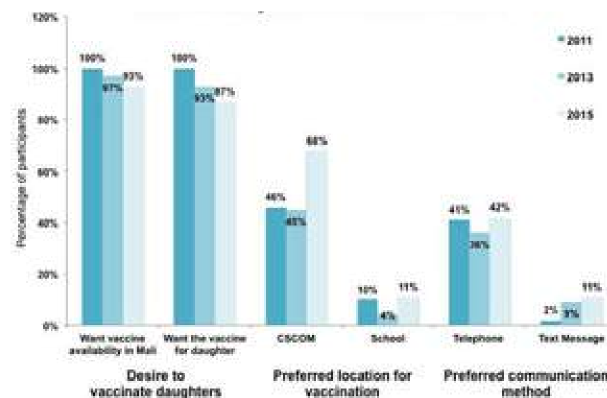
strengthens civil society organizations' (CSOs) performance to help close leaks in the HIV cascade. Increased organizational performance is measured using an organizational performance index (OPI) tool.
The OPI measures the outcomes of CD efforts and helps adapt CD programming to tailor support to the needs of CSOs to allow for greater impact on organizational performance.
Methods: Between November 2014 and September 2017, OPI scoring was completed with 65 CSOs across 12 countries, with 28 completing follow-up scoring beyond baseline. OPI scores were analyzed in Excel using quantitative descriptive analyses, and t-tests.
Results: The average baseline OPI score was 2.13 out of 4.0 with no significant regional difference between Caribbean (2.18; n=4) and African (2.15, n=7) scores.
For CSOs with two rounds of OPI scores, the average second-round score (2.79) is 31% higher ($p< 0.05$) than the average baseline score (2.13). The average score by OPI domain increased significantly ($p< 0.05$) by the second round for all domains (efficiency, effectiveness, relevance, sustainability) and eight subdomains.
As additional OPIs are conducted, updated data can be presented at the conference.
Conclusions: OPI scores measure organizational performance of CSOs, which is critical to HIV service delivery to KP. Baseline OPI results are consistently low across LINKAGES regions (average of 2.13 out of 4), which suggests that CD support continues to be necessary to improve CSO performance for HIV service delivery.
During the time that CSOs received tailored CD support under LINKAGES, the OPI scores of those with two rounds of scores increased significantly. These results suggest that CD support plays a role in improving capacity and organizational performance of KP-serving organizations.
Following LINKAGES CD support, KP-serving CSOs are likely better placed to more effectively deliver HIV services to KPs than they would have been without Pact's support.

THPED462

Barriers to vaccine delivery: Polling mothers to determine best practice for vaccine trials and vaccination campaigns in Bamako, Mali

L.Y. Diarra[1], K. Tounkara[1], I. Teguété[2], S. Coulibaly[3], A. Bagayoko[4], P. Fané[4], Y. Sylla[3], Y. Kone[1], F. Tembely[1], K. Sangare[5], S. Beseme[6], E. Squibb[6], O.A. Koita[5,7], A.S. De Groot[6,8]
[1]GAIA Vaccine Foundation, Bamako, Mali, [2]Gabriel Touré Teaching Hospital, Bamako, Mali, [3]Health Reference Center of Commune 1, Bamako, Mali, [4]Regional Health Department (Direction Régionale de la Santé), Bamako, Mali, [5]Laboratory of Applied Molecular Biology (Laboratoire de Biologie Moleculaire Apliquée), Bamako, Mali, [6]GAIA Vaccine Foundation, Providence, United States, [7]University of Science, Techniques, and Technologies of Bamako (USTTB), Bamako, Mali, [8]Institute for Immunology and Informatics (iCubed), University of Rhode Island, Providence, United States

Background: Logistics and parental preferences are an important factor in vaccination campaign design. Resistance to vaccination, often caused by lack of information, is becoming a global issue. GAIA Vaccine Foundation has focused a body of research on the HPV vaccine, because existing vaccines are safe and increasingly accessible. GAIA's research on Knowledge, Attitudes and Practices (KAP) related to HPV and cervical cancer (CC) and Willingness to Participate (WTP) in Bamako, Mali can provide a model for future campaigns.
Description: GAIA's HPV research has included: 2011 KAP/WTP study among 25 women, 2013 KAP/WTP study with 301 subjects, including 75 women, and 2013 KAP study among 236 women with CC. In 2015, GAIA developed an education campaign and KAP study to address a lack of information about HPV. The 6-month campaign promoted free CC screening at 5 Community Clinics (CSCOMs). Healthcare personnel mediated public educational events, and 500 women seeking CC screening were surveyed for KAP/WTP.
Lessons learned: All KAP/WTP surveys demonstrated that knowledge of HPV was low (13%, 2015) while knowledge of CC was high (75%, 2015). Desire for the HPV vaccine in Mali remained high over the years, and the majority of women wanted vaccination for their daughters. For vaccine delivery logistics, CSCOMs were preferred locations for vaccination, over school-based campaigns. Participants preferred phone call reminders, rather than text messages. 45% of women would provide consent for a child's vaccination, but 52% said they would contact their husbands for consent.



[Desire for HPV Vaccine Availability in Mali and Preferences for Vaccine Delivery and Communication Methods]

Conclusions/Next steps: HPV vaccination is strongly desired by participants in GAIA's KAP/WTP studies in Mali. Leveraging cervical cancer awareness, which is greater than HPV awareness, will improve the uptake of HPV vaccination in future campaigns. Since mothers have a degree of autonomy related to decision-making for their daughters in Mali, CC prevention (HPV vaccination) campaigns may be improved by linking CC screening of women to HPV vaccination of girls at the same site. Yet, as is true in other areas of West Africa, it will be important to engage men, and to gain the approval of key opinion leaders such as religious leaders, prior to the introduction of the vaccine.

THPED463

Better together? A systematic review examining the effectiveness of HIV prevention interventions that involve building or strengthening social ties in low- and middle-income countries

V. Fonner[1], C. Kennedy[2], K. O'Reilly[1], P. Yeh[2], M. Sweat[1]
[1]Medical University of South Carolina, Psychiatry and Behavioral Sciences, Charleston, United States, [2]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States

Background: Forging community bonds and grass-roots organizing have been essential to the HIV response. Interventions have also deliberately sought to create and strengthen such bonds as a means of facilitating HIV prevention, through changing both upstream risk factors (e.g., gender norms) and individual risk behavior. Terms such as "social capital" and "community mobilization" permeate the lexicon of HIV prevention; however, results from interventions aiming to increase social ties have not been synthesized, particularly in low-and middle-income countries. We systematically reviewed available evidence to understand how interventions created social ties, how ties were measured, and their effectiveness in preventing HIV.
Methods: We searched five electronic databases from January 1990-August 2016 to identify articles. Results were screened for eligibility by two independent reviewers. Studies had to be conducted in a low- or middle-income country, explicitly focus on building/strengthening social ties, and present pre/post or multi-arm results related to HIV prevention. We abstracted data into standardized forms in duplicate and synthesized results qualitatively.
Results: Of 4,801 unique citations screened, 25 articles evaluating 19 interventions met the inclusion criteria. We identified five intervention categories:
(1) Strengthening ties in general communities through social mobilization (n=2);
(2) Forming ties for collective action/group empowerment among at-risk populations (n=9);
(3) Forming peer groups for support and skills building (n=3);
(4) Expanding personal networks (n=2); and

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

(5) Forming ties between non-peers (e.g., between nurses and people living with HIV) (n=3).
Only 5 studies measured effects on some aspect of social relationships, including social cohesion, collectivization, social participation, peer interaction, and perceived community support. The vast majority of interventions demonstrated significant change in at least one HIV-related behavior, such as condom use. Several studies reported community-level change, such as decreases in social acceptance of intimate partner violence. One study measured the intervention's impact on community-level HIV incidence but found no effect. The rigor of study designs varied significantly.
Conclusions: Interventions were generally effective in facilitating individual-level behavior change, regardless of the intervention modality through which ties were strengthened. However, most studies seeking to alter social relationships did not directly measure such changes, limiting our understanding of the mechanisms through which these interventions prevent HIV.

[Intervention categories to increase social ties]

THPED464

MSM and TG/Hijra CBOs contribution to achieve SDGs: Promising practices and community system strengthening

U. Zarif
Bandhu Social Welfare Society, Policy, Advocacy & Communication, Dhaka, Bangladesh

Background: In Bangladesh, HIV prevalence is less than 1% and to reduce the impact of HIV amongst key population, different strategies have been taken by the GO, NGOs, Civil Society Organizations. As a part of commitment, a total of 30 TG/Hijra and MSM CBOs have been formed between 2011-2017 to strengthen the Community Systems and organized capacity building trainings and provided other technical assistance under Multi Country South Asia Global Fund Regional Grant. The objective of the support was to reduce the impact of HIV amongst MSM and TG/Hijra through developing local level network with local influential, practicing Good Governance, implement sustainable business plan.
Methods: Selection process was completed through organizational need assessment survey; developed Capacity Develop Plan, ensured support to all selective CBOs at 8 divisions in Bangladesh. Regular monitoring, support for organizational registration, arrangement of capacity building trainings to build the capacity of CBOs and staffs, developed different policies/strategies/guidelines of CBOs, introduced sustainable business plan for their self driven initiatives for future, established local level referral mechanism especially for HTC, and other support for HIV, STIs.
Results: More than 150 Hijra are in mainstream employment, 160 Hijra received NID cards as Third Gender, 14 CBOs got registration from Govt. authorities, Hijra are acknowledged as 3rd Gender by the Govt. of Bangladesh in 2013, 3rd box introduced in National Election Commission form, 10 CBOs introduced business plans and changed their livelihood, Hijra Manab Polli established where 90 Hijra are staying together, Anti discriminatory law drafted, inclusion of UPR, supplementary reading materials developed under direct supervision of National Curriculum and Textbook Board.156 positive articles produced as media campaign, Ministry of women and children affairs announced "Joyeeta Award" to Hijra for their social contribution.
Conclusions: These exemplary practices of CBOs in Bangladesh can contribute in achieving the targets of 90-90-90 by 2020, thus ultimately helping to attain SDGs. These practices of 30 CBOs may be documented, replicated and disseminated as pragmatic and do-able activities to reduce HIV in South Asia.

THPED465

Strengthening the identification and diagnosis of disability among children and adolescents living with HIV - a peer-led response

M. Mawodzeke[1], R. Makuvaza[2], T. Makamure[2], N. Willis[3], K. Madzeke[2], C. Nleya[4], V. Dzimba[5]
[1]Africaid-Zvandiri, Programmes, Harare, Zimbabwe, [2]Africaid-Zvandiri, Harare, Zimbabwe, [3]Africaid, Zvandiri, Zimbabwe, [4]Ministry of Health and Child Care, Harare, Zimbabwe, [5]Community Blind Mission, Harare, Zimbabwe

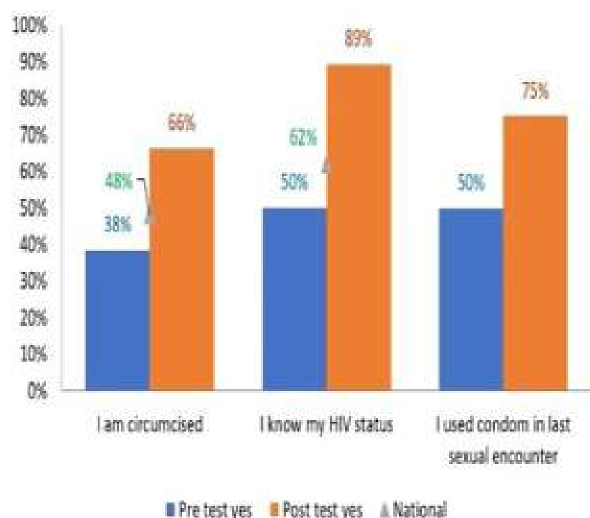
Background: Children with HIV worldwide are increasingly accessing HIV treatment, resulting in improved survival rates, although there is mounting concern regarding HIV-related disabilities amongst children growing up with HIV. The extent or nature of their disabilities is currently unrecognized, poorly understood and inadequately addressed. Africaid through the **'HIV & Disability Impact Mitigation'** project aims to improve the quality of life for children with HIV-related disabilities living in Harare (Zimbabwe), through increased understanding about HIV and disability by strengthening their access to appropriate quality health, rehabilitation and educational services.
Description: Since 2016 Africaid has been implementing the HIV and Disability Impact mitigation project where Community Adolescent Treatment Supporters (CATS) were trained on identification of disabilities/impairments among children and adolescents in the Zvandiri cohort aged 6 to 16 in Harare. The CATS utilise a simplified disability identification questionnaire which was developed in collaboration with Ministry of Health and Child Care Rehabilitation Department. The CATS work closely with the clinics and rehabilitation programme for referrals of cases identified at community level. The CATS continuously offer support to the children & adolescents with disability through adherence support done through home visits, sms reminders and support groups.
Lessons learned: 1502 children, adolescents living with HIV (CALHIV) in the Zvandiri care were screened for disabilities. The identification questionnaire was administered by CATS to all the children and adolescents identified at community level. Those at risk of disability were all referred for further screening for impairments by specialist health care providers. 808 of the 1502 (54%) children who were assessed were confirmed to be having significant physical and or intellectual disabilities that are interfering with their occupational and social functioning. The predominant impairments among those assessed were Visual (384), Hearing (323), Mobility (323), Cognition (476), Epilepsy (15). It is important to note that 328 CALHIV had multiple impairments.
Conclusions/Next steps: The prevalence of disability among this population of adolescents in Harare suggests that disability and impairments are a critical neglected concern. Further research is necessary to understand the prevalence and nature of disabilities among this group of young people so that disability can be integrated within HIV service delivery.

THPED466

Using an engendered, integrated community-based approach to HIV prevention among adolescent boys in peri-urban Swaziland

T. Churchyard[1], L. Kamugisha[2]
[1]Kwakha Indvodza, Mbabane, Swaziland, [2]UNICEF, Mbabane, Swaziland

Background: With an HIV incidence of 1.4% and prevalence of 27%, Swaziland has a severe HIV epidemic. Adolescents, especially girls, are increasingly at-risk. However, young Swazi men demonstrate low(er) uptake of HIV testing (48%), lower viral suppression (62.7%), poor transmission knowledge (66%), inconsistent condom use and low VMMC uptake (48%). This, coupled with the prevalence of patriarchal gender norms, GBV, and poor economic opportunities creates high HIV vulnerability among young men, and as a result, young women.
In 2017, Kwakha Indvodza (KI) and UNICEF provided a comprehensive package of adolescent behaviour change sensitizations and health services aimed at:
1) increasing uptake and referrals of quality HIV prevention service and products by 30%, and;
2) reducing violence against women and children by 15%.
Description: 235 boys and young men (15-25 years old, in and out-of-school), from three underserved peri-urban communities underwent an intensive curriculum of HIV prevention knowledge and services, gender sensitivity, GBV and economic empowerment. KI established male-focused youth centres which provided opportunity for service delivery, follow up and complementary services, such as psycho-social support, career guidance, parenting workshops and study support. The 5-month pilot programme integrated HIV prevention into other sensitizations and services to encourage uptake of HIV prevention services by combining referrals to existing health facilities and community-based youth-friendly HIV prevention services.
Lessons learned: Significantly increased participant status knowledge (89%), self-reported VMMC (66.3%) and self-reported condom usage at last sex (75%) among pivot-age course graduates. Substantial increase in gender-equitable norms and practices, including GBV awareness (38%) with 24% increase in GBV reporting at local police stations.
As a result of the study support, participants had improved parent-adolescent communication and better academic pass rate (15%-25%) at national exams than the average boys at their school.
Conclusions/Next steps: Integrated HIV prevention packages targeting young men should be implemented as an HIV prevention approach for young men *and* women.
Engaging adolescent males in HIV prevention requires more integrated approaches (combining medical, bio-medical, SBCC, skills development). Enhancing parent-adolescent HIV communication as HIV prevention approach needs further research. KI and partners hope to write a Facilitator's Manual and scale this pilot implementation model across Swaziland throughout 2018.



[Figure 1: Increase in HIV status knowledge and uptake HIV prevention products and services over the 5 months. 208 participants interviewed.]

THPED467

Center for friendly testing - network of people with HIV / AIDS Mar del Plata accessibility to HIV prevention, diagnosis and care in HsH, trans, sex workers

F.M. Parodi[1], R.E. Carrizo[2]
[1]Red de Personas con VIH/Sida Mar del Plata, Mar del Plata, Argentina, [2]Red de Personas Viviendo con VIH/Sida Mar del Plata, Mar del Plata, Argentina

Background: According to statistics from the National AIDS Directorate, the trans population has a prevalence of hiv of 34%, an average life of 40 years, the vast majority of which have sex work as a means of survival; men who have sex with men a prevalence of 12%; what makes it indispensable to address strategies to bring this population to the health centers to improve their quality of life and tend to decrease the transmission of HIV and meet 90-90-90.
Description: Creation of a rapid testing center generated, promoted and managed by key populations at the Headquarters of the Network of Persons with HIV / AIDS Mar del Plata in strategic association with civil society organizations related to sexual diversity and sex work, Secretary of Health, Secretary of Culture and Human Rights Directorate. Identify issues to generate interventions that bring the testing closer to the most excluded populations.
Lessons learned: Training of 10 people from the key populations to perform the test, counseling pre and post test accompaniment for access to the health system. 1 prevention campaign in the main bowling hall of sexual diversity Agreement with the Ministry of Labor to train 18 trans girls as multipliers in HIV / AIDS. Distribution of 15,000 monthly condoms to sex workers provided by the AIDS directorate. 1st Month 112 tests (F 40 - M 41 (29 HsH -12 Heteros) -Trans 31. Of the one hundred and twelve (112), eighty (80) corresponded to sex workers. 3 positives corresponding to After Migrants.
Conclusions/Next steps: Strengthen the training, education and empowerment of Trans girls, especially migrants, where we are detecting new cases of HIV and more difficulties we have to get closer to health centers. Intensify strategies with the Ministry of Health, Interior and Labor to facilitate the inclusions to the sanitary service of these population, work on Hormonization and implants of silicones.

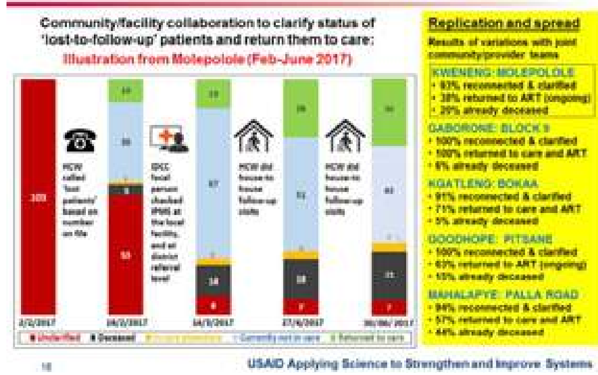
THPED468

Communities in the lead: The Botswana experience with community-led health improvement to achieve epidemic HIV control

K. Dikgole[1,2], C. Haverkamp[1,3]
[1]Human Resources for Health in 2030 Program, Gaborone, Botswana, [2]University Research Co., LLC, Gaborone, Botswana, [3]Chemonics International, Gaborone, Botswana

Background: Botswana has been hit hard by HIV/AIDS, and while largely successful, its national response has been costly, characterized by intensely vertical disease control efforts. Botswana's health system - once renowned for its proud embrace of Alma Ata and primary health care - was transformed through this emergency approach. Today, as the country is determined to think beyond HIV and re-balance its health system, focus is on the role of communities.
With more than one in five Batswana living with the virus, there is a strong call for an integrated community perspective that characterized Botswana before HIV.
Description: Under PEPFAR Botswana, the USAID-funded Applying Science to Strengthen and Improve Systems (ASSIST) project followed a community health system approach that applied quality improvement methodologies across seven districts in Botswana. Alongside local NGOs scaling HIV services under USAID's community platform, ASSIST reactivated existing but dormant community structures and reconnected them with district health systems.
Community teams under the mandate of traditional leaders received dedicated coaching to drive local efforts to improve HIV care. Tangible improvements in testing, retention and adherence were possible once

community and providers coordinated their activities around community preferences, and 're-wired' local accountability loops. These efforts achieved the return of unclarified (or 'lost') patients to ART at rates between 38% and 100%.



[Spreading 'what works': Addressing acute gaps in community ART retention across 5 districts]

Lessons learned: During dedicated 'Learning Sessions', community teams presented their results to national and district officials, ranging from community-led HIV testing to retention and adherence strategies. This demonstrated their willingness and capacity to contribute to common health goals, and the power of innovation that came from partnering with local providers to improve community health. In Botswana's unique context, traditional structures hold the promise of successfully revitalizing primary health care without undermining HIV control. In fact, they directly help in sustaining epidemic control- provided Botswana dedicates the necessary support to institutionalize new community partnerships.
Conclusions/Next steps: We continue to advise government on community-led service delivery strategies that differentiate care around community preferences and patient needs to improve integration and client orientation. The HRH2030 program will support the re-alignment and operationalization of health workforce frameworks to innovative models of care to 'deliver differently' in Botswana.

THPED469

Community entry experiences in implementing a model to prevent and respond to Gender Based Violence (GBV) and HIV in a highly prevalent GBV Community in Wakiso, Uganda

S. Mugamba[1], D. Kiwanuka[2], F. Nalugoda[3], G. Kigozi[4]
[1]Africa Medical and Behavioral Sciences organization, Kamplala, Uganda, [2]American Refugee Committee, Nairobi, Kenya, [3]Africa Medical and Behavioral Sciences, Kampala, Uganda, [4]Rakai Health Sciences Program, Grants, Science and Training, Kalisizo, Uganda

Background: .Previous studies have shown a link between Gender Based Violence (GBV) and increased HIV infections, and sexually transmitted infections. A significant reduction in GBV cases has been documented to be a promising strategy in reducing HIV incidence especially among high GBV prevalent communities. To ensure success of community based GBV interventions, systematic community entry and ownership of the programme by the community members remains a paramount factor. We describe experiences of implementing a community initiated model towards prevention and response to Gender Based Violence in this highly prevalent GBV Community.
Description: A combination of community entry packages were used including the following:
1) Strategic intervention mapping workshops to facilitate the community stakeholders own the intervention mapping,
2) Community driven selection of intervention activists that the community blesses and also believes in,
3) Early capacity building workshops for Community activists as a way of empowering the local communities to lead the implementation of the intervention, and;
4) Community participatory sessions to design GBV communication materials that are appealing and also resonate with the target audiences.
Community ownership and understanding of the intervention concepts are fundamental components in all community engagement activities.
Lessons learned: Sensitivity of GBV issues in the community, especially surrounding cultural backgrounds, beliefs and values require the use of strategies for community involvement to ensure ownership, continuity and sustainability. A well laid out community entry approach is key to successful implementation of community interventions. Involving community members to contribute to designing of GBV Communication materials guarantees suitability of appropriateness materials to the targeted audiences. Building capacity of community members to lead GBV programming significantly reduces the implementation budget and gives a variety of platforms to address the intervention messages.
Conclusions/Next steps: Early inclusion community members as lead persons in the implementation of GBV activities is as important as the interventions themselves. This significantly reduces cost of implementation and ensures a successful and quick roll-out plan that can be achieved through community ownership.

THPED470

Engaging MSM of color leaders in guiding HIV prevention, outreach and service delivery

E.T. Doctor[1], M. Shankle[2]
[1]HealthHIV, Capacity Building Manager, Washington, United States, [2]HealthHIV, Capacity Building Director, Washington, United States

Background: According to a Center for Disease Control and Prevention "Lifetime Risk of HIV Diagnosis" release, 1 in 2 black men who have sex with men (MSM) will become HIV positive in their lifetime if the current HIV diagnoses rates persist. Syndemic and proximity are directly related to the increase of HIV rates in MSM. Further, the social determinants of health (SDOH) and limited engagement in prevention research and public health strategies imply that HIV prevention efforts must be innovative. These approaches must engage MSM of color where service delivery structures have failed in empowerment and outreach.
Description: HealthHIV conceptualized and created the MSM of color Leadership Team (MLT) to provide valuable insight, constructive feedback, and creative recommendations for education and capacity building activities to be culturally informed and affirming to MSM of color. The MLT was formed to guide HealthHIV's national programs. The MLT are stakeholders that provide input to discern the intersections of engagement, mobilization, recruitment, and retention of MSM of color in HIV prevention and care. These 20 leaders were identified from geographic areas with higher prevalence of HIV in MSM of color. The MLT, diverse in age, education, socio-economic status, employment, and access to health care, advocates for the greater MSM of color community through an intimate understanding of High-Impact Prevention and HIV Treatment as Prevention.
Lessons learned: A critical lesson learned is that engagement of gay and bisexual men in public health strategies positively impacts service delivery and healthy outcomes of other MSM of color. The MLT brings a voice not previously heard in guiding service delivery and development of systems educational programs. The MLT has provided relevant and impactful perspective in curricula development, including modules on: Cultural Competency, Racism and Stigma, Peer and PrEP Navigation, and Motivational Interviewing.
Conclusions/Next steps: The MLT has informed national programs and activities in becoming more culturally competent. The MLT will continue to guide education and training activities. The MLT will continue to develop leadership capacity in HIV Prevention, leading toward more MSM of color guiding service delivery.

THPED471

Effect of duration of association with community-led organization on female sex workers' self-efficacy and self-confidence: Evidence from five Indian states

M. Walia[1], B. Mahapatra[1], M. Battala[1], S. Patel[1], S. Mukherjee[1], Y. Atmavilas[2]
[1]Population Council, HIV and AIDS, Delhi, India, [2]Bill and Melinda Gates Foundation, Delhi, India

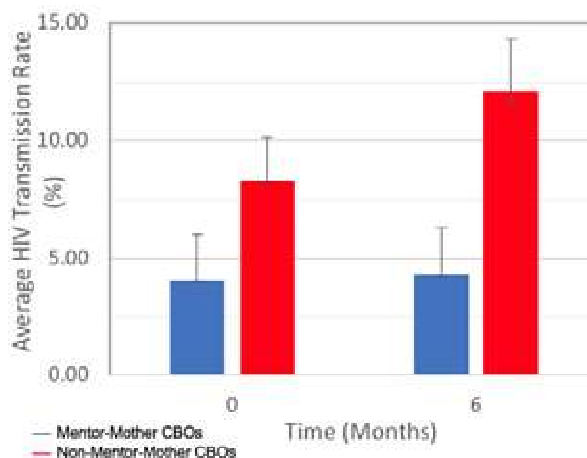
Background: Community-led programs have been leveraged and widely promoted in the recent years to reduce HIV prevention, social and financial vulnerability among the female sex workers (FSWs). One of the cornerstones of such programs is to improve the self-efficacy of individuals so that the collective efficacy of the community enhances. In this study, we examine the association between duration of association with community-led organizations (COs) and individual self-efficacy and self-confidence of FSWs in India.
Methods: The article uses data from a study conducted during in 2017 and involves a sample of 3,589 FSWs aged 18 years or older from four southern and one western Indian states. Self-efficacy was measured as FSW's ability to insist on using a condom with each client and partner under various circumstances, and their ability to get the reproductive health services from government or other clinics. Self-confidence was assessed based on their capacity to raise the voice to demand different services. Data were analyzed using bivariate analysis and multiple logistic regression models.
Results: Nearly three-quarter (72%) of FSWs had been members with the COs for more than 4 years. Compared to FSWs with less than four years of CO membership, those having longer association were more confidently speaking their opinion in the training or CO meeting (76% vs 67%, adjusted OR 1.33, 95% CI 1.12-1.58), and in giving advice to a fellow sex worker in accessing HIV services (71% vs 63%, adjusted OR 1.37, 95% CI 1.15-1.60). Similarly, duration of association with COs had positive association with FSWs' ability to insist on using a condom with the regular partners when he got angry with her (43% vs 34%, adjusted OR 1.56, 95% CI 1.32 to 1.84), and when FSW was offered more money by the client for sex without a condom (43% vs 34%, adjusted OR 1.39, 95% CI 1.18 to 1.63).
Conclusions: Community mobilization is the key to reduce vulnerability among FSWs. The findings from this study substantiate that sex workers who have been part of these community-led organizations for longer duration reported higher self-efficacy and self-confidence.

THPED472

The effectiveness of mentor mother programmes as a community intervention strategy to reduce vertical transmission of human immunodeficiency virus (HIV)

E. Moffatt
ViiV Healthcare, Positive Action, London, United Kingdom

Background: Following the UNAIDS Global Plan in 2011, vertical transmission of HIV was identified as a major contributor to the epidemic worldwide, with a particular focus in Sub-Saharan Africa. Mentor mother programmes employ HIV positive (HIV+) women to provide counselling, psychological support, and guidance to HIV+ pregnant women who are going through the prevention of mother-to-child transmission (PMTCT) care cycle. Comparing the health outcome indicators from Community Based Organisations (CBOs), the aim of this investigation is to assess and quantify how effective mentor mother models are at PMTCT of HIV.
Methods: The data used for this comparison was sourced from ViiV Healthcare's Positive Action for Children Fund (PACF) CBO partners, which was collected on an ongoing basis between January and July 2017 using a two stage sampling method; criterion sampling followed by simple random sampling. The health outcome data of 12 CBOs using a mentor mother model is directly compared to data from 12 CBOs that did not. The comparison aimed to show the critical impact of mentor mothers in communities in Sub-Saharan Africa in reducing the number of HIV+ children infected through the perinatal transmission of the virus.
Results: The results show that projects implementing a mentor mother model have significantly lower overall HIV transmission rate at 4.30%, compared to those that do not at 12.09%. Importantly, the mentor mother CBOs are having a significant impact on reducing HIV transmission rate between 0 and 6 months with an increase of only 0.23% from birth compared to 3.81% in non-mentor mother CBOs, a difference with p-value < 0.05.
Conclusions: Chi squared analysis demonstrates that the HIV transmission rate after 6 months is significantly lower in mentor mother CBOs compared to non-mentor mother CBOs, even when taking into account the errors of RDT. Most importantly the results show that the mentor mother model is particularly significant at reducing vertical transmission of HIV between the period of birth and 6 months whilst a mother is breastfeeding.



[Comparison of HIV transmission rates, at birth and at 6 months, between CBOs implementing a mentor mother model and those that are not.]

THPED473

Building HIV-positive and HIV-negative pregnant adolescent and young mother's knowledge, skills, resilience and problem solving abilities through a home visiting program (HVP) using a novel case management approach

H. Cornman[1], M. Levy[2], J. Odoyance Akuno[3], A. Berhan[4]
[1]JSI Research & Training Institute, Inc., Brattleboro, United States, [2]JSI Research & Training Institute, Inc., New York City, United States, [3]AIDSFree, Elizabeth Glaser Pediatric AIDS Foundation, Nairobi, Kenya, [4]AIDSFree, Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States

Background: Globally almost 60 percent of new HIV infections among 15-24 year olds are in adolescent girls/young women (AGYW), who face parallel risks of pregnancy and HIV. Data suggests mothers who received structured support from trained, supervised mentors were more likely to remain in care at 6-months postpartum compared with women receiving standard of care.
Description: The AIDSFree Program (June 2017-December 2019) aims to improve HIV and other health/social outcomes for both HIV-positive and HIV-negative pregnant adolescents (10-19), young mothers and their children. The program uses a case management approach comprised of a Home Visiting Team (HVT): peer-led mentoring for the pregnant AGYW/mother, support for parents/caregivers to address structural barriers to care, decrease stigma, and mobilize support (with male/female teams to reach men); and supervisory support for ongoing quality assurance. Through home-visits, HVTs support access to and retention in ante-natal care, including prevention of mother-to-child transmission (PMTCT) services and post-partum services for the mother-baby pair. Building resilience and problem-solving ability are key components as well as ensuring a strong bi-directional referral network to health/social services. Training for mentors and supervision of the HVT are important to overall success of the program.

Lessons learned: The project is implemented through two community-based organizations in Kisumu and Homa Bay counties, and will expand to Nairobi in 2018. The AIDSFree project completed a literature review in November 2017 and developed a comprehensive training curriculum specific to AGYW. Training covers topics including antiretroviral adherence and viral suppression; pre-exposure prophylaxis; partner disclosure; screening/referring for post-partum depression; and addressing gender-based violence. Training materials include standard operating procedures, job aids, and monitoring/evaluation tools. In January 2018, AIDSFree trained 24 HVT cadres (Mentors, Household Facilitators and Supervisors, total of 80 participants) on the 10-day training package including supplemental supervisor training. Community engagement sessions facilitate the commitment and support of community leaders. The project aims to reach 192 adolescents and their children.
Conclusions/Next steps: To reduce the gap of lack of services and programs designed for pregnant adolescents, young mothers and their children in Kenya and globally, program results will be shared with county and national governments and PEPFAR to assist with policy formulation and design.

THPED474

Good clinical treatment outcomes: A comprehensive community peer led model by reach out Mbuya Parish HIV/AIDS Initiative

J.S. Mambi
Reach Out Mbuya Parish HIV/AIDS Initiative, Community Support Department, Kampala, Uganda

Background: Reach out Mbuya Parish HIV/AIDS Initiative is a community, Faith Based Non-Government Organization which has been in existence for the last 17 years ROM delivers comprehensive HIV Care services using a unique holistic model of care to the urban poor and rural communities in Uganda.
Over the years, ROM has established Community peer models of HIV Patients in care, which relies heavily on community-based approaches that emphasize community ownership ensuring sustained impact in HIV epidemic control in Uganda. Using the different models, the community-facility linkages and referral systems,, client empowerment thus good community supported treatment outcomes.
Description: Through ROM's unique models of care, Community Health Workers are identified first as expert clients who have shown that good adherence to treatment and are willing to share their life experiences in regard to their treatment. The CATTS for example have been trained in basic counseling skills, facilitation in Health education sessions as a means to equip them with knowledge and skills to support clinical activities as well as Home Based Care activities like home visits, client follow ups, village meetings and Community Drug Distributions.
Lessons learned: In the first and fourth quarters of 2016, ROM realized client retention at 96.7 percent and 99 percent and adherence between 80.1 percent to 89 percent respectively. Most importantly, ROM has successfully maintained a zero percent transmission of HIV from mother to child since 2010.Effective Facility-Community linkages and feedbacks with regular communication to clients. At every village meeting, CHWs and clients use the fora to discuss critical service delivery to obtain feedback to Management.
Conclusions/Next steps: Treatment outcomes through the use of community peer models has proven to be an effective strategy for improving adherence to ART and leads to positive treatment outcomes. Teenage and adolescent supporters are key in supporting the transition process. M2M Community Based approach has helped strengthen the PMTCT strategies, including early Infant diagnosis and health facility based births.
Importantly, the utilization of CHWs ensures effective use of basic care packages and tracing missed appointments and Lost to follow-ups.

THPED475

Getting young people on board: How a community-based peer-led approach can improve SRH including HIV service uptake in rural Zambia

I. Phiri
Bwafwano Integrated Services Organization (BISO), Programs, Lusaka, Zambia

Background: Around 74% of Zambia's population is under 30. Zambian youths like others in developing countries face challenges such as high unemployment, poor educational opportunities, high rates of HIV, teen-pregnancy and early marriage. In Mkushi, young people face these same challenges, compounded by economic barriers, limited health infrastructure / personnel, / commodities, contributing to low uptake/retention to services - only 7% of 15-24 year olds had youth-friendly SRH service access in 2015.
The district has since set a target to increase this to 20% by 2019. Against this backdrop, national NGO BISO, began piloting the ADHERE project in 5 rural communities of Mkushi in 2017.
Description: The project facilitates access to youth-friendly SRH services focused on behavioural change interventions anchored on a strong peer-led approach building linkages between the community and health facilities. It addresses risk-reduction by targeting young people with high impact age-appropriate (10-15 and 20-24) HIV interventions empowering them with information/skills in HIV prevention and increasing access to/and uptake of HIV services. It closely works with community structures, leaders, schools, health facilities and parents/guardians. Interventions include establishment of school/community-based safe spaces, sports, referrals, screening for HIV/STIs/teen pregnancy/HIV testing and linkages to treatment.
Lessons learned: Peer-led approaches have increased access to and uptake of SRH services in Mkushi. In the first nine months of the project:
- Much improved engagement with health facilities, which previously struggled to reach this demographic
- 3,029 adolescents and young people tested for HIV
- 25.8% tested positive and referred for treatment - much higher than national prevalence of 12.9%.
- 6281 people engaged in safe spaces to talk openly about SRH
- 983 young people were tested for STIs and 1,174 for pregnancy with 36% and 20% testing positive respectively
Conclusions/Next steps: Empowering young people to mobilise their peers has been an effective approach to increasing SRH service uptake in this rural Zambian context. As the project develops, the need to provide greater support to adolescents/young people testing positive is emerging, as is the need for more engagement of parents to get their buy-in and challenging damaging norms, such as child marriage and abuse.

THPED476

"It's never too late" - building confidence of vulnerable adolescent girls to prevent HIV infection through sista2sista girls only clubs

T. Magure[1], R. Yekeye[2], A. Mpofu[3], S. Mpofu[4]
[1]National AIDS Council (NAC), CEO, Harare, Zimbabwe, [2]National AIDS Council (NAC), Operations, Harare, Zimbabwe, [3]National AIDS Council (NAC), M&E, Harare, Zimbabwe, [4]National AIDS Council (NAC), Harare, Zimbabwe

Background: The Programme was initiated in 2016 in 20 Hot Spot districts after a realisation that "Adolescent girls and young women (AGYW) in particular experience dramatically disproportionate burden and risk factors. Young women (20-24) have HIV prevalence 2.78 times greater than their male peers. 17.1% of women aged 15-19 who had sex in the last year did so with a partner that was ten or more years older (up from 15.2% in 2010 and 7.5% in 2005).
Further, 41% of girls report sexual debut before 18 years as unwanted and rates of transactional sex are high, and increasing." (Extended ZNASP III, 2015-2020).

The programme aims at:
Enhancing the self-efficacy of Adolescent girls to access and utilise integrated HIV prevention, SRH and GBV services, delaying sexual debut, standing up against child marriages, and reduction in teen pregnancies, reporting of sexual abuses.
Description: Vulnerable Girls are recruited into clubs by a sister mentor and taken through 40 week sessions covering five themes: Creating a Club Culture, Building Social Awareness, Increased Social Aptitude, Improving Sexual Knowledge and Financial Knowledge.
Lessons learned: A total of *10,367* girls were recruited into the club in 2017 and 6 609 were referred for HTS while 4,760 have accessed HTS and other services:

- The sista2siata club has proved to be a game changer for vulnerable girls who come out empowered to prevent HIV infection and other vulnerabilities as seen by the number of girls from the clubs who have accessed services.
- The sista2sista club has empowered the girls to start livelihoods projects which enables them to generate income.
- The club has assisted the girls to open up on GBV cases and some have gone to school.

Conclusions/Next steps: The sista2sista programme has greatly improved the health outcomes of vulnerable girls by improving knowledge level, addressing GBV and increased access to HIV services and need to be scaled up to national level.

Galvanizing the voice and action of religious and cultural leaders as champions and advocates for widows and orphans affected by HIV/AIDS in Kenya

W. Sila, J. Ng'ang'a
International Network of Religious Leaders Living with or Personally Affected by HIV (INERELA+) Kenya, Nairobi, Kenya

Background: In some Kenyan communities, widows and orphans are disinherited of their property immediately the father dies. The situation is worse for HIV-positive widows and OVC who, on the event of spousal or parental death, are disinherited by kinsmen and victimized through forceful eviction from ancestral land, resulting in displacement, poor quality of health, emotional and psychological trauma, and loss of livelihood.
Description: INERELA+ Kenya facilitated consultative forums to document experiences of disinheritance and displacement by HIV-positive widows and orphans. These experiences were shared with key opinion leaders, religious leaders, women leaders, Laikipia County leadership and the local administrative unit (Chief and sub-chief). Through support, training and mentoring, an Alternative Dispute Resolution Committee (ADRC) was formed. The committee has the capacity and commitment to address rights abuses against widows and OVC. As a result, 12 widows have been resettled in their matrimonial property and over 20 women have received necessary support towards settlement. Several OVC have access to family property. ADRC harmonized contradictions between modern and traditional culture and is intervening in disputes to promote women's and OVC land and property rights.
INERELA+ Kenya's technical assistance enabled the ADRC to implement advocacy programs through community '*Baraza's*' (forums) and congregational level responses to curb violations, administer and ensure referrals. There is now active representation by ADRC member in land boards that arbitrate inheritance disputes.
Lessons learned: Working with and mobilizing key religious, community, traditional and opinion leaders as advocates and champions for women and OVCs, especially in a highly patriarchal society, is a very effective method to promote access to land and property ownership.
Conclusions/Next steps: There is need to further build the capacity of the ADRCs on legal matters to enable them to advocate more effectively for the rights of HIV-positive widows and orphans.

THPED478

Empowering sub-Saharan immigrants in sexual health in Paris greater area: Results from the Makasi pilot study

A. Gosselin[1,2], C. Taeron[3], R. Mbiribindi[4], N. Derche[3], A. Desgrées du Loû[1,2]
[1]*CEPED (Université Paris Descartes, IRD, Inserm), Paris, France,* [2]*Institut de Recherche pour le Développement, Marseille, France,* [3]*Arcat, Paris, France,* [4]*Afrique Avenir, Paris, France*

Background: . In Europe, immigrants represented 37% of new HIV diagnoses in 2015 and immigrants from Sub-Saharan Africa are particularly affected (ECDC 2016). Between a third and half of HIV-positive immigrants in Europe acquired HIV post migration (Desgrées du Loû et al. 2016; Alvarez-Del Arco et al. 2017). Hence there is a strong need for efficient interventions to reduce immigrants' social and sanitary vulnerability. The aim of this study is to evaluate a community-based intervention for Sub-Saharan immigrants' empowerment in sexual health in Paris area.
Methods: Two community-based organizations (Arcat and Afrique Avenir) and three research teams conducted the pilot research. The formative phase was based upon participant observation in the two organization and strong peers' involvement. The resulting Makasi project is a two-component intervention: i) a mobile team of mediators identifying immigrant' needs through outreach thanks to a specifically designed tool and ii) two peer-health mediators delivering social support based on persons' expressed needs, orientation and navigation to health and social services with an empowerment approach. The pilot phase is taking place in February and March 2018. A randomized two-arm trial is led to compare the outcomes of the group receiving the intervention to a control group. Indicators of individual empowerment and intentions of behavioral changes are measured at baseline at three-month follow-up.
Results: Preliminary results show that a community-based multicomponent intervention is feasible and could reduce Sub-Saharan immigrants' vulnerability. A general-health-need approach, peers' involvement and the use of positive messages were identified as key elements of success.
Conclusions: A package of interventions designed to reduce social and sanitary vulnerability in order to reduce sexual health is feasible among Sub-Saharan immigrants' in Paris area.

THPED479

The role of ethnic identity and psychological empowerment in HIV and drug use prevention for Black and Hispanic female adolescents in the United States

I. Opara[1,2], R.J. Reid[1], P. Garcia-Reid[1]
[1]Montclair State University, Department of Family Science and Human Development, Montclair, United States, [2]New York University, Behavioral Sciences Training in Drug Abuse Program, National Institute on Drug Abuse, New York, United States

Background: Substance abuse and HIV/AIDS prevention research tends to overlook the resiliency skills that adolescents of color may possess. In addition, adolescent females of color, particular Black and Hispanic adolescents, are often viewed as a homogenous group with adolescent boys of color, thus ignoring unique gender-racial specific risk and protective factors to drug use and HIV/AIDS that may be present. Such an absence can lead to flawed outcomes in HIV and substance abuse prevention work that may continue to marginalize these groups. Using a strength based approach, this study aims to explore the role of psychological empowerment and ethnic identity on drug use and sexual and HIV risk behavior in Black and Hispanic adolescent females that reside in an impoverished and under resourced community located in Northeastern New Jersey, United States.
Methods: A sample of (N = 999) ethnic minority females' adolescents that were enrolled in a federally funded HIV/AIDS and Substance Abuse prevention program were used. Participants were between the ages of 10-17 years of age and identified as mostly African American/Black or Hispanic. Multiple regression models were conducted in order to show the associations of latent constructs that have an impact on sexual/HIV risk behavior and drug use in adolescent girls of color. Confirmatory factor analysis was conducted to reduce scale variables to create latent variables used in regression models.
Results: Multiple linear regression was used to develop a model for predicting drug use and HIV risk behavior in Black and Hispanic female adolescents. Preliminary findings revealed that ethnic identity and psychological empowerment significantly predicted drug use and sexual and HIV risk behavior in Black and Hispanic female adolescents ($p < 0.001$).
Conclusions: The findings suggest that adolescent girls of color in this community whom have strong ethnic identity and high psychological empowerment were less likely to engage in behaviors that place them at risk of contracting HIV. Implications from the study can inform preventive efforts by creating interventions and programming that seek to empower adolescent females of color and highlight ethnic identity as a method to HIV and drug use prevention.

THPED480

Exploring the role of social asset building in reducing risk of HIV infection among adolescent girls and young women in Mutare District, Manicaland, Zimbabwe

B.D.C. Mukome[1], G. Shumba[2]
[1]Family AIDS Caring Trust, OVC and Livelihoods, Mutare, Zimbabwe, [2]Family AIDS Caring Trust, Mutare, Zimbabwe

Background: AGYW aged 15-24 years account for 60% of new HIV infections globally. In Zimbabwe estimated number of new HIV infections per week among young women aged 15-24 years is 287. The DREAMS Initiative seeks to provide a comprehensive package of evidence-based strategies that go beyond the health sector, addressing the structural drivers that fuel AGYW's HIV risk, including poverty, gender inequality, sexual violence, social isolation, and limited schooling.
Description: Family AIDS Caring Trust (FACT) through the PEPFAR-funded DREAMS Initiative is implementing Social Asset building among AGYW in Mutare District. This is aimed at addressing social isolation and link to relevant services. 434 AGYW were drawn from ultra-poor households receiving Social Cash transfer grants, GBV Survivors, AG from early marriages, YWSS, Teenage mothers, and AGYW in high HIV burden communities. Community cadres and health professionals identified the AGYW together with trained mentors. They went through seven weeks sessions facilitated by a trained mentor aimed to delay sexual debut and marriage, prevent HIV infection and reduce tolerance of GBV in a fun and safe meeting space. Upon completion of the sessions the AGYW had a clear direction of what they want to achieve in life and the route to take, including staying HIV free.
Lessons learned: Out of 434 AGYW who graduated 75% went for an HIV test and received their results, 55 went for community apprenticeship programme, 78 for vocational skills training, 20 for non-formal education while 271 joined income and savings groups. Social asset building thus provides a good platform to access other critical services. Community based approaches using "safe spaces" are effective in the identification of at most risk girls and connecting them to the appropriate services that they need. Comprehensive programming for HIV risk reduction for AGYW requires significant investment to ensure services are accessed and utilized consistently.
Conclusions/Next steps: Social asset building presents as an emerging mechanism for addressing HIV risk factors among AGYW but its potential can be limited if services that can sustain their learning are inaccessible. There is need to consider targeting the community and family members who influence AGYW decisions

THPED481

Healthy Entrepreneurs: Using a business model to build sustainable community health systems, improving access to health products and HIV knowledge for adolescent girls and young women in rural Uganda

T. Beentjes[1], A. Lubega[1], H. Nakyeyune[1], F.C. Akello[1], C. Mwebaza[1], B. Facy[2], E. Nambozo[3], R. van der Oever[4], M. Weve[4], S. Nanziri[5]
[1]Healthy Entrepreneurs Uganda, Kampala, Uganda, [2]ICW-EA, Kampala, Uganda, [3]NAFOPHANU, Kampala, Uganda, [4]Aidsfonds, Amsterdam, Netherlands, [5]Sawa World, Kampala, Uganda

Background: In rural Uganda, access to accurate HIV-knowledge and sexual and reproductive health (SRH) products, such as condoms, is limited. The Sparked Women project, funded through PEPFAR's DREAMS Innovation Challenge, aims to reduce new HIV infections among Adolescent Girls and Young Women (AGYW), by strengthening local community health delivery systems through the social-enterprise: Healthy Entrepreneurs.
Description: In less than one year, Sparked Women, implemented by Aidsfonds, ICW-EA, NAFOPHANU, and Healthy Entrepreneurs, trained 907 female community health volunteers to become Community Health Entrepreneurs (CHEs); small business owners who collectively reach all parishes in six rural Ugandan districts. CHEs reach out specifically to AGYW, and to other community members with quality SRH-HIV messages, referrals, and health education videos on their electronic tablets, at the same time selling hard-to-come-by SRH products and over-the-counter medicine, critical in protecting AGYW against HIV acquisition. The small profit margin on the products is the Entrepreneur's income and covers the operational costs, thus maintaining a sustainable supply chain.
Lessons learned: The Healthy Entrepreneurs model improved community health delivery in less than one year (April-December 2017). CHEs spend more time on community health work than when working voluntarily and have increased self-esteem. CHEs each reach 1750 people on average per year, about 50% AGYW, with counselling sessions improving their SRH-HIV knowledge. In total 34,820 SRH-HIV education videos were watched by community members, who also benefit from locally available and reliable health products, reducing out-of-pocket expenses. The 907 CHEs provided 75,580 condoms, supported by Ugandan government, and sold 159,667 medicine and health products. The CHEs monthly income increased by 8.96USD, directly benefitting their families.
Conclusions/Next steps: The Aidsfonds' Sparked Women project proves Healthy Entrepreneurs is a cost-effective and feasible business model to increase SRH-HIV knowledge and strengthen community health systems. In a one-year period, with a one-time investment, a sustainable sales network is created guaranteeing continuation of the CHEs working in the communities when funding ends in September 2018.

Healthy Entrepreneurs is being scaled-up in Uganda to achieve national coverage of this sustainable community health delivery system improving communities' and AGYW's access to SRH-HIV knowledge and health commodities.

THPED482

Low-literate women leading the prevention of mother-to-child transmission of HIV in hard-to-reach areas of Cameroon

N.B. Lundi Anne Omam[1], E. Omam[2], G. Tabi[2], K. Azah[2]
[1]Reach Out Cameroon, Health/HIV, Buea, Cameroon, [2]Reach Out Cameroon, Buea, Cameroon

Background: Acess to antennal and Preventing mother-to-child transmission (PMTCT) services is very low in many hard-to-reach communities in Cameroon. In Bakassi, about 85% of pregnant women (PW) do not attend clinics (ANC) with almost 95% giving birth at home with Traditional birth attendants (TBAs). These low uptake of ANC services increases the risk of MTCT of HIV as prevalence of HIV amongst PW is above 15%. Furthermore, cultural beliefs, coupled to the insecurity and low literacy levels makes PMTCT/ANC service uptake to be very low (15%). We sought to pilot a project which capacitated low-literate women and TBAs to raise awareness on the importance of ANC, link pregnant women to clinics and follow up lost PW who were tested HIV positive.
Description: This project was piloted in 02 health areas in the Bakassi Health District. To inform communities about the project goals, advocacy meeting were held with community leaders. Forty TBAs and low-literate women were trained on community strategies to increase ANC uptake, effective linkage strategies for positive PW. This was followed by community awareness campaigns and follow up. The project was implemented from April 2015-March 2016.
Lessons learned: Representatives from 25 villages attended 02 advocacy meetings. Forty TBAs and community women were capacitated to lead community activities to increase ANC/PMTCT Uptake. A total of 6230 women, 5051 men and 504 PW received education on PMTCT and the importance of ANC. From the PW who were educated and referred, 120 were received at ANC1 with 11 tested HIV positive. A total of 306 people were tested during 03 VCP campaigns organised by the low-literate women. From the 306 tested, 161 were men and 145 were women. Forty persons tested HIV positive (07 men and 33 women). Strengthening community systems and TBAs offers opportunities to reach many PW and eliminate transmission of paediatric HIV.
Conclusions/Next steps: Ways of task shifting in post-conflict communities should be encouraged to reach vulnerable populations and increase HIV service uptake. Interventions that aim at empowering community members to conduct rapid HIV testing and community dispensation of ARVs in post-conflict areas will be exploited in the next phase of our projects.

THPED483

Optimism and acceptance of longitudinal community response to a HIV combination prevention package in Zambia, the HPTN071 (PopART) study

R. Ndubani[1], M. Simuyaba[1], B. Chiti[1], F. Ngwenya[1], D. Ziba[1], M. Gondwe[1], M. Simwinga[1], H. Ayles[1,2], V. Bond[1,3]
[1]ZAMBART, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [3]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, Faculty of Public Health and Policy, London, United Kingdom

Background: Community HIV care providers (CHiPs) delivering a combination HIV prevention package directly to households is part of the intervention being tested in the HPTN071 (PopART) trial in Zambia and South Africa. Using qualitative research methods, we evaluated community responses over time in 4 Zambian intervention communities.
Methods: Longitudinal qualitative data (2014-17) from 4 Zambian urban communities receiving the full intervention package included: eight Focus Group Discussions, eight household drop-in discussions, three in-depth interviews with traditional healers, 128 observations of door-to-door delivery, 20 community observations and over 400 researchers reflections on community responses. Group discussions and interviews were transcribed while observations and reflections were captured in structured report forms. Thematic and inductive analysis was conducted.
Results: The intervention initially met with some resistance emanating from fears of HIV disclosure within households and mistrust of staff, study motives and conduct. However, communities also hoped that the intervention might reduce HIV transmission and stigma and encourage HIV testing in men. Community concerns about men and traders missing out on the door-to-door delivery were confirmed by observations showing lower intervention uptake from men, which resulted in amending working hours. As the intervention progressed, community reported appreciation for: detailed HIV information, relatively private and confidential services, enabling less contact with the local clinic(s) (thereby reducing congestion), affording disabled people better access to services, linkage to other HIV services and a perceived reduction in mortality. However, stigma, acceptance of HIV-positive results and linkage to care remained challenging. Despite this, CHiPs, identified by uniforms and staff cards, became well known and rapport with and trust in them was evident. Indeed, cases of community members seeking out and requesting certain services from CHiPs increased over time. Familiarity and optimism nurtured during intervention years was accompanied by concerns about what would happen when the trial ended.
Conclusions: Community confidence in home delivery of HIV services took time to build. Once established, better community management of HIV played out into optimism and appreciation of home delivered services and increasing reliance on CHiPs. This represents a much supported novel direction for policy to achieve universal ART coverage.

THPED484

Engaging males who have sex with males (MSM) in community-based HIV prevention programs in South Africa: Examining positionality as subjects and objects of scientific enquiry

N.R. Hassan, Z. Kafaar, A. Kagee, A. Lesch, A. De Wet, L. Swartz
Stellenbosch University, Psychology, Cape Town, South Africa

Background: It is critically important to engage key-affected populations in HIV preventive and treatment programs, especially in Africa. Among South African MSM, HIV prevalence ranges between 9.9% and 49.5%; and unprotected anal sex is estimated to be 16-times more likely to transmit HIV, compared to unprotected vaginal sex. MSM community engagement, however, is hindered due to heteronormative healthcare spaces, which reinforces MSM as hidden, hard-to-reach and vulnerable for HIV infection. To overcome barriers to engaging MSM communities in HIV prevention efforts, researchers initially identify queer MSM who are socially visible and recruit them as outreach workers in research teams, thereby gaining access to their affiliated MSM social networks (e.g. respondent-driven sampling). There has, however, been limited attention paid to MSM´ positionality, as objects (insiders within the targeted population) and subjects (outsiders within a research team) of scientific enquiry, in relation to MSM' roles and experiences in clinical HIV prevention programs.
Methods: To examine MSM' experiences during engagement in clinical HIV prevention programs, qualitative interviews were conducted between November 2015 and January 2017. Three participant-cohorts were recruited from and in collaboration with a leading South African clinical HIV prevention research centre: (1) community-based MSM (n=10; M_{age}= 28.4y) from five Cape Town peri-urban areas; (2) MSM research participants (n=10; M_{age}= 25.1y) who have previously been enrolled in clinical HIV prevention studies; and (3) staff members (n= 10; M_{age}= 31.3y) tasked with MSM community engagement. All interviews were audio-recorded, transcribed verbatim, verified and analysed thematically using grounded theory.
Results: As objects of scientific enquiry, MSM compete together for queer visibility within heteronormative environments, in order to promote community-based HIV prevention efforts. However, MSM queer visibilities influences MSM' sense of safety and impedes community engage-

ment and development, especially among gender-conforming MSM. As subjects of scientific enquiry, MSM reported experiencing exploitation and limited transparent communication, related to differences in mutual understanding between MSM communities and research teams.
Conclusions: Without monitoring and evaluating MSM' queer visibilities and safety as part of the research process, through reflexive and supportive participatory practices, we may be inadvertently reinforcing HIV-vulnerability among the most hidden (e.g.: heterosexual-identified MSM), within the broader population.

THPED485

Key population-led health services are increasing access to HIV services among transgender women sex workers in Pattaya, Thailand

P. Potasin[1], T. Nakpor[1], N. Pravepray[1], S. Pengpum[1], S. Simla[1], A. Arunmanakul[2], S. Charoenying[2], C. Jeansuwannagorn[2], S. Mills[2], R. Janamnuaysook[3], R. Vannakit[4], P. Phanuphak[3], N. Phanuphak[3]
[1]Sisters Foundation, Pattaya, Thailand, [2]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [3]Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [4]United States Agency for International Development, Office of Public Health, Bangkok, Thailand

Background: Transgender women sex workers (TGSWs) experience multi-layer stigma and discrimination due to their gender, sexuality, and illegal work, which makes them highly vulnerable to HIV infection. Sisters Foundation, established in 2004 as the first transgender-led organization in Thailand, provides appropriate health and social services for TGSWs in Pattaya. Sisters also works directly with key stakeholders, including police officers and health care workers, to reverse negative stereotypes of TGSW through partnership-building activities, workshops, and research.
Description: Sisters integrated the key population-led health services (KPLHS) model into its drop-in Center (DIC) in 2015 through the implementation research. Well-trained transgender health workers provided health services they designed based on their understanding of TGSWs' needs. These included rapid HIV and syphilis testing, PrEP and PEP dispensing, counseling on use of gender affirmative hormone treatment (GAHT), and monitoring of hormone levels. Regular quality assessment/quality improvement visits were conducted by public health sectors to ensure high-quality services. KPLHS were provided to TGSWs at Sisters' DIC and through mobile clinics at cabaret venues, bars, and other hot spots. We evaluated data on KPLHS and community empowerment activities conducted by Sisters October 2016-September 2017.
Lessons learned: Sisters performed HIV testing for 604 TGSWs (43% DIC; 57% mobile clinics). Of those, 52 (8.6%) tested HIV positive, of whom 52% were successfully linked to antiretroviral treatment. Among HIV-negative TGSWs at high risk, 45 (6%) received PrEP. Sisters conducted 12 knowledge-sharing sessions on HIV, other sexually transmitted infections, and GAHT literacy to empower and increase knowledge and awareness among TGSW communities. GAHT counseling and hormone level monitoring were received by 285 TGSWs. Of 678 TGSWs tested for syphilis, 17 (2.5%) were syphilis reactive. Sisters provided legal assistance and referrals to 57 TGSWs who were victims of arbitrary arrest, gender-based violence, and discrimination regarding their transgender identity.
Conclusions/Next steps: Sisters successfully delivered KPLHS, building on their comprehensive social and legal services, to TGSWs at high risk for HIV in Pattaya. Hormone services integrated into HIV programming responds to high-priority health care needs of TGSWs and should be considered as part of a minimum standard of health care package tailored for TGSWs.

THPED486

Addressing high burden of tuberculosis in First Nations communities through the high incidence strategy: An evaluation project in northern Saskatchewan, Canada

S. Mahmoodi[1], S. Hourigan[1], I. Khan[2], N. Ndubuka[1]
[1]Northern Inter-Tribal Health Authority, Prince Albert, Canada, [2]First Nations and Inuit Health Branch, Department of Indigenous Services, Regina, Canada

Background: In Saskatchewan, the burden of tuberculosis (TB) disproportionately affects First Nations living on-reserve. There are 70 First Nations in Saskatchewan with a population of 75,165 people in 2016. To address TB burden, the TB High Incidence Strategy (TBHIS) was developed in collaboration with community leadership. The purpose of this evaluation was to assess the effectiveness of the TBHIS implemented from 2013 to 2016 to lower the rates of TB.
Description: TBHIS is a multi-faceted, community-specific strategy developed in 2013 to reduce incidence of TB through:
a) community engagement,
b) increasing public education,
c) early case detection,
d) active case finding, and
e) addressing social determinants.
The strategy was piloted in three communities in northern Saskatchewan.
We utilized a mix-methods approach to assess the success of the strategy. We examined the rates of TB and number of latent TB infections (LTBI) treated; performed 20 patients' chart audits; surveyed 511 community members on their TB knowledge; interviewed patients and health care providers about their experience with TB services; and reviewed operational capacity of TB services.
Lessons learned: This is the first formal evaluation of the strategy in First Nations. Our results showed that through the TBHIS, rate of newly diagnosed or reactivation TB in all communities decreased. More LTBI cases were offered treatment and active cases were identified earlier; communities were knowledgeable about active TB but there are gaps in understanding LTBI and taking preventive medications; clients had higher attendance rate to TB appointments if clinics were held in their communities; past negative experiences with TB treatment and impact of Indian residential schools influenced individuals' health seeking behaviour; and poor housing conditions contributed to the burden of TB. Our findings empowered community level programming and inspired other communities to implement similar strategies.
Conclusions/Next steps: Based of evaluation results, we recommendations as follows: 1) reform health care delivery of TB by engaging primary care providers and adopting trauma informed practices, 2) engage communities by addressing their past negative TB experiences, 3) provide ongoing advocacy to address the social determinants of indigenous health especially housing, 4) provide continuous education about TB and LTBI across all sectors of the communities.

THPED487

GET TEST: Use of entertaining social networks for attracting hard-to reach MSM to HIV testing and linkage to treatment

A. Radetskyi, A. Chernyshev
PO 'Alliance.Global', Kyiv, Ukraine

Background: GET TEST is an innovative project for Ukraine. It was active between January 2016 and September 2017. The main objectives of the project were to reach hard to reach MSM, who still wasn't reached by earlier prevention programs, involving them to rapid diagnosis for HIV/STIs/hepatitis; detection the new cases of HIV/STIs/HBV/HCV; linkage to care and support; assistance in obtaining of ARVs.
Methods: The involvement of MSM for testing took place in three cities (Kyiv, Odessa, Dnipro) in two ways:1) clients registered on testing at the www.gettest.com.ua, about which they learned through advertising, which we place on dating sites for MSM, mobile smartphone applications and social networks; 2) a social worker chosen web resources

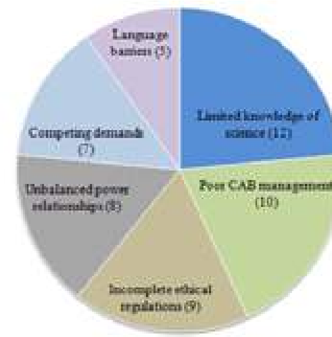
where they communicated singly with MSM, invited them to pass the rapid diagnosis and provided consultation „peer-to-peer". The social worker acted as a case manager and accompanied the client during take on the dispensary registration and motivated them to use ARVs.
Results: For the period from January 2016 to September 2017 3536 MSM have passed rapid testing for HIV, of which 214 persons received a positive HIV test result (6,1%). 161 MSM (76% of detected) were put at the dispensary registration in the AIDS centers, 126 persons (78% of those who were took on register) began to receive ARV therapy. Also, for the period from August 2016 to September 2017, 449 sexual partners of MSM who previously have been tested in the GET TEST were reached by the project, of which HIV-positive status was detected in 41 MSM (9.3%).
Conclusions: GET TEST showed itself as an effective model to attract hard to reach MSM category among Internet users. Advertising campaingn GET TEST helped us to get the target group's attention and get their trust on a different special commercial dating services where many hard-to-reach MSM searching sexual partners or selling sex. We`re focused on target group needs, reestablishment of the service provider' image, and new and more attractive conditions of the service. We developed peer-to-peer case management which decreases stress and improves trust of MSM who never received services in our NGO.

THPED488

HIV community advisory boards for clinical trials in low- and middle-income countries: A scoping review of challenges

Y. Zhao[1], J. Tucker[1,2], B. Huang[3], S. Day[4], L. Li[5], W. Cai[5], F. Hu[5]
[1]University of North Carolina - Project China, Guangzhou, China, [2]University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, United States, [3]South China Normal University, School of Public Administration, Guangzhou, China, [4]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [5]Guangzhou Medical University, Guangzhou Eighth People's Hospital, Guangzhou, China

Background: Community advisory boards (CABs) for HIV trials have expanded substantially beyond high-income countries (HICs), now playing a role in low- and middle-income countries (LMICs). Much research has examined HIV CABs in HICs, but fewer studies have examined CABs in LMICs. The purpose of this scoping review is to summarize the challenges of CABs for clinical HIV research studies in LMICs.
Methods: We searched five databases (PubMed, Embase, Global Health, Scopus and Google Scholar), examining CABs in HIV research studies in LMICs. Two researchers independently reviewed articles for inclusion. Data were extracted regarding country, membership, activities, funding sources, research foci and challenges. Thematic analysis was used to identify the challenges of implementing CABs for HIV research in LMICs.
Results: Our search identified 853 citations, of which 38 were selected for further analysis. Most studies (29) were published from 2008 to 2017. The five countries with the greatest number of studies included South Africa (12), China (9), Zimbabwe (4), Thailand (4) and India (4). The U.S. National Institutes of Health was the main source of support for CABs. CAB activities included reviewing clinical trial protocols, providing community literacy activities, and facilitating qualitative research related to clinical trials. Key challenges of implementing CABs for HIV research in LMICs included:
(a) limited knowledge of science among community members, which contributed to poor communication between researchers and communities;
(b) poor CAB management, e.g. lack of formal structure for participation and absence of CAB leadership;
(c) incomplete ethical regulations that led to exploitation;
(d) unbalanced power relationships between HIV researchers making decisions and local communities participating in studies;
(e) competing demands for time that limited participation in CAB activities; and
(f) language barriers between research staff and community members.
Conclusions: HIV research studies frequently use CABs to review clinical trials. Our results suggest several challenges with implementing CABs as part of HIV clinical trials in LMICs. These findings can help inform training and related activities to enhance HIV CABs in LMICs.



[Figure 1. The number of manuscripts describing each of the 6 identified challenges with CABs in LMICs, created by Yang Zhao.]

THPED489

A 2nd CHANCE (Creating a Healthy And Nurturing Community Environment): Linkage and retention for women living with HIV

C. Carey-Grant
WORLD (Women Organized to Respond to Life-threatening Disease), Oakland, United States

Background: In the U.S., African American/Black women represent the fourth largest population segment of new HIV diagnoses. Further, only 70% of women living with HIV in the U.S. are linked to care, with a mere 26% achieving viral suppression. Indeed, women living with HIV/AIDS often experience significant barriers to quality care, including poverty, substance use, violence, and social and cultural factors. Oakland, CA, where WORLD is located contains the highest percentage of diagnosed AIDS cases among women of any major metropolitan area in the western United States.
Description: 2nd CHANCE is an innovative linkage and retention initiative targeting women living with HIV/AIDS who are tenuously in care or who have fallen out of care. Enrollment began in 2014 for women of color aged 18 years or older with a confirmed HIV diagnosis and who were not in care for their HIV infection. Clients were assigned at random to either the intervention or control group. The intervention group received intensive case management services, through weekly contact with an Outreach & Linkage Specialist and Peer Advocate. In comparison, women randomized to the control group received the standard of service that WORLD would typically have capacity to provide, which consisted of monthly contact and less intensive interactions.
Lessons learned: Findings from the 2nd CHANCE evaluation show that WORLD was able to reach and enroll participants facing many barriers to accessing and engaging in HIV care. Despite the challenges facing many clients, WORLD staff was highly effective with engaging and retaining clients over the course of the study period. Of the 84 clients enrolled in 2nd CHANCE, WORLD achieved a 94% follow up rate and improved HIV-related indicators at 6 months.
Conclusions/Next steps: WORLD's Peer Advocacy model, in tandem with our innovative linkage to care strategy, have made a significant impact on the lives of hundreds women living with HIV in our area. Frequent contact with clients and removing barriers is key to retention.

THPED490

Community led Drop-in-Center (DIC) - an initiative towards sustainability

S. Sultana[1], K. Tarique[2], Z. Shams[3], L. Rahman[3], R. Begum[2]
[1]Save the Children, HIV/AIDS Program, Dhaka, Bangladesh, [2]Light House, Dhaka, Bangladesh, [3]Save the Children, Dhaka, Bangladesh

Background: Female Sex Workers (FSWs) are most at risk related to both sexual and reproductive health (SRH) problems which include unwanted pregnancies, unsafe abortion, maternal health problems, sexually transmitted infections (STIs) including HIV/AIDs. Bangladesh has

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

estimated 102,260 female sex workers. According to UNAIDS investment case (2016), 65% FSW should be covered by comprehensive HIV services to generate impact.
Description: Under the Global Fund grant, Save the Children and its partner organizations provide HIV prevention services for 18,500 FSWs (28% of the country target according to the NSP) through 29 Drop in center (DICs) at central & sub-national level. A significant portion left uncovered who are street based and more vulnerable in the society. Considering this factor, SCI-HIV program patronized the sex workers to establish their voice with the slogan of *'No sex worker on the street'.* Service delivery points namely DICs are considered as safe place for FSWs where they get counselling, condom, STI case management, HIV testing and psychological support including space for rest, bathing and recreation.
In Bangladesh, a representative from sex worker community replicated the DIC model in Dhaka, central part of the country in December 2016. Self-financed and managed DIC offer few services, at contributory price such as food, and make some clothes, make-up, and jewelry available for FSWs. This community led structure support peer education and selling condom to integrate with HIV prevention program. Furthermore, this DIC works as referral point and facilitating advocacy with multiple service providers to ensure health, legal and psychosocial needs of sex workers.
Lessons learned: During April-November, 2017, the Community DIC earned 2,220 USD. Whereas the initial investment was only 80USD for rent and utility cost. Such a cost-effectiveness measure became a major issue of well-being of the FSWs. Such economic empowerment initiatives with high community ownership are highly effective in reducing the HIV vulnerability of KPs.
Conclusions/Next steps: Community led initiatives can have positive impact on the lives of sex workers in low socio-economic settings. It has also been proven effective towards sustainability and to contribute SDG goal of health and well-being.

THPED491

Combining social science methods with mechanisms for community empowerment for the codesign of effective digital health interventions in HIV: Lessons learnt from the H2020 EmERGE project

M. Darking[1], B. West[2], K. Block[2], F. Henwood[3], B. Marent[3], J. Whetham[4]
[1]University of Brighton, School of Applied Social Science, Brighton, United Kingdom, [2]European Aids Treatment Group, Brussels, Belgium, [3]University of Brighton, Brighton, United Kingdom, [4]Brighton and Sussex University Hospitals Trust, Lawson Unit, Brighton, United Kingdom

Background: The European Commission's H2020 programme has funded a consortium of 13 organisations including a European-wide civil society organisation, local community partners, clinicians, academics and technology developers to codevelop, implement and commercialise a digital health platform for HIV care in 5 countries. The platform enables HIV-specific, patient data on results, appointments and medications held in the clinical database to be sent via a clinician-led, 'virtual clinic' to an application on the patient mobile phone through an ongoing process of inclusive codesign.
Description: The European Aids Treatment Group is a project partner and dissemination Workpackage Leader whose activist, capacity-building membership includes community partners in most European countries. In Phase 1 of the programme they mobilised a network of community partners to participate in codesigning the smartphone application. Codesign workshops brought together 97 PLWH and 65 clinicians in: Belgium, Croatia, Portugal, Spain and UK interested in sharing: ideas for app functionalities, concerns and views on the proposal that the app could support a reduction in visits to clinic for people whose HIV is stable. The University of Brighton coproduced this process with EATG ensuring findings were systematically analysed and embedded in the app design process.
Lessons learned: Community-generated ideas are fundamental to producing interventions that work and have a purpose that is clear and relevant to intended users. The methods used enabled ideas from PLWH to be embedded in the platform design, or else recorded within a schedule for ongoing platform development. Data security and ensuring shared decision making at local clinic-community level were significant concerns. Community education resources on understanding data security were co-produced and a guide to 'opportunities for local codesign' has supported community-clinic dialogue on digital health. Recognising patient access to data as an information right was identified as a key mechanism of empowerment.
Conclusions/Next steps: Community empowerment in digital health is not only individual self-management but inclusion in design processes and in ongoing decision-making on product development, commercialisation and sustainability. Balancing expectations against realisable technical goals is achievable through sustained dialogue. Research designs can generate and reinforce relationships and access to decision-making spaces and enable health policy making to be both empowering and inclusive.

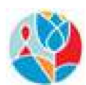
Social, political, and legal advocacy

THPED492

Two steps forward, one step back? Critiquing the repeal of a mandatory disclosure law in NSW, Australia

P. Kidd[1], N. Holas[2]
[1]HIV Legal Working Group, Melbourne, Australia, [2]Institute of Many, Melbourne, Australia

Background: Mandating pre-sexual HIV disclosure is a relatively common legislative response to HIV that has been extensively criticised as counterproductive to HIV prevention efforts as well as an unreasonable intrusion into the right to privacy of people living with HIV (PLHIV). In the Australian state of New South Wales (NSW), a mandatory disclosure law first passed in 1985 has been the target of community advocacy over many years. In 2016, the NSW government agreed to repeal the law but ultimately chose to refashion it into a new provision criminalising risky sex. Despite community concern, the new law was passed in 2017.
Methods: We examined the proposition that the change in the law has improved the legal landscape for PLHIV in NSW. Drawing on doctrinal legal analysis and statutory interpretation methods as well as discourses from HIV activism and social research, we compared the pre- and post-reform legal landscape for PLHIV.
Results: While the repeal of the mandatory disclosure law is welcome, this law has only rarely been applied to PLHIV and has in recent years been qualified by a complete defence based on reasonable use of risk-reduction practices. Under the new law, safe sex itself is mandated but disclosure is not required. The law requires PLHIV to use ´reasonable precautions´ to prevent transmission but does not define what these are, leading to uncertainty around the legal requirements imposed on PLHIV. The absence of a defence of informed consent means the new law potentially criminalises all sex that carries a risk of transmission, even where both parties are informed of and agree to accept that risk, a new intrusion on the sexual autonomy of PLHIV who do choose to disclose their status.
Conclusions: Opportunities for substantial legislative reform are rare. Despite extensive criticism and sustained advocacy, the NSW mandatory disclosure law remained on the statute book for more than thirty years. While the new law removes the requirement for pre-sexual disclosure, it has created a new incursion into the sexual lives of PLHIV by requiring that all sex, even with disclosure, meet an undefined standard of ´reasonable precautions´.



THPED493

Compromise and action: The engagement of 30 cities in Brazil to Fast Track their response and reach 90-90-90 by 2020

G. Braga-Orillard[1], C. Euzébio[2]
[1]UNAIDS, Brazil Country Office, Brasilia, Brazil, [2]UNAIDS, Brasilia, Brazil

Background:
(i) Over 50% of the world's population live in cities. In Latin America, the proportion is even larger: over 80%. Projections demonstrate that by 2020, 9 out of 10 Brazilians will live in urban areas;
(ii) The federative governance structure of Brazil empowers States and municipalities with independent budgets and framework for implementation;
(iii) compromise at Federal-level has not been enough to halt the epidemic: despite its efforts, Brazil has about 40,000 new HIV infections/year and about 12,000 deaths;
(iv) competing challenges are presented to cities, i.e. violence (over 60,000 people were assassinated in 2017), corruption, epidemics (such as zika and yellow fever).
Description: UNAIDS used the movement of Fast Track cities to gather support of Governors, Mayors and local level administrations to accelerate the response. Over 30 priority cities and the National Front of Mayors signed the declaration. The population in these cities is of 40 million people combined. This way, a network was formed at country-level and lessons can be shared.

[FastTrackCities]

Lessons learned: The Fast Track cities initiative is an excellent advocacy tool:
(i) for civil society to demand action at local level;
(ii) for the Federal structures to engage more with local level;
(iii) internally within the administrations, the Paris Declaration has become an instrument for health workers to ensure that HIV is in the agenda;
(iv) UNAIDS and the Joint Team on HIV/AIDS have used the declaration both a political tool to initiate dialogue and also to provide support at local level. As a result several innovative initiatives have been implemented, including:
i) expanding access to HIV testing, including self testing, with focus on gay men and other MSM
ii) PrEP demonstrative implementation projects;
iii) comprehensive health service dedicated for transgender women and men;
iv) decentralization of HIV care to primary services; among others.
Conclusions/Next steps: The Sustainable Development Goals Objectives aim to leave no one behind. To be able to reach these goals, action needs to be taken at local level. Further engagement will be promoted with the cities via the National Front of Mayors.

THPED494

Who's on deck? Building the leadership bench of women living with HIV in the federal policy advocacy arena

A. Rogers[1], E. Turk[2], T. Sullivan[1], K. Laffrey[3], R. Wang[4]
[1]Positive Women's Network - USA, Oakland, United States, [2]Positive Women's Network - USA, Organizing, Oakland, United States, [3]Sero Project, Milford, United States, [4]Positive Women's Network - USA, Policy, Oakland, United States

Background: Though women living with HIV (WLHIV), inclusive of women of transgender experience, face unique advocacy concerns at the intersection of HIV, gender and sexual and reproductive health and rights, spaces of influence within the federal policy environment have remained largely inaccessible, leaving the most pressing advocacy concerns of WLHIV under resourced and often ignored.
In response, Positive Women's Network - USA, launched the PWN-USA Policy Fellowship, a yearlong training and leadership development program in federal policy advocacy. The goal of the fellowship is to increase participant's ability to engage effectively in federal policy and advocacy and to support a growing pipeline of WLHIV, who are shaping policy, fighting stigma and discrimination, and generating a new discourse that calls for upholding full rights and dignity for all people living with and vulnerable to HIV.
Description: Participation in the fellowship was open to all women living with HIV inclusive of women of transgender experience living in the U.S.The 14 fellows of the inaugural cohort represented 9 different states and the District of Columbia. 12 fellows identified as women of color (Black or Latinx), and three fellows identified as being women of transgender experience.
Fellows participated in a series of interactive web-based and in-person policy skills building training sessions, collaborated on policy issue-based teams and received coaching from seasoned advocates. At the completion of their substantive training fellows embarked on a 3-month policy practicum to apply their knowledge and skills.
Lessons learned: Each fellow completed a pre-fellowship assessment evaluating their understanding of the branches and functions of the federal government, the legislative process, policy research and analysis and frameworks for advocacy interventions. Fellows also completed evaluations after each training session for ongoing programmatic feedback and completed a 6-month assessment designed to evaluate their knowledge, skills and shifts in positional power in advocacy spaces.
Conclusions/Next steps: Fellows who prior to participating expressed some to little understanding of policy advocacy not only have increased knowledge and skills, but also have demonstrated heightened engagement in the policy advocacy environment.

THPED495

Mobilizing civil society for the HIV treatment cascade: Measures of democracy and its impact on diagnosis rates among PLHIV

R.K.J. Tan[1], N. Kaur[2], C.S. Wong[2]
[1]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [2]Tan Tock Seng Hospital, Institute of Infectious Diseases and Epidemiology, Singapore, Singapore

Background: Civil society organizations (CSOs) play an essential role in the global HIV/AIDS response. Past studies have described the beneficial role of CSOs in meeting the UNAIDS 90-90-90 target, but have not explored how political conditions, which influence the ability of CSOs to organize, have an impact on the cascade. This study explores the relationship between measures of democracy and its association with diagnosis rates among people living with HIV (PLHIV).

Methods: This study analyses data derived from the Economist Intelligence Unit's Democracy Index (EIUDI), UNAIDS country estimates for PLHIV and PLHIV who know their status, World Bank's data on nominal gross domestic product (GDP) per capita and country population, and country estimates for PLHIV and PLHIV who know their status from other independent sources. An estimated HIV prevalence variable was constructed by dividing the estimated PLHIV population with the total population of a country. The analytic sample comprised countries where data on the estimated number of PLHIV and PLHIV who know their status was available (n=111).

Results: Of the 111 countries in the analytic sample, the mean democracy index score was 5.93 (out of 10), median estimated HIV prevalence was 0.20% (IQR 0.10-0.65), median GDP per capita (in thousands, US dollar) was 4.88 (IQR 2.11-13.79), and mean PLHIV who know their status is 67.1%. Preliminary analysis on the five component measures of the EIUDI (i.e. electoral process and pluralism, functioning of government, political participation, democratic political culture, and civil liberties) revealed multicollinearity, and thus the composite democracy index score was used as the measure for democracy. Multivariate analysis by linear regression revealed that democracy index scores (=2.15, SE=1.01, 95% CI 0.15-4.16), estimated HIV prevalence (=1.25, SE=0.55, 95% CI 0.16-2.34), and GDP per capita (in thousands; =0.36. SE=0.11, 95% CI 0.15-0.57) were positively associated with diagnosis rates among PLHIV.

Conclusions: Though an indirect means of measuring the impact of civil society on HIV diagnosis rates, the results suggest that democratic political cultures favouring civil society mobilization are associated with higher rates of diagnosis among PLHIV. Further research on the impact of political cultures on the ability of CSOs to organize is warranted.

THPED496

Social media utilization among HIV/AIDS organizations: A survey of the online community created by groups improving HIV health

R. Puttagunta[1], R. Puttagunta[2]
[1]Geisinger Health, Danville, United States, [2]University of Texas - Rio Grande Valley, Mcallen, United States

Background: Organizations improving the health of individuals with HIV have to balance individual care, community development, scientific advancement, and advocacy. Social media has been a cost-effective mechanism to help accomplish these objectives. Current social media advisory groups recommend groups focus on frequent content, direct consumer relevant material, and the incorporation of personal content into social media feeds. Social media has proven to be a powerful tool to recruit members, spread messaging, and enact positive change. Thus, we aim to evaluate how HIV/AIDS organizations utilize this space, with the goal to provide groups with cost-effective priorities when utilizing social media platforms to improve the organization's image, member recruitment, and community engagement.

Methods: We evaluated organizations committed to HIV health based on lists from the World Health Organization, International AIDS Society and other umbrella HIV societies. In January 2018, utilizing a blinded browser, we reviewed the top 100 search results of the formal institutions name on both Google and Bing to determine the placement of social media content regarding the institution. Then we studied the institutional Facebook, Twitter, and YouTube accounts for both quantity and content posted from January 2016 to December 2017. We categorized content into institutional announcements/promotion, health education, community/individual stories, research, and forwarded posts (e.g. retweets). Posts could be allocated to more than one category. A qualitative analysis compared institutions to determine both unique aspects and opportunity gaps.

Results: 103 institutions were evaluated with subgroup analysis by region and primary organizational mission. Over 6,000 Twitter and Facebook postings were categorized. We found that all large international organizations utilized multiple social media platforms on a regular basis (more than once a week). Across the institutions, content generally focused on advocacy, and organizational/program promotion. Based on the mission of the organizations, there was a wide variety of the messaging associated with individual posts, including incorporation of hashtags and usernames.

Conclusions: Based on these findings we would recommend organizations prioritize the following items:
1) Increase patient stories and images,
2) Forward/Repost relevant content from similar organizations, and
3) Utilize more novel communication modalities like videos.

THPED497

Civic engagement to end AIDS: Identifying predictors of voting and advocacy participation among community-based HIV service organization clients and staff

T. Ghose[1], M. Stanton[2], S. Ali[3], V. Shubert[4], P. Andrews[2]
[1]University of Pennsylvania, School of Social Policy and Practice, Philadelphia, United States, [2]Housing Works, Brooklyn, United States, [3]University of Houston, Houston, United States, [4]Housing Works, Research and Public Policy, Brooklyn, United States

Background: Internationally, civic engagement of HIV service users and providers has promoted a rights-based approach to combating structural HIV risk. However, scant research has examined HIV advocacy engagement or civic engagement within community-based HIV service organizations (CBHSO). This study examines advocacy participation and voting behavior among clients and staff of a large CBSHO in a major U.S. city.

Methods: CBHSO staff (N= 454) and clients (N=244) completed an anonymous survey about advocacy participation and voting following the 2016 U.S. Presidential election. Descriptive statistics captured rates of voting and advocacy activities. An ordered logistic regression model identified predictors of advocacy engagement. Logistic regression identified predictors of voting behavior.

Results: Among clients (70%) and staff (84%) who reported they were eligible and registered to vote, 87% of clients and 93% of staff voted in the 2016 U.S. presidential election compared to the 67% voting rate for all registered voters in New York State. Voting was positively associated with advocacy engagement (odds ratio 7.2), being lesbian, gay or bisexual (OR 2.5) and cis-female (OR 2.4) among clients, and with advocacy engagement (OR 2.9) and being cis-female (OR 3.9) and negatively associated with homelessness (OR 0.60) among staff.
64% of clients and 87% of staff participated in advocacy around health policy. For clients, advocacy was positively associated with being non-cisgender (OR 5.7), and older (OR 3.3). For staff, advocacy was positively associated with being employed (vs. volunteer) (OR 6.8), and lesbian, gay, or bisexual (OR 1.60), and negatively associated with being cis-female (OR 0.64), and younger (OR 0.46).

Conclusions: Voting was mediated by involvement in advocacy, especially for marginalized clients and staff members. Successful structural HIV interventions in agencies need to target civic engagement by involving clients and staff in advocacy around HIV policy issues.

Community mobilization and demand creation

THPED498

Social cohesion events: Suriname Men United's experience with an innovative outreach approach to reach new men who have sex with men and transgender people in Suriname

F.S. Cerson-Khodabaks[1], D.E. Sanrawi[1], K.I. van Emden[1], J.T. Moestadjap[2], R.L.C. Eersel[2]
[1]Foundation Suriname Men United, Paramaribo, Suriname, [2]FHI 360/ LINKAGES Project, Paramaribo, Suriname

Background: Men who have sex with men (MSM) and transgender people (TG) in Suriname experience stigmatization and marginalization that affect their uptake of HIV services. As part of the FHI 360 LINKAGES project, which is funded by USAID and PEPFAR, foundation Suriname Men United (SMU) has sought to address this issue through innovative outreach approaches. One approach is a one-day social cohesion event held specifically for MSM and TG.
Description: The purpose of social cohesion events is to strengthen MSM and TG's self-empowerment and increase their awareness of sexual health in a safe, informal setting, with the aim of increasing uptake of HIV services. The events have a central theme chosen in consultation with MSM and TG. They are conducted as workshops or entertainment events. Social cohesion events have specific structures: attendees are registered, guided to an information booth where they receive one-on-one information about sexual health, commodities and referral to HIV testing and other services, and participate in the planned activity. Lastly, attendees are approached one-on-one with information on HIV testing which are available on-site. After the event, the attendees are proactively contacted and encouraged to get tested or to make use of other services.
Lessons learned: Key population engagement in choosing the central themes for social cohesion events ensures active participation. Compared to other outreach methods, social cohesion events had the highest contribution (43 percent) to SMU's newly recruited MSM and TG in fiscal year 2017. Some of these newly recruited persons belong to networks not explored before. Social cohesion events provide the opportunity to build trust with the attendees, which is the first step needed to have further discussion on the importance of knowing one's HIV status. Twenty-four percent of the newly recruited MSM and transgender people were linked to testing services afterwards. Prior to the social cohesion events, the testing uptake was 15 percent in 2016.
Conclusions/Next steps: Social cohesion events contribute not only to uptake of HIV services, but also to gaining access to new networks. These social cohesion events should not only consist of small group interventions, but also include a one-on-one approach for successful uptake of services.

THPED499

Health services and LGBT population in Rio de Janeiro, Brazil: Talking about „be different, be you!"

L. Montenegro[1], M. Malta[1], L. de Andrade Ferreira[2], J.L. Monard Pereira[2], R. Rodrigues Alves Campitelli[2]
[1]Oswaldo Cruz Foundation, National School of Public Health, Rio de Janeiro, Brazil, [2]Prefeitura do Rio de Janeiro, Rio de Janeiro, Brazil

Background: Brazil has the unfortunate reputation of being one of the deadliest places in the world in terms of recorded anti-LGBTQI violence (LGBTQI: Lesbian, Gay, Bisexual, Transgender, Queer or Questioning, and Intersex). About one LGBTQI Brazilian is killed in a hate-motivated crime each day, but the police are often reluctant to register anti-LGBTQI crimes as hate attacks. The extreme social exclusion faced by Brazilian LGBTQI translates into increased vulnerability to HIV: transwomen face prevalences above 25% and men who have sex with men above 15%, while the prevalence among the general population is below 1%.
Description: Stigma and discrimination harm the wellbeing and increases the HIV-risk among the LGBTQI community in Brazil. Aiming at decreasing the experiences and feeling of stigmaa/discrimination within health facilities, we implemented the intervention „Be Different, Be You!". The group was planned and developed in close partnership with the LGBTQI community living in a large slum complex from Rio de Janeiro, Brazil. The intervention included permanent education targeting health professionals, community leaders and the LGBTQI community at large, and aimed at increasing the access and demand for free local health services, including HIV-testing, Prep, PEP and HIV-treatment.
Lessons learned: The including of a human rights approach and development of a low-threshold, user friendly health service increased the access of LGBTQI community. Health professionals promoted the "LGBTQI Visibility Day", promoted several strategies to mobilize and improve the dialogue between health professionals and the LGBTQI community living in this specific slum from Rio de Janeiro. Recreational and educational activities were implemented, as well as HIV-testing and treatment promoted.
Conclusions/Next steps: The strategy was very successful and overall well-being of the LGBTQI community increased over time. However Brazil is facing a political crisis and the conservative agenda of the new government might influence key decisions in the human rights and public health arena in Brazil. Most vulnerable groups such as the LGBTQ community might be severely affected and funds to replicate and/or improve this successful initiative might be not available anymore.

THPED500

Impact of HIV on infant- and young child-feeding practices and modelling the impact of resultant stunted growth on child mortality in Buhweju district, Southwest Uganda

J. Mukisa
Makerere University, School of Food Technology, Nutrition and Bio-engineering, Kampala, Uganda

Background: The HIV pandemic in Uganda amidst worsening severe food insecurity has increased the risk of stunting and child mortality particularly among households of people living with HIV. This study aimed to assess whether there were differences in infant- and young child-feeding (IYCF) practices among HIV-positive mothers and those of unknown HIV status. The study also modelled the impact of stunting on child mortality in the southwest region of Uganda.
Methods: Seventy-eight HIV-positive mothers of children aged 0-23 months were recruited at health centers that provide prevention of mother-to-child transmission (PMTCT) services. These mothers were matched (based on their child's age and area of residence) to 78 mothers of unknown HIV status from the general population. The Infant and Child Feeding Index (ICFI) was used to estimate the proportion of children receiving the recommended standard of IYCF. The Lives Saved Tool (LiST) was used to estimate the impact of stunting on child mortality and cases of stunting averted.
Results: Half of the mothers (50%) used pre-lacteals, 34% of the children were exclusively breastfed, and only 26% of the mothers practiced appropriate introduction of complementary foods. Compared to the mothers of unknown HIV status, the HIV-positive mothers were significantly more likely to introduce complementary foods before their children reached the recommended age of 6 months ($p < 0.05$). A majority of the children (88%) did not receive the recommended standard of IYCF, and feeding practices were significantly less likely to be in line with the recommended IYCF practices among HIV-positive mothers compared to those of unknown HIV status ($p < 0.05$). The high impact LiST model estimated that 1,297 children under 5 years would be saved and 24,850 cases of stunting averted in the study district.
Conclusions: There are large disparities in IYCF practices between HIV-positive mothers and those of unknown HIV status in rural areas of Uganda. These can be attributed to lack of knowledge about the recommended IYCF practices among health workers and mothers, breastfeeding discouragement, fear of mother-to-child HIV transmission, and missed opportunities to educate and counsel mothers on optimal IYCF practices.

THPED501

A behaviour-centred design approach to creating demand for oral PrEP among young women in Masiphumelele, South Africa

L. Myers[1], L.-G. Bekker[1], R. Aunger[2], K. Gill[1], A. van der Straten[3], J. Morton[4], M. McConnell[5], G. Breen[4], V. Curtis[2], C. Celum[4]
[1]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]RTI International, San Francisco, United States, [4]University of Washington, Seattle, United States, [5]Harvard University, Cambridge, United States

Background: Worldwide, South Africa has the highest HIV incidence among adolescents. There is a critical need to address young women's vulnerability to HIV through HIV prevention, including pre-exposure prophylaxis (PrEP), which women can control. We identified a need to generate awareness and demand for PrEP among this population.
Methods: The 3Ps for Prevention Study seeks to understand young women's choices whether to use PrEP and how those decisions are made. Formative research using the behaviour-centred design framework was conducted in 53 households in Masiphumelele to inform a behaviour change communication strategy for PrEP, which included a 90-second video, inviting youth to *'be part of the generation to end HIV'* (https://goo.gl/HDZ34D). Posters and brochures were also distributed. Impressions of the video were surveyed among 320 women (aged 16-25) and through 20 in-depth interviews of women enrolled in the 3P open label PrEP study.
Results: We uncovered several challenges that may hinder young women's demand for PrEP and which guided message development, including: low concern about HIV, low sense of personal HIV risk, cultural norms that are unaccustomed to preventative pill-taking, concerns about side effects, and socio-economic stressors that limit personal agency and future-oriented thinking. The video was well-received: 71% (n=227) of women reported liking or really liking it and 68% (n=217) reported they were *'definitely interested'* in learning more about PrEP after viewing it. Qualitative participants reported appreciating the invitation to join *'the generation to end HIV'*, found the video's characters relatable, liked the focus on peer support and the positive angle on PrEP (e.g. ease of pill-taking and low burden). Printed materials were said to legitimise PrEP for some interviewees' partners and family members, who were initially skeptical of a pill that prevents HIV.
Conclusions: Our initial research found healthy young women had low motivation to take a daily pill (with possible side effects) to prevent HIV, for which they didn't necessarily feel at risk. However, young women liked a video and printed materials that leveraged an empowerment theme. Effective future PrEP demand creation strategies will require multiple communications with powerfully motivating messages, community awareness events, and engagement by healthcare providers and community workers.

THPED502

Teenergizer.org — unique, youth-led on-line resource for teenagers from EECA

V. Fomina[1], A. Sardarian[2]
[1]Eurasian Union of Adolescents and Youth «Teenergizer», Kiev, Ukraine, [2]Teenergizer, Kyiv, Ukraine

Background: According to UNAIDS, number of new HIV cases among young people 15-24 years in 2016 in EECA — about 25,000. Over 400,000 people 15-30 years are living with HIV in Russia, over 5500 — in Ukraine, and 123 500 adolescents are at risk of getting HIV. To mobilize HIV-positive young people a unique web-platform was created. We found this step very rational, because a financial input to the development and maintenance of the site is not too large, but it is a good chance to involve large numbers of people including HIV-negative to strengthen the voice of adolescents in the EECA region and form tolerant attitude towards HIV+ people.
Description: Our unique resource developed by adolescence who defined the manner of representation of information for their peers. The team of authors leads the section «Living with HIV», which highlights key points of the life of HIV-positive teenagers, gives accurate and youth-friendly information about importance of ART, and describes that life of adolescents with HIV is not very different. In connection with the preparation to the conference was created the section «AIDS2018», where all the key moments were announced in a youth-friendly manner. There is also a section «Consultations» on teenergizer.org, that provides adolescents with peer counseling (delivered by peers) or with professional psychologists counseling.
Lessons learned: Through personal stories of activists, we encourage teenagers to take care of their health, form a tolerant attitude towards HIV-positive young people in society, and give the opportunity for HIV-negative adolescents to get to know reliable information about ways of transmission of the virus and necessity of regular HIV testing. All teenagers can get psychological support and express themselves by joining the team of authors. As of today web-site is visited by about 9000 unique users per month, who view 19 000 pages.
Conclusions/Next steps: This direction is crucial for young people; the Russian-language platform could attract and cover young people living with HIV and key populations from all over EECA region. In the future it is important to ensure the development of on-line counseling, to popularize this opportunity among adolescents and to increase the staff of equal consultants.

THPED503

Female sex workers (fsws) as game-changers, take up the challenge to organize towards ending HIV in Nigeria

C. Anonyuo[1], A. Anonyuo[1], C. Anidiobi[2], L. Amadi[3], S. Haruna[4]
[1]Renewed Initiative against Diseases and Poverty (RENAGAIDS), Abuja, Nigeria, [2]Advocates for Women's Health and Rights Initiative, Abuja, Nigeria, [3]Mind Renewal Women's Initiative, Lagos, Nigeria, [4]Society for Women Development, Abuja, Nigeria

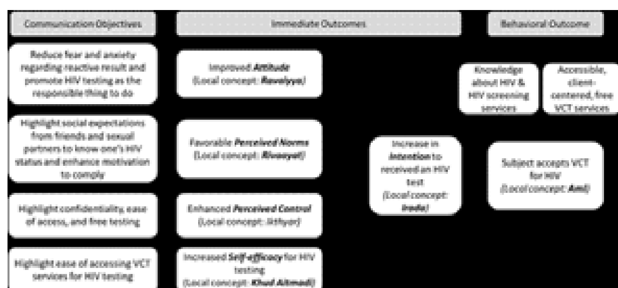
Background: HIV prevention interventions in the past targeting FSWs in Nigeria had been implemented by non-community members organizations for the community with little attention paid to addressing structural interventions that can create the needed support for HIV response for the Community. FSWs realized the need to change the current paradigm of HIV prevention and treatment management for them and therefore took decisive actions to make the much needed changes.
Methods: FSWs in Nigeria in 2015 grabbed the opportunity as presented by the Global Fund New Funding Model initiative to organize the inauguration of FSWs network in Nigeria. Discussions at the inaugural meeting included the need to self-organize to increase access of FSWs to HIV prevention services and STI management through demand for One-Stop-Shops (OSS) and how to improve the structural intervention needs of FSWs by directing national efforts to reducing violence, human rights abuses and harassments by law enforcement agents and clients/patrons. Additionally, strategies to institute safe guard measures for preventing HIV transmission were also highlighted. As take-off, representatives of FSWs were charged with the responsibility of organizing Focal Group Discussions (FGDs) at the state and community levels.
Results: 42 FGDs involving 1350 sex workers were held nationwide to step down the outcome of the inaugural meeting. The number of participants at each FGD ranged from 15 to 35. They requested that national stakeholders establishes OSS. These demands have resulted in the setting up of 24 OSS in Nigeria. Finally, FSWs have officially been an integral part of the Nigeria Response on HIV and have actively participated in both local and international activities, meetings and conferences. Highlighting and reinforcing the need to respect the human rights of FSWs, a national advocacy group led by FSWs and stakeholders have been inaugurated in 2017.
Conclusions: FSWs can mobilize and self-organize if and when given the opportunity and support. The FSW community in Nigeria would facilitate/implement tailored intervention for the community and make a difference for the national HIV response in Nigeria.

THPED504

Participatory empowerment education to increase effectiveness of peer-led health promotion for HIV testing among men who have sex with men (MSM) and transgender (TG) populations: Evidence from Pakistan

A. Asghar[1], X. Gul[2]
[1]Parwaz Male Health Society, Karachi, Pakistan, [2]Milken Institute School of Public Health, George Washington University, Washington D.C., United States

Background: Between 2005 and 2015 Pakistan saw an average increase of 17.6% in the number of new HIV infections. The low uptake of VCT services by MSM and TG populations continues to pose a serious challenge to HIV prevention in Pakistan. In the absence of evidence, there exists a policy vacuum around best practices for providing peer-led counseling for HIV prevention and treatment services.
Methods: A behavior change framework was developed to inform a training curriculum aimed at improving skills of MSM and TG field workers in promoting uptake of VCT services for HIV. Rooted in early Islamic scholarship, the curriculum applied the Integrated Behaviour Model, translated into culturally congruent concepts, to identify behavioural antecedents amenable to persuasive communication (Figure1).
The training curriculum used participatory approaches and was piloted with 15 TG and 29 MSM (n=44) outreach field workers from 6 CBOs across Pakistan. Participants were trained in using Participatory Reflection and Analysis (PRA) tools (timeline/daily routine, body mapping, and network diagram) for increasing critical consciousness regarding HIV testing among target audience. Participants' were assessed for knowledge about HIV transmission, self-efficacy for communicating effectively about HIV, and self-efficacy for using PRA tools before and after the training. Knowledge was assessed using 17 items with binary (1=True; 0=False) endpoints. Self-efficacy was assessed using three items each for communication and PRA use, (scale: 1-Strongly disagree-5-Strongly agree). Knowledge scores were summated, and mean scores were obtained for self-efficacy. All scores were converted to percentages and differences between the average pre and post scores were assessed using T-test.
Results: Participants' average score for knowledge of HIV transmission increased by 11.36 percentage points, while scores for self-efficacy for communicating about HIV and using PRA tools increased by 36.36 percentage points and 52.87 percentage points, respectively between pre-test and post-test. All differences between average pre and post-test scores were statistically significant (p< .001).
Conclusions: Participatory empowerment approaches are potentially well suited to Pakistan's low-literacy context. Resource allocation for further research is needed to evaluate whether theory-driven, peer-led participatory health education for HIV prevention can yield greater uptake of HIV testing among MSM and TG populations in hostile outreach settings.



[Figure 1: Theoretical Framework for the Curriculum: Application of the Integrated Behavior Model to the local cultural context]

THPED505

Community-based services for expanding HIV testing access, coverage and linkage to care from the perspective of combined prevention. A Ecuadorian experience

O. Montoya-Herrera[1,2], L. Orozco[3], M.E. Acosta[4], C. Acosta[5], C. Bonifaz[6], L. Riegel[7], R. Delabre[2], D. Rojas Castro[7], A. Herdoiza[8]
[1]Corporación Kimirina, Educación Comunitaria, Guayaquil, Ecuador, [2]Coalition PLUS, Community-Based Research Laboratory, Paris, France, [3]Corporación Kimirina, Research, Quito, Ecuador, [4]Corporacion Kimirina, Research, Quito, Ecuador, [5]Corporacion Kimirina, HIV Program Coordinator, Quito, Ecuador, [6]Corporación Kimirina, Evaluation and Monitoring, Quito, Ecuador, [7]Coaliton PLUS, Community-Based Research Laboratory, Paris, France, [8]Corporación Kimirina, Executive Direction, Quito, Ecuador

Background: Although a concentrated HIV epidemic in Ecuador among MSM and Trans women (TW) (11% and 32% prevalence respectively-ENS-MSP, 2012), both populations face severe limitations in accessing HIV testing services in the Public Health Network.
To strengthen collaboration between government and civil society, the National HIV Strategy and Kimirina Corporation designed, in 2015, the *Community-Based HIV Testing Services Program (CBHTSP)* in order to assess both the coordination mechanisms with the various levels of the Health Ministry and the HIV Strategy and its viability and acceptability. In 2016, the program was implemented in Quito and Guayaquil, where the highest number of HIV/AIDS cases are reported.
Description: Peer workers were trained in sexual health promotion, counseling and rapid HIV testing. HIV promotion and prevention activities were conducted in priority areas ("hot spots") identified through a Programmatic Mapping by peer workers and supported through Community Centers and Public Health Minister referral units. Two main objectives were identified: 1) increase early HIV diagnosis via „Community-based Testing for Key Populations"; 2) increase timely linkage to care to health units.
Lessons learned: Local HIV strategies were linked to program monitoring and evaluation, permitting service coordination and provision of HIV prevention and testing inputs for MSM and TW. MSM (n=11 118) and TW (n=1 258) participated in activities promoting/offering community-led peer HIV testing. A total of 4 084 rapid HIV tests were performed (3 645 among MSM and 438 among TW). Prevalence found was 1,83% (N=67) among MSM and 0,79% (N=10) among TW. All the people with an HIV-positive result was linked to the national health services.
Conclusions/Next steps: Peer community-led prevention and testing services close to key populations is acceptable, efficient, facilitates access to health services and may address barriers related to stigma and discrimination. The CBHTSP, which integrated combined prevention in the National HIV Plan, provided the opportunity to form alliances between the community and health providers to ensure coverage and improvement of care. This successful program may serve as a model for future community-led efforts to reach vulnerable populations.

THPED506

Strategies to engage men in HIV testing and care through community mobilization activities in rural Mpumalanga, South Africa

R. West[1], R. Mathebula[2], D. Rebombo[2], A. Julien[3], K. Kahn[4], D. Peacock[2], R. Twine[4], N. Haberland[5], J. Pulerwitz[5], S. Lippman[1,4], A. Pettifor[3,4]
[1]University of California San Francisco, Center for AIDS Prevention Studies, San Francisco, United States, [2]Sonke Gender Justice, Cape Town, South Africa, [3]University of North Carolina at Chapel Hill, Chapel Hill, United States, [4]MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [5]Population Council, New York, United States

Background: While men are known to test for HIV and access ART at lower rates than women, there is strong evidence that community mobilization (CM) can improve engagement in health services. We describe

a CM intervention designed to address social barriers to HIV counselling and testing (HCT) and engagement in HIV care by implementing activities that engage communities in social change.
Description: CM activities were implemented by trained community mobilizers in 8 intervention villages in the Agincourt Health and Demographic Surveillance Site; a rural, high HIV prevalence setting in Mpumalanga, South Africa. Clinical monitoring data revealed that HCT rates were low for males 18-49. To address challenges with engaging men, stakeholder meetings were held with traditional leaders, ward councilors, church leadership, and community development forums to identify novel ways to engage men in CM activities and HCT.
Lessons learned: During years 1 and 2 of the intervention, 6,962 males aged 18-29 and 4,857 men aged 30-49 were identified as „new faces" at CM activities. Strategies for engaging men included holding pool tournaments, using bars as CM venues, and providing traditional food to participants while conducting workshops and activities around HIV testing and treatment as prevention (TasP). A male-only support group was formed in partnership with an HIV-positive community leader. Soccer tournaments were successful in reaching men by using soccer skills and teamwork to discuss themes of behavior change, HIV prevention, TasP, and community building. „Fun Days" including music, free car washes, and provision of HCT were held on weekends near main roads to encourage men to test for HIV. Community Mobilizers also recruited men from CM activities who wanted to test for HIV and coordinated with a local NGO, clinics, and the Bushbuckridge Department of Health to conduct HCT in the community.
Conclusions/Next steps: In rural South Africa, strategies to reach men outside of the clinic setting are critical to increase of HIV testing. Men ages 18-49 were accepting of HCT services when providers were males from outside villages. In addition, holding CM activities in on the weekends, in late afternoon/evening, and in male-friendly spaces was effective in engaging men to learn about HIV TasP.

Use of mobile vehicle to scale up uptake of VMMC in rural Uganda: Experiences from use of The AIDS Support Organization-TASO Rukungiri mobile vehicle

N.R. Nuwamanya
The AIDS Support Organisation-TASO Uganda Ltd, Counselling, Kampala, Uganda

Background: TASO Uganda Limited-Rukungiri Center is supported by United States Agency for International Development-USAID to carry out VMMC in western Uganda. With the new target of 1,520 males to get VMMC by September 2018, it has increasingly became hard to get VMMC volunteers where VMMC camps are held. We identified the use of TASO Vehicle as a mobile van to take mobilization to communities. We examined the use of mobile van to mobilization of VMMC in January 2017 to December 2017.
Description: A branded TASO Designated Land cruiser with **"TASO HIV prevention and Care services"** was rolled out to help in the mobilization for VMMC volunteers. The land cruiser was mounted with a functioning public address system on top with SMC mobiliser and a Counsellor inside the vehicle to implement mobilization activities so as to get VMMC volunteers. The mobile vehicle is equipped with Information Education Communication-IEC Materials to distribute while in the communities. Those who get interested are carried to and from the VMMC sites form VMMC services.
Lessons learned: The mobile van benefits residents of the mapped areas where VMMC camps are planned as it has made access to information through IEC Material use much more available to residents in the catchment areas. 2,188 males have received VMMC services and followed up with (741Males 5-15years, 1440 of 15-49 and 7 males >49years. (TASO VVMC Annual report 2017). The mobile vehicle also serves as a mobile health education center in the community.
Conclusions/Next steps: The mobile vehicle is a feasible strategy for mobilizing VMMC Participants and recommended to Implementing Partners so as to cover wider areas and achieve VMMC Targets

How to make an active community in indifferent society: Young people who use drugs response to the drug use criminalization in Lithuania

E. Kurcevic
Eurasian Harm Reduction Association, Vilnius, Lithuania

Background: In 2017 Lithuanian laws on drug use and possession were criminalized. Moreover, the latest data showed that in 2017, the increase in number of new HIV cases among PWID was as high as 64% in comparison with 2016. These changes triggered dissatisfaction among young people and as a response to this, the first community of young people who use drugs (PWUD) was mobilized. The group was supported with a small grant (SG) in the framework of the project "International Harm Reduction Consortium".
The purpose of the given SG was to strengthen civil society advocacy in response to the increasing HIV incidence rates due to the present repressive drug policy in Lithuania.
Description: The SG project was implemented in Lithuania from June to December 2017. Key population involved in the activities - young PWUD. Activities implemented: young PWUD community mobilization, preparation of the rally as a response to the repressive drug policy, participation in the study visits, development of the national harm reduction strategy and submission of the appeal to the Parliament to support drug decriminalization.
Lessons learned: Young people from different communities of PWUD were mobilized and established an organization "Young Wave" ("YW"). The SG project showed that young PWUD with different drug habits can be united for one goal - response to the „draconic" drug policy. Advises and expertise from international partners helped to build a capacity and empower young PWUD to become drug policy advocates. "YW" got a several dozen requests from outer organizations/institutions to organize trainings/seminars/discussions on harm reduction in different settings; as well about sexual and reproductive rights (including HIV and other STDs).
Conclusions/Next steps: In a short time, organization "YW" became the first young people NGO in Lithuania, working in the field of harm reduction, drug policy, human rights advocacy and education. And most importantly, "Young Wave" became a voice of young PWUD in Lithuania. Next steps, which are the continuation of the results of the SG project are as following: welfare and PsyCare activities during music festivals, trainings on harm reduction for party/festivals organizers, seminars for young people on sexual and reproductive rights at schools and during festivals.

Couples- or family-centred approaches

Family dynamics and health-related quality of life of persons living with HIV/AIDS attending a comprehensive treatment and care center in Southwest Nigeria

O.B. Benson[1], A.M. Adebayo[2], A.O. Raji[2], G. Adeyemo[3,4]
[1]Lily Hospitals Limited, Warri, Nigeria, [2]University of Ibadan, Department of Community Medicine, Ibadan, Nigeria, [3]Students' for Microbicide (S4M), Abuja, Nigeria, [4]United Nations Population Funds (UNFPA), Abuja, Nigeria

Background: The advent of highly active antiretroviral therapy (HAART) has positive effects on the health related quality of life (HRQoL) of persons living with HIV/AIDS (PLWHA). However, the effect could be undermined if family correlates are not given due considerations. The support from the family is valuable to counter stigma as previous studies had shown positive relationship between social support and health outcomes. There is paucity of published literature on relationship between family dynamics and HRQoL of PLHWA in Nigeria where the burden of the disease is quite high.

This study was carried out to assess the association between family dynamics and perceived HRQoL of PLWHA attending a comprehensive HIV treatment and care center in South-West Nigeria.

Methods: This data was extracted from a descriptive longitudinal study conducted to test the effect of HAART of the HRQoL of 216 PLWHA who were yet to commence HAART. Family functionality was assessed using a 20-point family APGAR scale categorized into functional (≥15) or dysfunctional (≤14) families. Other family characteristics assessed were marital status, current employment status, occupational class,average monthly income using the Nigerian minimum wage of ₦18,000 ($60 @ ₦300/dollar) to categorize income into those that earn equal and above or below the minimum wage. The WHO QoL-HIV was used to assess HRQoL. Data were analyzed using descriptive statistics, Chi-square and linear logistic regression at p=0.05.

Results: The mean age of respondents was 38.4±8.5 years with M:F ratio of 1:2**.** About two-third (65.7%) of respondents were married, 86.1% were currently employed, 27.0% were in the high occupational class and 53.8% earned below the minimum wage. Over two-third (67.1%) came from functional families. Sixty-two percent perceived their HRQoL as being good and 72.2% were generally satisfied with life.Family life predictors of HRQoL were marital status, employment status, average monthly income and family functionality. Respondents from functional families were more likely to have good HRQoL than those from dysfunctional families (p< 0.001).

Conclusions: The study revealed positive relationship between family dynamics and HRQoL of PLWHA. Understanding the role of family dynamics and social support is important to combat stigma and discrimination and enhance unrestricted access to HAART.

THPED510

How will social norms about parenting influence parental support of adolescent girls and young women's (AGYW) use of PrEP? Perspectives from parents in Tanzania

N. Makyao[1], V. Saria[2], N. Jani[2], C. Kahabuka[3], L. Apicella[2], J. Pulerwitz[2], S. Mathur[2], N. Pilgrim[2]
[1]National AIDS Control Programme, Dar es Salaam, Tanzania, United Republic of, [2]Population Council, HIV & AIDS Program, Washington, United States, [3]CSK Research Solutions, Dar es Salaam, Tanzania, United Republic of

Background: Little is known about parents' perceptions towards oral pre-exposure prophylaxis (PrEP). Yet, parental consent is necessary for adolescents to access sexual and reproductive health services in many sub-Saharan African countries and parents can be a key influence in AGYW's access and use of health services. We explored how social norms and gendered parenting roles might influence parental support of AGYW's PrEP use in Tanzania.

Methods: We conducted 4 focus group discussion (FGDs) (n=28) with female parents and 4 FGDs (n=27) with male parents in Mbeya and Dar Es Salaam in May 2017. To acquaint parents with PrEP, a visual, standardized script of PrEP information and placebo pills was shared with participants prior to FGDs. Interviewers then explored PrEP perceptions and factors influencing parental support of PrEP use. Thematic content and constant comparative analyses were used.

Results: We found overwhelming support among parents for PrEP availability for AGYW. Further, parents noted strong support for AGYW's PrEP use, recognizing AGYW's high risk of HIV due to limited power to negotiate preventative behaviors and frequent violence in sexual relationships. However, social norms around adolescent sexuality influenced parental support. Parents were wary of being viewed as condoning pre-marital sexual activity, while they worried that AGYW could be stigmatized as promiscuous. Further, respondents noted differential parenting roles of mothers versus fathers, which would influence the type of support they would be able to provide to AGYW. Men, in particular, noted shame and embarrassment in communicating with their daughters about relationships and sex.

Despite these concerns, parents expressed a willingness to support AGYW access to PrEP and sought strategies for supporting their daughters. Female parents described creating a supportive environment for PrEP use (e.g., ensuring AGYW has good diet) while male parents described offering logistical and material support (e.g., providing transport to health centers).

Conclusions: Programmers may need to consider the role of parents when designing programs to support AGYW's PrEP use. Addressing social norms that hinder parental support of PrEP, and enhancing parents' ability to communicate effectively with AGYW about sexuality, HIV risk, and PrEP - may be avenues to engage and garner parental support.

THPED511

From serodiscordant to magnetic: The feasibility and acceptability of a pilot psychoeducational group intervention designed to improve relationship quality

A.D. Eaton[1,2], J.S. Cattaneo[3,4], J. Watchorn[1], C. Bilbao-Joseph[5], S. Bowler[6], M. Hazelton[7], J. Myslik[7], A. Ross[8], L.A. Chambers[9]
[1]ACT - AIDS Committee of Toronto, Support Services, Toronto, Canada, [2]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [3]ACT - AIDS Committee of Toronto, Monitoring and Evaluation, Toronto, Canada, [4]University of Toronto, Institute of Health Policy, Management, and Evaluation, Toronto, Canada, [5]Centre for Spanish Speaking Peoples, HIV/AIDS Program, Toronto, Canada, [6]Sinai Health System, Department of Psychiatry, Toronto, Canada, [7]Family Service Association of Toronto, David Kelley Services, Toronto, Canada, [8]Village Family Health Team, Toronto, Canada, [9]McMaster University, School of Social Work, Hamilton, Canada

Background: Serodiscordant or magnetic couples experience HIV-related issues that compound daily stressors. Psychoeducational couples group interventions can build coping skills and increase relationship satisfaction. However, most interventions for serodiscordant/magnetic couples are primarily aimed at reducing HIV transmission and most focus on heterosexual couples. Therefore, we used a community-based participatory approach guided by social action theory to engage gay male magnetic couples in the planning and piloting of a psychoeducational support group.

Methods: A quasi-experimental pretest/posttest design with no control group was used to enroll 12 gay men in same-sex magnetic relationships (i.e., six couples) to collaboratively design and participate in an 8-session psychoeducational support group. Participants attended two 3-hour planning sessions, followed by eight 3-hour group sessions, and two 3-hour evaluation sessions. Session evaluations were used to measure usefulness, interest, and quality of participation in the group. The Revised Dyadic Adjustment Scale (RDAS), where scores < 48/69 indicate clinically distressed relationships, was administered at three time points (pre-intervention, post-intervention, and 3-month follow-up).

Results: The intervention was feasible (i.e., recruitment was < 2 weeks, easy to coordinate) and acceptable (i.e., all sessions consistently rated 'very good' or 'outstanding'). Relationship quality improved significantly in all couples, regardless of whether couples agreed on how to manage HIV within their relationship. RDAS prescores (M=36.75, SE=2.68) were significantly different from postscores (M=46.75, SE=2.59) and follow-up (M=51.75, SE=1.78). Participant consensus was that 'magnetic' was a more strengths-based term than 'serodiscordant', highlighting that 'opposites can attract' in terms of HIV status.

Conclusions: This study provides proof-of-concept for preliminary feasibility and acceptability of a psychoeducational group intervention for gay male magnetic couples; the study's participatory approach may have contributed to these findings. It is useful to consider the degree to which changes in follow-up scores can be attributed to the group program and not time or other factors. A scale focused on relationship quality for gay men in magnetic relationships could have better captured this variable. This presentation will discuss how the participatory aspects created a foundation for a successful support group, alongside the group's key components, and a need for more holistic tools of measurement pertaining to serodiscordancy in gay men.

THPED512

Role of family dynamics in impacting HIV care in Tanzania: Implications for intervention development

V. Fonner[1], F. Chiwanga[2], E. Steven[3], J. Mbwambo[3], M. Sweat[1], S. Likindikoki[3]
[1]Medical University of South Carolina, Psychiatry and Behavioral Sciences, Charleston, United States, [2]Muhimbili National Hospital, Dar es Salaam, Tanzania, United Republic of, [3]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of

Background: Having a chronic condition often involves burdensome medication schedules, clinic visits, and self-care activities. Such an illness can affect an entire family, and family plays a role in both shaping disease risk and providing support for care management. Despite the importance of family, research to understand how family affects HIV-care in sub-Saharan Africa is scarce.
The Familia Kwanza study is seeking to understand what role families play in supporting a family member living with HIV and to assess the burden of comorbid chronic conditions, including diabetes and hypertension, among this population.
Methods: From August-October 2017 we recruited a representative sample of 359 adults living with HIV from the HIV clinic at Muhimbili National Hospital in Dar es Salam by selecting every third patient for inclusion. Participants completed a structured survey related to family relationships, HIV, and lifestyle (e.g., diet and exercise). We assessed family functioning using an adapted version of the Brief Family Relationship Scale, including a sub-scale for family cohesion (Cronbach's alpha= 0.83). We used logistic regression to assess the association between family cohesion and engagement in care, disclosure, and diet, controlling for age, sex, marital status, and income.
Results: The sample comprised 77 males and 277 females with a mean age of 45.8 years (SD=9.8). The majority of participants reported having been enrolled in HIV-care for at least five years (n=258, 71.9%), and all reported being on antiretroviral therapy. High levels of family cohesion were associated with immediate vs. delayed entry into care following diagnosis (aOR= 1.65, 95% CI: 1.01-2.69), disclosure of ARV use to household members (aOR=2.19, 95% CI: 1.09-4.41), and high consumption of fruit and vegetables (aOR=1.78, 95% CI: 1.10-2.90). Eighty-eight percent of participants (n=316) reported receiving health-related familial support, including reminders to take medication (77.5%), financial support (71.8%), and preparing food during times of illness (60%).
Conclusions: The association between family dynamics and health-related outcomes suggest that family-centered interventions could potentially improve HIV-related care outcomes, and family-centered interventions are especially relevant for people living with HIV who have co-morbid chronic diseases, such as diabetes or hypertension, given the relationship between family and lifestyle.

THPED513

What really matters? Moving towards a greater understanding of male partner involvement in PMTCT

K.H. Hampanda[1], M. Njuguna[2], A. Helova[3], T. Odeny[2], M. Onono[4], E. Bukusi[2], J. Turan[3], L. Abuogi[5]
[1]University of Colorado, Community and Behavioral Health, Denver, United States, [2]KEMRI, Kisumu, Kenya, [3]University of Alabama, Birmingham, United States, [4]UCSF, San Fransisco, United States, [5]University of Colorado, Denver, United States

Background: Across sub-Saharan Africa, male partner involvement (MPI) is positively associated with women's retention and adherence to prevention of mother-to-child transmission (PMTCT). The conceptualization of MPI varies across studies and is often defined solely as men's attendance at healthcare visits. The objective of this study is to improve the understanding of MPI in PMTCT and conduct preliminary testing of a MPI scale.
Methods: In 2017, we conducted a convergent parallel mixed methods sub-study within the Mother-Infant Visit Adherence and Treatment Engagement (MOTIVATE!) study (R01HD0808477) in southwestern Kenya. We surveyed HIV-positive women enrolled in the parent study on ART at 12 months postpartum (N=200). Twenty male partners also completed a qualitative in-depth interview. Psychometric, descriptive, regression, and thematic analysis highlight the scale's internal validity and specific behaviors and characteristics relevant to MPI in PMTCT.
Results: Among 200 women surveyed, 90% reported a stable male partner, and 96% of those had disclosed their HIV status to this partner. Only 49% of male partners attended at least one healthcare visit in the past year. The most commonly reported forms of MPI were encouraging a facility delivery and infant testing, followed by reminders about medication and HIV care (see Figure 1). Ten specific behaviors were used to establish an MPI scale (internal validity of alpha=0.90). Relationship characteristics associated with a higher MPI scale score include: cohabitating with the male partner (r=5.1; p< 0.01); HIV status disclosure (r=15.0; p< 0.001); and couple's HIV testing (r=5.6; p< 0.001). In addition, higher relationship satisfaction and social support are consistently correlated with higher MPI scale scores (see Table 1). In the semi-structured interviews, men concurred that reminders about care and medication are important. Men also discussed the importance of emotionally supporting their wives and helping with household chores in order to reduce stress, and the role of open communication within the couple.
Conclusions: As reported by both women and men, male partner involvement in PMTCT is not exclusively focused on male attendance at healthcare visits, but also includes other forms of instrumental, emotional, and informational support. This work furthers the conceptualization of male partner involvement in PMTCT.

Variable	N	Descriptive Findings Percent (n) / Mean (SD)	Correlation with Male Partner Involvement Scale (N=178) Coef. (95% CI)	p-value
Cohabitating with male partner (yes): % (n)	179	82.7% (148)	5.1 (1.5 - 8.7)	0.006
Disclosed HIV status to male partner (yes): % (n)	179	95.5% (171)	15.0 (8.4 - 21.6)	0.000
Ever tested for HIV as a couple (yes): % (n)	179	51.4% (92)	5.6 (2.9 - 8.2)	0.000
I feel satisfied with our relationship (completely/ almost completely/ mostly): % (n)	180	58.9% (106)	9.3 (6.9 - 11.7)	0.000
My relationship makes me very happy (completely/ almost completely/ mostly): % (n)	180	52.2% (94)	11.2 (9.0 - 13.4)	0.000
How often can you depend on your partner? (all the time/most of the time/more often than not): % (n)	175	58.9% (103)	8.9 (6.4 - 11.4)	0.000
How often does your partner show you that he loves and accepts you? (all the time/most of the time/more often than not): % (n)	178	63.5% (113)	9.0 (6.5 - 11.5)	0.000
How often does your partner make you feel valued/important? (all the time/ most of the time/more often than not): % (n)	180	67.2% (121)	9.3 (6.7 - 11.9)	0.000
How often does your partner encourage you not to give up? (all the time/most of the time/more often than not): % (n)	178	66.9% (119)	7.6 (4.9 - 10.3)	0.000

Uthando Lwethu "Our Love" intervention for South African heterosexual couples: Impact on couple communication, partner equality, and more equitable gender norms

L. Darbes[1,2], A. Conroy[2], T. Neilands[2], H. van Rooyen[3], K. Fritz[4], V. Hosegood[5,6], M. Johnson[2], T. Ngubane[7], N. McGrath[8,9]
[1]University of Michigan, Department of Health Behavior and Biological Sciences, Ann Arbor, United States, [2]University of California, San Francisco, Center for AIDS Prevention Studies, San Francisco, United States, [3]Human Sciences Research Council, Human and Social Development Program, Durban, South Africa, [4]International Center for Research on Women, Washington, United States, [5]University of Southampton, Department of Social Statistics and Demography, Southampton, United States, [6]Africa Health Research Institute, Durban, South Africa, [7]Human Sciences Research Council, Durban, South Africa, [8]University of Southampton, Department of Social, Human and Mathematical Sciences, Southampton, United Kingdom, [9]Southampton General Hospital, Faculty of Medicine, Southampton, United Kingdom

Background: Serostatus disclosure is critical to preventing HIV transmission in sexual partnerships. However, rates of disclosure remain low in South Africa, underscoring the importance of couples-based HIV testing and counseling (CHTC). Uthando Lwethu ("Our Love") was an efficacious couples-based intervention that aimed to improve uptake of CHTC—a process that facilitates mutual disclosure. Another goal of the intervention was to improve positive relationship dynamics. Facilitating couples' ability to communicate about HIV and fostering more equitable gender norms could confer additional benefits for couples, including potentially impacting intimate partner violence and health outcomes. In this analysis we identified whether the intervention improved relationship dynamics.

Methods: The intervention utilized two group (1 single-gender and 1 mixed-gender) and four couples counseling sessions delivered by lay counselors. Intervention content included communication skills, exercises to improve relationship quality and knowledge and awareness of gender dynamics. At 9-month follow-up, we collected data on relationship dynamics using validated scales, whether the couple received CHTC, and their HIV test results. For couples that engaged in CHTC, we fitted separate linear regression models for each relationship dynamic using couple-level sums. The key explanatory variable was randomization group. All models controlled for relationship length.

Results: Of the 332 couples randomized, 310 completed assessments at the 9-month visit. Among couples who participated in CHTC in both groups (N=99 couples), intervention couples reported significantly higher levels of equality (p = 0.029) and supportive communication (p = 0.028), more equitable gender norms (p = 0.002), and lower levels of demand-withdraw and blamed-based communication (p = 0.001) than control couples.

Conclusions: In addition to significantly increasing rates of CHTC, Uthando Lwethu significantly improved relationship dynamics for couples that opted for CHTC. Specifically the intervention appears to have improved couples' communication patterns to be more positive and constructive, and positively impacted gender norms such that couples endorsed more equitable power and decision-making. These findings suggest that couples-based interventions may not only positively impact health behaviors, such as CHTC, but may also facilitate changes in core relationship dynamics (e.g., communication). This demonstrates the influence that the relationship context can have on the psychological and physical welfare of couples.

THPED515

Transmission Information and support needs of the HIV-negative partner in HIV-serodiscordant relationships: Results from the Canadian national *Positive Plus One* study

S. Bullock[1], L. Calzavara[2], A. Daftary[3], J. Mendelsohn[4], B. Lebouche[3], B. Gladstone[2], L. Basaillon[5], D. Tan[6], A. Bourne[7], J.-P. Routy[3], M. Loutfy[8], T. Tompson[9], and the Positive Plus One Team
[1]University of Toronto, DLSPH, North York, Canada, [2]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [3]McGill University, Montreal, Canada, [4]Pace University, New York, United States, [5]University of Toronto, Toronto, Canada, [6]St. Michael's Hospital, Toronto, Canada, [7]LaTrobe University, Melbourne, Australia, [8]Women's College Hospital, Toronto, Canada, [9]Western University, London, Canada

Background: An estimated 23% of the 71,000 people living with HIV in Canada are in serodiscordant (SD) relationships, yet there are few services tailored for the HIV-negative partner. In our study we hypothesized that HIV-negative partners would report more need for: HIV-transmission information, HIV-support counselling, and relationship counselling than their HIV-positive partners; and we sought to identify the specific needs of the former.

Methods: *Positive Plus One* is a mixed-methods study of SD couples. Participants (n=570), in ongoing (88%) or past (prior 2 years; 12%) SD relationships were recruited from clinics and organizations across Canada during 2016-17. Surveys were conducted in English (92%) and French (8%); on-line (89%) or by telephone (11%). Analyses employed descriptive and multiple regression; in-depth qualitative interviews with 44 individuals were thematically analyzed.

Results: Participants included HIV-positive (58%) and HIV-negative (42%) partners in SD relationships, of mean age 42 years (range 18-72). 45% of people identified as gay men, 23% as heterosexual women; 18% as heterosexual men, and 15% as otherwise. Participants were from all Canadian provinces.

Participants quantitatively expressed a need for HIV-transmission information (11%), support counselling (18%), and relationship counselling (21%). HIV-negative partners only reported a greater need than positive partners for HIV-support counselling (24% vs 14%, p< 0.0001). Adjusting for sociodemographic characteristics, the longer HIV-negative partners knew about their partners' HIV-status, the less they required support (ref=knew 0-1 years; 2-5 years: AOR=0.812 (0.348-1.897); 6-14 years: AOR=0.307 (0.103-0.914); 15+ years: AOR=0.268 (0.078-0.923)). HIV-support needs did not differ by gender or sexual orientation (p=0.1839). Qualitative results indicated that early needs included peer support groups/therapy to address: concerns of transmission; isolation and loneliness due to non-disclosure; family planning; and as a way to meet fellow SD couples.

Conclusions: Only a small proportion of study participants indicated a need for HIV information and support; however, support needs were higher among the HIV-negative partners. As relationships evolve, needs diminish. Funding for HIV-support programs typically targets positive individuals; as life expectancy rises, more experience SD relationships. We argue for a more targeted approach to increasing participation of negative partners in HIV-support programs.

Understanding the barriers and facilitators to retention in the prevention of mother-to-child transmission care: A qualitative study of HIV positive women in Kenya

C. Karutu[1], M. Onyango[1], L. Messersmith[1], E. Feinberg[1], R. Wamai[2], N. Fulton[3]
[1]Boston University School of Public Health, Global Health, Boston, United States, [2]North Eastern University, African American Studies, Boston, United States, [3]Options Consultancy Services Ltd, Maternal & Newborn Improvement (MANI) Project, Bungoma County, Kenya

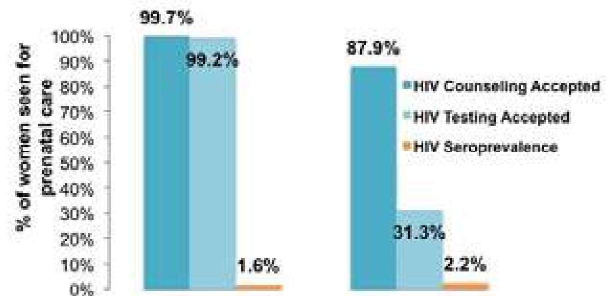
Background: To understand the experiences of HIV positive women who previously participated in prevention of mother-to-child transmission (PMTCT) services and their and male partners, and how these experiences influence their retention in PMTCT care.
Methods: This qualitative research was part of a mixed methods study that examined retention in PMTCT care among HIV positive women in three study sites in Central and Nairobi regions of Kenya. Forty women were selected for in-depth interviews from a sample of 548 HIV positive women identified in the larger retention analysis. In-depth interviews were also conducted with husbands of these women. A team-based approach was used to develop the codebook and content analysis was used to identify emergent themes. The Informational, Motivational, Behavioral (IMB) model was used to structure the interview guides, organize, analyze and explain the qualitative results.
Results: The facilitators of retention in PMTCT care included: supportive male partners; acceptance of one's HIV positive status; disclosure of HIV positive status to spouse, family, friends; desire to have an HIV negative baby; psychosocial support and peer counseling; and positive provider attitudes. The barriers to retention in PMTCT care were: unsupportive male partners; denial of one's HIV positive status; lack of disclosure to spouse, family, friends; internal stigma; financial pressures; negative provider attitudes; waiting and delays; negative perceptions regarding quality of care; stress; and a lack of PMTCT knowledge among participants.
Conclusions: This study demonstrates that the factors that enable or hinder retention in PMTCT care are complex and interconnected. As posited by the IMB model, possessing just one factor such as correct information of PMTCT, or having a supportive male partner, or receiving good quality care does not guarantee that an HIV positive woman will be retained in PMTCT care.

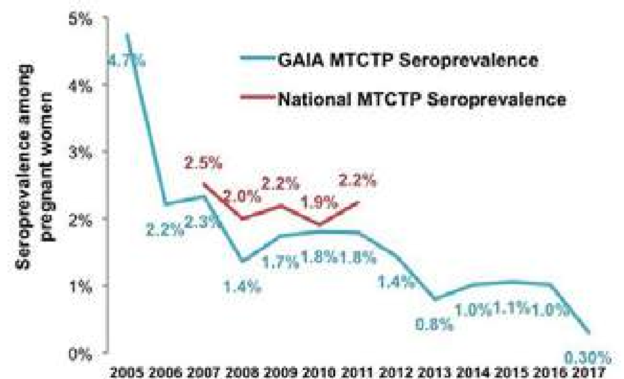
THPED517

Healthy moms and healthy infants: 12 years of successful mother to child HIV transmission prevention in a community health center in Bamako, Mali

L.Y. Diarra[1], K. Tounkara[1], Z. Koty[1], E. Squibb[2], S. Beseme[2], Y. Kone[1], F.S. Diallo[3], O.A. Koita[4,5], A.S. De Groot[2,6]
[1]GAIA Vaccine Foundation, Bamako, Mali, [2]GAIA Vaccine Foundation, Providence, United States, [3]Regional AIDS Prevention Sector (Centre Sectoriel de Lutte Contre le SIDA), Bamako, Mali, [4]Laboratory of Applied Molecular Biology (Laboratoire de Biologie Moleculaire Apliquée), Bamako, Mali, [5]University of Science, Techniques, and Technologies of Bamako (USTTB), Bamako, Mali, [6]Institute for Immunology and Informatics (iCubed), University of Rhode Island, Providence, United States

Background: Community clinics (CSCOMs) are the primary access point to healthcare in West Africa. While HIV testing is available in some CSCOMs, it is not consistently offered to all women seeking prenatal care. Even when offered, HIV test acceptance is extremely low (31%), often due to lack of supplies. GAIA Vaccine Foundation implemented a MTCTP program at a Bamako-based CSCOM in 2005. This study evaluates the program at the 12-year point.
Description: Starting in 2005, local clinic staff received formal training to encourage HIV testing and counseling. Staff systematically offered HIV tests to all women seeking prenatal care. Initially, HIV+ mothers were referred to a city hospital for treatment and GAIA covered transportation expenses, but in 2008, MTCTP treatment was provided directly at the CSCOM. All HIV+ women were provided with ARVs according to local protocols and encouraged to give birth at the clinic, where delivery costs were covered, and infants received ARVs immediately. Infant HIV testing was performed, initially by antibody testing at 18 months, followed by PCR/Viral load.
Lessons learned: Counseling and HIV tests were offered to 18309 pregnant women over the 12 years, and 99% of women accepted. HIV seroprevalence rates among pregnant women at the clinic reduced dramatically from 4.7% in 2005 to 0.3% in 2017. During 12 years, 100% of infants born to MTCTP-adherent mothers were HIV-seronegative. Cost was a significant barrier to effective prenatal care and childbirth for HIV+ mothers-to-be. By providing these services free of charge, GAIA was able to encourage increased participation in prevention services.





[HIV test acceptance and seroprevalence rates from 2005-2017 at GAIA's MTCTP Clinic in Bamako, Mali]

Conclusions/Next steps: This evaluation suggests that MTCTP interventions are feasible in low-resource settings as long as testing supplies are restocked consistently and staff receives adequate training. CSCOMs are the frontline of patient care across West Africa and should be equipped for HIV prevention.

THPED518

Systematic review of factors influencing access to HAART by pregnant woman living with HIV in Nigeria

Y. Adebisi[1], A. Ekpenyong[2], A. Bamisaiye[1], S. Adeyemi[3], N. Blaise[4], D. Oyedokun[1], D.Q. Olaoye[1], D.E. Lucero Priso III[5]
[1]Faculty of Pharmacy, University of Ibadan, Ibadan, Nigeria, [2]Faculty of Pharmacy, University of Uyo, Uyo, Nigeria, [3]Federal Medical Center, Pharmacy Department, Akure, Nigeria, [4]College of Health Sciences, Faculty of Medicine, University of Rwanda, Kigali, Rwanda, [5]Xi'an Jiaotong-Liverpool University, Department of Public Health, P.R, China

Background: Nigeria has the highest number of children acquiring HIV infection since 2009. Without urgent action, the global target, 90-90-90, is unlikely to be reached. The aim of our study was to systematically re-

view literatures to highlight the factors including the barriers and facilitators influencing access to Highly Active Antiretroviral Therapy (HAART) by Pregnant Women Living with HIV (PWLH).
Methods: Search for peer reviewed literatures was carried out in PubMed, Web of Science, Scopus and PsycINFO databases from 2006 through 2017. Studies eligible for inclusion in the review were those that were carried out in Nigeria, which addressed policy, neonatal HIV and socio-cultural issues influencing access to HAART by PWLH. 21 studies were selected: 15 qualitative, 3 quantitative and 3 mixed methods studies. Data was extracted and summarized to highlight the barriers and facilitators influencing accessibility of PWLH to HAART.
Results: At individual, community, interpersonal and service provision levels, the data revealed 10 barriers and 5 facilitators. Key barriers identified were: localization of antiretroviral centers in the urban areas; fear of stigmatization; poor enforcement of HIV/AIDS Antidiscrimination law; expensive antenatal care and government's failure to address stigmatization of PWLH. The two main facilitators identified included motivation of pregnant women to prevent their babies from having HIV and positive support from family members. Inaccessibility to HAART is mainly due to the fear of stigmatization from the public and only seven out of 36 states in the country enforce the HIV/AIDS Antidiscrimination Law. Economic recession, fertility rate, availability of antiretroviral medicines and numbers of patent medicine vendors are not prominent factors influencing access to HAART in PWLH.
Conclusions: Poor access to HAART by PWLH is the main issue causing increase in pediatric HIV prevalence in the country. The main limiting barrier is not only fear of stigmatization but defective government policy. Enforcement and awareness of the people about HIV/AIDS Antidiscrimination Law are not so solid in the country. We recommend mass sensitization of PWLH and the entire population on HIV/AIDS Antidiscrimination Act.

THPED519

Developing HIV consulting skills among gynecologists in Russia

E. Artemenko
FOCUS-MEDIA Foundation, Moscow, Russian Federation

Background: Project implementation has shown that gynecologists in Russia's regions lack knowledge and skills to provide effective consultations for women on HIV issues. Often, gynecologists consider it their primary obligation to send a woman to an AIDS center for an HIV test, and to prescribe medication if necessary. Inadequate knowledge about HIV infection and poor consulting skills mean that they hold stigmatizing opinions about HIV-positive patients, which prevents them from providing effective care to patients.
Description: The Public Health and Social Development Foundation FOCUS-MEDIA has been implementing the project „Improving the skills of gynecologists in providing women with consultations on HIV" since 2014. The project's aim is to prevent sexual and perinatal HIV transmission by training gynecologists in counseling, helping to reducing stigma and discrimination against HIV-positive women among gynecologists, and mobilizing local communities of HIV-positive women.
19 training events were organized in many of Russia's regions, attended by more than 500 obstetrician-gynecologists, pediatricians, neonatologists, psychologists and other medical specialists.
The training module is based on the Manual for Obstetricians and Gynecologists - Counseling on HIV-Infection (E. Stepanova, 2014). The manual introduces specialists to the principles of pre- and post-test counseling for women. Each participant is given the Manual with ready-made consulting algorithms for further use.
Lessons learned: The results of the project show that stigma and discrimination against HIV-positive women are based on fear of infection while working with such patients. Lack of skills in counseling and cooperating with patients mean specialists fail to offer patients pre- and post-test counseling, leading to low adherence to ARV-based PMTCT (reducing the patient´s commitment to timely chemoprophylaxis aimed at reducing the risk of perinatal HIV transmission). Training in consulting skills improves their knowledge and stimulates partnership and patient-centered service delivery.
Conclusions/Next steps: To improve the project's effectiveness, a training course for gynecologists to improve their skills was developed and certified. The 144-hour course is included in the curriculum of the Medical Educational Institution for improving doctors' skills.
The FOCUS-MEDIA Foundation will continue the project to motivate at least 80% of trained gynecologists to provide quality counseling to women of reproductive age.

THPED520

Mothers' experiences of early infant diagnosis for HIV in Option B+ programmes and the implications for their engagement in care: Qualitative evidence from South Africa

D. Etoori[1], A. Wringe[1], G. Reniers[1], J. Renju[1], V. Ndhlovu[2], S.D. Ndubana[2], E. Sihlangu[2], F.G.-O. Casas[2]
[1]London School of Hygiene and Tropical Medicine, Population Health, London, United Kingdom, [2]University of Witswatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit, Agincourt, South Africa

Background: Infant retention through the latter stages of the prevention of mother-to-child transmission (PMTCT) cascade is critical for preventing new paediatric HIV infections and reducing mortality through antiretroviral therapy (ART) initiation for infants testing positive.
However, uptake of early infant diagnosis (EID) is low: only 43% of exposed infants enrolled in follow-up before 2 months in Malawi and national data from South Africa show, only 35% of mothers intended to access EID services.
Methods: We conducted in-depth interviews with 19 women who initiated ART for PMTCT under Option B+ in South Africa to understand their experiences with EID. Interviews were recorded, transcribed, and translated. Analysis followed a thematic approach: a coding framework was developed iteratively, and emerging themes were identified.
Results: Key themes included barriers and facilitating factors to undergoing EID, and consequences for care engagement. Most mothers followed counsellors' advice on testing their infants, with some undergoing EID multiple times, fearing transmission through breastfeeding.
Furthermore, although most mothers were scared by the prospect of testing their infants, they were motivated by the desire to know their infant's status and learn what to do if the child tested positive. Barriers to EID were previous positive results for infants from earlier pregnancies, and the mother's own acceptance of her status.
Mothers expressed relief from learning that their infant was negative. However, a negative result could also lead to disengagement from care where mothers took the result as proof that they themselves were in fact negative.
Positive results caused stress and anxiety, but mothers generally felt they should accept this result and get the infant on ART in order to keep them healthy. For some participants, a positive result for their infant led to their own disengagement from care, due to the double burden of their own treatment visits and their infants, with these mothers opting to attend their infant's visit over their own.
Conclusions: Women's experiences and expectations regarding EID influenced their own engagement in HIV care. Retention in care for Option B+ mothers may be improved with additional counselling around the time of EID, and joint ART clinic visits for positive mother-baby pairs.

Partner disclosure patterns are associated with ART uptake and outcomes in Malawi's PMTCT program: A mixed method study

M. van Lettow[1,2], F. Cataldo[1], M. Landes[1,2], F. Kasende[1], P. Nkhoma[1], J.J. van Oosterhout[1,3], E. Kim[4], T. Kalua[5], E. Schouten[6], B.A. Tippett-Barr[7]
[1]Dignitas International, Research, Zomba, Malawi, [2]University of Toronto, Toronto, Canada, [3]College of Medicine, Blantyre, Malawi, [4]Centers for Disease Control and Prevention, Lilongwe, Malawi, [5]Malawi Ministry of Health, Lilongwe, Malawi, [6]Management Sciences for Health, Lilongwe, Malawi, [7]Centers for Disease Control and Prevention, Harare, Zimbabwe

Background: Evidence suggests that disclosure of HIV status to one's partner may influence outcomes in the prevention of maternal-to-child transmission of HIV (PMTCT). We report on partner disclosure status in relation to PMTCT utilization, treatment adherence and infant transmission among HIV-positive Malawian women at 4-26 weeks postpartum.
Methods: A mixed method study was conducted as part of the national evaluation of Malawi's PMTCT program. Between October 2014 and May 2016, quantitative data were collected from HIV-positive mothers attending under-5 clinics with their 4-26 week old infants in 54 health facilities; infants received HIV-1 DNA testing. Data collected included socio-demographics, partner disclosure status, uptake of maternal antiretroviral treatment (ART) and treatment adherence. Binary logistic regression analyses accounted for the survey design and other confounding characteristics. Between July 2016 and September 2017, in-depth interviews and focus group discussions were conducted with a subgroup of mothers (n=53), their partners (n=19), adolescent mothers (n=13), lost-to-follow up (LTFU) mothers (n=23), community leaders (n=23) and healthcare workers (n=154).
Results: Of 3153 mothers included in this analysis, 2882 (91.4%) reported having a spouse or cohabiting partner, while 271 (8.6%) reported being single. Among couples, both partners disclosed in 2090/2882 (72.5%), one partner disclosed in 623/2882 (21.6%) and neither partner disclosed in 169/2882 (5.9%). Being in a relationship in which neither partner disclosed was associated with no maternal ART uptake (adjusted odds ratio (aOR) 6.6; 95% confidence intervals (CI) 3.6-12.0) and suboptimal treatment adherence (aOR 2.0; 95%CI 1.3-3.2), when adjusted for region, age, and parity; and associated with infant transmission (aOR 2.2; 95%CI 1.1-4.4), when adjusted for regional strata, age, parity, uptake of maternal ART and infant nevirapine prophylaxis. Women's fear of being blamed by their partner was central to decisions not to disclose within couples and when starting a new relationship. LTFU mothers struggled to accept and disclose their HIV status, which hindered treatment initiation; some were unable to hide ART and feared unwanted disclosure.
Conclusions: Partner disclosure played a major role in women's decisions to start, continue and adhere to ART and should be actively supported in national HIV programs to maximize the uptake and outcomes of PMTCT.

Financial incentives, micro-finance, and other economic approaches

Financial education and improved financial management positively impacts transgender persons' livelihoods and reduces high-risk behaviours in Indonesia

G.M. Halim[1], Y. Setyawati[2], B. Zug-Castillo[3], S.M. Afsar[4]
[1]International Labour Organization, Jakarta, Indonesia, [2]Megawati Institute, Jakarta, Indonesia, [3]International Labour Organization, Geneva, Switzerland, [4]ILO, Geneva, Switzerland

Background: A needs-assessment for transgender organisations identified "over indebtedness" as the most common problem that transgender workers faced. To build the capacity of a group of 23 transgender participants (who had the potential to replicate the training to other beneficiaries) the ILO organized a training-of-trainers. The majority of participants, (20), were transwomen who actively engaged in sex work, full time or occasionally.
Description: The training relied on ILO's "financial education for families" modules. Information updates about HIV and AIDS in the world of work, and HIV-related labour policies and programmes complemented the training. The course also included practical training on how to replicate this training to others. Following the training, additional financial management assistance supported all participants.
Lessons learned: A short-term impact assessment three months after the training was answered by the majority of participants:
- pre-training: none of the participants had financial management skills, only 13% were aware of their total monthly expenses and 78% were heavily indebted.
- post-training: they felt empowered and capable of planning for short, medium and long-term financial goals. 78% reported they regularly manage their finances, have less debt and more savings. These newly acquired abilities also altered their behaviour at work. While selling sexual services, the improved handling of their personal financial situation increased their bargaining power to reject clients who refuse to use condoms. Five trainees started planning a job change, and one transgender included buying condoms in her budget plan. Six participants replicated the training further to reach their communities.

Conclusions/Next steps: The capacity to manage their finances has a positive impact on the lives and behaviour of transgender persons in Indonesia. It empowers them to refuse high-risk sexual relations, practise safe sex and enables them to apply knowledge on HIV prevention.

Men's perspectives on the impact of female-directed cash transfers on gender relations: Findings from the HPTN 068 qualitative study

M.N. Khoza[1], S. Delany-Moretlwe[1], F. Scorgie[1], J. Hove[2], A. Selin[3], J. Imrie[1], R. Twine[2], K. Kahn[2], A. Pettifor[3,4], C. MacPhail[1,2,5]
[1]Wits Reproductive Health and HIV Institute (WITS RHI), University of the Witwatersrand, Faculty of Health Sciences, Johannesburg, South Africa, [2]MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Sciences, Johannesburg, South Africa, [3]University of North Carolina, Department of Epidemiology, Gillings School of Global Public Health, Chapel Hill, United States, [4]University of North Carolina, Carolina Population Center, Chapel Hill, United States, [5]University of Wollongong, School of Health and Society, Wollongong, Australia

Background: HIV is an inherently gendered disease in eastern and southern Africa, not only because more women than men are infected, but also because socially constructed gender norms work to increase women's HIV-infection risk. The provision of cash transfers to young women alone in such a context adds another dimension to already existing complex social relations where patriarchal values are entrenched,

gender inequality is the norm, and violence against women and girls is pervasive. It raises concerns about complicating young women's relationships with their male partners or possibly even setting them up for more violence. In our attempt to understand how cash transfers influence social relations in the context of a trial among young women in South Africa, we used qualitative data collected during the trial to explore men's perceptions of the impact of cash transfers on male-female relationships, both intimate and platonic, peer relationships.

Methods: Between April 2012 and August 2015, we conducted focus group discussions (n=12) and interviews (n=20) with the male peers and intimate partners of young women aged 13-20 years, who were participating in a phase III randomised controlled trial of cash transfers for HIV prevention in Mpumalanga, South Africa. A thematic content analysis approach was used to analyse the data. The codebook was developed on the basis of the topic guides, with additional codes added inductively as they emerged from the data.

Results: Intimate partners were older (range 20-32 years) and more likely to be working. Both intimate partners and male peers were supportive of the cash transfer trial targeting young women; younger peers however expressed some concerns that the money might diminish their power and status in relationships. HIV testing requirements associated with the trial appeared to have improved communication about sex and HIV in intimate relationships, with some women even encouraging their partners to go for an HIV test.

Conclusions: Our findings reinforce evidence that cash transfers are not necessarily a source of tension or harm in male-female relationships. Linking cash transfer programmes to HIV testing and other prevention services should be explored in future cash transfer programming.

Safe housing, social protection and other care and support for people affected by HIV

THPED524

Homelessness and incarceration are associated with elevated mortality rate among people living with HIV in Ontario, Canada: Findings from the CIHR-funded positive spaces, healthy places study

S.B. Rourke[1], T. Bekele[2], J. Globerman[3], J. Watson[1], S.W. Hwang[1], K. Hambly[4], J. Koornstra[5], G. Walker[6], J. Bacon[2], Positive Spaces, Healthy Places Study Team

[1]St. Michael's Hospital, Centre for Urban Health Solutions, Toronto, Canada, [2]OHTN, Toronto, Canada, [3]Ontario Ministry of Health and Long Term Care, Toronto, Canada, [4]Fife House, Toronto, Canada, [5]Bruce House, Ottawa, Canada, [6]Positive Living Niagara, St. Catherines, Canada

Background: Social determinants of health (SDOH) are the economic and social environments that shape the health of individuals and communities. In people living with HIV, health outcomes including mortality are influenced by both individual and social-structural level factors. The objective of the current study was to examine SDOH with all-cause mortality among people living with HIV.

Methods: Study sample included 454 people living with HIV in Ontario, Canada who were enrolled in the Positive spaces, Healthy Places (PHSP) study, a longitudinal study examining housing and health outcomes. We verified mortality status of participants at 1-year, 3-year, and 5-year follow-up visits with information obtained from proxies (family members, partners, and friends), obituaries, and local AIDS memorial lists. We used logistic regression modelling to identify SDOH that were associated with all-cause mortality.

Results: Of these 454 people, 53 individuals (29 men who have sex with men [MSM], 10 women, and 14 heterosexual men) passed away during the follow-up period. Individuals who passed away were more likely to have low level of education, be unemployed or on disability, live outside of Greater Toronto Area, have suboptimal health, and report drug use, history of homelessness, and history of incarceration at baseline than those who were alive at 5-year follow-up. Results form time-updated multivariable logistic regression analyses showed that history of incarceration and homelessness (OR=2.1, 95% CI: 1:04 to 4.39) independently predicted high risk of mortality among MSM. MSM with suboptimal self-rated health at previous visit ("Good"; OR=2.7, 95% CI: 1.14 to 6.48; "Fair/Poor" (OR=5.1, 95% CI: 2.14 to 12.09) had higher odds of mortality than those who rated their health as "Excellent" or "Very good". Among women and heterosexual men, those who rated their health as "Good" (OR=4.1, 95% CI: 1.44 to 11.47) or "Fair/Poor" (OR=4.9, 95% CI: 1.75 to 13.55) had increased odds of mortality than those who rated their health as "Excellent" or "Very good.

Conclusions: Homelessness and incarceration may contribute to HIV disease progression and mortality. Intensive case management that increases retention in care and facilitates linkage to housing services may help to reduce excess deaths among people with HIV.

THPED525

Effect of family conferencing on psychological stress of caregivers: Single blinded randomized control trial on caregivers of infected children attending a HIV clinic in North Central Nigeria over 3 months

N. Ripiye[1], M. Akin[2], L. Shedul[3], N. Baamlong[3], A. Okechukwu[3], S. Haruna[1], B. Akor[3], R. Abdulkareem[3], J. Abu[1], O. Chira[1]

[1]University of Abuja Teaching Hospital, Family Medicine, Gwagwalada, Abuja, Nigeria, [2]National Hospital Abuja, Abuja, Nigeria, [3]University of Abuja Teaching Hospital, Gwagwalada, Abuja, Nigeria

Background: HIV infected children and their caregivers face both medical and psychosocial issues. The family plays an important role in any kind of treatment. Hence this study set out to explore the effect of family conferencing on the psychological stress of caregivers of HIV infected children with a view to improving clinical outcomes and family support.

Methods: The study was a single blinded randomized control trial of 114 caregivers. One group received family conferencing plus clinical care for the child and the other group received usual clinical care for the child only. An Interviewer administered questionnaire was used to obtain socio-demographic and clinical history of the caregivers. Their psychological stress was assessed using the Self Reporting Questionnaire-20 score(SRQ-20) at the beginning of the study and eight weeks after the family conferencing. Perceived Social Support (PSS -Fa) was used to assess family support while family function was assessed using family APGAR score (Adaptability, Partnership, Growth, Affection and Resolve).

Results: A total of 106 caregivers were analyzed with 50.9% of them having psychological stress. The mean SRQ -20 score at baseline was 5.02 (± 2.75) and 4.80(± 3.34) for the intervention and control groups respectively which reduced to 3.38 (±2.70) in the intervention arm after the family conferencing. The odds ratio for psychological stress among those receiving the family conferencing was 0.35, 95% CI: 0.13-.0.93 compared to caregivers who did not receive the intervention. Family size, function and support all had significant association with psychological stress. (p value = 0.045, p value 0.0071 and p value = 0.001 respectively)

Conclusions: Family conferencing was found to reduce the mean SRQ-20 scores which implies a reduction in psychological stress of caregivers of HIV infected children. Psychological well being of the caregiver may improve care of the child and subsequently improve clinical outcomes.

Development and poverty alleviation

Postnatal depression in women with HIV in Zimbabwe

R. Chingono[1,2], H. Mebrahtu[2], V. Simms[3], A. Rehman[3], Z. Mupambireyi[4], P. Ndlovu[5], R. Malaba[5], F. Cowan[4,6], L. Sherr[2]
[1]*CeSHHAR Zimbabwe, Adolescents, Harare, Zimbabwe,* [2]*University College London, London, United Kingdom,* [3]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [4]*CeSHHAR Zimbabwe, Harare, Zimbabwe,* [5]*World Education Inc., Harare, Zimbabwe,* [6]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Background: Mental health is an important feature of both HIV infection and pregnancy. Depression influences maternal coping and adjustment as well as subsequent child outcomes. We investigated the relationship between poverty and depression, parenting stress and common mental disorders in Zimbabwe.
Methods: Biological mothers of 0-24 month old infants enrolled in the CHIDO cluster-randomised trial (n=562) were assessed using the Edinburgh Postnatal Depression Scale (EPND) for depression, Shona Symptom Questionnaire short form (SSQ8) for common mental disorders, and Parental Stress Index short form (PSI-SF). Household socioeconomic status (SES) was generated by principal component analysis of maternal education, employment, housing type, sanitation facilities, water source and household assets. We used logistic regression to model the association between SES and the three outcomes, adjusted for infant's sex and age (0 to < 3m, 3 to < 6m, 6 to < 12m, 12 to < 18m and 18 to 24m). Robust standard errors were used to account for clustering by clinic as the primary sampling unit.
Results: Compared to mothers of high SES (40%), 55% of the mothers with low SES scored above the cut off for postnatal depression (AOR=1.84). Mothers with low SES (44%), had a higher prevalence of common mental disorders compared to 33% in those of high SES (AOR=1.69). Similarly 40% of those with low SES had stress, compared to 24% of those with high SES (AOR=2.12). Lower SES was associated with postnatal depression (p< 0.01), common mental disorders (p=0.08) and parental stress (p=0.01).
Conclusions: Socio-economic status was significantly associated with all measures of mental health. Poverty reduction may be important for management for women in low resource settings, to assist with managing their HIV care, pregnancy related challenges and child caring needs.

THPED527

A novel approach to addressing structural drivers of HIV: Community Benefits Agreements

M.V. Dabbah[1,2], A. Bernal[3]
[1]*Kedren Community Health Center, Inc, Administration, Los Angeles, United States,* [2]*Urban Point Partners, Los Angeles, United States,* [3]*The Urban Point, Los Angeles, United States*

Background: A Community Benefits Agreement (CBA) is a contract signed by community groups and a real estate developer that requires the developer to provide specific benefits to the local community. More communities are negotiating agreements to ensure that new developments create healthy neighborhoods. As such CBAs represent a novel approach towards reaching health equity.
Description: Often CBAs attempt to address income inequality in poor neighborhoods; which is one key component to addressing HIV-related disparities. A common example include the negotiation of living wages. In our CBA, we sought to not only address income inequality but also the social, vocational and educational capital of foster youth so that they would not continue to be at high risk for HIV. In collaboration with the developer, we created the C.O.R.N.E.R. initiative whereby we worked with the foster youth of a local community high school to provide them with mentors, aprenticehsips, creative social media outlets, and with a system navigator to address their healthcare needs as well as their childhood adverse trauma which has been found to be related to high risk sexual behaviors. Students felt that the C.O.R.N.E.R. was their home and thus their sense of self-efficacy and esteem increased and their sense of social connectedness allowed them to be "rooted" in their community. They also noted that they sought more immediate healthcare for STIs and felt more comfortable talking with their primary care provider.
Lessons learned: Community benefits agreements have emerged as a new approach to broaden our collective vision in addressing health equity and structural drivers of health, including HIV. The development of broad coalitions is key to bringing developers to the table as key new partners to structurally meet the needs of those at high risk for or affected by HIV.
Conclusions/Next steps: As CBAs are further developed as a health-equity tool, there is a need to increase awareness of said possible agreements amongst community members at-large. We also need to build up the capacity of communities to negotiate agreements. Health departments, community coalitions, and HIV/AIDS-related organizations should integrate CBAs into their planning tools and strategic plans.

Interventions to reduce stigma and discrimination

THPED528

On air with positive living youth outreach: How HIV-positive youth in Lesotho are using radio and community outreach to empower their peers and combat stigma

H. Hengelbrok[1,2], T. Motseki[3], N. Khesa[3]
[1]*Alive Medical Services, Kampala, Uganda,* [2]*Global Health Corps, New York City, United States,* [3]*Baylor College of Medicine Children's Foundation - Lesotho, Maseru, Lesotho*

Background: With an HIV prevalence rate of 24%, no one in Lesotho is unaffected by the disease. Yet, stigma and misinformation abound, the two perpetuating one another in a deadly cycle. Both factors cause a fear of disclosure and contribute to further infections. In 2017, eight 22 to 24-year-old Basotho HIV advocates formed Positive Living Youth Outreach (PLYO), aiming to provide health education and share life stories on HIV/AIDS, sexual and reproductive health, and other issues, by speaking at community centres, schools, health clinics, and on media outlets. The goal of PLYO is to spread awareness, decrease stigma, and raise the confidence of HIV-positive youth in Lesotho.
Description: One of the core activities of PLYO is a weekly radio show, "Positive Living", supported by Baylor College of Medicine Children's Foundation - Lesotho, during which PLYO members select HIV-positive youth and healthcare professionals to talk about their experiences, provide education on HIV and general health, and more. Since January 2017, PLYO have also given monthly health talks at health facilities and schools. Participants encourage members of their youth networks to participate in PLYO activities; to date, over 30 youth have presented on the radio. PLYO members were also invited to present at Radio Days Africa 2017, the biggest radio conference on the continent, to share their experience starting a community-based radio show. PLYO members have been featured on national and international media.
Lessons learned: PLYO has proven transformative not only in the lives of its members, but also in the lives of their immediate peers and community. All of the eight core committee members are now employed as peer educators/ambassadors by non-governmental organizations dedicated to fighting HIV/AIDS. Members report feeling free and more confident after sharing their story on air. Listeners call in to ask questions they fear raising in other contexts.
Conclusions/Next steps: PLYO has formed and registered its own non-governmental organization and plans to continue various forms of advocacy and HIV education targeting young people. PLYO is an example of a youth-focused and youth-led initiative that is changing the narrative surrounding HIV-positive youth both for their audience and, crucially, for the youths themselves.

THPED529

Interventions for healthcare providers to improve treatment access and reduce stigma and discrimination towards MSM-TG

T. Chopade, M. Sivasubramanian, V. Anand
Humsafar Trust, Capacity Building, Mumbai, India

Background: In India, Men who have Sex with Men (MSM) and Transgender (TG) population continue to be criminalized and are highly vulnerable and marginalized. Stigma, high HIV prevalence, and violence are associated with their sexual identity. Studies at Humsafar Trust conducted in health care have indicated lack of knowledge and unjust outlook towards MSM-TG issues and sexual health needs of the community. Additionally, due to the fear of being stigmatized and discriminated, MSM and TG face hesitate to access health services, further adding their vulnerability to HIV.
Description: The Humsafar Trust, a community-based organization is Sub-Recipient for Global Fund Round-9 funded Project, MSA, which focuses on building capacities and improving policy environments for MSM community across 27 states of India. Over the period of two years 2016-2017, ten training programs were conducted with 238 healthcare providers (Doctors, counselors and paramedical staff) were trained across 10 Indian states using the standard module. The standardized module included discussion, interaction with community members, and group work emphasizing issues related to sexual health needs of MSM/TG community.
Lessons learned: The aim of the intervention was to increase knowledge related to sexual and reproductive health (SRH) issues and building an awareness of issues faced by MSM and TG community. Apart from sexual health concerns, community health concerns like challenges while accessing care and treatment, harassment, delay in providing health care, and other mental health concerns were also discussed. At the end of these training, health care providers reported a better understanding of sexual health and community issues faced by MSM and TG groups.
Conclusions/Next steps: Community-led training programs are key in creating and fostering rational attitudes toward MSM-TG as they focus on promoting health/human rights and overall well-being of marginalized communities. Enabling environments and a better understanding of community health issues (SRH) furthers empower the community to seek healthcare care services and other services thus reducing their vulnerabilities. Programmatic and policy implications must consider incorporation of these models into national programs. It is important to engage healthcare providers in policy development, advocacy initiatives, and to create an enabling environment for MSM and TG Communities.

Developing a national strategy for addressing HIV stigma in Scotland: An effective tool in addressing HIV stigma

K. Smith[1], N. Sparling[1], J. Hirono[1], K. Smithson[2], C. Crawford[3], W. Dalgleish[3], N. Policek[4], F. Gilbertson[5], A. Hudson[6], E. Chahali[7], J. Zinger[8], K. Kasengele[8], N. Boydell[9], M. Gilbert-Straw[10], A. Ryan[11], L. McDaid[12], G. Valiotis[1]
[1]HIV Scotland, Edinburgh, United Kingdom, [2]National AIDS Trust, London, United Kingdom, [3]Lothian Patient Forum, Edinburgh, United Kingdom, [4]University of Cumbria, Carlisle, United Kingdom, [5]Recovering Justice, Durham, United Kingdom, [6]People Living with HIV Stigma Index, London, United Kingdom, [7]Hwupenyu Health and Wellbeing, Glasgow, United Kingdom, [8]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom, [9]University of Edinburgh, Edinburgh, United Kingdom, [10]Positive Help, Edinburgh, United Kingdom, [11]Terrence Higgins Trust, Glasgow, United Kingdom, [12]University of Glasgow, Glasgow, United Kingdom

Background: Addressing stigma is identified as the most ambitious outcome of the Scottish Government's Sexual Health and Blood Borne Virus Framework, which dictates health policy and practice in this area. To date, progress towards eliminating stigma in Scotland has not been demonstrated. The absence of an operational definition and evaluation matrix, fragmented interventions, and the challenges of addressing facilitators and drivers of stigma were seen as priority areas requiring a nationally coordinated response.
Description: Desktop research was conducted to map key populations in Scotland, people working with them, and relevant decision-makers. UNAIDS and WHO guidance on stigma were linked with, and assessed against, Scottish national policies and data. To ensure a coordinated work-plan a diverse group, comprised of community members and experts from relevant organisations, was brought together to form the HIV Anti-Stigma Consortium (n=20). The Consortium developed a strategy to address HIV stigma in Scotland, co-published in two parts: a theory summation, the Road Map to Zero and an Action Plan. We worked to create a common agenda among key policy- and programme-makers. A dynamic social media campaign (reach of 6.5 million people) promoted key messages among community members and decision-makers.
Lessons learned: This community-led work required a highly coordinated approach; linking community members, clinicians, service-providers and academics, and mediating varied priorities held by stakeholders. The work received widespread support by addressing government policy, creating political leadership, challenging inequalities, presenting best practice, and prioritizing community involvement. The strategy received support from Members of Scottish Parliament, clinicians, NGOs and statutory services. The launch campaign was endorsed by the First Minister of Scotland and Scottish celebrities. By adapting global targets for the Scottish context we have informed evidence-based programmes that take into consideration local barriers related to geography, political will, and the diversity of the population.
Conclusions/Next steps: Establishing a national strategy to address HIV stigma mobilized community and other stakeholders, reinvigorating interest and resources to address stigma. By creating links between national strategies and agreed global targets, we have (re)focused how best to tackle stigma and placed the elimination of HIV stigma high on the agenda of policy-makers, stakeholders and service-providers.

Intersectionality of stigmas in Senegal: Differences in stigma outcomes among people living with HIV, transgender women, and cisgender men who have sex with men

C. Lyons[1], O. Olawore[1], B. Liestman[2], D. Diouf[3], S. Ketende[1], K. Coly[2], F. Drame[3], G. Turpin-Nunez[1], D. Castor[4], A. Cheng[4], C. Ndour[5], S. Mboup[5], C. Toure-Kane[6], N. Leye Diouf[6], H. Diop[6], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Dakar, Senegal, [3]Enda Sante, Dakar, Senegal, [4]United States Agency for International Development, Crystal City, United States, [5]Ministry of Health, Division de La Lutte Contre Le Sida et Les IST, Dakar, Senegal, [6]CHU Aristide Le Dantec, Laboratoire de Bacteriologie-Virologie, Dakar, Senegal

Background: Stigma potentiates HIV risks through limiting engagement in HIV prevention, care, and treatment services. Stigma is prevalent among cisgender men who have sex with men (cis-MSM), transgender women, and has been associated with HIV infection and the limited uptake of services along the HIV treatment cascade across Sub-Saharan Africa. Stigma elimination remains one of the core pillars in achieving an AIDS-free generation, but there are limited data characterizing effective interventions or the role of gender or HIV-related intersectional stigmas.
Methods: People assigned the male sex at birth and reporting anal sex living with HIV were enrolled into a 24-month longitudinal cohort in Senegal and engaged in an integrated stigma mitigation intervention. Socio-behavioral questionnaires and biological HIV monitoring were administered approximately every 3 months. Longitudinal analyses were conducted using multivariable logistic regression for repeated measures with a focus on characterizing differences in stigma patterns among different populations.
Results: In total 191 participants were followed including 121 cis-MSM participants and 51 transgender women. At baseline, 40.3%(73/181) of participants were living with HIV. Fear of seeking health services reduced over 24 months of follow up($p< 0.001$). Participants living with HIV at baseline had a 3.4(95%CI: 1.6,7.2) increased odds of fear to seek health care services compared to those who tested negative for HIV at baseline. Avoidance of seeking health services reduced over 24 months ($p< 0.001$) and was associated with HIV status (adjusted odds ratio[aOR]3.2

95%CI:1.2,5.8). Transgender women had an increased odds of avoiding seeking services(aOR:2.7;95%CI:1.4,7.3) as compared to cis-MSM. Feeling mistreated in the health center reduced over 24 months(p=0.086), and HIV status was associated with feeling mistreated over follow up(aOR:6.7;95%CI:1.6,27.5).

Conclusions: Overall, there were significant decreases in stigma observed but clear differences in stigma patterns with HIV status and gender identity among participants in Senegal. While intersectionality of stigma as determinants of HIV have been understudied in much of Sub-Saharan Africa, these data highlight the need to consider specific strategies to address multiple intersecting forms of stigma as a means of improving HIV-related outcomes among cis-MSM and transgender women Senegal.

Reducing the negative impact of empty ARV bottles on environement by recycling them into Artifacts as communication tools, income generating household products and souvenirs for future generations

B. Kemigisa[1,2], R. Kikonyogo[3]
[1]Pill Power Uganda, Wakiso, Uganda, [2]Infectious Diseases Institute, Clinic, Kampala, Uganda, [3]Pill Power Uganda / Infectious Diseases Institute (IDI), Training / Prevention Care and treatment, Kampala, Uganda

Background: My daughter and I have been on ART since 2009. i would dump all our empty bottles in the toilet or use them to light our chacoal stove. In Uganda, this is the only stigma free disposal means for many adolecents and young adults living with HIV as the bottles are usually dumped in the late hours when no one is watching.

For the clients that dont usually carry their medicine in the bottles, the hospital is tasked to dispose the bottles off which has also been very expensive and not safe for the environment especially the fumes from the incinerators.

Methods: Through Pill Power Uganda, a partnership with different treatment and care centers was created to mobile adolescents and young adults struggling financially and with adherence challenges to create pill power units.

Pill Power Units are peer support groups of ten adolescents and young adults trained for five days in recycling empty ARV bottles to enable them deal with their stigma and are inspired to tell their HIV stories in their communities.

The centers sponsor the five days training and ensures that all clients return their empty ARV bottles so that they are available. Through outreaches and different display opportunities, together, we market the products made by these adolescents thus each one of them getting monthly allowances which improves their positive living.

Results: Three units were created thus 19 adolencents and 11 young people living with HIV are financially stable and adhering to their treatment well.

More than eight treatment and care centers have started telling their clients to return their empty ARV bottles and are mobilizing some reouces to facilitate the trainings.

There has been an increase in the general public to go for HIV testing and condom demand after getting tose and feel the reality of living with HIV with the number of bottles these adolescents display in their crafts especially when swallowed by one person.

Conclusions: Recycling empty ARV bottles has not only supported the key persons living with HIV but has prooved to be an all round approach and tool in the fight against HIV and AIDS.

THPED533

Police knowledge, attitudes and practices on key populations, HIV and health in South Africa

M. Katumba[1], A. Scheibe[2,3], B. Ndlovu[4], O. Tlhoaele[4], B. Langen[1], L. Artz[5], A. Müller[5]
[1]COC Netherlands, International Programmes, Amsterdam, Netherlands, [2]Independent Consultant, Cape Town, South Africa, [3]University of Cape Town, Desmond Tutu HIV Centre, Cape Town, South Africa, [4]South African Police Services, Employee Health & Wellness, Quality of Life, Pretoria, South Africa, [5]University of Cape Town, Gender, Health and Justice Research Unit, Division of Forensic Medicine, Cape Town, South Africa

Background: Key populations are vulnerable to HIV and poor health outcomes due to stigma, discrimination and rights violations. The South African constitution supports the right to health, diversity of sexual orientation and gender identity, but sex work and drug use are illegal. Worryingly, police actions that increase the risk of HIV infection (e.g. condoms confiscation and injecting equipment) and poor outcomes (e.g. antiretroviral therapy restricted access while in custody) among key populations have been reported in South Africa. We conducted a rapid qualitative assessment of police knowledge, attitudes and practices towards lesbian, gay, bisexual and transgender (LGBT) people, sex workers (SWs) and people who use drugs (PWUD) in three South African cities.

Methods: During September - October 2016, six commissioned police officers were interviewed and 32 non-commissioned police officers participated in four focus group discussions in Pretoria, Cape Town and Durban to understand police knowledge, attitudes and practices towards key populations concerning policing, rights and HIV. Police coordinated recruitment. An external researcher facilitated the sessions, audio-recorded, transcribed and analysed them using direct content analysis.

Results: Many police acknowledged limited understanding of sexual orientation and gender identity. Stigmatising attitudes towards LGBT people were hinted at, but discriminatory practices denied. Discussions revealed discordant understandings of the legislative framework around sex work. Police frequently linked SWs to crime. Police reported that arrests were made to reduce crime and several officers showed stigmatising attitudes towards SWs. No participants were aware of rights violations affecting SWs in their workplace. One officer reported distributing condoms to SWs. Knowledge of drug-related harms and treatment services were limited, but increasing drug use prevalence acknowledged. Excessive use of force when managing PWUD was reported. Public pressure and numeric policing performance measures were reported to influence the arrest of SWs and PWUD.

Conclusions: Police knowledge, attitudes and practices around key populations in South Africa is diverse. Efforts to build police knowledge around key populations' health and the benefits of non-stigmatising policing are needed. Mechanisms to monitor and address the unnecessary use of force and discriminatory practices by police towards key populations in South Africa are required for an effective HIV response.

THPED534

Unexpected benefits of a targeted web series on hiv and sexual health for "hidden" MSM populations in singapore

A. Tan[1], D. Le[1], R. Chan[2], S. Banerjee[3]
[1]Action for AIDS Singapore, Advocacy & Partnerships, Singapore, Singapore, [2]Action for AIDS Singapore, President, Singapore, Singapore, [3]Action for AIDS Singapore, General Manager, Singapore, Singapore

Background: Sexual health and HIV education programmes targeting MSM need to reach out to "hidden" subsets viz. youth, minority races and recreational drug users ("chem-sex"). These populations often test infrequently whilst continuing to have high-risk practices. There was an urgent need to address this issue in a manner that is effective yet respectful of prevailing socio-political sensitivities. We selected our platforms, mediums and themes carefully in order to meet our objectives.

Description: PLU (People Like Us) was conceived as a 6-episode web series, each episode lasting 5 minutes. Written to contain vital safer-sex information and skill-sets, presented in scenarios relevant and relatable to our targeted demographic. A pilot survey was conducted on 100

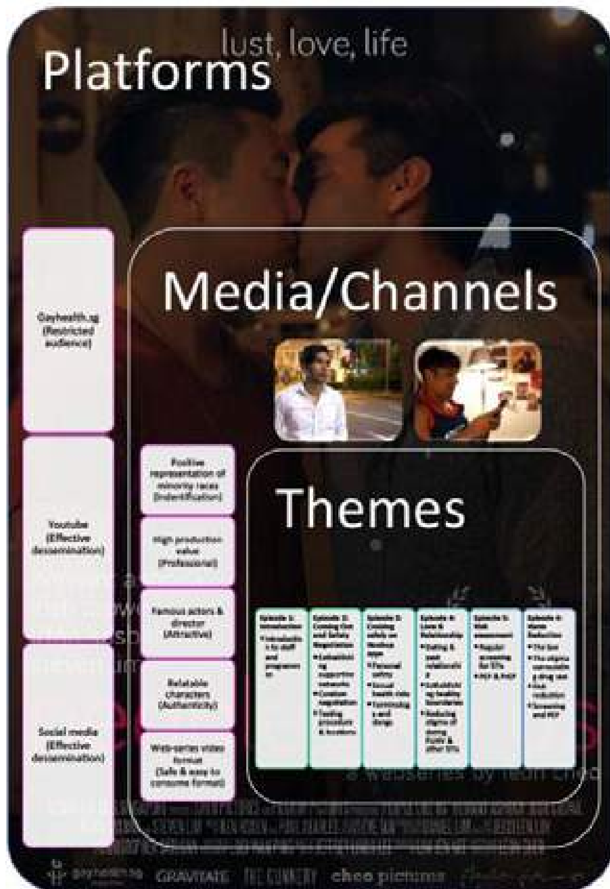
members of the MSM community to ensure that the scenes, topics and characters were recognisable and relatable, and that the platform, medium and themes were acceptable. Important sexual health messages were sent in a visually-attractive package, that would also circumvent traditional media channels and conservative media law in Singapore. Great care was taken to ensure authenticity of representation in terms of age, race, language, and socio-economic backgrounds of the actors, and also the appropriateness of venues and locations.

Lessons learned: Statistically PLU was an unqualified success in many ways:

- Singapore's first web series targeting gay and other MSM
- Nominated for 7 film festivals, winner of 3 awards
- Viewed approximately 400,000 times
- At only $0.13 per reach, it was a fraction of the cost of our previous online ($5/reach) and offline ($14/reach) campaigns.

More interestingly, we were able to determine that 30% of views came through pornographic sites that had unexpectedly tagged our web series. This taught us that greater thought and care during planning and design in ensuring relevance pays off in spades in terms of take up rates.

Conclusions/Next steps: Planning for Season 2 has started, where we would like to explore some of the themes more deeply, as well as some of the more novel channels for dissemination such as hook-up apps. Measuring information retention via surveys will allows us to fully measure the success of this programme.



[Carefully selected platform and themes]

Anticipated HIV stigma and HIV testing among Chinese men who have sex with men: A longitudinal cohort analysis

C. Liu[1], Y. Zhang[2], S. Pan[3], J. Ong[2,4], H. Fu[5], H. Lu[6], W. Huang[2], C. Wei[7], J. Tucker[2,6], W. Tang[2,6]

[1]University of California, San Diego, Department of Sociology, La Jolla, United States, [2]University of North Carolina Project-China, Guangzhou, China, [3]Xi'an Jiaotong-Liverpool University, Suzhzou, China, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Eastern Virginia Medical University, Norfolk, United States, [6]University of North Carolina at Chapel Hill, Chapel Hill, United States, [7]Rutgers School of Public Health, Piscataway, United States

Background: Anticipated HIV stigma is associated with multiple negative health outcomes among men who have sex with men (MSM). Previous studies have not observed factors associated with changes in anticipated HIV stigma over time. This study examines the association between reductions in anticipated HIV stigma and behaviors with a focus on HIV testing.

Methods: In July 2016, MSM ≥16 years old who self-reported as HIV-negative or with unknown status were recruited into a prospective online cohort in China. Data on sociodemographic, sexual behaviors, HIV testing (facility-based testing and self-testing), level of engagement in community events, and anticipated HIV stigma (a 7-item Likert-scale ranging from one (low) to four (high)) were collected every three months for one year. Reduction in anticipated stigma was a dichotomous measure (yes/no) calculated by comparing the mean score from the 7 stigma items at the last follow-up to the baseline score. To examine the relationship between behaviors and reduced stigma, we conducted a series of bivariate and multivariable logistic regressions, controlling for age, education, income, marital status and baseline anticipated stigma score.

Results: Among 879 MSM completing all follow-ups, the mean age was 25.3±6.5. Most participants completed high school (65.3%, 574), were never married (87.6%, 770), and had an annual income less than 9200 USD (76.2%, 670). 51.6% (454) men had decreased anticipated stigma scores over the year. 66.7% (586) of participants have been tested for HIV, with approximately half receiving a facility-based test (45.4%, 399) and half receiving a self-test (52.8%, 464). Reductions in anticipated stigma were associated with having more than one HIV test in the past year (Adjusted odds ration [AOR]=1.60, 95% Confidence Interval (CI): 1.16-2.20), having taken HIV self-tested (AOR=1.45, CI: 1.06-1.97) or HIV test at a facility (AOR=1.47, CI: 1.05-2.05) in the past three months, and with increased engagement in community events in the past year (AOR=1.28, CI: 1.02-1.61).

Conclusions: Our result suggests that HIV testing, particularly regular HIV testing, could decrease anticipated HIV stigma among MSM. Encouraging LGBTQ community engagement activities would also be an effective method to lower the anticipated HIV stigma.

THPED536

Stigma-reduction m-health programming and measurement: Evaluation study of most-at risk and most-in need populations in urban India

T. Khanna, L. Upal, R. Patel
MAMTA-Health Institute for Mother and Child, Delhi, India

Background: Adolescent and young key populations (A/YKPs) are disproportionally affected by HIV and have been largely excluded from national HIV response in India. Internalized stigma remains pervasive for adolescents and young MSM and TGs, impeding utilization of HIV testing and other health services. While many stigma interventions have been carried out worldwide, few have reached to the most unreached A/YKPs. An intervention study was undertaken to assess impact of integrated intervention (m-health app and telephonic counseling) in reducing self-stigma among A/YKPs in urban India.

Methods: A mix method pre-post study design was undertaken at baseline and endline at 12 month. A cohort of 117 was retained at end line out of 167 participants (15-24 years) in urban Delhi. Self-stigma was measured using validated stigma scale in Indian settings. The Cronbach's alpha showed good internal consistency (= 0.71). Further stigma scale was placed in three categories (using likert scoring) into low, medium and high. Bi-variate analysis was conducted using Chi-square test. Qualitative data was analysed using deductive content analysis approach.

Results: Majority of adolescent MSM and TGs reported high and moderate levels of self-stigma (74%) than their younger counterparts (58%) at baseline ($p < 0.001$). Study results showed intervention was successful in gradual decline of self-stigma more among adolescent than young key populations from high stigma to moderate ($p < 0.001$). Similarly, decline in internalize stigma was found more among MSM than TGs ($p < 0.01$). Overall, reduced self-stigma was significantly associated with telephone counseling and information through m-health app. More than 60 % of MSM and TGs who reported low stigma undertook telephonic counseling session ($p < 0.001$).

Conclusions: This technological intervention along with telephonic counseling has potential to be scaled up as a way of providing confidential and acceptable services to most at risk and most in need populations. Study demonstrated that combined use of m-health app along with telephone counselling was powerful in reducing self-stigma more among adolescent than young MSM/TGs. Therefore, reaching early adolescence provides window of opportunity for faster reductions in stigma since it is internalized, reinforced and sustained early. Also, stigma reduction for TGs requires more sustained and concentrated effort and action.

Harm reduction

THPED537

Low demand for harm reduction services and assistance for young people who use drugs in Makeyevka, Ukraine

H. Danylevych
NGO, Donetsk, Ukraine

Background: The level of involvement of young people who use drugs (PWUD) in the Harm Reduction Project (HRP), conducted in Makeyevka, in 2017, was significantly low (only 8%) in comparison with total number of HRP clients. NGO "Amicus Union" conducted a qualitative study to determine the reasons why young PWUD do not use services of HRP.

Description: The study was conducted from September to October, 2017. Study population was divided into two groups of HRP clients, according their age: 1) young PWUD (18-25 Y/O), 2) older PWUD (26-55 Y/O). In total 120 clients were interviewed based on a standard questionnaire: 21 persons of age 18-25 and 99 of age 26-55.

Lessons learned: The following reasons of why young PWUD do not use HRP services were determined:

- The services provided in the HRP do not meet their needs

Older PWUD mostly inject opiates and stimulants, while the young PWUD use synthetic drugs. HRP doesn't provide any specific services for the synthetic drug users and that's why young PWUD do not see the intent to use HRP services.

- Lack of knowledge/no knowledge about existing HRP services

The group of young PWUD is very closed and hard to reach for the outreach workers. The lack of trust creates a barrier to reach young people and involve them into HRP services.

- Counseling and advices from older PWUD are considered as unwanted and usually ignored

Young and older PWUD generations avoid contact with one another because of the different drug consumption habits. Indeed, contact is needed, because older PWUD have more experience and knowledge about drug use, overdoses, HIV and other STDs.

Conclusions/Next steps: Harm reduction services to young PWUD in Makeyevka are ineffective. To make it attractive and beneficial, the following steps should be taken:
- to provide harm reduction services, which meet young PWUD needs;
- to reach young PWUD online (Facebook, Telegram);
- to empower young PWUD, who are already in HRP services to become peer-to-peer educators and reach more young PWUD.

THPED538

Post-discharge peer telephone support program to help complex clients transition from hospital to community

A.D. Eaton[1,2], S.C. Carusone[3,4], S.L. Craig[2], E. Telegdi[3], G.F. Ginocchio[1], G.A. Wells[1,2], M. Montess[1], J.W. McCullagh[1], D. McClure[1], W. Wilson[1], K. Berney[1], A. Busch[1], N. Boyce[5], A. Stewart[6], C. Strike[7]
[1]ACT - AIDS Committee of Toronto, Support Services, Toronto, Canada, [2]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [3]Casey House, Toronto, Canada, [4]McMaster University, Department of Health Research Methods, Evidence, and Impact, Hamilton, Canada, [5]Ontario HIV and Substance Use Training Program, Toronto, Canada, [6]St. Michael's Hospital, Toronto, Canada, [7]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada

Background: Through collaboration between a community-based organization and an HIV hospital, we designed and piloted a peer telephone support program for complex clients being discharged from hospital. Peer interventions may be a desirable and cost-effective means to support continuity of care in complex clients, such as those who are actively using substances. The objective of the program was to ease the transition from hospital to community for people living with HIV who use drugs.

Description: The pilot was implemented from early-2017 to early-2018 in an urban Canadian city. People living with HIV, in hospital, actively using substances, and struggling with antiretroviral medication adherence were invited to participate. Participants set discharge goals with a nurse concerning antiretroviral medication adherence, substance use, and a self-identified goal (e.g., housing, social connectedness). These discharge goals were then shared with a 'peer volunteer' (also living with HIV and lived experience of substance use). The participant and volunteer met once pre-discharge, then connected by phone for six weeks post-discharge. Five peer volunteers aged 28-60 (four gay Caucasian men and one heterosexual Caribbean woman) were trained and each completed 2-3 matches, a phone log for each call, and attended individual supervision per match. Two group supervisions were also held, to share successes, challenges, and strategies for peer support.

Lessons learned: Participants and volunteers agreed that shared identities engendered rapport. Volunteers maintained a scope of practice, keeping a realistic sense of their role and referring to other services as needed. Clients who appeared to be self-motivated (i.e., initiated contact) participated more actively in the program than more passive participants. Volunteers identified that discussing shared social interests alongside HIV and substance use concerns led to greater engagement, as would a collateral contact to follow-up with if the participant was non-respondent.

Conclusions/Next steps: This pilot peer support program has established a strong working relationship between a hospital and a community-based agency, to continue collaborating for care transition via peer

support. This presentation will discuss the program's approach to training and supervision while highlighting the experiences of participants and volunteers, for other clinical and community-based agencies to consider adaptation of this partnered peer support program.

THPED539

Dispelling the myths and fallacies fuelling deadly drug policies in Southeast Asia

G. Lai
International Drug Policy Consortium, Bangkok Office, Bangkok, Thailand

Background: Southeast Asian countries have amongst the highest rates of HIV prevalence amongst people who inject drugs in the Asia-Pacific, fuelled by the fact that they are also home to the most punitive drug policies in the world, which plunged to extreme depths with the widespread killing of people suspected of drug use and supply in the Philippines. A significant factor driving such policies, which block or hamper HIV prevention treatment and care interventions for people who use drugs, is lack of evidence-based understanding about drug use and harm reduction. The International Drug Policy Consortium (IDPC) introduced a training programme in 2017 to address this gap with a primary objective of supporting the implementation of harm reduction approaches and rights protection for people who use drugs.
Methods: IDPC developed a training module to provide evidence-based education about drugs and drug use to dispel myths and fallacies about the 'evil' nature of drugs, eg. people who use drugs suffer irreversible brain damage and commit violent crimes. The module was delivered at a workshop in Malaysia by members of the Asian Network of People who Use Drugs (ANPUD), for participants from civil society, health services, and legal services sectors in Southeast Asia. Other modules from the IDPC training toolkit, on harm reduction and decriminalisation of drug use, were delivered by both ANPUD and a lawyer from the Philippines.
Results: Evaluation feedback from the workshop reflected the importance of learning from trainers who are themselves people who use drugs and experienced in the provision of harm reduction and drug treatment services. In contexts where lawyers are able to defend the rights of people who use drugs, their willingness to assist is not assured therefore requires additional advocacy.
Conclusions: High levels of stigma and discrimination against people who use drugs requires both evidence-based education about drugs targeting policymakers, practitioners and those who are able to ensure the promotion and protection of those rights, as well as ongoing advocacy for an enabling policy and legal environment for the HIV prevention, treatment and care of people who use drugs.

Traditional and complementary health care approaches

THPED540

The association between medical pluralism and treatment adherence among patients initiated on antiretroviral treatment in rural South Africa: A prospective cohort study

M. Moshabela[1,2], E. Slaymaker[3], N. McGrath[2,4,5]
[1]University of KwaZulu-Natal, Department of Rural Health, Durban, South Africa, [2]Africa Health Research Institute, Kwa-Zulu Natal, South Africa, [3]London School of Hygiene and Tropical Medicine, Population Health, London, United Kingdom, [4]University of Southampton, Social Statistics and Demography, Southampton, United Kingdom, [5]University College London, Research Department of Epidemiology and Public Health, London, South Africa

Background: Medical pluralism, the use of multiple sources of healthcare, is common in contexts with high HIV prevalence, including sub-Saharan Africa. With expanding access to ART and the advent of universal 'test and treat' policies, there is urgent need to establish the effect of medical pluralism on intermediate healthcare outcomes among users of ART, particularly ART adherence. To date, robust study designs have not been used.
Methods: Secondary analysis was carried out using data from a prospective cohort study conducted in rural South Africa, (2009-2012), with participants enrolled at ART initiation and followed up six-monthly through 36 months. Medical pluralism and ART adherence were measured at each follow-up visit through time-varying self-reports of healthcare-seeking behavior and ART adherence, respectively. Survival-time analysis was conducted, with Kaplan-Meier and smoothed hazards plots. Maentel-Haenszel and Cox proportional hazards were used to estimate crude and adjusted effects.
Results: A total of 362 participants (64.6% female) were included, and 1237 observations contributed 7276 person-years of follow up and 144 adherence failure events, 41 with pluralism. The crude adherence failure rates among those exposed and unexposed to medical pluralism were 35.6/1000 person-years and 16.8/1000 person-years, respectively. In multivariate analysis, medical pluralism was associated with increased hazard of adherence failure than non-pluralism (Adjusted Hazard Ratio (aHR) 1.60, 95%CI 1.10 - 2.32, p=0.013). Partial compared to complete knowledge of ART, aHR 2.04, 95%CI (1.45-2.89, p< 0.001), and presence compared to absence of ART-related side effects (aHR 2.35, 95%CI 1.63 - 3.39, p< 0.001) more than doubled the hazards of adherence failure.
Conclusions: In this analysis of time from ART initiation to first adherence failure, there was a significant association observed between medical pluralism and adherence failure, after controlling for covariates. This study suggests that medical pluralism is a risk factor for adherence failure, and should be systematically measured in future studies of ART adherence, both observational and experimental. Fear of drug-drug interactions and the lack of systems coordination between ART and non-ART providers may be responsible for these effects. The success of ART utilisation in HIV prevention and 'test and treat' programs will continue to depend of high levels of adherence.

Patterns of religious coping and anxiety among persons living with HIV/AIDS in Cape Coast, Ghana

F. Yirdong[1], F. Ocansey[2], A. Nkyi[2]
[1]University of Cape Coast, Department of Psychological Medicine and Mental Health, Cape Coast, Ghana, [2]University of Cape Coast, Department of Guidance and Counseling, Cape Coast, Ghana

Background: Sub-Saharan Africa has the highest prevalence of HIV/AIDS globally and mounting evidence shows that Persons Living with HIV/AIDS (PLWHIV) experience significant levels of anxiety which impairs their quality of life. Religious coping has been identified as the widely used resource to cope with psychological distress associated with HIV/AIDS. However, there is sparse literature on the use of religious coping and anxiety among PLWHIV in Ghana. This study examined the patterns of religious coping and its relationship to anxiety in PLWHIV in Cape Coast, Ghana.
Methods: A cross-sectional study conveniently sampled 138 PLWHIV seeking health care at the Cape Coast Teaching Hospital during a period of three months. The Brief RCOPE was used to measure the patterns of religious coping, whiles the anxiety questions on the Hospital Anxiety and Depression Scale (HADS-A) were used to screen for anxiety. Descriptive statistics were used to analyze all categorical data. Person Product-Moment Correlation coefficient was used examine the relationship between the patterns of religious coping and anxiety.
Results: Seventy-nine percent (109) of the respondents were female, males were 29 (21%), the mean (SD) age was 44.12 (11.30) years, the mean (SD) years since HIV diagnosis was 4.15 (3.36) years, 39.9 percent were married, and 45.7 percent identified themselves as Pentecostal/Charismatic Christians.
One hundred and twenty-five (90.6%) use positive religious coping, 84 (60.9%) experienced normal levels of anxiety and 28 (20.3%) PLWHIV reported abnormal levels of anxiety. A moderate positive relationship
(r = .330, n = 138, p< .0005) was found between negative religious coping and anxiety.

Conclusions: The results suggest that HIV/AIDS related anxiety is generally low among PLWHIV but high among those without formal education. Predominant use of negative religious coping is associated with high levels of anxiety. This suggest that assessment of religious coping and anxiety should be integrated into the treatment plan of PLWHIV to enhance their overall quality of care. Psychotherapy for symptoms of anxiety and negative religious coping should be adopted for PLWHIV. Consistent HIV/AIDS education should be given to PLWHIV with no or less formal education. Additional findings, implications for clinical practice and further studies are discussed.

THPED542

Prevalence of traditional medicine use by pregnant HIV positive women in an urban setting in Zimbabwe: A cross sectional study

T. Mawoza
University of Zimbabwe, Harare, Zimbabwe

Background: Due to increased cultural beliefs, many HIV-positive pregnant women continue to use antiretroviral medicines whilst using traditional medicines (TM) during pregnancy. This might interfere with antiretroviral drugs used for prevention of mother-to-child transmission. Information regarding types of traditional medicines being used by HIV-positive pregnant women and the extent of use in Zimbabwe has not been documented. This study was thus aimed at determining the prevalence of TM use by HIV-positive pregnant women.

Methods: A cross sectional study was conducted using an interviewer administered questionnaire on 280 conveniently sampled, HIV-positive pregnant women who visited City of Harare clinics in Zimbabwe from October 2017-January 2018. They were English or Shona speakers in their second or third trimester, and between the ages of 18-49 years. Collected data was coded and captured using REDCap and Stata was used to analyse the data. Ethical approval was obtained from the University of Zimbabwe.

Results: Of the 280 women interviewed, 272 (97.2%) were using Tenolam-E (tenofovir, lamuvidine and efavirenz), while 8 (2.8%) used a combination of azatanavir and ritonavir. 210 (75%) women had been diagnosed as being HIV-positive in 2017 during antenatal care booking. 138 (49.3%) women however, admitted to using traditional medicines during pregnancy and at delivery, whilst 142 (50.7%) did not. The 21-30 age group had the highest number of users (n=56, p=0.03), while only 6 (4.5%) were between 41-49 years. Women used traditional medicines in the third trimester mainly to facilitate child birth (n=94, p=0.04), treat/prevent HIV-related illnesses (n=24, 17.4%), protect the baby (n=9, 6.5%), prevent vaginal tears (n=6, 4.3%), and speed up labour (n=5, 3.6%), to mention a few. The medicines used included *Bidens pilosa*, elephant dung, soil from a burrowing mole, holy water, and *Fadogia ancylantha*. All the women however, did not inform their healthcare workers that they were using traditional medicines.

Conclusions: This study showed that the prevalence of traditional medicine use by HIV-positive pregnant women is 49.3%, which is high. Concomitant medicine use could facilitate failure of PMTCT programs due to drug interactions. Determination of the exact effects that these medicines have on ARV drug levels is however still on-going.

Access to appropriate healthcare services, including for co-infections and co-morbidities

Exploring the drivers of user costs as a barrier to accessing HIV testing from Rural Malawi

L. Sande[1], H. Maheswaran[2], C. Mangenah[3], L. Mwenge[4], P. Mkandawire[5], P. Indravudh[1], N. Ahmed[6], M. D'elbee[6], C. Johnson[7], K. Hatzold[8], E. Corbett[1,9], M. Neuman[10], F. Terris-Prestholt[6]
[1]Malawi-Liverpool-Wellcome Trust, HIV/AIDS Group, Blantyre, Malawi, [2]University of Liverpool, Institute of Psychology, Health and Society, Liverpool, United Kingdom, [3]Centre for Sexual Health and HIV AIDS Research (CeSHHAR), Harare, Zimbabwe, [4]Zambart, Lusaka, Zambia, [5]Population Services International, Lilongwe, Malawi, [6]London School of Hygiene & Tropical Medicine, Faculty of Public Health & Policy, London, United Kingdom, [7]World Health Organisation, Department of HIV/AIDS, Geneva, Switzerland, [8]Population Services International, Harare, Zimbabwe, [9]London School of Hygiene & Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom, [10]London School of Hygiene & Tropical Medicine, Faculty of Epidemiology and Population Health, London, United Kingdom

Background: HIV testing is free in Malawi. However, HIV testers incur high direct non-medical and indirect costs likely to deter or delay access to testing. We examined drivers of user costs and explored potential solutions to increase testing uptake in rural Malawi.

Methods: We estimated a multivariable fixed effect Tobit regression model with a log-transformed dependent variable on baseline household survey data (n=749) collected in 2016. The data were for a cluster randomised controlled trial investigating the impact of HIV self-testing in four high HIV prevalence districts.

Results: On average, the mean cost was US$2.45 (95%CI US$2.11-US$2.70). Both supply-side (test location and efficiency of testing delivery) and individual-level (gender, age, wealth and education) factors affected user costs incurred for HIV testing (Table 1).
Older adults, men, and those with higher levels of education incurred significantly higher costs than youth, women, and less educated participants. Wealth quintile, however, had no consistent trend on expenditure. Participants who used community-based testing incurred 34% lower costs than those who used facility-based testing, especially when the visit was specifically for the purpose of HIV testing. For each additional hour spent travelling or waiting to be tested, participants' average costs increased by 4%.

Determinants		Coefficient	95% CI

*** p<0.01, ** p<0.05, * p<0.1

[Table 1: Tobit Regression: Dependent variable: ln(user costs) in 2016 US dollars]

.

Conclusions: This study identified a number of modifiable supply side factors: notably, long travel and waiting times contribute to high opportunity costs. Further decentralisation of the primary care network, providing testing within communities, and increasing patient throughput at HIV testing facilities by increasing investment in rooms and staff each have potential to increase uptake of testing services,. More flexible test-

ing options, such as community and facility based HIV self-testing, may further reduce the opportunity cost of seeking testing and has potential for expanding testing access, especially for men.

THPED544

Barriers to healthcare and prevention among MSM in the Middle East and North Africa

E. Ballan
M-Coalition, Beirut, Lebanon

Background: HIV new infections in the MENA region are still on the rise, and though prevalence is relatively low (0.1%) the prevalence among MSM is quite high (3-10%). With restrictive and criminalization laws bounding MSM and TG lifestyles, and a conservative society, HIV prevention, testing and condom use are still challenged. Stigma and discrimination make it harder to access health services.
Methods: An online survey of 40 minutes was carried out in 6 MENA countries to 128 MSM, to inquire about health behaviors, discrimination and access to prevention and medical services.
Results: The age range of the sample was 16 - 43, most of which have a higher education which would imply have access to HIV prevention tools, knowledge or are capable of affording medical care. 78% of participants have received discrimination from a health care provider and a not surprising 72% do not discuss their behaviors or sexuality with their physician. 40% of MSM do not seek health services as they trust are not private. Of the sample study 12% are living with HIV. Barriers to testing include not realizing the importance of the test, fear of stigma simply for asking for the test or for being outed as MSM. More than one third of the study sample has ever contracted an STI, 40% of whom did not seek medical care, which gives way to advanced infections and more transmission. 75% of the study group have ever been engaged in condomless sex and mostly did not have condoms available or the partner did not like to use condoms, which insinuates poor condom negotiation skills.
Conclusions: As a concentrated epidemic among MSM, the numbers only suggest the situation will worsen. HIV prevention programs should specifically target MSM and focus on their needs. Health care providers are to be oriented on the negative effects of discrimination. MSM programming around condom use and HIV testing and condom negotiation are vital to better control new infections and teach individuals the responsibility of their health and their community health, in other words to bridge the gap between the populations and healthcare and service providers.

THPED545

Transport challenges can hinder access to HIV care and treatment services in fishing communities around Lake Victoria in Uganda: A qualitative study

C. Tumwine[1], S. Bell[2], P. Aggleton[1]
[1]*UNSW Sydney, Centre for Social Research in Health, Sydney, Australia,* [2]*UNSW Sydney, Kirby Institute, Sydney, Australia*

Background: Fisherfolk have been identified as a key population in the Ugandan response to HIV but face challenges in accessing HIV care and treatment.
Methods: To examine the influence of transport-related challenges on access to HIV care and treatment in fishing communities, semi-structured in-depth interviews were conducted with 42 HIV positive fisherfolk and 15 health care providers from two HIV clinics (one on Bugala island in Lake Victoria and another on the lakeshore at Entebbe), in Uganda.
Results: Study findings suggest that many HIV positive fisherfolk often face significant transport challenges that hinder their full involvement in HIV care and treatment. In some instances, fisherfolk had to cover long distances across the lake to attend treatment centres, and many islands on the lake were reported as not having public transport boats connecting them to other islands and the mainland where some of the HIV clinics are located. In addition, travel across the lake was reported to sometimes get hampered by high transport fares and seasonal rough weather characterised by strong winds, waves and heavy rains which force HIV positive fisherfolk and sometimes health workers to cancel planned journeys to treatment centres. These challenges are exacerbated by a general lack of sea worthy vessels. Coping strategies reported to overcome challenges such as seasonal rough weather include some HIV positive fisherfolk relocating out of fishing communities for periods of time when the weather is bad, while others reported relying on God for protection when travelling between their homes and HIV clinics during such periods. And in order to overcome the problem of high transport fares, some fisherfolk reported jointly hiring boats to travel together in groups to HIV treatment centres.
Conclusions: Transport challenges are a major hindrance to fisherfolk's access to and use of HIV treatment and care. But some of the coping strategies and responses that are currently being adopted by HIV positive fisherfolk to deal with the transport challenges they encounter can be reinforced - with external support - to facilitate fisherfolk's engagement in HIV care and treatment.

THPED546

HIV care is fine, but what if I get the flu?

I.A. Fortin Morales[1], J. Wheeler[2], S. Lungo[3]
[1]*Population Services International / PASMO, Evidence, Guatemala, Guatemala,* [2]*Population Services International, Evidence, Washington D.C, United States,* [3]*Population Services International / PASMO, Programs, Guatemala, Guatemala*

Background: In Guatemala, a concentrated epidemic within a highly stigmatizing social context creates an environment fraught with challenges for reaching, testing, and linking vulnerable men who have sex with men (MSM) and transgender women (TW) with HIV testing and care. As part of USAID's Combination Prevention Program in Guatemala, the Pan American Social Marketing Organization commissioned an ethnographic study in 2016-2017 to understand the sexuality, identity construction, health care seeking behaviors, and MSM/TW-health provider relationships to design consumer-focused strategies to facilitate access to HIV services.
Methods: This ethnography was conducted in the two Guatemalan *Departments* with the highest HIV prevalence (Guatemala and Escuintla) among a sample of 24 MSM and 26 TW. The study included in-depth interviews that integrated complementary data collection instruments. Results were validated in a focus group with the target population.
Results: While there are criticisms of public health services and some organizations, the quality of HIV services available is generally considered satisfactory more so for MSM than TW, mostly because the last suffer from higher stigma and discrimination in the public sector. Organizations are friendlier because they were created to serve these populations. HIV services are considered available and accessible at least in the urban areas, but they are seen as highly specialized to HIV. In contrast, MSM/TW lack a place to go where they can receive appropriate, integrated and gender-friendly health care services, for general and daily health issues such as the "flu". This leaves them with little alternatives that results in a lack of service provided or self-medication. Additionally, participants emphasized the need for including mental health as part of the HIV services for a more holistic and human approach.
Conclusions: The MSM/TW populations recognized many advances in the provision of gender-friendly HIV services, but these are not reflected in the provision of integrated health care. Vulnerable populations are reliant on the specialized HIV services provided by NGOs or HIV clinics, but have no appropriate options for primary care and mental health, and so there is need for synergy and appropriateness of healthcare services for MSM/TW.

Factors associated with non-vaccination in people living with HIV (PLH) in Argentina

V. Zalazar, O. Sued, I. Aristegui, L. Cahn, D. Fiore, F. Cahn, P. Cahn, C. Vizzotti
Fundacion Huesped, Buenos Aires, Argentina

Background: Argentina health care system guarantees free access to vaccines for the general population, and particularly for people with inmuno-compromising conditions such as HIV infection. Despite prevalence of vaccination is high in this group, there are still PLH who do not receive the recommended vaccines. Thus, there is a need to identify factors that affect access to vaccination among PLH.

Methods: Data for the present study was drawn from an online survey conducted between December-2017 and January-2018, which examined sociodemographic, information received last year and attitudes towards vaccines. The survey included several vaccines, but for this study, we considered only those who self-reported receiving influenza and pneumococcal vaccines. Attitudes were examined through an ad-hoc designed 5-item Likert scale: "I prefer not to have all mandatory vaccine and choose to what diseases get vaccination for", "I'm concerned that vaccines are not safe or produce side effects", "vaccines are not effective", "vaccines are poison", "vaccines are a business". Using multivariable logistic regression, this study examined the prevalence of and factors associated with non-vaccination.

Results: A total of 1025 PLH completed the survey. Median age was 37 (IQR: 29-40), 71.2% were male. We found 17.9% (n=183) of influenza and pneumococcal non-vaccination. A bivariable logistic regression showed that factors associated with non-vaccination were: younger age (OR=0.96, 95% CI:0.94-0.97), being male (OR=0.59, 95% CI:0.39-0.87), being homosexual/bisexual (OR=0.68, 95% CI:0.48-0.97), living outside from Buenos Aires Metropolitan Area (OR=0.73, 95% CI:0.52-1.01), not receiving information about vaccines (OR=0.32, 95% CI:0.23-0.45) and having a negative attitude towards vaccines (OR=2.44, 95% CI:1.74-3.42). In multivariate analysis, older age and receiving information were associated with more probability of being vaccinated, and having a negative attitude remained highly associated to non-vaccination.

Variable	Adjusted Odds Ratio (AOR)	95% Confidence Interval (CI)	p - value
Age	0.966	(0.94- 0.98)	0.000
Gender			
(Female vs. Male)	0.718	(0.38- 1.32)	0.284
Sexual orientation			
(Homosexual/bisexual vs. Heterosexual)	0.780	(0.45 – 1.35)	0.378
Living in Buenos Aires Metropolitan area			
(yes vs. no)	0.827	(0.57 – 1.19)	0.314
Received information			
(yes vs. no)	0.336	(0.23 – 0.48)	0.000
Negative attitude			
(yes vs. no)	2.118	(1.47 – 3.04)	0.000

[Table 1. Multivariable logistic regression analysis of factors associated with non-vaccination]

Conclusions: Although we found a small percentage of unvaccinated PLH, is relevant to work with this population in order generate corrective actions. Approximately half of PLH had negative attitudes toward vaccination, which was identified as the most important factor associated to non-vaccination. Therefore, interventions that address knowledge and knock down myths about vaccination, particularly for young PLH, could be critical to increase vaccination rate.

THPED548

HPV self-sampling acceptability and preferences among HIV-infected women in Botswana

R. Kohler[1,2], T. Elliott[3], B. Monare[3], N. Moshashane[3], K. Ramontshonyana[3], P. Chatterjee[1], D. Ramogola-Masire[3], C. Morroni[3,4,5]
[1]Harvard TH Chan School of Public Health, Boston, United States, [2]Dana-Farber Cancer Institute, Boston, United States, [3]Botswana UPenn Partnership, Gaborone, Botswana, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]Botswana Harvard Aids Institute Partnership, Gaborone, Botswana

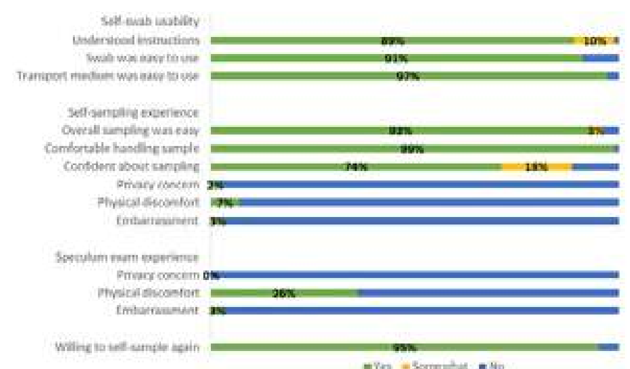
Background: HIV-positive women have increased risk of cervical cancer, however, screening coverage remains low in many high-burden countries like Botswana. Self-sampling has proven to effectively detect high-risk human papillomavirus (hrHPV) and increase screening participation in low-resource settings, especially among women who are hard to reach and or are reluctant to have a speculum exam. The objective of this study was to describe the acceptability, experiences, and preferences of HPV self-sampling among HIV-positive women.

Methods: We recruited HIV-positive women ≥25 years attending an infectious disease clinic in Gaborone, for an hrHPV self-sampling study. Women self-sampled with a flocked swab and had a speculum exam for a provider-collected cervical sample; samples were tested using Cepheid GeneXpert HPV. Descriptive statistics were conducted on interviewer-administered questionnaire responses. Open-ended questions were thematically categorized and compared across groups.

Results: We recruited 104 women, all of whom were on antiretroviral therapy. Most (94%) women had a history of visual inspection or pap screening, and 39 reported a previous negative experience with a speculum exam (Table 1). Over 90% agreed that self-sampling was easy, comfortable, and expressed confidence in doing it correctly (Figure 1).

	Speculum exam 84 (81%)	Self-sample 20 (19%)	Total N (%) 104 (100%)	p-value
Age, mean (sd)	45.2 (8.4)	44.8 (8.3)	45.1 (8.3)	0.43
Secondary or higher education (vs. none or primary)	51 (60.7)	17 (85.0)	67 (65.0)	0.04
Single, never married	60 (71.4)	14 (70.0)	74 (71.1)	0.89
Urban residence	43 (51.2)	16 (80.0)	59 (56.7)	0.02
Previous screening history	80 (95.2)	18 (90.0)	98 (94.2)	0.37
Previous negative screening experience (uncomfortable, painful, embarrassing)	29 (34.5)	10 (50.0)	39 (37.5)	0.20
No or little confidence about correctly self-sampling	10 (11.9)	0 (0)	10 (9.6)	0.14
Somewhat confident about correctly self-sampling	15 (17.9)	2 (10.0)	17 (16.3)	
Extremely confident about correctly self-sampling	59 (70.2)	18 (90.0)	77 (74.0)	

[Characteristics of HIV-positive women by preferred HPV screening method (n=104)]



[Vaginal self-sampling acceptability among HIV-positive women in Botswana (n=104)]

Although 12 women reported a problem handling the swab or transport medium, only three samples were inadequate. Nearly all women (95%) were willing to self-swab again; however, only 20 (19%) stated their preference for future screening was self-sampling over speculum exam. We

found no differences in willingness or preferences by screening history, but urban-residing women and those with higher education were more likely to prefer self-sampling. Self-sampling was preferred because it was more convenient, easier, less embarrassing and less painful. Speculum exams were preferred because of trust in providers' skills, being able to see where to swab, and women's low confidence to sample correctly.

Conclusions: Self-sampling for HPV is acceptable among HIV-positive women in Botswana. However, speculum exams were still preferred largely due to strong trust in providers' skills and women's low confidence for self-sampling correctly. Self-sampling may be an important alternative to provider screening, though education and support to self-sample will be critical to program success.

THPED549

Higher rates of vaccination among PLH compared to general population in Argentina

V. Zalazar, O. Sued, I. Aristegui, L. Cahn, D. Fiore, F. Cahn, P. Cahn, C. Vizzotti

Fundacion Huesped, Buenos Aires, Argentina

Background: Argentina guarantees all vaccines included in the National Immunization Schedule, which are mandatory at all stages of life for general population. In addition, there is a specific vaccine program focused in people living with HIV (PLH), who are among the groups more at risk of presenting complication or dying of preventable infectious agents. However, levels of vaccination in PLH and differences from rates in general population (GP) have still not been explored.

Methods: Data for the present study was drawn from an online survey, conducted between December 2017 and January 2018, which aim to investigate the prevalence of vaccination in PLH in Argentina. This study examined prevalence of dT, HVB, Influenza and Pneumococcal vaccination and compared them with the results of a national survey in GP conducted in 2013 (Tercera Encuesta Nacional de Factores de Riesgo para Enfermedades No Transmisibles).

Results: The final PLH sample included 1025 participants and the national GP survey comprised 32665. PLH receive vaccine information from their HIV provider in 89%, while in GP only 27.9% from a healthcare provider (70.5% referring had received information from the media). Rates of vaccination were uniformly higher among PLH for all the vaccines (dT 66.1 vs 50%, HBV 70.5% vs 21.7%, Influenza 75.1% vs 51.6% and pneumococcal 68.2% vs 16.2%). Differences remained the same in all gender, and educational level groups. Age differences were observed only among PLH, with higher rate of HBV vaccination among young PHL and influenza among older PLH.

Characteristics	dT %		HBV %		Influenza %		Pneumococcal %	
	HIV+	GP	HIV+	GP	HIV+	GP	HIV+	GP
Total *	66.1	49.8	70.5	21.7	75.1	51.6	68.2	16.2
Gender ª								
Man	65.1	49.5	67.9	18.5	72.0	48.5	57.2	14.0
Woman	66.6	50.1	77.1	24.8	81.3	53.8	72.6	18.4
Age group (years) ª

Secondary school and above	67.2	49.8	71.9	23.8	76.1	52.7	68.4	18.0

* HIV+=1025; GP=32665
ª Among participants with a valid response to this questions

[Table 1. Comparison of vaccination prevalence in general population and PLH in Argentina]*

Conclusions: PLH in Argentina show a high rate of vaccination, being higher than GP, particularly for HBV and pneumococcal vaccines. Infectious diseases specialist specialists are the main source of information. However, this data highlights the gap of information for GP and requires reconsidering the vaccination strategy for this population.

THPED550

Adversities, social support, resilience, and health-related quality of life among people living with HIV in Guangxi, China

Q. Zhao[1], X. Li[2], Y. Mao[2], S. Qiao[2], Y. Zhou[3]

[1]Nanjing University of Information Science and Technology, Nanjing, China, [2]University of South Carolina SmartState Center for Healthcare Quality, Columbia, United States, [3]Guangxi Center for Disease Control and Prevention, Nanning, China

Background: Adversities such as HIV-related stigma, comorbidity, and lower socioeconomic status (SES) can negatively impact health-related quality of life (HRQoL) among people living with HIV (PLHIV). Resilience is an individual's ability to cope or adapt in the face of adversities. Social support can reduce effects of adversities and enhance resilience. Given there is a general dearth of research on the mitigating role of resilience and social support between adversities and HRQoL among PLHIV in China, the aim of the study is to examine the associations between several adversities and HRQoL, and whether individual resilience and perceived social support can help mitigate the negative effects of adversities on HRQoL.

Methods: Cross-sectional data from 2,987 PLHIV in Guangxi, China were analyzed. Participants reported their perceived HRQoL, individual resilience, perceived social support, HIV-related stigma, comorbidity, SES, as well as background characteristics. Path analysis was performed in SAS 9.4 to identify the associations of interest.

Results: Considered together, HIV stigma (=-.18, p < 0.001), lower SES (=-0.19, p < .001), and comorbidity (=-.11, p < 0.001) were negatively associated with HRQoL, while resilience was positively associated with HRQoL (=.38, p < 0.001). Resilience buffered the negative effects of HIV stigma and lower SES on HRQoL given HIV stigma had an indirect effect on HRQoL through resilience (=-.09, p < 0.001), and lower SES had an indirect effect on HRQoL through resilience (=-.04, p < 0.001). Perceived social support was positively associated with resilience and had an indirect positive effect on HRQoL through resilience (=.13, p < 0.001). Perceived social support buffered the negative effects of stigma on resilience given stigma had an indirect effect on resilience through perceived social support (=-.04, p < 0.001).

Conclusions: Interventions to improve the HRQoL among PLHIV in Guangxi need to focus on reducing their HIV stigma, helping them find possible ways to improve their livelihoods and coping with comorbidity, enhancing perceived social support, as well as fostering their individual resilience.

THPED551

Factors associated with high STIs in Murehwa district, Mashonaland East province, Zimbabwe

W. Dube[1], T. Magure[2], E. Muzulu[3]

[1]National AIDS Council of Zimbabwe, Programs, Marondera, Zimbabwe, [2]National AIDS Council, Management, Harare, Zimbabwe, [3]National AIDS Council, Monitoring and Evaluation, Marondera, Zimbabwe

Background: Out of the nine districts in Mashonaland East province of Zimbabwe, where concerted prevenive efforts to decrease the number of new sexually transmitted infections have been in place for the past five years, one district, Murewa, continue to record high figures. Increase in STI infections is considered as a proxy for HIV infection.

The study sought to identify factors associated with acquisition of sexually transmitted diseases in the district and to measure knowledge, attitudes and perceptions of people accessing services at health centres in the district. The aim being to provide interventions to reduce STI infections.

Methods: The study used the unmatched case control study design, using both quantitative and qualitative approaches. Using chi-square and t-test, those with a history of STIs were compared with those who said they had experienced an STI, on demographic; attitude, knowledge and practice were picked. Variables that were statistically significant were entered into logistic regression to identify variables associated with STI. Qualitative data was also collected through key informant interviews.

Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

Results: Using multivariate analysis to control for confounding factors, source of income was statistically significant in determining having or not having an STI, (P-< 0.001). Those whose survived through sex work had a significantly higher rate of infection than all the other sources of income, at 94%. Other variables that were significant included having an STI before, (p-< 0.001), number of sexual partners in the last three months, (p-0.001). Unavailability of adequate medicines in health centers also contributed to recurrence of STIs in the district. Specific ethnic groups were also associated with having STIs.
Conclusions: Significant factors associated with sexually transmitted infections in Murehwa district are; having had an STI before, source of income, and number of sexual partners. Unavailability of adequate medicines in health centers is also a key factor contributing to recurrence of STIs in the district.

Anal cancer screening in HIV-infected youth at an urban community health center: Performance evaluation

U. Belkind[1], W. DeWitt[2], P. Carneiro[2], P. Meacher[2], A. Radix[2]
[1]*Callen-Lorde Community Health Center, Health Outreach to Teens (HOTT), New York, United States,* [2]*Callen-Lorde Community Health Center, New York, United States*

Background: Anal cancer incidence in HIV-infected MSM is between 70-144/100,000. Cytological screening of the anal canal may allow detection of precancerous dysplastic lesions or treatable early invasive disease and reduce incidence of invasive anal cancer . The New York State AIDS Institute "Anal Dysplasia and Cancer Guideline" recommends anal cytology at baseline and annually in HIV-infected MSM.
HIV-infected youth are less likely to be engaged in care and/or achieve viral load suppression. Given the challenges faced by this population in accessing care and other related services, we investigated anal cancer screening rates for patients ≤24 years in order to identify adherence to guidelines and racial, ethnic, or gender identity disparities.
Description: This is a quality improvement initiative to assess adherence to anal cancer screening guidelines in HIV-infected youth ≤24 years in a New York City community health center that specializes in care of LGBT and HIV-infected patients.
We conducted a retrospective chart review and analyzed data for patients ≤24 years who accessed HIV care from January 2016 to December 2017 (n=158). Variables included age, race, ethnicity, gender identity, last viral load and anal cytology.
Table 1 shows the prevalence of anal cancer screening rates January 2016-December 2017.

		Anal Cytology Performed (%)
Total	N=158	81 (51.3%)
Gender	Male, n=117	65 (55.6%)
	Transgender Female, n=39	16 (41%)
	Female, n=2	0
Race	White, n=29	19 (65.5%)
	Black, n=71	25 (35.2%)
	Other, n=20	13 (65.%)
Ethnicity	Hispanic, n=68; Non-Hispanic, n=49	39 (57.4%); 23 (46.9%)
Last Viral Load	≤200 copies, n=126; >200 copies, n=32	73 (57.9%); 8 (25%)

[Table 1]

81 patients had anal cytology performed (51.3%). 50 (61.7%) had abnormal results (22 ASC-US, 22 LSIL, 5 HSIL). 50% with abnormal results had high-resolution anoscopy performed.
Lessons learned: This first report of anal cancer screening in HIV-infected youth shows that abnormal anal cytology findings are common. Nearly 50% of this population failed to receive anal cancer screening as per guidelines. Disparities in anal cancer screening were observed across sub-populations in this age group.
Conclusions/Next steps: Monitoring of clinic-wide data is necessary to evaluate all aspects of HIV-related care and expose gender/race disparities. Next steps include reinforcing guidelines with healthcare providers, developing workflows that facilitate anal cancer screening (e.g. self-collected samples), follow-up of abnormal findings, and development of patient education materials.

Policies regarding HIV services and programmes

Beyond 90-90-90: The legacy of the 2014 International AIDS Conference in Melbourne and Victoria, Australia

J. Manwaring[1], E. Wright[2,3], B. Allan[4,5], S. Lewin[6], M. West[1], L. Galloway[1], S. Ruth[7], C. Millar[8], A. Fischer[6], J. Hoy[2,9], M. Hellard[3], C. Fairley[10], N. Roth[11], B. Eu[11], M. Catton[12], G. Brown[13], S. Malhotra[8], C. Carter[14], E. Crock[15], B. Price[9], A. Boughey[16], A. Coelho[17]
[1]*Department of Health and Human Services, Melbourne, Australia,* [2]*The Alfred Hospital, Melbourne, Australia,* [3]*The Burnet Institute, Melbourne, Australia,* [4]*International Council of AIDS Service Organizations, Toronto, Canada,* [5]*Australasian Society of HIV, Viral Hepatitis and Sexual Health Medicine, Sydney, Australia,* [6]*The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia,* [7]*Victorian AIDS Council, Melbourne, Australia,* [8]*Living Positive Victoria, Melbourne, Australia,* [9]*Monash University, Infectious Dieseases, Melbourne, Australia,* [10]*Melbourne Sexual Health Centre, Melbourne, Australia,* [11]*Prahran Market Clinic, Melbourne, Australia,* [12]*Victorian Infectious Diseases Reference Laboratory, Melbourne, Australia,* [13]*La Trobe University, Australian Research Centre in Sex, Health and Society, Melbourne, Australia,* [14]*North West Melbourne Primary Health Network, Melbourne, Australia,* [15]*Bolton Clarke, Melbourne, Australia,* [16]*Positive Women Victoria, Melbourne, Australia,* [17]*Centre for Culture, Ethnicity and Health, Multicultural Health and Support Service, Melbourne, Australia*

Background: The selection of Melbourne, Victoria to host the 2014 International AIDS Conference created a unique policy opportunity to accelerate the state's HIV response. Against the backdrop of a new Australian HIV strategy; the goal of the AIDS 2014 Legacy Statement to end new transmissions of HIV by the end of 2020; and approximately 300 new notifications per year and 8000 people living with HIV (PLHIV) in Victoria, the Victorian Government sought to identify and implement new policies, programmes, and initiatives.
Description: The Victorian HIV response is built on partnerships between community, government, clinicians, and researchers. The Department of Health and Human Services (DHHS) convened an HIV working group from these groups to optimise the state's response. The working group identified the development of a state-specific HIV strategy to create an enabling environment for system-level reforms. Between 2012 and 2017, in partnership with stakeholders, the government undertook a series of reforms and innovative initiatives, including: establishing Australia's first peer-led community-based rapid point-of-care testing service (PRONTO!) and pre-exposure prophylaxis study (VicPrEP); funding an expanded PrEP study (PrEPX); funding the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance (ACCESS); repeal of an HIV-specific provision from the *Crimes Act*; funding mainstream express testing clinics; developing an HIV doctor training program; joining the Fast-Track Cities Initiative (FTCI); releasing the *Victorian HIV Strategy 2017-2020*; and establishing an HIV cure research consortium.
Lessons learned: Hosting the International AIDS Conference reinvigorated and accelerated the local and national HIV response. AIDS 2014 facilitated the strengthening of Victorian partnerships, identification of new opportunities and renewed commitment to achieve the virtual elimination of new HIV notifications by the end of 2020. Hosting the first meeting of FTCI at AIDS 2014, in partnership with the City of Melbourne, was integral to Melbourne and Victoria becoming Australia's first and only member jurisdictions.
Conclusions/Next steps: The Victorian Government led development of the Australian AIDS 2014 Legacy Statement, which has been critical to development of the *Victorian HIV Strategy 2017-2020*, and underpins involvement in FTCI. DHHS has reconvened the HIV working group to guide the implementation of the HIV strategy with the aim of achieving the UNAIDS 95-95-95 goals for 2030.

THPED554

Health provider perspectives on implementation of same day ART initiation 6 months after policy change in South Africa

D. Onoya[1], I. Mokhele[1], T. Sineke[1], B. Mngoma[2], M. Vujovic[2], J. Langa[2], M. Fox[3,4]
[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Right to Care, Johannesburg, South Africa, [3]Departments of Global Health, Boston University School of Public Health, Boston, Massachusetts, United States, [4]Departments of Epidemiology, Boston University School of Public Health, Boston, Massachusetts, United States

Background: In September 2016, South Africa began implementing the universal-test-and-treat (UTT) policy in hopes of attaining the UNAIDS 90-90-90 targets by 2020. Guidance for antiretroviral therapy (ART) initiation on the same day of HIV diagnosis for clinically stable patients was later provided following policy recommendation by the WHO in July 2017. We conducted a qualitative study to determine progress to UTT policy assimilation and examine health providers' perspectives on implementation of same-day ART initiation 6 months after the policy change.
Methods: We conducted in-depth interviews with three clinic managers and four lay HIV counsellors of four primary health clinics in Johannesburg (South Africa) between October and December 2017. The key informant interviews covered topics including current health system capacity, implementation processes, as well as patient treatment readiness. Interviews were conducted in English, Sotho or Zulu, transcribed verbatim, translated to English and analysed thematically.
Results: There seems to be a disagreement across health care facilities and between counsellor and nursing providers regarding implementation of same-day ART initiation. While nursing providers understood and highlighted the clinical benefits of early ART initiation, there was concerns that, for some patient same day ART initiation may be too abrupt and patients who are not afforded the space to process the new diagnosis are likely to disengage from care after the initial acceptance of ART. As a results the implementation of same day ART initiation is slow because of provider ambivalence, infrastructure and human resources limitations. The process for assessing patient readiness is poorly defined and inconsistent and mainly counsellor dependent. Providers are unclear of the process to ensure patients who defer treatment return for ongoing counselling.
Conclusions: Our results highlight important gaps in the drive to achieve the second UNAIDS 90% (diagnosed patients on ART) target. Specifically, the study demonstrates the need for further engagement with health care providers about same day ART initiation implementation particularly infrastructural/capacity needs. Additionally, improved promotion efforts of same day initiation both in health care settings and in media communication is needed to increase patient demand for ART.

THPED555

The precarious balancing act between evidence and policy making; key factors that affect evidence use for HIV prevention policy

J. Koch
Mott MacDonald, EHPSA, Johannesburg, South Africa

Background: Policymakers face the complex task of considering a wide range of evidence on HIV prevention to inform policy and strengthen programming. This is additionally challenging for policymaking around MSM, prisoners and adolescent girls, as evidence must compete with beliefs and values.
This abstract summarises the main factors affecting evidence in HIV prevention policymaking in eastern and southern Africa.
Methods: The study triangulated three sources of evidence: a knowledge synthesis of 63 published papers and 14 case studies on the role of evidence in health policymaking in the ESA region; survey responses policymakers (N=19), and interviews with key HIV policymakers (N=9).
Results:
- High-level policymakers do not have sufficient time to gather, read and synthesise evidence.
- All stakeholders describe challenges in finding expertise to address the inter-disciplinary nature of HIV prevention.
- Policymakers' lack of access to research and journals constrains evidence informed decision-making.
- Staff relationships and power structures, attitudes towards evidence and research influence how available resources and capacity are deployed.
- Health policymakers support the use of evidence to inform HIV prevention policy, but this is less so at subnational levels and in non-health sectors.
- Beliefs and opinions about what counts as 'good' evidence are potent in the health sector, where evidence-based medicine is deeply influential and certain research, methodologies are more highly valued than others.

Conclusions:
- Public agencies are underfunded and overstretched, and human, financial, infrastructural and administrative capacities are fundamental factors shaping evidence use.
- Mid-level staff should be supported to gather and communicate evidence to high-level policymakers.
- Multilaterals play a powerful role in evidence generation, a feature of a sector which is almost entirely donor funded.
- Initiatives to provide access to journals can strengthen the use of evidence in policymaking.
- The disconnect between national and subnational and health and non-health sectors is an obstacle to effectively addressing the interdisciplinary nature of HIV prevention.
- Start early and engage continuously and responsibly throughout the research continuum for maximum policy influence, tackling persistent beliefs and opinions about the evidence base.

THPED556

National policy on nurse-initiated management of ART supports decentralization of HIV services in Namibia

J.F. Mdala[1], S. Wabomba[1], P. Kalimugogo[1], P. McQuide[1], N. Hamunime[2], R. Indongo[3]
[1]IntraHealth International, Windhoek, Namibia, [2]Ministry of Health and Social Services, Windhoek, Namibia, [3]USAID, Windhoek, Namibia

Background: Namibia's Ministry of Health and Social Services (MOHSS) has provided antiretroviral therapy (ART) services since 2003. At first ART could only be initiated by a medical doctor and mainly in hospitals; this limited accessibility and increased indirect costs for patients. From 2008 MOHSS recommended decentralizing ART to primary health care (PHC) facilities where trained nurses could provide follow-up care to patients who had been initiated by a doctor.
In 2012 the MOHSS introduced a policy on Nurse-Initiated Management of ART (NIMART), a task-shifting initiative to equip nurses to initiate and manage ART comprehensively. With USAID funding, IntraHealth International assessed how NIMART has contributed to expansion of ART services in Namibia.
Description: After NIMART training and all requirements are met, the supervising doctor declares the nurse competent in NIMART. The MOHSS training center issues a certificate of authorization. With ongoing support from HIV mentors and PHC coordinators, nurses provide NIMART at all levels of the health system. Our review focused on the expansion of NIMART from 2015-17 in 8 districts in northern Namibia that have 7 hospitals and 65 PHC facilities among them.
Lessons learned: During this period, 78 nurses completed NIMART certification and PHC facilities providing NIMART grew from 4 in September 2015 to 58 in September 2017. Currently 42,713 clients are receiving ART in these districts, 43% from PHC facilities, up from 24% in September 2016. The number of clients started on ART increased from 390 in July-September 2016 to 707 in July-September 2017. Between July and September 2017 over 95% of ART initiations (1,250 clients) were conducted by NIMART-trained nurses. PHC facilities have maintained a viral load suppression rate similar to district hospitals at 86%.

Conclusions/Next steps: The MOHSS NIMART policy has created an enabling environment for the efficient use of available human resources through task-shifting. Furthermore, quality of services is maintained through stringent certification requirements, continuous supervision and mentorship. This initiative makes a significant contribution to the UNAIDS 90-90-90 treatment targets by ensuring a greater number of individuals are initiated on ART and viral loads adequately monitored.

THPED557

Unclogging antiretroviral therapy clinics for people living with HIV: Success of community based delivery of antiretrovirals in Cameroon

A.M. Nga[1], L. Bonono[1], S.-C. Billong[1], A.F. Zeh Meka[2], C. Kengne[1], A.M. Essono[1], J.B. Elat[1]
[1]Ministry of Public Health, National AIDS Control Committee, Yaounde, Cameroon, [2]Ministry of Public Health, Regional Technical Group for the Fight against AIDS, Yaounde, Cameroon

Background: Of an estimated 520 00 people living with HIV (PLHIV) in Cameroon, 251 882 were receiving antiretroviral therapy (ART) as of 31st December 2017. At the end of the year 2015, the care of PLHIV was essentially done at antiretroviral therapy (ART) clinics leading to their congestion, sub-optimal service delivery quality and poor retention on ART. We therefore sought to assess the feasibility of unclogging congested ART clinics through implementation of community-based delivery of antiretroviral (ARV) (CBDA).

Description: We developed strategic documents to guide and ease implementation of CBDA which defined the role of the two key structures. On the one hand, the ART clinic was assigned as responsibilities: HIV diagnosis, referral of diagnosed PLHIV to community based-organizations (CBO), supply of ARVs to the CBO, mentoring to ensure standards are practiced and maintained, conduct biological follow-up tests of CBO patient cohort. On the other hand, the CBO was in charge of delivering ARVs to referred patients in conformity with national guidelines and ensure their retention in care.

A patient considered eligible for CBDA was defined as an adult aged ≥ 20 years, on treatment for ≥12months, clinically stable with a suppressed viral load or CD4 cell count ≥500 cells/mm³, not pregnant and on 1st line ART. A total of 73 CBOs who met the predefined enrolment criteria were conveniently selected for this experimental phase: be legally registered, have working space with ≥2 rooms, be an association of PLHIV, affected by HIV or involved in the fight against HIV. The strategy was implemented over a 15 month period (1st October 2016-31st December 2017).

Lessons learned: A total of 7635 clients were transferred out from ART clinics for community management out of 11701 who met the criteria, representing 65% of eligible clients and 3% of the total number of PLHIV on ART nationwide. We did not record any complaint that led to transfer in of clients back to health facilities.

Conclusions/Next steps: Community-based delivery of ARVs is feasible in Cameroon and we recommend scale-up to reduce the workload in health facilities, improve retention on ART and access to ART for all.

THPED558

Cities leadership as a gamechanger making sustainable 90-90-90 achievable in HIV and TB in EECA region

T. Deshko, I. Kushnir
Alliance for Public Health, International Programs, Kyiv, Ukraine

Background: Cities in EECA are hubs to HIV and TB, some 38% of PLHA in most affected countries of the region reside in urban settings. Donors are transitioning from EECA and local leadership is needed to cover the emerging gap.

Description: Alliance for Public Health together with AFEW International, licit, UNAIDS EECA office and Stop TB Partnership with the support of the Global Fund initiated regional program to establish sustainable models of HIV/TB responces on city level in Almaty (Kazakhstan), Beltsi (Moldova), Odesa (Ukraine), Sofia (Bulgaria) and Tbilisi (Georgia), starting 2017.

Lessons learned: The following lessons emerged after first implementation year:

1. City leadership and committment plays strong role in facilitating 90-90-90. In Odesa which first signed Paris declaration in February 2017, strengthened coordination on city level, designated city program allowed to reach unprecedent 44% growth in ART coverage during 2017 (compared to 18% nationally).
2. Exchange between cities plays a strong peer role. After exchange with Swiss cities, Mayors of Odesa and Beltsi declared plans to open first safe injection rooms in their respective cities and are currently progressing toward the target.
3. Municipal situation awareness and planning allows to allocate city resources to the most needed interventions. Beltsi designed city program with city annual allocation increase from 6000 USD in 2016 to 40000 USD in 2020.
4. Cities pilot strategic interventions to lower thresholds to HIV testing (Almaty) and transition to outpatient primary healthcare models on TB (Odesa) that have the capacity to inspire and support national health reforms.
5. Key populations engagement with the support of regional key populations networks helped to focus city planning towards the needs of local key groups.

Conclusions/Next steps: More cities will get involved into city health leadership: Kishinev and Batumi are joining the city leaders´ groups. Research on city models will further inform transition processess in program countries and beyond. City Health International conference will take place in Odesa, Ukraine, in September 2018 and will become the sharing platform for successful city health solutions.

THPED559

What would it take to build a stronger infrastructure to understand PrEP utilization?

P. Carneiro, A. Cantor, R. Vail, P. Meacher, A. Radix
Callen-Lorde Community Health Center, New York, United States

Background: The implementation of Biomedical Interventions (BI) around the globe has given new life to a generation of advocates and grassroots mobilization around HIV prevention, with Pre Exposure Prophylaxis (PrEP) leading the way.

Because PrEP users do not live with a given illness, it is important that health informatics and medical systems formalize methods to address and survey PrEP and other BIs.

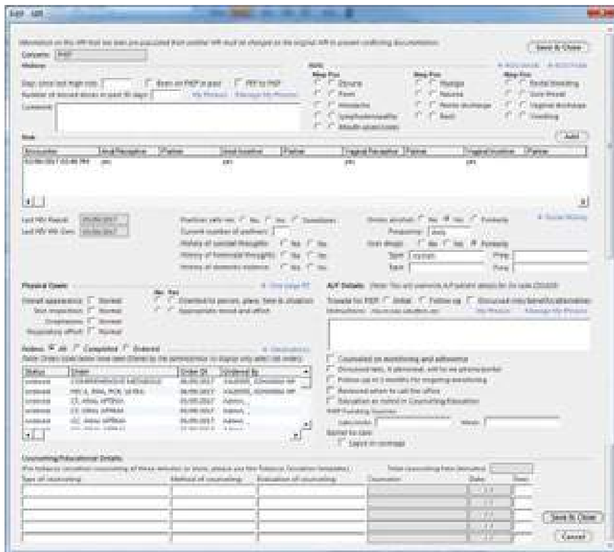
Callen-Lorde Community Health Center has initiated over 4000 people on PrEP since 2015 and has been formalizing data collection for the past 3 years. We discuss here our findings and challenges.

Description: Electronic health records (EHRs) and prescription data are the main sources of information about PrEP utilization, yet prescriptions alone can only tell one side of the story. A standardized EHR template (Figure 1) was developed to help providers have assurance on the care provided to patients, set reminders of care guidelines, and normalize PrEP care. Standardizing PrEP along other chronic conditions like diabetes care, hypertension care and even HIV care can help providers find confidence in the care provided and allow ease of incorporation into ordinary primary care.

In 2016 Callen-Lorde set forth a policy guidance suggesting clear and consistent utilization of specific International Statistical Classification of Diseases and Related Health Problems (ICD-10) codes for BIs, which would further improve one's ability to understand healthcare utilization by various populations accessing BIs.

Lessons learned: EHR templates for PrEP are needed and well accepted. PrEP templates must include collection of sexual health, adherence recall, 3-site STI screening orders, HIV screening and counseling, and information about last screenings - if viable. Callen-Lorde recommends the usage for the following ICD-10 codes for BIs: · Pre Exposure Prophylaxis (PrEP): Z20.6; Non Occupational Post Exposure Prophylaxis -Sexual Contact (nPEP), Z20.2; Non Occupational Post Exposure Prophylaxis -Non Sexual Contact (nPEP), Z20.828; Occupational Post Exposure Prophylaxis (oPEP) , Z20.828 AND an additional code that signifies injury in the workplace, otherwise known as Y92 codes. See Table 1 for definitions.

Conclusions/Next steps: Ratification of medical care systems such as Electronic Health Records, Diagnosis coding and other systems to include BIs are needed to streamline and integrate them into mainstream Primary Care.



[Figure 1 Shows the Customized EHR Template developed to streamline PrEP Care]

ICD-10 Code	Description	Biomedical Intervention
Z20.6	Contact with and (suspected) exposure to HIV	Pre Exposure Prophylaxis (PrEP)
Z20.2	Contact with and (suspected) exposure to infections with a predominately sexual mode of transmission	Non Occupational Post Exposure Prophylaxis -Sexual Contact (nPEP)
Z20.828	Contact with and (suspected) exposure to other viral communicable diseases	Non Occupational Post Exposure Prophylaxis -Non Sexual Contact (nPEP)
Z20.828 AND Y29	Contact with and (suspected) exposure to other viral communicable diseases AND an additional code that signifies injury in the workplace, otherwise known as Y92 codes	Occupational Post Exposure Prophylaxis (oPEP)

[ICD-10 Codes for Biomedical Interventions]

THPED560

Aligning Botswana's national HIV testing services guidelines to the era of Treat All

N. Majingo[1], C. Petlo[2], S. Lesotlho[2], E. Mmatli[2], M. Ngombo[2], O. Phumaphi[3], S. Mawandia[3], J. Ledikwe[3]
[1]*Ministry of Health & Wellness, HIV AIDS Prevention & Care, Gaborone, Botswana,* [2]*Ministry of Health and Wellness, HIV AIDS Prevention and Care, Gaborone, Botswana,* [3]*International Training and Education Center for Health, Gaborone, Botswana*

Background: To achieve the UNAIDS 90-90-90 targets, Botswana adopted "Treat All" in 2016, encouraging ARV initiation for all HIV-positive clients regardless of CD4 count. The Botswana HIV Testing Services (HTS) guidelines were revised to update HTS for implementing Treat All, address gaps in the existing guidelines, ensure alignment with the 2015 WHO Consolidated Guidelines on HTS and guide program managers and service providers in planning and implementing HTS in the Treat All era.

Description: Revision of the Botswana HTS Guidelines was led by the Ministry of Health and Wellness, which fostered a strong collaborative partnership including donors, implementing partners, NGOs and CSOs. In the guidelines, quality standards were improved. Ethical guidance was aligned with WHO's "5 C's". Innovative HTS approaches, such as 'self-testing and partner notification were adopted to promote services for under-served populations in facility and community based settings. Serial-testing algorithm was adopted for cost-effectiveness as well as retesting of HIV positive clients prior ART initiation. Additionally, program monitoring and evaluation was strengthened by updating and standardizing recording and reporting tools. Standardized refresher trainings were implemented to execute the revisions.

Lessons learned: Active participation of a wide group of stakeholders leveraged expertise to ensure development of comprehensive guidelines that met international standards while tailored to the local context. Strengthening quality guidance decreased discordant results to 0.3%. As the revised guidelines were implemented, strategies to provide services for hard-to-reach populations were identified. For example, the provision of facility-based extended-hours testing increased HIV case identification among men. Transitioning from parallel to serial algorithm required intensive coordination by training and supply chain management teams. Implementation of these policy changes standardized service delivery at facility and community testing sites, integrated HTS across primary care, led to the development of Linkage to Care and Partner Notification policies and ultimately reduced HTS burden at health facilities.

Conclusions/Next steps: Botswana's experience of adapting the WHO HTS Guidelines is a significant step in reaching epidemic control of HIV, demonstrating the nation's commitment to rigorous strategies that ensure all Batswana know their status and have timely access to prevention and treatment services. Lessons learned from this process will benefit other countries implementing Treat All.

THPED561

Toward early diagnosis of HIV infection: A population-based case-control study of routine opt-out testing services in Taiwan

Y.-H. Chen[1], C.-T. Fang[1,2]
[1]*National Taiwan University, Institute of Epidemiology and Prevention Medicine, Taipei, Taiwan, Province of China,* [2]*National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, Province of China*

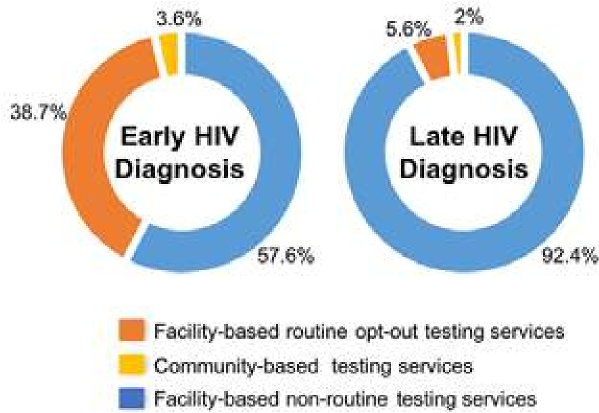
Background: To achieve the World Health Organization goal that 90% HIV infected people know their HIV status by 2020, it is critically important to emphasize on HIV testing services that are acceptable for people in their early stage of HIV infection. This population-based case-control study aims to investigate the role of different testing service scenarios in early diagnosis of HIV infection in Taiwan.

Methods: We analyzed the national HIV/AIDS registry database in Taiwan. Late diagnosis was defined as the onset of AIDS within 90 days after HIV diagnosis. We classified the testing services into three scenarios: facility-based routine opt-out testing services (e.g. antenatal care clinic, sexual transmitted infection clinic, blood donation, routine health examination for occupational health, in military recruitment, or in criminal justice system), facility-based non-routine testing services (e.g. client-initiated anonymous testing or provider-initiated testing at facility in non-routine contexts), and community-based testing services (e.g. outreach, campaign, or self-testing at home). Logistic regression was used to identify the protective factors against late HIV diagnosis, adjusting for age and different HIV risk factors.

Results: From 1984-2014, there were 28,711 domestic HIV patients. Among them, 6,350 (22.1%) were late diagnosed. Compared with late diagnosed HIV patients (cases), early diagnosed patients (controls) are more likely from facility-based routine opt-out testing services (38.7% vs 5.6%) and community-based testing services (3.6% vs 2.0%) (both $p < 0.001$) (Figure).

Multivariate logistic regression showed that facility-based routine opt-out testing services (adjusted odds ratio [OR] = 0.23; 95% CI = 0.20 - 0.26) and community-based testing services (adjusted OR = 0.41; 95% CI = 0.33 - 0.50) were independent protective factors against late diagnosis (Table).

Conclusions: Facility-based routine opt-out HIV testing service is a scenario that provides opportunity for early HIV diagnosis in Taiwan. Beside the community-based HIV testing services, facility-based routine opt-out testing service is another approach that warrants further expansion and refinement to better serve the need of people at risk of HIV infection.



[HIV Testing Scenarios and early Diagnosis]

	adjusted OR	95% CI		P-value
Facility-based routine opt-out testing services vs Facility-based non-routine testing services	0.23	0.20	0.26	< 0.001
Community-based testing services vs Facility-based non-routine testing services	0.41	0.33	0.50	< 0.001
HIV risk factors: Sexual vs Injecting drug user	7.93	6.64	9.47	< 0.001
Age < 25 vs 25-34	0.51	0.46	0.56	< 0.001
Age 35-44 vs 25-34	1.91	1.76	2.07	< 0.001
Age 45-54 vs 25-34	3.21	2.87	3.59	< 0.001

THPED562

How AIDS advocacy supports universal health coverage

S. Teemanka
AIDS Access Foundation, Bangkok, Thailand

Background: Thailand has battled the HIV epidemic for over three decades and has given priority to treating PLHIV with the latest drugs at affordable prices. However, ARV drugs alone are not enough to ensure quality standard care. Thus, Thai AIDS activities mobilized an advocacy effort for a national health insurance program which covers every individual and every condition.

Description: In the beginning of the Thai epidemic, PLHIV were severely marginalized individuals and, thus, had to form self-help groups with assistance from health NGOs. That network of support helped pressure the government to expand access to treatment as it became available. Despite the advent of effective ART, negative attitudes by health providers and cost of treatment still impeded access for PLHIV. Accordingly, in 2002, the NGO network and PLHIV campaigned for a universal health care system absent of discrimination against anyone for any reason. This advocacy was successful and, in 2004, the National Health Security System offered subsidized care to any Thai citizen, including treatment for HIV infection. However, this equitable service is under threat from Big Pharma and hospitals who are losing income from formerly-lucrative drugs sales, and are pressuring the government to return to a less subsidized approach.

Lessons learned:

- Creating a sense of the people's ownership of the national health insurance program was part of the reason that HIV/AIDS was included in Thailand's universal health care benefits package.
- Such an advocacy effort requires systematic participation and unified objectives. The network needs to spearhead mobilization with the message that broader health coverage serves all Thais.
- A diverse network which represents multiple populations and patient groups is more effective for public advocacy than a single-issue-defined group.

Conclusions/Next steps: Progress in the AIDS agenda requires participation of the broader Civil Society - not just those working with PLHIV. AIDS advocacy must be seen as the responsibility of everyone, and universal health coverage is a viable strategy to begin with. That said, advocacy networks need to guard against powerful special interests which threaten to undermine a people's movement for equitable and affordable health care for all.

THPED563

Treat All: WHO policy adoption and implementation status in countries

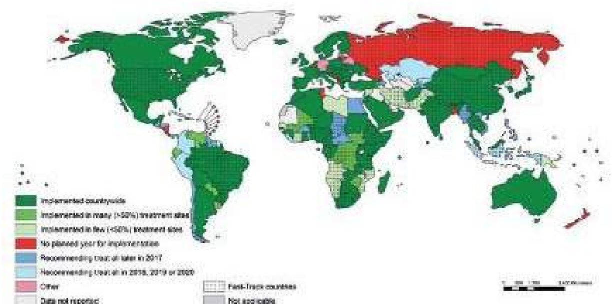
M. Doherty, M. Beusemberg, M. Vitoria, N. Ford, D. Low Beer, G. Hirnschall
World Health Organization, HIV/AIDS Department, Geneva, Switzerland

Background: With the 2016 consolidated ARV guidelines WHO updated and launched new policy recommendations on the clinical and service delivery aspects of HIV treatment and care, and raised the bar to treat all PLHIV regardless CD4 count (Treat All strategy).

Methods: Data from country surveys and Global AIDS Response Progress Reporting (GARPR) have been triangulated and validated for the adoption and implementation of major HIV treatment policies within 139 low and middle income countries (LMICs) and 35 focus countries for Fast Track (FT) support.

Results: Global data are presented through November 2017:
• 70% of LMIC and 89% of FT countries have adopted a Treat All policy, while another 10% of all LMIC and 6% of FT countries plan to adopt Treat All before the end of 2017. This is in contrast to 33% of all LMIC adopting Treat All policy measured one year ago.
• By the end of 2017, 80% of all LMIC and 94% of FT countries will have adopted Treat All.
• However, implementation is just getting underway and only 69 (50%) LMIC have already put the policy for Treat All fully into practice and 8 (6%) LMIC have implemented treat all in a majority of treatment sites.
• Lifelong ART for pregnant women is nearly universally adopted and moving towards full implementation.
• By November 2017, 68% of LMIC and 83% of Fast-Track countries had adopted treat all for children (less than 10 years).
• Dolutegravir (DTG) is soon available at a lower price point combined in fixed-dose combination with TDF/3TC and many countries are moving to adopt DTG as part of first line treatment.
• 72% of LMIC adopted TDF/[3TC or FTC]/EFV as the preferred first-line therapy, whereas an additional 40% of LMIC are making shifts to DTG containing regimens.
• Routine HIV viral load monitoring is fully implemented in 58% of LMIC and partially implemented in 25% of LMIC.

Conclusions: WHO has rapidly updated global guidance to reflect new science regarding the benefit of early HIV treatment and is now planning to update the ARV recommendations in 2018 to address new science and innovations.



[Implementation of Treat All ART recommendation among adults and adolescents living with HIV (situation as of November 2017)]

THPED564

Scaling up harm reduction, but too slowly: Removing legal barriers to supervised consumption services in Canada

R. Elliott[1], C. Kazatchkine[2], D. Macpherson[3], A. Foreman-Mackey[1,4], S.K.H. Chu[1]
[1]Canadian HIV/AIDS Legal Network, Toronto, Canada, [2]Canadian HIV/AIDS Legal Network, Paris, France, [3]Canadian Drug Policy Coalition, Vancouver, Canada, [4]University of Toronto, Toronto, Canada

Background: Use of non-sterile injection equipment accounted for 16.3% of new HIV infections overall in Canada (and 45.3% of new infections among Indigenous people) in 2014 (Public Health Agency of Canada, 2016). The opioid overdose crisis continues unabated, with more than 4000 deaths expected for 2017 (Government of Canada, December 2017). Supervised consumption sites (SCS) reduce both risks. However, until early 2017, there were only two SCS operating with a legal exemption from the federal Health Minister protecting clients and staff from drug possession charges.
Description: One barrier was the *Respect for Communities Act*, enacted in June 2015 by the then-Conservative government in response to a 2011 Supreme Court of Canada ruling compelling it to extend the existing exemption for Vancouver's SCS "Insite." The law established numerous unwarranted requirements, creating a veneer of legal "justification" for any government decision to refuse new exemptions. Advocates pressed the issue during the 2015 federal election. While the Liberal Party that ultimately won repeatedly declared its support during the campaign for SCS and harm reduction generally, it then balked at changing the law, despite it being a clear impediment to scaling up SCS. Advocates lobbied and kept up public calls in the media for legislative reform; communities mobilized with direct action highlighting the worsening overdose crisis. In December 2016, the government finally introduced Bill C-37 to repeal the earlier law, substantially streamlining the legislative framework for SCS exemptions. The bill became law in May 2017.
Lessons learned: With a simplified legislative framework, administered by a government supportive of harm reduction and under sustained pressure to act, as of February 2018, there were 17 SCS in Canada offering services under a ministerial exemption; 10 additional sites had valid provisional exemptions and were undergoing renovations.
Conclusions/Next steps: Advocates welcomed the legislative reforms, but cautioned the government against maintaining unnecessary hurdles in its policy or practice in handling SCS exemption applications. Initial indications, including Health Canada's own guidance material, suggest continued cause for concern, despite legislative improvements. The Canadian HIV/AIDS Legal Network is investigating whether, and which, hurdles remain; results to be reported in June 2018.

THPED565

Barriers to transition from donor support to Uganda government ownership in context of PEPFAR´s ´geographic prioritization´ policy: A qualitative study

H. Zakumumpa[1], L. Paina[2], F. Ssengooba[1], M. Mukuru[1], S. Bennett[2]
[1]Makerere University, School of Public Health, Kampala, Uganda, [2]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States

Background: Although transitions from donor HIV funding are becoming increasingly common, there is little research seeking to understand barriers to effective transitions of HIV funding from donors to local sources. Between 2015 -2016, PEPFAR implemented the ´geographic prioritization´ (GP) policy in Uganda whereby it withdrew direct support for HIV services in >800 health facilities and 10 districts with low HIV burden and intensified support in high-burden districts. The objective of our analysis was to explore local stakeholder perspectives on barriers to transition to Uganda government ownership of HIV services previously funded by PEPFAR.
Methods: A total of 106 in-depth interviews were conducted in June 2017(round 1) and November 2017 (round 2) with national-level HIV program managers (n=26), representatives of PEPFAR implementing organizations (n=24), district health leaders (n=22), facility in-charges (n=16), HIV clinic managers (n=18) to elicit transition barriers. Sampling was based on 6 districts (Pader, Amuru, Bulambuli, Luuka, Sironko, Kampala), with an embedded case-study of 6 health facilities (1 from each district) with sufficient variation by ownership-type. Data were analyzed by coding and thematic analysis based on themes derived from Amaya (2014) transition framework (national context, country capacity, actor incentives).
Results: *National context:* While health facilities reported being informed well in advance of PEPFAR´s phasing out of support, participants described GP as misaligned with national-level priorities (national budget cycles, HIV strategic plans, national AIDS levy). *Country capacity:* The 10 transitioned districts were described as newly created ,with weak management capacity for devising transition responses.
Facility-level participants described districts as unable to shoulder the financial burden associated with loss of PEPFAR support. *Actor incentives:* Participants reported that transition was accorded a low priority by district and central government actors given the absence of transition mitigation plans, suggesting leadership and governance deficits.
Conclusions: The low priority accorded to transition responses by government actors, weak district management capacity and a lack of alignment of GP with national context were identified as barriers to full country ownership of HIV services previously funded by PEPFAR. Civil society advocacy could enhance political commitment to transition causes. This study potentially informs future transitions from donor HIV funding especially in low-income countries.

THPED566

A framework for value-based financing of integrated care for persons living with HIV

S. Vermeersch[1], R. Demeester[2], S. De Wit[3], S. Callens[4], L. Annemans[5], BREACH Consortium
[1]Hict NV, Bruges, Belgium, [2]University Hospital of Charleroi, Internal Medicine and Infectious Diseases, Charleroi, Belgium, [3]University Hospital St Pierre, Infectious Diseases, Brussels, Belgium, [4]Ghent University Hospital, Internal Medicine and Infectious Diseases, Ghent, Belgium, [5]Ghent University, Public Health, Ghent, Belgium

Background: Delivery of patient-centered, integrated care is paramount to meet the HIV challenge: reducing undiagnosed patient numbers, improving the continuum of care (90-90-90 treatment targets) and achieving the 'fourth' health-related quality of life treatment target through management of comorbidities and self-perceived quality of life. Integrated care systems, however, face the same (financial) pressures as the healthcare system as a whole as payers struggle to balance costs and outcomes. We developed and deployed an integrated framework to (i) shift the discussion from costs to value and value for money (ii) quantify value impact to bolster value messages and (iii) translate value messages to practical value-driven financing approaches, applied to Belgian AIDS Reference Centers (ARC).
Methods: Our framework consists of 4 pillars: (i) a value-framework translating ARC activities to value-based outcomes; (ii) a modeling approach to quantify and extrapolate these value elements in terms of disease and budget impact; (iii) a logical framework approach to define a value-based indicator set and (iv) an approach to apply this toolkit to develop a value-oriented financing approach for Belgian ARCs.
Results: We focused on 10 value-adding ARC activities:
(i) prevention of new infections,
(ii) reduction of the number of undiagnosed patients,
(iii) linkage to and
(iv) retention in care;
(v) achieving and maintaining virologic control;
(vi) supporting quality of life;
(vii) managing and reducing comorbidities;
(viii) maintaining sexual and reproductive health;
(ix) performing data collection and
(x) driving and executing research.
The health and budget impact and return on investment (or cost of non-investment) of the first five value elements was modeled leveraging the existing BELHIVPREV model, the results of which are presented elsewhere. From these foundations, an indicator set was developed which was used to engage payers in developing a value-driven financing agreement.

Conclusions: We developed an actionable approach to shift financing towards a value-driven, indicator-based model. By focusing on the 'big picture' goals rather than deconstructed costs supported by quantified value messaging and its structured approach to translate this value framework to indicator-supported financing, it provides a platform to engage payers on and support integrated care delivery.

THPED567

Improving access to HIV testing & counselling services in men

M.L. Mabitsi
Anova Health Institute, Public Health, Johannesburg, South Africa

Background: HIV testing & counselling (HTC) services are freely available at all public health facilities in South Africa (SA) and are continuously being promoted through different media platforms to encourage individuals to know their HIV status. However, the uptake of HTC in men is lower than in women. Innovative approaches aimed at attracting men to HTC services are required to meet 909090 objectives.

Methods: Anova in partnership with Johannesburg Health District set up a male friendly HTC site at a shopping complex in July 2016, with three other sites being subsequently opened in other areas across the District. The sites offer HTC to males aged 21 and above, close at 18H00 on weekdays, and 14H00 on weekends to cater for men who are unable to take time off work to access Primary Health Care (PHC) facilities. These locations (shopping complexes) were selected as men could access HTC while shopping, and on their way to & from work. The waiting time at the sites is around 30 minutes, catering for men who are unable to wait for a longer time as is usually the case in clinics. Health promoters mobilise men around the plaza, taxi rank, workplaces, etc. while Community health workers mobilise within nearby communities. HTC services are provided in line with SA DoH guidelines.

Results: From 1st July 2016- 30th December 2017, 31 000 men received HTC at these sites, with 1751 diagnosed HIV positive, overall 6% positivity yield. Of note, 32%, 22% and 20% of those who received HTC were aged 30-34, 35- 39 and 40-49 respectively. The positivity yield was highest in 40-49 year olds (10%), with a yield of 8% in men aged 25-29 and those above 50 respectively.

Conclusions: HTC services can be attractive to men if offered at sites and times convenient for men and efforts should be targeted at men above 40 to increase their uptake of HTC as the positivity yield was found to be highest in this group.

THPED568

Trilateral cooperation between Brazil, Japan and Mozambique: Unifying practices and expertise to strengthen the decentralization process in Gaza and Nampula provinces in Mozambique

V. Cervantes[1], J. Oliveira Dantas[2], R. Alencar de Souza[2], M.C. Gianna Garcia Ribeiro[2], J. Ferreira Nunes Neto[3], R. Paulo Moreira Nandene[4], A. Manhique[5], S. Samuel[6], A. Silva[6], H. Hasegawa[7], S. Victorino[7], T. Sadamori[7]
[1]Secretaria de Estado da Saúde CRT DST/Aids, Assessoria de Planejamento, São Vicente, Brazil, [2]Programa Estadual IST/Aids, São Paulo, Brazil, [3]Agência Brasileira de Cooperação Internacional, Brasilia, Brazil, [4]Conselho Provincial de Combate ao SIDA - Gaza-Moçambique, Gaza, Mozambique, [5]Conselho Distrital de Combate ao SIDA de Chókwè - Gaza-Moçambique, Gaza, Mozambique, [6]Conselho Provincial de Combate ao SIDA de Nampula, Nampula, Mozambique, [7]JICA Moçambique (Agência Japonesa de Cooperação Internacional), Nampula, Mozambique

Background: The HIV epidemic in Mozambique, affect social and economic development. 1.8 million people are living with HIV in Mozambique (IMASIDA, 2015). HIV prevalence is 13,2% amongst adults (IMASIDA, 2015), with higher prevalence amongst female (15,4%) versus male (10,1%). Gaza province presents the highest prevalence in the country (24.4%). Nampula (5.7%).

Since 2013, the Coordination for STI/AIDS of Sao Paulo (CE-STI/AIDS-SP), Brazil, in collaboration with the Japan International Cooperation Agency (JICA), has been supporting efforts for the decentralization of the AIDS response in collaboration with Mozambican autorities. Different than other cooperation, these players used a combined approach to enhance knowledge and capacities in order to generate solutions across the system of HIV responses.

Description: The CE-IST/AIDS-SP approached strengthening management, including related people, tools, and working processes, first by training 24 high-level staff on planning and trainees were comprised managers and activists from NGOs. The interaction and subsequent improvements to working processes has generated specific dynamics amongst the participants/organizations. The training stimulated participants power for change through the learning processes. As it was designed for this cooperation, its implementation has highlighted and commitment of each player. In Gaza, after this training process which took 80 hours, eleven professionals were selected as facilitators who would emulate their own experience for lower-level managers and activists. A total of 291 people were ultimately trained in twelve districts and three provinces. A similar experience happened in Nampula, resulting 82 providers trained.

Lessons learned: Involvement of strategic players at provincial level strengthened the collaboration and alignment amongst managers response at different levels. The facilitators had gained visibility at provincial and national levels, eventually multiplying the diffusion of this integrated model. We observed that it also reduced boundaries between public and private sectors, bringing the communities closer to system and enhancing collaboration and social accountability.

Conclusions/Next steps: Relevant and influential facilitators serve as a regional reference to the amplify strategic and focused planning processes. The combination of expertise and diverse cultures have enriched the processes and the outcomes, showing the potential of horizontal and South-to-South collaboration—triangulated with a Northern agency—has, especially in settings where financial resources become scarce.

THPED569

Monitoring strategies for HIV drug resistance in PrEP rollout settings

L. Levy[1], L. Kudrick[2], B. Chohan[3], I. Mukui[4], K. Rebe[5], J. McIntyre[6], M. Dunbar[7], O. Mugurungi[8], T. Mutasa-Apollo[8], E. Gwavava[9], I. Yacobson[10], J. Peterson[11], M. Fawzy[10], K. Torjesen[10], J. Mellors[12], U. Parikh[12]
[1]FHI 360, Washington, DC, United States, [2]University of Pittsburgh, Pittsburgh, United States, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]National AIDS & STI Control Programme, Ministry of Health, Nairobi, Kenya, [5]Anova Health Institute, Department of Medicine, University of Cape Town, Cape Town, South Africa, [6]Anova Health Institute, School of Public Health, University of Cape Town, Cape Town, South Africa, [7]Pangaea Zimbabwe AIDS Trust, Oakland, United States, [8]Ministry of Health and Child Care, AIDS and TB Programme, Harare, Zimbabwe, [9]Populations Services International Zimbabwe, Harare, Zimbabwe, [10]FHI 360, Durham, United States, [11]FHI 360, Lilongwe, Malawi, [12]University of Pittsburgh, Division of Infectious Diseases, Pittsburgh, United States

Background: HIV drug resistance among pre-exposure prophylaxis (PrEP) seroconverters is a concern as some antiretrovirals are used for both HIV prevention and treatment. Evidence on HIV drug resistance in PrEP seroconverters is limited and comes from PrEP efficacy studies with different HIV testing intervals and adherence support strategies compared to PrEP rollout. More data are needed to understand the risk of HIV drug resistance in real-world implementation.

Description: Approaches to HIV drug resistance monitoring may include:

1. Standalone **research protocols** that include drug resistance testing (DRT)
2. Adding DRT to ongoing PrEP **demonstration projects**
3. Incorporating DRT into **national PrEP guidelines** and policies
4. Incorporating DRT into ongoing surveillance for antiretroviral therapy failures/pre-treatment surveillance as part of **national surveillance programs**

The Global Evaluation of Microbicide Sensitivity (GEMS) project, in collaboration with country stakeholders, initiated drug resistance assessment projects in Kenya, South Africa and Zimbabwe utilizing Approach-

es 1 and 2. Protocols were developed to assess drug resistance among a national sample of PrEP users (Kenya and Zimbabwe), and among select key populations, including men who have sex with men and sex workers (South Africa). DRT for seroconverters was also incorporated into existing demonstration projects in Kenya and South Africa, involving adolescent girls, young women, MSM and serodiscordant couples.
Lessons learned: Countries have varying degrees of resources and stakeholder engagement for integrating DRT for PrEP delivery, impacting the strategy for resistance monitoring. Countries are supportive of conducting a time-limited evaluation of drug resistance (Approach 1 and/or 2) in the absence of clear data and during early stages of PrEP rollout. The need for long-term monitoring (Approach 3 and/or 4) will be assessed after initial data are analyzed.
Conclusions/Next steps: As PrEP is implemented, early assessment of resistance risk is critical for understanding the implications for oral PrEP programs at scale. Approaches to drug resistance monitoring will vary and may evolve as new data are analyzed. The methods proposed by GEMS, along with its implementation support materials, will assist countries in developing policies that best fit their PrEP program needs and resources.

THPED570

"Nothing for us without us"- community ownership of treatment progrmmes through monitoring of OI/ART services by PLHIV in Zimbabwe

T. Magure[1], R. Yekeye[2], A. Mpofu[3], S. Mpofu[2]
[1]National AIDS Council (NAC), CEO, Harare, Zimbabwe, [2]National AIDS Council (NAC), Programmes, Harare, Zimbabwe, [3]National AIDS Council (NAC), M&E, Harare, Zimbabwe

Background: The Community monitoring Programme in Zimbabwe is a good example of how community involvement in the national response can be achieved. Through this programme, PLHIV as major stakeholder in the national response are able to assess the state of affairs of ART and diagnostic equipment in health centres and ensure that corrective measures are taken by the service providers. The programme aims to:
· To assess the availability of ARVs in the OI clinics and discuss best practices and challenges of the ART Programme with health workers and clients
· To assess the state of diagnostic equipment for OI/ART services.
Description: PLHIV conduct interviews with health practitioners and clients of the ART programme through structured tools in a bid to triangulate the information collected from both sources. A report is compiled and shared with representatives of the policy makers from Ministry of Health, the National Laboratory and National Pharmacy, National AIDS Council and PLHIV at all levels. This is done by PLHIV themselves in the spirit of MIPA.
Lessons learned:
- OI/ART clients still travel long distances to access services but implementation of Community ART Refill Groups are assisting with access.
- The community monitoring programme has greatly assisted the Ministry of Health to unlock bottlenecks in the delivery system of ARVs, DBS and diagnostic equipment and enabled swift corrective action especially where bottleneck are a result of human error.
- PLHIV were able to appreciate the workload that health practioners have and the operational environment
- The Programme has managed to put to the fore the state of diagnostic equipment resulting in prioritising diagnostic equipment such as viral load PIMA machines in the Global Fund Proposal.
- Meaningful Involvement of PLHIV has been enhanced whereby PLHIV, plan, Implement, monitor and advocate for quality delivery of ART services.

Conclusions/Next steps: Community monitoring improves access to ART services and assists in bringing together the services providers and consumers towards a common goal in fulfilling the MIPA philosophy of "Nothing for us without us" Local teams set up for routine monitoring.

Policies addressing social and economic determinants of vulnerability

THPED571

Mobilizing local governments' responses towards the welfare of hijras/transgender women in India: Steps towards improved social well-being of trans people

J. Ignatious[1,2], J. Williams[1], V. Arumugam[1], K. Pramod[3], L. Das[3], R. Dhas[3]
[1]Voluntary Health Services, Projects, Chennai, India, [2]APCOM, MSA-DIVA - Project, Bangkok, Thailand, [3]Voluntary Health Services, Projects Division, Chennai, India

Background: Local governments (district panchayat) are responsible for addressing the needs and priorities of all people in their constituencies. Given the critical lack of awareness and understanding of transgender people, integrating/implementing trans welfare policies or programmes at grassroots level is quite challenging.
Description: Voluntary Health Services (VHS), with support from the Global Fund, is implementing a four-year project (2014-18) titled *'Diversity in Action'* in India to reduce the impact of HIV on hijras/transgender women. A focus area of the project was to conduct policy dialogue with various key stakeholders, especially district panchayat leaders and political parties, on issues faced by hijras/transgender women. As a first step towards creating awareness about the issues and rights of hijras/transgender women, VHS conducted a series of policy dialogue meetings with 85 members of panchayats in 03 districts in Kerala. A promising outcome from these policy dialogue meetings was securing earmarked funds of INR 11 lakh (USD 18,000) for transgender welfare schemes by district panchayats in Kerala. Similarly, another outcome was the inclusion of transgender welfare programmes in the election manifesto of a dominant political party, the Left Democratic Front (LDF), in Kerala.
Lessons learned: Local governments play a crucial role in creating enabling and safe environments for their constituencies, including trans people. Active support and commitment from political parties and leaders have raised hopes for strengthening enabling environments for trans people and improve their social well-being.
Conclusions/Next steps: Trans communities from these districts will monitor the use of the earmarked funds and also follow up with the implementation of the trans-specific action plan announced in the election manifesto. The lessons learnt from this initiative will be helpful in designing and scaling up similar activities in others states in India.

Policies addressing HIV in the workplace and/or educational institutions

THPED572

The case of Peru: Evidence-based sexuality education in the curriculum contributes to reduce inequalities and to prevent HIV in schools

C. Murguía Pardo
UNFPA Peru, Adolescence and Youth, Lima, Peru

Background: In 2016, Peru finished the reform of learnings and the revision of the educational curriculum to strengthen its impact in students life, including their autonomy, decision making competency, self-care and HIV prevention. The incorporation of comprehensive sexuality education (CSE) in the curriculum was key to: respond to limitations in its conceptual and pedagogical treatment, call for political support, make the issue visible and reduce the resistance of conservative sectors .
It was an opportunity to consolidate gender and human rights approaches thanks to the recognition of international cooperation in its role of evidence-based technical assistance.
Description: An intense process of political dialogue and technical assistance based on evidence aimed to MoE was launched by UNFPA and UNESCO to incorporate CSE in the curriculum, impacting at politi-

cal, programmatic and operational levels, involving multiple actors. The process involved the review of evidences, south to south cooperation, participatory forums at the national level, specialized technical assistance and two public opinion surveys on CSE to collect the perceptions of the citizenship. The process ended with the official approval of the curriculum that includes competencies and learnings to the exercise of a healthy sexuality.
Lessons learned: Technical assisstance based on evidence, face to face with officials of the education sector, at national and local level, was highly valuable to answer doubts as well as false concepts about CSE, sexuality, HIV prevention, current legal norms, and to sensitize them around the fundamental role of school in the protection and respect of adolescents human rights.
In the processes of reviewing the curriculum it was key to involve the different areas of the MoE, not only basic education, in order to ensure normative coherence, enrich the proposal from an interdisciplinary perspective, generate consensus regarding the changes to be proposed and ensure the subsequent approval and/or implementation of the curriculum and CSE as key part of it.
Conclusions/Next steps: To support the progressive implementation of the curriculum as planned by the MoE maintaining gender and human rigths approaches as well as CSE as key axes to prevent unwanted pregnancies, gender based violence and STI /HIV and AIDS. The training of teachers is key.

THPED573

Equal rights to health: Reducing discrimination towards persons living with HIV in healthcare settings in China

R. Wu, B. Zug-Castillo
International Labour Organization, Geneve, Switzerland

Background: Persons living with HIV (PLHIV) face discrimination in accessing medical treatment in China. A 2011 study by China's Alliance of PLHIV (CAP+) showed a person living with HIV would normally experience more than six denials of treatment or referrals to other hospitals before finally accessing the services. What are the reasons for this?
Description: The ILO and the China Center of Disease Control researched into the reasons for discriminatory attitudes of healthcare workers towards PLHIV and found two main reasons:
- poor and unsafe working conditions healthcare care workers face; and
- lack of training on the prevention of occupational safety and health (OSH) in healthcare settings and on the adoption of universal precautions.

The ILO and the China STD/AIDS Prevention and Control Association, adapted the ILO/WHO HealthWISE Training Manuals and translated it into Chinese. Four training workshops, covering 70 major hospitals, were organized to share the HealthWISE knowledge and tools with healthcare practitioners and guide them to prevent and manage occupational exposure to blood-borne pathogens, including HIV. 30 senior managers committed to improving OSH and reduce discrimination towards people living with HIV. 50 hospitals already implemented HealthWISE. Their healthcare workers identified occupational hazards and risks in their workplace and found low or no-cost solutions. 15 hospitals created an occupational safety and health management system to address OSH and HIV-related discrimination issues in a systematic manner.
Lessons learned:
- Attention to improving working conditions in healthcare settings, access to information and buy-in of senior management are essential to protect healthcare workers from exposure to occupational diseases, including HIV, and improve the quality care for persons living with HIV.
- It is important to institutionalize the work: HIV and OSH committees have been created under the China STD/AIDS Prevention and Control Association.

Conclusions/Next steps: The programme is to be scaled up and results to be shared with other countries for replication.

THPED574

A human rights approach to successfully change national aviation laws to enable people living with HIV to train as pilots

N. Sparling[1], J. Bushe[2], G. Valiotis[1]
[1]HIV Scotland, Edinburgh, United Kingdom, [2]Community Advocate, Glasgow, United Kingdom

Background: People living with HIV are restricted from gaining required certification to train as Commercial Airline Pilots (CAP) based on medical assessment guidelines set out by the European Aviation Safety Authority (EASA). Although EASA allows for member states to deviate from these guidelines, whilst maintaining a high level of safety, the United Kingdom had refused to grant medical certificates to first time applicants living with HIV. Without coordinated efforts toward updating the policies on medical assessment, the Civil Aviation Authority (CAA) would be in opposition of the Equality Act 2010.
Description: HIV Scotland, the national HIV policy NGO, worked with community members, clinicians, media, and politicians to outline the human rights implications and identifying existing evidence that illustrated that the CAA policies were not in accordance with current medical evidence and international best practice. The British HIV Association and the National Gay Pilots Association provided national and international evidence that supported a change in this policy that people living with HIV on effective treatment did not have neurocognitive impairments that would impact on safety, and therefore should be granted a medical certificate to enable applicants to become a pilot.
Through work with journalists and community activists who were directly impacted by this policy, we were able to raise the profile of this story, whilst highlighting contemporary information HIV. The campaign created opportunities for political leadership and was supported by Scotland's First Minister.
Lessons learned: This community-led work illustrated that by using human rights principles, and partnering with relevant organisations, we were able to advocate to change policy to be in accordance with current medical evidence. This approach allowed the CAA to deviate from the EASA regulations by awarding medical certificates to people living with HIV who would otherwise pass a medical examination. This has resulted in people living with HIV being able to take up training programmes to become CAPs in the UK.
Conclusions/Next steps: By creating links between human rights legislation and the CAA policy, and by building an effective media strategy, we were able to place this discriminatory policy high on the agenda of policy-makers and stakeholders which lead to the discrimination being overturned.

Success of inter-associative advocacy strategies for access to dolutegravir in Morocco

M. Ahmar[1,2], O. Mellouk[3], H. Himmich[1], M. Karkouri[1]
[1]ALCS, Casablanca, Morocco, [2]Coalition PLUS Community-Based Research Laboratory, Paris, France, [3]ITPC, Marrakech, Morocco

Background: Dolutegravir (DTG) is an ARV developed by ViiV. Commercialized since 2014, it has become considered one of the best ARVs and is now recommended as alternative first line by WHO. However, access remains limited in developing countries due to price barriers. A voluntary license (VL) negotiated by ViiV and generic companies through the Medicines Patent Pool (MPP) gives access to generic DTG in 92 countries. As a middle-income country (MIC), Morocco was initially excluded from the license.
Description: Moroccan authorities conducted unsatisfactory negotiations with ViiV with a too high end price of US$ 1500 pppy while generic companies were announcing prices of US$ 44 pppy. Unsuccessful ne-

gotiations would have given the ability to Morocco to issue a unilateral compulsory license (CL) and produce and/or commercialize generic DTG despite patent protection.
Two Moroccan CSOs, ITPCMENA and ALCS partnered to advocate to ViiV, Ministry of Health (MoH) and MPP for access to generic DTG.
1) Advocates met bilaterally ViiV's representatives to demand the integration of Morocco in the VL advancing that Morocco could otherwise issue a CL.
2) Advocates had several encounters with the MPP to discuss access strategies for Morocco.
3) Advocates asked the MoH to issue a CL or formally ask the MPP to be integrated in the VL. They supported the MoH to formally request from ViiV its integration to the VL.
On the occasion of AFRAVIH 2016, ViiV announced the inclusion of Morocco to its license.
Lessons learned: Morocco did not issue a CL however discussions with Moroccan authorities introduced the idea that it was a possible strategy. On the other hand the probability that Morocco could issue a CL prompted ViiV to accept inclusion of Morocco in the VL to avoid losing its market altogether. Finally, discussions with MPP encouraged them to push for Morocco's inclusion in the VL. The strategy of ITPCMENA and ALCS to advocate towards multiple actors enabled access to generic DTG for Morocco.
Conclusions/Next steps: Following civil society's efforts, Morocco now has access to generic DTG. ITPCMENA and ALCS are currently advocating for the immediate inscription of DTG in the therapeutic guidelines as a first line ARV therapy.

THPED576

Mercosur-European union free trade agreement: Impact analysis of TRIPS-plus measures on public purchases and domestic production of HIV and hepatitis C medicines in Brazil

M.C. Fogaça Vieira[1], G. Costa Chaves[2], W. Britto Gaspar[2]
[1]Consultant, AccessIBSA, Sao Paulo, Brazil, [2]Sergio Arouca National School of Public Health, Oswaldo Cruz Foundation, Department of Medicines Policy and Pharmaceutical Services (NAF), Rio de Janeiro, Brazil

Background: The European Union (EU) and Mercosur countries are negotiating a free trade agreement (FTA) containing a chapter on intellectual property rights (IPR) with TRIPS-plus measures that can negatively impact access to treatment. The study assess the public health impact of TRIPS-plus measures on public expenditures on medicines and sales of domestic production in Brazil, with focus on antiretroviral (ARV) medicines used in the treatment of HIV/Aids and medicines used for hepatitis C.
Methods: We applied the Intellectual Property Rights Impact Aggregate (IPRIA) Model to estimate the impact of TRIPS-plus provisions on the public expenditures and domestic sales of medicines in Brazil. We simulated five different scenarios to estimate the impact of including the two main TRIPS-plus provisions proposed by the EU both separately and together (patent term extension and data exclusivity). We also simulated the impact of removing a TRIPS-plus provision that is already included in Brazilian law.
Results: The results show an increase in public expenditures with purchase of medicines and a reduce in sales of domestic production in case of adoption of TRIPS-plus provisions and savings in public resources and increase in domestic production sales in case of removing already existing TRIPS-plus provision. The figures are summarised on table 1.
Conclusions:
1. Strategies adopted to negotiate price and remove patent barriers (TRIPS flexibilities) have reduced the negative impact of IPR on access to ARV allowing for the treatment of more people with small increase in total expenditures.
2. The adoption of TRIPS-plus measures proposed by the EU, besides the increase in public expenditures and reduction of domestic sales, would also reduce the policy space currently available to adopt measures to reduce the negative impact of IPR on health policies. That could lead to higher increase in public expenditures and decrease of sales by national producers in the whole pharmaceutical market;
3. Public expenditures on medicines have been increasing in the past years, consuming rising shares of the total public health budget as a result of incorporating medicines under market exclusivity. The adoption of new measures that increase market exclusivity is detrimental to the sustainability of the public health system.

Scenario	Time period	Variation in ARV expenditure compared to base scenario (BRL)	Variation in expenditure on medicines for hepatitis C compared to base scenario (BRL)
Alternative (Alt) 1	2015-2050 for ARV and 2016-2051 for hepatitis C	-2,054,436,157.85	-16,862,109,838.52
Alt 2		1,255,011,241.61	16,326,989,040.47
Alt 3 (5-years DE)		2,452,784,149.22	31,451,189,948.91
Alt 3 (8-years DE)		3,740,179,503.19	47,861,780,962.03
Alt 4 (5-years DE)		3,707,795,390.84	46,639,086,730.75
Alt 4 (8-years DE)		4,995,190,744.80	63,049,677,743.86

[Table1. Summary of findings]

THPED577

Assessing the effect of test and start policy on HIV treatment uptake in Nigeria: A segmented regression analysis

B.O. Onifade[1], C. Nzelu[2], S. Aboje[2], G. Eluwa[3], O. Folajinmi[4]
[1]National AIDS/STIs Control Programme, Public Health, Federal Ministry of Health, Abuja, Nigeria, [2]National AIDS/STIs Control Programme, Public Health, Abuja, Nigeria, [3]Population Council, Abuja, Nigeria, [4]AIDS Healthcare Foundation, Abuja, Nigeria

Background: Nigeria has an estimated 3.2 million people living with HIV (PLHIV) but only 1,050,594 clients are on antiretroviral treatment (ARTs) as at December 2017. In 2016, Nigeria approved the implementation of the Test and Start policy as a means to increasing access to ARTs and as a means of prevention. We assessed the effect of this policy on initiating newly identified HIV positive clients into treatment.
Methods: Data on HIV treatment were pooled across 10 states between July 2016 and December 2016 representing pre-policy period and between January 2017 to June 2017 representing post-policy period. Segmented linear regression was used to analyze the effect of the intervention as shown by „Yt = $_0$ + $^*_1$time + $^*_2$intervention + $^*_3$postslope + $_{1}$.
Yt is the outcome variable (number of clients initiated on ART) at time t; $_0$ captures the baseline level of the outcome at time 0; $^*_1$ estimates the growth rate in ART uptake independently from the intervention; $^*_2$ estimates the immediate impact of the intervention and $^*_3$ reflects the growth rate in outcome, after the intervention.
Results: A total of 31,631 and 27,402 clients were initiated on treatment in the pre-policy and post-policy periods respectively. Segmented regression analysis showed that at baseline, on the average, 7,684 ($_0$) clients were newly initiated into treatment monthly. There was no significant month-to-month change in the number of clients newly initiated on treatment in the pre-policy ($^*_1$:689 clients; p=0.110) period, however there was an insignificant decline in the post policy period ($^*_3$:29 clients; p=0.940). In addition, there was no immediate effect of the policy on initiation of new clients into treatment ($^*_2$:1,122; p=0.570).
Conclusions: The test and start policy in Nigeria has not yielded any significant increase in the number of new clients initiated into treatment. This directly mitigates the possibility of Nigeria attaining the second "90" of the UNAIDS 90:90:90 goal which aims to ensure that 90% of HIV positive clients are initiated on treatment. Robust evaluations of implementation strategies are urgently required to identify the gaps and consequently design appropriate and effective interventions.

THPED578

Humanitarian crisis and access to HIV services in Nigeria: An analysis of national ART programme coverage from 2014 - 2016 in states with humanitarian crisis

O. Michael Kayode[1], S. Oshagbami[1], J. Aneni[2], G. Ujam[1], S. Aliyu[3]
[1]National Agency for the Control of AIDS, NACA, Policy, Planning and Coordination, Abuja, Nigeria, [2]National Agency for the Control of AIDS, NACA, Monitoring and Evaluation, Abuja, Nigeria, [3]National Agency for the Control of AIDS, NACA, Abuja, Nigeria

Background: The goal of Nigeria ART programme is to utilize available resources to improve ART coverage towards achieving the UNAIDS 90-90-90 targets. Nigeria has 983,980 patients accessing ART out of an estimated 3.2 million patients in 2016. This study analyzed the relationship between ART coverage and humanitarian crisis on national ART indicators in states affected by humanitarian crisis between 2014 and 2016.
Description: Nigeria has suffered severe humanitarian crisis which has resulted in disruption of services and displacement of persons from their communities in many states. The number of displaced persons rose from less than 400,000 in 2013 to above 1.9 million in 2016 and displaced persons are not included in the national ART. The selected states for this study are; Borno, Yobe, Adamawa, Taraba, Kaduna, Plateau, Benue and Nasarawa.
This study analyzed 2014 to 2016 ART coverage in the above eight states and compared the data with ART coverage in the following eight states with similar HIV burden but without humanitarian crisis; Oyo, Abia, Cross Rivers, Kano, Delta, Bauchi, Rivers and Ogun. The data were critically reviewed and described on the following indicators:
(1) Facilities reporting ART services,
(2) Patients currently on ART, and;
(3) Patients Lost to Follow Up(LFTU).
Lessons learned: In Indicator 1, the numbers decreased in 62.5 % and flattened in 37.5% of the states with humanitarian crisis while it increased in 50% and flattened in 50% of the states without humanitarian crisis.
On indicator 2, the numbers decreased in 50%, flattened in 25%, increased in 25% of states with humanitarian crisis and increased in all the states without humanitarian crisis.
on indicators 3, the numbers increased in 37.5% and flattened in 62.5% of the states with humanitarian crisis and decreased in 62.5% and flattened in 37.5% of the states without humanitarian crisis.
Conclusions/Next steps: The result showed a relationship between humanitarian crisis and disruptions to ART services in the states with humanitarian crisis in Nigeria. This has implication for ART wide service gaps in Nigeria (70%).
Nigeria needs urgently a policy and guideline on HIV services for humanitarian emergencies to address the effect of Humanitarian crisis on HIV service gaps.

THPED579

Civil society mobilization for the Compulsory License in Perú

L. Lopez, J. Llamoza
Acción Internacional para la Salud, Advocacy, Lima, Peru

Background: In Peru, less than 5% of the 30,000 PLWH that receive ARV treatment are on a combination with atazanavir, but in 2014, the procurement of this drug cost more than half of the budget. In 2013, Peru paid the highest price for atazanavir 300mg, compared to all the other countries in the region, and 43.5 times the price of the generic version, also available in Latin America.
Description: Accion Internacional para la Salud (AIS) led meetings and demostrations pressing the government to declare atazanavir public insterest and apply the compulsory license in order to optimize resources, contributing to the sustainability of the response. This demand was supported by many civil society organizations from Peru, Latin America and the world including the significant participation of PLWH.
The Government refused to grant the Compulsory License and asked Brazil for donations until the end of 2017. AIS and other CSO, sponsored by the Congress of the Republic, developed a bill that declares atazanavir to be of public interest, which is expected to be soon debated in plenary.
The company, holder of the patent in Peru, responded to civil society pressure with bias communication campaign. However, in 2015, it had to reduce its price by 35%.
Lessons learned: The compulsory licensing process can have as an intermediate result, significant savings in the purchase of medicines. Between 2015 and 2017, due to donations and price reduction, Peru saved more than US 13 million in the purchase of atazanavir.
During the company campaign to distort information, it was key to strengthen civil society organizations to maintain the pressure for compulsory licensing. The support of international organizations from developed and developing countries, was also of critical importance.
We work on intellectual property literacy, in particularly on TRIPS flexibilities with Government officials, politicians, and other stakeholders.
Conclusions/Next steps: In countries such as Peru, active engagement of civil society organizations should encourage the use of TRIPS flexibilities as the compulsory license to promote competition in the market, in order to have more affordable prices for ARVs and contribute to the sustainability of HIV response.

THPED580

Advocacy for gender affirmation care in the United States: Learning from the injectable estrogen shortage and its implications for HIV

K.J. Smith, MPA[1], T. Horn[2], S. Geffen[3], S. Cahill, Ph.D.[4,5]
[1]Callen-Lorde Community Health Center, Administration/Policy, New York, United States, [2]Treatment Action Group, New York, United States, [3]Fenway Community Health Center, Inc., Health Policy Research, Boston, United States, [4]Fenway Institute, Fenway Community Health Center, Health Policy Research, Boston, United States, [5]National Center for Innovation in HIV Care, Washington D.C., United States

Background: Hormone therapy to affirm gender identity is a medically necessary intervention for many transgender individuals. From 2015 to 2017, a reliable supply of 40 mg/mL injectable estrogen was not available in the United States, and reports suggest that shortages have reoccurred for years and continue in 2018. Lack of access to hormone therapy poses a significant health equity issue for transgender women and presents a structural barrier to HIV prevention and care.
Description: In response to the U.S. shortage, an advocacy campaign was developed to emphasize the importance of injectable estrogen for transgender women, educate the transgender community about the health risks of seeking estrogen outside of clinical settings, highlight the failure of the U.S. Food and Drug Administration's (FDA) and pharmaceutical companies' ability to guarantee a supply of injectable estrogen, and outline ways to remedy the shortage. The campaign included a sign-on public comment, co-authored by two community health clinics and a global treatment advocacy organization, which generated 570 signatories. Other advocacy actions included meetings with FDA representatives, an issue brief, and mobilization efforts to encourage individuals to submit public comment. A short-term solution of restocking all formulations of injectable estrogen was proposed.
Lessons learned: Ineffective FDA and manufacturer responses to repeated estrogen shortages are due partially to a lack of research and approved prescribing guidance that recognizes transgender women as a population dependent on continuous access to preferred hormone therapy formulations. Long-term solutions are needed to address the lack of federally-funded research and, consequently, evidence-based practice, on hormone therapy for gender affirmation.
Conclusions/Next steps: The FDA ensures the safety and efficacy of estrogen for menopausal, cisgender women through on-label use informed by clinical trials, but allows off-label use of estrogen for transgender women to remain the standard of care. Such disparate treatment is a health equity issue and presents barriers to HIV prevention and care for transgender women. Advocates will need to push the FDA to accept responsibility for ensuring correct prescribing and usage information of injectable estrogen and further demonstrate to the FDA that the use of prescription injectable estrogen is common among transgender women and supports positive health outcomes.

THPED581

The Strategy of ART optimization in regional AIDS Centers of Ukraine

M. Parkhomenko, L. Hetman, S. Riabokon, O. Svyryd, M. Varyvoda, L. Lehkostup, T. Starichenko, L. Nychyporenko
State Institution 'Public Health Center' of the MoH of Ukraine, Kyiv, Ukraine

Background: Ukraine is low/middle income country with significant number of people living with HIV (PLWH) with great importance to allocate the scarce state budget resources most effectively with maximum health outcome. At the beginning of 2017, estimated number of PLWH was nearly 238,000 (aged 15+; 0.61% of the total population in this age category). At the initiative of State Institution „Public Health Center of the Ministry of Health of Ukraine" (PHC of MoH) taking into account the access for Ukraine to the possibility of purchasing modern generic antiretoviral drugs (Dolutegravir/DTG), the Strategy of ART optimization was developed.

Description: Trying to bring guidelines in accordance to international recommendations the MoH supported the initiative of adoption of recommendations for the early start of ART for all HIV-infected patients, switching patients to modern treatment regimens, as well as work on a new ART protocol. The recommendations were sent by official letter of MoH to all 25 regional AIDS Centers of Ukraine in the procurement process when requirements for antiretroviral drugs at the expense of State Budget 2017 were developing. The following percentage of antiretroviral drugs was recommended for ART regimens in 2017:
· AZT/3TC - 25%
· ABC/3TC - 10%
· TDF/FTC - 25%
· TDF/FTC/EFV - 40%
· LPV/r - 20%
· EFV - 10%
· DTG - 30%

Lessons learned: The strategy gives possibility for the network of 25 AIDS centers of Ukraine at the same time:
· to use modern and effective drugs (Dolutegravir),
· to reject of highly toxic and outdated ART forms (Nevirapin, Stavudin, Didanosin, Zidovudin),
· to deny of non-recommended ART regimens: (3 NRTI),
· to transit to generic drugs (Abacavir, Abacavir/Lamivudine, Tenofovir/Emtricitabine/Efavirenz, Dolutegravir, Atazanavir)

Conclusions/Next steps: As of September 2017, it was planned to maintain recommendation character of the Strategy about subsequent procurements at the expense of the state, international and non-governmental budgets
(Transition from AZT-regimens in favor of TDF-regimens, rejection from NVP and LPV in 1st line of ART in favor of DTG (recommended) and EFV (alternative). Annex)
The Strategy became a basis for National Plan of ART Optimization for 2018-2020, which has to be approved by the order of MoH.

[Present and future of ART regimens (as of September 2017).]

Policy analysis and indicators of policy effectiveness

THPED582

Better targeting of existing investments in prevention is needed to focus on interventions with proven impact: Prevention resources need to double by 2020 to reach Fast Track targets

J.A. Izazola-Licea, D. Mattur
UNAIDS, Strategic Information, Geneve, Switzerland

Background: The response to HIV/AIDS must address funding of efficient and effective prevention, treatment and discrimination reduction. The resource needs for prevention should be focused on the interventions/services with proven impact and for the population/location where needed. UNAIDS has promoted 5 pillars for effective prevention: investment in prevention for key populations (KP), Condoms, Pre-Exposure Prophylaxis (PrEP), and voluntary medical male circumcision (VMMC) and cash transfers for young women and girls (CTYWG) in high prevalence settings.

Methods: Available data from National AIDS Spending Assessments, GARPR/GAM reporting and program coverage data for each service/intervention and estimated unit costs were used to estimate expenditures in 112 low- and middle-income countries (LMICs) by end-2013 and end-2014, which were the baselines for the 2015-2030 Global Resource Needs estimates to reach the End of AIDS as a Global Public Health threat by 2030. 2013/14 data was compared to 2020 targets.

Results: The estimated prevention expenditures totaled US$3.7 and US$3.7 billion in 2013 and 2014 respectively (17.2% and 17.5% of the total HIV resource availability in LMICs respectively).
The major international sources (PEPFAR and GFATM) disbursed $1.1Bn, $1.3Bn and $1.2Bn in prevention in 2013, 2014 and 2015.
Only 36% in 2013 and 43% in 2014 were invested on the 5 pillars of prevention: $608m and $811m for condoms, $335m and 330m for KP, $400m and $424m for VMMC respectively; additionally $350m and $314m on prevention of parent to child transmission of HIV (PMTCT); the rest in various services.
The estimated resource needs for prevention in LMICs by 2020 are $7Bn: $2Bn for condoms, $2.7Bn for KPs, $560m CTFYWG, $781m for PrEP, $485m for VMCC. $476m would be needed for PMTCT.

Conclusions: There is significant room to improve the allocation of prevention expenditures for a more efficient mix. It is unlikely that more resources from international sources can be made available.
Prevention investments needs to double by 2020 compared to 2013/14; improved allocative efficiency by stopping the expenditures in services with no proven impact can help bridge the gap by almost $2Bn per year. Tracking the resources for effective prevention requires granular programme data to be systematically and periodically monitored.

THPED583

A "foreign agents" law in Russia: Away from the "90-90-90" agenda

P. Aksenov
A Free-Lance Expert, Moscow, Russian Federation

Background: The 2012 Russian legislation obliges any NGO receiving foreign funding and performing 'political activities' to voluntarily register itself as 'foreign agent'. The Russian authorities declared the Law as non-restrictive and serving only to enhance public awareness.
NGOs-'foreign agents' need to meet entangled reporting requirements (estimated for the extra USD 4,000 annually), and to label all their information sources accordingly. Otherwise, they are subject to ridiculously high penalties (min eqv. of USD 5,000 for the Organization and 1,800 - for its Director as an individual). Over 150 NGOs have acquired this status since 2012. There are over 100 cases in the European Court of Human Rights on the subject.

Description: The Law is vague defining 'political activities'. Despite a special provision excluding health care, social prevention, culture and other social fields, it gives wide manipulation tools for the authorities. Seemingly, NGO's work in HIV sphere falls under the exclusion, so no one applied for registration and faced legal actions before 2015.
By 2017, 9 NGOs working in HIV were selectively labeled as "foreign agents" and subjected to penalties. Almost half of them discontinued having faced compelling legal, financial and reputational barriers. The Amnesty International (2015) has said: "While the 'foreign agents law' was intended to discredit and stigmatize NGOs in the eyes of the general public by using the Cold War terminology to brand them as spies, the new law was designed to cut off their funding".
Lessons learned: The "foreign agent" Act is a restrictive step to move civil society away from the State agenda, incl. HIV/AIDS. The relevant label affects NGO reputation closing any domestic funding opportunities. Along with administrative fines, it puts NGOs above the risk tolerance among international donors as well. The Act gives strong message to the NGO community to avoid any public debates or dialogues with the authorities.
Conclusions/Next steps: The Law contradicts the Sustainable Development Goals, 90-90-90 Strategy and fundamental Human Rights provisions. The Russian authorities need to be called for lifting this Act. NGO community need to be empowered to resist the pressure. The linkage between this Act and the rapid HIV growth should be studied.

THPED584

Trends of rapid initiation of antiretroviral therapy among newly diagnosed HIV-positive patients at a tertiary referral center in Taiwan

Y.-C. Huang[1], Y.-Z. Luo[2], P.-Y. Wu[2], W.-C. Liu[1], H.-Y. Sun[1], C.-C. Hung[1], S.-C. Chang[1]
[1]National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, Province of China, [2]National Taiwan University Hospital, Center of Infection Control, Taipei, Taiwan, Province of China

Background: Taiwan has adopted the "treat-all" combination antiretroviral therapy (cART) policy since 2015. Recent WHO guidelines recommend rapid initiation of cART, defined as cART initiation within 7 days after confirmed HIV diagnosis, to reduced morbidity and mortality among HIV-positive patients in 2017. The real-world data of rapid initiation of cART is still unknown in Taiwan.
Methods: Medical records of newly diagnosed HIV-positive patients seeking HIV care at the National Taiwan University Hospital between March 2014 and December 2017 were reviewed and information on clinical characteristics were collected. Patients who were aged < 18 years (n=5), had been treated at another hospital (n=40), or enrolled in a clinical trial (n=48) were excluded.
Results: During the 4-year study period, 614 HIV-positive patients were included, with a mean age of 32.6 years, 98.7% being male and 9.3% with acute HIV infection. The mean CD4 count was 318 (SD, 235) cell/μl and 35.0% of the patients (n=200) had CD4 counts < 200 cell/μl at diagnosis. The mean interval between HIV diagnosis to cART initiation decreased from 128 days (SD, 232) in 2014 to 10 days (SD, 13) in 2017. The percentage of patients with rapid cART initiation increased from 16.9% in 2014 to 55.6% in 2017. The mean interval between HIV diagnosis to viral suppression (PVL < 200 copies/ml) decreased from 227 days in 2014 to 83 days in 2017. The median interval between HIV diagnosis to viral suppression were 107 days among patients who received cART within 7 days of diagnosis and 344 days among patients who initiated cART at least 30 days after HIV diagnosis. Before achieving viral suppression, a total of 37 incident cases of syphilis were identified; the incident rates were similar between patients who were rapid initiators of cART (16.7 per 100 person-years of follow-up [PYFU]) and those who delayed cART (17.1/100 PYFU) (p=0.23).
Conclusions: Increasing trends of HIV-positive patients initiated cART within 7 days of HIV diagnosis in Taiwan, which resulted in a shorter interval from HIV diagnosis to viral suppression. The high rates of syphilis before achieving viral suppression implied potentially onward HIV transmission among those who delayed cART initiation.

THPED585

Not "Siri" but SIMONE! - technological and data-driven solutions to improve treatment retention rates among people living with HIV in Bolivia

C.L. Cardozo Martinez[1], W. Velasquez Martinez[2]
[1]Fundacion Hivos, Direccion, La Paz, Bolivia, [2]Fundacion Hivos, Monitoring an Evaluation, La Paz, Bolivia

Background: Hivos and partners have conducted continuous in-depth assessments to promote and increase retention rates of people living with HIV (PLWHIV) and key populations (KPs) across the HIV treatment cascade in Bolivia. These assessments identified different weak points across the care continuum, and in response a specialized HIV Information System software and online platform for Monitoring and Evaluation -called SIMONE, for its abbreviation in Spanish- was developed to address and identify the gaps and it was implemented since 2011.
Description: Currently, SIMONE links -online and on real time- the information received from the voluntary testing and counselling (VTC) points with the databases with the treatment and follow-up centers in charge of antiretroviral therapy (ART) provision. This linkage allows for personalized follow-up with each of the programme's registered patient living with HIV.
Thanks to this technology, SIMONE is able to generate data that allows the programme to monitor the treatment and health status of patients over time, as well as measure program performance in health facilities and in different geographic settings. This information is available in real time for all users of the system in order to: promote transparency, allow early identification of ART abandonment cases generating automatic alerts for doctors, and facilitate data collection and analysis of all key HIV cascade indicators.
Additionally, the SIMONE system also provides information for the adequate quantification of national needs for reactive drugs and supplies, which allows the programme to procure the required medicines and resources in a timely and cost-effective manner.
Lessons learned: SIMONE's value is ultimately dependent on the quality of information that is uploaded. The programme conducts recurring capacity-building activities with specialized staff to ensure both that only high quality data is uploaded in the system, and also the sustainable and effective use of the resources of the online platform.
Conclusions/Next steps: SIMONE provides the country with updated and accurate information to:
· Maintain high ART retention rates.
· Design strategies to address any potential gaps in HIV treatment cascade.
· Enable evidence-based advocacy by civil society.
· Avoid stock-outs of medicines, resources and reactive.
· Comply with international public health reporting standards.

THPED586

Religion in the United Nations (UN) political declarations on HIV/AIDS: An interdisciplinary, critical discourse analysis

S. Smith[1,2]
[1]UNAIDS, Community Support, Social Justice and Inclusion, Geneva, Switzerland, [2]University of Glasgow, College of Arts, Glasgow, United Kingdom

Background: There is tension around issues of HIV and SRHR at the UN in negotiations that seek to achieve consensus on the text of Political Declarations on HIV/AIDS. The consequences of this are compromises in the text, which lead to limitations in national HIV responses and distorted funding flows. Religion is implicated as a source of this tension and conflict.
Methods: A policy analysis was undertaken of Political Declarations on HIV/AIDS adopted by the UN (2001, 2006, 2011 and 2016). A critical discourse analysis methodology (with a cultural studies lens) was applied; with analysis time frame 2010-2017. This study was framed as embedded research, conducted by an 'insider researcher' with dual positionality as an academic/researcher and practitioner within the UN.

Results: The research identifies four discourses in the declarations and two in the wider AIDS response, relevant to policy tensions; i) public health, biomedical; ii) human-rights, gender equality and community engagement discourses: iii) Political discourses of leadership and national sovereignty; and iv) a traditional religio-cultural discourse. In the wider AIDS response a broad bridge-building religious discourse and secularist discourse are evident, but not in the text of the declarations.
The traditional religio-cultural discourse operates to: limit public health and rights-based approaches HIV prevention; influence the tone of paragraphs, framing women and girls as victims, without agency to exercise rights. Compared against UNAIDS strategies the declarations are missing: commitments to address the risks of key populations to HIV and reference to positive contributions of faith communities to the epidemic. The traditional religious discourse is implicated in gaps in the text on key populations and rights. The broad religious discourse includes supportive approaches to public health, human-rights and gender equality, with the potential to bridge gaps. The dominance of secularism at the UN is implicated in exclusion of the broad religious discourse.
Conclusions: Potential solutions to the tension lie in the broad religious discourse, present in countries which practice 'hard' secularism in political negotiations. Locking a broad religious discourse out of the debate maximises space for the conservative voice to dominate. Are States willing to explore counter-intuitive partnerships and ways of working to reverse this trend?

Monitoring and evaluation of policies and their impact on people living with HIV and key populations

THPED587

Removing legal barriers to reduce HIV-related impacts on key populations in ten African countries

L. Ferguson[1], A. Nicholson[1], D. Patel[2], D. Owolabi[2], A. Saha[2], T. Sellers[2], S. Gruskin[1]
[1]Program on Global Health and Human Rights, Institute for Global Health, University of Southern California, Los Angeles, United States, [2]United Nations Development Program, Regional Service Centre for Africa, Addis Ababa, Ethiopia

Background: As part of the Global Fund's Africa Regional HIV Grant for Removing Legal Barriers to Access, UNDP organized a partnership of organizations to reduce the impact of HIV and tuberculosis (TB) on key populations in ten countries (Botswana, Côte D'Ivoire, Kenya, Malawi, Nigeria, Senegal, Seychelles, Tanzania, Uganda and Zambia). Four sub-recipient (SR) organisations administer the grant: the AIDS and Rights Alliance of Southern Africa (ARASA), Enda Santé (ENDA), Kenya Legal & Ethical Issues Network on HIV and AIDS (KELIN), and the Southern Africa Litigation Centre (SALC). UNDP contracted the Program on Global Health and Human Rights (GHHR), University of Southern California to conduct the baseline assessment.
Methods: Using human rights as the framework for this evaluation, we conducted document and literature reviews, 44 key informant interviews and 16 focus group discussions with project implementers and beneficiaries.
Results: Across the region, the legal and policy environment poses distinct but related challenges ranging from bad and conflicting laws to insufficient knowledge, implementation and use of what good law exists. Key populations have a clear understanding of how their rights are being infringed, but their capacity and ability to organize varies by population and location. Stigma remains a key challenge. Cultural and religious leaders play vital roles in communicating messages about HIV and related issues both positively and negatively.
With attention to the specificity of country contexts and populations, evaluating the impacts of policies on key populations requires looking not only at policies and their implementation or at how they are felt and understood within communities but the linkages between a range of factors and actors.
Understanding these interactions and the actions needed to both foster supportive policies and ensure their impact requires qualitative work that considers the combination of actors, existing and potential engagement and collaborations between government actors and key populations and different processes through which positive change might be achieved.
Conclusions: Lessons from this review can support efforts to implement human rights-based approaches to evaluation bringing into focus not only the effectiveness, relevance and sustainability of activities carried out but attention to equality and non-discrimination, inclusion, participation, and accountability.

THPED588

Does awareness of the 2010 Cross River state HIV/AIDS anti-discrimination law influence the experience of HIV stigma among people living with HIV/AIDS in Cross River state of Nigeria?

O.N.O. Nwankwo[1], S. Ameh[1], C.N. Obionu[2], G.I. Nwankwo[3], E. Ugwu[4], O.A. Nwankwo[5]
[1]University of Calabar Teaching Hospital, Community Medicine, Calabar, Nigeria, [2]University of Nigeria Teaching Hospital, Community Medicine, Enugu, Nigeria, [3]Federal Teaching Hospital, Paediatrics, Abakaliki, Nigeria, [4]Center for Clinical Care and Clinical Research, Enugu, Nigeria, [5]Cedacrest Hospital, Labaratory Services, Abuja, Nigeria

Background: HIV stigma is an impediment to dealing effectively with the HIV epidemic.The Cross River state HIV anti-discrimination law was enacted to safeguard the rights of People living with HIV/AIDS(PLWHA) in the state.The law prohibits individuals/institutions from denying PLWHA of their right to job,healthcare,admissions amongst other rights due to their status.However,the effectiveness of such laws in preventing enacted,internalized or anticipated HIV stigma amongst PLWHA have been largely unexplored.This study aimed to assess the impact of awareness of the law on the experience of HIV stigma amongst PLWHA in the state.
Methods: The study was carried out in two randomly selected local government area in Cross River state,Nigeria.All eligible patients attending the comprehensive HIV clinics in the areas from November to February were asked to participate.Data was obtained from 714 PLWHA through a validated,structured questionnaire.Domains of HIV stigma(anticipated,internalised and enacted)was measured based on agreement/disagreement to a 40-item statements based on participants actual/perceived experiences with stigmatization as described in the validated Berger's HIV stigma scale.Descriptive statistics was carried out using frequencies,proportion while inferential statistics was done with chi-square.
Results: Majority of respondents were female(522,70%),married (387,52%) with an average age of 39 years and a monthly income of below 50 USD/day(466,63%).About half,(56.5%)were aware of the HIV anti-stigma law with a minority(11.9%)having ever read its content.Those with tertiary education were more aware of the law compared to those with no formal education(69.0% vs.41.2%,p< 0.0001).Males were more aware of the law than females(64.9%vs.53.0%,p=0.004),with those accessing care in urban area being more aware compared to their rural counterpart(61.7% vs. 51.1%,p=0.04).There was less experience of overall stigma amongst respondents who were aware of the Law compared to those not aware(36.1% vs.41.0%,p=0.002).On examination of the different domains of stigma,awareness to the law was significantly associated with fewer experience of enacted stigma(p=0.013)and internalized stigma (p=0.003).It was also associated with fewer perceived public attitude stigma-a proximate pointer to anticipated stigma(p=0.001).
Conclusions: This study reveals there is socio-economic disparity in awareness of the law and that knowing about the law is associated with fewer reported stigmatizing experiences.Thus the law has a potential to enforce people´s(PLWHA)recognition of their human rights and reduce feelings of stigmatization.

Independent multi-country review of community engagement in global fund grant processes: Lessons learned, key principles, and ways forward

N. Rafif[1], M. O'Connor[2], L. Messerschmidt[3], C. Baran[4],
CLAC Indépendant Review
[1]*The Global Forum on MSM and HIV, Policy, Oakland, United States,* [2]*ICASO, Toronto, Canada,* [3]*Independant Consultant, Portland, United States,* [4]*Independant Consultant, Los Angeles, United States*

Background: Evidence shows that HIV programs are more effective when affected communities, including men who have sex with men, transgender people, sex workers, people who use drugs, and people living with HIV are involved in their design and delivery. The Global Fund's strategy (2017-2022) includes an objective to support meaningful engagement of key and vulnerable populations and networks in Global Fund-related processes. To help achieve this meaningful engagement objective, the Fund commissioned CLAC (a collaboration among global key population networks) to carry out an independent study to solicit recommendations and identify key strategic actions and mechanisms to ensure greater accountability by the Global Fund.

Methods: The study took place October to December 2016 and involved a desk review of current best practices, 90-minute interviews with 19 key informants nominated by CLAC and representative of all regions, diseases and population groups. The findings from interviews were synthesized into a working definition of meaningful engagement and a draft set of strategic recommendations. 7 one day in-country consultations were hosted (100 participants in total) to review the recommendations and provide additional country specific context.

The recommendations were summarized into five categories, with ten strategic actions and follow-up activities directed at the Global Fund and other partners.

Results: There was considerable consistency and agreement about what will foster better community engagement in Global Fund process. These included

· Effective and proportional representation in planning and decision-making bodies and processes

· Adequate time and resource allocation to communities to understand systems, derive shared priorities, contribute to debate and discussion, and deliver programs

· Independent oversight of grant negotiations and implementation

· Ongoing efforts to strengthen the capacities of community organizations and community leaders, so that they are able to take on increasing responsibilities and have greater impact

Conclusions: This independent review was conducted at the outset of the 2017-2019 funding cycle. Ongoing monitoring is required to ensure that the recommendations are being heard and acted upon. An agreed definition of meaningful engagement and a measurement tool would help to ensure that the meaningful engagement strategic objective is implemented, and the Global Fund is held to account.

THPED590

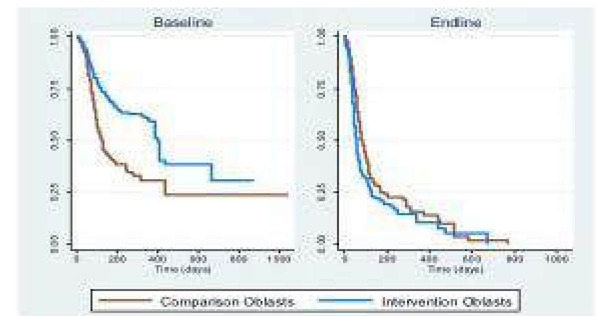
How does integrating HIV and TB services affect health outcomes for HIV-TB coinfected patients in Ukraine? Results from an impact evaluation

S. Agarwal[1], S. Curtis[1], S. Mullen[2], M. Skiles[1], Z. Charyeva[3], K. Brugh[4], C. Suchindran[5], O. Zaliznyak[6], T. Senik[6], P. Brodish[1], S. Eagan[7]
[1]*MEASURE Evaluation, University of North Carolina, Chapel Hill, United States,* [2]*MEASURE Evaluation, John Snow, Inc., Virgina, United States,* [3]*MEASURE Evaluation/University of North Carolina at Chapel Hill, Palladium, Chapel Hill, United States,* [4]*MEASURE Evaluation, Palladium, Chapel Hill, United States,* [5]*University of North Carolina, Department of Biostatistics, Chapel Hill, United States,* [6]*IFAK Institut, Kyiv, Ukraine,* [7]*JSI, Washington, United States*

Background: Ukraine is one of the 10 countries with the highest incidence of multi-drug resistant TB, and about a quarter of all TB patients are also infected with HIV. The USAID-funded Strengthening Tuberculosis Control in Ukraine (STbCU) project aims to strengthen the integration of TB and HIV services to improve timeliness of care and enhance the life expectancy of patients with HIV-TB coinfections. This study evaluated the impact of the STbCU project on HIV and TB service utilization and mortality.

Methods: The study employed a mixed-methods approach, with a quasi-experimental quantitative evaluation design, complemented by qualitative interviews. Using data abstracted from HIV and TB health facility records at baseline in 2012 (N=2,491) and endline in 2015 (N=2,993), we employed a Cox-proportional hazards model with a difference-in-differences approach to assess the impact of integration on screening, diagnostic testing, and treatment for HIV and TB at each of the health facilities.

Results: The HIV-TB integration program was associated with a significant increase in timely initiation of antiretroviral therapy (ART) in HIV centers (HR=1.49, $p<0.05$), and was significantly associated with the likelihood of patients in TB centers receiving a diagnostic HIV test (HR=1.28, $p< 0.05$) and starting ART (HR=2.91, $p<0.001$) (Figure 1). Despite improvements in timely initiation of ART, we did not detect an impact on survival. The survival models did not control for disease severity, due to a large amount of missing data on important variables such as CD4 cell count and TB disease stage.



[Figure 1: ART initiation among coinfected patients at TB dispensaries]

Conclusions: The study suggests that the STbCU program has a positive impact on integrating HIV and TB services and is associated with improvements in timely testing and treatment. At the individual level, having complete records is critical to clinical decision making. At the population level, it is not possible to understand how well interventions are working without complete data. To address this, facility-level measures to ensure data completeness and quality control should be instituted. Efforts to develop digital databases with protocols for sharing confidential patient information across facilities should be strengthened.

THPED591

Effects of PEPFAR's geographic prioritization on HIV and non-HIV services and health systems in Kenya: A mixed methods evaluation

D. Rodriguez[1], C. Mackenzie[2], J. Wilhelm[1], M. Qiu[3], D. Mohan[1], S. Bennett[1]
[1]*Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States,* [2]*Ipsos-Kenya, Nairobi, Kenya,* [3]*ThinkWell Global, Washington, DC, United States*

Background: PEPFAR initiated its Geographic Prioritization (GP) process in 2015 to prioritize its investments in high-burden areas. Seven counties in Northeast Kenya were transitioned to government central support (CS) in September 2016. We conducted a mixed-methods study of USAID-supported CS facilities to assess the GP effects on HIV and non-HIV service delivery and health systems indicators.

Methods: A cluster-based survey of 230 health facilities (173 CS, 57 Maintenance) and analysis of DHIS2 data were combined with national-level qualitative interviews and longitudinal case studies of select facilities. Survey data from health facilities focused on shifts in PEPFAR support for health service delivery and systems. We also extracted four years of service delivery data from DHIS2 for select HIV and non-HIV services. Qualitative data described the GP planning and implementation process.

Results: Service coverage indicators show minimal effects of GP thus far and are confounded by health worker strikes. 10% of transitioned facilities discontinued provision of ART, but DHIS2 data show the number of

patients currently on ART rising faster in CS facilities than in Maintenance following GP (IRR=1.020; p=0.016). Trends in HIV testing, outpatient visits, facility deliveries, and immunizations were either similar or showed CS facilities having better results. Only for ANC visits, which were heavily affected by strikes, were CS facilities worse off (0.987; p=0.024). Study data indicate that effects of GP in CS facilities have been greater, including more health worker terminations, and less training and supervision for HIV services; viral load testing delays; discontinuation of outreach services; and decreasing access to care across population groups. Although county governments have partially stepped in to replace lost support, engagement and investments are uneven.
Conclusions: PEPFAR's GP has not had immediate negative consequences for coverage of HIV or non-HIV services in facilities transitioned to CS in Kenya; however, the losses in health systems investments for HIV services suggest potential for delayed effects of transition resulting in future reduced access and care. As prioritization of HIV efforts receives greater emphasis, more attention must be paid to how to sustain investments in order not to jeopardize gains made thus far to reach 90-90-90.

THPED592

Building bridges to improve HIV-positive women's access to breast-milk substitutes: Research from six different regions in the Russian Federation

N. Petrova[1], E. Shastina[2], E. Ivanova[3], E. Burina[4], N. Sukhova[3], Y. Derevenchuk[5], I. Evdokimova[6], E. King[7], I. Sergeeva[3]
[1]Association EVA, Ulyanovsk, Russian Federation, [2]Association EVA, Orenburg, Russian Federation, [3]Association EVA, St. Petersburg, Russian Federation, [4]Association EVA, Yekaterinburg, Russian Federation, [5]Association EVA, Tyumen, Russian Federation, [6]Nuzhna Pomosh, Moscow, Russian Federation, [7]University of Michigan, Ann Arbor, United States

Background: Russian recommendations on PMTCT state that HIV-positive mothers should not breastfeed. The Action Strategy for Children's Interests includes a point about the government's obligation to provide breast-milk substitutes (BMS) for HIV-positive mothers. Supply of BMS is based on regional budgets. Given high levels of poverty among families with children, < 30% HIV treatment coverage, and frequent interruption in ART after giving birth, there is a risk for ineffective PMTCT. It is unclear to what extent BMS is available in all regions. The goal of our research is to determine the accessibility of BMS in Russia and to identify gaps in provision and perceived quality of BMS.
Methods: Research was conducted in six locations: St. Petersburg, Leningradskaya, Ulyanovskaya, Orenburgskaya, Tyumenskaya, and Sverdlovskaya Regions. Since October 2017, regional activists studied epidemiological data, regulatory documents on assurance of BMS, submitted requests for information to government officials, conducted 20 interviews with specialists at AIDS Centers and clinics, and surveyed 89 HIV-positive mothers.
Results: Regulation of BMS provision varies regionally: available to all women unable to produce milk, offered to low-income women, based on HIV-positive serostatus or other medical reasons. However, it is not always available everywhere. The survey showed that only 44% of HIV-positive women were told during pregnancy about eligibility to receive BMS. Two-thirds received formula, but only 25% received a full supply and 10% only once. Moreover, 55% of the women needed to change formulas because they were not suitable for their infants, but only 14.5% received a different formula. Providers at AIDS Centers who were not providing formula often did not know about algorithms for BMS provision and did not inform women. Some providers reported stockouts in the purchasing of BMS, insufficient quantity, and the inability to provide another formula if one is unsuitable for the child. Some providers supported providing BMS to motivate women to more frequently visit AIDS Centers.
Conclusions: Bridges were built among community activists, HIV-positive women, and healthcare professionals. Joint efforts were made to improve availability of BMS as part of HIV-prevention by fixing the identified gaps in the system. Further advocacy work on improving access to BMS is planned.

THPED593

Evaluating the impact of the Affordable Care Act on HIV trends in the US

S. Shittu[1], P. Fueta[2], O. Adebayo[3]
[1]Emory University, Department of Epidemiology, Atlanta, United States, [2]Emory University School of Medicine, Department of Obstetrics and Gynecology, Atlanta, United States, [3]American University of Antigua, Coolidge, Antigua and Barbuda

Background: HIV remains a major epidemic in the US today. The Affordable Care Act (ACA) stemmed from the need to increase access to health care for more Americans by increasing health insurance coverage. The implementation of the ACA in 2010, and its subsequent expansion ensured that people living with HIV enjoyed greater health insurance coverage. We seek to highlight the impact that the implementation and expansion of the ACA has on the HIV trend in the US.
Methods: The National Health and Nutrition Examination Survey (NHANES) dataset was used to conduct the statistical analysis for this study. The NHANES dataset is cross-sectional and weighted to represent the entire US population. 4 cycles of data were collected; 2007 - 2008 (cycle 1), 2009 - 2010 (cycle 2), 2011 - 2012 (cycle 3) and 2013 - 2014 (cycle 4) and the analysis was conducted in SAS 9.4. We created 2 datasets, 2007 - 2010, and 2011 - 2014 merged by sequence numbers to compare HIV trends before and after the passage of the ACA. Two-sample T-Tests were used to compare the difference in means between HIV status by insurance status in the two datasets.
Results: In the 2007 - 2010 dataset, 73.3% had insurance coverage, and 0.86% of the population were HIV positive. T-Test results revealed no statistical difference between having insurance coverage and HIV status 95% C.I (-0.172 - 0.004) with a p-value (0.0606). While in the 2011 - 2014 dataset, 78.8% had insurance coverage, and 0.89% of the population were HIV positive. T-Test results revealed significant statistical difference between having insurance coverage and HIV status 95% C.I (-0.213 - -0.064) with a p-value (0.0003).
Conclusions: The results highlight the positive change in health insurance coverage and a decline in the HIV trend after the implementation of the ACA. The importance of increasing access to care in the fight against HIV cannot be overemphasized. It is therefore imperative that efforts be made to expand on the gains made by the ACA with the aim of providing coverage to all, especially the people living with HIV.

THPED594

Changes in HIV and Non-HIV service delivery outcomes at the subnational level associated with PEPFAR funding shifts in Kenya and Uganda

E.G. Sutherland, C.B. Agala, K. Xiong, S. Watson-Grant
University of North Carolina at Chapel Hill, Carolina Population Center MEASURE Evaluation, Chapel Hill, United States

Background: In 2014, PEPFAR changed its investment strategy within priority countries. This policy shift increased PEPFAR funds and support to some subnational units (SNU), while leaving investment unchanged—or virtually eliminated—in others, according to HIV disease burden. We aimed to identify shifts in HIV and non-HIV service delivery outcomes associated with changes in PEPFAR investment at the SNU level between 2015-2017 in Kenya and Uganda.
Methods: MEASURE Evaluation extracted quantitative data from relevant national HIV health information system databases (e.g., DHIS 2, TiBU [Kenya], iHRIS, etc.) between 2015-2017. Outcomes examined included HIV testing, initiation on ART, and adherence, ANC 4, or 4+ visits, confirmed malaria cases, and TB case detection rate. Qualitative interviews were conducted with SNU health teams to better understand the trends observed. Longitudinal multivariate analyses were conducted to determine the level of statistically significant changes in study outcomes by year, by change in PEPFAR investment, and for an interaction effect between year and PEPFAR investment level.
Results: Preliminary analyses of data between 2015-2016 suggest changes in PEPFAR investment did not immediately affect the direction of trends observed in HIV or non-HIV outcomes at SNU level. However,

the magnitude of changes in outcomes observed in the post-PEPFAR prioritization period did significantly vary for some health outcomes by level of PEPFAR investment. For example, the proportion of newly identified HIV-positive individuals initiated on ART in Ugandan districts that lost PEPFAR funding increased significantly less than the same proportion in districts with maintained or increased PEPFAR support.
Conclusions: Because there were some significant differences in the magnitude of changes in health delivery outcomes (both HIV and non-HIV) associated with PEPFAR investment status at the SNU, findings suggests that shifts in PEPFAR investment (and by extension other large shifts in donor investment) may contribute to or worsen pre-existing health outcome disparities among subnational units within countries. However, as this study used aggregate SNU data, there could be a lag time between the implementation of investment shifts within countries, implementation of new interventions, and when changes in service delivery outcomes can be observed.

THPED595

The working group on criminalization of HIV exposure: A multisector partnership at the intersection of law, policy and science

É. Fleury[1], L. Pelletier-Marcotte[2,3]
[1]Ministère de la Santé et des Services Sociaux, Direction de la lutte contre les ITSS, Montreal, Canada, [2]COCQ-SIDA, Human Rights and HIV/Aids Sector, Montreal, Canada, [3]Coalition PLUS, Community-Based Research Laboratory, Pantin, France

Background: Canadian criminal law requires people living with HIV to disclose their status before engaging in sexual activities that involve a "realistic possibility" of transmission. Although there is no evidence that criminalization effectively prevents transmission, criminal law is often used in the name of public health. Quebec has the second highest rate of prosecutions for HIV exposure in Canada. The mediatised *D.C.* case spurred a dialogue between Quebec's key stakeholders on criminalization. To further this dialogue, the Working Group on Criminalization of HIV Exposure (WGCHE), a multisector partnership (MP), was established in 2011.
Description: As a MP, the WGCHE aims at solving a complex issue - criminalization of HIV exposure - by involving multiple actors and their specific expertise. The WGCHE advises the Ministry of Health and Social Services (MSSS) and the Ministry of Justice (MJ) on the interplay of justice and public health policies, in light of scientific data and legal principles. Its membership is comprised of twelve (12) public health experts, community members, lawyers, scientists, law enforcement and ministerial representatives (MSSS, MJ and Public Security).
Lessons learned: The WGCHE's mandate evolved to reflect changes in the scientific and legal landscape. From ensuring that the latest scientific data is considered by the criminal justice system, it now aims to highlight the intrinsic relationship between public health, public policies and criminal law. Although prosecutorial guidelines have yet to be adopted, the WGCHE ensures that prosecutors have access to the latest scientific and legal findings by developing and offering them trainings and tools (ex: tables tracking the evolution of jurisprudence/sentencing).
Conclusions/Next steps: Over the years, the WGCHE has allowed for the accommodation of different visions, languages and missions, uniting stakeholders in the pursuit of a common goal. While criminal law is still being used in cases of HIV exposure, the WGCHE is engaged in a long-term dialogue to ensure that the latest scientific advances and public health prevention messages are taken into account. Important gains have been made, and improvement areas will be identified following Justice Canada's recent report on the criminal justice system's response to non-disclosure of HIV.

THPED596

Availability and affordability of ARV´s: Observatory of access to medicines in Argentina

M. Bacigalupo[1], M.L. Di Giano[1,2]
[1]Fundacion Grupo Efecto Positivo, Buenos Aires, Argentina, [2]REDLAM, Buenos Aires, Argentina

Background: Civil Society has a key role in monitoring access and availability of ARV´s in many countries. In Argentina, FGEP holds an Observatory that contributes to monitor access to HIV and Hep C medicines in Argentina, through the analysis of public purchases -since in Argentina State provides ARV´s to 68% of the people living with HIV- and the impact of further policies.
The Observatory has been conducted since 2013, with annual conclusions related not only to availability, but also to affordability of treatments and sustainability of public budgets. This proposal is to introduce the specific methodology and the comparative results for 2016 and 2017.
Methods: The Observatory collects information from different sources related to public information, direct purchases and competitive biddings. The information collected is checked with the National Aids Program official provided information, and compared with international studies and price publications related to generic prices in the world, for instance MSF or Liverpool University.
The information is systematized and related with other macroeconomic variables that can be related with most of middle income countries.
Results: The main findings of the Observatory show:
a) there is a significant difference between prices from public bids or direct purchases,
b) the introduction of new ways of purchasing can drop down prices,
c) pediatric medicines are the most expensive,
d) ARV´s prices rises in general 42%.
Conclusions: Sustainability of health provisions programs is at risk when big pharma and direct purchases increases the annual investment in ARV´s, this risk could be minimized by managing programs with predictability, strategic planning and prices reduction strategies in order to assure access to treatments for PLWH.

THPED597

A critical evaluation of drug policy environment in Ukraine: Implications for prevention and treatment of substance use disorders and HIV among people who use drugs

L. Vlasenko[1], S. Sereda[2], S. Rudyi[3], T. Kiriazova[4], O. Zvinchuk[2], A. Latypov[5]
[1]Independent Consultant, Dnipro, Ukraine, [2]Deloitte Consulting LLP, SAMHSA Ukraine Legal and Policy Project, Kyiv, Ukraine, [3]Independent Consultant, Kyiv, Ukraine, [4]Independent Consultant, Odesa, Ukraine, [5]Deloitte Consulting LLP, Kyiv, Ukraine

Background: Over the past decade, policy improvements in Ukraine have contributed to advancing the treatment and prevention of substance use disorders (SUD). However, people who inject drugs continue to face disproportionate HIV risks in Ukraine, with HIV prevalence rate standing at 21.9% in this group in 2016. In 2017, through SAMHSA Ukraine Legal and Policy Project, we conducted a desk review of policy environment for SUD to identify drug policy impediments and to help systematically address existing challenges.
Description: The review offers a snapshot of advantages and disadvantages of Ukraine's current systems of SUD treatment, prevention, education, and research and evaluates the degree to which the legal and policy environment supports treatment and prevention of HIV and legal protections for people with SUD.
Lessons learned: Ukraine has one of the largest networks of opioid substitution therapy sites in the region, with 177 sites serving 9,615 clients across 25 regions. Methadone, buprenorphine, vivitrol, naltrexone, naloxone and disulfiram are authorized as part of SUD treatment. The country aims to meet the European standards in substance use care and has confirmed its commitment through various international agreements.
However, the focus of SUD policies and response measures is shifted to prohibition and law enforcement, with treatment and social support

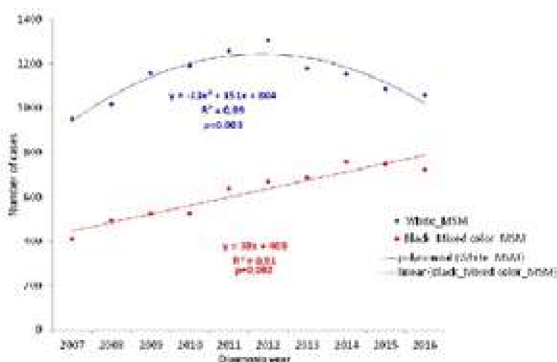
under-prioritized. Evidence-based approaches to SUD treatment are applied on a limited scale, whereas HIV care is poorly integrated into psychiatric services. The SUD treatment curricula of graduate and post-graduate medical institutions are outdated, with content often based on knowledge operationalized during the Soviet era. The SUD care system continues to retain restrictive elements, as evidenced by mandatory patient registration that leads to multiple negative ramifications for SUD patients.
Conclusions/Next steps: Our study provides recommendations for the development of SUD system governance and coordination in Ukraine, including the structure of service providers, the scope of services to be offered in the context of substance-use driven HIV epidemic, human resources and financing issues, and standards of SUD care. This review serves as a basis for informing next steps and for establishing a national unit that would be responsible for effective policy development and organization of services for people who use drugs.

THPED598

Trends of greater vulnerability of black and mixed color men who have sex with men (MSM) to develop and die of AIDS compared to white MSM São Paulo State, Brazil

A. Olhovetchi Kalichman, M.C. Gianna, R. Alencar Souza, A. Tayra, C.S. Bruniera Domingues, S. Romera da Silva, I. De Paula, P. Sousa, N.J. Seabra Santos, M. Vono Tancredi
Centro de Referência e Treinamento DST/Aids, CCD - São Paulo State Health Department, São Paulo, Brazil

Background: Highly Active Antiretroviral Treatment (HAART) is available in the Brazilian Public Health System since 1996 and its indication was expanded to all people living with HIV since 2013, also as a prevention strategy. Before HAART the trends of HIV infection (HIV+), AIDS cases (AC) and AIDS related deaths (ARD) were similar, just lagging in time due to HIV infection physiopathology. After HAART the vulnerability to develop and die of AIDS became highly dependent on having or not an opportune access to HIV diagnosis and treatment. In the State of Sao Paulo MSM are one of the most vulnerable population for HIV/AIDS. We compared the trends of HIV+, AC and ARD among white and black/mixed color (BMC) MSM to access disparities in their vulnerability related to social and institutional racism, stigma and discrimination (R,S&D).
Methods: Trend analysis study performed through polynomial regression models using data from all mandatory reported events of HIV+, AC, ARD among MSM >13years until 06/2017. The numbers of events as dependent variable (Y) were compared between White and BMC MSM using calendar year as independent variable (X). The goodness of fit via r^2 and $p < 0.05$ were used to determine models and data appropriateness.
Results: 24,648 HIV+, 17,549 AC from 2007 to 2016 and 4,818 ARD from 2007 to 2015 reported among MSM were analyzed. Trends of HIV+ grew expressively and linearly among BMC and white MSM [Y=159x+54; r^2=0,97;p=0,001] and [Y=226x+294; r^2=0,96;p=0,001], respectively. AC trends for BMC MSM rose linearly all the period [Y=38x+408; r^2=0,91; p=0,002] and trends for white MSM increased until 2012 and then decreased [Y=-13x^2+151x+804; r^2=0,89;p=0,003] (chart1).



[Graph 1. Trends of AIDS reported cases in MSM by race-color, State of Sao Paulo, 2007 - 2016]

Deaths among white MSM remain stable and among BMC MSM presented increasing trends [Y=9x+ 110; r^2=0, 78; p=0,022].
Conclusions: There is an increasing vulnerability for HIV infection among White and BMC MSM not averted by current prevention strategies. White MSM may have a higher access to HIV test compared to BMC MSM. Despite universal access to healthcare and HAART through a public policy, R,S&D seems to increase individual, programmatic and social vulnerability of BMC MSM to develop and die of AIDS when compared to trends among white MSM.

THPED599

Revisit methadone maintenance treatment service in Indonesia after 14 years

N. Afriana[1], E. Hastuti[2], T. Nisa[3], F. Siagian[4], S. Riyadi[3]
[1]Ministry of Health of Indonesia, National AIDS Program, Jakarta Pusat, Indonesia, [2]Ministry of Health, National AIDS Program, Jakarta Pusat, Indonesia, [3]WHO Country Office of Indonesia, Jakarta Pusat, Indonesia, [4]University of Indonesia, Depok, Indonesia

Background: In 1999, there were estimated 40,000 PWID in Indonesia. Surveys in early 2000, reported 50% HIV prevalence among PWID. Methadone Maintenance Treatment (MMT) Program was piloted by NAP in 2003 as part of harm reduction efforts, with scale up of services in 2006. In 2016 there are 92 MMT services, with 2000 clients across country. The maximum number of clients were 3000 in 2010, and until 2016, the number of clients in MMT program continue to decrease, with 6 months retention in the program only 54%. MOH conducted s to explore contributing factors and develop recommendation for improvement.
Methods: In-depth interview, focus group discussion, literature review and observation were held with various stakeholders at national level, program implementer in hospitals (RS), primary health center (Puskesmas), NGOs, and Client in 3 cities (Jakarta, Denpasar, Makassar). The data or information collected includes: driving and inhibiting aspect of service utilization (based on clients´ and provider´s perspectives), and experience/lessons learned by providers in MMT program.
Results: There were two issues in reduced number of methadone clients;
1. Lack of new MMT client; this results from the change in drug use trend from opioid to amphetamine, National PWID size estimation reduced from 70,000 in 2012 to 30,000 in 2015, that leads to lack of referral from NGO to MMT service.
2. Low retention; due to personal factors such as mixed drug use, bored, perception of more severe withdrawal symptoms and only shift the addiction to methadone, no role model. Health service factors such as tight criteria for take home dose, unmet need of addiction counseling, due to overburdened of health facilities.
Conclusions: MMT services needs to be maintained to continue providing service for the clients and anticipate the trend of drug use back to opioid. A comprehensive program needs to be redesigned to improve retention, such as program involving family to support MMT clients, networking with existing psychological services to provide addiction counseling, evaluate and revisit the implementation of take home dose and adjust/update the MMT national guideline.

THPED600

"Without insurance and without Ryan White and without Virginia ADAP, I don't know where I would be:" clients' perspective on the Virginia AIDS Drug Assistance Program's Affordable Care Act Implementation

K.A. McManus[1], C. Debolt[2], S. Elwood[1], T. Saint-Surin[2], C. Winstead-Derlega[2], R.O. Brennan[3], R. Dillingham[1], T.E. Flickinger[4]
[1]University of Virginia, Infectious Diseases and International Health, Charlottesville, United States, [2]University of Virginia, School of Medicine, Charlottesville, United States, [3]Infectious Diseases Associates of Central Virginia, Lynchburg, United States, [4]University of Virginia, Internal Medicine, Charlottesville, United States

Background: The Virginia AIDS Drug Assistance Program (ADAP) offered to purchase Affordable Care Act Qualified Health Plans (QHPs) for low-income people living with HIV (PLWH). The object of this study was to gain information about the process of enrollment, decision-making, and the experience of enrolling in health insurance.
Methods: English-speaking PLWH, ages 18-64 who were eligible for AIDS Drug Assistance Program-funded QHPs were recruited at three HIV clinics in Virginia. The goal was to enroll ≥5% of those who were eligible for ADAP-funded QHPs in two Virginia Department of Health planning districts. Participants were surveyed about demographics and socio-economic characteristics, and semi-structured interviews were performed. Descriptive analyses were performed for cohort characteristics. Using a Grounded Theory approach, codebooks were generated for the interviews by a single reviewer. The codebook was then refined until excellent reliability between two reviewers was achieved (kappa statistic 0.85). All interviews were coded.
Results: The cohort of 53 participants met our recruitment goal. All participants enrolled in an ADAP funded-QHP. Within the category "Impact to Care After Enrollment," 77% of participants described a positive impact on their medication delivery and 71% described a positive impact on medical providers. The most common perceived and actual barriers to enrollment were concerns about privacy (87%), computer and internet access/literacy (69.2%), mental health (64%), insufficient assistance (64%), substance abuse (62%) and physical barriers (60%). In terms of privacy, the concerns centered on QHP-mandated use of mail-order pharmacies. 67% reported that their ACA/QHP knowledge was formed at their HIV clinic, specifically through working with case managers and social workers.
Conclusions: To our knowledge, this is one of the first studies to examine barriers to enrollment and re-enrollment of QHPs under the ACA, specifically among PLWH. Our findings indicate that addressing privacy concerns may encourage enrollment.
Given the high frequency of privacy concerns, further evaluation of logistics of mail delivery service, or the option to opt-out, would be constructive. Case managers and social workers are often the primary source of knowledge for patients about insurance options and their assistance is crucial for enrollment.

THPED601

Evaluating progress towards triple elimination of mother-to-child transmission of HIV, syphilis and hepatitis B in the Netherlands, 2012-2015

M. Visser[1], C.P.B. van der Ploeg[2], C. Smit[3], F. Abbink[1], C.W.P.M. Hukkelhoven[4], B.H.B. van Benthem[1], E.L.M. Op de Coul[1]
[1]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [2]Netherlands Organisation for Applied Scientific Research (TNO), Leiden, Netherlands, [3]HIV Monitoring Foundation, Amsterdam, Netherlands, [4]Perined, Utrecht, Netherlands

Background: In 2014 the World Health Organisation (WHO) established validation criteria for elimination of mother-to-child transmission (EMTCT) of HIV and syphilis. Additionally, the WHO set targets to eliminate hepatitis, including hepatitis B (HBV). We evaluated to what extent the Netherlands has achieved the combined WHO criteria for EMTCT of HIV, syphilis and HBV.
Methods: Data of HIV, syphilis and HBV infections among pregnant women and children (born in the Netherlands with congenital infection) for 2012-2015, and data required to validate the WHO criteria were collected from multiple sources: the antenatal screening registry, the HIV monitoring foundation database, neonatal registration of congenital syphilis diagnoses, and national HBV notification data.
Results: Prevalence of HIV, syphilis and HBV was stably low among pregnant women and children (Table 1). With a screening coverage of >99% since 2012, the WHO criterion of antenatal screening for HIV and syphilis (>90%) was amply met in the Netherlands. All WHO criteria specific for HIV were also met: antiretroviral treatment of pregnant women of ≥90% (Netherlands: 96% in 2014 and 100% in 2015), case rate of HIV of ≤50 per 100,000 live births (0.57 in 2014 and 0.00 in 2015), and MTCT rate of ≤2% (0.75% for 2014 and 2015 combined). For HBV all targets were accomplished as well: vaccination coverage for children was ≥90% (universal vaccination coverage 93.1% for birth-cohort 2014, birth-dose vaccination and immunoglobulin admission at birth to children of HBV-positive mothers >99% in 2014 and 2015), and prevalence among children was ≤0.1% (0.0% in both 2014 and 2015). For syphilis, data were lacking to validate the goal of ≥95% treatment of syphilis-seropositive pregnant women. Data on congenital syphilis were partly lacking and only included live born children, but the WHO goal of ≤50 cases/100,000 live births is not expected to be exceeded.

	HIV		Syphilis		Hepatitis B	
	Estimated prevalence among pregnant women[a] (n screened positive)	Case rate per 100,000 live births among children[b] (n infections)	Estimated prevalence among pregnant women[a] (n screened positive)	Case rate per 100,000 live births among children[c] (n infections)	Estimated prevalence among pregnant women[a] (n screened positive)	Case rate per 100,000 live births among children[d] (n infections)
2012	0.07% (113)	0.57 (1)	0.06% (101)	1.14 (2)	0.31% (536)	0.57 (1)
2013	0.06% (99)	0.58 (1)	0.08% (135)	1.75 (3)	0.30% (529)	0.00 (0)
2014	0.06% (100)	0.57 (1)	0.06% (97)	1.14 (2)	0.32% (559)	0.00 (0)
2015	0.06% (105)	0.00 (0)	0.06% (98)	n.a.	0.29% (506)	0.00 (0)

Sources: a Antenatal screening registry, RIVM; PSIE process monitor (TNO/RIVM) b HIV monitoring foundation; Stichting HIV Monitoring c Paediatrician data on diagnoses of congenital syphilis; Perined d National notification data; OSIRIS (RIVM) n.a. not yet available

[Table 1 Estimated prevalence for HIV, syphilis and hepatitis B among pregnant women and case rate among children in the Netherlands, 2012-2015]

Conclusions: In the Netherlands, the antenatal screening programme has a very high coverage and the prevalence of maternal HIV, syphilis and HBV is low. Congenital infections are extremely rare. The WHO criteria for validation of EMTCT are met for HIV and HBV, but for syphilis more data are needed to prove elimination.

THPED602

Using the 2016 UN general assembly special session and the 2019 high level meeting on drugs to strengthen the HIV response for people who inject drugs

F. Murphy[1], O. Szubert[2]
[1]Harm Reduction International, Advocacy, London, United Kingdom, [2]Harm Reduction International, London, United Kingdom

Background: In 2014 Harm Reduction International established a global working group of harm reduction organisations and networks of people who use drugs to coordinate advocacy around the 2016 UNGASS on Drugs.
Description: The Group agreed to advocate for
- A health pillar within the UNGASS outcome document
- Commitments to harm reduction within that pillar
Our methods:
· Launching our 10 by 20 campaign, highlighting the disproportionate amount spent on drug control compared to harm reduction
· Launching a Harm Reduction Declaration. Working with high-profile signatories to ensure visibility at key events including the Dec 2015 PCB
· Inserting our messages into UN agencies' pre-UNGASS reports

· Reviewing draft UNGASS outcome documents. Coordinating group members to communicate our edits to governments
· Releasing mathematical modelling showing that with 7.5% of funds currently spent on drug control, we could end AIDS among people who inject drugs by 2030
Outcomes
· The UNGASS document includes a chapter on demand reduction, prevention, treatment and health
· UNGASS para 1(o) urges States to consider "medication-assisted therapy", "injecting equipment programmes", antiretroviral treatment and naloxone, and calls for harm reduction in prisons - both firsts in a UN document on drugs
· Messages on rebalancing funds from drug control to harm reduction included in UNAIDS, WHO, UNDP and GFATM reports.
Lessons learned:
· Pooling members' contacts enabled the working group to reach a significant number of governments with coordinated messages
· Inserting messages into UN agency reports was highly impactful
· The 10 by 20 campaign, Declaration and mathematical modelling research helped profile our messages around major events.
Conclusions/Next steps: By getting key interventions into the UNGASS document, the working group´s advocacy has given governments a clear signal that harm reduction is an acceptable, internationally-endorsed response to drug use.
In our 2018 Global State of Harm Reduction report, HRI will measure whether countries are increasingly implementing these interventions.
Our coordinated work ensured that a growing number of countries are now willing to defend harm reduction. HRI is coordinating a "Champions Network" of governments, UN agencies and civil society to secure further progress at next year's High Level Meeting on Drugs.

THPED603

Monitoring of access to treatment and social services for people living with HIV and its impact on treatment adherence in Russia: Results of SIMONA+ community-based project

A. Petrova[1], S. Prosvirina[2], S. Golovin[3], A. Ladonkin[2]
[1]Patient Controle, Saint Peterburg, Russian Federation, [2]Patient Controle, Kaliningrag, Russian Federation, [3]ITPCru, Saint Petersburg, Russian Federation

Background: Currently, only 35.5% of people living with HIV (PLHIV) in Russia receive treatment. Patients face problems, including drug shortages, regimen changes, treatment initiation deferral. These problems lead to poorer treatment adherence. In 2017, at least 21 903 patients chose to stop treatment, according to Federal AIDS Centre. A monitoring project SIMONA+ was implemented by the patient community Patients Control, with a goal to analyze barriers to specialized medical and non-medical services and develop recommendations, with a focus on vulnerable groups.
Description: The project was realized from June 2016 to January 2018 and consisted of two parts: monitoring and evaluating the quality of medical and non-medical services and implementing activities to improve the service quality, with a focus on key groups. Interviews were conducted with **2387 patients** from 13 regions. Researchers also used interviews with specialists, drug procurement data, as well as replies from government agencies. Based on the monitoring results, meetings with stakeholders and press-conferences were organized in several regions to address the problems identified.
Lessons learned: The research shows that 50% of respondents faced problems with treatment. 25.5% of patients stopped treatment for a long time period. Every third patient needs more information of HIV. Key barriers to HIV treatment, as identified by the analysis, include: lack of access to medical services, delays in delivery of ART, treatment regimen changes, social pressure associated with stigma and discrimination, and lack of awareness about different aspects of HIV among patients.
Conclusions/Next steps: Based on the results, recommendations have been developed for the Russian Ministry of Health, AIDS centres and non-profit organizations:
1) take measures to ensure all PLHIV have access to antiretroviral treatment;
2) ensure emergency funds in regional budgets to cover treatment gaps if they occur due to supply failures on the federal level;
3) promote full use of the existing register of PLHIV;
4) develop a network of infectious disease clinics in remote areas, i.e. decentralization of services;
5) develop non-medical services and ensure multi-professional approach to improve motivation and adherence to treatment.
These recommendations serve as a basis for the activities of the Patients Control movement.

THPED604

An updated assessment of WHO guidelines of treating and preventing HIV infection. Concerns on methodology and transparency

E. Sánchez, F. Rossi, C. Vargas
Fundacion IFARMA, Bogotá, Colombia

Background: To update of the assessment of quality and reporting of "Consolidated guidelines on the use of antiretroviral drugs for treating and preventing HIV infection. Recommendations for a public health approach second edition 2016" by World Health Organization (WHO).
Methods: Two individuals independently assessed the second edition of consolidated guidelines developed by WHO regarding the use of antiretroviral drugs for treating and preventing HIV infection, using the Appraisal of Guidelines for Research and Evaluation instrument (AGREE II). Supplementary material, when available, was examined, such as evidence reviews, feasibility, value and preferences reports.
Results: We established methodological deficiencies in domains 2, 3, 4 and 6 of AGREE II in the guideline quality assessment. On Domain 2 " Stakeholder Involvement. Is impossible to know if members of guideline development group are an appropriate match for the topic and scope On Domain 3 "Rigour of Development", the methods used to search for evidence were not available so neither the criteria for selecting the evidence nor methods for formulating the recommendations were clearly described. In Domain 4 "Clarity of presentations" we found strong recommendations despite low quality of evidence, for instance on oral pre-exposure prophylaxis to prevent HIV infection or use of integrase inhibitor in first line even thought the poor information about it safety. Last, in Domain 6 "Editorial Independence" we found the most worrisome issue related of the lack of transparency and credibility of recommendations, as well as we realize in a previous assessment of the first edition of this guideline. The Guideline Development Group members were not declared all conflict of interest, co-chair of Clinical Guideline Development Group, was board member of a pharmaceutical company that produce one of the recommend treatment. Other advisory members have receipt consulting fees or declared financial support through grants for research not only for pharmaceutical companies but also for funding body.
Conclusions: The overall assessment was 43% and keeping in mind the low quality of the guideline we do not recommend it. Since the independence and transparency of WHO is a matter of global controversy, countries must conduct a revision before the adoption of guidelines.

Interventions to increase demand, uptake, and retention of key populations for HIV services and programmes

THPED605

Empowering community-based organizations led by men who have sex with men to increase demand, uptake and retention in HIV prevention and treatment Côte d'Ivoire: Three years of cascade results

C. Trout[1], A. Kouadio[2], K. Hervé[2], K. Venance[2], Y. Esso[2]
[1]*Heartland Alliance International, Technical, Los Angeles, United States,* [2]*Heartland Alliance International, Côte d'Ivoire, Abidjan, Cote D'Ivoire*

Background: According to a bio-behavioral study in Abidjan-Côte d'Ivoire, in 2012 the HIV prevalence among men who have sex (MSM) was 18%, almost five times that of men in the general population in the same city (4.1%, EDS-2012). Since 2011, Heartland Alliance International (HAI) and the US Centers for Disease Control and Prevention have empowered MSM-led organizations (MSMLOs) in Côte d´Ivoire to increase demand, uptake and retention in HIV/AIDS prevention, care and treatment.

Description: HAI provided technical assistance to MSMLOs on best practices at each step of the "prevention-treatment cascade". MSM peer educators increased the offer of HIV testing services (HTS) in community settings and during home visits. MSM peer navigators led support groups for HIV-positives and provided case management and gender-based violence prevention and care. MSM were significantly involved in the selection of the health centers providing HIV care and treatment services sensitive to their needs.

Lessons learned: Overall, 12,646 MSM were reached through communication strategies between October 2014 and September 2017 (three years) and 45.6% of them (n= 5,224) were tested for HIV. Of those tested, 8.7% (n= 499) were HIV-positive of whom 70.1% (n=350) were linked to care; of whom 95.4% (n=475) started ART. Retention (0-6 months) was high (83.4%, n=242).

ART start and retention were high throughout the three years. Due to greater emphasis on HTS, the total receiving HTS and the percentage of those reached tested tripled by 2017 but HIV+ yield dropped slightly, due to saturation of testing in MSM communities as well as the higher denominator. Linkage also improved in 2017. However, large numbers of MSM who tested positive at night were difficult to refer to clinic the following morning. Note that the project closed and reopened in 2017 Semester 2. (Table 1, Graph 1)

Conclusions/Next steps: In 2018, HAI will target HTS using a risk assessment, expand to new sites and test partners of HIV positives. For linkage, HAI will start ART in the field. Transport support would further improve linkage. HAI will continue to use community-based, peer-led approaches to promote good health outcomes. Finally, there will be greater emphasis on trauma-informed psychosocial support and access to justice.

THPED606

From incarceration to community-based drug addiction treatment in Asia

B. Wang[1,2], T. Cai[1], S. So[3], T. Luo[1], O.T.H. Khuat[4]
[1]*AIDS Care China, Kunming, China,* [2]*International HIV/AIDS Alliance, Brighton, United Kingdom,* [3]*KHANA, Phnom Penh, Cambodia,* [4]*Centre for Supporting Community Development Initiatives, Hanoi, Vietnam*

Background: Faced with ever-increasing HIV and Hepatitis B and C epidemics amongst PWUD, several countries in Asian begun to adopt harm reduction approaches over the past two decades. However, these harm reduction programmes operate only within the drug control framework where compulsory centres for 'treatment' and rehabilitation' remain as the predominant response to drug use. Despite efforts from the UN agencies urging the national government in East and Southeast Asia to close down these centres there is very little progress. Due to lack successful models of community-based drug addiction treatment that can be adapted to use nationally or regionally, some governments' effort trying to close these centres end up replacing them with new prisons or similar closed settings.

Methods: Since 2011, the Alliance has been piloting community-based treatment models in China, Cambodia and Vietnam. These pilot model started in close cooperation with the local police and health authorities. Over 400 opioids users were enrolled into these pilots. These pilots changed the local police´s practices through different models of agreement with the police whereby they stopped arresting people who use drugs and put them in prisons or compulsory rehabilitation centres. Results of these pilots demonstrated significant improvement the adherence of MMT, reduced new HIV infection and at the same time, reduced the consumption of illicit drugs and drug related crime. The Chinese government are now investing their own resources to replicate these pilots.

Results: Harm reduction was initially started in many countries in Asia purely as a way to control HIV among people who inject drugs. The community-based drug addiction treatment pilots have been proven to be effective not only in preventing new HIV infection, but also in reducing drug use and drug related crimes. The model was appreciated by the local police.

Conclusions: International HIV/AIDS Alliance will work with AIDS Care China who piloted the model in China and Cambodia to Thailand and Myanmar. These models primarily target only opioids users. The Alliance is exploring models that can serve other substance users in partnership with local police and public health authorities.

THPED607

Facilitated Transition in closure of trials involving HIV positive participants in Uganda: A grounded theory study

S. Nalubega[1], K. Cox[2], H. Mugerwa[3], C. Evans[4]
[1]Soroti University, Health Sciences, Soroti, Uganda, [2]University of Kent, Kent, United Kingdom, [3]Joint Clinical Research Centre, Kampala, Uganda, [4]University of Nottingham, Nottingham, United Kingdom

Background: Although the field of post-trial care is gaining recognition in clinical research practice, significant gaps exist in the area of post-trial ethical regulation. There is need to develop contextualized guidelines on HIV-related post-trial care in low income settings based on research with relevant stakeholders. This study aimed to understand the closure process of HIV drug trials involving HIV positive participants, and their transition from research-based to non-research based healthcare facilities in Uganda.

Methods: A qualitative grounded theory study was conducted with 21 adult HIV positive post-trial participants and 22 research staff from three clinical trials, between October 2014 and August 2015. Semi-structured interviews were used to collect the data. Ethical approval was gained from the UK and Uganda.

Results: The findings showed that HIV clinical trial closure is a complex transition process for HIV positive participants, involving three main phases. (i) The pre-closure phase represents events occurring before the actual trial closure but that influence post-trial care. These events include personal circumstances such as ill health and low-socio economic status, and structural factors such as care inequalities between research and public health facilities in a low-income context. (ii) The trial closure phase is when participants are exited from the trials and linked to non-research facilities. In this phase, participants undergo an emotional reaction, attributed to the fear of leaving better standards to lower standards of care, and to practical concerns associated with re-establishing in non-research care facilities. (iii) The post-trial phase represents events occurring after trial participants have been linked back to non-research facilities up to 12 months later. Here, participants experience psychosocial challenges such as increased stigma and financial needs. The different needs across the transition process require specific interventions. The transition process is presented as a conceptual model of 'Facilitated Transition'.

Conclusions: The trial closure process of HIV drug trials among HIV positive participants in a low-income setting is complex and can be represented by the model of Facilitated Transition which suggests guidance in implementing a person-centered approach to post-trial care provision. Further research needs to be done to verify the model in other contexts.

THPED608

Young key populations in Myanmar's first national youth policy

M.T. Oo[1], S. Naing[2], E.M. Kyaw[3], L. Hendriksen[4], O. Golichenko[5]
[1]Myanmar Youth Stars Network, Management, Pyay, Myanmar, [2]HIV/AIDS Alliance in Myanmar, Yangon, Myanmar, [3]Myanmar Youth Stars Network, PITCH Advocacy, Yangon, Myanmar, [4]International HIV/AIDS Alliance, Policy (PITCH), Brigton, United Kingdom, [5]International HIV/AIDS Alliance, Policy, Brighton, United Kingdom

Background: In Myanmar sexual and reproductive health and rights information/services for young people are scarce, particularly for key populations (KPs). Until recently, there was no national youth policy.

Description: During 2016 National Youth Forum young people called on government to develop a National Youth Policy. Ministry of Social Welfare led the process in partnership with other ministries, UN Agencies and National Youth Congress. It involved state public consultations with young people, including young KPs. Myanmar Youth Stars Network (MYS) - a network working with and for young KPs affected by HIV/AIDS, including MSM, sex workers, people who use drugs, and people living with HIV - took part at national and state levels. Our main advocacy messages were: meaningful inclusion of marginalized young people to ensure HIV services are friendly for young KPs; ending HIV related stigma and discrimination; the importance of formulating a sustainable financing strategy; and young KPs should be identified as priority groups in the policy. In November 2017, the Government adopted the Youth Policy in Myanmar. Young KPs are priority groups for policy implementation. In 2018 relevant ministries, the UN and youth representatives will develop the National Strategic Plan detailing the package of health and social services available to young people, budgets available and progress indicators.

Lessons learned:
- Multi-lateral partnerships of public and private sectors and youth organizations can effectively influence policy to secure services and rights for young KPs.
- It is important to have a clear vision about anticipated policy change and language in the policy document and communicate consistent messages.
- Influencing by activists from young key populations movements is important at every stage of policy development.
- It is vital to keep broader movement of young key populations informed through diverse communication channels, including social media.

Conclusions/Next steps: The methodology used in influencing the policy development in Myanmar by young people from key populations community can be useful for national and regional policy development in other countries as well as internationally.

Evaluation of Integrated social marketing campaign to promote HIV treatment and health insurance coverage in Vietnam

B. Dao[1], V. Nguyen[1], C. Wong[2], C. Hoang[3], H. Nguyen[3]
[1]FHI 360, Strategic Information, Hanoi, Vietnam, [2]FHI 360, Global Health, Population and Nutrition, North Carolina, United States, [3]Hanoi School of Public Health, Health Policy and Legislation, Hanoi, Vietnam

Background: In 2015, Vietnam still relied on donors for approximately 60% of funding for its HIV response. The country is facing a formidable challenge as these international contributions decline. Social health insurance (SHI) is one proposed solution to address this challenge. However, only approximately 35% of people living with HIV (PLHIV) were covered by SHI in 2015. In 2016, the USAID SMART TA Program led a social marketing campaign in Nghe An and Dien Bien provinces to encourage PLHIV to enroll in treatment and SHI, and reduce healthcare provider and community stigma and discrimination (S&D) against PLHIV. This descriptive qualitative study aimed to explore stakeholder and target audience members' opinions of the campaign's messages and communication channels, and provide insights for future program activities.

Methods: We conducted 23 in-depth interviews and eight focus group discussions with target audiences exposed to the campaign and relevant stakeholders in Nghe An and Dien Bien. Participants included 87 key informants from PLHIV and key populations vulnerable to HIV infection, family members and community networks surrounding PLHIV, health service providers, and representatives of local health authorities. Interview transcripts were imported and analyzed using Nvivo 7 software.

Results: Results show that to all participants the campaign's messages were well-received and they increased awareness of the availability and benefits of HIV treatment as well as SHI. They also gained awareness of the vital role of reducing S&D to encourage PLHIV to integrate into daily social life and HIV interventions. Regarding communication channels, healthcare providers' advice, loudspeakers, posters and leaflets were identified as the most effective methods while TV and radio were mentioned as less effective i. Adding other channels such as text messages via mobile phone and social networks was also suggested.

Conclusions: Results from the study were indicative of the utility of social marketing to promote HIV treatment and SHI enrollment during a transition from donor-funded programs to country management. Multiple communication strategies should be used to reach different target audiences, possibly mobile phone and social networks to expand coverage to otherwise unreachable groups.

THPED610

The peer navigation model successfully facilitates linkage of eligible key populations to treatment in India

B. RaviKumar[1], M. Parthasarathy[1], D. David Raj[1], E. Ajay Kumar Reddy[1], G. Shreenivas[1], B. George[1], J. Baishya[2]
[1]FHI 360, LINKAGES, New Delhi, India, [2]USAID, Project Management Specialist, New Delhi, India

Background: India adopted a 'Test and Treat' policy in April 2017, but operational challenges still constrain implementation at scale, especially among key populations (KPs) - female sex workers (FSW), men who have sex with men (MSM), transgender women (TG) and people who inject drugs (PWID). The national HIV prevention program for KPs is implemented through 'targeted interventions' (TI) that are run by nongovernmental organizations. India has achieved renowned prevention successes among KPs through its domestic investments in the TI program, but has identified a need for stronger links between the TI and antiretroviral treatment (ART) services. About 50% of KP living with HIV (KP PLHIV) are yet to be initiated on ART.

Description: To complement the prevention-focused peer outreach of the TI program, the USAID- and PEPFAR-supported LINKAGES project engaged a Peer Navigator (PN) in each of the 24 TI localities in three high HIV prevalence districts of south India to mobilize and link all KP PLHIV to ART facilities and initiate ART. In close coordination with national program staff of the TI program and ART centre, PN sought to reengage and link to treatment all recorded previously diagnosed and pre-ART KP PLHIV. In the process, the registries were updated to exclude all truly lost-to-follow up and deceased clients.

Lessons learned: By July 2017, 798 KPLHIV were identified, of which 55.5% were already on ART and 30.8% were either deceased or lost-to-follow up. PN followed up the remaining 109 clients; 97% were initiated on ART by September (72 FSWs, 20 MSM, 12 TG and 2 PWID). From September to December, the program detected 61 new HIV infections and 86.8% of them were initiated on ART (47 FSW, 5 MSM and 1 PWID).

Conclusions/Next steps: Results from peer navigation demonstrate the benefits of extending the focus of the KP prevention program to include care and treatment. PN effectively bridged the ART and KP program divisions of the National AIDS Control Organization at facility level and improved access to ART among KPs. LINKAGES advocates that the national KP HIV prevention program integrate peer navigation within the existing package of services for KPs.

THPED611

Improving care and treatment access for children and adolescents affected by HIV/AIDS in Zimbabwe through the expanded integrated model for paediatric AIDS care and treatment (EIP)

R. Malaba, P. Ndlovu
World Education, Inc., Harare, Zimbabwe

Background: Children and adolescents are disproportionately affected by access issues to comprehensive HIV care. In 2014, Zimbabwe was a high burden HIV/AIDS country with 15.4% HIV prevalence, including 2.99% among children aged 0-14 years and 48% of eligible children receiving ART, in comparison to 85% of the adult population. A model to accelerate access to testing and care, particularly in underserved districts, was warranted.

Description: World Education's Bantwana Initiative employed a combined community/facility approach to increase identification, enrolment and retention of HIV+ children and adolescents into a continuum of comprehensive care. From 2014-2017, EIP's community-based interventions across 17 districts centred around training of community cadres to identify children for testing and link children/adolescents living with HIV to health facilities. Case management, parenting education and economic strengthening services engaged caregivers to promote children's treatment adherence. Clinic-based training, mentorship and supportive supervision was deployed to build clinical provider capacity in diagnosing and managing paediatric cases, with Results Based Financing (RBF) to incentivize attainment of paediatric ART benchmarks. EIP supported HIV testing for over 460,000 children; initiated 10,904 children onto ART and increased HIV+ children enrolled in case management from 28% to 86%; provided 3,697 mothers with parenting education and economic resilience groups; trained 3,189 community health workers to support HTS linkage and follow-up; trained 217 nurses in comprehensive HIV service delivery; and provided RBF to 248 clinics.

Lessons learned: Effective engagement of key ministries, local leaders, and community cadres to mobilize communities around paediatric ART, coupled with strong clinical-community linkages contributed to increased community awareness of paediatric and adolescent HIV services. Together with Treat All policy shifts, EIP contributed to universal paediatric ART coverage in project districts, up from 42% coverage in project districts at baseline (2014). A case management approach demonstrated to be an effective strategy for follow-up of affected children and families.

Conclusions/Next steps: Emerging lessons underscore the need for expanding and tailoring HIV case finding and case retention modalities to promote good clinical and social outcomes particularly for adolescents affected by HIV/AIDS. We continue to hone ways to introduce more differentiated care options that better meet the needs of children, adolescents and other key sub-populations.

THPED612

Case management approach to upscale antiretroviral therapy (ART) uptake among people who inject drugs (PWIDs) in HIV high prevalence states, Malaysia

H. Jonet[1], T. Kurusamy[2], M.Y. Yusoff[3], S. Linggie[2]
[1]The Malaysian AIDS Council, Special Initiatives Project, Kuala Lumpur, Malaysia, [2]The Malaysian AIDS Council, Programme, Kuala Lumpur, Malaysia, [3]The Malaysian AIDS Council, Global Fund Project, Kuala Lumpur, Malaysia

Background: In Malaysia, despite decentralized HIV care with free ART for all, ART uptake only 37% (2016) across PLHIV. The Integrated Bio-Behavioural Survey (IBBS) 2014 among Key Populations (KPs), showed HIV prevalence among 1,445 PWIDs is 16.3%, with only 37.8% had tested in the last 12 month for HIV and know their results, and 29.1% of them received ART.

Description: From July 2016, five NGOs from five states with the highest HIV prevalence among PWID (44.7%, 30%, 27.1%, 21.3% and 5.7%) are chosen to implement the Case Management Project funded by the Global Fund.

The case management approach aims to link PWIDs to the public primary healthcare clinics. Community case workers were trained on knowledge on HIV/TB/Hepatitis C/OST treatment and supportive counseling skills to link PWIDs from community to the local clinic. Collaboration standard operating procedures (SOPs) workshops between NGOs and key stakeholders from public clinics under the Ministry of Health were organized at all selected states in July 2016, aimed to increase the understanding of clinics to challenges and facilitating factors of treating HIV positive PWIDs, and streamline the referral process of PWIDs to health clinics. Case workers also serves as facilitators between PWIDs clients and clinics to minimize issues such as miscommunication, stigma and discrimination in the clinic.

Lessons learned: Twenty five case workers has been trained to understand client's needs and the best strategy to link PLHIV among PWIDs to care. Collaboration with the clinics has increase the uptake of HIV screening and OST. However, challenges remained to HIV treatment enrollment as PWID faced additional challenges along the process, such as criminalization of drug use in the country and compulsory drug rehabilitation programme by Anti-Drug Agency, making high drop-out rate of PWID from clinic follow up for ART and OST. Only 22% of HIV+ PWID in the programme has initiated ART in 2017.

Conclusions/Next steps: Malaysian AIDS Council (MAC) will advocate for decriminalizing of drug use from the removing legal barriers activities. Invited on national platform of drug policy reform working group to explore voluntary based treatment centers and rights to access for treatment by PWID. The country is committed Drug Policy Reform.

THPED613

Reaching the unreached through the use of social media application for service delivery

K. Shetty
GAURAV, Grassroot Community Based Organisation, Mumbai, India

Background: In today's digital life, social media and social web-based platforms, provide new opportunities to more effectively reach and engage MSM and transgender populations with HIV testing and treatment. Men who have Sex with Men (MSM) have been impacted extremely by high rates of sexually transmitted infections, including HIV as the community is stigmatized, marginalized and criminalized.

Description: Due to changes in outreach patterns and community access, if is difficult to reach all at-risk individuals through existing physical outreach. Considering the current issue and availability of modern technology platforms, the organization took need-based initiatives to develop the use of social media application i.e. WhatsApp application for service delivery. Methodology adopted:

1. Community Sensitization and Consent
2. Whatsapp group: groups were made by community outreach workers with the purpose of coordination between outreach workers and community members, sharing organizations activities and health camp schedule, social humor and immediate crisis response.
3. Whatsapp broadcast group: Broadcast groups are for HIV testing and Regular medical Checkups

Outputs:

· Out of 2479 registered population, 42% approached for service delivery in from January 2017 until December 2017
· 29% availed HIV Testing service and 36% availed Regular Medical checkups using WhatsApp application
· 207 crisis were immediately responded and successfully solved.

Lessons learned: Social media and Internet and communication technology (ICT) use for HIV prevention isn't just for *fun* - WhatsApp application is a promising way to inform HRGs about their due services such as HIV Testing. - It's an innovative and low-cost approach.

Conclusions/Next steps: Currently, the reach of this application is still less than 50 percent of the population covered. Lessons learned will need to be systemically analyzed to see the feasibility of scaling up this intervention to other sites with a bouquet of specialized services and manpower.

[Adopted Methodology, Data flow and Glimpses of groups and services]

THPED614

Brazilian eHealth strategy for expanding, strengthening and monitoring ART adherence

J.G. Netto[1,2,3], A.F. Kolling[1,4], R. Viana Brizolara[1], M. Camelo Madeira de Moura[1], F. de Barros Perini[1], A. Schwartz Benzaken[1]
[1]Ministry of Health of Brazil, STI, AIDS and Viral Hepatites, Brasilia, Brazil, [2]Global e-Network of People Affected by HIV, Communication, Brasilia, Brazil, [3]Centers for Disease Control and Prevention of United States of America, Curitiba, Brazil, [4]University of Brasilia (UnB), PhD student on Collective Health, Brasilia, Brazil

Background: The Ministry of Health (MoH) of Brazil developed Viva Bem app, in order to provide free tools for strengthening self-care and promoting adherence of people living with HIV (PLHIV) to treatment, and recognizing that technology has been achieving an important space in people´s lives about health care.

Description: The app concept came from the perception that treatment information influences self-care and adherence to antiretroviral therapy. The development was supported by PLHIV of different age groups, genders and social classes. The app uses data from logistic control and

laboratory tests (viral load, CD4 and HIV genotyping) systems, showing tests results, ART information and allowing users to create alerts for medical appointment, laboratory tests and vaccines. The app allows the users to report the quality of health services and side effects. All information is saved in the MoH database.

Lessons learned: Viva Bem was released in September 2017 and has not been yet widely released, however, it already has 3,200 active users and 235,000 pageviews. 81.3% of users have returned to the app in less than 14 days, with 20.4% searching for laboratory test results and 6.3% for information about their medications. Access is higher among young people aged 18 to 34 years (61%), of both genders and all regions of the Brazil (51% from the Southeast region). Feedback from users reinforce the need for greater dissemination of the app. They report the impact that information quality has on their self-care, leading them to make more appropriate decisions about their health care, thus improving adherence to treatment. The tool for access test results in almost 9 days (less than before the app creation) has been the most praised tool.

Conclusions/Next steps: It is recommended to update the app with attractive, informative and useful content for its users and create functions that allow the app to collect more data about the use and about the impact of it in self-care and adherence to treatment, allowing create public policies and develop effective interventions with eHealth strategies.

THPED615

Comprehensive model of the client involvement in HIV testing and treatment: USAID RESPECT Project Experience

O. Vynogradova[1], O. Bryzhovata[2], D. Dmitriev[2], O. Petrash[2]
[1]All-Ukrainian Network of PLWH, Innovative Programs Unit, Kyiv, Ukraine, [2]All-Ukrainian Network of PLWH, Kyiv, Ukraine

Background: The National PLHIV Stigma Index research (All-Ukrainian Network of PLWH, 2016) indicates that HIV-related stigma and discrimination (S&D) resulted in 11% of them deliberately avoid hospitalization and 8% faced with obstacles in access to health services. As of January 1, 2016, the estimates totaled 290,000 of PLHIV in Ukraine (with about 130,000 registered with AIDS centers). As a part of the RESPECT Project, the Network implemented the Client Involvement to Testing and Treatment (CITT) Model aimed at decreasing HIV-related S&D at healthcare facilities (HCF) and reaching the UNAIDS targets 90-90-90.

Description: Six regions of Ukraine have been covered with the CITT Model; 73 pilots HCF from those regions implemented the following activities:

· Gender-sensitive policies and awareness campaign to decrease HIV-related S&D among healthcare practitioners.

· Legal and psychological counseling and assistance for PLHIV; collecting the PLHIV rights violation cases, protecting of the patient rights, and preventing self-stigmatization.

· Provider-initiated HIV testing and counseling (PITC) according to clinical indications and risk behavior screening.

· Approved patient referral algorithm (different for each HCF, according to the local specific features and requirements) aimed at patient successful involvement in testing and treatment.

Lessons learned: The designed and piloted algorithms results are as follows: 5,513 people tested for HIV; out of them, 939 are HIV+ and 797 registered with AIDS service. The overall testing yield is at 17%. The following key findings and lessons learned can be stated:

1. To be efficient, an algorithm must take into account such factors like HCF organizational structure, local situation with ongoing health reform, availability of the rapid HIV test kits, and political factors
2. Trainings and policies for healthcare practitioners increase their motivation to providing PITC
3. The role of a social worker is crucial in algorithm implementation.

Conclusions/Next steps: The CITT Model has proved its effectiveness in Ukraine; its components have been approved by chief doctors of the pilot HCFs. Patient referral algorithms will be used under the USAID HealthLink Project to be launched by the Network in March 2018.

THPED616

Reaching people online via chat-based PrEP navigation services: The PleasePrEPMe: Connect experience

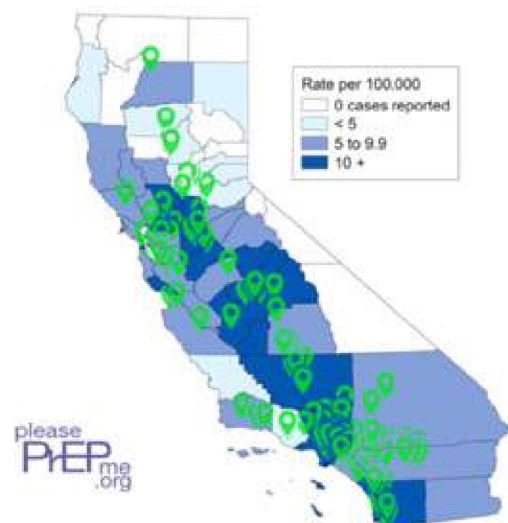
S. Weber[1], Y. Oseguera-Bhatnagar[2], A. McCord[3], C. Romero[4], R. O'Neal[2], L.M. Lazar[1]
[1]University California, Family and Community Medicine, San Francisco, United States, [2]PleasePrEPMe.org, San Francisco, United States, [3]Project Inform/PleasePrEPMe.org, San Francisco, CA, United States, [4]Project Inform/PleasePrEPMe.org, Los Angeles, United States

Background: In the U.S., uptake of PrEP has been high among white, gay men in urban centers where access to PrEP has been fostered by convenient and attractive clinical services supported by benefits navigation. Uptake of PrEP is lower than the CDC's estimated 1.2 million U.S. adults who could benefit; an estimated 98,732 having started PrEP by the end of 2016. Reasons for not using PrEP include lack of PrEP awareness, denial of HIV risk, fear of high costs associated with PrEP care, and concerns about side effects and HIV-related stigma. Navigation is essential to assure potential users access insurance coverage, state and local government PrEP services, and industry-sponsored services. New information reveals people whose social interactions are primarily online are at higher risk of acquiring HIV, highlighting the potential impact of finding novel ways to improve engagement with vulnerable populations through online services.

Description: PleasePrEPMe:Connect provides HIV prevention education and resources through online chat in English and Spanish, aiming to reach potential PrEP users ages 13 and up not already engaged in services. Email, text and telephone follow-up are offered. PleasePrEPMe:Connect utilizes a sexual health coaching model helping Californians find PEP/PrEP services through PleasePrEPMe's directory and resources. Online outreach targets geographic locations and populations currently underserved by existing services. Follow up surveys, assessing satisfaction and referrals to providers, are sent immediately and two weeks following.

	n	%
Total Connects	1119	100%
Connects (relevant chat)	700	63
Non-Connects - excluded from analysis (incomplete/ irrelevant/inappropriate chat)	419	37
Topics* (n=700, more than one topic may be discussed per Connect)		
Navigation (explaining the healthcare and coverage systems)	413	59
PrEP (safety, effectiveness, side effects, dosing, adherence)	181	26
Identified a specific medical provider/clinic	253	37
Spanish chats	62	9
Average length of chat	8 minutes, 24 seconds	

[Characteristics of Connect interactions April 2016- January 2017.]



[2015 Syphilis rates in California counties and PleasePrEPMe:Connect chat locations from April 2017 - January 2018.]

Lessons learned: During April 2017-Jan 2018 there were 128,000 visitors to PleasePrEPMe.org. 86,000 were offered proactive chat. 700 engaged with PleasePrEPMe:Connect -providing navigation and HIV prevention information via chat (44%); email (3.2%); text, social media and telephone calls (1.7%) (Table 1). Connects originated from a wide geographic range across California (Figure 1).
Conclusions/Next steps: While PleasePrEPMe:Connect visitors come from diverse California regions, mapping chats geographically illustrates further outreach is needed to areas of moderate-to-high syphilis incidence. Paid advertising and partnerships with online and offline community leaders have been key in increasing visitors. Further evaluation is needed to understand the service needs of the 22,000+ monthly visitors who do not engage in chat.

THPED617

Leveraging mobile technology through helpline counseling: An effective strategy for accelerating progress toward Ghana's 90/90/90 targets for key populations

E.K. Bruce[1], A. Nyanor[1], P. Tapsoba[1], H. Nagai[1], W. Tun[2], E. Adiibokah[1], K. Eifler[1], S. Maher[3], Y.A. Abdul Rahman[1], D. Nartey[4]
[1]JSI Research & Training Inst., Inc., Accra, Ghana, [2]Population Council, Accra, Ghana, [3]JSI Research & Training Inst., Inc., Washington, United States, [4]JSI Research & Training Institute Inc., Monitoring and Evaluation, Accra, Ghana

Background: The USAID Strengthening the Care Continuum Project (Care Continuum), implemented by JSI, collaborates and builds Government of Ghana and civil society partners' capacity to provide quality, comprehensive, and stigma-free health services for key populations (KPs) and people living with HIV (PLHIV). In Ghana, national policy guidelines protect and promote all basic, fundamental human rights and freedoms, including the rights of vulnerable groups.
Description: Innovative technology approaches are required to better link KP to HIV related services. The Care Continuum trained 16 Helpline Counsellors (HLCs) in stigma reduction and HIV-related issues as an innovative approach to improving KP information and access to HIV services through live, confidential phone-based counseling services across all five regions. The unique feature about the strategy is to provide private, confidential and accessible services to those that may not seek HIV services at facilities. The Helpline Counsellors (HLCs) are also volunteers who work at Anti-Retroviral Therapy (ART) and Sexually Transmitted Infection (STI) clinics, facilitate referrals to their units, provide testing and counselling. They also accompany KP positives to get their laboratory tests, to collect ART drugs, and to help them follow-up treatment and support adherence plans.
Lessons learned:
- KP referrals by HLCs accounted for 42% of all KP enrollment and initiation in treatment from April 2017 to September 2017.
- Helpline counsellors trained in stigma reduction provide quality confidential HIV services to KP.
- Recruiting volunteer professional counselors at ART and STI clinics as HLCs is cost effective because they do not need much additional training.

Conclusions/Next steps:
- Scale-up training of moreHLCs at ART and STI clinics to reach more KP and PLHIV.
- Training HLCs from private sector will expand options for KPs to access quality services.
- This HLC intervention can be scaled at low cost by the government since it builds from current professional volunteers.

THPED618

Dating App to prevent HIV: A Brazilian eHealth project with/for young gay people

J.G. Netto[1], J.A. Paz Paz[1], D. Callisto[1], V. Araujo Rocha[2], A. Schwartz Benzaken[1]
[1]Ministry of Health of Brazil, STI, AIDS and Viral Hepatites, Brasilia, Brazil, [2]Global e-Network of People Living with HIV, Brasilia, Brazil

Background: In Brazil, smartphones and apps are majority used by the youngest ones (higher access in some regions and groups). In this context, the Close Certo project was developed during the Rio 2016 - Olympics and Paralympics games, a non-costs partnership with the Ministry of Health of Brazil (MoH), dating app Hornet, UNAIDS and UNESCO.
Description: A total of 18 young gay men from 15 Brazilian cities volunteered for the project. They previously took part in a youth leadership training. A special miniguide was prepared to support their performance online. Labels and hashtags indicated on their profile availability to chat (some opened-up their serostatus). During 49 days, over 1,000 messages were exchanged between Brazilian Hornet users and volunteers. Four messages were sent to over 1 million users about combination prevention (PEP, PrEP, condom and no discrimination). Daily experiences received mentoring in a confidential WhatsApp group, coordinated by the Ministry's collaborators.
Lessons learned: Dating Apps help to prevent HIV, but one has to understand people´s expectations without pushing too hard: users were looking for sex, not to chat about health. The project helped the Brazilian MoH´s to improve the use of online channels and peer-to-peer strategies to reach out to the young population. New types of activism was also discussed. Some people questioned the project, when #closecerto (a youth slang, that means "nice done") was "tweeted" live in the MoH press conference. Some thought the project was full of prejudice. It was an opportunity to discuss about it with a wide audience. Gradually, internet users began to understand the ideas behind the Close Certo. Among the Hornet users, within the dating app chats, there was no registration of criticism, only supportive messages.
Conclusions/Next steps: eHealth strategies can be combined with traditional communication strategies to spread the message in different ways to reach the HIV epidemic key populations, such as young gay men and MSM. Governments need to know the dating apps culture and develop new online communication strategies (in partnership with the apps). The challenge is to approach the key population through suitable messages.

THPED619

Easy to preach difficult to practice - experiences of evidence-based programme management

D. Kumar[1], V. Arumugam[1], U. Chawla[2], F. Joseph[3], S. Mehta[4], N.R. Manilal[5]
[1]Inida HIV AIDS Alliance, Strategic Information - Monitoring and Evaluation, New Delhi, India, [2]Inida HIV AIDS Alliance, Technical Support, New Delhi, India, [3]Inida HIV AIDS Alliance, Programme, New Delhi, India, [4]Inida HIV AIDS Alliance, Chief Executive, New Delhi, India, [5]Inida HIV AIDS Alliance, Project Director and Principal Investigator: Nirantar, New Delhi, India

Background: With the support of CDC, India HIV/AIDS Alliance implements "Nirantar" programme to complement, aid and supplement National AIDS Control Organisation (NACO) in strengthening specific key areas of National AIDS Programme in selected three states (Madhya Pradesh, Chhattisgarh and Orrisa) through strategic information and utilisation of programmatic data of 124 targeted interventions (TIs) sites for prevention. However, it was observed that there was a huge discrepancy in data entry and data quality in all the three states and only 17% TI provided error-free data out of 124 TIs.
Description: Nirantar has collected and reviewed 0.11 million individuals' data from 124 TIs implemented by NGOs. Further data analysis was carried-out to effectively strategize prevention interventions for all KP groups. This data is currently being exported into a geographical information system (GIS) application to generate and establish evidence-based-monitoring system in the three states. During the review, the gaps were identified, which led to a bit of mistrust in NGOs from government.

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

Nirantar provided capacity building trainings, mentorship, technical support and handholding support to the 124 TIs in the three states on data management, data quality assurance methodology.

Lessons learned: Intensive technical support and capacity building of field level implementers on data management significantly increased quality and timely reporting from 17% to 95%. The analytical engine and GIS software has enabled efficient monitoring of TIs at the state and national level on KP profiling, risk practices, vulnerability aspects and service uptake.

Conclusions/Next steps: By providing technical support Nirantar team was able to regain the faith of government in NGOs and with increased capacities, NGOs also felt confident to do the better implementation for the communities.

THPED620

Desired characteristics of an eHealth enabled peer support intervention to address psychosocial and health system barriers to care among HIV-positive men who have sex with men in China

K. Muessig[1], C. Li[1], W. Dong[1], G. Lei[2], P.Y. Tang[1], D. Giovenco[3], C. Golin[1,4], E. Fisher[1], H. Jiang[5,6]
[1]University of North Carolina at Chapel Hill, Department of Health Behavior, Gillings School of Global Public Health, Chapel Hill, United States, [2]Aibai Culture & Education Center, Chengdu, China, [3]University of North Carolina at Chapel Hill, Department of Epidemiology, Gillings School of Global Public Health, Chapel Hill, United States, [4]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States, [5]Sichuan Provincial People's Hospital, Institute for Emergency and Disaster Medicine, Chengdu, China, [6]University of Electronic Science and Technology of China, School of Medicine, Chengdu, China

Background: Peer support offers tools for reducing multi-level barriers to timely appraisal and initiation of antiretroviral therapy (ART) among men who have sex with men (MSM) in China. Under half of HIV-positive MSM receive a CD4 count within 6 months of diagnosis (a step required to initiate ART as recommended), and less than half who qualify for ART initiate timely therapy. We aimed to understand the roles community-based organization (CBO) practices and internet-based support play in HIV-positive MSM's illness self-management in order to adapt an evidence-based peer support model to assist throughout the continuum-of-care.

Methods: We interviewed HIV-positive MSM (n=30) recruited in Chengdu, China, about interpersonal and systems-level influences on care, quality of life, and desired peer support services. We thematically analyzed transcripts in order to identify ways in which peer support might address barriers and challenges to care.

Results: Participants had lived with HIV 1.6-10.6 years. All were taking ART. Half reported symptoms consistent with mild/moderate depression (PHQ-9) and 5/30 reported thoughts of suicide or self-harm. In managing HIV diagnosis and treatment, participants used a range of support services including in-person (group and individual counseling) and electronic sources (online forums, chat groups, smartphone apps). CBOs were especially helpful post-diagnosis in coping with emotional difficulty and supporting linkage to care. Participants continued to encounter HIV-related fear and discrimination in societal and medical contexts, particularly from providers outside HIV care. Valued peer support functions included: accurate HIV/ART information, mental health support, information on gay/HIV-friendly providers, ART adherence assistance, and accompaniment to medical appointments. Prioritized characteristics of a peer supporter were HIV knowledge, kindness, providing an example of hope, non-judgmental, trustworthy, viewed as an equal, and HIV-positive.

Conclusions: Non-integrated HIV care systems, stigma, fear, distress, and minimal social support hindered service utilization. Peer-support was viewed as a desirable service among HIV-positive MSM to cope with systemic and psychosocial barriers to care. Formalizing an evidence-based peer support intervention for "one-stop" delivery through trusted CBOs could enhance CBO capacity and intervention accessibility and impact. Offering multiple options to engage with peer supporters (e.g. in-person and online, pair and group) could increase appeal and uptake.

THPED621

Nurse-led open access program to improve engagement in HIV treatment and care services at an urban community health center

P. Meacher, L. Comstock, D. Latimer, C. Trossello, A. Radix
Callen Lorde Community Health Center, New York, United States

Background: The HIV treatment cascade, particularly engagement in care, is critical to improved outcomes. Some patients face individual-level and structural barriers to medical visit adherence. Neither a rigid, traditional appointment schedule nor an entirely open-access unscheduled visit model is ideal for all patients. At Callen-Lorde, 20% of patients account for 80% of missed appointments underscoring the need to develop new and flexible models of care access.

Description: Callen-Lorde, a community health center in New York City, provides comprehensive primary care to the lesbian, gay, bisexual & transgender (LGBT) communities and people living with HIV (PLWH). The clinic provides care to 3485 PLWH, predominantly MSM (90%) and transgender women. When reviewing the center's HIV treatment cascade, missed visits predicted loss of viral suppression as well as uptake of preventive care services. We pilot-tested open access same-day HIV appointments. It became clear that most patients preferred traditional scheduled appointments. A more targeted, triage nurse-led open access program (NLOAP) was implemented. Using triage was key as patients missing routine appointments still have interim urgent care needs. Patients missing ≥three scheduled appointments within six months were eligible. Additionally alerts were placed in patients' charts to alert staff that patients were NLOAP eligible should they present for case management, medication refills or other face-to-face or phone encounters. Open-access eligible patients receive same-day appointments that address both urgent and HIV primary care needs with care delivered by a primary care provider with HIV expertise. The patient can opt to obtain all future HIV care using the open-access model or return to scheduled appointments.

Lessons learned:
- Nursing triage is an ideal way to identify patients who are lost to care for referral to an open-access care model
- HIV treatment and care can be successfully delivered in an embedded, targeted open-access program model
- The program was well received by patients and staff
- Patients re-engaged in care have improved HIV-care outcomes
- Some patients have subsequently decided to use only the open access program for HIV services

Conclusions/Next steps: Further study is needed to determine and compare long-term outcomes for patients using only open-access HIV care models, hybrid models or traditional models of HIV care delivery.

THPED622

The role of community organisations in negotiating with generic suppliers for equitable access to PrEP

H. Paynter
Australian Federation of AIDS Organisations, Sydney, Australia

Background: In Australia, most HIV infections occur among gay and bisexual men. With evidence showing that PrEP is highly effective at preventing HIV transmission among this group it is critical that national policies enabling rapid scale up of PrEP among key populations are adopted. Australia's health system subsidises medication on the grounds of cost-effectiveness. Gilead Sciences, the original patent holder of the medication used for PrEP would not release their drugs to the Australian Government at a cost effective price. AFAO introduced competition into the system to break the monopoly and deliver equitable and affordable PrEP access in Australia. The gap between political will and cost effective access to PrEP was resolved through a well-intentioned productive relationship between community, generic manufacturers and government.

Description: The prospect of system failure compromised equitable access to PrEP in Australia. The solution was to create competition and break Gilead Sciences' monopoly. Invariably it is the patent holder that

initiate applications for government subsidisation in Australia. The situation with PrEP was different as the medication was an established drug that had come off patent. AFAO's role was to act as an intermediary and broker conversations between generic manufacturers and the Australian Government. In effect, AFAO supported formal submissions from bona fide generic manufacturers into an unfamiliar process enabling a cost-effective price to be negotiated in competitive pricing environment. As a community-led organisation, AFAO's unique role in establishing a relationship with generic manufacturers and government agencies brokered a solution to an impasse that placed Australia's progress towards meeting its target to end HIV transmission in jeopardy.
Lessons learned: Relations between pharmaceutical companies and HIV community organisations are often characterised through the power imbalance between capital and consumer.
AFAO's role in brokering equitable access to PrEP in Australia challenges this narrative and provides a window into the opportunity for community to influence outcomes that are in the public interest when relations with government and pharmaceutical companies are based on trust and goodwill.
Conclusions/Next steps: The goodwill and trust between government and HIV community organisations in Australia enabled AFAO to engage with genereic providers of PrEP to broker equitable access to PrEP.

THPED623

Equitable access of PMTCT services in humanitarian setting with the involvement of conflict affected community

M.K.M.M. Oo
UNICEF, YCSD, Mandalay, Myanmar

Background: Kachin is one of the states where there is highest HIV prevalence in Myanmar. As long-term conflict between Myanmar Army and KIA starting since June 2011, there are over 31,000 internally displaced persons (IDPs) from 4700 households of 480 villages in Bhamo District, Kachin under non-government controlled area (NGCA). Most of IDPs depend on camp clinics for basic health care and there is no PMCT services before. Only 35% of the area are covered by basic health staff under Ministry of Health & Sports (MOHS) in Government control area(GCA) and some of the rest area are covered only by KBA volunteers.
Description: UNICEF initiated partnership with KBA in delivering PMTCT services for most vulnerable pregnant women at NGCA through agreement with MOHS under equity based humanitarian response in 2013. Kachin Baptist Association, Bhamo (KBA-BD) is the religious organization which is the most influential faith based organization among Kachin ethnic people. KBA-BD is delivering prevention of mother to child transmission of HIV (PMTCT) cascade services including HIV counselling & testing (HCT) by rapid test kits and referral to nearest health facility for confirmation & treatment by 20 trained volunteers from conflict affected community.
Lessons learned: With support of UNICEF, 787, 897, 710 pregnant mothers were tested and positivity rate is 3.2%, 3.4% & 5.2 % in 2015, 2016, 2017 respectively. Positivity rate is very high compared to national HIV prevalence of pregnant women, 0.6% in 2016. The significant achievement is 100% of HIV positive pregnant mothers receiving ARV in every year. Moreover, spouse testing rate is 4.7%, 2.7%, 8.3% in 2015, 2016, 2017 respectively so spouse testing is still needed to be strengthened. Early Infant Diagnosis has been introduced in 2017 and only 13 exposed babies were tested.
Conclusions/Next steps: These above successful evidence-based results are remarkable. Considering the sustainability of partnership and providing health care services at conflict situation in line with Do-No-Harm principle is very critical.

THPED624

Reaching the "unreached": Secondary distribution of needles/syringes for people who inject drugs reduces harm for the most vulnerable in Northeast India

B. George[1], A. Singh[2], P. Goswami[2], S. Mathew[2], N. Bakshi[2], K. Ditya[2], T. H. Holtz[3], S. Kumar[3]
[1]FHI 360, Country Director, India, Gurgaon, India, [2]FHI 360, New Delhi, India, [3]Division of Global HIV and TB, Centers for Disease Control and Prevention, New Delhi, India

Background: In India, harm reduction for people who inject drugs (PWID) focuses on needle-syringe (NS) exchange. An outreach worker provides clean NS to PWID on a daily/weekly basis at injecting sites or drop-in centers (DIC), referred to as primary distribution of NS. However, primary distribution is unable to reach PWID in remote locations in India. PWID face barriers in NS collection including adjusting schedules to outreach hours, travel to DIC, and disruption of outreach by police.
Description: In March 2016, Project Sunrise, implemented by FHI 360 and funded by Centers for Disease Control and Prevention (CDC), addressed the issue of reaching PWID unable to access NS through primary distribution in Northeast India. Consultations were conducted with PWID and local stakeholders. Sites were mapped to ascertain which locations might effectively reach most vulnerable PWID. Subsequently, secondary NS outlets were identified including government facilities, pharmacies and tobacco shops. NGOs provided NS to secondary outlets. PWID were provided coupons for collecting NS based on demand. By December 2017, 40 secondary outlets were established across 13 districts, reaching 1,000 "hard to reach" and "unreached" PWID.
Lessons learned: Prior to establishing secondary outlets, community consultations and site-mapping are essential. Secondary distribution of NS can be successful even in government health facilities (primary health centres and rural clinics) which are often the only access points in remote locations. A coupon system allows clients to collect and track the distribution of NS. Injecting sites are dynamic, thus, a flexible approach of shifting "secondary" sites are important.
Conclusions/Next steps: In cases where primary distribution is unable to reach the most vulnerable populations, secondary distribution of NS should be explored. Secondary distribution outlets provide NS access to PWID, however, it should be ensured that they serve as an entry point for PWID to access other services including HIV testing, medically assisted treatment and linkage to ART. Project Sunrise will advocate with the Indian National AIDS Control Organization to include secondary distribution of NS as a key strategy in national guidelines on HIV prevention and treatment services for PWID in India.

THPED625

Combining research and advocacy is key to the HIV response. An example from Morocco

M. Ahmar[1,2], A. Benmoussa[1], F.Z. Hajouji[1], L. Ouarsas[1], H. Himmich[1], M. Karkouri[1]
[1]ALCS, Casablanca, Morocco, [2]Coalition PLUS Community-Based Research Laboratory, Paris, France

Background: Halting the HIV infection epidemic among key populations can only be achieved by deploying additional and innovative tools, such as Pre-Exposure Prophylaxis (PrEP) and community-based testing. In that sense, Association de Lutte Contre le Sida (ALCS), a major NGO in the field of HIV response in Morocco, has conducted advocacy based on research to enable access to these two strategies to Moroccan key populations.
Description: ALCS conducted from March to October 2015 a research project on community based HIV testing (CBHTS) operated by lay providers in four Moroccan cities. The results were extremely compelling: 68% of beneficiaries tested for the first time and 95% of them reported being satisfied with the experience, citing in particular ease in communication and respect of confidentiality. The study results were used to advocate towards the Ministry of Health (MoH), leading to the authorization given to ALCS to continue CBHTS as per the project before a national roll out.

Regarding PrEP, advocacy enabled research. After mapping of existing obstacles in the Moroccan context, ALCS developed position papers based on scientific proof and institutional recommendations and circulated them to the MoH. As a result, ALCS were cleared to conduct a demonstration project on PrEP, which was elaborated jointly by the research and advocacy teams at ALCS. The project, including 400 MSM and SW, started in May 2017 and is currently ongoing. But, as the preliminary results are already encouraging, PrEP has been included in the 2018-2021 HIV/AIDS National Strategic Plan. The final results of ALCS's study will be used by the MoH to decide future modalities of PrEP implementation.

Lessons learned: These two examples show interdependence of research and advocacy: advocacy enables the development of research projects, whose results legitimize and feed advocacy actions. Under the umbrella of Coalition Plus, ALCS has developed over the past years structured research and advocacy departments capable of working in a coordinated manner.

Conclusions/Next steps: The common experience of research and advocacy of ALCS has already shown impact. Today, ALCS is attempting to consolidate its research and advocacy workforce to achieve new objectives ie implementation of HIV self-testing or exploration of differentiated ARV distribution models.

THPED626

Evaluation of PrEP demand creation and uptake among young women in a Cape Town township: The 3P study

K. Gill[1], L.-G. Bekker[1], M. Duvyer[1], L. Myers[1], J. Morton[2], R. Aunger[3], V. Curtis[3], M. McConnell[4], A. Van der Straten[5], G. Breen[2], J. Baeten[2], C. Celum[2]

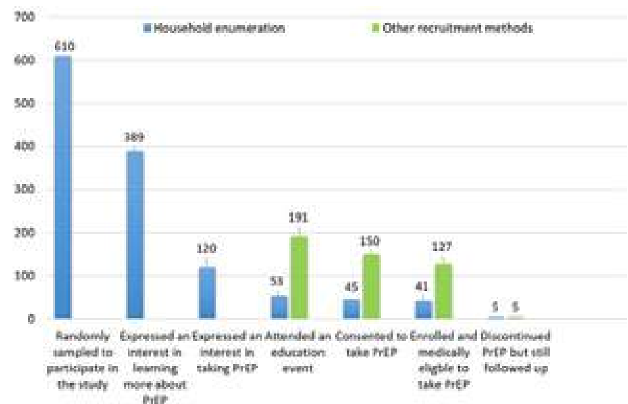
[1]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [2]University of Washington, Seattle, United States, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Harvard University, Boston, United States, [5]RTI International, San Francisco, United States

Background: Oral Pre-exposure prophylaxis (PrEP) may significantly reduce HIV incidence among young South African women, who are particularly vulnerable to HIV infection. While PrEP has proven to be safe and effective, an implementation gap exists in terms of understanding how to create demand for PrEP among young women who would benefit the most. We developed a social marketing campaign to raise awareness and educate young women about oral PrEP, enumerate interest and quantify the PrEP cascade in Masiphumelele Township near Cape Town, South Africa.

Methods: We developed a 90 second video about PrEP in collaboration with McCann Global Health, based on ethnographic research using behaviour-centered design, in Masiphumelele. The 2016 Masiphumelele census estimated 2092 young women ages 16-25, of which a random sample of young women were asked to complete a survey and to watch a short recruitment video. Participants who were interested in learning about PrEP were referred to community PrEP education sessions. Young women who were interested in PrEP and who had not been sampled were also invited to join the education sessions. All young women who had attended sessions were also invited to screen for a PrEP demonstration project.

Results: Of the randomly sampled 610 young women, 389 expressed an interest in learning more about PrEP and of these, 120 reported an interest in taking PrEP. Of those, 50 attended an education session and 45 consented to take PrEP. One hundred and ninety one young women who had not been sampled but were curious about PrEP came to the clinic to attend an educational session and of those 150 consented to take PrEP.

Conclusions: Even though our social marketing campaign was specifically tailored towards our target population, the PrEP cascade showed that the video stimulated interest in PrEP, but a minority followed through for additional information. Other recruitment strategies, including word of mouth, youth community education events, provider discussions, and social media (e.g., Facebook, WhatsApp) were complimentary components of PrEP demand creation.



[Figure 1: The PrEP cascade]

Funding for HIV programmes and services

Costing comprehensive approaches to address human rights-related barriers to HIV services

D. Burrows[1], C. Schutte[2], A. Iovita[3], G. Arustamyan[4], R. Armstrong[2], L. Ferguson[5], A. Stangl[6], R. Jurgens[7]

[1]APMG Health, Sydney, Australia, [2]HEARD, Johannesburg, South Africa, [3]The Global Fund to Fight AIDS, TB and Malaria, Community, Rights and Gender Department, Geneva, Switzerland, [4]The Global Fund to Fight AIDS, TB and Malaria, Community, Rights and Gender Department, Vernier, Switzerland, [5]University of Southern California, Los Angeles, United States, [6]ICRW, Washington DC, United States, [7]The Global Fund to Fight AIDS, TB and Malaria, Grand Saconnex, Switzerland

Background: There is an urgent need to reduce human rights-related barriers to HIV services, such as stigma, discrimination and gender inequality. Despite UN member state commitments to support the 7 key programs known to reduce these barriers (stigma and discrimination reduction; training for health care providers on HR and medical ethics; sensitization of law-makers and law enforcement agents; reducing discrimination against women; legal literacy; legal services; and monitoring and reforming laws, regulations and policies), these programs have nowhere been sufficiently scaled up. Information about how much it will cost to address human rights-related barriers has also been missing. An initiative of the Global Fund to Fight AIDS, TB and Malaria (GFATM) is assessing human rights-related barriers to HIV services and supporting the scale-up of programs to reduce those barriers. A central element of this work is improved costing of these programs to facilitate planning and scale-up.

Description: An extensive consultation identified 20 countries for this effort . Country-level research assessed barriers to HIV services and whether existing programs addressed these concerns. Retrospective costs of existing services were estimated, alongside prospective costs of a proposed comprehensive five-year response to these barriers.

Lessons learned: Preliminary results show that investments in these programs remain far too low, sometimes representing under 5% of reasonable estimates of needed program support. Legal literacy programs are among the least funded. The GFATM's estimates of investment needed over five years for a comprehensive response to rights-related barriers represent a significant increase from current levels, but the expected benefit in terms of access to and retention in HIV services is great.

Conclusions/Next steps: Multi-stakeholder consultations in the 20 countries are finalizing costed five-year plans to scale up programs to reduce rights-related barriers, with intensive evaluation and costing of programs to continue over that period. Additional GFATM funding is being made available to the 20 countries to kick-start the scale-up while contributions from other donors are sought. The unprecedented trove of information on cost of rights-related HIV programs from this initiative will enable modeling of impact of human rights programming and will inform advocacy and program planning worldwide.

THPED628

Contributing one dollar for HIV&AIDS by businesses: A sustainable funding strategy for workplace and community responses

G. Tamale
Federation of Uganda Employers, Business Development Services, Kampala, Uganda

Background: Since 1982 of battling HIV&AIDS burden in Uganda, its financing has largely been relied on external funding of national, workplace and community interventions. With hardly any domestic funding, workplaces are most hit as businesses reluctantly invest in HIV&AIDS programmes despite impacting on productivity and competitiveness.
In 2016 businesses in Uganda coordinated by Federation of Uganda Employers, the private sector one dollar HIV&AIDS initiative (ODI) was started and implemented. ODI aims at mobilizing local domestic resources from private sector organizations and individual business persons to intensify responses targeting working men and women and general population through prevention, treatment and care programmes.
Description: ODI identifies, mobilizes and organizes resources; in-kind & financial to provide meaningful and sustainable investment to HIV&AIDS workplace responses in Uganda targeting employees, suppliers and consumers. This corporate sustainability approach receives contributions of not-less-than one dollar from corporate organizations and business individuals making available technology, learning services and networks. Resources are channeled and invested into prevention, treatment and care of HIV&AIDS infected and affected working population, supply chains and consumers.
Lessons learned: Private sector presents untapped resources, opportunities and tested models to supplement efforts for sustaining gains achieved in the workplace HIV&AIDS responses if well mobilized and coordinated.
-Workplace HIV&AIDS responses require simple innovative approaches with clear demonstration on impact to the bottom line attracting support from multiplicity of partners.
-Efficient and transparent HIV&AIDS financing mechanism processes and systems attract investment from micro, small, medium and large enterprises across sectors including informal economy to invest in HIV&AIDS workplace programmes on a sustainable basis of up to 25% contribution towards national annual HIV&AIDS budget.
-In-kind investment from hotel, media and manufacturing sectors through free seminar venues, Air-time on electronic media and beverage products with HIV&AIDS messages reach the vulnerable adolescent girls and boys who comprise over 70% of general population.
Conclusions/Next steps: -Engaging private sector corporate sustainability approaches can support critical HIV&AIDS gaps and challenges accruing benefits to businesses.
-Demonstrating impact to company´s bottom-line is vital and effective for buy-in to support HIV&AIDS prevention initiatives in their workplaces,
-Robust tools for monitoring and assessing HIV&AIDS investment and spending are critical to attribute sector contribution.

THPED629

There may be harm in not asking: The state of behavioral and social science research in global HIV prevention research

K. Fisher[1], F. Riaz[2], M. Warren[1]
[1]*AVAC, New York, United States,* [2]*AVAC, Policy Data and Analytics, New York, United States*

Background: With recent advances and some disappointing trial results, the biomedical HIV prevention research field has pivoted to examining data on questions of acceptability, adherence, scalability within and across populations and communities at risk of HIV, but the key *behavioral and social science research (BSSR)* is often missing.
Methods: Since 2004, the HIV Vaccines and Microbicides Resource Tracking Working Group has employed a comprehensive methodology to track trends in HIV prevention research. Data on BSSR grants identified as relevant to HIV prevention were collated and analyzed for 2016 for global funders of this work. BSSR was defined as those grants with an explicit focus on the understanding of behavioral or social processes impacting HIV incidence, the understanding of these processes as they affect HIV incidence, or biomedical research in the context of such processes. Research was divided by biopsychosocial, cohort studies, applied research and population-specific implementation research.
Results: In 2016, global funding for HIV prevention biopsychosocial and population-specific applied/implementation research totaled US$59 million, with an additional US$43 million in cohort studies. BSSR research was distributed among biopsychosocial research (31%), trial network core BSSR support (0.3%), cohort studies (35%), non-intervention specific applied research (16%) and implementation research in specific populations (17%). Intervention specific implementation research was highly concentrated in work to test new behavioral interventions or to improve uptake of PrEP (25%) and TasP (59%) through treatment linkage and adherence. For BSSR, where populations were identified, the areas of interest were women (19%), youth (17%), men who have sex with men (20%) and people who use drugs (7%).
Conclusions: Of the US$1.17 billion investment in HIV prevention research in 2016, designated BSSR research comprised approximately 0.5% and biopsychosocial research within that 0.3% of total investment. Yet, BSSR is critical to inform development of treatment and prevention interventions with positive public health impact and effectively engage civil society in development of products through end-user research and community perceptions/opinions. BSSR remains an underfunded and underutilized tool to inform the development of new prevention interventions.

THPED630

Story mapping to maximize resource allocation for key population (KP) HIV intervention in Ghana

D.T. Nartey[1], Y.A. Abdul Rahman[1], F.C. Matute[1], P. Appiah[1], E.K. Bruce[1], K. Eifler[2], H. Nagai[1]
[1]*JSI Research & Training Inst., Inc., Accra, Ghana,* [2]*JSI Research & Training Inst., Inc., Boston, United States*

Background: For over a decade in Ghana, USAID (PEPFAR) and Global Fund (GF) have supported Civil Society Organizations (CSO) in reaching Female Sex Workers (FSW) and Men Who Have Sex with Men (MSM) KP groups with critical HIV and STI information and services at 'hotspots'. The lack of maps or databases to track shifting hotspot locations has resulted in disproportionate KP access to HIV and STI services and ineffective coordination among CSOs and public sector planners. A Story Map of funders, services and hotspots is a powerful tool to depict the KP experience in health service seeking while helping multi-donor agencies effectively coordinate HIV programs for greater impact.
Description: The USAID Strengthening the Care Continuum Project, implemented by JSI, collaborates with and builds the Government of Ghana and CSO partners' capacity to provide quality, comprehensive, and stigma-free health services for KPs. The Project developed an Esri Story Map of funders, 140 service delivery points (SDPs), and 1,700 KP hotspots in collaboration with 13 project grantee CSOs in 23 priority districts by efficiently aggregating information from multiple sources in 2 short workshops in March 2017. CSO participants and the Care Continuum used Google maps on web-browsers and smartphones to navigate, capture, and validate geographic coordinates for SDPs (i.e., public sector KP-friendly health facilities and CSO KP Drop-In Centers). The resulting web-based, password-protected Esri Story Map filters information by KP type, CSO, and funder, while integrating narrative and photos to holistically convey KP's experiences. The map masks locations at close range according to approved IRB protocols to prevent location tracking.
Lessons learned: The Story Map shows hotspots in relation to CSOs funded by USAID / PEPFAR and G, proving useful for stakeholders to better visualize collaboration and overlap areas, and estimate for 90-90-90 activity scale-up.
Conclusions/Next steps: Story mapping is an effective, efficient, replicable tool which improves geo-scope coordination, while protecting KP and hotspot privacy.
Using common apps (i.e., Google Maps) to collect data is low-cost, where data collectors routinely report updated hotspot locations securely to a master map designer without requiring extensive technical support.

Lessons learnt from a novel HIV care & treatment funding model for health facilities in Nigeria, a resource constrained country: The reimbursement for incidentals (RFI) funding model

O. Yemisi Bolanle[1], O. Agbaje[1], I. Osaigbovo[1], I. Utuk[1], C. Momah[1], C. Agbakwuru[2], O. Adedokun[2], O. Olayemi[1], H. Khamofu[1], E. James[3], S. Raj Pandey[1]
[1]FHI 360, Program Management, Garki, Nigeria, [2]FHI 360, Monitoring and Evaluation, Abuja, Nigeria, [3]United States Agency for International Development (USAID), Abuja, Nigeria

Background: Partnership between the governments of Nigeria(GoN) and the United States (USG) through PEPFAR aims to strengthen the capacity to scale up HIV prevention, care and treatment services in Nigeria. While PEPFAR streamlined operational health facility costs in 2014, the GoN was unable to adequately fund operational HIV/AIDS related services. As a result, health workers were using their personal funds to pay for operational costs, and when they could not, services were not administered. In response to these gaps in care, the SIDHAS project developed the RFI funding model to better cover health facility operational costs. The RFI model reimburses health facilities through service providers, for operational cost incurred during service delivery. This abstract describes lessons learnt using the RFI funding model.
Description: The RFI funding model for 13 SIDHAS-supported states in Nigeria was developed to cover operational health facility costs such as telephone cards and home visits for HIV clients, internet costs for data entry, transport for sample logging to hub laboratories, and quality improvement measures. Funds reimbursed for operation costs to each health facility were calculated at 110 naira ($0.31 US) per client currently on ART in comprehensive treatment facilities and 300 naira ($0.83 US) per pregnant woman tested for HIV in PMTCT standalone facilities. The model reimbursed health workers monthly using standardized verifiable activity request and report forms.
Lessons learned: The RFI funding model was adopted in 100% of health facilities across 13 SIDHAS supported states in Nigeria. Health workers were motivated because of the RFI model directly reimburses cost incurred during service delivery. Improvement in service delivery was recorded, resulting in more clients visiting health facilities. Monthly pay out to health facilities improved from an average of 57% in 2015, to 66% in 2016 and 84% in 2017.
Conclusions/Next steps: The RFI model has proven to be a motivational tool for health workers and a means to fund and improve HIV care treatment related operational costs in a resource-constrained country such as Nigeria.

THPED632

Integrating viral hepatitis, HIV, and opioid addiction advocacy: A successful campaign in North Carolina

L. Storrow[1], D. Rowan[2]
[1]NC AIDS Action Network, Raleigh, United States, [2]University of North Carolina at Charlotte, School of Social Work, Charlotte, United States

Background: Since 2010, the North Carolina AIDS Action Network (NCAAN) has led HIV/AIDS treatment and prevention advocacy and lobbying efforts in North Carolina (NC), a state in the southern United States. In 2017, NCAAN expanded its scope of advocacy to include hepatitis testing and linkage to the hepatitis C (HCV) cure. Further, NCAAN explored trends in the opioid addiction epidemic occurring across the state. Due to the impact of the opioid crisis on the middle and upper classes, it has garnered the attention of conservative legislators who are not typically in support of expanded public health policy.
Description: According to NC Department of Health and Human Services (DHHS), HCV is the most common blood-borne infection and accounts for prevalence of 110,000 infections in NC. Nationally, about one-third of people with HIV are co-infected with hepatitis B (HBV) or HCV.
To build support for state funding for treatment and prevention of hepatitis infections, NCAAN hosted six regional advocacy trainings across the state and organized an advocacy day at the NC state capitol. Advocates met with NC legislators to discuss HIV and hepatitis infection trends and how they align with opioid addiction trends. Hepatitis testing was provided in a public location to raise visibility. Professional lobbyists worked closely with key legislators to ensure funding was included in early drafts of the state budget.
Lessons learned: Based on interviews with legislators and lobbyists, NCAAN's advocacy efforts were critical in securing a state appropriation of US $600,000 in 2017 to fund increased hepatitis testing and train staff to link individuals to the cure.
Framing increasing rates of hepatitis as a consequence of the opioid epidemic was politically strategic and helped generate support with more conservative, Republican lawmakers.
The resulting funding appropriation supported increased testing for individuals at high risk across the state, and staff in the two regions of the state with the highest incidence of hepatitis.
Conclusions/Next steps: In 2018, NCAAN will generate and share data on increased HCV testing and cure rates in order to justify continued funding. During the next legislative session, NCAAN will be lobbying for US $1.2 million in state appropriations to support expanded efforts.

THPED633

Active position during procurement process to cut the price of ARVs and diagnostic helps to expand the access to treatment

E. Rudenka
All-UkrainianNetwork of People Living with HIV/AIDS, Kyiv, Ukraine

Background: The corrupted system, economic crisis, are preconditions of unfavorable conditions for procurement of drugs under prices available at the market.
Description: In order to reduce the costs for treatment and monitoring of HIV Network use a various methods:
- regular negotiations with suppliers of antiretroviral drugs and diagnostics with the purpose to less the price. Negotiations even with winners of tender procedure, or with suppliers in conditions of limited market or even in case if market represented only by one (soul) sours. In all negotiations we rely on prices available on world market.
- use of reduction bidding procedure when purchasing ARVs.
- Increase the volume of procurements combining the needs for 2 or even 3 year in one procurement, which also helps to obtain better prices.
- procurement of drug combination instead of separate drugs.
All indicated methods can be effective. The costs spend by Network for ARVs decreased from year to year.
TDF+FTC+EFV (generic) - price per yaer course
$186,24 - 2014
$101,16 - 2015
$101,16 - 2016
$87,24 - 2017
This experience helps to achieve savings, expand treatment, advocate price reduction at the level of other procurement structures, incl. the state level facilities, such as Ministry of health.
The difference in prices between Network procurements an procurements performed by MoH was significant, that fact helps to advocate the transferring of procurement functions from MoH to international procurement agencies, which resulted the huge economy of state budget, and possibility to cover additional need in treatment.
Lessons learned: regardless of the situation on the market, the use of various cost-cutting methods is always relevant, considering the goals of treatment expansion. Low prices can be a good argument for advocating price reductions at the state level procurements in conditions of corrupted system.
Conclusions/Next steps: such an approach will be applied in the further, if possible, not only with the purchase of antiretroviral therapy, but also other products.

Integration of HIV and sexual and reproductive health services

THPED634

Working with children and young people as agents of change for better SRH/HIV health outcomes in Zambia

K. Meda[1], C. Chomba[2], L. Chingandu[3]
[1]SAfAIDS Zambia, Programmes, Lusaka, Zambia, [2]SAfAIDS Zambia, Country Representative, Lusaka, Zambia, [3]SAfAIDS Zambia, Harare, Zimbabwe

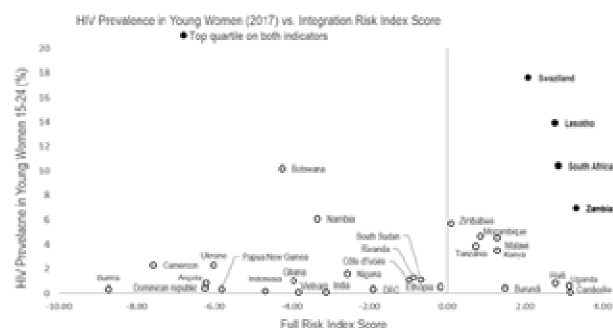
Background: Zambia has a young population which faces various SRH/HIV challenges that threaten their health including early sexual debut, teenage pregnancy, child marriages & HIV. The country has over the past two decades been at the epicenter of the HIV epidemic resulting in 13.3% of young population aged 15-49 estimated to be HIV-positive (ZDHS,2014). The current Ministry of Health policy is to allow adolescents, from the age of 16 years, to access HIV services without parental consent. In addition, the Family Planning policy states that mature minors can also access SRH/HIV services. Although evidence has shown that policy pronouncements have prioritised SRHR services for adolescents and young people but is it a main concern in Zambia? It is against this background that SAfAIDS is implementing a Social Accountability Project whose aim is to strengthen social accountability and advocacy skills of adolescents as the right holders to hold duty bearers accountable in public resource management for SRH/HIV.
Description: SAfAIDS built capacity in 20 Social Accountability Monitors to take action and responsibility for their SRHR and hold government accountable in public resource management in the provision of SRHR services. The monitors analyze the documents from the health facilities such as the activity workplans, annual reports and budgets. Apart from analyzing the documents the monitors also conduct meetings with the youths that access services from the youth friendly corners at the health facilities in order to encourage them to realize their rights to accessing SRH services as a lived capability thus resulting in an increase in the uptake of services.
Lessons learned: Young People can be powerful drivers of social change, when availed with requisite tools, resources, confidence and entry into strategic and safe spaces to navigate the SRH/HIV allocations to meet their specific needs. Evidence generated by the monitors has paved way for evidence based monitoring and engagement of key stakeholders at community level and community level advocacy has resulted in key actions at national level for provision of ASRH services.
Conclusions/Next steps: Hosting of national policy dialogues with key government representatives to ensure the young people access to SRH information, access to care centers and adequate services.

THPED635

Mapping the impact of the expanded Mexico City Policy for HIV/ family planning service integration in PEPFAR-supported countries: A risk index

J. Sherwood[1], A. Sharp[1], B. Honermann[1], C. Horrigan[2], A. Jones[1], C. Cooney[2], G. Millett[1]
[1]amfAR, Public Policy Office, Washington DC, United States, [2]Planned Parenthood Federation of America, Washington, United States

Background: The previously named Mexico City Policy (MCP) -which prohibited non U.S.-based non-governmental organizations (NGOs) from receiving U.S. family planning (FP) funding if they advocated, provided, counseled, or referred clients for abortions, even with non-U.S. funds - was reinstated and expanded in 2017. For the first time, the expanded MCP (EMCP) applies to HIV funding through the President's Emergency Plan for AIDS Relief (PEPFAR) in addition to FP funding. Previous, and more limited, iterations of the policy forced clinic closures and decreased women's contraceptive access, prompting the need to examine where and how the EMCP may impact in-country FP/HIV service integration.
Methods: The likelihood of FP/HIV service de-integration under the EMCP was quantified using a composite risk index for 31 PEPFAR-funded countries. The index combines six standardized indicators from publically available sources organized into three sub-indexes: 1) The importance of PEPFAR for in-country service delivery of HIV and FP services; 2) The susceptibility of implementing partners to the EMCP; and 3) The integration of FP/HIV funds and programming through PEPFAR and USAID.
Results: Countries with the highest overall risk scores included: Zambia (3.3) Cambodia (3.2), Uganda (3.1), South Africa (2.9), Haiti (2.8), Lesotho (2.8), Swaziland (2.1), and Burundi (1.5). Zambia's risk score is driven by sub-index 1, having a high proportion of country HIV expenditures provided by PEPFAR (86.3%). Cambodia and Uganda's scores are driven sub-index 3, with both countries reporting 100% of PEPFAR supported HIV delivery sites were providing integrated FP services in 2017. South Africa's risk score is driven by sub-index 2, where roughly 60% of PEPFAR implementing partners are non U.S.-based NGOs. Of the countries with the highest risk scores, Swaziland, Lesotho, South Africa, and Zambia are in the top quartile of PEPFAR countries for HIV prevalence among young women [Figure 1].



[Figure 1. HIV Prevalence in Young Women (2017) vs. Integration Risk Index Score]

Conclusions: This analysis highlights where and why the EMCP may have the greatest impact on FP/HIV service integration. The possible disruption of service integration in countries with generalized HIV epidemics highlights significant risks. Researchers, national governments and non-U.S. funders can consider these risk factors to help target their responses to the EMCP and mitigate potential harms of the policy.

THPED636

Assessing the family planning needs of people living with HIV in Cross River and Akwa Ibom states, Nigeria

M. Saleh[1], E. Oladele[1], N. Mba-Oduwusi[2], B. Nwagbara[1], M. Salawu[1], A. Abu[3], C. Agbakwuru[1], K. Afolabi[4], D. Ogundehin[5], E. James[5], N. Ojehomon[5], M. Jagun[5], K. Badiane[5], H. Kang[5], H. Khamofu[1], S.R. Pandey[1]
[1]FHI 360, Abuja, Nigeria, [2]Insight Health Consulting, Abuja, Nigeria, [3]FHI 360, Uyo, Nigeria, [4]Federal Ministry of Health, Abuja, Nigeria, [5]USAID, Abuja, Nigeria

Background: There is now sufficient evidence to demonstrate integrating family planning (FP) and HIV services significantly reduces unmet need for FP among HIV infected women. In Nigeria, where unmet need for family planning (16% NDHS 2013) is high, as is HIV prevalence (3.2%, 2014), there is little known about the specific FP needs of people living with HIV (PLHIV). With funding from PEPFAR through USAID, FHI 360, lead implementing partner on the Strengthening Integrated Delivery of HIV Services (SIDHAS) project, conducted a study to determine the FP needs of PLHIV in selected sites in southern Nigeria.
Methods: A cross- sectional quantitative study was conducted in September 2016 in Akwa Ibom and Cross River states in southern Nigeria. Forty-three of the 100 PEPFAR facilities supported for FP-HIV integration were selected based on the criteria of providing both HIV and FP services and having a minimum of 1000 HIV-positive clients on treatment. All PLHIV attending clinic in the two states were approached to participate in the study. Respondents who consented were interviewed using

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

structured questionnaires. Questions asked include current contraceptive use, future fertility desires and linkage to FP. Data were entered in Microsoft Excel and exported to SPSS for descriptive analysis.
Results: Overall, 470 men and women living with HIV were interviewed; 443 (94.3%) were >18 years. Over half of all PLHIV age 18+ (234; 52.8%) were currently using FP. Of these 96.5% (226) used a single FP method mainly: male condoms (79.9%) and injectables (6.8%). Overall 44.7% (198) men and women did not use any FP method. Majority (94.7%) of non-users reported they were neither offered nor referred for FP services by their HIV provider. Amongst HIV positive women aged 18-49 (285), 52.8% (151) reported currently using FP while the unmet need for FP amongst them was 38.2% (49).
Conclusions: The low dual method use, high unmet need and poor linkages between HIV and FP services reported in the study underscore the need for an integrated approach which leverages FP and HIV funding to increase contraceptive uptake. This would reduce unmet need and unintended pregnancies among PLHIV in Nigeria.

THPED637

Integration of prevention of mother-to-child transmission within antenatal and postnatal care, and its impact on HIV service delivery and utilization: A mixed methods study in rural Tanzania and Malawi

F. Hassan[1], J. Songo[2], A. Dube[2], L. Luwanda[3], E. Geubbels[3], T. Kalua[4], J. Renju[5], A. Crampin[2], E. Metta[3], A. Wringe[6]
[1]Ifakara Health Institute, Health System and Impact Evaluation, Dar es Salaam, Tanzania, United Republic of, [2]Malawi Epidemiology and Intervention Research Unit, Karonga, Malawi, [3]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [4]Minstry of Health Malawi, Lilongwe, Malawi, [5]London School of Hygiene and Tropical Medicine, Kilimanjaro, Tanzania, United Republic of, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Integration of prevention of mother-to-child transmission (PMTCT) services within antenatal and postnatal care (ANC/PNC) in African settings has been shown to increase uptake of HIV care and treatment, and to improve retention by reducing clinic visits during pregnancy and postnatal periods. However, there are limited data on how service integration has occurred in practice at the health facility level, and how differences in implementation across settings may influence women's experiences of using these services.
Methods: A mixed methods study was conducted that included a policy review of World Health Organization (WHO) guidance and national HIV policies in Malawi and Tanzania over the period 2003-2017 to capture the evolution in policy adoption pertaining to the delivery of antenatal and HIV services, including those for PMTCT.
In-depth interviews were conducted in rural Malawi (Karonga District) and rural Tanzania (Ifakara District) with health providers (5) and women (15) receiving ANC/PNC, PMTCT or routine ART services to explore their experiences in receiving or providing ANC/PNC and HIV services. Data were recorded, transcribed, translated and analysed thematically.
Results: A review of six (6) national policy documents indicated that Malawi and Tanzania adopted a policy of providing integrated PMTCT and ANC/PNC services since 2005 and 2007 respectively, which was after the first recommendation by WHO in 2004. In Malawi, policy stipulates that following the delivery of the baby, women living with HIV should be transferred to routine ART care at six weeks, in contrast to Tanzanian policy which indicates referral to routine ART services when the child reaches two years and breastfeeding often ceases.
The qualitative data indicated that ANC/PNC providers in both settings appreciated integrated services, and often found means to adhere to policies and guidelines. Pregnant women living with HIV and receiving ANC/PNC services spoke favourably of integration, particularly in rural Tanzania where it enabled them to collect ART without being identified as attending a HIV clinic.
Conclusions: WHO recommendations on integration of PMTCT into ANC/PNC have been adopted differently in Tanzania and Malawi. These differences should be considered when investigating variation in retention in care for HIV-infected mothers across Africa settings.

Assessments of cost-effectiveness: provider and community perspectives

Results of a cost-effectiveness analysis of HIV testing algorithms in Ukraine

M. Duda[1], L. Khomych[1], N. Avaliani[1], V. Galayda[2], A. Latypov[1]
[1]Deloitte Consulting LLP, USAID Project 'HIV Reform in Action', Kyiv, Ukraine, [2]Independent Consultant, Kyiv, Ukraine

Background: Ukraine has one of the highest HIV burdens in Eastern Europe and Central Asia, with an estimated 243,000 people living with HIV. The HIV epidemic is mainly concentrated among key populations. Expansion of HIV diagnostic services is needed to reach the UNAIDS 90-90-90 targets. The Ministry of Health requires a cost-effective strategy to inform evidence-based policy-making and optimize budget allocation. This study estimated and compared the cost of identifying one new HIV-positive case using three testing modalities used in Ukraine: ELISA, Rapid, and 'Sorting' testing algorithms.
Methods: A comparative cost-effectiveness analysis of Ukraine's HIV testing algorithms was conducted in 2017. The model includes programmatic data and data on equipment, supplies, personnel, overhead, and transportation costs associated with these tests. Data were collected from the National Public Health Center of the Ministry of Health, a Regional AIDS Center Laboratory, and NGOs working in prevention programs. Effectiveness, measured as the cost per one new HIV identified case, was compared across the HIV rapid testing, ELISA, and Sorting algorithms. The specificity of the various HIV tests' and HIV prevalence rates were analyzed and included in the calculations.
Results: Based on specificity and sensitivity of the tests and the number of tests required for identifying one new HIV case, rapid HIV tests are cheaper than ELISA across all HIV prevalence rates. The cost of identifying a new HIV case in a population with 1.0% prevalence is 159.1 USD using the HIV rapid testing algorithm, 165.1 USD using the 'sorting' algorithm, and 303.1 USD using the ELISA algorithm (all assuming 99.5% specificity). Comparative analyses indicate large cost savings when using rapid HIV tests versus the ELISA algorithms, ranging from a saving of 10.9 USD in populations with 20% prevalence to 274.2 USD in populations with 0.5% prevalence.
Conclusions: When comparing the cost of detecting a single HIV-positive case, rapid HIV tests are more cost efficient than conventional HIV ELISA tests across all prevalence levels. Expansion of HIV diagnostic services in Ukraine should be implemented using rapid HIV tests in non-specialized healthcare facilities and for outreach interventions.

THPEE639

Reaching the first "90" in HIV testing: Implications for efficiency and resource allocation decisions in Malawi

S. Vyas[1], J. Songo[2], A. Nkhata[2], L. Guinness[1], J. Renju[1], M. Crampin[3], S. Geis[3], T. Kalua[4], J. Todd[1], A. Wringe[1]
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Karonga Prevention Study, Malawi, Karonga, Malawi, [3]Malawi Epidemiology and Intervention Research Unit, Lilongwe, Malawi, [4]Ministry of Health, Lilongwe, Malawi

Background: By 2016 an estimated three-quarters of HIV-positive females and two-thirds of HIV-positive males knew their HIV status in Malawi. Facility-based HIV testing services has been a mainstay for this achievement and for moving further towards the first "90" target. Yet cost information for assessing efficiency and resource requirements of testing and how this might change as the epidemic evolves is limited. This study estimates and compares the levels of technical efficiency of facility-based testing services (routine, e.g. antenatal care, and voluntary) in Karonga district, Northern Malawi.
Methods: Provider costs of HIV testing services (e.g. wages) were collected at five rural facilities with differing characteristics. HIV test prices were collected from the Global Fund price list. Technical efficiency was defined as the cost per HIV case diagnosed. Data on personnel time was

allocated to HIV testing based on patient load. Routine data on persons tested were extracted from facility registers for October 2016-September 2017. The costs per person tested and per person diagnosed with HIV were calculated and compared across the facilities.

Results: A total of 17'655 persons were tested for HIV (range 507-8'950), with 549 (3.1%) cases of HIV detected. The average cost per person tested is $2.19US (range $1.73 - $4.0). The cost per HIV case diagnosed ranges from $55.16-$104.44US. Health worker time, on average, represents 61.2% of the cost per person tested (range 50.7%-77.5%). There is no clear relationship between the cost per HIV case and the number of people tested (scale) or HIV prevalence (Figure 1).

Conclusions: The costs of facility-based testing services estimated in this study are consistent with recent facility-based studies in low income Southern Africa (cost per person tested ranges from $4.24 - $14.12US). Both cost per person tested and cost per diagnosis show considerable variation across the facilities. While scale and HIV prevalence are often considered key drivers of the cost per HIV diagnosis, our data suggests that additional factors, such as the nature of the facility and the interaction between scale of operation and HIV prevalence, may also need to be considered in making resource requirements estimations for reaching the last 90.

Facility / Type of facility	Number of HIV tests (1st / conf.)	% HIV	Total Annual Cost ($)*	Staff cost as a % of total annual cost	Cost per person tested ($)	Cost per HIV case ($)
Sangilo / Faith-based health clinic	507 / 32	6.3%	2,030	77.5%	4.00	63.44
Barracks Military health facility	3,404 / 136	4.0%	11,392	74.2%	3.35	83.77
Chilumba Rural Hospital Public health facility	8,950 / 280	3.1%	15,444	50.7%	1.73	55.16
Fulirwa Public health clinic	1,469 / 35	2.4%	2,859	56.9%	1.95	81.70
St Anne's / Faith-based health facility	3,325 / 66	2.0%	6,893	59.9%	2.07	104.44
Average	3,351 / 110	3.1%	7,724	61.2%	2.19	70.34
Total	17,655 / 549		41,619			
* Unit cost Determine (1st Test) $0.80; Unit cost confirmatory test (Unigold) $1.60; costs of test kits plus personnel (previously shown to be 80-90% of total costs).

THPEE640

PrEP for priority populations in Vietnam has the potential to cost-effectively decrease HIV incidence in urban settings: A mathematical modeling analysis

T. Herrick[1], S. Gannon[1], D. Green[2], H.T. Nguyen[3], K. Green[3], R. Cummings[1], R. Barnabas[4]

[1]PATH, Seattle, United States, [2]University of Washington, Department of Epidemiology, Seattle, United States, [3]PATH, Hanoi, Vietnam, [4]University of Washington, Department of Global Health, Seattle, WA, United States

Background: HIV remains a public health threat in Vietnam, with 11,000 new infections and 7,800 AIDS-related deaths in 2016. The epidemic is concentrated among key populations, especially injecting drug users, men who have sex with men, and female sex workers and their partners. Large cities are a focus of the concentrated epidemic. Antiretroviral pre-exposure prophylaxis (PrEP) decreases HIV acquisition by approximately 90% and has the potential to decrease HIV incidence among key populations.

Methods: We adapted and validated a dynamic HIV transmission model (Spectrum) for the urban centers of Hanoi and Ho Chi Minh City (HCMC). We estimated the impact and cost of PrEP scale-up to key populations between 2018 and 2050. Assuming a five-year scale-up beginning in 2018, PrEP coverage varied, from 20% to 80%, with 80% adherence and 90% efficacy. The cost of PrEP also varied, from US$89 to $246 per person per year. Net costs were calculated as the difference in PrEP and averted antiretroviral therapy costs.

Results: The model predicted that at 60% PrEP coverage among high-risk populations in Hanoi, by 2050 almost 30% of new HIV infections could be averted each year. This could prevent more than 7,200 new infections over the forecast period. Additionally, more than 15% of AIDS deaths could be averted each year and almost 1,800 deaths prevented over the forecast period.

In HCMC, almost 50% of new HIV infections could be averted each year by 2050 by scaling up PrEP to 60% coverage in high-risk populations. This could lead to prevention of more than 24,300 new infections over the forecast period. In addition, almost 30% of AIDS deaths could be averted each year and more than 5,500 deaths prevented by 2050.

Overall, with low PrEP costs, scaling up PrEP could cost-effectively prevent incident HIV infections (incremental cost-effectiveness ratio: $4,500/incident case averted). PrEP would be more cost-effective in HCMC than in Hanoi, due to higher HIV prevalence in HCMC.

Conclusions: PrEP has the potential to cost-effectively, substantially reduce HIV incidence and HIV-associated mortality in a concentrated epidemic setting. Targeting PrEP to key populations in an urban setting could be a high-yield strategy.

THPEE641

Cost and efficiency of short messing service (SMS) and peer navigation to improve linkage and retention for patients newly enrolled in HIV care in South Africa

S.B. Shade[1,2], E. Agnew[2], J. Grignon[3], H. Gilmore[2], J. Sumitami[3], M.-J. Ratlhagana[3], W. Steward[2], S. Lippman[2]

[1]University of California, San Francisco, Institute for Global Health Sciences, Department of Epidemiology and Biostatistics, San Francisco, United States, [2]University of California, San Francisco, Division of Prevention Science, Department of Medicine, San Francisco, United States, [3]University of Washington, International Training and Education Center for Health, Pretoria, South Africa

Background: Short messaging service (SMS) and peer navigation (PN) show promise in facilitating linkage to and retention in HIV care. However, the cost and efficiency of these interventions have not been established in sub-Saharan Africa where cost-effective programs to improve care engagement are urgently needed. We estimated the incremental cost per patient linked to and retained in care within SMS and PN interventions among patients newly HIV diagnosed in North West Province, South Africa.

Methods: We conducted a three-arm randomized trial in 17 clinics in Bojanala Platinum District comparing standard of care (SOC, 4 clinics), an SMS intervention (SMS, 6 clinics) and an SMS plus peer navigation in-

tervention (PN, 7 clinics). Participants were over 18 years and diagnosed with HIV in the prior year. We conducted standardized micro-costing and time-and-motion studies to determine the incremental costs of the two interventions. We employed chart abstraction to assess linkage (within 30 days) and 12 month retention (Pre-ART clients: biennial CD4 screening, spaced 4-8 months apart; ART clients: 4 clinic visits over 12 months, < 4 months between visits). We employed generalized estimating equations to assess outcomes and estimated the incremental cost and efficiency of SMS and PN compared to SOC.

Results: We enrolled 752 individuals across trial arms (see Table). Over the entire trial, the incremental costs (over SOC) of SMS were $19,458 and the incremental costs of PN were $151,286. Compared to SOC: PN, but not SMS was associated with increased linkage to (OR=2.70, 95% CI=1.57-4.96; OR=1.64, 95% CI=0.87-3.10, respectively) and retention in care (OR=2.90, 95% CI=1.67-5.06; OR=1.30, 95% CI=0.78-2.18, respectively); the incremental cost per patient of PN ($511) was higher than the incremental cost per patient of SMS ($67); the incremental cost per patient linked of PN was $1251; and the incremental cost per patient retained of PN was $1428.

Arm	N	Patients Linked	Patients Retained	Incremental Cost Overall	Incremental Cost per Patient	Incremental Cost per Patient Linked	Incremental Cost per Patient Retained
PN	296	204 (69%)	183 (62%)	$151,386	$511	$1251	$1428
SMS	289	159 (55%)	155 (54%)	$19,458	$67	Not Effective	Not Effective
SOC	167	83 (50%)	77 (46%)	--	--	--	--

[Enrollment, Outcomes and Incremental Cost and Efficiency of SMS and PN]

Conclusions: Although the SMS intervention cost less than the PN intervention to implement, only the PN intervention was effective at increasing linkage to and retention in care and thus an efficient use of resources. It will be important to test how these interventions can be used together to maximize both efficiency and cost-effectiveness.

THPEE642

Discontinuing cotrimoxazole preventive therapy in ART-stable HIV-positive adults in Uganda: An economic evaluation

S. Torres-Rueda[1], P. Munderi[2], J. Levin[3], J. Lutaakome[2], Z. Anywaine[2], A. Abaasa[2], R. Kasirye[2], S. Sweeney[1], K.R. Katumba[2], S. Settumba[2], A. Vassall[1]
[1]London School of Hygiene & Tropical Medicine, Global Health and Development, London, United Kingdom, [2]MRC/UVRI Uganda Research Unit on AIDS, Entebbe, Uganda, [3]School of Public Health, University of Witwatersrand, Johannesburg, South Africa

Background: Cotrimoxazole preventive therapy (CPT), which reduces opportunistic infections and malaria, is part of the package of care for HIV-positive people in Africa. However, the added value of long-term CPT has been questioned given its cost, related haematological adverse events, and the wide availability of effective antiretroviral therapy (ART). A placebo-controlled trial in Uganda investigated the safety of discontinuing CPT in ART-stable patients. We carried out an economic evaluation using trial data to determine the cost-effectiveness of CPT discontinuation.

Methods: Data were collected from a provider's perspective for the trial duration (average 26.8 months per participant). Patient-specific data on resources used to diagnose and treat CPT-preventable events, malaria cases, and severe CPT-related haematological adverse events, as well as CPT use, were collected from patient files. Morbidity data (frequency and duration of individual events) and mortality data were collected from the trial dataset. An expert clinician panel determined illness severity, from which disability weights were derived. Disability-adjusted life years (DALYs) were calculated and an incremental cost-effectiveness ratio (ICER) estimated.

Results: The trial enrolled 1089 participants in the placebo arm and 1091 in the CPT arm. Discontinuing CPT led to statistically-significant increases in CPT-preventable events and malaria, and a decrease in severe CPT-related haematological adverse events. More deaths were observed in the placebo arm, but the difference was not statistically significant. Despite additional costs of treating more CPT-preventable events and malaria in the placebo arm, total costs were lower in the placebo arm ($21,013) than in the CPT arm ($37,686) largely due to the cost of co-trimoxazole in the latter. Mean costs per person/year were $8.75 in the placebo arm and $15.23 in the CPT arm. Better health outcomes were observed in the CPT arm than in the placebo arm (with means of 0.06 and 0.03 DALYs averted per person during the trial, respectively), largely driven by improvements in mortality. The ICER of CPT discontinuation was $631/DALY averted.

Conclusions: Discontinuing CPT is cost-effective using thresholds of 0.5x or 1x GDP per capita. However, our findings need to be interpreted with caution pending further uncertainty analysis as differences in mortality were not found to be statistically significant.

THPEE643

Cost-effectiveness of integrating buprenorphine/naloxone for opioid use disorder into treatment for HIV/HCV co-infected persons who inject opioids in the U.S.

J. Barocas[1], J. Morgan[2], D. Fiellin[3], B. Schackman[4], M. Stein[5], K. Freedberg[1], B. Linas[2]
[1]Massachusetts General Hospital, Boston, United States, [2]Boston Medical Center, Division of Infectious Diseases, Boston, United States, [3]Yale School of Medicine, New Haven, United States, [4]Weill Cornell Medical College, New York, United States, [5]Boston University School of Public Health, Boston, United States

Background: Untreated opioid use disorder (OUD) impacts the care of HIV/HCV co-infected persons who inject drugs (PWID). A proportion of this population is engaged in HIV care, adherent to HIV medications, and increasingly offered HCV treatment. Integrating medications for OUD such as buprenorphine/naloxone (BUP-NX) into care may improve outcomes, but the clinical impact and costs are unknown. We evaluated the cost-effectiveness of integrating BUP-NX into onsite HIV/HCV treatment for this population compared with the status quo.

Methods: We used a Monte Carlo simulation model to compare the cost-effectiveness of:

1) standard HIV care with onsite HCV treatment and referral to offsite OUD care (*status quo*);

2) standard HIV care with onsite HCV and BUP-NX treatment (*integrated care*).

All individuals begin the simulation in HIV care. We used national databases, clinical trials, and observational cohorts to inform model inputs, including demographics (66% male, mean age 45y), HIV and HCV care characteristics (HIV: 71% ART adherence, HCV: 94% initiation, 97% completion), HCV treatment efficacy (up to 100%), and HCV re-infection risk (12 cases/100PY). Outcomes included life expectancy (LE), discounted quality adjusted-life years (QALYs), lifetime discounted costs, incremental cost-effectiveness ratios (ICERs), deaths, and HCV reinfections. Costs ($US) and QALYs were discounted at 3% annually, and ICERs compared to a threshold of $100,000/QALY.

Results: The *status quo* resulted in LE of 10.85y and 3.61 QALYs at a cost of $364,400. *Integrated care* extended LE by 0.35y, provided an additional 0.23 QALYs, and, compared to *status quo*, had an ICER of $59,100/QALY. The *status quo* resulted in 642 reinfections/1,000 individuals and *integrated care* resulted in 46 fewer reinfections. In the near-term (5 years) the benefit of *integrated care* was preventing fatal sequelae of opioid use (28 fewer deaths/1,000). In the long-term (20 years), *integrated care* also decreased the burden of liver-related mortality (2.9 fewer liver-deaths/1,000). Findings were robust in sensitivity analyses assessing variation in reinfection risk, cost of BUP-NX, and BUP-NX duration and efficacy, except when both reinfection rates and BUP-NX costs were higher (ICER=$129,000).

Conclusions: Integrating BUP-NX into treatment for HIV/HCV co-infected PWID improves life expectancy, is cost-effective, and should become part of routine treatment.

THPEE644

Modeling the cost-effectiveness of repeat maternal HIV testing in Kenya and South Africa

J. Meisner[1], K.A. Thomson[1], C. Quinn[2], S. Farid[3], E. Marum[2], R. Barnabas[3,4], R. Baggaley[2], S. Essajee[5], C. Johnson[2,6], A.L. Drake[3]
[1]*University of Washington, Epidemiology, Seattle, United States,* [2]*World Health Organization, HIV Department, Geneva, Switzerland,* [3]*University of Washington, Global Health, Seattle, United States,* [4]*University of Washington, Medicine, Seattle, United States,* [5]*UNICEF, HIV Section, New York, United States,* [6]*London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom*

Background: Repeat HIV testing during pregnancy/breastfeeding can help detect new maternal HIV infections and prevent mother-to-child HIV transmission (MTCT). Many African countries have introduced repeat testing approaches; however, economic analysis and public health impact of approaches have not been conducted.
Methods: We constructed a Markov decision-analytic cohort model for MTCT to assess the cost-effectiveness of repeat testing in Kenya and South Africa. Model parameters incorporate maternal HIV infection status and stage of seroconversion, pregnancy/postpartum status, maternal antiretroviral therapy, infant antiretrovirals, and viral suppression. We estimated the potential impact of varying the timepoint and frequency of repeat maternal testing on infant HIV infections averted under various testing scenarios:
1) late gestation/delivery,
2) 6 weeks postpartum,
3) 6 months postpartum, and
4) late gestation/delivery plus 6 weeks postpartum.
Repeat testing was cost-effective if the incremental cost-effectiveness ratio (ICER) was < 3 times the threshold national per capita gross domestic product (US$1500 in Kenya and US$5500 in South Africa).
Results: Assuming a population of 1,600,000 for each country, the number of infant infections averted during pregnancy and through 12 months postpartum attributed to repeat maternal testing ranged from 2,296-6,289 in Kenya and 2,960-42,454 in South Africa (Tables) under scenarios 3 and 4, respectively. The ICER for repeat maternal HIV testing ranged in Kenya from $440 (scenario 1) to $3,113 (scenario 3) and in South Africa from $461 (scenario 1) to $3,285 (scenario 3) per infant infection averted. Compared to the base case model, repeat testing at 2 time points (scenario 4) averts the largest proportion of MTCT (21% reduction in Kenya vs. 34% in South Africa). Using a single repeat testing strategy, repeat testing during late gestation/delivery resulted in the largest reduction in MTCT (16% in Kenya vs. 30% in South Africa).
Conclusions: In our model, all repeat maternal testing scenarios were cost-effective and averted infant infections in Kenya and South Africa, but repeat testing in late pregnancy/delivery or at 6 weeks postpartum resulted in substantially larger reductions in MTCT than at 6 months after delivery. These findings have important implications for designing repeat testing approaches as a strategy to prevent MTCT and improve maternal health.

Testing strategy (a)	Incremental costs (b)	Infant infections averted (b)	ICER (b)	Percent of maximum potential benefit achieved (c)
SOUTH AFRICA				
Strategy 1	16,650,531	37,852	440	30.5
Strategy 2	12,650,573	11,973	1,057	9.7
Strategy 3	9,216,296	2,960	3,113	2.4
Strategy 4	23,033,301	42,454	543	34.3

Cost effectiveness analysis results. a) Strategy 1= testing at first antenatal care (ANC) visit and in late gestation or delivery; strategy 2= testing at first ANC, 6 week maternal child health (MCH) visit; strategy 3= testing at first ANC, and 6 month MCH visit; strategy 4=testing at first ANC, late gestation or delivery, and 6 week MCH visit. b) ICER= incremental cost effectiveness ratio, in 2017 US$ per infant infection averted; base case assumes testing at first ANC only. c) The percent of maximum potential benefit achieved is the number of infant infections that could be averted by the testing strategy divided by the total number of infants expected to be infected under the base case scenario (testing at first ANC alone) in a population restricted to women eligible for HIV testing under model assumptions.

[Table 1: Cost-effectiveness of repeat maternal HIV testing under model scenarios, South Africa]

Testing strategy (a)	Incremental costs (b)	Infant infections averted (b)	ICER (b)	Percent of maximum potential benefit achieved (c)
Kenya				
Strategy 1	4,064,181	4,567	890	15.5
Strategy 2	3,441,495	2,977	1,156	10.1
Strategy 3	2,946,144	2,296	1,283	7.8
Strategy 4	6,668,310	6,289	1,060	21.4

Cost effectiveness analysis results. a) Strategy 1= testing at first antenatal care (ANC) visit and in late gestation or delivery; strategy 2= testing at first ANC, 6 week maternal child health (MCH) visit; strategy 3= testing at first ANC, and 6 month MCH visit; strategy 4=testing at first ANC, late gestation or delivery, and 6 week MCH visit. b) ICER= incremental cost effectiveness ratio, in 2017 US$ per infant infection averted; base case assumes testing at first ANC only. c) The percent of maximum potential benefit achieved is the number of infant infections that could be averted by the testing strategy divided by the total number of infants expected to be infected under the base case scenario (testing at first ANC alone) in a population restricted to women eligible for HIV testing under model assumptions.

Work and home productivity of HIV-positive and HIV-negative individuals in Zambia and South Africa: A cross-sectional baseline survey of the HPTN071/PopART trial

R. Thomas[1], R. Friebel[2], K. Barker[2], L. Mwenge[3], S. Kanema[3], N. Vanqa[4], A. Harper[4], N. Bell-Mandla[4], P. Smith[2], S. Floyd[5], P. Bock[4], H. Ayles[5], N. Beyers[4], S. Fidler[2], R. Hayes[5], K. Hauck[1], HPTN 071(PopART) Study Team
[1]*Imperial College London, Infectious Disease Epidemiology, London, United Kingdom,* [2]*Imperial College London, London, United Kingdom,* [3]*University of Zambia, ZAMBART Project, Lusaka, Zambia,* [4]*Desmond Tutu TB Centre, Stellenbosch University, Cape Town, South Africa,* [5]*London School of Hygiene and Tropical Medicine, London, United Kingdom*

Background: Little is known about the impact of HIV on the work and home productivity of HIV-positive individuals in sub-Saharan Africa. Most existing evidence originates from individuals employed in the formal sector and at specific disease stages, which are not representative of the general working population. This study compared the number of work days lost to illness or accessing health care for HIV-positive and HIV-negative individuals in South Africa and Zambia.
Methods: As part of the HPTN 071 (PopART) study, data from approximately 2000 randomly selected adults aged 18-44 years were gathered between November 28, 2013, and March 31, 2015, from each of 21 communities in Zambia and South Africa. Information on the number of productive days lost in the last 3 months, laboratory-confirmed HIV status, labour force status, age, ethnicity, education, and recreational drug use was collected. Differences in productive days lost between HIV-negative and HIV-positive individuals at various lengths of time on treatment were estimated with negative binomial models. Results are presented in differences in productive days lost.
Results: From data for 19,750 respondents in Zambia and 18,941 respondents in South Africa, HIV prevalence was 21.0% (Zambia) and 22.2% (South Africa). HIV-positive individuals lost more productive days to illness than HIV-negative individuals in both countries. Excess productive days lost by HIV-positive individuals in a 3-month period were 0.74 (95%CI:0.48-1.01;p< 0.001) in Zambia and 0.13 (95%CI:0.04-0.23;p=0.007) in South Africa compared to HIV-negative individuals. Results for excess days lost disaggregated by ART status were as follows:

	Zambia	South Africa
HIV-positive individuals not on treatment	0.61 (95%CI:0.30-0.92,p<0.001)	0.03 (95%CI:-0.05-0.11,p=0.416)
HIV-positive individuals on treatment for less than one year	1.24 (95%CI:0.34-2.14,p=0.007)	1.41 (95%CI:-0.004-2.82,p=0.051)
HIV-positive individuals on treatment for one to two years	1.08 (95%CI:0.06-2.11,p=0.038)	0.18 (95%CI:-0.19-0.54,p=0.341)
HIV-positive individuals on treatment three years or more	0.79 (95%CI:0.16-1.41,p=0.014)	0.001 (95%CI:-0.13-0.14,p=0.961)

[Excess days lost disaggregated by ART status]

Conclusions: There is a significant burden in lost work and home productivity due to HIV in the general population, but it is smaller than existing estimates for samples dominated by formal sector workers. Productive days lost need to be considered when evaluating the benefit of HIV prevention from a societal perspective. The findings will support policy makers in building an investment case for HIV interventions.

THPEE646

Economic evaluation of HIV self-testing in outpatient departments in Malawi: Results from EQUIP

B.E. Nichols[1,2], O.A. Offorjebe[3,4], R. Cele[2], F. Shaba[5], L.C. Long[1,2], S. Rosen[1,2], K. Dovel[5,6], on behalf of EQUIP
[1]Boston University, Global Health, Boston, United States, [2]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]University of California, David Geffen School of Medicine, Los Angeles, United States, [4]Charles R. Drew University of Medicine and Science, Los Angeles, United States, [5]Partners in Hope, Lilongwe, Malawi, [6]University of California, Division of Infectious Diseases, Department of Medicine, Los Angeles, United States

Background: The provision of HIV self-testing (HIVST) in outpatient departments (OPD) has been shown to increase facility capacity for HIV testing in Malawi, given high OPD patient volumes and substantial waiting times. To assess the feasibility of HIVST scale-up at OPDs in Malawi, the cost per new HIV-positive patient identified using HIVST in the OPD was calculated and compared to routine provider initiated testing and counseling (PITC) and Optimized-PITC.
Methods: A three-arm cluster randomized controlled trial of HIVST was conducted at 15 sites in Malawi:
1) PITC;
2) Optimized-PITC (additional training and job-aids); and
3) HIVST (HIVST demonstration, distribution, and kit use in OPD, private spaces for kit interpretation, optional HIV counseling).
Costs were estimated from a provider perspective at 5 sites using a bottom-up costing approach. Optimized-PITC costs included facility staff training, while HIVST costs included research staff training and salaries, community sensitization, and the cost of HIVST kits. A cost per newly identified HIV-positive patient ("new positive") was calculated for three scenarios
(1) trial-based costs (baseline),
(2) routine implementation costs (use of local staff, annualized training and community sensitization costs), and
(3) negotiated HIVST cost (routine implementation costs with the price of HIVST reduced to the price of a standard HIV test (from $2 to $1)).
Results: In scenario 1, the average cost per patient tested was $2.33, $4.68, and $4.73 for PITC, Optimized-PITC, and HIVST, respectively. The average cost per "new positive" was $95, $152, and $179. The cost drivers were HIVST kit price, training and community sensitization. In scenario 2, the average cost per new positive dropped substantially to $79, and $92, for Optimized-PITC and HIVST respectively, and remained the same for PITC. In scenario 3, HIVST became cost saving at $54 per new positive. Cost savings for HIVST remain even when the HIV-positive yield is reduced by 40%.
Conclusions: While identifying a new HIV-positive patient through HIVST in the OPD is slightly more expensive ($7) than PITC in routine implementation, HIVST may become cost-saving if the cost of HIVST kits can be reduced. For high volume or overcrowded clinics, HIVST may offer one approach to increasing capacity and efficiency.

THPEE647

Model estimated cost-effectiveness of integrating cervical cancer screening and treatment with LEEP vs. cryotherapy into HIV care clinics in Kenya

M. Sharma[1,2], E. Vodicka[3], S. Green[4], M. Chung[1], C. Regan[2], S. Sy[2], R. Barnabas[1], J. Kim[2], N. Campos[2]
[1]University of Washington, Department of Global Health, Seattle, United States, [2]Harvard T. Chan School of Public Health, Department of Health Policy and Management, Boston, United States, [3]University of Washington, Health Services, Seattle, United States, [4]University of Washington, Epidemiology, Seattle, United States

Background: HIV-infected women have 2-fold higher risk of developing cervical cancer (CC). Integrating screening and treatment of precancerous lesions into HIV clinics may be an efficient strategy to reduce CC. Lesions are often treated with cryotherapy in resource-limited settings. A randomized clinical trial (RCT) in Kenya found loop electrosurgical excisional procedure (LEEP) was more effective than cryotherapy for treating precancerous lesions in HIV-infected women (31% vs. 44% lesion recurrence at 12 months, respectively). However, LEEP is resource-intensive and cost-effectiveness should be evaluated.
Methods: Using effectiveness data from an RCT comparing cryotherapy vs. LEEP and cost data from a micro-costing in the same clinic, we parameterized an individual-based mathematical model of HPV and CC pathogenesis in HIV-infected women. We projected health benefits and costs associated with CC screening strategies using cytology, visual inspection with acetic acid (VIA), and HPV DNA testing combined with treatment using either cryotherapy or LEEP at 70% screening coverage of HIV-infected women on ART.
Results: VIA testing five-times per lifetime (every five years, age 25-45) was projected to reduce lifetime cervical cancer risk by 30% when combined with cryotherapy treatment and 34% with LEEP treatment. The corresponding incremental cost-effectiveness ratios (ICERs) were $187 and $1,341 per year of life saved (YLS) for treatment with cryotherapy and LEEP respectively. Both strategies fell below Kenya's per capita GDP of $1,540 USD, the WHO recommended threshold for cost-effectiveness. HPV DNA testing five times per lifetime with LEEP treatment was the most effective strategy that was also cost-effective, reducing CC burden by 45% with an ICER of $1,445 per YLS. Strategies using cytology were dominated (i.e. more costly and less effective) than other strategies. At screening frequencies higher than seven times per lifetime, strategies with LEEP exceeded the cost-effectiveness threshold.
Conclusions: Integrating screening with VIA or HPV DNA testing and treatment with LEEP into ART clinics provides moderate health benefits over cryotherapy and is cost-effective at screening frequencies of seven or fewer times per lifetime. Screening with VIA followed by cryotherapy was the most efficient strategy at higher screening frequencies. Integrating screening and treatment into ART clinics is a promising strategy for reducing CC burden.

Economics of affordability

Costs of two rounds of home-based HIV testing and counselling in Zambia: Evidence from the HPTN 071(PopART) study

R. Thomas[1], S. Kanema[2], L. Mwenge[2], S. Floyd[3], P. Bock[4], H. Ayles[3], N. Beyers[4], S. Fidler[5], R. Hayes[3], K. Hauck[1], HPTN 071(PopART) Study Team
[1]Imperial College London, Infectious Disease Epidemiology, London, United Kingdom, [2]University of Zambia, ZAMBART Project, Lusaka, Zambia, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Desmond Tutu TB Centre, Stellenbosch University, Cape Town, South Africa, [5]Imperial College London, London, United Kingdom

Background: The HPTN 071(PopART) trial is a 3-arm RCT offering a combination prevention intervention comprising annual rounds of home-based HIV testing (HBTC) delivered by Community HIV-care Providers (CHiPs) who also support linkage to care, ART retention and other HIV-related services in 21 communities in Zambia and South Africa. In Zambia, 8 communities received the CHiPs community wide intervention. We estimated total and community-specific unit costs over two rounds of the intervention.
Methods: We applied micro-costing methods to estimate the economic costs of HBTC delivered to over 250,000 individuals between December 2013 and December 2016. Total costs, cost per person tested, and cost per person tested positive were calculated. Data on salaries, equipment, supplies, transport, and general administration were extracted from program records, and merged with outcome indicators from program data. Probabilistic sensitivity analysis (PSA) by random sampling from specified distributions was conducted to determine the sensitivity of estimates to uncertainty in cost components. Costs are presented as means and standard deviations from the PSA simulations.

Results: In the first round, 126,208 individuals were tested, and among those 9,196 (7%) tested HIV-positive. In the second round, 136,966 individuals were tested and among those 4,921 (3.6%) tested HIV-positive. Costs by rounds are presented in Table 1.

	Round 1	Round 2
Total economic costs	US$ 3.37mn (SD=110,911)	US$ 3.40mn (SD=125,450)
Average cost per population	US$ 7.61 (SD=0.25)	US$ 7.67 (SD=0.28)
Cost per person tested	US$ 26.77 (SD=0.89)	US$ 25.42 (SD=0.94)
Cost per person tested HIV-positive	US$ 367.00 (SD=12.06)	US$ 691.88 (SD=25.49)

[Table 1: Costs of home-based HIV testing and counselling by rounds]

The costs per person tested (round1: min=US$ 22.00, max=US$ 42.11, round2: min=US$ 20.30, max=US$ 36.28) did vary across communities and rounds. The costs per person tested positive (round1: min=US$ 252.29, max=US$ 751.99, round2: min=US$ 538.66, max=US$ 1,087.69) varied substantially across communities and increased between rounds.
Conclusions: The findings suggest that costs are sensitive to community-specific factors related to service delivery or population characteristics. The cost per person tested HIV-positive nearly doubled between rounds, which is partly explained by a reduction in the number of persons tested HIV-positive in the second round. The costs of HBTC can be compared with standard healthcare facility-based testing, to inform policymakers on the merit of intensified testing and counselling campaigns in high-prevalence settings. Further analysis is required to evaluate the cost-effectiveness of HBTC in terms of their wider health and non-health benefits.

THPEE649

Capacity building of rural healthcare providers used as a tool to scale-up early infant diagnosis in Southeast Nigeria

A. Oniyire[1], O. Adebayo[2], A. Eyo[3], O. Onyedinachi[4]
[1]Jhpiego-Johns Hopkins University, Obstetrics and Gynecolgy, Abuja, Nigeria, [2]Jhpiego-Johns Hopkins University, Enugu, Nigeria, [3]ECWES, Uyo, Nigeria, [4]Enugu State Ministry of Health, Enugu, Nigeria

Background: A significant number of pediatric HIV infection is through mother-to-child transmission and Nigeria is responsible for 30% globally. LOCATE CDC funded project supported PMTCT services, including early infant diagnosis (EID) for HIV exposed infants (HEIs) in 209 health facilities in Southeast Nigeria. In 2013/2014, none of the healthcare providers at LOCATE supported primary healthcare centers (PHCs) were able to collect dried blood spot (DBS) for EID and send to the designated comprehensive care and treatment (CCT) centers, thus project staff often carried out this activity.
Description: LOCATE provided hands-on mentoring on DBS sample collection, drying, packaging and transportation, to healthcare providers at CCT sites, established a "hub and spoke system" that enabled these providers to transfer skills to low cadre providers at the PHCs at no extra cost to the project. Phone directories were developed for timely intervention for EID. The healthcare providers at the CCT hubs served as back up on need basis, thus promoting ownership and sustainability, while project staff provided supervisory and logistics support. The PMTCT Jhpiego team did a retrospective data collation of two targeted indicators from the supported health facilities at 6 months before- and 6 months after-the intervention. The data was reviewed and analyzed using Chi square.
Lessons learned: Six months pre-intervention, only 24% of eligible HEIs had EID and 13% of healthcare workers demonstrated the availability for EID services at PHCs. This increased to 81% ($p < 0.05$) and 87% ($p < .001$), respectively, 6 months post-intervention. Similarly, all DBS samples were collected by project staff pre-intervention; post-intervention, DBS collection was by healthcare providers. The increase in the two target indicators is attributable to the government healthcare providers in supported facilities taking ownership of this specific intervention for HEIs.
Conclusions/Next steps: The findings demonstrate the value of using empowered healthcare providers as mentors to their colleagues in ensuring that infants of HIV infected women have EID services, especially in rural hard to reach areas at no extra cost to both the caregivers and the project.

THPEE650

Characteristics and costs of optimized background therapy for treatment of heavily treatment-experienced adults with multidrug-resistant HIV-1 in the US: A clinical trial analysis

S. Talbird[1], J. Fulton[2], E. La[1], Z. Miao[3], A. Brogan[1], S. Lewis[4]
[1]RTI Health Solutions, Research Triangle Park, United States, [2]Westat, Rockville, United States, [3]Theratechnologies Inc., Montréal, Canada, [4]TaiMed Biologics Inc., Irvine, United States

Background: Heavily treatment-experienced adults with multidrug-resistant (MDR) HIV-1 infection have limited remaining antiretroviral treatment options and are typically treated with optimized background therapy (OBT) based on individual resistance profiles. Composition and cost of OBT are not well described in the literature. This study assesses the characteristics and cost of OBT for participants in a phase 3 clinical trial for adults with MDR HIV-1 treated with ibalizumab plus OBT (TMB-301; 2015-2016).
Methods: Patient-level antiretroviral therapy regimens were analyzed at baseline using descriptive statistics. Costs of individual antiretroviral drugs were applied using wholesale acquisition costs (2017) to calculate annual OBT costs. Outcomes included composition of OBT; number of antiretroviral drugs; use of fixed-dose combination and investigational drugs; and annual cost, with and without generic drug use.
Results: Among trial participants (n=40), the most frequent antiretroviral drugs used as part of OBT were tenofovir disoproxil fumarate (DF) (72.5% total, 62.5% as emtricitabine/tenofovir DF, 10% as tenofovir DF alone), dolutegravir (60%), ritonavir (57.5%), darunavir (65% total, 50% boosted with ritonavir, 15% as darunavir/cobicistat), investigational agent (42.5%), and etravirine (12.5%). Other antiretroviral drugs were used by ≤ 10% of participants. All protease inhibitors were boosted. On average, OBT consisted of 4.7 antiretroviral drugs (range: 1-7), with more drugs used by those treated with an investigational agent (mean: 5.5; range: 3-7) than by those not treated with an investigational agent (mean: 4.0; range: 1-6). As part of OBT, 85% of participants used ≥ 1 (range: 0-2) fixed-dose combination drug.
Assuming brand prices and standard dosing for all antiretroviral drugs, the mean annual cost of OBT was $51,551 (range: $18,697-$105,533). Annual OBT costs were higher among those treated with an investigational agent (mean: $56,797; range: $19,086-$105,533) than among those not treated with an investigational agent (mean: $47,673; range: $18,697-$78,920). Few participants' OBT regimens included drugs with generic options available (7.5%); costs for these participants were 6%-41% lower if generic options were used.
Conclusions: For heavily treatment-experienced patients with MDR HIV-1 infection, the composition of OBT is heterogenous with high associated costs. New, potent therapies with a new mechanism of action are needed for this patient population.

THPEE651

Cost data to inform purchasing of antiretroviral treatment services across borders: A cross-country comparison of first and second line adult and pediatric antiretroviral treatment costs in Kenya, Rwanda and Uganda

A. Gatome[1], M. Costa[2]
[1]Swiss Tropical and Public Health Institute of Basel, Basel, Switzerland, [2]Abt Associates Inc, 10 Fawcett Street, Cambridge, United States

Background: The East African Community (EAC) partner states-Burundi, Kenya, Rwanda, South Sudan, Tanzania and Uganda-collectively have 4.9million people living with HIV (PLHIV)-13% of the global PLHIV population. The EAC Common Market Protocol facilitates movement of people across the six countries necessitating access to healthcare services across countries. Easy mobility also puts additional pressure on HIV/AIDS services to meet the needs of transiting populations. Countries will need to discuss how to purchase antiretroviral treatment (ART) services across borders to reduce treatment defaulters, improve treatment out-

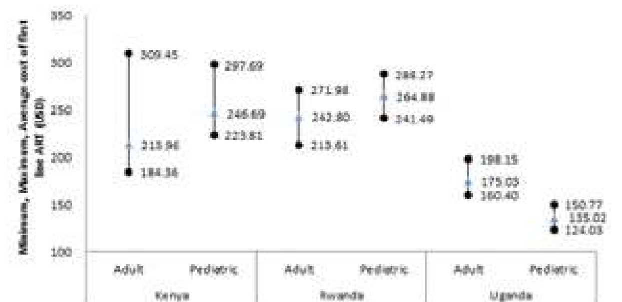
comes and reduce transmission across borders as PLHIV move across countries. The objective of this study was to provide cost data for HIV/AIDS services in Kenya, Rwanda, and Uganda for use by policymakers addressing HIV/AIDS service provision and financing across the region. This specific presentation reviews first and second line adult and pediatric ART costs only.

Description: USAID-funded Cross-Border Health Integrated Partnerships Project collected July 2014-June 2015 data at public and private clinics, health centres, and hospitals within five kilometers of five cross-border locations in Kenya, Rwanda and Uganda. Service provision inputs were collected from facility records and through interviews with clinicians. An excel-based tool was used to analyze the data from a provider perspective and generate average unit costs.

Lessons learned: Annual costs of first line and second line adult and pediatric ART varied between countries. In Kenya and Rwanda, average costs were higher than Uganda - first line ART in Kenya was $213.96 (adult) and $246.69 (pediatric), in Rwanda $242.80 (adult) and $246.88 (pediatric), and in Uganda, $175.03 (adult) and $135.02 (pediatric). ART drugs cost was the key cost driver. The differences between countries were also attributable to personnel costs which were highest in Kenya, frequency and type of laboratory monitoring which was highest in Rwanda, and frequency of visits which was lowest in Uganda. Similar trends were observed for second line ART.

Conclusions/Next steps: These results give insight into the differences in costs of HIV services and their cost drivers and can inform planning and purchasing of HIV services across borders. These costs can also be used to benchmark facilities and identify opportunities for efficiency gains.



[Maximum, minimum and average unit cost of first line adult and pediatric ART in US dollars (Kenya, Rwanda and Uganda)]

THPEE652

Relationship between client age profile and unit expenditure among PEPFAR-supported voluntary medical male circumcision programs for HIV prevention, 2015

S. Davis, H. Nasrallah, S. Pals, B. Batayeh, G. Parent, C. Toledo
US Centers for Disease Control and Prevention, Atlanta, Georgia

Background: Voluntary medical male circumcision of males 10 years and older is a key component of PEPFAR-supported HIV prevention in 14 southern and eastern African countries. Since 2015, PEPFAR's priority client age band for circumcision has been 15-29 years, for immediate HIV prevention. However, demand is intrinsically higher in 10-14-year-olds although services packages are the same, and the focus on older males has raised concern that unit expenditures (UEs), expenditures per circumcision, may increase. Routinely-collected 2015 PEPFAR program data allows exploration of whether this association currently exists.

Methods: Implementing partner-level fiscal year 2015 circumcision UE and client age distribution data (age bands 10-14, 15-19, 20-24, and 25-29 years) were used. Partner-level descriptive analysis was performed, followed by univariable and multivariable linear regression of log-transformed UEs on percent of total clientele represented by each age band, adjusting for country due to intercountry variations in operating costs.

Results: Thirty-nine implementing partners (counted once for each country of operation) in 12 countries had data. The median unit expenditure was $93.7, with range $40.4-727.1. The median percent of clients aged 10-14 was 39.1 (range 0.0-72.2); the median percent aged 15-29 was 48.7 (range 11.6-88.2). In univariable analysis, each 1% increase in percent of clients aged 10-14 was associated with a 1% decrease in UE; a 1% increase in percent aged 15-29 had almost no association (anti-log slope = 1.003). After adjustment for country, the association with age 10-14 did not change, but each 1% increase in clients 15-29 years was associated with a 2% UE increase. By 5-year age bands, a negative association with UE was seen for 10-14 and 15-19 years, and a positive association with 20-24 and 25-29 years.

Conclusions: In this cross-sectional analysis, programs with more 10-19-year olds had slightly lower UEs than those with more 20-29-year-olds, and programs with more clients in the combined priority age band of 15-29-year-olds had slightly higher expenditures. If these associations persist over time with successful targeting of this age range, modest UE increases could be seen. However, programs often achieve decreasing UEs over time due to increased productivity, so this association may be mitigated.

THPEE653

Hepatitis C treatment regimens in Russia in 2017: Drug choice compromises in the context of intellectual property and registration barriers

S. Golovin[1], K. Babikhina[2]
[1]Treatment Preparedness Coalition, IP and Access, St. Petersburg, Russian Federation, [2]Treatment Preparedness Coalition, St. Petersburg, Russian Federation

Background: Hepatitis C epidemic is a major threat to public health in Russia, with an estimated number of 6 million people with HCV antibodies, and 1.8 million confirmed cases. The HIV/HCV coinfection is also widespread, with at least 200,000 confirmed cases. The HCV treatment in Russia is gradually changing with the introduction of direct-acting antivirals (DAAs), which are more effective and safe than pegylated interferon and can be safely used in people with HIV, with regard taken to drug-drug interactions with antiretroviral medicines. ITPCru continuously monitors HCV drug procurement in Russia: this abstract summarizes the data for 2017.

Methods: We analyzed 781 tenders for HCV drugs in Russia in 2017. International non-proprietory names were obtained from the official register grls.rosminzdrav.ru.The research focused on the following key parameters: drug regimens (based on National HCV treatment guidelines and leaflet), number of patients who could potentially be treated (based on the recommended regimen duration), and price per patient. The research has limitations as it focuses on procurement figures; also, it does not include standard interferon.

Results: The key HCV treatment regimens were as follows: PEG-IFN/RBV (4512 treatment courses, 24 weeks); simeprevir/PEG-IFN/RBV (1814); dasabuvir/ombitasvir/paritaprevir/ritonavir (1146); daclatasvir/asunaprevir (870); narlaprevir/PEG-IFN/RBV (598); sofosbuvir/daclatasvir (180). No SOF-based fixed-dose combinations were registered in Russia in 2017. No generics of DAAs were officially registered; however, several biosimilars were available.The total number of patients who could potentially receive treatment lies between 9100 and 10,000. The prices can be found in Table 1.

Regimen	Average Weighted Price per patient, USD
PEG-IFN/RBV*	2 442,60
SIM/PEG-IFN/RBV*	12 246,25
3D	14 838,67
DCV/ASV	13 773,55
NPV/PEG-IFN/RBV	8 286,22
DCV/SOF	18 694,33

[Table 1]

Conclusions: The data shows that the majority of patients are still treated with PEG-IFN-based regimens, the key reason being the finanical one. The price for PEG-based regimens is several times lower than the price of all-oral regimens. The only WHO-recommended first-line regimen is SOF/DCV. Due to IP constraints, generics cannot enter the market, and the price of SOF/DAC in 2017 was over 18,000USD for 12 weeks.

Neither SOF/LDV nor SOF/VEL are registered, which is a consequence of the difficult registration system in Russia requiring local clinical trials. Measures for reducing DAA prices, including IP interventions, are recommended to significantly scale up access to HCV treatment in Russia.

THPEE654

Enhancing program efficiency through service integration, population focus and geographic localization: Finding and treating HIV, syphilis, and cervical cancer in Zambia

Y. Mulenga[1,2], M. Kalufyanya[1], K. Mapoma[2], C. Mukelebai[1,3], G. Mburu[3]
[1]PCI, Programs, Lusaka, Zambia, [2]Zambia Defence Force Medical Services, HIV/AIDS Programs, Lusaka, Zambia, [3]PCI Global, HIV/AIDS Programs, Washington DC, United States

Background: In a context of diminishing funding for HIV programs, there is need for efficient allocation of available finite resources on interventions, populations and geographic contexts that maximise programmatic impact. In Zambia where the national HIV prevalence is 12%, prevalence is higher among women (15%) compared to men (10%). On average, 4% of women screened for cervical cancer are found with precancerous cervical lesions. Rapid syphilis testing (RST) is not routinely provided in Zambia.
Description: Between November and December 2017, PCI set out to improve program efficiency by adopting three strategies:
1) integrating mobile HIV testing, cervical cancer screening, and RST services,
2) geographically focussing this intervention in Southern Province, where prevalence of HIV among adults is higher than the national average at 13%, and;
3) intensifying efforts to reach women, which is the population at highest risk of HIV.
Women testing positive to HIV and RST were immediately linked to antiretroviral therapy and syndromic treatment of STI, respectively. Women found with early precancerous cervical lesions were treated on site using cryotherapy while those with advanced lesions were referred for further management.
Lessons learned: A total of, 571 women, mean age 34, were reached with integrated HIV testing, Cervical Cancer Screening, and RST services in the three sites: 174 in *Livingstone A*; 149 in *Livingstone B*; and 248 *in Choma*. The yield rates of HIV were higher than the national and regional average in all the three sites at 35.6%, 31.8% and 16.1% respectively. Similarly rates of cervical dysplasia were much higher than program/national average at 6.8% and 7.4% in Livingstone A and B respectively. In *Choma* cervical dysplasia was at lower at 2.5%. Positive RST tests were reported at two sites: Livingstone A (3.3%), and Choma (2.5%).
Conclusions/Next steps: Results demonstrates that combining population focus, geographic localisation and an integrated package of screening services can enhance programmatic efficiency. This approach increased HIV yield, enhanced early detection of cervical cancer and identified cases of syphilis that would otherwise have been undetected, and can inform future scale-up of effective screening services for women of reproductive age.

THPEE655

Cost effectiveness analysis of nationally scaled point-of-care diagnostic platforms compared to central laboratory models for routine viral load monitoring of HIV-positive Kenyans on antiretroviral therapy

E. Mangone[1], C. Cintron[1], R. Haider[1], B. Johns[1], C. Avila[1], Y. Vartanova[2]
[1]Abt Associates, Health Finance and Governance Project, Rockville, United States, [2]Abt Associates, Cambridge, United States

Background: The National AIDS and STI Control Programme (NASCOP) in Kenya has scaled up its program for routine viral load (VL) monitoring to serve one million HIV-positive Kenyans receiving antiretroviral therapy (ART). Yet the traditional model of batching blood samples to national laboratories is expensive and presents logistical challenges including delays and loss of test results. Point-of-care (POC) technology presents an alternative to laboratory monitoring that may improve timeliness of test results, retention in care, and health outcomes.
Methods: A Markov model was developed from a health system perspective to compare routine POC to laboratory VL testing among a hypothetical cohort of 100,000 adult HIV-positive Kenyans initiating ART. The model follows the cohort over a ten-year time horizon through first and second-line treatments using a six-month cycle length to accommodate NASCOP/WHO testing guidelines. Patients were modeled to be at risk of death, loss to follow up, and increased probability of transmission due to uncontrolled VL. Costs in 2017 USD were pulled from a parallel costing study which considered Cepheid GeneXpert-IV and Alere POC diagnostic platforms and Abbott and Roche laboratory technology. Clinical input parameters were derived from primary data collection on turnaround times and published literature. Parameters uncertainty was assessed through probabilistic and univariate sensitivity analyses. Costs and effects were discounted by 3% annually.
Results: Over the ten-year time horizon, POC implementation cost $4.48 million more than laboratory monitoring. POC implementation resulted in 852 quality-adjusted life years (QALYs) gained, 297 HIV transmissions averted, and 89 deaths averted. The incremental cost effectiveness ratios (ICERS) per QALY gained, transmission averted, and death averted over ten years were $5,259, $15,094, and $50,392, respectively. Using the 2016 Kenyan PPP adjusted, per capita GDP of $3,161 as a threshold and considering income elasticities from 1 to 2.5, POC implementation was not cost-effective. Model outcomes were most sensitive to probabilities of delay in test results.
Conclusions: POC implementation at national scale in Kenya is not cost-effective possibly due to strong NASCOP investment in laboratory infrastructure over the past decade. However, POC platforms may be cost-effective in remote areas of Kenya and in countries with weaker infrastructure and HIV monitoring programs.

THPEE656

Differences in antiretroviral drug prices between low and middle income countries

A. Hill[1], J. Sim[2], R. Smith[3]
[1]Liverpool University, Translational Medicine, Liverpool, United Kingdom, [2]Imperial College London, Faculty of Medicine, London, United Kingdom, [3]MetaVirology Ltd, London, United Kingdom

Background: Antiretroviral (ARV) prices have fallen substantially in low-income countries, but low prices may not be consistently available in middle-income countries with large HIV epidemics where key ARVs are still on patent. We examined price differences between countries within and outside sub-Saharan Africa.
Methods: Prices and transactions for ARVs used in national treatment programmes (2017 data) were extracted from the WHO Global Price Reporting Mechanism database for >100 countries. Prices were recorded as US$ per person per year for each given ARV treatment. Median prices were calculated for each country for 2017. For each treatment, price differences were calculated as percentage increases relative to the lowest median price for that treatment.
Results: Prices of generic ARVs in sub-Saharan Africa were much different to prices outside sub-Saharan Africa (NonSSA). Two originator drugs had significantly higher median prices when sold outside sub-Saharan Africa: LPV/r $546 (NonSSA) vs $268 (SSA), DRV $3503 (NonSSA) vs $651 (SSA). Central Asian countries reported originator DRV prices >900% of the minimum reported originator DRV price of $422 in Myanmar; Ukraine $5467, Tajikistan $4821, Kazakhstan $4519. Six NonSSA countries and South Africa all reported LPVr prices >400% of the minimum reported price of $123 in Eritrea; El Salvador $748, Armenia $740, Albania $733, Kyrgyzstan $733, Ukraine $731, South Africa $660, Viet Nam $622. Further price differentials were observed in ATVr prices.
Conclusions: There are still significant differences in HIV drug prices between countries with similar GNI. Mechanisms to ensure fair pricing across middle-income countries need to be improved to ensure the sustainable treatment access.

Viral hepatitis C elimination strategy in Vietnam: Willingness to pay for treatment among patients receiving antiretroviral therapy and methadone treatment

T. Nguyen[1], T. Cao[1], H. Nguyen Van[2], T. Nguyen[2], J. Sacks[3], J. Tebor[3], C. Boeke[3], C. Ramers[4], K. Nguyen Van[5]
[1]Clinton Health Access Initiative, Ha Noi, Vietnam, [2]Hai Duong Provincial HIV/AIDS Center, Hai Duong, Vietnam, [3]Clinton Health Access Initiative, New York, United States, [4]Clinton Health Access Initiative, San Diego, United States, [5]National Hospital of Tropical Diseases, Ha Noi, Vietnam

Background: HCV treatment remains costly, posing a challenge for scale-up, particularly in Vietnam where patients are required to pay out-of-pocket for diagnostic and treatment, even with health insurance. Understanding the maximum amount that patient populations are willing to pay may help to guide future pricing discussions and HCV elimination strategy. A brief assessment of willingness to pay at Hai Duong was conducted where rates of HCV infection are high especially among high-risk groups, such as individuals receiving methadone maintenance treatment (MMT) and people living with HIV.

Methods: A structured interviews conducted with 251 anti-HCV positive patients at an ART clinic and 165 anti-HCV positive patients at a MMT clinic from January-May 2017. Patients were asked about insurance coverage and the maximum amount of money they would be willing to pay for 3 months of HCV treatment. Degree of fibrosis was assessed using APRI scores. Analysis was primarily descriptive, with the percentage of patients per category calculated. Willingness to pay was also assessed in relation to other patient characteristics using multivariable linear regression.

Results: In the ART clinic, 880 adults were screened for HCV; 251 (28.5%) were anti-HCV positive. Of those, 96.4% had health insurance. 47.8% had APRI score < 0.5 and 7.2% had an APRI score $^{3}2$; 23.5% were willing to pay up to $1100 (converted to approximate USD values), whereas 22.3% were willing to pay if treatment was < $220. In contrast, in the MMT clinic, 288 adults were screened; 165 (57.3%) were anti-HCV positive. Of those, only 17.0% had health insurance (p< 0.001 compared to ART clinic). 64.2% had APRI < 0.5 and no patients had an APRI score $^{3}2$. 72.1% were willing to pay < $220 and 12.1% were willing to pay up to $1100. Patients with lower fibrosis score (p=0.04) and MMT patients (p=0.002) were willing to pay significantly less for HCV treatment.

Conclusions: MMT patients had much lower insurance coverage than HIV patients on ART and most were not willing to pay more than ~$220 for treatment. Greater willingness to pay was related to higher fibrosis score. Price reductions is needed to eliminate HCV in this patient population.

Supporting effective linkages between Maternal and HIV services

THPEE658

Integrating PMTCT into primary health care services for virtual elimination of mother-to-child transmission of HIV: Facilitators for and barriers to integrated services in South Africa

J.C. Mutabazi[1,2], H. Trottier[1,3], C. Zarowsky[1,2,4]
[1]University of Montréal, School of Public Health-Department of Preventive and Social Medicine, Montréal, Canada, [2]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montréal, Canada, [3]Centre de Recherche du Centre Hospitalier Universitaire Sainte Justine, Montréal, Canada, [4]University of the Western Cape, School of Public Health, Cape Town, South Africa

Background: The PMTCT cascade is increasingly well delivered and virtual elimination of mother-to-child transmission (MTCT) in the era of B+ option seems achievable when services aiming to combat HIV/AIDS, reduce child mortality and improve maternal health are integrated into existing health care services. We explored facilitators and barriers to PMTC services integration into comprehensive primary health care (PHC) services in South Africa.

Methods: We conducted 10 semi-structured interviews with national and local key informants and 9 semi-structured interviews with clinic managers, nurses and midwives in disadvantaged facilities in Cape Town. All interviews (N=19) were in person between June 2016 and October 2017 and were audio-recorded and transcribed. Atlas.ti software was used to assist thematic analysis.

Results: All participants underlined the importance of PMTCT integration to the extensive MTCT reduction in South Africa but report uneven progress. Slow and partial integration of PMTCT in PHC followed its initial roll out in the post AIDS denialism era. Pressure from the ground due to high HIV prevalence and AIDS related deaths mobilised health care professionals and the health system. Working with non-profit organisations and community health workers especially in post-partum follow-up helped to bring and keep women and their babies under treatment and reduce new paediatric infections. Nurse-initiated and managed antiretroviral therapy and related PMTCT trainings have also been a key facilitator to PMTCT integration especially in the well-established antenatal care system, but not to the overall PHC services.
However, major barriers impede full integration of PMTCT and consequent virtual elimination of MTCT in South Africa. In addition to small spaces and other infrastructure related challenges at PHC, these barriers include bureaucratic slowness and lack of managerial accountability, poor quality of care including suboptimal fidelity to algorithms, shortage and poor training of staff, work overload, high staff turnover, attitudinal issues, discrimination, stigma and loss to follow-up.

Conclusions: Multiple barriers to PMTCT integration remain a roadblock towards achieving virtual elimination of MTCT in South Africa. Our findings contribute to the efforts for enhancing PMTCT integration at PHC level towards virtual elimination of MTCT.

THPEE659

HIV/Syphilis co-infection among antenatal clinic attendees and their partners in Njombe region, Tanzania

E. Okechukwu[1], J. Gamaliel[1], B. Christian[2], A. Ikonje[3], M. Ndile[3], P. Swai[4], J. Bisimba[4], M. Njelekela[3]
[1]Family Health International (FHI 360), Global Health, Dar es Salaam, Tanzania, United Republic of, [2]Management and Development for Health, Programs, Dar es Salaam, Tanzania, United Republic of, [3]Deloitte Consulting Limited, Dar es Salaam, Tanzania, United Republic of, [4]US Agency for International Development, Dar es Salaam, Tanzania, United Republic of

Background: Antenatal clinic (ANC) setting has provided a good platform for integrated healthcare delivery among pregnant women. Although HIV and syphilis screenings are routinely offered to ANC attendees in Tanzania, HIV screening has received more attention than other sexual transmitted infections. Also, the major focus has been on pregnant women with lesser attention to the male partners especially for other diseases. ANC setting serves as a platform for reaching men (male partners of the pregnant women). In this study, USAID Boresha Afya Southern Zone project evaluated HIV/Syphilis infection and co-infection cascade among both pregnant women and their male partners in Njombe region.

Methods: A retrospective cross-sectional study of three months (April - June 2017) routine ANC services in 10 project supported health facilities was conducted. Facilities were selected based on the provision of integrated MCH/HIV services. Monthly data was collected from the ANC service delivery registers and summary forms, recorded in the excel sheets and analyzed using STATA 15.1 where the proportions were calculated.

Results: A total of 1,571 pregnant women attended first ANC, 51% and 99% were screened for syphilis and HIV respectively. This showed poor syphilis screening coverage among the ANC attendees in general. Syphilis screening among positive pregnant women was 42%, revealing missed opportunities. It also revealed high co-infection rate among the HIV positives screened for syphilis (10.4%). Overall, Syphilis treatment

coverage among those tested positive to syphilis was good (91%). Twenty percent (318) of male partners were screened for syphilis, out of which 5% (16) tested positive and 88% of them received syphilis treatment. Only 2% of HIV male partners were screened for HIV showing missed opportunities and the co-infection rate among male partners tested was high (29%).

Conclusions: HIV/Syphilis co-infection is high among pregnant women and their partners attending ANC services. Individual program resources should be leveraged to facilitate and monitor the delivery of a more comprehensive integrated health service package for both the pregnant women and their male partners using a one-stop shop model.

THPEE660

Post natal clubs: A differentiated model of care integrating maternal, child health and prevention of mother to child transmission (PMTCT) in Khayelitsha, South Africa

A.K. Nelson[1], T. Cassidy[1,2], L. Trivino Duran[1], A. Hoxha[1], K. Buchanan[1], A. Shroufi[1], R. Uenishi[1], N. Matangana[1], L. Mdani[1], E. Mohr[1], V. De Azevedo[3], S. Abrahams[3], C. Hofmeyr[4], J. Igumbor[4]
[1]MSF South Africa, Cape Town, South Africa, [2]University of Cape Town, Division of Public Health Medicine, School of Public Health and Family Medicine, Cape Town, South Africa, [3]City Health of Cape Town, Cape Town, South Africa, [4]mothers2mothers, Cape Town, South Africa

Background: With the advances of option B+ implementation, mother to child transmission (MTCT) in South Africa has fallen from 16,000 (2010) to 5,100 (2015). However, post-natal MTCT stays high (4.3%) at 18 months. Furthermore, access to post natal services and uptake of infant HIV testing is poor. We describe an integrated primary care intervention to improve uptake of HIV services for mother and infant pairs (MIP).

Methods: We adapted the adult ART adherence club model to provide double integration of care (maternal health, child health and HIV services) and components of the first 1000 days (mental health, nutrition advice and early childhood development activities) to HIV-positive mothers (stable and high risk) and their HIV-exposed-uninfected infants. The model was piloted at Town2 clinic, where antenatal prevalence is 34%, from June 2016 until now. Post Natal Clubs (PNC) were formed according to the infants' dates of birth into clubs of 2-10 MIP and were held at regular intervals (1-3 monthly) until 18 months of age. We analyzed and described maternal and child data routinely collected during the intervention.

Results: From July 2016 to December 2017, we recruited 227 mothers (8 high risk) and 232 infants (5 twins). Of the mothers who joined a PNC from week 10, 78% were still in care at 18 months (see graph 1). For the overall cohort, uptake of infants' 9 months and 18 months tests was 140/153 (91.5%) and 44/52 (84.6%) respectively with 0% positivity rate. Infants' vaccination coverage at 12 months was 75/93 (84.6%). Of the 88 mothers completing the 18 months intervention, 47 received a pap smear (53.4%) and 12 had an intra-uterine device inserted (13.6%). There were 46 instances of positive mental health screens out of 432 done (10.1%). Maternal viral load testing decreased over time but suppression remained high (see graph 1).

Conclusions: PNCs have shown good early retention-in-care for the MIP, good viral load suppression for the mother, optimal testing uptake for the child and efficient integration of services for the mother and infant pair. Implementation and monitoring challenges of the model are being worked on for future scalability and qualitative research is being conducted.

Viral Load	Number due	Complete*	Suppressed
week 10	166	151(91%)	146 (97%)
month 6	127	107(84%)	102 (95%)
month 12	72	44(61%)	43 (98%)
month 18	26	15(58%)	14 (93%)
*some capturing still underway			

[Table 1: Viral load completion and suppression in the PNC]

THPEE661

Challenges to implementation of prevention of mother-to-child HIV transmission in Kalimantan, Indonesia

A.B. Pratiwi[1,2], M.S. Hidayat[1,3], T.A. Sugiyatmi[4], V. Kania[1]
[1]Centre for Health Financing Policy and Health Insurance Management, Faculty of Medicine, Universitas Gadjah Mada, Yogyakarta, Indonesia, [2]Faculty of Medicine, Universitas Gadjah Mada, Medical Education and Bioethics, Yogyakarta, Indonesia, [3]Universitas Ahmad Dahlan, Public Health, Yogyakarta, Indonesia, [4]Tarakan District Health Office, Tarakan, Indonesia

Background: According to the Indonesian Ministry of Health, more than 30% of people living with HIV are women. In the newly formed province, North Kalimantan, an increasing number of newly reported cases in Tarakan municipality are among women who acquired HIV sexually. Although government programs to prevent vertical transmission of HIV exists, low utilisation and lost to follow up in the program cascade, indicates that it is suboptimal. This study explores the barriers and facilitators to implementation of HIV counselling and testing for pregnant women in Tarakan.

Methods: We conducted six focus group discussions and seventeen in-depth interviews between March and October 2017 to collect the data. The participants consisted of stakeholders and implementers in the prevention of mother-to-child-transmission (PMTCT) program, including health care workers in public and private health care facilities, District Health Office staff, management in the private hospital, HIV counselling and testing team in the public hospital, and women living with HIV. We applied coding and thematic approach to analyse the transcripts. Investigator triangulation was conducted to ensure validity of the analyses.

Results: There is a gap in implementation of PMTCT in public and private health care facilities, while HIV counselling and testing is available in public primary health care facilities, they are not available in the private. Pregnant women choosing to visit the private healthcare providers for antenatal care have missed the opportunity to get HIV counselling and testing during their pregnancy. In addition, interacting factors are affecting the individual decision in utilising PMTCT services, namely fear that their confidential data will be shared, stigma and discrimination from health care workers, time and transportation constrain.

Conclusions: In order to increase the coverage of counselling and testing and to avoid missed opportunities for pregnant women, private health care sectors need to be engaged in the implementation of this program. Regulation, facilities, and trained staff in the private healthcare sector should be initiated to increase the coverage of HIV counselling and testing as part of the PMTCT cascade. This would provide the opportunity to save more mothers living with HIV and their children.

Supporting effective linkages between Maternal and HIV services

THPEE662

Non-presentation to antenatal care impacts birth outcomes and PMTCT uptake in Botswana

M.D. Diseko[1], R. Zash[1,2,3], J. Mabuta[1], G. Mayondi[1], S. Lockman[1,3,4], C. Petlo[5], G. Mogomotsi[5], M. Mmalane[1], T. Sekoto[1], N. Seonyatseng[1], J. Makhema[1], R. Shapiro[1,3]
[1]Botswana Harvard AIDS Institute, Gaborone, Botswana, [2]Beth Israel Deaconess Medical Center, Boston, United States, [3]Harvard TH Chan School of Public Health, Boston, United States, [4]Brigham and Women's Hospital, Division of Infectious Disease, Boston, United States, [5]Ministry of Health and Wellness, PMTCT, Gaborone, Botswana

Background: Non-presentation to antenatal care (ANC) increases pregnancy complications and adverse birth outcomes, but its specific impact among HIV-infected women and efforts to prevent mother-to-child HIV transmission are unknown.
Methods: We abstracted data from obstetric records for all women who delivered at 8 government hospitals in Botswana (~45% of nationwide deliveries). Outcomes evaluated by ANC presentation status included stillbirth (SB), preterm delivery (PTD) (< 37 weeks gestational age (GA), and receipt of HIV testing and ART during pregnancy. Because women with PTD may have less opportunity to initiate ANC, we conducted sensitivity analyses restricted to outcomes occurring >=28 weeks GA.
Results: Between Aug 2014-Aug 2016, 47,027 women delivered at surveillance sites. ANC status was known in 46,502 (98.9%), and median GA at first ANC visit was 17 weeks [IQR 13,22]; 1,539 (3.3%) had no ANC visit and were classified non-presenters (NPs). NPs were more likely to be unmarried, unemployed, non-citizens, HIV-infected, have low education, and >4 prior pregnancies (Table 1).

	Women who received no antenatal care (N=1539) (N, %)	Women who received antenatal care (N=44963) (N, %)	P-value
Maternal Age, yrs (median, IQR)	26 [22,31]	26 [22,32]	0.16
Married	124 (8.8%)	4963 (11.2%)	0.005
Not a Botswana Citizen	327 (19.8%)	1162 (2.6%)	<0.0001
Low education	195 (15.5%)	3546 (8.0%)	<0.0001
Employment Status			<0.0001
Student	75 (6.0%)	3602 (8.3%)	
Unemployed	843 (67.8%)	24238 (55.9%)	
Salaried	325 (26.2%)	15560 (35.9%)	
Primigravid	354 (24.4%)	16393 (36.5%)	<0.0001
Grand multip (>4 prior preg)	191 (13.1%)	4561 (10.2%)	0.0004
Delivered at a tertiary maternity	948 (61.6%)	22116 (49.2%)	<0.0001
HIV status unknown	292 (19.0%)	168 (0.4%)	<0.0001
HIV-infected	393 (31.5%)	11539 (25.5%)	0.02
Timing of HIV test			<0.0001
HIV diagnosed prior to pregnancy	193 (49.1%)	7711 (67.6%)	
HIV diagnosed during pregnancy	87 (22.1%)	3546 (31.1%)	
HIV diagnosed at the time of labor and delivery	77 (19.6%)	27 (0.2%)	
HIV-infected and received no antiretrovirals during pregnancy	220 (56.0%)	822 (7.2%)	<0.0001

[Table 1: Characteristics of women by ANC presentation status in Botswana]

Adverse birth outcomes were increased among NPs compared with ANC presenters, including stillbirth (9.4% vs. 2.3%) and PTD (52% vs. 17%) (both p< 0.0001). When outcomes were restricted to >=28 weeks GA, NPs still had more stillbirth (7.0% vs. 1.8%) and PTD (45% vs. 16%) (both p< 0.0001). Among NPs with known HIV status, 393 (31.5%) were HIV-infected, compared with 11,539 (25.5%) presenters (p< 0.0001). HIV-infected NPs had a similarly high risk for stillbirth compared with HIV-uninfected NPs (8.7% vs. 8.4%, p=0.91) and higher risk for PTD (58.3% vs. 48.1%, p=0.003). Among HIV-infected NPs, 220 (56%) received no ART during pregnancy, including 77 (20%) diagnosed with HIV at delivery; in contrast, only 7.2% of presenting HIV-infected women received no ART. NPs accounted for 63% of women with unknown HIV status and 21% of HIV-infected women who received no ART in pregnancy.
Conclusions: The small number of women who do not present for ANC in Botswana represent the majority of those who are not HIV tested and a large proportion of HIV-infected women without ART receipt in pregnancy. In order to further reduce pediatric HIV infections, efforts are needed to engage these women in care.

Supporting effective linkages between Maternal and HIV services

THPEE663

Acceptability and primary outcomes of an integrated early childhood development (ECD) program for Option B+ mothers in Malawi

S.E. Deressa[1], E. Udedi[2], K. Dovel[1,3], A. Schooley[1,3], L.C. Bruns[3], T.J. Coates[3]
[1]Partners in Hope, Lilongwe, Malawi, [2]Partners in Hope, Programs, Lilongwe, Malawi, [3]University of California Los Angeles (UCLA), Division of Infectious Diseases, David Geffen School of Medicine at UCLA, Los Angeles, United States

Background: Successful strategies in the fight against HIV have changed the agenda for HIV infected and affected children from survival to thriving. Both HIV infection and the strained caregiving environment experienced by HIV affected families have negative impacts on children's cognitive development. Responsive and stimulating parenting plays a vital role in improving cognitive development, although such skills are rarely taught in low-resource, sub-Saharan settings. This study examines the acceptability and primary outcomes of an early childhood development (ECD) programme that imparts responsive, stimulating parenting skills to Option B+ mothers in Malawi.
Methods: The integrated Option B+/ECD program was conducted in two rural antiretroviral therapy (ART) clinics in central Malawi. Pregnant, Option B+ women were approached to participate in an interactive ECD skills development program starting from when the child was 6 to 8 weeks of age. The intervention was comprised of 9 monthly sessions (approximately 1-hour each) that coincided with mothers' scheduled ART appointments. Trained ECD counselors led each session using the WHO-UNICEF "Care for Child Development" package. Baseline and follow-up home visits and exit interviews were conducted at 2 and 9 months of age to assess changes in mothers' ECD knowledge and practice. Descriptive statistics and McNemar Tests were used to analyze the data.
Results: Between April-December 2016, 149 mother-infant pairs were enrolled in the program. Of the enrolled mothers, 114 (77%) graduated from the ECD program. There were no socio-demographic differences between mothers who dropped out of the program and those who graduated. Among graduates, 96 (84%) attended ≥8 of the 9 ECD sessions. Graduates' knowledge and observed practice of ECD activities significantly improved following the 9-month program. Availability of homemade toys, reading and singing to the child showed a 2 to 5-fold increase at the end of the program (Table 1).

Variables	Baseline	Follow-up	P-Value
Mother's knowledge of ECD stages	53%	93%	<0.001
Books available for the child in home	19%	54%	< 0.001
Homemade toys available in home	42.6%	85%	< 0.001
Child plays with household objects	31%	85%	< 0.001
Reading books to the child	14%	73%	< 0.001
Telling stories to the child	55%	95%	< 0.001
Singing songs to the child	19%	90%	<0.001

[Change in ECD Related Variables at the End of the Program (Data from Home Visit and Questionnaire)]

Mothers believed that the ECD program improved their parenting skills overall, and increased familial involvement in child-rearing, especially among fathers. Four mothers also reported initiating ECD group activities in their communities, suggesting desire for such programs.
Conclusions: High retention and positive ECD outcomes provide encouraging indications of the acceptability and effectiveness of an ECD intervention integrated into HIV care.

THPEE664

Paraprofessional home-visiting improves maternal caregiving for mothers living with and without HIV over the first two years of life in rural South Africa

L. Stansert Katzen[1], M. Tomlinson[2], J. Christodoulou[3], C. Laurenzi[2], I. le Roux[1], V. Baker[1], K. le Roux[4], M.J. Rotheram-Borus[3], L. Li[5]
[1]Philani Maternal, Child Health and Nutrition Project, Cape Town, South Africa, [2]Stellenbosch University, Department of Psychology, Stellenbosch, South Africa, [3]University of California, Department of Psychiatry and Biobehavioral Sciences, Semel Institute, Los Angeles, United States, [4]Zithulele Hospital, Mqanduli, South Africa, [5]University of California, Department of Psychiatry and Biobehavioral Sciences, Los Angeles, United States

Background: More than 50% of Africa's population lives in rural areas, which have few professional health workers. South Africa has adopted task-shifting health care to paraprofessionals to achieve the Sustainable Development Goals, however little is known about their efficacy in rural areas. This study examines whether home visiting by paraprofessional community health workers (CHWs) is associated with variations in maternal and child outcomes for mothers living with HIV (MLH) over the first two years of life in a deeply rural district of South Africa.
Methods: Almost all mothers giving birth (95.3%; N=494) in the Zithulele Hospital catchment area of the OR Tambo District were recruited and reassessed five times over two years after birth with 84.7-96% follow-up rates. Based on geographic location, mothers received either standard antenatal and HIV care (SC) (N=313 mothers) or SC with paraprofessional home-visiting (HV) (N=157 mothers, 37 CHWs). Almost one-third of mothers were mothers were mothers living with HIV (MLH) (N=139/470). By chance, there were significantly more MLH receiving HV than SC. Multiple linear and logistic regressions evaluated maternal comorbidities, maternal caretaking, and child development over time.
Results: MLH were older on average, less likely to report alcohol use after learning about pregnancy, and were more likely to be employed, married, and non-primipara. MLH attended more antenatal clinic appointments on average and were more likely to breastfeed exclusively for three months compared to uninfected mothers. Despite HIV infection, compared to mothers receiving SC, mothers with HV had significantly lower depression scores, were more likely to attend the recommended four antenatal care visits, and were less likely to consult traditional healers at 3 months. Infant growth and achievement of developmental milestones for children of MLH, whether receiving SC or HV were similar to un-exposed peers over the first two years of life.
Conclusions: HV result in better maternal caretaking for both MLH and uninfected mothers but did not directly benefit infant growth or developmental milestones in their first two years of life. This study examines a comprehensive, home-visiting model that will inform the upcoming broad implementation of CHW programs by South African Government in rural areas.

Approaches to effective HIV/SRH integration

THPEE665

Achieving the first two 90s through provider-initiated testing and counselling at family planning clinics in Ibadan, South West Nigeria

O. Ayinde[1], A.B. Usman[2,3], O.O. Oleribe[4]
[1]Ministry of Health, Public Health, Ibadan, Oyo State, Nigeria, [2]LAUTECH Teaching Hospital, Department of Community Medicine, Osogbo, Nigeria, [3]Nigerian Field Epidemiology and Laboratory Training Program, Abuja, Nigeria, [4]Excellence and Friends Management Care Center (EFMC), Abuja, Nigeria

Background: HIV testing is the first step in the 'HIV treatment cascade, therefore integrating Provider Initiated Testing and Counseling (PICT) into family planning/reproductive health (FP/RH) services is of great importance, as women of reproductive age are at risk of both HIV infection and unintended pregnancies. The integration will also contribute to primary prevention of HIV, achieving the United Nations "90-90-90" global targets, and Sustainable Development Goals (SDGs). FP providers have not successfully integrated PITC into FP services over the years in Nigeria and Oyo state, as implementation was met with inconclusive outcomes and inadequate documentation.
This study seeks to determine the outcome of PITC capacity building intervention for FP providers on HIV Testing services (HTS), linking and initiation of HIV positive clients on antiretroviral treatment (ART) in Ibadan, Oyo State, Nigeria.
Methods: An evaluation of FP/HIV integration was conducted in 20 purposively selected facilities, providing FP services, in Oyo State, by retrospectively reviewing 6 months HTS in the facility registers. FP health care providers were then trained in order to implement PITC strategy. The trained HCP was monitored and supervised. Six months after the training, FP/HIV integration was re-evaluated. Data was analyzed using SPSS version 20.
Results: A total of 14,032 clients visited the facilities six months pre-training, out of which 39, were tested for HIV and only 1 (0.3 %) was positive. After the training, 15,974 utilized FP services, and 48 (23.6%), were positive. The new clients increase from 8,066 pre-training, to 8,311 post-training, others were re-visit clients. At post-training, a total of 5,654 clients were offered HTS. The increase, in the number of clients that were tested for HIV, and those that tested positive, post-training, were statistically significantly, ($P<0.05$). A total of 48 clients were referred and linked to ART initiation.
Conclusions: It was established that PITC, not only increased the number of clients tested, but also revealed HIV positive clients, who were previously unaware of their HIV status. This also strengthened the linkage and initiation of ART among the clients. It is therefore recommended that this strategy be strengthened to achieve the United Nations "90-90-90" global targets.

Approaches to effective HIV/TB service delivery

THPEE666

Clinical characteristics of people with tuberculosis drug resistant according to HIV status in Brazil

G.T. Magnabosco[1], A. Veras de Oliveira[1], B. Reis Santos[1], A. Coelho Brito[1], R. Souza Junior[1], K. Bonfim Andrade Alves[1], R. Coelho[2], G.F. Mendes Pereira[2], F. Dockhorn Costa Johansen[1], P. Bartholomay Oliveira[1], D. Arakaki-Sanchez[1]
[1]Ministry of Health, National Tuberculosis Control Program, Brasilia, Brazil, [2]Ministry of Health, Department of Sexually Transmitted Disease, AIDS and Viral Hepatitis, Brasilia, Brazil

Background: Tuberculosis (TB) is one of the leading causes of death among infectious diseases in the world, and its control remains a challenge, mainly due to the number of new cases associated with human immunodeficiency virus (HIV). Additionally, TB-HIV coinfection is often related to the development of drug resistance in TB treatment, which worsens the patients clinical situation, extends the treatment time, and raises the cost of control actions. This study aimed to identify clinical characteristics of people with TB Drug Resistant (TBDR), according to HIV status in Brazil, from 2013 to 2017.

Methods: It is a longitudinal database study. The database from TB Special Treatment Information System (SITE-TB) was analyzed. SITE-TB records all treatments that showed some resistance to first-line drugs, cases of nontuberculous mycobacteria (NTM) and TB special treatments. Cases classified as TBDR were eligible, excluding those who did not test for HIV or presented inconclusive results. Frequency statistics was used to data analysis of the variables: case type, form, and associated comorbidities.

Results: There were 5,878 cases of TBDR in Brazil from 2013-2017, of which 661 were HIV positive (11.2%). The percentage of cases classified as type "return after lost follow-up" (16.9%), as form: extrapulmonary (8.9%) and extrapulmonary+pulmonary cases (12.0%), as well as those with the comorbidities: viral hepatitis (4.8%), mental disorders (3.1%), cancer (1.3%), ilicit drugs (30.8%), and tobacco (29.3%) was higher in TBDR coinfected than in non-coinfected TBDRs (Figure 1).

		TBDR			
		HIV + (n=661)	%	HIV - (n=[illegible])	%
Case type					
	New Case	478	72.3	2733	76.1
	Lost to follow-up	112	16.9	342	9.5
	Relapse	17	2.6	60	1.7
	Failure after first treatment	23	3.5	199	5.5
	Failure of Retreatment	12	1.8	155	4.3
	Scheme change	7	1.1	11	0.3
	Change in resistance pattern	3	0.5	54	1.5

Subtitle: TBDR – Tuberculosis Drug Resistant; * Number of cases; # For associated comorbidities the total number of new cases was used (N=478 for HIV+ and N=2733 for HIV-).

[Clinical characteristics of Tuberculosis Drug Resistat cases in coinfected and non-coinfected by HIV. Brazil, 2013-2017.]

Conclusions: TBDR-HIV coinfected people had complex clinical characteristics. The results reinforce the complicacy of care beyond the biological challenges in TBDR-HIV coinfection cases. Studies have shown that TB-HIV coinfected people have difficulty in adhering to treatment due to adverse effects and drug interactions favoring the lost follow-up. In this sense, TBDR and HIV interaction remain an important challenge for the both diseases control programs, requiring early detection of cases, adequate treatment and comprehensive care.
It is imperative that TB and HIV programs develop joint strategic actions to favor the timely and correct diagnosis of both infections, as well as comorbidities, ensuring adequate treatment and person-centered follow-up aiming of improving favorable outcomes and better quality of care.

THPEE667

Policy implementation gap of isoniazid preventive therapy (IPT) among people living with HIV in limited resource setting: Lessons from Nepal

K. Deuba[1], U. Shrestha[1], B. Rawal[2], R.P. Khanal[1], R.K. Bhattarai[3], B.D. Pandey[2], R. Shrestha[4], A.M. Ekstrom[5]
[1]National Centre for AIDS and STD Control/ Global Fund Programs, Kathmandu, Nepal, [2]National Centre for AIDS and STD Control, Ministry of Health, Kathmandu, Nepal, [3]Save the Children, Kathmandu, Nepal, [4]Public Health and Environment Research Centre, Lalitpur, Nepal, [5]Karolinska Institutet, Department of Public Health Sciences, Stockholm, Sweden

Background: Tuberculosis (TB) is one of the most common opportunistic infections that cause high morbidity and mortality rate among people living with HIV (PLHIV) in Nepal. Since 2014 Nepal has adopted the WHO recommendations to initiate Isoniazid Preventive Therapy (IPT) among PLHIV who does not have active TB. From early 2015 the Nepalese government's AIDS centre designed a project to increase the coverage of IPT and to reduce the burden of TB among PLHIV in Nepal.

Description: PT had been rolled out across all Nepal's 69 HIV treatment centres. Monitoring visits, meetings and brief orientations on the IPT guidelines was conducted with all HIV health personnel. The targets for IPT were finalized by the estimating number of PLHIV each year using mathematical modelling. To summarize the progress, we analyzed routine program data from July 2015 to November 2017.

Lessons learned: The overall cumulative coverage (2015-2017) of IPT among eligible PLHIV was low (18%; 5488/29952) whereas the coverage differed significantly between men (14%; 2637/18512) and women (25%; 2851/11440). In 2015, the IPT coverage among women (5.3%) was slightly higher than among men (3.2%) whereas not much difference was observed between age groups. The IPT coverage among women increased to 14% in 2016 whereas it increased only marginally to 8% among men. In 2017, the IPT coverage came down again for both men (3%) and women (7%) in 2017. There were no changes in the incidence of TB among PLHIV between 2015 and 2017. The qualitative findings showed a reluctancy among clinicians' to initiate IPT among eligible PLHIV because of a lack of local evidence on the effectiveness of IPT, and fear of interaction with antiretroviral therapy causing drug resistance among PLHIV. The low acceptance rate of IPT among PLHIV was seen as another major barrier blamed on increased pill burden and side effects.

Conclusions/Next steps: Findings suggest that future policy recommendations need to be more clearly discussed with front-line care providers before roll out of activities in routine health programs. Ensuring active participation from care providers during the policy-making process would also help the implementation of recommendations and contribute to achieving planned outcomes.

THPEE668

Expanding use of TB-LAM for HIV+ individuals with CD4< 200: Evidence from MSF operational research and beyond

K. England[1], E. Fajardo[1], G. Ferlazzo[2], H. Huerga[3]
[1]Médecins Sans Frontières (MSF) Access Campaign, Geneva, Switzerland, [2]Médecins Sans Frontières (MSF) Southern Africa Medical Unit (SAMU), Cape Town, South Africa, [3]Médecins Sans Frontières (MSF) Epicentre, Paris, France

Background: World Health Organization (WHO) recommends the use of TB-LAM (LAM) to detect TB in HIV+ individuals with CD4 ≤100 cells/mm³ or who are severely ill irrespective of their CD4 counts. MSF operational research and published literature were analysed to provide evidence for expanding use of LAM to diagnose TB among HIV+ individuals with CD4 < 200 cells/mm³.
Description: Presented are the results from MSF operational research in three locations (Kenya, Mozambique and Malawi), which included an analysis of using LAM as a diagnostic tool for HIV+ individuals with CD4< 200. In Kenya, MSF analysed the incremental diagnostic yield achieved by adding LAM to standard algorithms in ambulatory and hospitalised HIV+ individuals. In Mozambique, LAM was used as a diagnostic tool in ambulatory settings for people with symptoms of TB and CD4< 200. In Malawi, LAM was used to diagnose TB for HIV+ individuals regardless of symptoms and CD4 count. Furthermore, a literature review was conducted of diagnostic performance studies of LAM compared to a reference standard (culture, composite standard or Xpert) for HIV+ individuals with CD4 < 200 from March 2015 to date.
Lessons learned: Data from Homa Bay, Kenya demonstrated that 68.2% (88/129) of patients with bacteriologically confirmed TB and CD4 < 200 were diagnosed using LAM. The additional diagnostic yield when adding LAM was 19.3% for this cohort, compared with clinical signs and microscopy alone. In Maputo, Mozambique, using LAM as a diagnostic tool for all ambulatory patients with symptoms of TB and CD4< 200 demonstrated a positivity of 44.8% (128/286). Positivity rate among patients with CD4 100-199 specifically was 44.4% (24/54). In Chiradzulu, Malawi, using LAM in hospitalised patients regardless of symptoms showed a positivity of 30.0% (60/200) in patients with CD4< 200 and 20.6% (13/63) in patients with CD4 100-199. Finally, the literature review identified 14 additional studies published since March 2015 which further substantiate the need to expand use of LAM to HIV+ individuals with CD4< 200.
Conclusions/Next steps: In conclusion, WHO should consider expanding current guidelines to include the use of LAM to diagnose TB in an expanded cohort of HIV+ individuals with CD4< 200.

THPEE669

Using a targeted approach to boost TB case-finding among vulnerable children - the SMILE experience

C. Anoje[1], T. Lan[1], E. Olashore[1], M. Bebia[1], A. Efuntoye[1], O. Temitayo[2], P. Gado[2]
[1]Catholic Relief Services, Abuja, Nigeria, [2]United States Agency for International Development, Abuja, Nigeria

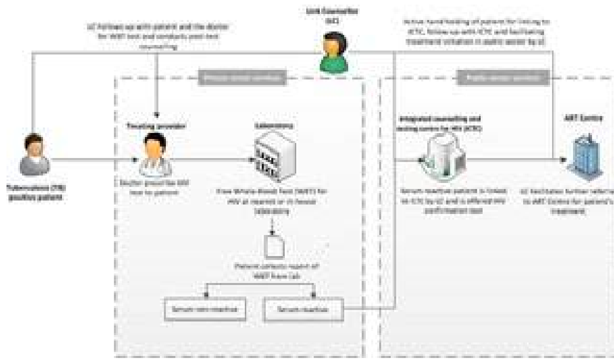
Background: The World Health Organization (WHO) estimates that one million children (< 15 years) currently suffer from tuberculosis (TB) worldwide, and that more than 210,000 die each year Nigeria's children, especially those living in high-density, slum communities, are at high risk for contracting TB. Nigeria has the highest TB burden in Africa, with an estimated half a million new TB cases every year. TB case notification rates are alarmingly low, with only 100,433 TB cases notified in 2016 representing approximately 20% of actual cases. In the face of limited access to TB services at the health facilities, weak health extension services and health seeking behaviour, innovative approaches are required to increasing TB case detection.
Description: Sustainable Mechanisms for Improved Livelihood and Household Empowerment (SMILE) is an OVC project funded by the USAID and implemented by Catholic Relief Services.
As per a funding agreement with USAID, SMILE integrated CTBC activities into its existing child-focused interventions in Benue state, aiming to identify presumptive pediatric TB cases from among the program's targeted beneficiaries. The approach include house -to-house screening, school based screening and index contact tracing. Using a child focused screening tool, trained case managers and volunteers identified presumptive TB cases, these presumptive cases were immediately referred and escorted by trained to health centers for TB diagnoses.
Lessons learned: A total of 11,125 children were screened for TB between February and August 2017 with 2,553 presumptive TB cases referred for further diagnosis. A total of 1,767 children (69%) completed their referrals, with 466 children diagnosed with active TB including 20 newly tested HIV positive. This TB case-finding represents a dramatic increase over performance in the three preceding years (2014 [79 cases], 2015 [112 cases], and 2016 [116 cases]. 424 children commenced TB treatment and 147 had successfully completed their 6-9 month course by December 31, 2017; the majority of those remaining are on track to complete treatment by the end of February 2018.
Conclusions/Next steps: Integrating a pediatric TB initiative into an OVC program has the significant advantage of leveraging the skills, infrastructure, relationships and credibility of a child-focused, community-based mechanism to increase case finding of TB amongst children.

THPEE670

Engaging private medical practitioners for early HIV screening and treatment initiation of tuberculosis (TB) patients in Maharashtra

J. Thakker[1], P. Bogam[1], R. Taralekar[1], S. Vijayan[1], L. Sadasivan[2], R. Chopra[1], A. Ali[3], D. Gangurde[4], S. Acharya[5]
[1]PATH, International Health, Mumbai, India, [2]PATH, International Health, Washington DC, United States, [3]Maharashtra Janavikas Kendra, Mumbai, India, [4]Alert India, Mumbai, India, [5]Mumbai District AIDS Control Society, Mumbai, India

Background: Per World Health Organization's estimates, India had 2.8 million TB patients in 2016, one-fourth of global incidence. Among notified patients, 87,000 were HIV co-infected of which 12,000 (14%) died. TB patients notified in the public sector go through HIV screening, however there is no information on the HIV status of about 1 million TB patients that would seek care in the private sector who are not notified. From 2014-17, PATH implemented a Private Provider Interface Agency (PPIA) model which notified 40,000 TB patients by engaging private healthcare providers in Mumbai. In 2016, the project began working with private providers to screen TB patients for HIV and refer them to public sector for treatment.
Description: The intervention aimed to screen all TB patients notified by private providers in engaged facilities of Thane, Mumbai, and Pune for HIV at accredited private laboratories and enable free testing. After HIV screening, Link Counsellors (LCs) accompanied patients to Integrated Counselling and Testing Center (ICTC) for confirmation of HIV and further linkage to public sector's Anti-retroviral treatment (ART) centres for treatment initiation. A dedicated cadre of LCs handheld patients throughout the pathway of care. Public sector providers were trained to fast track private-sector patients for HIV testing and treatment.
Lessons learned: From March 2016 to November 2017, out of 12,535 TB patients notified from 135 private facilities, 9,098 (75%) were screened for HIV. Of these, 262 were TB-HIV co-infected patients (2.9% HIV positivity). Of these, 79 (30%) were already on ARV treatment; and of the 183 newly diagnosed patients, 157 (85%) were linked to ICTCs, of which 147 (94%) were linked to ART centres. The LC model shortened time between linkages compared to the public sector to, on average: 5 days for linkage from private center to ICTC center, 7 days for ART registration, and 14 days for treatment initiation.
Conclusions/Next steps: The intervention demonstrated successful early HIV screening of TB patients in private sector linked with public sector for timely treatment initiation. The intervention provides an important platform to engage government for scaling up in 100 HIV high-burden districts of India ensuring high yield HIV case finding.



[Comprehensive processes involved in the TB-HIV project for Private Health Sector, Mumbai, India, 2016-17]

Categories	Number	Proportion
Total number of TB patients notified in selected facilities	12535	100%
TB patients screened for HIV	9095	75%
Male	4276	47% (n=9096)
Female	4822	53% (n=9096)
HIV positive	262	2.9% (n=9096)
Male	157	3.6% (n=4276)
Female	105	2.1% (n=4822)
5-34 years	84	32% (n=262)
35-50 years	126	48% (n=262)

Achieving systemic and scalable quality assured private sector engagement in HIV/TB care and prevention in Nigeria - successes and lessons learnt from the building models for the future (BMF) project

V.A. Adepoju[1], P. Edo[2], F. Egbedeyi[3], A. Asumah[3], M. Brunetti[4], K. Schuts[5], N. Kamp[6], K. Fiekert[7]

[1]KNCV Tuberculosis Foundation, TB/HIV Prevention, Care and Treatment, Lagos, Nigeria, [2]KNCV Tuberculosis Foundation, TB/HIV (Monitoring and Evaluation), Lagos, Nigeria, [3]Pharmaccess Foundation, Quality Manager (Health Systems Strengthening), Lagos, Nigeria, [4]KNCV Tuberculosis Foundation, Monitoring and Evaluation Officer, The Hague, Netherlands, [5]KNCV Tuberculosis Foundation, Project Officer, The Hague, Netherlands, [6]KNCV Tuberculosis Foundation, Senior Technical Advisor (Building Model for the Future Project), The Hague, Netherlands, [7]KNCV Tuberculosis Foundation, Senior TB Consultant/ Team Co-ordinator Health Systems & Key Populations, The Hague, Netherlands

Background: Since 2015 KNCV and PharmAccess implement the project "Improved TB/HIV prevention and care - Building models for the future" in collaboration with the Lagos State TB Program. The objective is to increase affordable access to quality TB screening, early diagnosis and treatment in the private sector.

Description: The project integrated the international SafeCare quality improvement standards with the International Standards for TB Care (ISTC) into a quality improvement tool. Implementation of the tool in private facilities started with a participatory baseline assessment. Identified gaps such as absence of SOPs, IEC materials, knowledge and standard M&E forms were addressed. Targetted trainings were given on TB/HIV, staff retention, quality management and "healthy business" topics. Training was complemented with on-site support and mentoring during joint supervision with public TB officers. The intervention was scaled from initially 37 to 60 engaged private health facilities by end 2017.

After introducing active TB screening, we observed a five-fold and three-fold increase of presumptive and confirmed TB diagnosis respectively. Improved access to diagnostics through a sputum transportation system increased TB patients diagnosed using Xpert_MTB/RIF from 43% to 82%. Improved contact investigation tripled eligible children placed on IPT. TB literacy of patients improved by introducing the patient charter and the TB literacy tool. Orientation of HCWs and District TB supervisors on the patient charter led to increased knowledge and referrals of presumptive TB patients.

Treatment success increased from 59% at baseline to 87%. In less than one year 43% of facilities with poor adherence to ISTC standards reached 100% compliance. The implemented model has contributed to a marked quality improvement in all facilities enrolled.

Lessons learned: A facility wide quality improvement approach that integrates TB/HIV quality standards into overall health care can increase TB/HIV case finding and quality care in the private sector.

Conclusions/Next steps: The next step is to translate the model into building sustainable health systems, exploring health financing options and business models and integrate the ISTC quality tools into the Lagos State quality inspection standards and National TB program supervision tools.

Funded by the Dutch Government

THPEE672

Community health workers facilitate access to tuberculosis (TB) diagnostic services for clients with limited access to health care

C. Lesedi, B. Segwabanyane-Morapedi, J. Irige, G. Morineau

Family Health International 360 Botswana, Advancing Partners and Communities Project, Gaborone, Botswana

Background: In Botswana, the HIV prevalence among TB patients is 61%. The Advancing Partners and Communities project- Botswana (APC) is a three-year USAID-funded project implemented by FHI 360 through community based organizations by integrating TB/HIV activities at community level and promoting TB cure in eight districts. Community Health Workers (CHWs) are trained on four-symptom TB screening to conduct contact tracing, intensive and active case finding. The report on evaluation of community tuberculosis approaches in Botswana (2012-2013) recommends that CHWs collect and transport sputum for TB investigation to improve referral completion and TB diagnosis.

In 2016 the project experienced challenges with referral completion of presumptive TB clients identified in the community. From 1,978 presumptive TB clients identified and referred to facilities for further investigations, 1,053 (53%) had completed referrals. Barriers to referral completion include lack of transport, long distance to facilities and nomadic clients, among others. The project then emphasized community sputum collection to close the gap of referral completion.

Description: CHWs were trained on safe home sputum collection and transport from community to the facility. CHWs were provided with cooler boxes, gloves, sputum bottles, and respiratory masks to collect and transport sputum from community to facilities.

Lessons learned: Out of 1,237 presumptive TB clients identified and referred to facilities in 2017, 816 (66%) clients completed referral. Among those who had completed referral, 267 clients (33%) had their sputum collected at community level. Fifty-four APC clients were diagnosed with TB through community TB screening, including 16 TB patients (30%) who had their sputum collected within the community. HIV testing was proposed and provided to those with unknown HIV status.

Conclusions/Next steps: With the implementation of community sputum collection, the referral completion rate has increase from 53% in 2016 to 66% in 2017. Community sputum collection enhances TB diagnosis, particularly for clients far from facilities and those nomadic. The project will continue to support CHWs in high TB/HIV districts of Botswana to collect sputum at community level.

THPEE673

Low ART coverage of TB/HIV infected patients in Central Asia: Results from Kazakhstan and Kyrgyzstan

Y. Kudussova[1], T. Ellman[2], A. Deryabina[1]
[1]ICAP at Columbia University, Central Asia, Almaty, Kazakhstan, [2]ICAP, Mailman School of Public Health, Columbia University Medical Center, Division of Infectious Diseases, New York, NY, United States

Background: Tuberculosis (TB) remains the leading cause of morbidity among people living with HIV (PLHIV) in Central Asia. WHO recommends that all TB patients co-infected with HIV (TB/HIV patients) start TB treatment first and then ART within 8 weeks of TB treatment initiation, unless CD4 < 50 cells/µl when ART should be started within 2 weeks, given the demonstrated survival benefit. In 2016, ICAP conducted a study to assess initiation of ART in TB/HIV patients at nine HIV care and treatment sites in Kazakhstan and Kyrgyzstan.

Description: To assess ART initiation rates, we conducted a retrospective review and analysis of 590 records of TB/HIV patients that were enrolled in HIV care and started TB treatment during 2015. Nine sites were selected on the basis of geographical location, strategic role for the country, number of PLHIV enrolled in care, and the number of TB/HIV cases. To determine obstacles to prompt ART initiation, we conducted semi-structured small group interviews with 37 physicians that provide HIV treatment services.

Lessons learned: During 2015, there were 316 new and 180 relapse TB cases in Kazakhstan. Among them, 221 and 123 patients started ART during TB treatment. In Kyrgyzstan, there were 74 new and 20 relapse TB cases with 48 and 15 of them respectively started on ART during TB treatment.

Overall, ART coverage of TB/HIV patients during TB treatment was 70% among new and 68% among relapse TB cases in Kazakhstan, and 65% and 75% in Kyrgyzstan respectively. Many physicians were reluctant to initiate ART in patients receiving TB treatment fearing patients' poor adherence. In the opinion of physicians, patients were also hesitant to start ART while on TB treatment because of concern for high pill burden and complicated regimens.

Conclusions/Next steps: ART coverage among TB/HIV patients is low. Physicians do not initiate ART during TB treatment in sufficient numbers as they fear poor adherence. Additional training to promote early ART initiation among medical staff, as well as introduction of optimized one-pill a day ART regimens may increase ART initiation in TB/HIV patients. In addition, increased integration between TB and HIV services may also help increase ART coverage in TB/HIV patients.

THPEE674

Task shifting increased Isoniazid preventive therapy uptake and completion among people living with HIV in secondary health facilities South-East Nigeria

O. Onyedinachi[1], O. Eghaghara[2], O. Adebayo[3], A. Eyo[1], G. Odutuga[2]
[1]Excellence Community Education Welfare Scheme (ECEWS), Clinical Services Unit, Abuja, Nigeria, [2]Excellence Community Education Welfare Scheme (ECEWS), Clinical Services Unit, Enugu, Nigeria, [3]JHPIEGO, Clinical Services Unit, Abuja, Nigeria

Background: People living with HIV (PLHIV) have a 20-fold higher risk of developing Tuberculosis (TB), which is responsible for over 33% mortality in PLHIV. Although Isoniazid Preventive Therapy (IPT) is effective in the prevention of active TB in this people, a retrospective review of 2014/2015 Isoniazid (INH) data from 9 secondary health facilities in south-East Nigeria, revealed poor uptake and completion rate of the six months course. This was mainly due to workload on the physicians who often fail to initiate eligible PLHIV on Isoniazid Preventive Therapy (IPT) . Excellence Community Education Welfare Scheme (ECEWS), LOCATE Project introduced task shifting to address this gap.

Description: In March 2015, ECEWS (LOCATE project) trained, supported and provided Job Aids for non-physicians including Pharmacy technicians and Treatment Support Staff on identification, initiation and completion of Isoniazid Preventive Therapy (IPT) for PLHIV. Pharmacists and other treatment support staff were mentored on adverse drug reaction monitoring. PLHIVs were educated (during Support group meetings) on benefits of IPT, adherence, 6 months completion; and the need to prompt dispensers when INH was omitted.

Lessons learned: The percentage of eligible PLHIV (3459) initiated on Isoniazid Preventive Therapy (IPT) increased from 8% (n=277) before intervention to 85% (n=2940) 9 months post-intervention. Similarly, 99.5% of them completed the 6 months course as against 0% completion rate recorded pre-intervention. IPT was discontinued in three (0.2%) PLHIV due to side effects, while 6 (0.3%) clients declined medication.

Conclusions/Next steps: Task shifting was found to be effective in Isoniazid Preventive Therapy (IPT) uptake and completion. This demonstrates the value of using none-physicians to optimize HIV care and support services, especially in resource limited settings.

Supporting resilient health systems

THPEE675

Strengthening capacity of county planning and budgeting for sustainable health financing: An experience from the devolved health system in Lamu County, Kenya

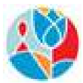
T. Oneko[1], D. Koech[1], D.S. Were[1], P. Abonyo[1], V. Tole[2]
[1]Palladium Group - Afya Pwani, Health Systems Strengthening, Nairobi, Kenya, [2]Lamu County Government, Health Services, Lamu Island, Kenya

Background: The Constitution of Kenya assigns the functions of health policy and service delivery to national and county governments, respectively. Health sector resources are envisaged to be mobilized from three sources—nationally-allocated revenue, county-generated revenues and donors. Evidence shows that the devolved county governments have inadequate capacity to effectively undertake health planning and budgeting to ensure sustainable health financing, against a backdrop of declining donor support to programs such as HIV, malaria and tuberculosis.

Description: Sustainable health care in a devolved system requires appropriate skills and understanding of the new planning and budgeting requirements. The Afya Pwani project, funded by USAID, has strengthened the planning and budgeting of health departments through capacity building of health managers on programme-based budgeting to improve allocative efficiency and establishing stakeholder forums to foster transparent consensus-building in aligning health sector goals. In addition, the project facilitated the use of evidence, such as budget analysis, in high-level advocacy efforts between the Department of Health, County Assembly, and Treasury to create an informed enabling environment that improves political will for sustainable health financing. It is expected that the improvement in overall institutional capacity will increase the health sector's fiscal space for sustainable health financing.

Lessons learned: The transition to programme-based budgeting in Lamu enabled health department to influence increased sector allocation ceilings and align their resources to priority programmes. The approach provided a mechanism to establish a budget line item for HIV in addition to creating an opportunity to leverage partner funding to address county-specific health priorities.

Conclusions/Next steps: Effective adoption and implementation of programme-based budgeting at the county health department and health facility level has enhanced the institutions' ability to identify, prioritize, set goals, allocate resources and exercise control to deliver health sector programmes more efficiently. Centralization remains a hindrance to effective planning and budgeting at the facility level and there is a need to progressively decentralize decision making to hospital management teams to undertake planning and budgeting functions. In addition, the health department needs to put in place legislation that allows health facilities to retain and utilize revenue generated for the improvement of health care service delivery.



THPEE676

Results from a rapid health workforce assessment of PEPFAR-supported facilities in three counties in Kenya

S. Mbaabu[1], M. Ochieng[1], W. Owino[1], A. Vinluan[2], J. Muriuki[1], P. Milo[1]
[1]IntraHealth International, Nairobi, Kenya, [2]IntraHealth International, Chapel Hill, United States

Background: IntraHealth International's USAID-funded Human Resources for Health (HRH) Kenya Mechanism conducted an assessment in PEPFAR-supported health facilities using the rapid site-level HRH assessment tool. The PEPFAR HRH Technical Working Group developed the tool, which assists countries to establish availability and quality of HRH to meet 90-90-90 targets.

Methods: We employed a cross-sectional study design using a mixed-methods approach to data collection. In-person interviews with health facility in-charges, supervisors and health workers were conducted at 21 PEPFAR-supported health facilities and 6 community units within Kisumu, Kilifi and Nakuru counties. The assessment adopted a purposive stratified and multistage sampling design to select facilities on basis of HIV disease burden, geographical distribution, facility tiers and PEPFAR support.

Results: The facilities had total daily patient attendance of 5,485 with 27,416 ART patients. The proportion of staff available, compared to WHO norms and standards, indicated a severe shortfall with only 43% (n=2,774) of staff needed to deliver Kenya's Essential Package for Health. On average, facilities provided HIV services only 39% of business hours in a week. HIV services at community units were open 24% of business hours. The highest full-time equivalent staff for HIV services was nurses at 238 followed by support staff (125) and HIV testing and counseling (HTC) providers (73). Community-based HIV services were predominantly provided by nurses; HIV testing and linkages by HTC providers; and ARV initiation by clinical officers.

Inadequate infrastructure was identified as the top HRH challenge, followed by health worker shortages, and recruitment, contractual and/or payroll processes. Staff quit their jobs because of insufficient salary and benefits, reassignment by government, and better opportunities in the private sector.

Conclusions: Low percentage of staff available to deliver HIV services has major implications on the successful rollout of Kenya's 90-90-90 strategy. Results indicate need to hire more staff in a sustainable manner; institutionalize in-service trainings; address space constraints; improve recruiting, deployment, supervision, and perfomance management processes; and better transfer skills from experienced staff to new employees. Data show need for advocacy and/or decision-making to address cadre deployment and distribution gaps, reconfigure HRH task allocation and explore new HIV service delivery models.

THPEE677

Increasing availability and access to life-saving ART commodities through improved inventory management and forecasting using a commodity management supportive supervision scored checklist: Case study of five coastal counties of Kenya

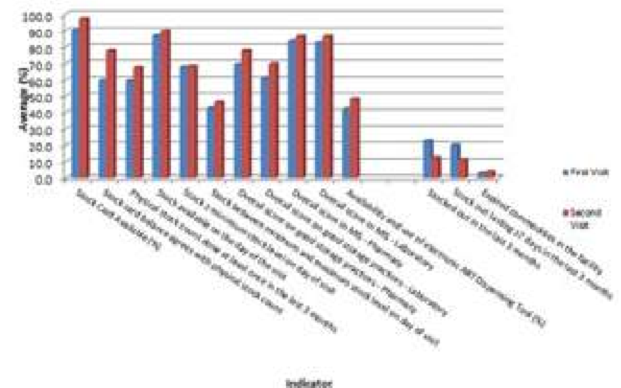
A.I. Mwangi
Pathfinder International, Programs & Impact, Watertown, United States

Background: Health products and technologies is one of the six pillars of health identified by the WHO. Existing national mechanisms for commodity data reporting in Kenya (KEMSA LMIS and DHIS2) collect consumption data to inform forecasting, quantification and resupply for health facilities. However, health facilities lack effective monitoring systems to track commodity management, including stock outs and inventory management, which are important for proper quantification. The USAID's Afya Pwani project, which is active in five coastal counties (Mombasa, Kilifi, Kwale, Taita Taveta and Lamu), adopted a supportive supervision checklist to assess the baseline gaps and monitor progress. Baseline assessment in the facilities showed a weak inventory management system with 40% of tracer commodities showing a discrepancy between recorded balance and physical count, and unacceptable level of stock outs. 22.8% of tracer commodities had a stock out lasting more than 7 days in the previous three months.

Description: To promote uninterrupted availability of antiretroviral and TB/HIV medicines, rapid HIV test kits, HIV nutrition products and other vital health products, joint supportive supervision on commodity management is conducted by project staff and county health department managers using the scored checklist. Focus areas include inventory management, storage practices, reference materials (guidelines and SOPs), and availability and use of management information system tools. The checklist automatically aggregates scores for pharmacy and laboratory departments. The score informs the commodity management situation in the counties. Analysis of data from 31 health facilities supported by Afya Pwani yielded important indicator-based statistics as shown in the attached graph.

Lessons learned: Stock outs in the previous three months reduced from 22.8% to 12.4%, and discrepancies between recorded balance and physical count reduced from 40% to 22.3%. Designing corrective interventions such as on-the-job training, provision of job aids and guidelines became easier. The checklist data provides information on vital commodities shortages or stock outs. This allows lacking commodities to be sourced from elsewhere and resupplied as forecasting, quantification and ordering improves.

Conclusions/Next steps: Evidence justifies continued use of the checklist during supervision and scale up to all other facilities in the project-supported counties.



[Commodity Management Indicator Analysis for Facilities Visited Twice (N=31)]

Making health systems work for adolescents

THPEE678

Advancing youth-led social accountability in adolescent and youth HIV/sexual reproductive health and rights programs in public health facilities within 4 districts of Uganda: Achievements & lessons learnt from 2015 to 2017

Q. Matovu[1], J.K. Tumusiime[1], D. Mulesa[1], P. Ibembe[2], P. Ojulong[3], S. Baumgartner[4]
[1]Reproductive Health Uganda, Programs, Kampala, Uganda, [2]Reproductive Health Uganda, Kampala, Uganda, [3]Action Group for Health Human Rights and HIV/AIDS Uganda, Kampala, Uganda, [4]International Planned Parenthood Federation (IPPF), London, United Kingdom

Background: The global community's growing enthusiasm for the potential of social accountability approaches to improve health systems' performance and accelerate health progress remain unmatched. Promising evidence suggests that social accountability contributes to citizen empowerment, service provider and power-holder effectiveness, ac-

countability responsiveness and spaces for negotiation between the two that are expanded, effective and inclusive. Reproductive Health Uganda (RHU) as part of its approaches to strengthen provision of quality adolescent & youth friendly services in 10 public health facilities in Uganda *(2014/2016-Gulu, Tororo-Access to Services & Knowledge "ASK"-project, 2017-Iganga, Bugiri;-Get Up Speak Out for youth rights "GUSO" project)* adapted the use of youth-led social accountability model using a tailored community score card as the key assessment tool.

Description: The process involved identification of 20 young people for capacity building as expert facilitators, developing a community score card with input track indicators drawn from national policies and standard guidelines, conducting self evaluation by health facilities, community(young people) performance assessment, stakeholders' interface meetings, action planning and monitoring. It was rolled out in 10 public health facilities, 10 action plans were developed and implemented with progressive assessments after every 3 months within 3 years. Key findings were documented and disseminated at sub-county and district level. Progressive reports indicated improvement of youth friendly service delivery especially service providers' attitudes, health facilities ambiance, adherence to service delivery standards and meaningful youth participation.

Lessons learned: The community score card built trust, strengthened relationships between service users (young people) and service providers as it focused on settling group scores rather than personal opinions. Engaging young people in monitoring programs at community level strengthened advocate for youth HIV/SRHR issues at district level resulting into quick wins.

Stakeholders' involvement in the problem identification facilitated quick actions towards improvement of the adolescent and youth sexual and reproductive health services in the health facilities and districts at large.

Conclusions/Next steps: Youth-led social accountability strengthened community ownership of service delivery processes, created a peer to peer model of identifying and resolving challenges using local resources, designation of youth friendly spaces, adolescent/youth service time among other. RHU plans to scale-up the same approach to in 2 more districts in 2018.

THPEE679

Reaching at-risk adolescent men who have sex with men through social media and instant messaging in Thailand for HIV prevention service provision

W.N. Songtaweesin[1], T. Teerawit[2], N. Teachatanawat[3], T. Monta[2], K. Termvanich[3], S. Bureechai[2], S. Thammasala[4], N. Phanuphak[3], T. Puthanakit[1]

[1]Chulalongkorn University, Center of Excellence for Pediatric Infectious Diseases and Vaccines, Bangkok, Thailand, [2]Chulalongkorn University, Department of Pediatrics, Faculty of Medicine, Bangkok, Thailand, [3]The Thai Red Cross AIDS Research Center, Prevention, Bangkok, Thailand, [4]The HIV Netherlands Australia Thailand Research Collaboration, Bangkok, Thailand

Background: Men who have sex with men (MSM) are a key population contributing to over half of all new HIV infections in Thailand, the highest incidence being in adolescent MSM. Unfortunately, several barriers exist in the access of this population to healthcare services, including uncertainty about how to access sexual health services, stigma, and fear of judgement by healthcare staff. Online technology availability has enabled service delivery to reach previously difficult to reach key populations.

Description: We advertised our new youth-focused HIV prevention services at the Thai Red Cross Anonymous Clinic targeting youth aged < 20 years through social media. This consisted of a poster with contact details through social media for MSM aged 15-20 and a desire to have safe sex. Within 2 months, 102 participants added us on social media and 69 requested services. Of those who revealed their age (N=21), 28% were under 20 and 72% were 20-35 years old. Thirty-eight (55%) participants contacted us out of regular office hours. We responded back to all queries within 1-6 hours. Sixty-five (94%) made contact exclusively through instant messaging rather than telephoning.

Commonest queries were regarding access to free pre-exposure prophylaxis (PrEP) 34 (49%), suspected exposure to risk 16 (23%), how to take PrEP 13 (18%), emotional support following an HIV diagnosis 4 (5%), and post-exposure prophylaxis (PEP) 4 (5%). There was one telephone call from a client recently diagnosed with HIV who was suicidal. Psychosocial assessment and counselling were provided to all clients, along with referral support to nearest suitable services. Twenty-three (33%) cases lived outside Bangkok and were referred to other service locations. Three (4%) cases had PEP posted to them within 72 hours of exposure.

Lessons learned: Health care teams serving youth need to be flexible in offering out-of-hours services and be knowledgeable in providing and/or linking clients to a wide variety of services according to their needs including HIV prevention, sexual health, HIV testing, and initial mental health assessment and counselling.

Conclusions/Next steps: There is scope for development of virtual online clinics to support young people to stay safe and link them to appropriate HIV services.

THPEE680

Understanding organizational incapacities on reaching adolescents living with HIV in Lagos, Nigeria

M. Onuenyenwa[1], C. Ifekandu[2]

[1]Military Hospital Lagos, Infectious Disease Clinic, Lagos, Nigeria, [2]Federal University Lafia, Sociology, Lafia, Nigeria

Background: Sexual and reproductive health (SRH) issues are mostly seen as exclusive right of married adults in Africa. Despite studies showing that average age of sexual debut in Nigeria is below 13years old, and adolescents between the ages of 15-19 consist of the 21% of the HIV infection in Nigeria, Health service providers and policy makers are yet to prioritize HIV-Youth friendly services in Nigeria. The need to address the situation informed the Healthcare sensitivity training to health facilities to evaluate the quality of treatment, care and services rendered to HIV-Positive adolescents in Nigeria.

Methods: A total of 122 HIV focal persons drawn from 10 health facilities in Lagos states. The participants were requested to complete a semi-structured questionnaire to assess their level of working experience with adolescents. Participants included male and female doctors, nurses and counselors/testers. A test was administered to measure their knowledge on adolescents sexual risk practices, HIV prevention and healthcare needs and also to assess their attitudes (including substance misuse) beliefs and norms and how it affects service uptake by adolescents particularly girls below the age of 20.

Results: The mean age of the HCP was 38years. Of the 34 HCPs, 45% were female, 55% 85% counsellor/testers; 15% doctors and nurses; 92% work in government facilities. 81% of HCPs had never had any sensitivity training on provision of youth-friendly services. 34% believed that adolescents were stigmatized because they engaged in premarital sex which is an immoral behavior. 54% strongly agreed that sex education should be for young persons from age 18 and above. 61% agreed that sex education for adolescents below 18 is unAfrican/something brought by foreigners while 85% reported that they must report adolescent who visits their facility to their parents.

Conclusions: Scaling up youth friendly sensitivity training for Nigerian HCPs is likely to be a timely and effective means to improve their understanding of adolescent-related health issues, reduce prejudice and enhance their capacity to provide responsive HIV prevention, treatment and care services in a supportive and non-stigmatizing environment.

THPEE681

Providing peer-led female sexual reproductive health (SRH) services to adolescents in rural South Africa: Lessons learned from delivering youth services in rural KwaZulu-Natal

H. Humphries[1], M. Mdladla[1], S. Phakathi[1], Q. Abdool Karim[1,2]
[1]*CAPRISA, Durban, South Africa,* [2]*Columbia University, Department of Epidemiology, Mailman School of Public Health, New York, United States*

Background: Adolescent sexual reproductive health (SRH) service provision remains a critical gap in South Africa. New, innovative approaches for providing SRH services that are feasible, sustainable and have high acceptability from young women are needed. We discuss the impact of peer-led demand creation on the uptake of SRH services.

Description: We used a novel approach to providing SRH services to female students attending 5 high schools in rural KwaZulu-Natal between May 2013 and November 2016. The SRH service included:
(i) in-school group SRH information and awareness sessions;
(ii) in-school SRH services through mobile clinics, which included, individual SRH counselling, customised HIV counselling and testing (CCT), TB screening, screening, counselling and referrals for those experiencing gender-based violence, STI screening, pregnancy testing, contraception provision and basic primary health care;
(iii) peer recruitment and (iv) referrals to, clinic services at the research clinic or public sector primary healthcare clinics.
Quarterly adolescent "boot-camps" were held to discuss and provide SRH information.

Lessons learned: Our SRH service provision model was successful at providing services to adolescents in schools. Using early adopters of the service, peer-led demand creation had a significant impact on service access at the mobile clinics. Post-implementation in May 2014, visits at the mobile clinic increased from an average of 4 visits/month, to an average of 37 visits/month in the first 4 months' post-intervention, peaking at an average of 75 visits/month in the last 3 months of the year. Visits to the mobile clinic remained high (approximately 90 visits/month), and indicate the importance of peers in creating demand. In total, CAPRISA SRH service provided SRH services to over 1441 high-school students aged between 12 and 25 years. Of those who accessed services, 87.9% had at least one HIV test, 27.1% consistently accessed contraception, and 51% of those testing positive initiated HIV treatment.

Conclusions/Next steps: Using early adopters as ambassadors for increasing adolescent SRH services is an important strategy for increasing uptake.

THPEE682

Feasibility and challenges of mobile phone peer mentoring and education support in Nigeria

E. Iwu[1,2], G. Adamu[2], D. Yahaya[2], J. Aghatise[2], G. Asuquo[3,4], M.A. Ya'u[5], I. Takuma[5]
[1]*Rutgers University, School of Nursing, Newark, United States,* [2]*Institute of Human Virology Nigeria, Abuja, Nigeria,* [3]*Association of Positive Youths in Nigeria, FCT, Abuja, Nigeria,* [4]*National Agency for Control of AIDS (NACA), Abuja, Nigeria,* [5]*Association of Positive Youths in Nigeria, Abuja, Nigeria*

Background: With high perinatal HIV infection rates, Nigeria has a burgeoning number of Adolescents Living with HIV (ALHIV) facing extreme challenges with psychosocial support and access to health services. While peer education is effective for supporting ALHIVs, peer educators require supportive mentoring and timely feedback to efficiently perform their roles. This project explored the feasibility and challenges of implementing complementary peer mentoring and continuing education using a mobile phone application in Nigeria.

Description: A structured WhatsApp group was initiated to: engage newly trained ALHIV peer educators (n=30) and mentors (n=10); provide biweekly interactive continuing education; and complement traditional face-to-face mentoring support. Although 40% of the Peer Educators (PE) and 100% of the peer mentors owned phones, only 20% and 40% respectively had access to WhatsApp. Both mentors and PEs posted questions, requests and comments, but only two lead mentors who were savvy with social media groups, were assigned to moderate discussions and manage new consumer driven topics biweekly. Educational topics included: HIV myths/facts, ART, adherence, HIV disclosure, stigma, STI prevention and reproductive health, PMTCT and conference updates. PEs had access to all mentors in the group for support.

Lessons learned: While WhatsApp groups is a viable tool for engaging PEs to provide timely guidance and support, more basic mobile platforms and traditional mentoring strategies are still required in Nigeria. Many of adolescents do not own phones. Fewer PEs and mentors owned internet-ready phones, therefore, access and participation were limited. Some PEs preferred private chats on self-related issues, which were carefully utilized to generate discussion topics while maintaining confidentiality. Frequent reminders were needed to curtail non-related posts. To ensure accuracy of information, program staff must consistently provide tools, materials and guidance for educational posts.

Conclusions/Next steps: Despite growing availability of cellphones globally, very basic technology and traditional mentoring should remain core strategies in Nigeria. Creative, inclusive strategies to deliver continuing education and engage PEs should be utilized e.g. facility-based mentoring, text messages and quarterly retreats. Mobile health grants and partnership with hospitals to implement sustainable mobile phone access for assigned PEs could facilitate PE access and participation in WhatsApp group support and education activities.

THPEE683

Innovative Africaid Zvandiri model increasing uptake of HTS among HIV positive adolescents in 10 high burden districts in Zimbabwe

T. Chimbidzikai[1], T. Napei[2], N. Willis[2], S. Chamoko[2], K. Madzeke[2], M. Mawodzeke[2], B. Mutede[3]
[1]*Africaid Zvandiri, Harare, Zimbabwe,* [2]*Africaid, Harare, Zimbabwe,* [3]*EGPAF, Harare, Zimbabwe*

Background: Providing HIV care and treatment services to adolescents presents unique challenges that must be met with innovative programs to succeed. While the number of new infections among children aged 0-9 in Zimbabwe has been reduced significantly, the number of new infections among adolescents (aged 10-19), especially girls and young women, continues to grow. Africaid is therefore implementing the Accelerating Children's HIV/AIDS Treatment (ACT) Adolescents Project in Zimbabwe working with EGPAF providing technical assistance to the MOHCC. The project aims at increasing demand for, access to, and uptake of adolescent HIV testing within 60 health facilities and surrounding communities.

Description: The ACT project employed the different strategies to improve identification of ALHIV including optimising PITC at all entry points where adolescents encounter the health system.120 Community Adolescents Treatment Supporters (CATS) were recruited, trained and placed at 60 health facilities across 10 districts. The CATS promoted community-based HIV testing of adolescents through index case testing and adolescent community dialogue days. Africaid Zvandiri Mentors and EGPAF Community Linkages Coordinators (CLICs) provided ongoing mentorship and technical support to health care workers and CATS in the 60 facilities. The CATS identified index cases from different entry points at both facility and in the community.

Lessons learned: 603 index case home visits were conducted by CATS in 2017. 343 adolescents were referred to the nearest health facility for HIV testing and confirmed to receiving an HIV test. 44 adolescents were diagnosed HIV positive, translating to a positivity rate of 12.8%. CATS facilitated the linkage of 86% of those identified positives to ART services. The improved performance was attributed to HCW capacity building for differentiated HIV service delivery including on-site coaching and mentoring. CATS facilitated the enrolment of 1,073 ALHIV into support groups.

Conclusions/Next steps: To achieve the first 90, targeted testing to maximise the identification of new ALHIV is critical. Declining yields from conventional facility and community-based HIV testing modalities (outreaches) require innovation. Peer-led approaches like the Zvandiri model are essential to reaching AYP in both urban and rural/ farming communities with HTS. Targeting of siblings, sexual partners and immediate family members of ALHIV index cases achieves an excellent yield rate.

THPEE684

Addressing stigma and discrimination in Tanzania: The missing piece to make a health system work for youth

A.N. Sabasaba[1], E. Mangi[1], S. Shoko[2], G. Lija[2], B. Rabiel[2], A. Ramadhani[2], W.O. Akyoo[3], E. Mlanga[4], M. Balampama[5], C. Stewart[6], R. Mbuya-Brown[5], P. Mingkwan[6], S. Bowsky[5], L. Nyblade[6]

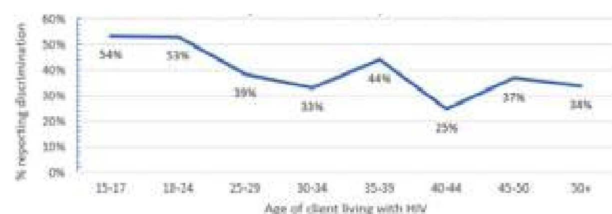
[1]Muhimbili University of Health and Allied Sciences (MUHAS), Dar es Salaam, Tanzania, United Republic of, [2]National AIDS Control Programme (NACP), Dar es Salaam, Tanzania, United Republic of, [3]Muhimbili University of Health and Allied Sciences (MUHAS), Epidemiology and Biostatistics, Dar es Salaam, Tanzania, United Republic of, [4]United States Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [5]HP+/Palladium, Washington, United States, [6]HP+/RTI International, Washington, United States

Background: Stigma and discrimination (S&D) are barriers to every aspect of the HIV response. Globally, including in Tanzania, youth living with HIV demonstrate lower rates of adherence to ART and higher virologic failure than children or adults. Recognizing that youth account for a disproportionate number of new infections and face S&D when trying to access HIV and sexual and reproductive health services, the USAID-and-PEPFAR-funded Health Policy Plus project included youth (15 - 24) living with HIV in a study to: 1) determine the prevalence and actionable drivers of HIV-related S&D in the health system from the perspective of health facility staff (HFS) and clients; 2) inform the design of a tailored HIV-stigma reduction intervention 3) support evaluation.

Methods: Survey data was collected from 233 HFS (148 female / 83 male/2 not stated), 243 adults living with HIV, (166 female / 77 male) and 88 youth living with HIV (40 female / 44 male) in two district hospitals, Morogoro region, Tanzania (July - September 2017).

Key measures included among staff: presence and levels of S&D key drivers (fear / attitudes / health facility environment) and observed discrimination among staff. Among clients: anticipated, observed, and experienced S&D in health services and avoidance / delay of health services among youth clients.

Results: Youth reported routinely receiving supportive care and high satisfaction with HIV services. However, over 50% also reported having experienced discrimination in the past three months, more than all other age groups (Graph 1), with little variation by sex. HFS also reported high observed discrimination toward all categories of youth (Table 1), greatest toward unmarried pregnant youth (41%).



[Figure 1. Experienced discrimination (at least 1 of 9 acts of discrimination) in HIV services, last 3 months]

Observed at least 1 of 3 acts of discrimination: unwillingness to provide care, provision of poorer quality of care, and talking badly about a youth client, last 3 months	Medical Staff (n=149)	Administration Staff (n=21)	Support / Auxiliary Staff (n=38)	Total (n=208)
Sexually-active adolescents	43.6% (65/149)	38.1% (8/21)	26.3% (10/38)	39.9% (83/208)
Young people living with HIV who did not acquire HIV perinatally	42.3% (63/149)	38.1% (8/21)	21.0% (8/38)	38.0% (79/208)
Perinatally infected young people living with HIV	40.9% (61/149)	38.1% (8/21)	23.7% (9/38)	37.5% (78/208)
Unmarried pregnant adolescents	46.3% (69/149)	38.1% (8/21)	23.7% (9/38)	41.3% (86/208)

[Table 1 Observed discrimination toward youth living with HIV in the health facility during the 3 months before the survey, by job category]

Stigmatizing attitudes toward youth were prevalent among staff with over 90% reporting a least one of four stigmatizing attitudes and highest among medical staff (93%). 46% of HFS believed that youth living with HIV should not have sex. More staff reported negative attitudes towards sexually active girls (69%), compared to their male counterparts (46%).

Conclusions: These data are informing design and evaluation of health facility-based stigma-reduction interventions with youth participation at all levels, starting with questionnaire development. Measuring and addressing S&D towards youth within health facilities is critical to improve health systems, ensure equitable access to care, reach and retain youth in HIV services, and strengthen the quality of service delivery for youth.

THPEE685

Status of access to HIV and sexual & reproductive health care services for adolescents and young people in Tanzania: Findings from an abstraction of secondary routine health facility data

R. Kirkegaard[1], S. Kimambo[1], U. Gilbert[1], V. Chuwa[2], M. Rutaihwa[3], G. Mallya[3]

[1]UNICEF, Dar es Salaam, Tanzania, United Republic of, [2]UNICEF, Gaborone, Botswana, [3]Ministry of Health, Community Development, Gender, Elderly and Children, Dar es Salaam, Tanzania, United Republic of

Background: With more than 200,000 people aged 10-24 living with HIV and comprising 40% of new infections, adolescents and young people (AYP) in Tanzania face one of the highest burdens of HIV globally in addition to various sexual and reproductive health (SRH) issues with 27% of females having begun childbearing by age 19. Yet, little is known about the extent to which this age group accesses health care due to the limited availability of age and sex disaggregated data. To address this gap, this study aimed at establishing national disaggregated estimates for AYP's utilization of HIV and sexual and reproductive health services.

Methods: A retrospective cross-sectional cohort study was conducted for the period January-December 2015. Data were abstracted from HIV and SRH registers and databases from a two-stage proportionate to size sample of 114 health facilities located in 16 districts with high HIV testing and HIV burden. Descriptive and retention analysis was conducted for three different age bands: 10-14, 15-19 and 20-24 and disaggregated by sex.

Results: AYP contributed to 19% (64% female) of all people accessing HIV testing and counselling services, of which 7% were adolescents (10-19 years). Of the 7.8% AYP testing HIV positive, 63% (78% female) were linked to pre-ART care (prior to updated WHO guidelines) and 51% (81% female) were initiated on ART. ART retention at 12 months decreased with increasing age to 84% for young adolescents (10-14 years), 75% for older adolescents (15-19 years) and 70% for youth (20-24 years). In contrast, 44% of all pregnant women accessing antenatal care were AYP, of which 13% were adolescents and 56% received screening for sexually transmitted infections. 22% of family planning clients were youth and 4% older adolescents.

Conclusions: The findings suggest the existence of gender and age-differentiated disparities in access to HIV and family planning services for AYP in Tanzania, including better linkages to HIV treatment and care for females than males. Further research on disparities and their causes is needed to inform the design of targeted interventions and service delivery models that better address the health care needs and retention challenges of male and female AYP at different ages.

[Figure 1: Linkage to care and treatment initiation]

THPEE686

Implementing adolescent and youth friendly services in Cape Town, South Africa

N. Ahmed[1], L. Mtwisha[1], A. Sondinga[1], C. Herman[1], T. Naledi[2], L.-G. Bekker[1]
[1]The Desmond Tutu HIV Centre, Cape Town, South Africa, [2]Western Cape National Department of Health, Cape Town, South Africa

Background: Adolescence is a period of developmental transition between childhood and adulthood. Navigating their way through this time of physical, psychological and social development, young people need appropriate and accessible services that recognise and support their needs. Amongst other programmes developed by the South African National Department of Health (DOH) for supporting adolescents and youth, is the Adolescent and Youth Friendly Services (AYFS) package. We aimed to implement the package in 24 healthcare facilities in Cape Town, South Africa.
Description: A programme was designed by the Desmond Tutu HIV Centre with Pathfinder International to support AYFS assessment, implementation and accreditation of healthcare facilities in the Klipfontein/Mitchell's Plain subdistrict. This includes introduction and training of the AYFS package to all personnel, formation of a task team led by a facility champion, adolescent focus groups, regular mentoring and progress review, and a quarterly learning forum with other facilities to share progress. The final step involves DOH validation and accreditation.
Lessons learned: The AYFS programme commenced in April 2017 with all 24 healthcare facilities enrolled. Baseline assessments were conducted at all, with follow-up assessments at nine facilities to date. The standards scores are shown in figure one; following AYFS package implementation improvements have been seen in all standards. Three Champion's learning forums held, showcased progress made, including dedicated youth clinics after school hours, youth spaces and committees. Facilities shared innovation including youth clinic launch events, regular school clinics and fast-track youth cards. The forum identified and addressed challenges including some clinics having a maximum quota for patients seen daily resulting in adolescents turned away, and the need for adolescent health profiles. Peer navigators have been placed at all facilities, proving to be essential in meeting and greeting youth on arrival, and navigating them quickly and efficiently through the service.
Conclusions/Next steps: Adolescents face many barriers to accessing health services. AYFS addresses these by making services more attractive to young people and retaining them within care to support ongoing needs as they develop into adulthood. Our programme provides structured support and mentorship to clinics, and encourages a shared learning environment. Youth feedback is ultimately needed to solidify this AYFS package.

[Figure 1. AYFS Standards Score across 24 Healthcare Facilities]

THPEE687

Operationalizing and implementing the U.S. CDC's guidelines for youth: Will this stop new infections and improve health outcomes?

M.J. Rotheram-Borus[1], I. Fernández[2], K. Nielsen-Saines[3], D. Swendeman[1], J. Lee[1], S.E. Abdalian[4], E. Arnold[5], B. Kapogiannis[6], Adolescent Medicine Trials Network (ATN) CARES
[1]UCLA, Psychiatry & Biobehavioral Sciences, School of Medicine, Los Angeles, United States, [2]Nova Southeastern University, Fort Lauderdale, United States, [3]UCLA, Department of Pediatrics, Los Angeles, United States, [4]Tulane University School of Medicine, Department of Pediatrics, New Orleans, United States, [5]University of Central Florida, Center for Behavioral Health Research and Training, Orlando, United States, [6]National Institutes of Health, Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States

Background: The number of youth living with HIV (YLH) in the U.S. has doubled in the last 10 years and is focused among gay, bisexual, and transgendered youth (GBTY), and incarcerated, and homeless substance abusing youth. These youth at high risk (YHR) for HIV acquisition and YLH are not utilizing or adhering to the HIV Prevention or the HIV Treatment Continuua. The U.S. CDC has recommended quarterly testing for HIV, linkage to medical care, utilization of PrEP/PEP and ART over time by YHR and YLH. A set of studies was launched to evaluate if new infections can be averted and YLH will optimize adherence to these Continuua.
Methods: Three inter-related studies are designed to operationalize these guidelines, with one deviation - only three assessments were scaled per year (i.e., for testing HIV or viral load, STI, and substance abuse rapid diagnostic tests [RDT]), rather than four. For both YHR and YLH a cadre of behavioral and mobile/social media interventions are evaluated within randomized controlled trials (RCT). In each study, youth are randomized to receive a set of low-cost, mobile interventions, increasing the intensity to a higher cost, peer-support and, then, an interpersonal coach to test stepped care model of intervention. Study 1 aims to optimize the HIV prevention continuum for YHR (N=1500). Study 2 evaluates if YLH become virally suppressed (N=220). Study 3 examines viral reservoirs among acutely infected YLH over time compared to treatment- naïve YLH with established infection (N=72).
Results: YHR, YLH, and acutely infected youth can be successfully identified and engaged through a combination of clinics and community-based agency sites serving high risk youth. Rapid, 4th gen HIV testing, STI and substance abuse testing can be conducted in field settings efficiently. Over six months of recruitment, 607 youth (549 YHR, 49 YLH, and 9 acutely infected/treatment naive YLH were recruited.
Conclusions: Monitoring youth three times annually, with a set of innovative interventions will identify if the CDC's recommendations are feasible and effective in the U.S. with YHR and YLH.

THPEE688

Adolescent-specific provider training and provision of services is associated with retention in Kenyan HIV clinics

K. Wilson[1], C. Mugo[2], H. Moraa[3], A. Onyango[3], M. Nduati[3], I. Inwani[4], J. Slyker[1,5], B. Guthrie[1,5], B. Richardson[1,6], G. John-Stewart[1,5,7], D. Bukusi[8], D. Wamalwa[9], P. Kohler[1,10]
[1]University of Washington, Global Health, Seattle, United States, [2]University of Nairobi/Kenyatta National Hospital, Nairobi, Kenya, [3]University of Nairobi, Nairobi, Kenya, [4]Kenyatta National Hospital, Nairobi, Kenya, [5]University of Washington, Department of Epidemiology, Seattle, United States, [6]University of Washington, Department of Biostatistics, Seattle, United States, [7]University of Washington, Department of Medicine, Seattle, United States, [8]Kenyatta National Hospital, VCT and HIV Prevention Unit/Youth Centre, Nairobi, United States, [9]University of Nairobi, Department of Pediatrics and Child Health, Nairobi, Kenya, [10]University of Washington, School of Nursing/Department of Psychology and Community Health, Seattle, United States

Background: Adolescents and young adults (AYA) have disproportionately worse clinical outcomes. We measured retention in HIV care, and evaluated correlates of retention, among AYA at 24 public HIV clinics en-

rolled in a stepped-wedge randomized trial of standardized patient actor training to improve quality of care and AYA clinical outcomes (SPEED Study).
Methods: Eligible records were from AYA ages 10-24 enrolled at 24 HIV clinics with ≥40 AYA active clients in Central (Nairobi, Kiambu counties) and Western (Kisumu, Homa Bay counties) Kenya during the 15 months preceding the trial (11/1/2015-3/31/2017). Sociodemographics, clinical characteristics, and visit dates were abstracted from electronic medical records (EMR). Facility-level surveys assessed any prior AYA-focused training and services. Surveys with individual health providers working in AYA HIV care (3-10 per facility) assessed self-reported history of AYA-specific trainings, experience caring for AYA, and self-rated competency; facility-level means were derived from individual responses. Retention in care was defined as return for first follow-up visit within 3 months among newly enrolled or recently re-engaged AYA. Multi-level regression modeling was used to estimate risk ratios (RRs) and 95% Confidence Intervals (CIs) between facility and individual cofactors and AYA retention. Final models adjusted for AYA age and clinic volume (total AYA enrolled during period).
Results: Among 3,656 AYA records at first eligible visit, most were female (75.0%), older (20-24 years: 54.3%), and on ART (79.5%). Overall, 2,636 AYA were retained (72.1%), with retention higher among females (73.1% vs. males 68.9%), older AYA (20-24 years: 75.0% vs. 10-14: 69.2%, 15-19: 68.0%), and at Western Kenya clinics (82.7% vs. 66.0% Central) (Table 1). Clinics where >20% health providers reported being trained in adolescent-friendly care had higher AYA retention than those with ≤20% of providers trained (85.4% vs. 66.4%, aRR 1.18, 95%CI:1.08-1.29). Clinics using the Kenyan government's AYA package of care checklist had significantly higher overall AYA retention (88.9% vs. 69.2%;aRR 1.14, 95%CI:1.06-1.23).
Conclusions: Results suggest sub-optimal retention among HIV-positive AYA in Kenya. This is one of the first studies demonstrating that adolescent-specific health provider training and services may improve AYA retention, suggesting that health provider interventions are necessary to achieve the '90-90'-90' targets for AYA.

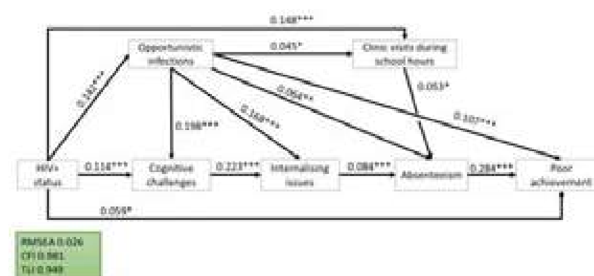
THPEE689

Tracking through teaching: Using schools to reach the first 90 for adolescents living with HIV

E. Toska[1,2], L. Cluver[2,3], M. Orkin[2], A. Bains[4], L. Sherr[5], M. Berezin[2], L. Gulaid[6]
[1]University of Cape Town, AIDS and Society Research Unit, Cape Town, South Africa, [2]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [3]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [4]UNICEF ESARO, Nairobi, Kenya, [5]University College London, London, United Kingdom, [6]UNICEF ESARO, Johannesburg, South Africa

Background: It is essential that adolescents living with HIV (ALHIV) are reached for treatment, care and support. However, many slow progressors and newly HIV-infected adolescents remain unidentified and disconnected from health systems, especially in high-prevalence settings. This study examines differences in educational outcomes for ALHIV, in order to:
i) identify educational markers for targeting HIV testing, counselling and linkages to care, and
ii) to identify essential foci of educational support for ALHIV.
Methods: Quantitative interviews with N=1,057 ALHIV and N=467 uninfected community control adolescents (10-19 year olds) included educational outcomes (enrolment, fee-free school, school feeding schemes, absenteeism, achievement), physical health, cognitive difficulties (difficulties remembering to take medicine, to concentrate at school and home), internalising issues (depression, stigma), missing school to go to the clinic, and socio-demographic factors. Validated scales and measures were used where available. Voluntary informed consent was obtained from adolescents and caregivers (when adolescent < 18 years old). Analyses included multivariate logistic regressions, controlling for socio-demographic covariates, and structural equation modelling using STATA15.
Results: ALHIV reported accessing educational services (enrolment, free schools, school feeding schemes) at the same rates as other adolescents (94%, 30%, and 92% respectively), suggesting that school is a valuable site for identification. ALHIV reported poorer attendance: missing >2 weeks in the past term (OR2.1 95%CI1.4-3.2 p< 0.001); achievement: behind >1 grade (OR1.9 95%CI1.5-2.4 p< 0.001); more opportunistic infections OR2.6 95%CI2.1-3.3 p< 0.001; missing school to go to the clinic (OR6.0 95%CI3.4-10.5 p< 0.001); more internalising issues (OR1.6 95%CI1.3-2.0 p< 0.001), and greater levels of cognitive difficulties (OR1.9 95%CI1.5-2.4 p< 0.001). A structural equation model with good model fit (RMSEA=0.027, CFI 0.984, TLI 0.952) indicated that negative educational outcomes were associates with a series of poor physical health and cognitive difficulties which led to negative educational outcomes



[Figure 1. Cascades to poor educational outcomes among ALHIV (N=1,527)]

Conclusions: ALHIV have high access to schools and educational services such as feeding schemes. Key school-based markers for identifying unreached adolescents living with HIV may be low attendance, frequent sickness, low mood and slow learning. Educational support services for ALHIV are necessary to support their school achievement and success, by helping them to cope with physical, emotional and cognitive difficulties.

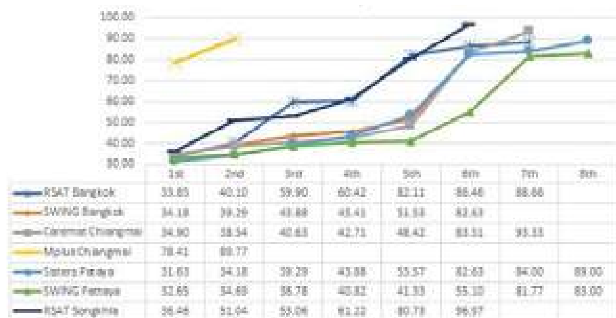
Community participation in systems for health

THPEE690

Sustainable laboratories for key population-led HIV services in Thailand: Mentoring and twinning lead to government accreditation and financing

C. Sa-nguansilp[1], O. Monkongtanakit[1], N. Praweprai[2], P. Thapwong[3], A. Udomjirasirichot[4], S. Petchaithong[5], S. Saiwaew[6], R. Apiputthipa[7], A. Inyasom[8], P. Phiayura[9], T. Pankam[9], S. Pengnongyang[9], S. Charoenying[1], S. Mills[1], J. Robinson[1]
[1]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [2]Sisters Foundation, Chonburi, Thailand, [3]Service Workers IN Group (SWING) Foundation, Bangkok, Thailand, [4]Service Workers IN Group (SWING) Foundation, Chonburi, Thailand, [5]Rainbow Sky Association of Thailand (RSAT), Songkhla, Thailand, [6]Rainbow Sky Association of Thailand (RSAT), Bangkok, Thailand, [7]Mplus Foundation, Chiang Mai, Thailand, [8]Caremat, Chiang Mai, Thailand, [9]Thai Red Cross AIDS Research Centre, Bangkok, Thailand

Background: In laboratories for key population-led HIV services (KP-LHS), knowledge of recognized quality diagnostic practices and Quality Management Systems (QMS) is weak, which hinders quality service delivery, including HIV and Sexually Transmitted Infections (STI) diagnostic services. Through the USAID- and PEPFAR-supported LINKAGES project, FHI 360 implemented a systems strengthening program with the following organizations that provide KP-LHS, primarily for men-who-have-sex-with-men (MSM), transgender people (TG), and sex workers (SW): Sisters Foundation, SWING Foundation, The Rainbow Sky Association of Thailand (RSAT), Mplus Foundation, and Caremat.
Description: Using the Thailand Medical Technologist Council (TMTC) checklist, we conducted quarterly laboratory assessments to identify gaps, set goals, and provide recommended actions and mentorship. FHI 360's Laboratory Quality Manual was adapted to suit the laboratories and translated into Thai. On-site training was provided on how to implement the Manual and establish systems for QMS to comply with the TMTC standards. Trainings in QMS and Good Clinical Practice were provided to strengthen knowledge and technical assistance (TA) was provided to implement that knowledge. Quality control and external quality assurance samples were provided to monitor testing accuracy and to help with correction of errors. We also established a twinning program for the KP-LHS laboratories whereby accredited KP-LHS laboratories served as mentors to other laboratories.
Lessons learned: After only 18 months of support, significant progress was achieved, as evidenced by the increases in the quality compliance scores of the KP-LHS laboratories over time (Figure).



[Figure. Laboratory Assessment Score]

One laboratory has been accredited by the TMTC, one has applied for Laboratory Accreditation, three are in the process of Medical Technologist Clinic registration, and the remaining two are implementing QMS. This success was facilitated by understanding of the need for QMS, capacity building of assessors and mentors, teamwork and support, and regular TA to guide progress.
Conclusions/Next steps: This program demonstrated that community public laboratories can meet accepted national laboratory quality standards. Through a model of assessment, mentorship, and twinning for the KP-LHS network, the laboratories showed significant progress towards ensuring that the HIV testing services provided by community laboratories are accurate and reliable.

THPEE691

Vulnerability of PLHIV to nutrition, food security shocks in Rwanda

C. Ouma, M. Mumma, D. Nsengiyumva
WFP Nairobi Region Bureau, Nairobi, Kenya

Background: Limited data is available regarding the present status of nutrition as well as food security among PLHIV in Rwanda. With the aim of guiding decision makers to appropriate nutrition and food assistant interventions, a national survey was conducted by the RBC/HIV, STIs and OBBI Division of Rwanda Ministry of Health, with support of WFP, to determine nutrition and food security status, as well as vulnerability among People Living in HIV (PLHIV).
Methods: The sample was 2252(816 males and 1436 females) who received comprehensive HIV services in 30 districts and 60 health facilities. 418 (18.6%) were Pre-ART and 1834 (81.4%) were on ART. Two stage cluster-sampling method was used: health facilities as the primary sampling unit, and PLHIV aged from two years old and above attending the selected HF as the secondary sampling units. Tracnet ID was used for random selection. Data was collected from 17th August to 5th September 2015. SPSS ver.24 and the BMI calculator were used for data cleaning and analysis.
Results: The prevalence of underweight among children under 5 and adolescents below 19 years was more than double (15.7%) compared to overweight/obesity (7.4%). Southern Province and Kigali City had the highest prevalence of thinness (20% and 19%, respectively). Boys were thinner (18.7%) than girls (10.5 %).
In adults, the prevalence of overweight/obese was higher (17.5%) than that of underweight (13.7%). 68.3% were mildly underweight,18.7% moderate and 13% severe. prevalence of overweight was higher among women (22.1%) than men (10.3%). By residence, Kigali city had the highest number of overweight (30.1%) and the lowest prevalence of underweight (8.1%). only 38.8% of them had acceptable food consumption score, while 19.5% had borderline and the majority (40.7%) had poor food consumption score. This went hand in hand with their low dietary diversity: only 7%had good dietary diversity and more than half (64.4%) had low diet diversity.
Conclusions: Very poor food consumption score among PLHIV and low dietary diversity is predominant among PLHIV indicating worse coping strategies. The emergence of obesity among PLHIV in urban areas calls for specific investigations and interventions.

THPEE692

Curated "meet-ups" to engage online men at risk of HIV in a service delivery program in Jakarta, Indonesia

A. Noegroho[1], S. Samba[2], B. Eveslage[3], C. Francis[1], A. Human[4]
[1]FHI 360, Jakarta, Indonesia, [2]N/A, Jakarta, Indonesia, [3]FHI 360, Phnom Penh, Cambodia, [4]FHI 360 Indonesia, Jakarta, Indonesia

Background: Putting mega cities like Jakarta on the "fast-track" to end HIV requires reaching key populations (KP) in the online settings where they are present. However, in going online, HIV programs reach new sub-populations whose voice may not be represented by status quo community partners. How, then, will HIV programs engage the voice of online KP in Jakarta?
Description: In August 2017, the USAID- and PEPFAR-supported LINKAGES program in Jakarta began integrating the voice of online men at risk of HIV into its online outreach approach. Program staff engaged in relevant online social networks, then approached and eventually met potential representatives of the online, at-risk community in Jakarta in-person to ease into sensitive topics of sexuality, sex, and HIV. LINKAGES formed a community advisory team ("team" henceforth) including men at risk of HIV in Jakarta with distinctive backgrounds such as a social media influencer, openly HIV positive stylist, doctor, lawyer, LGBT advocate,

and other expat-scene oriented community members. In December 2017, the team was convened and a "meet-up" was hosted at a trendy co-working space in South Jakarta for the dual purpose of advising LINKAGES' online outreach activities and facilitating insightful dialogue with stakeholders.

Lessons learned: Young program staff active on social media were necessary to identify initial community representatives, who then successfully engaged additional suitable representatives of the online at-risk community in Jakarta. It took time to follow and engage these representatives on social media and meet in-person, ensuring suitable fit between the team and representative. The team curated meaningful and safe "meet-ups" by facilitating representatives' input into the team's terms of reference and the program committing to finance relevant activities/events led by team members.

Conclusions/Next steps: LINKAGES hosts quarterly meet-ups for representatives to review and advise the program's online outreach strategies, tools, and communications. Through these meet-ups, several representatives now lead new program activities including generating demand for Pre-Exposure Prophylaxis (PrEP) and engaging a broader range of social media influencers. The program continues to document its experience of meaningfully engaging online men at risk of HIV in Jakarta and outcomes on uptake of HIV services among this population.

THPEE693

Barriers in access to treatment, care and support services for people living with HIV in Bangladesh

H. Akter, M.S. Alam
Ashar Alo Society, Management, Dhaka, Bangladesh

Background: Recently Treatment, Care and Support (TCT) services for people living with HIV (PLHIV) in Bangladesh has been shifted from NGO led service delivery to government hospital without sufficient preparation and transition plan. As a result, PLHIV are facing huge barriers for getting TCT services from hospitals. The aim of this study is to establish levels of access to treatment, care and support services of PLHIV. The study findings will be used to inform the relevant policy makers to reduce barriers in access to services.

Methods: It was a cross-sectional study based on face-to-face interviews conducted during October to November 2017. HIV treatment-related issues such as access to pre-ART care, ART, ART adherence, treatment literacy, Attitude of health care providers (HCP) etc were the core issues of this study. A total of 200 PLHIVs over 18 years, recruited through community groups and hospitals, sampling based on quotas regarding geographic distribution, age, gender. A simple questionnaire was developed containing the basic demographic information. After interview, data was cleaned and inputted in SPSS software for analysis.

Results: The study included 50% men 45% women and 05% TG; mean age 36 years, 65% rural and 35% urban. By self categorization of perceived HIV vulnerability, majority (41 percents) were international migrant workers, followed by wife of migrant workers (33 percent). It was reported that CD4 cell count was done only 30 percent and no viral load test was done in the last year. Average duration to reach ART center is 4±3.2 hours. Plus, PLHIV are to wait 04 hours at ART center for receiving ART from hospital. HIV Treatment Literacy level was found poor. No medicine is provided from hospital for opportunistic infection and 72% did not buy prescribed medicines due to costs. Almost all the respondent doesn't have any insurance coverage or home based care facilities. Treatment delay was found higher (92.9%) among the respondents considering test and treat.

Conclusions: Regarding access to TCT, the study identified specific systemic barriers compared to general population. These call for structural solutions, such as strengthening of hospital system and increasing access to health insurance for PLHIV.

THPEE694

Ending AIDS: Harmonising the role of adolescents and young people living with HIV (A/YPLHIV) networks in Africa

H.S. Soeters[1], J. Alesi[1,2,3], N. Westerhof[2], G. Caswell[4], K. Kintu[5], L. Essink[2], C. Ninahazwe[3], A. Ronan[1], L. Hatane[1]
[1]Paediatric-Adolescent Treatment Africa, Cape Town, South Africa, [2]Aidsfonds, Amsterdam, Netherlands, [3]The Global Network of YPLHIV, Amsterdam, Netherlands, [4]International HIV/AIDS Alliance, Cape Town, South Africa, [5]African Young Positives Network, Kampala, Uganda

Background: Despite increasing attention and interest in meaningful youth participation in the HIV response, limited investment is made into youth leadership and developing youth-led structures. Networks of adolescents and young people living with HIV (A/YPLHIV) face challenges in securing the requisite capacity, experience and resources to fulfil their mandate and contribute as equal and influential partners in the response. Efforts to better engage A/YPLHIV networks are often poorly coordinated, ad hoc, tokenistic and focused on delivery of short-term activities.

Description: To build capacity of A/YPLHIV networks and harmonise advocacy efforts, an informal partnership was established between Aidsfonds, International HIV/AIDS Alliance, Paediatric-Adolescent Treatment Africa (PATA), African Young Positives Network (AY+) and the Global Network of YPLHIV (Y+). Through their projects in sub-Saharan Africa (GUSO, PITCH, P2Z, READY), partners coordinated information sharing and advocacy initiatives, and held a regional A/YPLHIV networks meeting in April 2017, to build and link networks for a stronger and expanded youth-led response. Baseline capacity self-assessments were completed by 13 A/YPLHIV networks from 12 countries (Burundi, Kenya, Malawi, Mozambique, Nigeria, Rwanda, South Africa, Swaziland, Tanzania, Uganda, Zambia, Zimbabwe).

Lessons learned: Self-assessment data has contributed to better understanding A/YPLHIV network perspectives, capacity gaps and challenges, and resulted in improved coordination and resource pooling to address them. Table 1 highlights that capacity varies between networks and across benchmarks. Based on these outcomes, network capacity development plans have been integrated, supported and funded through each partners' projects. Preliminary findings show progress in certain areas of development, such as A/YPLHIV network registration. The regional meeting resulted in joint network and advocacy commitments, with peer-to-peer learning and support.

Benchmarks	Poor	Average	Good	Excellent
Strategic, financial and annual operating plans in place	4 (30.7%)	3 (23.1%)	3 (23.1%)	3 (23.1%)
Monthly payroll for staff	4 (30.7%)	4 (30.7%)	2 (15.4%)	3 (23.1%)
Opportunities for professional development of staff and volunteers	1 (7.7%)	4 (30.7%)	5 (38.5%)	3 (23.1%)
Successful proposal applications in the last year	3 (23.1%)	2 (15.4%)	3 (23.1%)	5 (38.5%)
M&E system for internal and external activity reporting in place	2 (15.4%)	4 (30.7%)	6 (46.1%)	1 (7.7%)

[Table 1: A/YPLHIV networks self-assessment ratings across various organisational benchmarks (n=13)]

Conclusions/Next steps: A/YPLHIV networks in sub-Saharan Africa demonstrate varying degrees of organisational infrastructure, capacity and experience. Capacity self-assessment can mask the fragile situation of networks, yet emphasise the importance of capacitating youth-led structures beyond short-term activities. Joint regional coordination and implementation of capacity strengthening strategies are urgently needed to ensure meaningful engagement and mentoring of youth-led structures. For A/YPLHIV networks to meaningfully contribute to the HIV response, it is critical that we reframe how we work together, with funding investments being longer-term and aligned with clear organisational assessments and development strategies.

THPEE695

Peer navigators develop mobile application for enhancing HIV knowledge in the fight against stigma among youths in Western Kenya

S.B. Nga'Zi[1,2], B. Kwendo[3], E. Apondi[4], C. McAteer[5]
[1]Academic Model Providing Access to Healthcare (AMPATH), Rafiki Clinic, Eldoret, Kenya, [2]Aids Clinical Trial Group (ACTG), Moi University Clinical Research Center, Eldoret, Kenya, [3]Academic Model Providing Access to Healthcare (AMPATH), Peer Mentor, Eldoret, Kenya, [4]Academic Model Providing Access to Healthcare (AMPATH), Care Program Leadership, Eldoret, Kenya, [5]Academic Model Providing Access to Healthcare (AMPATH), Department of Pediatrics, Eldoret, United States

Background: The number of young people in sub-Saharan Africa using smart phones is increasing, and most of them use mobile applications to get information and news. Mobile platforms can also provide information and autonomy for the user to engage in the information when needed, as well as marketing and personalized communication. A mobile platform targeted at improving HIV knowledge among youth in sub-Saharan Africa could provide needed information, even to those not currently accessing HIV services.

Description: ""HIVFactSheet" is a youth-friendly mobile application, developed in western Kenya that can be downloaded from Google Play store. Once installed in an Android mobile device, the app works offline to provide access to multi-media educational components on: HIV prevention, HIV testing, General HIV knowledge, Antiretroviral Therapy, Adherence, Disclosure, and CD4 count. Some of the application content including short films and narratives were developed within an NIH-funded study to develop a counseling intervention to improve HIV disclosure. The mobile application was developed by two peer navigators in the AMPATH system in western Kenya, who provides mentorship, advocacy, and connection to HIV services. The HIVFactSheet application includes a portal where young people were able to call text or email, a counselor who offered counseling to them and referred them to clinics for further support whenever needed.

Lessons learned: Since the launch on 1st December 2017, 322 young people have accessed comprehensive HIV information using the HIV-FactSheet application. 62 counseling services was offered, while 28 referrals were made in various clinics. Lessons learned through the development and implementation of this app is that HIV factual information is key in enhancing positive living and eliminating stigma & discrimination among young people. It also facilitates informed decision-making and enables community members to understand HIV better, potentially improving testing and reducing stigma. Youth development of this resource enhanced both cultural relevance and appropriateness for the youth population.

Conclusions/Next steps: The use of mobile platforms tailored to youth in sub-Saharan Africa can help us improve access to comprehensive HIV information and bridge the gap for access to resources and care, which can be utilized by youth and other key populations.

THPEE696

Healthcare workers' and patients' experiences during implementation of the Fast Track model: Piloting differentiated ART service delivery in Zambia

L. Jere[1], C. Cheelo[1], M. Mukumbwa-Mwenechanya[1], C. Mwamba[1], S. Nkwemu[1], A. Sharma[1], C. Bolton[1], S. Topp[2], W. Mutale[3]
[1]CIDRZ, CommART, Lusaka, Zambia, [2]CIDRZ/James Cook University, CommART, Vienna, Australia, [3]CIDRZ/UNZA, CommART, Lusaka, Zambia

Background: Fast Track (FT) is an accelerated drug pick-up model where stable HIV positive patients are given three rather than one month of ART supply through a dedicated treatment room. FT was piloted in two primary health centres in Lusaka, Zambia, to explore feasibility and effectiveness in improving patient retention.
We sought to understand the experiences of health care workers (HCW) and patients after approximately six months of implementation to identify needed improvements or midcourse changes.

Methods: From January-March 2017, we conducted an exploratory qualitative study using six Focus Group Discussions (FGDs) with patients and eight In-depth interviews (IDIs) with HCW's to collect data on their lived experiences with the FT model. All interviews and discussions were audio-recorded using a voice recorder and transcribed into English. Thematic analysis was conducted using Nvivo 11.

Results: Both HCW and patients viewed FT as having the ability to decongest the clinic by spacing ART pick-ups and reducing time spent in the clinic by providing dedicated services. The latter was reported as particularly attractive to both patients and HCWs who expressed concerns regarding patient wait times under routine care. However, patients requested that all other services such as measuring weight and blood pressure be incorporated into the dedicated service room. They also complained about long wait times during clinical visits because clinicians did not appreciate the fact that the patients had come early to the FT room. HCWs emphasized the importance of orientation and information dissemination to bring all HCWs at the facilities on board, foster a sense of ownership and to avoid patient perceptions of staff favouritism or nepotism that may negatively impact patient-provider relations. HCWs further expressed concern regarding the time allocated for adherence support during the patient pharmacy visits as the focus was only on drug pick-up.

Conclusions: Overall, the FT model was reported to be highly applicable and acceptable. The segregation of other services (e.g., weight) and clinical reviews still being offered under routine conditions made the model less attractive. A dedicated FT day may be more efficient and equitable than mixed FT and routine services.

THPEE697

The reality of "Universal Test and Treat" strategy for clients tested in the community: Measuring the linkage to care time frames and its impact on the implementation of UTT

S. Bokolo[1], M. Mntambo[2]
[1]Aids Foundation of South Africa, HIV Prevention Programmes, Johannesburg, South Africa, [2]AIDS Foundation of South Africa, HIV Prevention, Durban, South Africa

Background: South Africa adopted the UNAIDS Universal Test and Treat strategy in September 2016 aimed at broadening ART initiation for HIV positive clients. The UTT strategy supports the UNAIDS 90-90-90 target to be reached by 2020 which are the basis for many HIV prevention programmes implemented in South Africa.

Description: Community testing reaches a wide-range of clients in community spaces that they occupy. A number of testing strategies have been employed by Aids Foundation of South Africa as a community testing organisation, including door-to-door, wellness days, testing of indexed clients and others. This testing happens outside of fixed health facilities. Targeted clients are children aged 0-19 years, consent for children < 12 years is obtained from the parent/guardian of the child. Children receiving an HIV positive test are referred to the facility for ART initiation. Linkages are made with local facilities to receive clients coming from the community for ART initiation. Within 5 days of referral, a follow-up visit is conducted to assess the linkage status. Subsequent follow-up visits depend on the outcome of the initial visit until successful linkage to ART is confirmed.

Lessons learned: The linkage to care rate for the programme was at 90.6%, in line with 90-90-90 targets. An investigation was done to ascertain the period of time it took to link clients for ART initiation. On average it took a referred client 8 days to be initiated on ART at a health facility. This varied between 5 and 53 days. Based on this data, we emphasised timely follow-ups and providing continuous counselling to encourage clients to visit facilities after HIV diagnosis.

Conclusions/Next steps: Measuring the period from HIV diagnosis to HIV initiation sheds light on the effectiveness of UTT implementation for clients tested in the community. While, the UTT strategy aims to put clients on ART after they receive an HIV positive result. The reality for clients tested in community is different, it takes an average of 8 days for clients to be initiated on ART according to the programmes data.

THPEE698

The effectiveness of different pediatric HIV testing approaches in reaching the first 90 in Lesotho

K. Sindelar[1], J. Joseph[2], C. Maponga[3]
[1]Clinton Health Access Initiative, Pediatric HIV, Maseru, Lesotho, [2]Clinton Health Access Initiative, Applied Analytics, Denver, United States, [3]Clinton Health Access Initiative, Maseru, Lesotho

Background: With expanding pediatric HIV programs in Lesotho, significantly more children (0-14 years) have been diagnosed and linked to care, making case finding increasingly challenging. Community-based testing strategies were implemented to find children who weren't receiving health services at facilities and therefore not accessing conventional testing touchpoints. In a resource limited setting, it's crucial to understand the most effective approaches in achieving the first-90.

Methods: Five testing approaches were examined from October 2015 to September 2017 in two districts of Lesotho to understand the most effective strategies, measured through three metrics - testing volumes, identifications, and yields over time. **Facility testing** (FT) data were summarized from PEPFAR's data warehouse. **Mobile outreach clinics** (MOC), **household index testing** (HIT), **sidewalk tent testing** (STT), and **door-to-door testing** (D2D) data were collected through routine paper-based reporting.

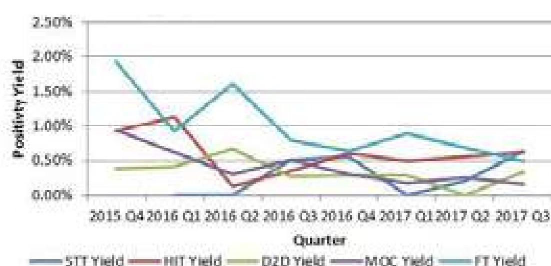
Results: Figure 1 shows FT accounted for 74.72% of pediatric tests and 86.03% of identifications. MOCs tested and identified the highest number of children among the community-based approaches, 11.76% and 6.55%, respectively. The non-targeted approach of D2D tested over 8% of children but had the lowest yield, 0.32%. Conversely, the targeted strategy of HIT had the highest yield among community approaches at 0.67%, but tested 2.96% of children.D2D tested 8.43% and identified 3.68%; HIT tested 2.96% and identified 2.64%; and STT tested 2.13% and identified 1.09%. Yields, when examined over time (Figure 2), show MOCs and FT experienced the greatest relative decrease in yields between the first and last quarter, 74.26% and 83.22% respectively.

Conclusions: In Lesotho, pediatric HIV identifications are rare, making each diagnosis significant. The approaches offering integrated services at fixed locations - FT and MOC - had the highest testing volumes and accounted for >90% of all identifications; however, experienced the largest drop in yields. A targeted approach like HIT had a more consistent yet still low yield, but tested fewer than the other household-based approach of D2D.

It is recommended that FT remain the backbone of pediatric testing programs, coupled with community-based opportunities that provide integrated services. As yields significantly decrease with static approaches, household-based approaches must be introduced to fully close the gap and reach the first-90.

Approach	Pediatric Test Volumes	% of Pediatric Tests Among All Approaches	Pediatric HIV+ Identifications	% of Pediatric Identifications Among All Approaches	Overall Positivity Yield
Sidewalk Tent Testing (STT)	4,977	2.13%	19	1.09%	0.38%
Household Index Testing (HIT)	6,911	2.96%	46	2.64%	0.67%
Door-to-door (D2D)	19,700	8.43%	64	3.68%	0.32%
Mobile Outreach Clinics (MOC)	27,481	11.76%	114	6.55%	0.41%
Facility Testing (FT)	174,598	74.72%	1,497	86.03%	0.86%

[Figure 1: The volumes, proportional percentages, and positivity yields of all pediatric tests and identifications among 5 HIV testing approaches.]



[Figure 2: The volumes, proportional percentages, and positivity yields of all pediatric tests and identifications among 5 HIV testing approaches.]

THPEE699

Lessons learned in implementing China Aids Fund for non-governmenetal organizations

S. Sha[1], J. Li[1], W. Yang[1], J. Jin[1], G. Zhang[2], M. Li[1], W. Yang[1], P. Wang[1]
[1]Chinese Preventive Medicine Association, Beijing, China, [2]National Center for AIDS/STD Control and Prevention, China Center for Disease Control and Prevention, Beijing, China

Background: In 2015, approved by the State Council, National Health and Family Planning Commission, Ministry of Civil Affairs and Finance of the People's Republic of China jointly established the national-level public welfare fund - CHINA AIDS FUND FOR NON-GOVERNMENETAL ORGANIZATIONS (CAFNGO). It raises money from government, enterprises and other lawful ways to support NGOs to expand the intervention and testing coverage of key populations and services for PLHIV. The establishment of CAFNGO reflects the strong commitment of Government to support NGOs involvement in AIDS response, and is a fundamental step fast tracking 90-90-90 and intervention targets of national AIDS strategy 2016-2020.

Description: In 2016-2017, CAFNGO funded $10 million to support NGOs in 31 provinces to provide outreach, HIV testing and referral services for key groups (FSW, MSM, DU). CDCs provide technical support and CAFNGO Management Committee Office manages funding allocation and implementation, and organizes capacity building activities for NGOs.

In two years, NGOs provided outreach and interventions among key populations for over 2.43 million person-times. More than 580,000 people received HIV testing services with more than 16,000 positive confirmed. The number of positive cases detected by CAFNGO in 2016 accounted for 40% of the national cases in the same period, while confirmed HIV cases among MSM by CAFNGO made up 49.4% of the total HIV cases nationwide in the same period.

Lessons learned: NGOs have been playing an irreplaceable role in expanding HIV testing among key populations. CAFNGO is the innovation of social governance system in public health system, while guidance and support from local administrative departments and public health institutes for NGOs development and involvement in AIDS response are insufficient. Management mechanism and capacity of NGOs are major challenges for CAFNGO to more effectively contribute to national AIDS response.

Conclusions/Next steps: CAFNGO provides an unique platform for NGOs to participate in national AIDS response and is widely recognized by the society and community. Furthermore, CAFNGO needs to optimize working mechanism to enlarge the engagement of NGOs in social governance for AIDS response at all levels, deepen the multi-sectoral communication and cooperation, promote the release of related policies and encourage the whole societies' participation.

THPEE700

Chikurubi maximum prison: Good practice to support the implementation and scale-up of differentiated ART delivery for key populations living in prisons and correctional facilities

T. Ponde
Voluntary Service Overseas, Health, Harare, Zimbabwe

Background: Prison populations have high incidence of HIV and TB[i] whilst access to health services including TB treatment and Antiretroviral Therapy (ART) is often overlooked and improvements, not well documented.

Chikurubi Maximum is the largest prison in Zimbabwe averaging 2600 inmates, many classified high risk with long sentences. 17% of the prison population is HIV+ and in dire need for HIV health services and peer support.

[i] https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3006347/

Description: Access to HIV information at Chikurubi is through differentiated peer service delivery, an approach that simplifies and adapts HIV services to better serve the needs of inmates living with or at risk of acquiring HIV. Through this approach, 178 peer educators have been trained.

Seven support groups, have provided psycho-social support, coping mechanisms to manage TB/HIV, poor living conditions, and stresses of separation from family.
Lessons learned: This approach results in risk reduction of STIs, TB, HIV and AIDS transmission for inmates through prevention, ART adherence, care and support, increased knowledge, attitudes and behaviour change.
Formal training and informal peer-to-peer interactions, have reached over 90% of inmates with 27062 referrals made to the prison hospital in 2017 (2250 referrals per month). ART adherence improved from 50% in June 2015 to almost 100% in February 2017. The prison recorded significant reduction in prisoner deaths from 50 in 2015 to 8 in 2017, attributed mainly to improved ART adherence, improved awareness, peer support and role of support groups.
Unique to this approach, is how peer educators support bedridden inmates through cell based care; bed baths, feeding sick peers, administering prescribed medication and offer counseling support and ART adherence.
Conclusions/Next steps: These activities have enhanced accountability from the prison system and empowered inmates to demand quality health services from the prison authorities. This model has enhanced inclusion for highly excluded populations contributing to HIV global targets.

THPEE701

Leveraging a community-led HIV testing approach to reach female sex workers in the geographic areas uncovered by the national program in India

P. Mugundu Ramien[1], S. Dandu[2], R. Bandi[2], D. Damara[2], A.K. Reddy[1], G. Shreenivas[1], B. George[1], J.J. Baishya[3]
[1]FHI 360, LINKAGES Project, New Delhi, India, [2]FHI 360, LINKAGES Project, Vijayawada, India, [3]USAID, Project Management Specialist (HIV/AIDS), New Delhi, India

Background: The Indian HIV prevention program offers a package of prevention services to key populations (KP) through well-structured 'targeted intervention' (TI) facilities run by non-governmental organizations. TI are established in a geographic area for a stipulated number of KPs. Areas with more geographically dispersed or fewer KP tend to be uncovered by the TI. The TI program reports a 0.11-0.66% HIV case-finding rate. The USAID- and PEPFAR-supported LINKAGES project in India piloted a peer-led model to reach female sex workers (FSW) in a geographic pocket not covered by the national program.
Description: During November-December 2017, eight adjoining sub-district units unreached by the TI program in high HIV prevalence East Godavari district of India were targeted. A community-based organization (CBO) led by FSWs was engaged as lead partner. Consulting with the CBO leaders, a small team of peer mobilisers (to identify peers), a peer navigator (to link FSWs detected HIV positive to treatment) and a community coordinator was formed and nominally compensated for their time. HIV testing kits were procured from the government testing centre. FSWs were provided with prevention education and offered HIV testing at a community-convenient site and time. A lab technician was hired to mentor and monitor the HIV testing performed by the peer mobilizers.
Lessons learned: Of the 219 FSWs mobilized and provided HIV counselling and testing services, 42 (19.2%) were identified HIV-positive. Of those detected positive, 17 were linked to ART by December, although the peer navigation is on-going. The majority of the FSWs mobilized by peers belonged to the 25-29 age group. In addition, nine out of the 15 sexual partners tested were detected HIV positive. By leveraging the existing CBO and government systems, the piloted model argues for its sustainability.
Conclusions/Next steps: The pilot demonstrated high case detection rate among FSWs who otherwise would not have been reached by the national TI program. It may imply that the 'right population' was targeted with 'right approach'. We advocate with the national program to integrate community-based testing approaches, engaging the community proactively, to improve the efficiency of TIs in reaching KPs in unreached geographical pockets to achieve the 90-90-90 targets.

THPEE702

A sustainable MSM-led HIV prevention, care and treatment service provision model in Vietnam

N. Anh Ngoc[1], L. Minh Thanh[1], O. Banos[2], N. Tuong An[1], H. Phuong[1], N. Thi Thu Vu[3,4]
[1]G-link Vietnam, Ho Chi Minh City, Vietnam, [2]Global Forum on MSM and HIV (MSMGF), Oakland, United States, [3]Institute of Preventive Medicine and Public Health, Hanoi Medical University, Hanoi, Vietnam, [4]Centre for Promotion of Advancement of Society (CPAS), Hanoi, Vietnam

Background: With 8.2% of HIV prevalence, Men who have sex with men (MSM) in Vietnam are disproportionately affected by HIV and their involvement in HIV interventions is limited. Worldwide, there is evidence MSM are actively involved in providing HIV services. In the context of donor transitions from direct funding to technical assistance support, a more effective and sustainable provision of HIV services for MSM is needed.
Description: Initially established as an MSM-led social enterprise in 2010 in Ho Chi Minh City, Vietnam, G-link has become a professional HIV service provider. G-link's budget includes self-raised funding and donor grants, including Global Fund, PEPFAR and MSMGF. In response to the emerging needs for an MSM-friendly-and-culturally-adapted services, G-link established a private clinic to provide a comprehensive HIV and STIs-related service package provided by MSM medical staff, including: innovative online HIV outreach, HIV rapid testing, STIs screening and treatment, PEP, PrEP, ART. To better serve the community, G-link has used the MSMIT tools to improve existing services offering more flexible service hours compared to those of public clinics; 24/7 hotline service; and subsidized cost policy to MSM with modest income. Recently, G-link has been nominated Hero Award by APCOM as a groundbreaking and innovative community clinic in the Asia and Pacific region.
Lessons learned: Our outcomes show our service model increases accessibility and sustainability of services for the historically marginalized MSM reluctant to access government clinics. G-link has proven its efficient use of donors' funding to establish holistic health services for MSM. In 2017, 7,900 MSM received HIV testing; 474 were referred to ARV treatment, 203 received ART at G-link clinic; 420 received PEP and 238 received PrEP. With database of 5,000 MSM, G-link manages to longitudinally follow up both HIV-negative and HIV-positive clients for HIV testing reminders, timely assistance with ART enrolment and adherence support.
Conclusions/Next steps: G-link is the first community-led healthcare provider in Vietnam and its proven success could be seen as a sustainable community-led HIV service provider in the region. With MSMGF's technical support, G-link is documenting its service model to be shared and replicated in Vietnam and in the Southeast Asia region.

THPEE703

Crowdsourcing to expand HIV testing services: A pragmatic, stepped wedge randomized controlled trial in China

J. Tucker[1,2,3], SESH Crowdsourcing Team
[1]UNC Project-China, Guangzhou, China, [2]LSHTM, London, United Kingdom, [3]SESH Global, Guangzhou, China

Background: HIV testing rates are suboptimal among many key populations. Crowdsourcing may be a useful tool to increase HIV testing. Crowdsourcing has many people solve a problem and then shares the solution with the public. This study used a stepped wedge cluster randomized controlled trial to evaluate a crowdsourced intervention to promote HIV testing among men who have sex with men (MSM) in China.
Methods: Public crowds developed the intervention through a national image contest, a regional strategy designathon, and local message contests. These three activities generated images, strategies, and messages, respectively, for the final intervention (Figure 1). A pragmatic stepped wedge cluster randomized controlled trial evaluated the crowdsourced intervention to promote HIV testing among MSM in eight Chinese cities over 12 months (ClinicalTrials.gov number, NCT02796963). MSM were recruited through Blued, a gay social networking mobile application. The

primary outcome was HIV testing in the past three months. Secondary outcomes included HIV self-testing, condomless sex, and WeChat (an instant messaging application) communications about HIV testing in the past three months. Generalized linear mixed models were used to analyze primary and secondary outcomes.
Results: Most of the 1381 MSM participants were ≤ 30-years-old (82%), unmarried (86%), and had a college degree or higher (65%). In intention-to-treat analysis, the odds of receiving an HIV test during the intervention periods was significantly higher than during the control periods (estimated odds ratio (OR)=1.67, 95% confidence interval (CI) 1.27-2.21). The proportion of individuals receiving an HIV test within a city was 8.9% (95% CI 2.2-15.5) greater during the intervention periods. There was no change in the secondary outcome of condomless sex. The intervention increased HIV self-testing (OR = 1.98, 95% CI 1.47-2.66, P< 0.001) and WeChat discussions about HIV testing (OR=1.73, 95% CI 1.34-2.23, P< 0.001). HIV self-testing rates were sustained following the immediate three-month period of the intervention.
Conclusions: A crowdsourced intervention was effective in promoting HIV testing among Chinese MSM. This study has implications for the scale-up of HIV testing services among MSM across low- and middle-income countries.

*[Figure 1. Steps in Intervention Development. *Exceptional defined by ranking after scores from three independent judges.]*

THPEE704

Improving retention of HIV positive clients in care by conducting real time follow up of clients using full time community health workers (CHWs): An experience of five districts in Western Uganda

I. Namuleme Ddumba[1], B. Kunihira[2], P. Ajuna[3], S. Amodot[4], A. Kekitiinwa[5], Rwenzori region
[1]Baylor College of Medicine Children's Foundation Uganda, Health Systems Strengthening, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation Uganda, Monitoring and Evaluation, Kampala, Uganda, [3]Baylor College Children's Foundation Uganda, Care and Treatment, Kampala, Uganda, [4]Baylor College of Medicine Children's Foundation Uganda, Community Services, Kampala, Uganda, [5]Baylor College of Medicine Children's Foundation Uganda, Executive Director, Kampala, Uganda

Background: Retention in care is an indicator of good adherence and a requirement for Viral suppression among people living with HIV on ART. poor retention remains a major hindrance to the attainment of the 90-90-90 goals in Uganda. The 12 months retention was low below the 90% target for 3/5 districts. The objective of this intervention was to improve the retention of clients in care using full time CHWs to conduct daily real time follow up of clients who miss clinic appointments.
Description: CHWs, a newly recruited cadre of support community staff were recruited and attached to health facilities providing ART in 5 scale up districts in western Uganda. CHWs updated the clinic appointments daily and developed lists of clients that had missed clinic appointments. This was different from the use of VHTS that work on a volunteer basis and conduct monthly follow up of clients.
Lessons learned: There was marked improvement in the retention of clients in all five districts. 4/5 districts registered retention above 90% and the fifth district improved from 85% to 89%. clients were more receptive to the CHWs who conducted the home visits because they had interacted with them at the health facility. The clients were not familiar with the VHTS were not regular at the health facility.
Conclusions/Next steps: The use of CHWS as full time recruited staff and attached to health facilities are able to conduct real time daily follow up of clients who miss appointments. The clients are more responsive to health workers with whom they have interacted with which reduces the likelihood of receiving wrong locator information.

[Retention rates for five districts of the Rwenzori region in Western Ugand for a period of 12 months]

THPEE705

Community/facility strategies to promote adherence to ART and VL awareness amongst PLHIV in Botswana

B.M. Morapedi, G. Morineau, J.M. Irige, B. Mantu, O. Sokwe, C. Lesedi, C. Pheko, K. Poloko
FHI 360, APC Botswana Project, Gaborone, Botswana

Background: The Advancing Partners and Communities (APC) project in Botswana funded by PEPFAR through USAID established a community HIV care program to support people living with HIV (PLHIV) to reach their treatment goal in a differentiated care model lead by community health workers (CHWs). Adherence is associated with efficacy of antiretroviral treatment (ART) whilst the viral load (VL) remains the marker for treatment success. In the era of 'Treat All' in Botswana, adherence counselling and awareness of importance of VL monitoring requires partnership between community and facilities.
Description: Health facilities provided trained CHWs with lists of PLHIV newly initiated on ART and defaulters for enrollment in community care. CHWs conducted home visits to enroll consenting PLHIV in community care and provided individual client assessments, adherence counselling and monitored clients' compliance to scheduled health checks including laboratory monitoring appointments with specific focus on VL monitoring. Home visits were repeated monthly or quarterly depending on clients' adherence to treatment.
Lessons learned: From October 2016 to September 2017, out of the 7,734 adults enrolled in community care, 7,462 (96%) self-reported adhering to ART in the past 30 days, 88 (1.1%) did not take pills and 184 (2.3%) missed pills frequently. 5,116 (69%) reported being virally suppressed, 1,401 (19%) had a detectable VL, and 1,217 (16%) did not know their VL. CHWs referred those without a documented VL in the last six months to facilities for VL measurement. All reporting adherence challenges were provided adherence counseling and followed-up monthly to evaluate progress.
Conclusions/Next steps: The limited proportion of self-reporting on viral suppression is a matter of concern. CHWs are adding value to health system by promoting viral load awareness as an indicator of treatment success rather than the CD4 count as it was the case in the old ART protocol. Joint facility and community efforts have proven to be necessary to promote ART adherence and sustained VL suppression. Task sharing ART monitoring between health workers and lay CHWs can help Botswana reach the UNAIDS 2nd and 3rd 90 targets.

From blueprint to action: On track to Ending the Epidemic (ETE) by end of 2020 in New York State through policy and program changes and community engagement

J. Morne[1], D. Daskalakis[2], C. King[3], T. Wilder[4], V. Shubert[5]
[1]New York State Department of Health, AIDS Institute, Albany, United States, [2]New York City Department of Health and Mental Hygiene, Division of Disease Control, New York City, United States, [3]Housing Works, Inc, President and CEO, New York City, United States, [4]Mount Sinai Institute for Advanced Medicine, HIV/AIDS Education and Training, New York City, United States, [5]Housing Works, inc, Advisor on Policy and Research, New York City, United States

Background: In June 2014, Governor Andrew Cuomo committed to end AIDS as an epidemic in New York State (NYS). An ETE Blueprint was developed by a Governor-appointed Task Force, consisting of representatives from state and local governments and other stakeholders.
Description: The community engagement and transparency embedded in the NY ETE effort continues, and the gains are astounding. The number of people newly diagnosed with HIV in NYS has fallen to historic lows, proving that efforts to End the Epidemic are making a significant impact.
Lessons learned: One example of ETE program change is a rapid access to treatment pilot to ensure immediate access to antiretroviral therapy for persons newly diagnosed; the initial cohort of rapid access participants reached viral suppression in just 41 days. Access to pre-exposure prophylaxis, or PrEP, has been expanded through dedicated funding and programs resulting in 2,300 persons having been prescribed PrEP by PrEP Specialists, the number of Medicaid recipients taking PrEP increased fourfold between 2013 and 2015, and active enrollment in the NYS PrEP Assistance Program (PrEP-AP) for the most recent one-year period is 1,627. Recently developed clinical education tools to support medical providers offering PrEP have also contributed to increased PrEP uptake. Recent policy changes aim to ensure no population is left behind when accomplishing ETE goals. In 2016, NYS eliminated the existing upper age limit of 64 for purposes of offering routine HIV testing. State regulations were recently modified to enable minors to consent to HIV treatment, including preventive treatment. In 2016 NYC became the first jurisdiction in the world to ensure every low-income person with HIV who is homeless or unstably housed has access to publicly funded rental subsidies.
Conclusions/Next steps: ETE Implementation is having an impact in NYS. Workshop participants will be able to: discuss elements and implementation of ETE Blueprint recommendations; identify opportunities to inform global and country-level policy and programs; develop strategies to promote and support local initiatives to end AIDS. Data, policy, program presentation from City, State and Community representatives, with Q&A. A "fishbowl" brainstorming session will provide the opportunity to interact with NY ETE stakeholders, and discuss local efforts to end AIDS.

THPEE707

An innovative approach to HIV prevention: Equipping healthcare providers with knowledge, tools and empathy to provide inclusive, rights based and gender sensitive services to MSM and TG

T. Doan Thanh[1], O. Banos[2], L. Nguyen Thi Phuong Linh[1], T. Phung Ba[3], D. Luc Quach Binh[4]
[1]Lighthouse Social Enterprise, Ha Noi, Vietnam, [2]The Global Forum on MSM and HIV, Los Angeles, United States, [3]Lighthouse Social Enterprise, Ha noi, Vietnam, [4]Lighthouse Social Enterprise, Hanoi, Vietnam

Background: In Vietnam, HIV prevalence among men who have sex with men (MSM) is 8,2% and transgender people (TG) is 17% and is predicted to increase rapidly in the coming time. Besides, they are facing many challenges in accessing HIV/STI related services. According to the Vietnam Administration of HIV/AIDS control, only 41,3% MSM has used of HIV testing and 11,7% accessed STI screening in last three months. Our previous studies suggest stigma and discrimination by healthcare providers is one of the primary barriers to service access. To strengthen clinical capacity to friendlier services provision, Lighthouse evaluated the effect of an MSM and TG-led intervention to sensitize health care providers.
Description: The intervention, from October 2016 to December 2017 in the Nam Tu Liem district center in Hanoi, Viet Nam and in partnership with the MSMGF, included five steps:
(i) mapping of healthcare facilities popular among MSM and TG community;
(ii) training of the trainers for MSM and TG involved in the intervention;
(iii) conducting pre- and post-assessment of targeted and participating healthcare facilities, including client surveys, staff interview, and simulated patients;
(iv) trainings of healthcare providers based on identified needs and issues;
(v) providing a set of recommendations based on the assessments of the clinic.
Lessons learned: The clinic improved its quality of services provision, particularly in the domains of overall friendliness and counselling on gender and sexuality. A total of 11 healthcare providers were trained and improved their knowledge on gender and sexuality, counseling skills, and communication with MSM and TG. The healthcare facility focused on reaching MSM and TG on social media with our technical assisstant. Overall, client satisfaction increased from 3.6 (out of 5) to 4.1 (out of 5), and the number of MSM and TG using services has doubled.
Conclusions/Next steps: This intervention increased community demand for HIV-related services. It increased MSM&TG's satisfaction with services provided. Its effectiveness underscores the need for collaboration between MSM-led groups and public clinics and the modeling and implementation of adequate services for MSM and TG. While focused on a Vietnamese population, this intervention provides a model that can be implemented in other provinces and countries.

Delivering paediatric HIV services

THPEE708

Parental predictors to uptake of HIV testing among children and adolescents in the context of index case testing strategy in Cameroon

H.A. Yumo[1,2], J.J. Nforbewing Ndenkeh[1], R.A. Ajeh[1], I. Sieleunou[1,3], D. Nash[4], A. Kathryn[5,6], M. Beissner[7], T. Loescher[7], C. Kuaban[8]
[1]R4D International Foundation, Yaounde, Cameroon, [2]Ludwig Maximilian University, Center of International Health, Munich, Germany, [3]University of Montreal, School of Public Health, Montreal, Canada, [4]CUNY Graduate School of Public Health and Health Policy, New York, United States, [5]Albert Einstein College of Medicine, Department of Epidemiology & Population Health, New York, United States, [6]Montefiore Medical Center, New York, United States, [7]Ludwig-Maximilians-Universität München, Department of Infectious Diseases & Tropical Medicine, München, Germany, [8]University of Bamenda, Faculty of Health Sciences, Bamenda, Cameroon

Background: Targeting children born to people living with HIV/AIDS (PLHIV) for HIV testing also known as index case HIV testing is emerging as a priority strategy to reduce the current gap in pediatric and adolescents antiretroviral treatment coverage, especially in Sub-Saharan Africa. This study aimed at identifying parental factors associated with HIV testing uptake among children of PLHIV in Cameroon.
Methods: This was a cross sectional study conducted from June-December 2016 in two district hospitals (Abong-Mbang and Ndop) in Cameroon. During this period, socio-demographic information of PLHIV in care and consenting to participate in the study were collected using standardized questionnaires. In addition, they were invited to have their biological children aged 6 weeks - 19 years tested for HIV. Logistic regression was performed using SPSS and significance set at 5%.
Results: 645 parents were included in the study through whom 1438 children were enrolled for HIV testing. The parents were predominantly females (81.5%) and the age ranged from 17 to 59 years with a median of 35 years. 57.8% (373/645) of parents tested at least one child and 57.6%

(829/1438) of children enrolled were tested for HIV. Factors associated with HIV testing uptake among children included: female gender (OR=1.49; p=0.049), higher education level (OR=1.61, p< 0.0001), single parent (OR= 1.91; p< 0.0001), and student occupation (OR=3.62; p=0.001). When adjusting for confounders we found that female gender (aOR=1.79, p=0.023), age older than 40 years (aOR=1.47, p=0.013), higher education level (aOR=1.46; p< 0.0001) and single parents (aOR= 1.77; p< 0.0001), were parental predictors associated to HIV testing uptake among children and adolescents.
Conclusions: PLHIV of male gender, less than 40 years, less educated and married were less likely to test their children for HIV. This suggests the need to enhance HIV counselling and testing for children among these sub-groups, especially among males and married parents in order to optimize the outcome of the index case testing strategy among children and adolescents.

THPEE709

Reaching the second 90: Improving coverage of paediatric ART uptake and quality of care using a technical assistance strategy at 46 health facilities in Haiti: Results from EQUIP

E. Emmanuel[1], S. Magwaza[2], M. Leonard[1], M.L. Excellent[1], D. Lauture[1], F. Jean Louis[1], J.W. Domercant[1]
[1]EQUIP-MatCH, Pétion-Ville, Haiti, [2]EQUIP-MatCH, Durban, South Africa

Background: According to 2016 UNAIDS Report, Haiti's paediatric HIV treatment coverage was only 49%. Provider-initiated HIV testing and counselling (PITC) is necessary to identify HIV-infected children, and clinical skills and competencies are critical for their treatment. Despite roll-out of revised HIV treatment guidelines, PITC has not been consistently implemented and providers remain reluctant to initiate children on ART. Instead, children are transferred to facilities with onsite paediatrician. Only 13% of the facilities have a paediatrician and weak bi-directional referral systems. Therefore, health outcomes for these children are unknown.
Description: EQUIP-Haiti designed a technical assistance package to improve paediatric HIV clinical management. In April 2017, EQUIP provided 3 training sessions to 59 healthcare providers from 46 institutions on PITC, PCR testing, tracking of mother-infant care, management of HIV-infected children and shared best practices on linkage to treatment. Supportive mentorship visits were conducted post- training to assist healthcare providers on correct ARV dosing and preferred regimens for HIV-infected children. Moreover, EQUIP supported the facilities by providing job aids, M&E tools, and clinical stationery to ensure proper documentation and reporting of data. A social media forum was established after the trainings to allow real-time and continuous support for clinical paediatric HIV case management.
Lessons learned: The trainings and mentorships improved skills and confidence with an increased median score of 24% between pre and post-test, facilitated facility-community linkages, tracking and re-testing of infants and children. The establishment of a social media forum provided a real-time advisory portal to address provider questions on clinical management of HIV-infected children, drug management, data collection, documentation, and analysis. To date, 45 health care providers are actively using this forum. The linkage to care rate for children infected with HIV increased from 27% to 59% to 76% and 80% in Q1, Q2, Q3, and Q4, respectively.
Conclusions/Next steps: Bridging the knowledge-skills gap is one of the key challenges to be addressed for a sustainable upwards trajectory of paediatric ART initiation. EQUIP's successful training and technical assistance package can be rolled-out at other facilities in Haiti for capacity building and quality improvement of HIV paediatric care and treatment.

THPEE710

Keeping the next generation HIV free: Collaborative effort on scaling up of early infant diagnosis in Myanmar

T.H. Oo[1], S.M. Lwin[2], S. Hone[3], L.L. Kyaw[4], H.N. Oo[3]
[1]Clinton Health Access Initiative, Yangon, Myanmar, [2]UNICEF, Yangon, Myanmar, [3]National AIDS Program, Nay Pyi Taw, Myanmar, [4]National Health Laboratory, Yangon, Myanmar

Background: The prevention of Mother to Child Transmission (MTCT) of HIV program in Myanmar was facing challenges of scaling up the early HIV diagnosis (EID) for infants born to HIV infected pregnant women. According to National AIDS Program´s report, only 25% (558/2195) of HIV exposed infants received EID in 2014. The major drawback was being lack of proper tracking on follow-up testing and treatment services for HIV exposed infants.
Description: The Laboratory Information Management System (LIMS) for Early Infant Diagnosis was established with the collaborative effort of National AIDS Program, National Health Laboratory, Public Health Laboratory, UNICEF and CHAI in January 2015. The EID mentoring program was established at 28 AIDS/STD teams and 12 hospitals with high caseload to strengthen the follow-up mechanism and proper linkage for infant testing and prompt initiation of ART with the support of PLHIV volunteers and Basic Health Staff. In addition, 17 SMS printers and 23 mobile phones were set up to shorten the turnaround time of result delivery.
Lessons learned: From January 2015 to December 2017, there were 3,585 HIV exposed babies in the project areas, out of which, 3,269 (91%) received EID. 1,586 (44%) were tested before 2 months of their age; this result was an increase from 32% in 2015. There was a decrease in HIV DNA PCR positive rate from 9.8% in 2015 to 6.5% among tested HIV exposed babies in 2017. The percentage of HIV exposed babies tested positive and referred for ART initiation was 44% in 2015 and increased to 79% by the end of December 2017. However, the LIMS indicated that the average turnaround time of EID testing in 2017 was 38 days mainly due to the delay in sending Dried Blood Spot samples to central labs, the delay in arrival of reagents and the high turnover rate of laboratory staff.
Conclusions/Next steps: The point-of-care EID testing at local level and the proper supply planning for laboratory commodities should be established in order to reduce the turnaround time of EID testing. In addition, the collaborative effort of PMTCT stakeholders in Myanmar should be strengthened to achieve elimination of MTCT by 2025.

THPEE711

Building the capacity of health care workers and rural clinics to implement early infant diagnosis in Zimbabwe

R. Malaba, P. Ndlovu
World Education, Inc., Harare, Zimbabwe

Background: Availability of paediatric HIV testing and treatment services in Zimbabwe had long been limited to district health centres. In 2013, with a desire to change that, the Ministry of Health and Child Care (MoHCC) undertook an accreditation assessment to understand the existing human resource capacity, pharmacy supply chain management, laboratory services, monitoring and evaluation processes, and infrastructure for HIV diagnosis and treatment at rural clinics nationwide. This assessment identified factors affecting Early Infant Diagnosis (EID) in rural clinics, including a lack of health provider confidence in diagnosis and management for infants and low capacity to test and treat.
Description: The Bantwana Initiative's Expanded Integrated Management of Paediatric AIDS Care and Treatment Program (EIP) was designed to address critical gaps in rural health service delivery for improved paediatric HIV services across 17 underserved districts. Between 2014 and 2017, in consultation with MoHCC, the program introduced training and clinical mentorship to rural health providers on diagnosis and management of paediatric HIV, counselling, ART initiation, and retention in care. Supplemental offsite support from Roving Mentors, as well as through online platforms and learning visits to provincial hospitals was availed. The program addressed resource constraints within rural clin-

ics by working with clinic staff on supply chain management, providing critical inputs (e.g., refrigerators for reagents, medicines), and introducing Results Based Financing to incentivize attainment of paediatric ART benchmarks. The program supported HIV testing for over 460,000 children; initiated 10,904 children onto ART; trained 217 nurses in advanced paediatric HIV management; and provided clinical mentorship to 170 clinical staff.

Lessons learned: On-the-job coaching and practical hands-on mentorship is effective in enhancing skills and confidence of primary level cadres in EID and initiation of HIV+ infants on ART. EID turnaround time in target districts was reduced from 12 to 2 weeks and specimen rejection rates reduced from 11% to 4%. To date, all 248 clinics supported by the program have graduated to ART initiation sites.

Conclusions/Next steps: The program has helped equip rural clinics with the capacity to respond to community HIV/AIDS needs through the introduction and scale-up of much needed comprehensive paediatric ART services previously provided only at district health facilities.

THPEE712

Understanding barriers and needed actions to improve HIV care for children in low income settings: Insights from five Ugandan districts

J. Rujumba[1], D. 't Hart[2], S. Ahumuza[3], R. Ochen[4], A. Tushabe[3], M. Musinguzi[2], TAFU Program Uganda
[1]*Makerere University, Paediatrics and Child Health, Kampala, Uganda,* [2]*Aidsfonds, Amsterdam, Netherlands,* [3]*Agency for Capacity Building, Kampala, Uganda,* [4]*Health Need Uganda, Soroti, Uganda*

Background: While Uganda has made remarkable progress in the fight against HIV, the delivery of treatment and care services for children living with HIV (CLHIV) remains a challenge. Treatment coverage for children 0-14 years living with HIV is estimated at 62%, far from realising universal treatment coverage. To address this gap, Aidsfonds and partners in Uganda are implementing a 2-year 'Towards an AIDS free generation in Uganda' program in five rural districts. To inform the program, we explored barriers and needed actions to improve HIV care for children.

Methods: Operational research was conducted in Soroti, Mubende, Mityana, Kyenjojo and Ntungamo Districts. Data were collected in August and December 2017, through 10 in-depth interviews (5 with CLHIV and 5 with their caregivers), 53 focus group discussions with CLHIV, village health teams, networks of people living with HIV, mothers in PMTCT, fathers, children in school and teachers. Seventy-nine key informant interviews with health workers and district leaders were conducted. Data were analyzed using content thematic approach.

Results: Stigma at home, in schools and communities; distant health facilities, delays at health facilities, stock out of drugs, lack of support groups for children, shortage of food and poverty makes access and adherence to treatment for children difficult. Phase out of HIV programs disrupted service provision and use. The major actions needed to improve care for CLHIV are: improving the quality of care at health facilities, strengthening linkages between health facility and community support structures, initiating support groups for children and empowering community resource persons especially expert clients to identify, refer, follow-up and support children. Supporting families to reduce stigma, meet food, education and other livelihood needs of children is key.

Conclusions: Study findings reveal the intersecting reality of stigma, distant and non-functional health facilities and vulnerabilities related to food insecurity and poverty as major barriers to children's access and retention into HIV care. Phase out of HIV programmes should be better coordinated to reduce the strain on health facility and community support systems. Strengthening community and lower level health care systems is critical in attaining universal treatment coverage for children living with HIV.

Lack of disclosure of HIV status and ART intake from pregnant women at delivery may jeopardize the optimal choice of PMTCT strategy. Preliminary results of the ANRS 12344-DIAVINA trial

G. Breton[1], A. Martin[2], O.H. Diallo[2], O.H. Diallo[3], S. Soumaoro[4], M. Cissé[5], Y. Koita[6], G. Peytavin[7], A. Montoyo[8], R. Becquet[9], P. Frange[10], C. Rouzioux[11], R. Tubiana[12]
[1]*SOLTHIS, Bagnolet, France,* [2]*SOLTHIS, Conakry, Guinea,* [3]*Fondation Espoir Guinée, Conakry, Guinea,* [4]*Hopital Ignace Deen, Conakry, Guinea,* [5]*CHU Donka, Conakry, Guinea,* [6]*PNPCSP, Conakry, Guinea,* [7]*CHU Bichat Claude Bernard, Paris, France,* [8]*ANRS, Paris, France,* [9]*Université de Bordeaux, INSERM UMR 1219, Bordeaux Population Health Research Center, Team IDLIC, Bordeaux, France,* [10]*CHU Necker Enfants Malades, EA 7327, Université Paris Descarte, Paris, France,* [11]*CHU Necker Enfant Malades, Paris, France,* [12]*CHU Pitié-Salpêtrière, Paris, France*

Background: Globally 45% of HIV-infected children are born in West and Central African countries where prevention of mother-to-child transmission (MTCT) programs are still limited. The last revision of WHO guidelines included a reinforced HIV preventive therapy for infants at high risk of acquiring HIV that needs to be further investigated in the field.

Methods: The ANRS 12344-DIAVINA trial investigates in Conakry, Guinea, the operability of a strategy combining reinforced preventive antiretroviral therapy (ART) in infants at high risk of MTCT (mother diagnosed with HIV at delivery or having received ART for <4 weeks before delivery) and early infant HIV diagnosis. We present here the proportion of pregnant women at high risk of MTCT and the results of maternal HIV-RNA performed at delivery.

Results: From February to December 2017, 5062 pregnant women were admitted for delivery at Ignace Deen hospital. HIV testing was offered to 5008 women (99%), of which 95% accepted it. Overall, 91 women were HIV-infected (1.9%), 42 (46%) had received ART for >4 weeks and 49 (54%) were at high risk of MTCT: 8 (9%) initiated ART < 4 weeks ago and 41 (45%) discovered their HIV infection at delivery. Among the 43 women included in the trial, HIV-RNA was performed at delivery in 40 patients. HIV-RNA was < 250 copies/ml in 21/40 (53%) women: 6/8 (75%) on ART for < 4 weeks and 15/32 (47%) with HIV diagnosed at delivery. Blood samples taken at delivery were retrospectively further investigated for the 10 first women with HIV-RNA < 250 copies/ml at delivery (4 on ART for < 4 weeks and 6 with HIV infection diagnosed at delivery): HIV-1 was confirmed by Western-Blot, HIV-RNA was confirmed < 250 copies/ml and ARVs were detected in plasma in all samples.

Conclusions: A significant proportion of women are at high risk of MTCT, however this risk can be overestimated by the lack of disclosure of HIV status and ART intake by some women to caregivers at delivery. A systematic measurement of maternal HIV viral load at the end of pregnancy seems crucial to adequately estimate the risk of MTCT and adapt the neonatal ARV prophylaxis.

THPEE714

Optimizing EID outcomes: A cluster-randomized efficacy trial of the HIV infant tracking system (HITSystem) in Kenya

S. Finocchario Kessler[1], C. Wexler[1], A.-L. Cheng[2], N. Nazir[3], R. Lwembe[4], M. Maloba[5], K. Goggin[2,6], M. Brown[1], S. Khamadi[4], T. Odeny[2,7], B. Gautney[8], HITSystem Study Team
[1]University of Kansas Medical Center, Family Medicine, Kansas City, United States, [2]University of Missouri-Kansas City, School of Medicine, Kansas City, United States, [3]University of Kansas Medical Center, Preventative Medicine, Kansas City, United States, [4]Kenya Medical Research Institute, Center for Virus Research, Nairobi, Kenya, [5]Global Health Innovations, Kisumu, Kenya, [6]Children's Mercy Hospital, Health Services and Outcomes Research, Kansas City, United States, [7]Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya, [8]Global Health Innovations, Dallas, United States

Background: Outcomes for HIV-exposed infants (HEI) depend on the quality and efficiency of early infant diagnosis (EID) services.
In Kenya, we evaluated the impact of the HITSystem (system-level intervention linking EID stakeholders via e-alerts for providers and SMS for mothers of HEI) on key EID outcomes.
Methods: In this non-blinded, phased, cluster randomized controlled trial (NCT02072603), 6 hospitals matched on region, resource level, and volume were randomized to receive the HITSystem (n=3) or standard of care (SOC; n=3). Eligible participants (HIV+ women ≥18 years with HEI < 24 weeks) enrolled between February 2014 and December 2016 were followed to evaluate the primary outcome of complete EID; defined as receipt of all EID services through 18-months (HIV-uninfected infants) or ART initiation (HIV+ infants). HITSystem was hypothesized to improve retention, ART initiation, and results turnaround times (TAT) compared to SOC. Using a stepwise approach, we conducted separate multivariate logistic and Poisson regression analyses with intervention group, site volume, and significant covariates as fixed effects in the models. Bonferroni corrections for multiple comparisons were applied.
Results: Among 809 eligible HEI, data from 690 were analyzed (n=392 intervention, n=298 SOC); excluding 28 deaths and 91 documented transfers/moved. Median age at enrollment was 6.0 weeks; 50% were male. Infants enrolled in HITSystem were significantly more likely to receive complete EID services compared to controls (85.2% [.82-.89] vs. 61.02% [.55-.66], p< 0.008), including the following: receipt of OI prophylaxis (99.7% vs 89.6%), PCR results returned to hospital (100% vs 96.98%), mothers notified of result (98.9% vs 89.3%), re-testing among HIV-uninfected infants at 9-months (96.8% vs 91.1%) and 18-months (84.7% vs 69.3%), and ART initiation for HIV+ infants (100% vs. 72.7%). Mean results TAT (24.6 vs 49.2 days, p< 0.003) and mother notification (19.0 vs 29.8 days, p< 0.003) were faster at intervention sites. Receipt of initial HIV test was similar and time to ART was faster at SOC sites (median 68 vs. 51 days, p=0.045).
Conclusions: HITSystem significantly increased completion of EID services and reduced TAT for results and notification. Hindered by intervention settings requiring multiple adherence counseling sessions prior to initiation, time to ART was faster in SOC sites.

EID Variables	Intervention N=392 N (%), 95% CI	Control N=298 N (%), 95% CI	P value
OI prophylaxis	391 (99.74%), .98-1.0	267 (89.60%),.86-.93	.003
Initial DBS collected	392 (100%), 1.0-1.0	296 (99.33%), .98-1.0	.80
PCR result returned to hospital	392 (100%), 1.0-1.0	289 (96.98%), .95-.98	.004
Mother notified of result	388 (98.98%), .98-1.0	266 (89.26%), .86-.93	<.001
HIV+ infants started on ART	21 (100%), 1.0-1.0	8 (72.73%), .46-.99	.08
Retested at 9M	360 (96.77%), .95-.98	265 (91.07%), .88-.94	.013
Retested at 18M	315 (84.68%), .81-.88	201 (69.31%), .64-.75	<.001
Complete EID	**334(85.2%), .82-.89**	**180(61.02%), .55-.66**	<.001
*Bonferroni calculations applied to p values to adjust for multiple testing			

[Impact of the HITSystem on Complete EID Services]

THPEE715

Predictors of timely ART initiation among HIV-positive infants in Kenya

C. Wexler[1], N. Nazir[1], B. Gautney[2], M. Brown[1], M. Maloba[2], K. Goggin[3,4], S. Finocchario-Kessler[5]
[1]University of Kansas Medical Center, Kansas City, United States, [2]Global Health Innovations, Dallas, United States, [3]Children's Mercy Hospital, Health Services and Outcomes Research, Kansas City, United States, [4]University of Missouri-Kansas City, Kansas City, United States, [5]University of Kansas Medical Center, Family Medicine, Kansas City, United States

Background: Early initiation of ART (before 12 weeks of age) among HIV-infected infants reduces infant mortality by 76% and slows disease progression. Both the World Health Organization and Kenyan National Guidelines recommend immediate ART initiation for all HIV-infected infants; however, inefficiencies in early infant diagnosis prevents timely ART initiation among HIV-infected Kenyan infants. This study assesses timing of ART initiation and predictors of timely ART initiation among HIV-infected Kenyan infants.
Methods: We retrospectively reviewed data from 96 infants identified as HIV-infected between January, 2013 and December, 2017 at 6 Kenyan government hospitals. The primary outcomes were:
(1) infant receipt of ART by 12 weeks of age and;
(2) immediate ART initiation (within 3 days of maternal notification of the infant's positive test result).
We assessed bivariate and multivariate predictors of ART initiation by 12 weeks of age.
Results: Among 96 HIV-infected infants, 82 (85.4%) infants started ART. Average infant age at ART initiation was 19.3 weeks and average time from mother notification of a positive result to ART initiation was 22.5 days.
Of the 82 infants that started ART, only 17 (20.7%) initiated ART by 12 weeks of age. Even when diagnosed early (<7 weeks), more than half (57.9%) failed to initiated ART by 12 weeks of age.
Of the 78 infants with recorded dates of mother notification and infant ART initiation, only 30 (38.5%) received ART within 3 days. In multivariable logistic regression analyses, infants tested <7 weeks of age and those who initiated ART within 3 days of result notification were significantly more likely to initiate ART by 12 weeks of age (AOR 143.8 [6.1->999], p=0.002) and (AOR 20.1 [1.9-213.2], p=0.013), respectively.
Each additional week for results notification significantly reduced the odds of ART initiation by the 12 week target (AOR 0.39 (.21-.75), p=0.004).
Conclusions: Delays in initiation of ART compromise the benefits of life-saving ART for HIV-infected infants. These findings highlight the need for urgent engagement with key stakeholders (clinicians, patients/guardians, and policy makers) to ensure immediate initiation of ART for HIV-infected infants to significantly increase the proportion of HIV+ infants initiating ART by 12 weeks of age.

THPEE716

Evaluation of a comprehensive approach to close the paediatric HIV programme gap in Johannesburg, South Africa

C. Tait[1], K. Monchwe[1], T. Chiloane[1], M. Mabitsi[1], H.E. Struthers[1,2], J.A. McIntyre[1,3], R.P.H. Peters[1]
[1]Anova Health Institute, Johannesburg, South Africa, [2]University of Cape Town, Division of Infectious Diseases and HIV Medicine, Department of Medicine, Cape Town, South Africa, [3]University of Cape Town, School of Public Health & Family Medicine, Cape Town, South Africa

Background: Since the rollout of the South African HIV programme, the country has made tremendous progress in expanding paediatric treatment coverage. Despite this, considerable effort is required to ensure that all HIV-infected children are linked to treatment. The Paediatric and Adolescent Scale-up Project collaborative aimed to close this programme gap.
Description: We implemented a comprehensive approach of technical assistance and direct service delivery by roving teams to target children (< 15 years of age) missing from the HIV programme in sub-districts CDEG in Johannesburg Health District, between September 2015 and Decem-

Tuesday 24 July

ber 2017. Interventions included case-finding strategies, data driven linkage to care support, paediatric case management strengthening and data systems improvement. Routine operational and programme data were collected and analysed.

Lessons learned: Over a two-year period, a total of 84097 children were tested for HIV at facilities in the supported sub-districts; 2317 (2.8%) of whom tested HIV-positive. 69.6% (n=58544) of the total tests were in under-five children, and 51.4% (n=1192) of the positive tests were in this age group. Project implementation resulted in a significant increase in testing uptake (from 1050 to 3504/month; p< 0.001) and number of children testing positive (from 61 to 96/month; p< 0.001); test positivity rate dropped from 4.0% to 2.3% (p< 0.05). The absolute number of children initiated on ART remained in a similar range, at around 800 per year, illustrating reduction in linkage to care. Despite intensive efforts, programme retention rate decreased over time with one-year loss to follow-up increasing from 18% to 21% overall, but 27% in under-fives; one-year viral suppression rate also decreased from 72% to 56%.

Conclusions/Next steps: Our comprehensive model has successfully enhanced scale-up of paediatric HIV testing and case finding in regions CDEG of Johannesburg over time, although other factors could also have played a role. The high rate of loss to follow-up and low rate of viral suppression warrant attention, especially in children under 5. In order to close the paediatric HIV programme gap, focus of effort should shift from case finding strategies to strengthening the quality of care and psychosocial adherence support to dramatically improve linkage and retention in care.

THPEE717

Evaluation of PMTCT program performance using HIV exposed infants final outcomes in eight districts of mid-western Uganda

E. Mugisa[1], D.J. Birungi[2], D. Damba[3], A.S. Lutaaya[3], A. Kekitiinwa[4]
[1]Baylor-Uganda, PMTCT, Kampala, Uganda, [2]Baylor-Uganda, HIV Prevention, Kampala, Uganda, [3]Baylor-Uganda, Monitoring and Evaluation, Kampala, Uganda, [4]Baylor-Uganda, Research, Kampala, Uganda

Background: The Uganda AIDS Control Program with support from the Centres for Disease Control and Prevention (CDC) and Implementing partners began implementation of HIV Exposed Infant (HEI) birth cohort monitoring in April 2016. Using the birth month and year, each exposed infant is followed up longitudinally for a recommended period of 18 months. At every visit, HEI receives comprehensive clinical care including HIV testing, growth monitoring and Cotrimoxazole prophylaxis. This study evaluates performance of Prevention of Mother to Child Transmission of HIV (PMTCT) programs using HEI final outcomes.

Description: We conducted a retrospective data review of final outcomes for HEI that turned 18 months of age using monthly final outcomes reports from 126 health facilities in eight districts of western Uganda. At the end of the follow up period, HEI received a final HIV test if they previously tested HIV negative or if previously tested HIV positive-they continue receiving antiretroviral treatment. HEI not active in care are documented as: lost, transferred out or died before 18 months of age.

Lessons learned: A total 4484 HIV exposed infants were registered in the birth cohort of January to December 2015. Eighteen months later, 81% (3653/4484) received HIV testing services within the recommended two months of age. 76% (3429/4484) completed 18 months follow up and were discharged HIV negative while 3% (136/4484) tested HIV positive and 95% of positive infants were initiated on lifelong antiretroviral therapy. 2.5% (111/4484) died, 9% (397/4484) were lost to follow and 11% (513/4484) were transferred to other health facilities before the recommended 18 months of age. 2.2% (100/4484) of HEI were active in care at 18 months but not tested for HIV.

Conclusions/Next steps: In predominantly breastfeeding populations, the proportion of HEI that tested HIV positive at 18 months of age was less than the World Health Organization PMTCT target of < 5%. Given that Mother to Child Transmission of HIV is a key PMTCT outcome indicator; the above HEI final outcomes indicators are useful in evaluating effectiveness of PMTCT in resource limited settings.

THPEE718

Factors affecting formal education of children living with HIV in Coastal Kenya: Findings from a qualitative inquiry

A. Shamsudin[1], J. Kwatampora[2]
[1]AIDS Healthcare Foundation - Kenya, Mombasa, Kenya, [2]AIDS Healthcare Foundation - Kenya, Nairobi, Kenya

Background: The HIV pandemic has had a profound negative impact on the education sector globally and in Kenya. HIV infected children living in sub-Saharan Africa have been disproportionately affected in terms of their academic progression and achievement. With over 1.5 million people living with HIV (PLWH) in the country, Kenya has the fourth largest HIV epidemic globally. Of these PLWH, close to 100,000 are children aged 15 years and below. The objective of this study was to explore factors that affect the formal education of children living with HIV (CLWH) in Coastal Kenya.

Methods: A qualitative study design using the phenomenological approach was employed. In-depth interviews and focused group discussions were conducted with 42 caregivers and school teachers of CLWH in Mombasa, Mtwapa and Kilifi towns of Coastal Kenya. The study participants were recruited through purposeful and snowball sampling. Data were collected between November and December 2017 and subjected to thematic content analysis. Ethical considerations were observed in accordance with the principles of the Declaration of Helsinki.

Results: The major themes identified were: (i) Socioeconomic difficulties in skipped-generation households where children orphaned by HIV had to drop out of schools and become breadwinners for their siblings and aging grandparents. (ii) Stigma and discrimination because of the children's HIV status affected their access to formal education. (iii) Absenteeism from school because of prolonged illness and frequent clinic visits prevented CLWH from doing well in school. (iv) The psychological impact of HIV on children leading to fear, depression, anxiety, hopelessness, and self-guilt affected their academic performance.

Conclusions: Access to quality education is a fundamental right of all children and it should continue to be an important agenda of all Public Health interventions targeting CLWH. Further research is needed to elicit perspectives among population segments not sampled in this study.

THPEE719

A move towards targeted case-finding: A comparison of HIV testing modalities implemented by two unfinished business clusters

A. Mntambo[1], S. Bokolo[2], T. Kunene[3], S. Phakathi[4], T. Naidu[4]
[1]Aids Foundation of South Africa, HIV Prevention, Pietermaritzburg, South Africa, [2]Aids Foundation of South Africa, Durban, South Africa, [3]Aids Foundation of South Africa, Pietermaritzburg, South Africa, [4]Zoë-Life, Durban, South Africa

Background: UNAIDS 90-90-90 targets set country goals for HIV case finding, ART initiation and retention in care. Based on recent evidence, there has been shift from general testing to targeted approach of HIV case-finding. To increase efficiency of HIV testing services, new approaches are being adopted to identify priority populations. This analysis seeks to explore differences in testing yields from different testing modalities, at a community level.

Description: Data on HIV testing strategies were collected from two districts of KwaZulu Natal, one peri-urban and one predominantly rural community. Strategies for finding HIV positive children 18months - 19years included: adult index client tracing, targeted door-to-door testing and wellness days targeted at high risk areas. This analysis includes data collected over a period of seven months. The different testing modalities were tried out in the different sites and recording of the data under the appropriate testing modalities was done.

Lessons learned: HIV testing yields differed between the two clusters, and between testing strategies. Door-to-door testing, which has over the years been a main strategy in the community, initially showed a higher yield (7.0% in May 2017) in the peri-urban community where hot spots and informal settlements were targeted. However, this yield reduced af-

ter six months, reaching 1.0% by Nov 2017. This reduction was thought to result from team exhausting households with individuals at higher risk, in the area. In the predominantly rural community, adult index tracing showed slightly higher yield. Index testing yield started picking slowly but soon increased in August to reach 7.0%, far exceeding the other strategies. Wellness days held in both peri-urban and rural communities showed low yields compared to the other strategies.
Conclusions/Next steps: A blanket approach in adopting HIV testing modalities cannot be applied, as different settings have different modalities that yield higher positivity. Both index tracing and targeted door-to-door approaches could produce higher yield, if implemented in the correct context.

THPEE720

Improvements in pediatric HIV case identification across 17 health facilities in Lagos, Nigeria: A quality improvement collaborative approach

O. Olatoregun[1], B. Banigbe[1], K. Njoku[2], P. Okonkwo[1], T. Jolayemi[1], R. Olaitan[1], O. Eberendu[1], E. Aiyenigba[2], R. Boccanera[3], D. Ikeda[4], B. Agins[4]
[1]AIDS Prevention Initiative Nigeria (APIN), Abuja, Nigeria, [2]IHI, Boston, United States, [3]Health Resources and Services Administration, Rockville, United States, [4]HEALTHQUAL - UCSF, San Francisco, United States

Background: Over 300,000 children (<15 years) are estimated to be living with HIV in Nigeria, yet less than 15% are receiving antiretroviral therapy (ART). Despite national recommendations to offer HIV testing to pediatric patients of unknown HIV status with high suspicion of infection, testing coverage among these patients remains low, indicating suboptimal uptake of these recommendations.
Description: AIDS Prevention Initiative Nigeria (APIN) partnered with HEALTHQUAL at the University of California, San Francisco to implement a quality improvement collaborative (QIC) with the aim of improving pediatric HIV case identification in high-yield service delivery points across 17 primary and tertiary health facilities in Lagos State. Facility-level training, guidance, and coaching on quality improvement (QI) methods were provided by APIN with technical support and mentorship from HEALTHQUAL and improvement advisors from the Institute for Healthcare Improvement. Performance measurement data on HIV testing rate and yield were reported on a fortnightly basis, with facilities conducting root cause analyses, process mapping, and rapid-cycle PDSAs to devise interventions based on analyses of performance data. Teams from participating sites were convened on a routine basis to present implementation plans and compare progress.
Lessons learned: In the first quarter of QIC implementation, testing coverage of eligible pediatric patients increased by 27% compared to baseline. Among 16,146 children who received HIV testing services in the QIC's first quarter, 69 (0.43%) were newly identified as HIV-positive, representing a 36% increase in the number of newly diagnosed children compared to baseline. Change ideas adopted by facilities to improve case identification included intensified index case finding, training of healthcare workers on HIV testing services and optimal documentation, and screening of all children using a validated screening tool (Bandason et al. 2016). QIC implementation is ongoing as of February 2018.
Conclusions/Next steps: Implementation of a QIC led to improvements in case identification of HIV-infected children in Lagos State, and to the compilation of evidence-based interventions ("a change package") that will be spread to APIN-supported facilities in Benue State in 2018.

THPEE721

Reaching the unreached HIV positive children with quality care & treatment through telemedicine: An innovative pilot initiative

M.V. Manglani[1], Y. Gabhale[1], M.M. Lala[1], S. Balakrishnan[2], K. Bhuyan[2], B.B. Rewari[3], P. Singh[4], I. Kundan[4], M.S. Setia[5]
[1]The Pediatric Center of Excellence for HIV Care, Lokamanya Tilak Municipal Medical College & General Hospital, Department of Pediatrics, Mumbai, India, [2]UNICEF, Mumbai, India, [3]NACO, New Delhi, India, [4]Maharashtra State AIDS Control Society, Mumbai, India, [5]The Pediatric Center of Excellence for HIV Care, Lokamanya Tilak Municipal Medical College & General Hospital, Epidemiology, Mumbai, India

Background: The study was designed to compare the outcomes in Children Living with HIV/AIDS [CLHA] receiving care & treatment from ART centres linked to Pediatric Center of Excellence for HIV Care through telemedicine versus those that are not linked and to determine if the initiative has improved the quality of care in the linked ART Centers compared to the non-linked ART Centers.
Methods: A retrospective analysis of 5411 children upto 18 years of age, from 31 Telemedicine Linked [19 Linked-regular (≥12 video-conference sessions) and 12 Linked-irregular (≤12 video-conference sessions)] centres and 28 Non-Linked centres in the state of Maharashtra, India. We compared CLHA alive on Pre-ART/ ART, lost to follow-up (LFU) on Pre-ART/ ART; death during the Pre-ART/ ART, eligible but not initiated on ART; baseline CD4 counts (actual and number missing), latest CD4 counts, and regular visits between these three types of centres.
Results: Of the total children, 3676 (68%) were on ART and 1735 (32%) were in the Pre-ART group. In the Pre-ART group, the proportion of children alive was high in the Linked-regular centres compared with Linked-irregular centres, and Non-Linked Centres (79% vs 76% vs 70%, p=0.001) and proportion of children who were LFU was lower in Linked centres (regular and irregular) compared with Non-Linked centres (6% vs 5% vs 8%, p=0.09). In the ART group, the baseline CD4 counts were missing in a significantly lower proportion of children in the Linked-regular centres compared with Linked-irregular centres and Non-Linked centres (6% vs. 11% vs. 7%, p< 0.05), and the latest CD4 counts were missing in a significantly lower proportion in the Linked-regular centres compared with Linked-irregular centres and Non-Linked centres (12% vs. 31% vs. 30%, p< 0.001). Comparison between three groups is in Table 1.
Conclusions: Our study showed that the centers linked through regular telemedicine performed better in terms of patient care & treatment - higher proportion of CLHA alive and fewer LFUs. Overall, this pilot project of Telemedicine for Pediatric HIV has proved to be acceptable, feasible, and effective in improving the quality of care for children living with HIV across the state of Maharashtra.

	All Centers	Non-Linked Centers	Linked-irregular Centers	Linked-regular Centers	p value

Approaches to minimising loss in the prevention/treatment cascade

THPEE722

High rates of successful tracing and re-engagement in HIV care using Expert Clients in Malawi

E. Chikuse[1], K. Phiri[1], P. Kalande[1], K. Dovel[1,2], M. Sarena[1], A. Schooley[1,2], EQUIP Innovations for Health
[1]Partners in Hope, Lilongwe, Malawi, [2]University of California, Los Angeles, Division of Infectious Diseases, Los Angeles, United States

Background: Tracing and re-engaging HIV-positive clients who have difficulty staying in care is a growing challenge for the health system in Malawi. Partners in Hope, an EQUIP partner, introduced Expert Clients (ECs), who are HIV-positive volunteers from the local community, to assist in client tracing and follow-up.
Methods: Between October - December 2017, ECs received a 2-day training on client tracking tools and strategies for re-engaging HIV-positive clients in care. Facility data clerks reviewed medical records at 69 EQUIP supported health facilities and generated lists of clients with one or more criteria for tracking (defined as: defaulted from ART; missed ART appointment, high viral load; new positive but not initiated ART; or HIV-positive infants). Clients from the list were assigned to ECs for tracing and follow-up through phone calls, SMS, or home visits. Tracing outcomes were documented by ECs on a standardized client follow-up form. Client follow-up forms were reviewed to determine the proportion of clients traced, outcomes and re-engagement in care.
Results: 12,008 clients met one or more criteria for tracing, with nearly half of clients missing an ART appointment (Table). 9,685 (80.7%) of clients were traced and 6,698 (69.1%) of those traced re-engaged in care. Defaulters and HIV-positive clients who never initiated ART were least likely to return to care (48.9% and 51.4%, respectively). Reasons for not re-engaging in care included death, undocumented transfer to another health facility, or unwilling to come back to care.
Conclusions: We were able to reach a high proportion of clients in need of tracing through the use of EC volunteers who were familiar with the local community. In order for countries to meet the 90/90/90 goals interventions for retaining clients in care are needed. This study demonstrates one low-cost solution. Based on the lower proportion of re-initiates, new strategies for re-engaging clients who default or never initiate ART may be warranted. Additional work is needed to identify methods to reduce lost-to-follow-up and to ensure that clients who re-engage in care receive additional support to avoid future loss-to-follow-up. Additional comparison studies including costing evaluations should be conducted.

Classification	# Out of Care	# Traced	Returned to Care (of those traced)
Defaulters	3437 (28.6%)	2646 (77%)	1317 (49.8%)
Missed appointments	5651 (47%)	4689 (83%)	3635 (77.5%)
Clients with high VL	1642 (13.6%	1358 (83%	1083 (79.7%)
New Diagnosis without ART initiation	1201 (10%)	923 (76.8%)	618 (51.4%)
HIV Positive Infant	77 (0.6%)	69 (90%)	45 (65.2%)
Total	12,008	9685	6698

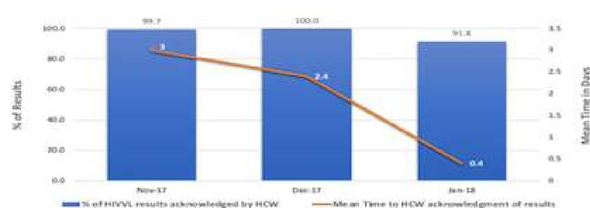
[Table. Description of clients in need of tracing and tracing outcomes by criteria type (n=12,008)]

THPEE723

Improving the efficiency and timeliness of healthcare workers to manage HIV viral load and EID patients through a digital result reporting platform

N. Gous[1,2], F. Chirwa[2], J. Chikonda[3], J. Takle[2], A. Schooley[3,4]
[1]SystemOne, Johannesburg, South Africa, [2]SystemOne, Springfield, United States, [3]Partners in Hope, Lilongwe, Malawi, [4]David Geffen School of Medicine at the University of California, Los Angeles, United States

Background: As HIV antiretroviral (ART) programs scale, paper-based reporting of centralized HIV viral load (HIVVL) and early infant diagnostic (EID) results are adding strain on overburdened clinics, leading to delays in clinical outcomes due to lost/misplaced results and difficulties in scheduling patient return appointments. In Malawi, 650 ART sites manage over 600,000 HIV-positive patients. Healthcare workers (HCW) are faced with increasing workloads and few tools to improve efficiency of patient management.
A platform was developed to improve timeliness of HIVVL/EID result delivery, data management and patient care by increasing the efficiency of HCW to act on results compared with paper reporting.
Methods: Aspect Reporter™(SystemOne) is a self-contained, solar-powered clinical device that receives digital HIVVL and EID results from the laboratory using an Android-based tablet. It allows HCW's to review, acknowledge, search, quickly identify flagged results, and receive alerts. Reporter was piloted in 12 clinics in Malawi to assess: time and reliability of digital result delivery;% of results acknowledged and time to acknowledgement; and user acceptance (questionnaire).
Results: November 2017-January 2018: Mean time to delivery of results using paper (22 days; n=487) versus Reporter (1.4 days;n=1,742)(P< 0.001); 5% of paper results reported missing in register; no results on missing Reporter.
Of 653 results delivered to Reporter in November 99.7% were acknowledged; December 100% (604/604) acknowledged; January 92% (445/485) acknowledged; Mean time for HCW acknowledgement of results declined from 3 days to 0.4days (Figure 1). Manual review of clinic register showed that 52% of results received on Reporter were transcribed into the VL register. Questionnaire (n=11 HCW);91% logged onto Reporter daily;89% found result lookup easier than manual paper review;82% reported it assisted with work;100% satisfied with design.
Conclusions: Reporter allowed HCW's to remotely confirm delivery of results, access and identify abnormal results within a significantly shortened TAT compared to paper reporting. Usage was high, indicating easy integration with workflow but no increase in proportion of results entered into the VL register. This indicated that updating the register is an additional burden to HCW. Providing an end-to-end solution (additional fields in Reporter for all steps in cascade) would increase utility and lower effort of HCW.



[Y axis shows the percentage of digital HIVVL results acknowledged on Reporter by HCW; secondary Y axis shows the mean time in days to acknowledgement]

THPEE724

Progress towards elimination of new HIV infections in Oyo State, Nigeria, through prevention of mother to child transmission of HIV

O. Ayinde[1], B. Ladi Akinyemi[2], O. Ogunsola[2]
[1]Ministry of Health, Public Health, Ibadan, Oyo State, Nigeria, [2]APIN Public Health Initiative in Nigeria, Ibadan, Oyo State, Nigeria

Background: The global community has set an ambitious target in agreement with the Sustainable Development Goals of "virtual elimination" of pediatric HIV. This appears feasible, due to new advances in health policies. Efforts have been made to prevent mother-to-child transmission (PMTCT) of HIV in sub-Saharan Africa. Nigeria still has the second highest burden in PMTCT. Little evidence has been published on eliminating MTCT of HIV, in Nigeria. This study seeks to analyze PMTCT implementation progress, towards elimination of HIV infections among children. in Oyo State, Nigeria.

Methods: A cross sectional retrospective study was carried out. A 5-year (2012 to 2016), data, was collected from all PMTCT facilities in Oyo State. The study population included all pregnant women who utilized ANC and PMTCT services during the study period. Data collected was analyzed, using SPSS version 20.

Results: PMTCT facilities increased from 9 in 2012, to 176 in 2016. A total of 486,677 (56,951 in 2012 and 109,221 in 2016), pregnant women, aged16 to 44 years, (mean, 26.6 ± 5 years) attended ANC. Women tested for HIV at ANC increased significantly, (t = 8.502; CI = 95%; $P<0.05$), from 55,666 in 2012, to 104,551, at the end of 2016. During every first ANC visit, women had 86.6% likelihood of getting tested for HIV (r = 1:0.866; $P<0.05$). The HIV positivity rate decreased from 1572 (2.28%) to 1,475 (1.40%), at $P<0.05$. Positive women treated increased from 1053 (67%), to 1,235 (83.73%). Early Infant Diagnosis (EID) services showed that HIV Exposed Infants (HEI), placed on ARVs increased significantly from 416 (26%) to 768 (52%), significant at $P<0.05$. The increase was significantly influenced by the number of HIV positive women receiving ARV, by 90.8% (F = 29.76; R^2 = 0.908; $P<0.05$. HEI who had Cotrimoxazole prophylaxis increased by 39% (from 478 to 783) and first DNA PCR by 31% (from727 to 1055).

Conclusions: In conclusion, there was progress towards elimination of new HIV infections among children. Further studies are recommended to determine how best to reach children with effective services in the state, to eliminate MTCT of HIV in line with UNAIDS (2016), Start-Free, Stay-Free, AIDS-Free Framework.

THPEE725

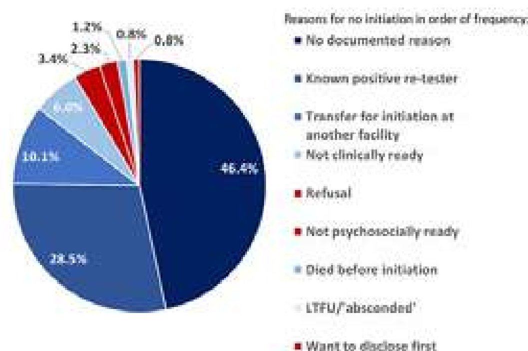
Are you ready? Patient readiness for ART in treat all era, Zimbabwe

K. Webb, V. Chitiyo, N. Tungwarara, S. Page-Mtongwiza, T. Maphosa, P. Nesara, B. Engelsmann
Organization for Public Health Interventions and Development (OPHID), Operational Research, Harare, Zimbabwe

Background: Failure to link to treatment following HIV positive diagnosis accounts for greatest leakages across the HIV care cascade. With an adult prevalence of 14.6%, linkage to HIV treatment is a key performance indicator in Zimbabwe's HIV Care and Treatment Program. However, aggregate data precludes routine reporting of reasons clients fail to initiate ART after diagnosis. Our objective was to establish the reasons for failure to start ART among clients newly testing HIV positive.

Description: We conducted a retrospective cohort analysis of routinely collected facility data among clients testing HIV positive from Oct-Dec 2017 at 7 purposively selected health facilities in 5 Districts of Zimbabwe. Selected facilities had < 85% linkage of new HIV positive clients to ART initiation in aggregate program data. Client characteristics, ART initiation, and reasons for no ART initiation were entered into MS Access and analysed using STATAV12. A facility survey of perceived facilitators and barriers to patient readiness for ART was conducted with health care workers and PLHIV to identify key operational themes.

Lessons learned: Among 894 patients diagnosed HIV positive, 29.3%(n=262) had no documented ART initiation. There was no reason documented for 46.4% (n=124) of clients not initiated. The most commonly documented reason for no ART initiation was client subsequently identified as already on ART with known HIV positive status during pre-ART counselling 29.0% (n=76). 'Not ready' factors (psychosocial, disclosure or refusal) accounted for 6.5% (17/262) of documented reasons for failure to link to ART.



[Reasons for failure to initiate ART following HIV positive test result Sept-Dec 2017 (N=262)]

Men were more likely than women to have not started ART due to existing opportunistic infections or TB treatment/investigations (13.3% vs. 2.3%; p= 0.0021). Enhanced pre- and post-test counselling, assisted problem solving and more 'take away' information were key themes among interventions to enhance patient preparedness for early ART.

Conclusions/Next steps: 'Patient readiness' factors were infrequently cited reasons for failure to start ART following HIV positive diagnosis. High proportion of undocumented reasons for failure to link, has resulted in programmatic actions including weekly identification of unlinked clients and active follow-up for return to care and outcome documentation. Future research should identify cost-effective interventions to strengthen testing-treatment linkages in routine public health settings.

THPEE726

Patients' satisfaction with HIV care providers in public health facilities in Lusaka - a study of patients who were lost-to-follow-up from HIV care and treatment

N. Mukamba[1], O.N. Chilyabanyama[1], S.R. Schwartz[2], L.K. Beres[2], S. Simbeza[1], K. Sikombe[1], N. Padian[3], C.B. Holmes[4], I. Sikazwe[1], E.H. Geng[5], Better Info Study Group
[1]Centre for Infectious Disease Research in Zambia (CIDRZ), Lusaka, Zambia, [2]John Hopkins University, Baltimore, United States, [3]University of California, Berkeley, United States, [4]Georgetown University, Washington DC, United States, [5]University of California, San Fracisco, United States

Background: In North America and Europe,health systems routinely survey patient satisfaction in order to improve health services.Despite widespread problems with retention of HIV patients in Africa in HIV care,assessments of patient perspective as a basis for improvement activities remain rare.We assessed satisfaction among patients previously lost-to-follow up from HIV care in Zambia and associations with re-engagement in care at a new facility.

Methods: Lost patients (>90 days late for last visit) identified through electronic medical record review were randomly sampled and intensively sought in Lusaka province.We used a structured 9-item questionnaire to measure patients' satisfaction with their healthcare providers,adapted from Adult Primary Care Questionnaire,previously validated in the US. Internal consistency across items was assessed with Cronbach's alpha. Exploratory and confirmatory factor analysis was used to assess tool performance and develop a satisfaction score subsequently used in logistic regression to model association between patient satisfaction and care status.The satisfaction score was a summation of responses to all 9 items on 5-point Likert scale (range: 9-45).A score >27 indicated satisfaction while ≤27 indicated dissatisfaction.

Results: Of patients contacted in person (n=615), 402 completed the satisfaction scale; overall among the 402, 57% (n=228) were out-of-care, while 43% (n=174) were in-care. The Cronbach's coefficient alpha for patient satisfaction scale was 0.98. Results indicated a high overall satisfaction of 76% (n=306) with healthcare providers. However, there were

higher levels of dissatisfaction with regard to time that healthcare providers spent with patients (37%) and carefully listened to them (29%).After adjusting for age, gender, facility type and CD4 count, satisfaction with healthcare providers was associated with higher odds of being in care (adjusted odds ratio: 2.95 [95% CI:1.58, 5.50], p< 0.01).Re-engagement at a new facility was 23% among those with low satisfaction and 48% among those with higher satisfaction.

Conclusions: An existing patient satisfaction scale from US exhibited construct validity in Zambia. Among lost patients,those expressing satisfaction were about twice more likely to have re-engaged in care even in an environment where structural (e.g. transport costs) and psychosocial barriers (e.g. stigma) are common. HIV services may want to routinely measure satisfaction to improve performance of HIV care and services in Africa.

THPEE727

Determining denominator - national effort to firm data on Lost to Follow up (LFU) on treatment for optimization of resources

R. Chauhan[1], M. Bamrotiya[2], R.S. Gupta[2], S. R M[1], P. Kumar[3], G. Pandey[1], S. Chakraborty[1], B. Bhagwan Ubarhande[1], V. Arumugam[1], R. Huidrom[3], U. Chawla[3], S. Mehta[3]
[1]India HIV/AIDS Alliance, Strategic Information, New Delhi, India, [2]National AIDS Control Organization, Care and Support Treatment, New Delhi, India, [3]India HIV/AIDS Alliance, Program and Policy, New Delhi, India

Background: Lost to follow up (LFU) on treatment is universal problem which most countries cannot resolve. India has an estimated 2.1 million people living with HIV, of which 1.2 million are registered and on ART. As per NACO data, 493,300 are LFU for treatment. Vihaan care and support programme that partners with NACO promises to bring the LFU cases back to treatment. However, there was a challenge in sharing the LFU list with outreach workers with traceable address. As principle recipient, India HIV/AIDS Alliance carried out collaborative intensive LFU drive with national, state and treatment units across the country between March 2017 to December 2017 to firm up the traceable LFU clients and bring back to the treatment for improved health outcome.

Methods: 437,774 LFU clients' line lists (till December 2017) were collected from 537 ARTCs. Collected line lists were transferred to standardized uniform formats and checked the quality in terms of completeness and accuracy at central level. Duplications and unclean data was removed. Cleaned line lists were shared with CSCs for tracing LFU clients and update the current status. During this validation process, ARTC documents and CSC records were reviewed and updated including the current status of client details. After data verification and validation, the updated LFU lists were collected back and analyzed to firm up the traceable clients.

Results: Out of the 437,774, 79.2% were contacted by CSCs. Of which, 12.2% were definite outcome (including brought back, death or transfer); 46.1% (201,781) with indefinite outcome (migrated or incorrect address); and the remaining 42% of the clients need focused intervention to link back to the treatment. The list now became half than the original which looked manageable. The list has been shared with respective CSCs to continue follow up and ensure re-link to treatment.

Conclusions: Effective collaboration between government and civil society led in firming up and re-link for higher retention in treatment. It took courage from government to clean up data, investment from NGO to invest in the process and hard work by the community outreach workers who actually was able to spend time and efforts with people who really needed them.

THPEE728

Early linkage to care by index patient design at large scale - experience from Vihaan care and support programme India

P. Kumar
India HIV AIDS ALLIANCE, Programme, New Delhi, India

Background: India HIV/AIDS Alliance and its partners implements the Global Fund supported Vihaan programme across India through 361 care and support centres (CSCs) complementing the national treatment programme. It promotes early HIV diagnosis and linkages to treatment service for sexual partners and family members of PLHIV. Vihaan works closely with national Integrated Counselling and Testing Centres (ICTCs) and antiretroviral therapy (ART) centres. Outreach workers from PLHIV community through home visits motivates family members for HIV testing by counselling on importance of early testing.

Methods: CSC report on HIV testing and linkages to ART centre of sexual partners and family members reported in management information system from CSCs between January to September 2017 was reviewed and analysed. Health parameter (CD4) were analysed for clients linked by CSC to ART centres and compared with state average CD4 of the PLHIV registered in the same period (between January to September 2017) at ART centre to measure early linkage.

Results: Among total 232,956 sexual partners and family members of PLHIV registered with Vihaan programme, 13,068 are eligible for HIV testing (6%). Among eligible clients, 7,209 (55%) got their HIV test done, received their report and 164 of them found positive, which accounts for 2% positivity (nationally positivity is <1% as per ICTC data). Descriptive analyses found that median CD4 of Vihaan linked PLHIV is higher (404 cells/mm^3) than the national CD4 average of those registered in the same period (254 cells/mm^3).

Conclusions: Focused intervention amongst family members of PLHIV who are most at risk of acquiring HIV through a peer led outreach and treatment literacy approach is effective for early detection and linkages with treatment. While India's public health system is working effectively, community-based models are essential to support the health and well-being of PLHIV and ensure successful HIV control across the country.

THPEE729

How a mobile HIV testing service in South Africa uses a centralised call centre to strengthen linkage to care among newly-diagnosed HIV positive clients

K. Pahl, B. Forgrieve, S. Stafford
Shout-it-Now, Tokai, South Africa

Background: In service to South Africa's 90-90-90 goals, Shout-it-Now (S-N) provides a community-based mobile HIV testing service (HTS) that has engaged more than one million clients since 2007, of whom 64,650 have been identified as HIV+. Linking community diagnosed HIV+ clients to care is a global challenge, and S-N has strived to minimize attrition from the "first 90" to the "second 90" through an iterative design of its linkage to care (LTC) services.

Description: From 2007-2011, S-N provided a standard LTC service for newly-diagnosed HIV+ clients comprised of onsite post-test counseling and a referral letter to a local clinic. Seeking improvements in its LTC rate, in 2012 S-N launched a multi-layered LTC process that utilized re-trained test site Counselors to immediately support clients, Community Liaisons to build stronger referral relationships with local clinics, and Care Coordinators (CCs) to provide free, 24-hour telephonic LTC support from a centralized Call Centre. Daily, a list of newly identified HIV+ individuals is automatically uploaded by S-N's integrated database to the Call Centre. Within 48 hours of an HIV diagnosis, a CC from the Call Centre contacts clients to commence a LTC support process.

CCs continue weekly telephonic contact with clients until they self-report a visit to a clinic for HIV treatment. In 2016 the Call Centre was further enhanced by the appointment of a dedicated manager, the hiring of additional CCs, and the training of all CCs in Motivational Interviewing.

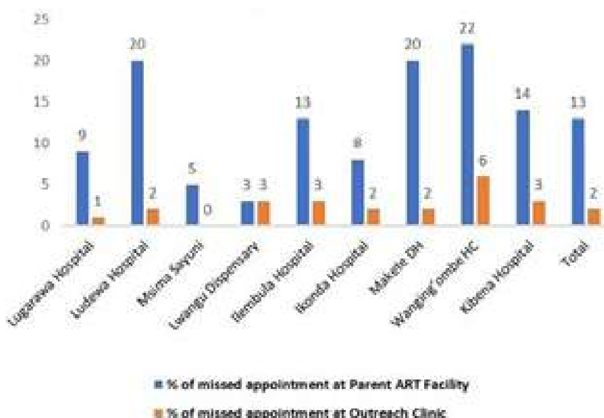
Lessons learned: Between 2007-2011, S-N's basic LTC service linked an average 37% of HIV+ clients to care. The revamped LTC program launched in 2012 resulted in an annual 51% LTC rate, and this approach incrementally improved to 61% by the end of 2015. Further Call Centre enhancements in 2016 improved S-N's LTC rate to 86% by 2017. Overall, slightly more females (79%) were linked to care than males (75%).
Conclusions/Next steps: At an average cost per client LTC of about $12.50, a mixed approach of onsite counselling and Call Centre delivered support provides a successful model for scaling up more robust LTC efforts for other community-based HTS programmes.

THPEE730

Decentralization of ARV refill in Njombe region, Tanzania; USAID Boresha Afya Southern Zone strategy towards reaching the 'hard-to-reach' patients

E. Okechukwu[1], J. Gamaliel[1], S. Msuka[1], E. Mlacha[2], B. Christian[3], M. Njozi[2], A. Ikonje[2], M. Ndile[2], J. Bisimba[4], P. Swai[4], M. Njelekela[2]
[1]Family Health International (FHI 360), Global Health, Dar es Salaam, Tanzania, United Republic of, [2]Deloitte Consulting Limited, Dar es Salaam, Tanzania, United Republic of, [3]Management and Development for Health, Dar es Salaam, Tanzania, United Republic of, [4]US Agency for International Development, Dar es Salaam, Tanzania, United Republic of

Background: Successful Antiretroviral therapy (ART) depends critically on good medication adherence, which in turn depends on regular ARV refill and retention on treatment. Since ART is lifelong, this need to be sustainable by the clients. Distance and transportation costs to the health facility are known barriers. In this study, USAID Boresha Afya Southern Zone program evaluated decentralized ARV outreach strategy implemented in 'hard-to-reach' areas in Njombe Region, Tanzania.
Description: The program proactively tracks 'missed appointments' and document tracking outcome. Analysis of these data from nine ART facilities in Njombe Region revealed that distance to the facility and cost of transportation were the major factors. The 'returned clients' were counselled and re-assessed. Using their addresses, all patients who were categorized as 'stable on ART' were mapped and assigned to Dispensaries serving as ´Community ARV Refill Centers´ in the communities closer to their homes. A team of healthcare providers (Adherence Counselors and Clinicians) from the ART facilities conducted monthly ARV refill outreach on designated days at these Dispensaries. The clients were evaluated using the national tools and those with additional need were referred to the 'parent' ART facility. Six months (May-November 2017) data on the missed appointments and ARV pick up rate in both centers were analyzed and compared using STATA 15.1.
Lessons learned: Overall, 13,762 and 1,585 ART clients were served at ART health facilities and Dispensaries respectively. The mean percentage of missed appointment at ART health facilities was 12.6 (7.3-18.0) while for Dispensaries was 2.4(1.1-3.7). This result shows a significant difference in missed appointments between patients served at both centers, 10.2 (5.4-15) p=0.001. Also, using ARV refill rate as a proxy for adherence; good medication adherence was observed among those served at the Dispensaries (98%) compared to those served at the ART facility (87%).



[Comparison of Missed Appointment at 'Parent ART' Facilities and Outreach Clinics, May - November 2017]

Conclusions/Next steps: Decentralization of ARV refill for stable patients significantly reduces 'miss appointments'; thus, improves patient adherence. This reduces clinic congestion, provider workload and overall patients' waiting time at both facilities. Programs should continue to use service delivery data to develop suitable patient-tailored local interventions to respond to emerging clients' needs.

THPEE731

High linkage and retention in HIV treatment among men who have sex with men receiving health navigation services in Guatemala City

N. Farach[1], E. Noj[2], M. Anton[3], R. Calderon[2], S. Northbrook[1], R. Mendizabal-Burastero[2]
[1]Centers for Disease Control and Prevention (CDC), Division of Global HIV and Tuberculosis, Central America Regional Office, Guatemala City, Guatemala, [2]Universidad del Valle de Guatemala, Guatemala City, Guatemala, [3]Ministerio de Salud Publica, Guatemala City, Guatemala

Background: Men who have sex with men (MSM) have a high HIV prevalence in Guatemala City and face multiple barriers to health, including suboptimal linkage and retention in HIV treatment. We implemented a health navigator model in three government-run clinics offering HIV testing and counseling to MSM in Guatemala City to increase adherence to treatment among individuals newly diagnosed with HIV.
Description: The model included three distinct phases: HIV result acceptance, linkage to care, and retention and adherence to treatment. Individuals newly diagnosed with HIV were offered health navigation services on the same day they were diagnosed. Consenting individuals discussed their preferences regarding HIV treatment access and social support with the assigned navigator. Navigators worked with patients to establish a date for their first medical appointment or create a follow-up plan if the patient was not emotionally ready. In the subsequent 6 months, navigators followed up via phone calls or visits to check on patient's medical and emotional status and their experience receiving clinical care. Navigators engaged with HIV reference hospital clinical staff to ensure patients received a clinical evaluation, had laboratory tests conducted (including HIV viral load and CD4 count), and received prophylactic treatment for opportunistic infections. When requested, navigators assisted patient disclosure of HIV status to their social network, partner referral to HIV testing, and linkage to social support programs.
Lessons learned: From October 2016 to September 2017, 264 individuals were newly diagnosed with HIV at participating sites. Of these, 95% consented to navigation services, 92% were linked to ART clinics within a median of 3 days (IQR 1-6.5), and 85% were retained in treatment at 6 months, compared to the national average of 56% for both linkage and retention. Navigators frequently provided emotional support in non-working hours. For optimal results, navigator workload should not exceed 20 newly diagnosed and 40 follow-up clients per month.
Conclusions/Next steps: The Ministry of Health could integrate navigation into its HIV service portfolio and expand the model to additional HIV testing sites in high burden areas. Strategies to hone navigator's emotional support skills, promote assisted partner notification, and maintain viral suppression among navigated patients should be considered.

Bridging communication gap in HIV treatment programs through Closed user group (CUG) mobile technology: Approach to HIV patient monitoring and referrals services on the strengthening integrated delivery of HIV/AIDS services project

O. Yemisi Bolanle[1], O. Agbaje[1], I. Utuk[1], C. Momah[1], C. Agbakwuru[2], E. James[3], O. Olayemi[1], H. Khamofu[4], S. Raj Pandey[1]
[1]FHI 360, Program Management, Garki, Nigeria, [2]FHI 360, Monitoring and Evaluation, Abuja, Nigeria, [3]United States Agency for International Development (USAID) Nigeria, Abuja, Nigeria, [4]FHI 360, Prevention Care and Treatment, Garki, Nigeria

Background: Timely and complete referrals for HIV clients in need of care within health facilities, facility-community and inter facility is crucial in closing the gaps for HIV care. Monitoring, tracking and routine interaction with HIV clients by health workers and case managers has been proven to reduce leakages in treatment cascades and improve retention in care.
However, most health facilities in Nigeria are challenged by the non-existence of communication infrastructure or resources required to facilitate timely tracking and completion of referrals for HIV positive clients. The USAID-funded Strengthening integrated delivery of HIV/AIDS services (SIDHAS) project implemented the provision of closed user group (CUG) mobile technology as a strategy to closing the gap.
Description: SIDHAS procured 2,606 mobile phones and lines, distributed to 785 health facilities, laboratories and 28 community based organizations across 13 states in Nigeria. Mobile networks were distributed according to the strength of network available in the locale. The CUG allowed health workers providing HIV care and treatment services to call each other within the network with zero charges and to follow up HIV clients referred within service delivery points and those referred to other health facilities to ensure complete referrals. A desk review was conducted on the CUG directory and communication logs for 4 states between June - December 2017.
Lessons learned: Review of the phone directory and call logs shows evidence of inter and intra facility communications, therefore contributing to improved referral and linkage rate from 39% to 74% within the period for some states. Data collected from 4 states also showed about 2240 defaulters returned within the period compared to 785 that returned to care before the CUG implementation. Overall, Improvement in completion rates for referrals and tracking and provision of adherence support to HIV clients was recorded.
Conclusions/Next steps: Given the results demonstrated by removing communication barriers and bridging the gap through CUG innovation, expanding CUG distribution to support groups in communities can be explored to reducing stigma and closing communication gaps amongst infected individuals.

Getting policies into practice

THPEE733

Time to first viral load testing among HIV positive pregnant women initiated on Option B+ at 5 government clinics in Kampala

P. Atuhaire[1], F. Matovu[1,2], D. Guwattude[2]
[1]Makerere University - Johns Hopkins University Research Collaboration, Kampala, Uganda, [2]Makerere University College of Health Sciences, School of Public Health, Kampala, Uganda

Background: Timely viral load (VL) testing is critical in the care of Human Immunodeficiency Virus (HIV) infected pregnant women in order to measure treatment success and assure elimination of mother-to-child transmission (eMTCT) of HIV to unborn children. Though the World Health Organization (WHO) recommends Time to First Viral Load (TFVL) testing as 6 months post initiation of Anti-retroviral therapy (ART), this is not always logistically feasible in resource-limited settings. We sought to establish the TFVL testing and associated patient factors at five eMTCT clinics in Kampala, Uganda.
Methods: We extracted clinical and VL test data from maternal ART records of a retrospective cohort of HIV infected ART naïve pregnant women who initiated Option B+ between 01 January 2015 and 31 Dec 2015. The data were verified against laboratory VL registers. TFVL (in months) was calculated based on the time difference between date of ART initiation and that of first VL test. Descriptive and Cox regression analyses of data up to 30 Sep 2017 (33 months later) were done.
Results: Based on the electronic data base master list, 622/913 (68%) records were successfully retrieved. The rest (32%) were misplaced. Through the 33 months review period, 174/622 (27.9%), 23/622 (3.7%), and 1/622 (0.16%) respectively were lost to follow-up, transferred out, and died. Of 424 women retained in care, 182/424 (43%) had at least one VL result post ART initiation, 30/424 (7%) had a second VL, while 242/424 (57%) had no VL performed. At six, nine, and twelve months; only 8/424 (1.9%), 47/424 (11.1%), and 96/424 (22.6%) had VL testing performed respectively. The median TFVL testing was 6 months (95 CI 5.02-6.98) beyond the recommended time point. Across the five clinics; age, number of previous pregnancies, baseline CD4 cell count, WHO clinical stage, and adherence at 6 months were not statistically significant.
Conclusions: A dismal 1.9% rate of achieving WHO recommended TFVL testing, with a median TFVL testing of six months beyond recommended time were observed. The non-association of patient factors to these observations and 32% missing records may suggest a serious need to review health system factors likely associated with these observations and their effective interventions.

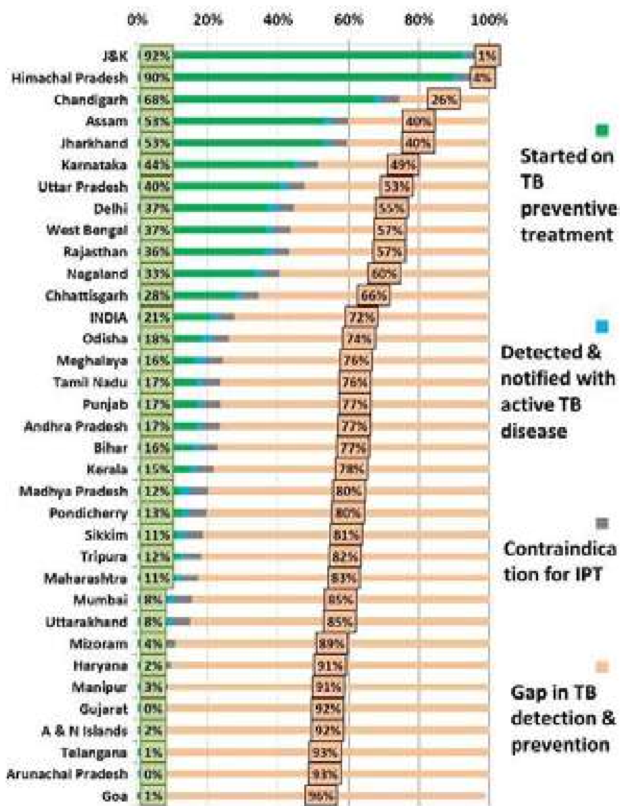
THPEE734

Status of provision of isoniazid preventive therapy for people living with HIV and lessons learnt from the challenges in the programmatic implementation and expansion in India

D. Balasubramanian[1], M. Gorla[2], R. Rao[2], N. Kumar[2], M. Bamrotiya[1], K.S. Sachdeva[1], R.S. Gupta[1], S.D. Khaparde[2], K.K. Rade[3]
[1]Ministry of Health & Family Welfare, National AIDS Control Organization, New Delhi, India, [2]Ministry of Health & Family Welfare, Central TB Division, New Delhi, India, [3]World Health Organization Country Office India, New Delhi, India

Background: Isoniazid Preventive Therapy (IPT) is one of the key interventions recommended by WHO to reduce the burden of TB in PLHIV. The initiative was launched by Ministry of Health, Government of India (GoI) on 01st December 2016. This article describes the progress from the policy decision, uptake of IPT and the programmatic challenges in its implementation.
The uptake of IPT across ART centres for 2017 was analysed using secondary program data & interaction with programme personal & health providers during meetings cum routine field visits.
Description: The IPT Implementation plan was approved in National Technical working group (NTWG) in August 2013 and the procurement of drugs were budgeted in New Funding Model Global Fund for AIDS Tuberculosis and Malaria (GFATM) Grant joint concept note for HIV/TB for 2014-17. The operational manual on IPT was approved in June 2016 and trainings of all ART centre staff were completed in September 2016. The GoI formally launched the initiative on 01st December 2016 for all ART centres in the country.
As of December 2017, all States/UTs except Arunachal Pradesh were implementing IPT services, with nearly 74% (392/533) ART centres having initiated patients. Among the 1.2 million eligible PLHIV, 21% (0.27 million) were initiated on IPT, with wide variation among the states ranging from 1% in Goa to 92% in Jammu & Kashmir. The gap in coverage of PLHIV by absolute numbers was highest in Maharashtra (0.18 million), followed by Andhra Pradesh (0.14 million).
Lessons learned: The slow uptake of IPT services in the ART centres was due to knowledge gaps in provision of IPT, non-availability of adequate quantities, especially Tablet Pyridoxine, and recommended dosage of drugs. Moreover there was incomplete documentation of cascade of patient's initiated on IPT. Capacity building on screening of

PLHIV, IPT eligibility and documentation was ensured during meetings and supervisory visits, permission was given to states to locally procure the non-available drugs and recommended dosages of Pyridoxine were modified based on local availability.



[State-wise coverage & gaps in TB preventive treatment for PLHIV]

Conclusions/Next steps: In order to fast-track initiation of PLHIV on IPT, an ongoing capacity building activity along with supportive supervisory visits and continuous availability of drugs may be undertaken.

THPEE735

Program science, program planning, and HIV/STD program practices in Miami, Florida, USA 2012-2018

W. Darrow
Florida International University, Health Promotion and Disease Prevention, Miami, United States

Background: At the National STD Prevention Conference held in Minneapolis, Minnesota, on March 12, 2012, the Associate Director for Science for the Division of STD Prevention at the Centers for Disease Control and Prevention (CDC) and her colleagues introduced “Program Science: A New Approach to STD Prevention Programs.” Program science with its “systems thinking” was proposed as “complementary” to traditional “linear thinking.” Importantly, “systems science” was offered as a vehicle to close the gap between interdisciplinary scientific research and program practice.
The purpose of our research was to evaluate the impact of the new “systems science” initiative on HIV/STD program planning and practices in Miami-Dade County, Florida, from 2012 to 2018.
Methods: Process evaluation was conducted by participant observation at publicly announced planning meetings of the Florida Department of Health and Ryan White Partnership, reviews of meeting notes and minutes, and studies of epidemiological reports, program updates, and other relevant documents distributed electronically or as photocopies. Content was reviewed for “program science,” “systems dynamics,” “network analysis,” “microsimulation” and other terms and phrases that local planners might have used to suggest the application of systems thinking and program science to the development of innovative HIV/STD prevention programs.

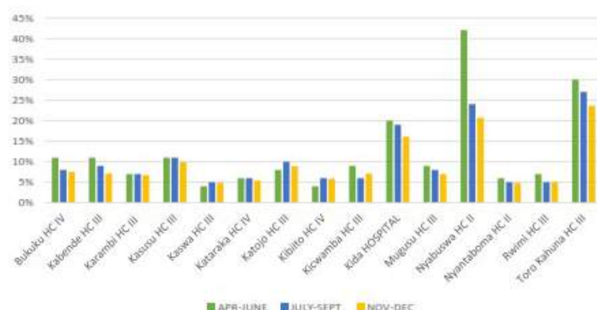
Results: The Miami-Dade HIV/AIDS Partnership Comprehensive Plan for 2012-2015, 2017-2021 Florida Department of Health Integrated Plan for HIV Prevention and Care, 2017 Mayor’s Task Force Final Report for “Getting 2 Zero-Miami,” and all other documents obtained and searched contained no reference to “program science” or to any of the concepts central to “systems thinking.” All HIV/STD planning documents produced from 2012 to 2018 in Miami-Dade County focused almost entirely on the goals of the 2010 and updated 2015 National HIV/AIDS Strategy.
Conclusions: The effort by CDC leadership to introduce program science into HIV/STD prevention planning and practices had no discernible impact in Miami-Dade County. The local program continued to select “high impact” biomedical interventions and supported enhanced pre-exposure and post-exposure prophylaxis, testing in non-traditional settings, linkage and retention in medical care. Future research must determine why HIV/STD programs adopt, ignore, or resist recommended changes for improving their theoretical methods, practical applications, and prevention services.

THPEE736

Role of onsite mentorship and coaching in reducing viral load sample rejection rates: A case study of Kabarole district in western Uganda

I. Namuleme Ddumba[1], I. Baganzi[2], P. Ajuna[3], P. Nahirya Ntege[4], P. Amuge[5], A. Kekitiinwa[6], Kabarole district
[1]*Baylor College of Medicine Children’s Foundation Uganda, Health Systems Strengthening, Kampala, Uganda,* [2]*Baylor College of Medicine Children’s Foundation Uganda, Monitoring and Evaluation, Kampala, Uganda,* [3]*Baylor College Children’s Foundation Uganda, Care and Treatment, Kampala, Uganda,* [4]*Baylor College of Medicine Children’s Foundation Uganda, Knowledge Management, Kampala, Uganda,* [5]*Baylor College of Medicine Childrens Foundation Uganda, Research, Kampala, Uganda,* [6]*Baylor College of Medicine Children’s Foundation Uganda, Executive Director, Kampala, Uganda*

Background: To attain the third 90 in line with the UNAIDS strategy, Uganda has scaled up the use of Viral load monitoring for all ART patients, however VL sample rejection remains one of the major hindrances to the achievement of VL coverage. Kabarole district registered a high rejection of VL samples at 43%. Poor quality of samples and incomplete filing of the VL requisition form were main causes for rejection. A project was started to assess the impact of quality improvement on reducing VL rejection rates through mentorship and coaching.
Methods: 15 sites with VL rejection rates above **5%** were selected for the project, a team of competent clinical mentors in VL monitoring were identified, paired and assigned to the 15 health facilities. 5 teams each comprising of a clinician and a laboratory technician were used to mentor each site was for 3 days. The onsite mentorship process involved each team working the health workers in the HIV clinics. Coaching was done for skills in phlebotomy and filing in of the VL requisition form. Each facility received 4 rounds of mentorship quarterly for 9 months. Data on VL sample rejection rates were monitored using the national VL system and reviewed quarterly for 9 months.



[Viral load sample rejection rates in targeted sites of Kabarole district]

Results: There was a decline in the rejection of VL samples from 43% to 3%. The decline was different across the 15 health facilities and was gradual over time. Health workers were more competent in sample collection and VL requisition. Non laboratory health care workers were able

to do DBS phlebotomy which reduced client waiting time. An increase in the rejection rates was observed when new staff attempted to do DBS VL phlebotomy for the first time, this improved with coaching and mentorship.
Conclusions: Mentorship and coaching is critical to building skill and capacity in the collection of VL samples using DBS and filing of the sample requisition VL form. Follow up of is critical to the effectiveness of the mentorship and acquisition of skill to address the capacity gaps of newly enrolled staff.

THPEE737

Guidelines on the go: Evaluation of clinical cards for New York State medical providers

J. Steinke[1], B. Levandowski[2], I. Rivera[2], N. Harris Tolson[1], T. Wilder[3]
[1]Mount Sinai Institute for Advanced Medicine, New York, United States, [2]University of Rochester Medical Center, Rochester, United States, [3]Mount Sinai Institute for Advanced Medicine, HIV/AIDS Education and Training, New York, United States

Background: New York State (NYS) clinical guidelines exist online to assist clinicians in delivering quality HIV and hepatitis C (HCV) screening and prevention. Clinical cards disseminate guidelines and policy information through a concise and portable reference. The NYS Department of Health AIDS Institute Clinical Education Initiative (CEI) has developed clinical cards on post-exposure prophylaxis (PEP), pre-exposure prophylaxis (PrEP), and HCV testing. These double-sided cards provide clinically relevant information on regimens, screening protocols, lab tests, and monitoring. These cards are free, can be ordered online, and are distributed at statewide training events.
Methods: A REDCap survey was launched on September 5, 2017 and closed on October 20, 2017. Comprised of quantitative and qualitative questions, it was sent to individuals who ordered clinical cards and via CEI's regular marketing channels (e-blasts, social media). Univariate and bivariate statistics were conducted using Stata v.15.
Results: 118 people completed the survey. The majority had ordered clinical cards (77%) with the rest obtaining them through other means (e.g., training events). Respondents could order more than one card; 89% ordered PrEP, 82% ordered PEP, and 61% ordered HCV testing. Of those ordering the cards, the majority ordered them for clinicians in their health agency (54%), communities (28%), medical society (6%), or for themselves as clinicians (35%) (note: they could choose more than one response). Of clinician respondents who have at least one card, between 68-82% found each card "very or extremely useful". Between 41-64% used the cards at least monthly. Between 77-91% reported they were "very" or "extremely likely" to recommend the clinical cards to other NYS clinicians. Positive qualitative feedback was grouped into the following categories: helpful resource and reminder, convenient and easy to use, concise, and informative. Suggestions for improvement include increasing the print size and updating the cards.
Conclusions: As NYS moves toward ending the AIDS epidemic and eliminating HCV, it is critical that clinicians have PEP, PrEP, and HCV information easily available. Next steps include updating the PrEP card, assessing and addressing gaps in geographic distribution, and developing new clinical card content.

THPEE738

Lessons learnt from delivering Pre-Exposure Prophylaxis (PrEP) to vulnerable populations at high risk of HIV infection in the public health sector in Brazil

E. Zucchi[1], L. Ferguson[2], D. Ferraz[3], T. Alencar[4], T. Pinheiro[5], D. Estevam[6], R. Munhoz[6], A. Grangeiro[5], Combine! Study Team
[1]Universidade Católica de Santos, Graduate Program on Collective Health, Santos, Brazil, [2]University of Southern California, Program on Global Health & Human Rights, Los Angeles, United States, [3]Fundação Oswaldo Cruz, Brasilia, Brazil, [4]Ministry of Health, Department of STI, AIDS and Hepatitis, Brasilia, Brazil, [5]Universidade de São Paulo, Department of Preventive Medicine, São Paulo, Brazil, [6]São Paulo State Department of Health, Centro de Referência e Treinamento em DST/Aids, São Paulo, Brazil

Background: Making PrEP delivery compatible with the diverse organizational structures of health services and realities of most vulnerable populations so as to scale-up PrEP to universal coverage has been a global challenge. We analyzed PrEP uptake and aspects of service organization over the first year of PrEP implementation in the Combine! Study in Brazil.
Description: Combine! is a pragmatic clinical trial on the effectiveness of post-exposure prophylaxis (PEP) for consensual sexual activity, combination HIV prevention and PrEP. PrEP delivery began in Nov 2016 in five public HIV clinics in southeastern, northeastern, and southern regions in Brazil.
Lessons learned: By December 2017, 526 participants were taking PrEP. Participants had a high risk of HIV infection: in the previous six months, 25% had been treated for an STI, 40% had 10-49 sexual partners, 10% had engaged in sex work, and 53% had used PEP. Most participants were males (96.5%), homosexual (93.4%), white (63.7%), and had high education (59.7%). Retention was high (90%), and no participants became infected after starting PrEP. Three HIV-negative individuals got infected between triage and first medical consultation. As a result of insufficient staffing, services were sometimes interrupted/delayed due to providers' vacation and doctors' limited schedule. Health workers reported resistance to providing PrEP, citing fears of side effects, perceived superior efficacy and safety of other prevention methods, and lack of time. Duplication of procedures by different providers occurred in complex facilities offering a wide range of services. In services focused on HIV treatment, counsellors were not available while voluntary counselling and testing services struggled with timely drug safety checks and patient follow-up. All services had frequent difficulties enrolling new patients.
Conclusions/Next steps: Simplified protocols with fewer initial and follow-up procedures would help increase uptake of PrEP. Additional, complementary strategies required include: promoting access to PrEP for vulnerable populations and populations at high risk of HIV infection; routinizing the offer of PrEP in HIV services; ensuring access to follow-up; and increasing the number of health workers trained in and confident to deliver PrEP. These lessons are equally applicable to other countries offering PrEP as part of combination HIV prevention services.

THPEE739

Time to antiretroviral therapy initiation under universal test and treat strategy in Swaziland: A stepped-wedge implementation trial

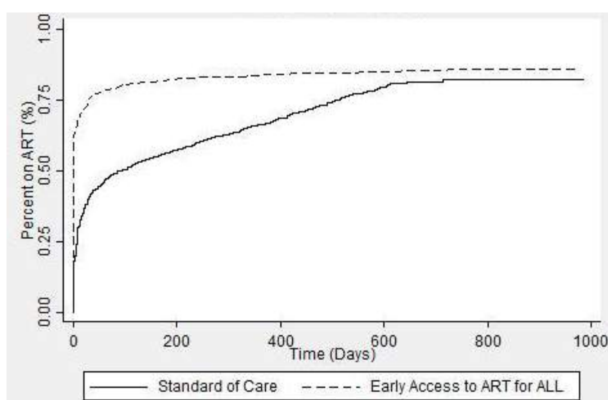
S. Khan[1], F. Walsh[2], D. Spiegelman[3], S. Mazibuko[4], M. Pasi[4], C. Lejeune[1], V. Okello[4], T. Bärnighausen[3,5]
[1]Clinton Health Access Initiative (CHAI), Mbabane, Swaziland, [2]Clinton Health Access Initiative (CHAI), Boston, United States, [3]Harvard T.H. Chan School of Public Health, Boston, United States, [4]Ministry of Health, Mbabane, Swaziland, [5]Heidelberg Institute of Public Health, University of Heidelberg, Heidelberg, Germany

Background: In 2015, the World Health Organization (WHO) released guidelines that removed all limitations on eligibility for antiretroviral therapy (ART) and recommended that countries offer ART to anyone infected with HIV upon diagnosis. However, no study so far had examined the changes in time to ART initiation with the adoption of a Universal Test and Treat (UTT) strategy in a "real world" setting under a public health sector.

Methods: We conducted a stepped-wedge implementation trial in 14 health facilities in Swaziland's public health sector. Clinics were paired and each pair was randomly assigned to transition at four month interval from the current standard of care (SOC) (2013 guidelines) to UTT, or intervention, on pre-specified start dates. All ART-naïve 18 years or older clients, who are not pregnant or breastfeeding were eligible to enroll in the study. This secondary analysis presents the time to ART initiation under SOC versus UTT. The analysis was conducted using survival analysis with time-varying exposure.

Results: Between September 2014 to August 2017, 3405 eligible clients were enrolled in the study. Sixty-two percent of clients were female and 36% were between 30-40 years old. Sixty-one percent (95% CI: 59-63) of UTT clients and 16% (95% CI: 15-18) of SOC clients initiated ART on the same day, while 70% (95% CI: 68-72) and 33% (95% CI: 31-35) in two weeks, respectively. In multivariable Cox proportional-hazards regression model, time to ART initiation was two times shorter under UTT (HR 2.13 (95% CI: 1.99-2.29)) than SOC, while age, sex and CD4 were not significantly associated.

Conclusions: Adoption of UTT was associated with shorter time to ART initiation in Swaziland's public health sector. The results suggest acceptability of the clients to initiate ART under UTT. However, there still remain outstanding questions on long-term retention and viral suppression of clients initiating under UTT strategy to achieve the long-term health benefits.



[Time to ART initiation for clients under Standard of Care (SOC) and Universal Test and Treat (UTT)]

Assessment of barriers towards achieving the 3rd 90: Experiences from Midlands province in Zimbabwe

T.T. Fusire[1], C. Chikanda[2], M. Sibanda[3], F. Chirowa[4], B. Chirwa[5], C. Ajayi[6]
[1]Khethimpilo Aids Free Living, Programs, Harare, Zimbabwe, [2]EQUIP Innovation for Health, Johannesburg, South Africa, [3]Khethimpilo Aids Free Living, Programs, Bulawayo, Zimbabwe, [4]Khethimpilo Aids Free Living, MER, Harare, Zimbabwe, [5]Khethimpilo Aids Free Living, Harare, Zimbabwe, [6]USAID Zimbabwe, Harare, Zimbabwe

Background: The Zimbabwe HIV Viral Load Scale-up Plan provides a road map to guide viral load (VL) testing scale-up from 3% in 2015 to a target of 90% by 2018. Approximately 62% of people living with HIV were receiving ART in 2015 in Zimbabwe. The Technical Duty Yonder, (TDY), a joint team from supporting partners assessed the facilities' systems in trying to achieve the 3rd 90. The aim of the assessment was to identify gaps and barriers in VL testing scale up in Midlands and to recommend efficient context appropriate strategies according to the national guidelines.

Description: An assessment of the afferent and efferent loops for VL testing to identify facility gaps and barriers for efficient VL testing scale up was conducted in 2 facilities in Midlands Province of Zimbabwe, in November 2016. Key informant interviews were conducted with with key personnel at each facility, observations and review of registers and patient notes was conducted, including ART registers, VL testing registers and patient ART books.

Lessons learned: Only 5 out of 27 nurses in one facility were trained on VL monitoring. The nurses were not trained in switching to second-line ART in cases of treatment failure. The facilities had a VL suppression rate of 87%. However, there was no structured communication system of recalling patients with unsuppressed VLs. Approximately 3% of the samples processed were rejected due to insufficient sample collection. Frequent use of VL consumables for other laboratory tests resulted in commodity shortages.

Conclusions/Next steps: Adressing the gaps and barriers identified is expected to lead to an increase in VL uptake in line with the global targets of having 90% of clients on ART being virologically suppressed. There was need to facilitate training of primary health care nurses on VL monitoring. The training of nurses would also include second line treatment management. There was need to facilitate mobile health service communication between facilities and clients when results are ready for collection to ensure timely collection. The laboratory consumables supply chain system needed to be strengthened to avoid misuse of laboratory commodities in the facilities.

THPEE741

Understanding the impact of policies for delivering universal antiretroviral therapy on the health workforce in Tanzania and Malawi: Evidence from repeated health facility surveys from 2013-2017 and qualitative interviews

J. Songo[1], F. Hasan[2], E. McLean[3], A. Dube[4], S. Vyas[5], T. Kalua[6], E. Geubbels[2], A. Crampin[1], A. Wringe[7], J. Todd[8], J. Renju[5]
[1]Malawi Epidemiology and Intervention Research Unit, Lilongwe, Malawi, [2]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [3]London School of Hygine and Tropical Medicine, Lilongwe, Malawi, [4]Malawi Epidemiology and Intervention Research Unit, Karonga, Malawi, [5]London School of Hygine and Tropical Medicine, Moshi, Tanzania, United Republic of, [6]Malawi Ministry of Health, Lilongwe, Malawi, [7]London School of Hygine and Tropical Medicine, London, United Kingdom, [8]London School of Hygine and Tropical Medicine, Mwanza, Tanzania, United Republic of

Background: Policies for universal antiretroviral therapy (ART) may negatively impact on the health workforce in African settings if task-shifting and training efforts are outpaced by growing patient numbers and evolving guidelines. Our study examines the impacts of universal ART policies on the health workforce in Malawi and Tanzania from 2013-2017.

Methods: Three rounds of facility surveys were conducted (2013, 2015, 2017) in health facilities serving the populations of rural demographic surveillance sites in Malawi (n=5) and Tanzania (n=10). Data were collected on HIV counseling and testing (HCT), ART and prevention of mother-to-child transmission (PMTCT) services. In-depth interviews were conducted with HIV providers to understand their experiences of offering care in the context of changing ART guidelines. Interview transcripts were coded and analyzed thematically.

Results: In both sites, increasing patient numbers in HCT, PMTCT and ART services were not always met with corresponding increases in providers. This resulted in progressively higher patient loads per HCT provider in both sites, and a nearly 4-fold increase in patient load for ART providers in Tanzania between 2013 and 2017 (Figure 1). The cadre mix of providers varied by site and changed over time, with a higher and growing proportion of lower cadre staff in Malawi (Figure 1). Overall, a higher proportion of HCT providers reported undergoing refresher training compared to PMTCT or ART providers (Table 1). The proportion of PMTCT providers undergoing refresher training peaked in 2013 in Malawi and 2015 in Tanzania, following Option B+ implementation.

Providers in both sites reported that high patient loads and insufficient training hampered the quality of care. Furthermore, training was more often described as being „on the job" in Tanzania, which some providers felt hindered their learning. In Malawi, the introduction of lay counsellors eased the workload of HCT providers, but challenges included their integration within clinics.

Conclusions: Although increasing patient numbers in both settings bodes well for achieving the first two 90 targets, the quality of care may be undermined by increased workloads for many providers. Task-shifting strategies are helping to address workload concerns in Malawi but should be carefully monitored to ensure effective implementation.

Implementation of the action plan for health sector response to HIV for WHO European Region: Early results from EECA and non-EU/EEA countries

E. Vovc, M. Mansfield, A. Stengaard, M. Dara
WHO Regional Office for Europe, Copenhagen, Denmark

Background: The Action plan for the health sector response to HIV in the WHO European Region, accompanied by a resolution, was officially adopted at the 66th session of the WHO Regional Committee for Europe in September 2016. It advocates for an urgent and accelerated health sector response to HIV epidemic; promotes comprehensive combination prevention, a "treat all" approach, and asks Member States to define and deliver an essential package of HIV services, to be included in the national health benefit package, which are patient-centred, accessible, integrated and focused particularly on key populations in a manner appropriate to the local context.

Methods: An evaluation questionnaire was developed prior to and disseminated at the regional consultation of HIV programme managers of eastern Europe and central Asia (EECA) and non-EU/EEA countries based on actions stipulated in the Action plan structured around five strategic directions: information for focused action; interventions for impact; delivering for equity; financing for sustainability; and innovation for acceleration. The questionnaire assessed the alignment of current national policies with the the regional WHO Action plan.

Results: 15 countries participated in the National HIV Programme managers meeting of EECA and non-EU/EEA countries in September 2017 and completed the questionnaire. The self-reported data showed that most of the actions and interventions recommended by the regional Action plan are integrated into the national strategies. Major gaps included lower level of integration of: needles and syringes exchange programmes in prisons (27%), PrEP for populations at substantial risk (33%), HIV testing by lay providers (33%) and HIV self-testing (20%). An essential comprehensive package of HIV services integrated into the national health benefits is defined by national strategies in 60% of countries.

Conclusions: Regional policy uptake is overall adequate on most of the actions per the results of this early assessment of countries' progress. However, particular attention is required to improve NSP in prisons settings and PrEP. Provision of HIV testing by lay providers and HIV self-testing are areas to which WHO may consider increasing advocacy and policy review activities. Integrating the essential comprehensive package of HIV services into the national health benefits package is essential to reach the 90-90-90 targets.

Policy intervention stipulated in the Action plan on health sector response to HIV in the WHO European Region	% of countries aligning with an indicated action from the Action plan, self-reported as of 09/2017, EECA and non-EU/EEA
National HIV strategy defines an essential comprehensive package of HIV services is integrated into the national health benefits package	60%
National HIV strategy prioritizes community-based HIV service provision	60%
National strategy includes needle and syringe exchange programmes in prisons	27%
National strategy includes opioid substitution therapy programmes in prisons	60%
National strategy includes pre-exposure prophylaxis (PrEP) for populations at substantial risk of HIV	33%
National strategy promotes early congenital syphilis diagnosis of infants and immediate treatment for all infants diagnosed with congenital syphilis	53%
National strategy promotes HIV testing conducted by trained lay service providers	33%
National strategy promotes HIV self-testing	20%
National strategy encourages innovative financing in the HIV response	67%

[Gaps in aligning national strategies to WHO policy]

Control and treatment of tuberculosis among migrants in Almaty City, Kazakhstan

U. Lukpanova[1], Y. Lukpanov[1], Z. Sapiyeva[2], K. Zhorayeva[3]
[1]Zabota, Almaty, Kazakhstan, [2]NTP, Almaty, Kazakhstan, [3]AIDS Foundation East-West in Kazakhstan, Almaty, Kazakhstan

Background: Almaty is the largest city in Kazakhstan, due to this, it has the biggest amount of the migrants. The city has one of the highest rates of TB/HIV cases in the country. Along with the external migrants, a vulnerable group for tuberculosis cases is internal migrants, who often change their place of residence, don't have registration in the public hospital and, therefore, don't have free access to free medical care. The unregulated legal status, lack of documents, labor exploitation do not allow migrants to seek medical care at the proper time. Medical staff of the public hospitals shows stigma towards them.

Description: NGO "Zabota" created effective partnership between the TB service, PHC and NGOs, aimed at increasing the access of labor migrants to the diagnosis and treatment of tuberculosis, HIV testing, reducing stigma and discrimination towards migrants on behalf of the medical staff.

Lessons learned: Within the project, preventive fluorographic examinations of migrants are carried out in the places of their accumulation - markets, construction sites, the Center for the Adaptation of people

without a place of residence. At the same time, 186 people of the medical staff of public hospitals and 101 employers of the migrants were trained on the questions of "TB/HIV" and "stigma and discrimination". The results of the successful work served as a basis for creating a mechanism for cooperation between NGOs and state bodies. In 2017, for the first time, the Almaty City Health Department provided 2 state social orders for carrying out activities for the prevention of tuberculosis and HIV infection among migrants.
Conclusions/Next steps: 27806 migrants were informed about tuberculosis, of which 85% were external migrants. It was revealed and given assistance in organizing the treatment of 9 internal migrants who did not have registration, documents, a certain place of residence, and had other social problems. All migrants are recieveing the proper legal consultations. The NGO will continue work towards building an effective system for redirecting migrants to obtain the necessary medical and legal assistance, inform employers and representatives of local authorities about the rights of migrants and the rights to detect and treat TB/HIV.

THPEE744

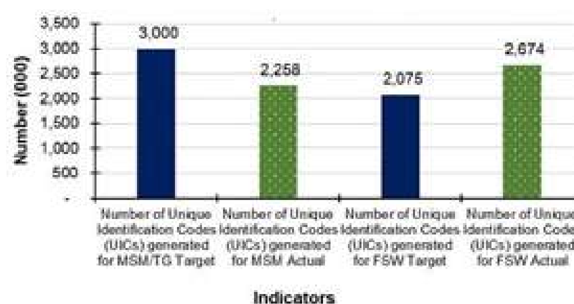
Scaling-up HIV testing, treatment, care and support for men who have sex with men, transgender and sex workers in Liberia

I. Sempungu[1], E.Z. Addy[2]
[1]Stop AIDS in Liberia, Monitoring and Evaluation, Monrovia, Liberia, [2]Stop AIDS in Liberia, Programs, Monrovia, Liberia

Background: In Liberia, HIV prevalence rate among (15-49) age group is 2.1%. Among the key population however, it is 19.8% among men who have sex with men (MSM), 9.8% among female sex workers (FSWs), and 5% among People Who Inject Drugs (PWID). Limited access to HIV testing, treatment, and care services; stigmatization; are major contributing factors.
Description: Stop AIDS in Liberia (SAIL) implemented a project titled: HIV Prevention, Care, and Support for the Key Population, People Living with HIV, and the General Population. Funding was provided by the Global Fund against AIDS, Tuberculosis, and Malaria (GFATM), and Population Services International (PSI) Liberia. Between July 2016 and December 2017, the project trained MSM, Transgender (TG), and FSW as peer educators to: register project participants using Unique Identification codes (UICS); disseminate HIV and STI information, distribute condoms and lubes, organize question and answer HIV/STI community-based support group meetings; and link project participants to health facilities for HIV and STI testing and treatment. On the other hand, 3 drop in centers (DICs) were established to provide: STI diagnosis and treatment; HIV counseling and Testing; TB symptomatic screening; ART enrollment and referral; and Legal and psycho-social support.
Lessons learned: An approximate of 2,258 out of 3,000 targeted MSM/TGs, and 2,674 out of 2,075 targeted FSWs were registered using Unique Identification Codes. About 1,387 MSM/TG tested for HIV, (4.5%) were HIV positive, and 46 were enrolled into antiretroviral therapy (ART). Similarly, 532 FSWs tested for HIV, (11%) were HIV positive, and none was enrolled into (ART). Service linkages with seven (7) government health facilities across Liberia got established, and key stakeholders including 97 police personnel (29 female), 60 religious leaders (24 female), and 62 medical practitioners (10 female) were trained in human rights advocacy for the key population.
Conclusions/Next steps: An integrated approach promoted access to HCT and SRHR services for the key population, and enabled client tracing through UICS. HIV stigma is however, still high affecting disclosure and ART enrollment. We need to improve on documentation of project outcomes for evidence-based advocacy, and involve other key population groups such as, people who inject drugs (PWID) in HIV programming.

Indicator	Number
Number of MSM and TG that received an HIV test during the reporting period & know their results	1,387
Number of FSW that received an HIV test during the reporting period & know their results	532
Total	1,919

[Access to HIV counselling and Testing (July 2016-December 2017)]



[MSM/TG and SW enrolled into Key Population Project (July 2016 to December 2017)]

THPEE745

Reaching the rural in Uganda: A cluster-randomised exploration of community health entrepreneurs' impact on sexual and reproductive health

R.A.J. Borst[1], M.O. Kok[1,2], I. Jonker[3], D. Muhangi[4]
[1]Erasmus University Rotterdam, Erasmus School of Health Policy & Management (Health Care Governance), Rotterdam, Netherlands, [2]Amsterdam Public Health, Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands, [3]Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands, [4]Makerere University, Social Work and Social Administration, Kampala, Uganda

Background: The international health community aims to reach universal health coverage by 2030. Recent reports, however, hint at access to sexual and reproductive health services being far from universal; holding especially true for rural, hard-to-reach areas. A proposed solution is organising primary care through community health entrepreneurship. Community health entrepreneurship is a sustainable approach to reach underserved populations by harnessing the entrepreneurial skills of existing community health workers.
This study provides a first evaluation of the impact of the 'Healthy Entrepreneurs' social enterprise model. This model may be key in HIV prevention by proactively ensuring rural populations access to the knowledge and means required for increasing and sustaining sexual and reproductive health.
Methods: The study was conducted using tablet-based surveys in a cluster-randomised cross-sectional cohort study. The sample entailed household members from 25 villages in a rural West-Ugandan district. The association between four validated sexual and reproductive health outcome indicators and exposure to community health entrepreneurship was assessed using wealth-adjusted mixed-effects logistic regression models.
Results: Data were obtained from 1202 household members who volunteered to participate (83% female). Table 1 shows the wealth-adjusted odds ratios per indicator. The results show that household members who lived in areas where community health entrepreneurs were active had both higher odds on currently using modern contraception and having knowledge of modern contraceptive methods, sexually transmitted infections, and the symptoms of sexually transmitted infections.

Indicator	Males (n=203)	Females (n=999)
1. Knowledge of modern contraceptive methods	6.49 (2.46; 17.17)	8.24 (2.56; 26.47)
2. Current use of modern contraceptive methods	1.63 (0.60; 4.40)	2.12 (1.35; 3.33)
3. Knowledge of sexually transmitted infections	2.04 (1.01; 4.12)	1.81 (1.08; 3.03)
4. Knowledge of symptoms of sexually transmitted infections	3.58 (1.86; 6.87)	1.63 (1.02; 2.60)
*** For exposed:unexposed, adjusted for International Wealth Index (IWI)**		

[Table 1. Adjusted odds ratios (ORA) with 95% confidence interval per key indicator]*

Conclusions: Household members in areas where community health entrepreneurs were active had higher odds on using modern contraceptives and had more knowledge of modern contraceptive methods, sexually transmitted infections, and symptoms of sexually transmitted infections.

Author Index

This study thus provides evidence of the key role that community health entrepreneurship has in preventing HIV infection and transmission by guaranteeing underserved populations access to sexual and reproductive health products, services, and knowledge.

THPEE746

Medicycles: Using micro-financed motorcycle taxis and cost-sharing to ensure continuity of care in difficult-to-reach Ugandan villages

K. Gibbons
Health Access Connect, Kampala, Uganda

Background: HIV service providers are using models of "differentiated care" to target key populations with interventions that are suited to their contexts. One key population in Uganda is fishing communities where HIV prevalence rates have been documented to be as high as 35%. Many of these communities are over 5km/3miles from the nearest health facility and have high ART default rates.

Description: Health Access Connect (HAC) is a Ugandan NGO that has been implementing the Medicycles program since August 2015. ***Monthly, one-day comprehensive health outreach clinics*** are set up in remote villages in the Lake Victoria region with high HIV prevalence. The HAC model has three components:

1) Partner health facilities identify villages to target, and then use HAC **micro-financed motorcycle or boat taxis** to transport staff and supplies to remote villages.

2) During the **monthly one-day outreach clinics**, 3-to-5 health workers provide comprehensive health services, including HIV testing, ART, maternal & child healthcare, vaccinations, and essential health services.

3) **Community oversight and cost-sharing** is achieved through community mobilization by Community Health Workers (CHWs) as well as patient contribution of $0.55 to cover transportation expenses ($22-28/day).

Between August 2015 and December 2017, over 3,900 patients (57.3% female, 42.7% male, 31.6% under 18yo) were served, including distributing ART to 1,945 clients in 10 remote villages with an average of 50.6 patients/clinic.*

**Reporting data are for patient services distributed. Many patients are repeats.*

Lessons learned:

- Microfinance helps to lower cost while providing quality services.
- HAC originally used community groups to coordinate clinics and found using CHWs for community mobilization improves attendance and coordination.
- Coordination with district and facility health leadership is critical to ensuring continuity and quality of care.
- Targeted outreach clinics increase numbers of clients accessing HIV testing (90#1), receiving treatment (90#2), and suppressing viral load (90#3), thus contributing towards Uganda's pursuit of 90-90-90 by 2020.

Conclusions/Next steps: The HAC model emphasizes providing transportation and cost sharing to provide continuity of care to difficult-to-reach populations. Expansion to villages in the districts of Kalangala, Masaka, and Rakai District has demonstrated that the model can be adapted to many contexts.

THPEE747

Main adverse reactions motivating the substitution of Dolutegravir in antiretroviral therapy regimens in Brazil

C.J.B. Batista, R.G. Corrêa, K. Sakita, J.C. Monteiro, A.S. Benzaken
Ministry of Health, STI/AIDS and Viral Hepatitis, Brasilia, Brazil

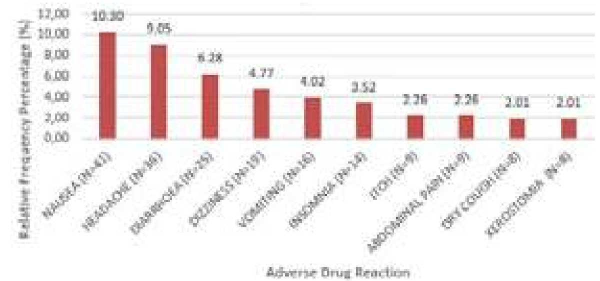
Background: The Brazilian AIDS policy has included the free distribution of antiretroviral drugs since 1996, and since 1997, the government has conducted the logistic management of these drugs and patient clinical monitoring through the Medication Logistics Control System (SICLOM), with online access nationwide. In this context, the Ministry of Health started, in 2017, the distribution of the antiretroviral drug Dolutegravir (DTG) 50mg to all people living with HIV who start first line Antiretroviral Therapy (ART), as well as for third-line in substitution to Raltegraveir 400 mg. Although DTG is seen as having better tolerability levels and lower possibility of causing adverse reactions, there is the need to continuously evaluate the safety profile of the drug in the population. In order to assess the safety profile of DTG in Brazil, an active pharmacovigilance project was implemented, consisting of interviews and online questionnaires made available by SICLOM. This study proposes to study the main reactions that motivated the substitution of this drug and the frequency percentage of each one in active pharmacovigilance project.

Methods: SICLOM's database was used to verify the list of patients who had DGT substituted in their therapy regimens due to adverse reactions in the period between April and December 2017. Based on this list, the 10 main adverse reactions were identified as well as the percentage frequency of each one.

Results: Out of the 72,032 people on DTG in Brazil, 149 (0.20%) had their therapy regimens changed due to adverse reactions - demographic data can be observed in Table 1. 398 adverse reactions were reported and the main and most frequent ones are shown in Figure 1.

Characteristic	Male (n = 86)	Female (n = 63)	Total (n = 149)
Age, years			
Median	44	45	45
Mean	45	46	45
Race/color			
White/yellow	47 (59%)	32 (41%)	79
Black/brown	25 (58%)	18 (42%)	43
Indigenous	0	1 (100%)	1
Unknwon	14 (54%)	12 (46%)	26

[Table 1 - Demographic data of patients who changed antiretroviral therapy due adverse reactions to Dolutegravir, Brazil.]



[Figure 1: Main adverse reactions that motivated the substitution of DTG in therapy regimens in Brazil.]

Conclusions: Data indicate that the most of the adverse reactions that motivated the discontinuation of DTG in Brazil are described in the package leaflet. Nausea, diarrhea, and headaches are the most frequent (>10%); dizziness, insomnia, vomiting and abdominal pain are commonly associated with the use of Dolutegravir (1 to 10%); and hypersensitivity presents lower frequency and are considered unusual (0.1 to 1%). This finding, however, corroborates the more consolidated knowledge of the medicinal product and, therefore, for greater patient safety.

THPEE748

Health4All: A technology-enabled, locally relevant campaign to reduce stigma and discrimination against key populations

K. Pedersen[1], K. Stratten[2]
[1]*IntraHealth International, Chapel Hill, United States,* [2]*IntraHealth International, Programs, Chapel Hill, United States*

Background: Key populations (KP) disproportionately impacted by HIV (including men who have sex with men, transgender populations, sex workers, and people who inject drugs) report stigma and discrimination (S&D) from health workers as significant barriers to seeking or continuing HIV care and support.

Description: IntraHealth International, a key partner in the USAID- and PEPFAR-supported LINKAGES project led by FHI 360, supports the Health4All campaign designed to both champion and ensure stigma-

free, rights-based, and high-quality KP services and support. Developed to be flexible and meet local needs, components of Health4All include:
1) Locally relevant trainings of health workers with KP participation to address stigmatizing and discriminatory attitudes and KP clinical competencies;
2) Technology-enabled self-assessments by health workers and service quality surveys from KP clients who visited, or wanted to visit, facilities—called the SMS Service Quality Monitoring System (SMS²), and;
3) Ongoing health worker, facility, and community support efforts—partially informed by SMS² data—to reduce S&D. Since 2016, 15 countries in Africa, Asia, and the Caribbean have implemented at least one Health4All component.
Lessons learned: Pre/post-test evaluation findings from training activities, now conducted in 12 countries, suggest the trainings consistently improved participants HIV- and S&D-related knowledge and attitudes. Lessons learned from trainings include the need to identify trainees carefully, support active KP engagement, and carefully plan post-training support. An important enhancement has been to focus on the needs of young KP and KP who engage in multiple high-risk behaviors. Monitoring of SMS² data after the training supports strong links among communities, health workers trained through Health4All, and program stakeholders to target post-training follow up.
Conclusions/Next steps: Our experiences suggest the importance of ensuring the S&D- and KP-friendly trainings are included in both health worker pre-service training programs and larger HIV service delivery improvement efforts. All health workers that interface with KPs, including clinic security guards and receptionists, must be sensitized to and able to offer KP-friendly support. In addition, the use of ongoing S&D self-assessments by health workers to complement trainings and KP assessments using SMS² can prompt targeted action by HIV program implementers.

THPEE749

Lessons from implementing SKILLZ for life: A sport-based HIV and life skills programme for youth with intellectual disabilities in Namibia, Nigeria, and South Africa

N. Mutongizo[1], R. Banciu[1], S. Miller[1], K. Hughes[2], S. Oboh[3]
[1]Grassroot Soccer, Inc., Norwich, United States, [2]Special Olympics International, Washington, DC, United States, [3]Special Olympics Nigeria, Lagos, Nigeria

Background: SKILLZ for Life (SfL) equips youth with intellectual disabilities (YWID) with HIV and life-skills information. YWID are especially vulnerable to HIV infection[1], and findings from this evaluation suggest they are often excluded from HIV education programmes. Special Olympics (SO) and Grassroot Soccer (GRS) implemented SfL in Namibia, Nigeria and South Africa (SA).
The intended outcomes of SfL are increased HIV knowledge, malaria / HIV testing, self-esteem, knowledge of sexual rights and improved attitudes towards health services.
Description: SfL consists of six, 60-minute sports-based sessions and a graduation, coupled with a voluntary counselling and HTS event. Sessions are delivered in schools or camps by trained "Coaches", to YWID ("Athletes") and participants without intellectual disabilities ("Partners"). Athletes and Partners are paired-up in a "buddy-system" and learn about HIV prevention, support each other to lead healthy lifestyles and identify abuse. SfL was implemented in Namibia (2009-2012), Nigeria and SA (since 2014 and 2016).
Lessons learned: A 2015 external evaluation[2] showed that SfL largely accomplished its objectives, determining positive change in the knowledge, attitudes and communication on HIV of its participants. A 2017/18 process evaluation included interviews and focus groups with staff, coaches, parents and teachers, to assess its scalability. It concluded that SfL can be successfully scaled, once certain conditions are met that are delineated below.

THEMES	RECOMMENDATIONS
Set-up, resources and capacity needed	1. Consider the higher initial program set-up phase burden (capacity building and staff-structure, written guidelines for policies and procedures); 2. Ensure adequate, long-term funding (+/-5 years); 3. Optimum community sensitization, stakeholder (including government institutions) engagement and show-casing for smooth implementation.
Curriculum content	1. Ensure rigorous curriculum adaptations and field-testing; 2. Simplify curriculum and reduce the number of key messages; 3. Remove abstract activities with symbolism; 4. Use repetition as a way to ensure learning; 5. Emphasize sensory learning by using context-appropriate visuals
Delivery model	1. Use sports for dual benefits (engagement and fitness); 2. Carefully consider the Partner-Athlete ratio; 3. Use of events such as Family Health Forums as a way to engage parents and community members.
M&E	1. Use images to assess change in knowledge and attitudes among Athletes, instead of words. 2. Pre/post test insufficient to assess change in knowledge and attitudes
Training	1. Train coaches, parents and teachers on working with YWID.

[Table 1. Summary Themes and Lessons Learned]

Conclusions/Next steps: SfL has been shown to benefit YWID and their families. The lessons learned indicate that SfL, requires significantly more investment of human and financial resources in sensitisation, training and ongoing oversight. The findings in Table 1 provide viable next steps to scale scale-up SfL, and for other organizations that implement programmes for YWID.

Implementation of a comprehensive HIV and stimulant prevention intervention with Cambodian female entertainment and sex workers reduces sexual and drug risk and addresses multiple vulnerabilities

K. Page[1], A. Carrico[2], E. Stein[3], J. Evans[4], M. Sokunny[5], S. Ngak[5], C. Sophal[6], Y. Neak[7], C. McCulloch[4], L. Maher[8]
[1]University of New Mexico Health Sciences Center, Internal Medicine, Albuquerque, United States, [2]University of Miami, Public Health Sciences and Psycholog, Miami, United States, [3]University of California, Global Health, San Francisco, United States, [4]University of California, Epidemiology and Biostatistics, San Francisco, United States, [5]FHI 360 Cambodia, Phnom Penh, Cambodia, [6]Kingdom of Cambodia MInistry of Health, Mental Health, Phnom Penh, Cambodia, [7]Cambodia National Authority for Combatting Drugs, Phnom Penh, Cambodia, [8]Kirby Institute, University of New South Wales, Sydney, Australia

Background: Comprehensive HIV prevention targeting female entertainment and sex workers (FESW) in Cambodia is needed due to syndemic risk for HIV, including sexual risk, widespread use of amphetamine-type stimulants (ATS), and poverty. Using an implementation science approach, we delivered multi-level interventions to FESW to decrease ATS use and improve health and social vulnerabilities within HIV risk reduction.
Methods: The Cambodia Integrated HIV and Drug Prevention Implementation (CIPI) trial used a cluster randomized stepped-wedge design to test effectiveness of a multi-level intervention to reduce HIV and ATS risk in 10 provinces. CIPI leveraged an existing HIV prevention platform for FESW -SMARTGirl -as an innovative cross-sectoral cross approach to jointly tackle the multiple vulnerabilities experienced by FESW. CIPI added a conditional cash transfer with cognitive-behavioral aftercare (CCT+AC) intervention to reduce ATS use among women identified with ATS use disorder.
A microenterprise opportunity that included a 3-day financial literacy training was offered to ATS-free women, including those who successfully completed CCT-+AC. 1198 enrolled women were surveyed pre-intervention. Co-primary outcomes were assessed in 600 FESW purposively targeted at 6-month intervals over an 18-month follow-up,

including: 1) number of sexual partners (past 3 months); and 2) positive urine toxicology results for ATS (ATS Tox+). Secondary outcomes included alcohol use, reproductive health, psychological distress, and income.
Results: Relative to baseline, at 6 months, participants had 60% lower odds of ATS Tox+ (AOR=0.40; 95%CI=0.25-0.65; p< 0.001). At 12 months, FESW reported 50% fewer sexual partners (ARR=0.50; 95%CI=0.25-0.95; p=0.035). Women had significantly lower odds of testing positive for alcohol disorder at 6 and 12 months, and 57% and 79% lower odds clinically significant psychological distress. Reproductive health visits declined at all visits. Women did not report reductions in monthly income at any time, despite reporting fewer sex partners and reduced ATS use (p's>0.14).
Conclusions: Findings support the robust, short-term effectiveness of the sequentially delivered CCT+AC and microenterprise interventions for optimizing HIV prevention for Cambodian FESW. Further implementation-science research is needed to inform the scale up and improve the durability of this comprehensive approach to reduce HIV risk and address syndemic vulnerabilities of women and girls engaged in sex work in Asia.

THPEE751

Scalability of *SKILLZ for Life:* A sports-based behaviour change HIV/AIDS and Malaria programme for young people with intellectual disabilities

N. Mutongwizo[1], R. Banciu[1], S. Oboh[2], S. Miller[1], K. Hughes[3]
[1]Grassroot Soccer, Inc., Norwich, United States, [2]Special Olympics Nigeria, Lagos, Nigeria, [3]Special Olympics International, Washington, DC, United States

Background: While HIV prevalence is relatively low in Nigeria (3.4%), it is second only to South Africa in the number of people living with HIV (PLHIV) at 3.2 million (UNAIDS, 2016). To contribute to the prevention response in both countries, SKILLZ for Life (SfL) was designed for youth with intellectual disabilities (ID) aged 8-30, to increase health-seeking behaviors and facilitate access to and uptake of malaria and HIV services. SfL consists of a sports-based behaviour change programme comprised of six, 60-minute sessions and a graduation. Special Olympics implemented SfL in Nigeria and South Africa in partnership with Grassroot Soccer (GRS). An internal evaluation was conducted from June 2017 - January 2018 to ascertain whether SfL is scalable in other geographies.
Methods: A mixed-methods design was utilised, incorporating ten in-depth interviews (IDIs); 7 focus group discussions (FGDs); 3 observations; and quantitative surveys. For the qualitative methods, respondents were purposively selected from Special Olympics program staff in Nigeria and South Africa, Grassroot Soccer staff, Coaches delivering SfL in Nigeria, teachers, and parents. IDIs, FGDs, and observation visits were conducted both in-person and via Skype. Qualitative data were analysed using Nvivo10, while quantitative data measuring changes in participants' knowledge, behaviour and attitudes in Nigeria and South Africa programmes were analysed in R and significance was assessed using Wilcoxon Signed Rank Test (n= 1,932).
Results: Evaluation findings point to scalability and expansion possibilities of SfL due to positive programme outcomes and strategic programme components such as visual resources and GRS Culture. Pre/post survey results from SO Nigeria show significant positive change from baseline to endline as seen in Table 1. Evaluation respondents stated the specific conditions that must be met for scale include curriculum adaptation to local context and training community stakeholders with the intention of sustaining health behaviour outcomes.

Pre/Post Outcome Analysis	Baseline	Endline	% Change	P Value*
HIV Stigma: Have you ever talked to anyone about HIV (i.e. prevention, treatment, or transmission) outside of the SKILLZ for Life Program?	39%	66%	69%	<0.001
HIV Transmission: Which of these can protect you from HIV?	36%	59%	64%	0.035
HIV Transmission: Which of these CANNOT spread HIV?	41%	49%	18%	0.494
Malaria: Which of these can spread malaria?	79%	90%	14%	0.683
Malaria: Which of these can protect you from malaria?	65%	87%	33%	<0.001
Malaria: Who can give you the best malaria medicine?	70%	93%	34%	0.079
Identifying Abuse: Would you tell someone if you were touched in a way you did not like?	57%	76%	35%	0.001

*[Table 1: SKILLZ for Life Special Olympics Nigeria Pre/Post Outcome Analysis. *Assessed via Wilcoxon signed rank test (n=92)]*

Conclusions: Based on this study, the evaluators deem SfL scalable. The program has been very effective at changing knowledge and behaviours around HIV and malaria, reducing community stigma around ID and is considered a success story for how to engage youth with intellectual disabilities in behaviour change communication and stigma reduction programs.

THPEE752

Increasing HIV screening, diagnosis, and treatment in a large Zambian correctional facility: Interim results from a prison-focused universal test and treat program

S. Hatwiinda[1], H. Smith[1], M. Nanyangwe[1], P. Chilembo[1], M. Siyambango[1], L. Kashela[1], C. Yenga[1], A. Kayuni[1], C. Moonga[1], M. Muyoyeta[1], C. Chisela[2], Y. Lungu[2], S. Reid[3,4], S. Topp[3,5], M. Herce[3,6]
[1]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [2]Zambia Correctional Service, Ministry of Home Affairs, Government of the Republic of Zambia, Kabwe, Zambia, [3]Centre of Infectious Disease Research in Zambia, Lusaka, Zambia, [4]University of Alabama at Birmingham, Division of Infectious Diseases, Department of Medicine, Birmingham, United States, [5]James Cook University, College of Public Health, Medical & Veterinary Sciences, Townsville, Australia, [6]University of North Carolina at Chapel Hill, Division of Infectious Diseases, Department of Medicine, Chapel Hill, United States

Background: We conducted an interim impact evaluation of a universal test and treat (UTT) program implemented with the Zambian Ministry of Health (MOH) and Correctional Service (ZCS) within a large Zambian correctional facility, Lusaka Central.
Methods: Applying RE-AIM, we evaluated reach, effectiveness, adoption, implementation and maintenance of a UTT program using routine and prospective data collected over the program period spanning 1st July 2016—30th June 2017. We compared RE-AIM measures between the program period and the year prior to UTT introduction (1st June 2015 - 30th July 2016).
Results:
Reach: During the program period, the total cumulative inmate population, including the static population plus all new admissions, was 6,850. Of these, we offered HIV testing services (HTS) to 3,419 (n/N=3,419/6,850, 49.9%). HTS reach was significantly higher in the program versus baseline period (n/N=714/7,355, 9.7%) (p< 0.001).
Effectiveness: 92.3% (n/N=3,157/3,417) of inmates offered HTS accepted testing. Significantly more newly HIV-diagnosed inmates initiated ART over the UTT program period (n/N=327/416, 78.6%) compared to the 12 months prior (n/N=110/187, 58.8%) (p< 0.001).
Adoption: HIV treatment was fragmented by release and transfer procedures uncoordinated with health services, resulting in 41.0% (n/N=134/327) of newly ART-initiated inmates being released or transferred

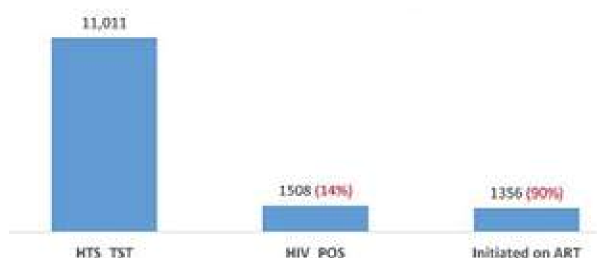
during the program period. 46.3% (n/N=62/134) of inmates who were released or transferred did so within the first three months of initiating ART.
Implementation: HTS uptake (92.3%) exceeded our program target (75%) and 90.0% (n/N=294/327) of newly diagnosed HIV-positive inmates started ART within 1 day, meeting our same-day ART target.
Maintenance: A key obstacle to maintenance was high turnover of corrections officers and lay and professional health workers initially trained on UTT. During the program period, we re-trained 80 inmate peer educators and cell captains over 3 sessions after initially training 55. We also re-trained 48 staff from ZCS and MOH over 4 sessions, after first training 24.
Conclusions: We achieved high uptake and fidelity of HTS and same-day ART, as well as improved HIV service reach and effectiveness within Lusaka Central. Long-term UTT maintenance may be threatened by limited staffing and resourcing of the prison health system, and uncoordinated transfer and release for inmates newly starting ART.

THPEE753

Partnering with correctional authorities to improve access to HIV prevention and linkage to antiretroviral therapy for prisoners in Zambia

T. Malebe[1], M. Phiri[1], A. Malumo[1], K. Stratten[2]
[1]IntraHealth International, Lusaka, Zambia, [2]IntraHealth International, Chapel Hill, United States

Background: Estimated global HIV prevalence among prisoners is 3%. In some settings, HIV prevalence in prisons is 15 times higher than in the general adult population according to the World Health Organization. This situation increases the risk of HIV transmission between inmates and to sexual partners after inmates are released from prison. However, access to HIV prevention, treatment and care programs is often lacking in correctional services due to limited resources. In Zambia, with CDC funding, IntraHealth International implements a comprehensive HIV prevention and treatment program in partnership with correctional service authorities in three selected correctional facilities in Southern and Western provinces.
Description: In partnership with prison authorities and District Medical Offices, IntraHealth has trained correctional officers and selected inmates as lay providers (LPs) to deliver HIV testing services (HTS) in correctional facilities. The training also equips them with knowledge and skills to provide HIV information, education and screening for sexually transmitted infections (STIs) and tuberculosis (TB). Positive health, dignity and prevention packages and supportive care services are provided by LPs to inmates who test positive. Trained LPs provide escorted referrals for same-day ART initiation in the prison clinics.
Lessons learned: The district coordinators engaged with prison authorities to facilitate the implementation of HIV interventions at correctional services, which has increased access to testing, care and treatment services for inmates and prison workers. From October 2014-November 2017, a total of 11,011 inmates were tested; 1,508 (14%) were HIV-positive and 1,356 (90%) of those were initiated on ART. LPs also screened HIV-positive clients for TB resulting in 1,187 (78%) presumptive cases out of which 623 (52%) were confirmed for TB and commenced treatment. The LP/peer approach has increased access to HIV testing and TB screening services to all inmates, who are now motivated to test for HIV and start treatment if found positive within the prison.
Conclusions/Next steps: These interventions will be expanded to more correctional services in Zambia and offer a model for replication in other settings.



[2014-2017 Inmate HTS and Linkage to Treatment]

THPEE754

Virtual communities of practice effectively support providers attending to underserved populations in settings with high HIV burden in Africa and Asia

B.B. Struminger[1], S. Arora[1], S. Zalud-Cerrato[1], J. Lehmer[1], L. Bikinesi[2], N. Hamunime[2], D. Naitore[3], R. Issayeva[4], Z. Trumova[5], A. Deryabina[5], F. Tsiouris[6], G. Taasi[7], S. Bakengana[8], R. Pati[9], L. Tison[9], C. Roscoe[10], J. Wright[11], J. Scott[12], K. Unruh[12], B. Wood[12]
[1]University of New Mexico Health Sciences Center, ECHO Institute, Albuquerque, United States, [2]Ministry of Health and Social Services of Namibia, Directorate of Special Programmes, Subdivision HIV and STIs Control, Windhoek, Namibia, [3]ICAP at Columbia University Kenya, Nairobi, Kenya, [4]Kazakh Medical University for Continuous Education, Almaty, Kazakhstan, [5]ICAP Columbia University Central Asia, Almaty, Kazakhstan, [6]ICAP Columbia University, New York, United States, [7]Ministry of Health Uganda, Kampala, Uganda, [8]Uganda Virus Research Institute, Entebbe, Uganda, [9]The U.S. Centers for Disease Control and Prevention, Atlanta, United States, [10]The U.S. Centers for Disease Control and Prevention in Namibia, Windhoek, Namibia, [11]The U.S. Centers for Disease Control and Prevention Central Asia, Almaty, Kazakhstan, [12]University of Washington, Seattle, United States

Background: Project ECHO® (Extension for Community Health Outcomes) HIV tele-mentoring programs aim to bring best practice HIV care to underserved populations worldwide. These virtual communities of practice expand access to HIV expert support, strengthen workforce capacity, improve provider satisfaction, and reduce isolation.
Description: Namibia, Kenya, Cote d'Ivoire, Tanzania, Kazakhstan, and Kyrgyzstan have adapted and implemented HIV care and treatment ECHO programs over the last two years connecting hundreds of HIV doctors, nurses, and other cadres. Tanzania and Uganda conduct ECHO programs to improve HIV rapid testing for several hundred testers with no lab training at a dozen sites combined. National experts connect with the local sites for weekly 60 to 90 minute sessions that include a short didactic presentation and case discussions. The laboratory programs use the video capability for hands-on demonstrations. Curricula cover a wide range of HIV and quality improvement topics based on the national guidelines of each country. Programs are monitored by surveys, pre- and post-knowledge tests, and focus group discussions.
Lessons learned: Implementation of the ECHO model has improved the knowledge, skills, and confidence of HIV providers and non-laboratory testers working in low-resource settings with high HIV burden in Africa and Asia. Use of video-conferencing to leverage local expertise supports local ownership and provides a cost-effective method for training providers. Participants reported feeling less isolated in comparison to the time before attending ECHO sessions and they gained access to continuing professional development credits without having to travel to trainings. The IT infrastructure sufficiently supports good quality video conferencing through cellular, satellite, or fiber optic internet connections. Programs innovate by using anonymous polls during the video-conference to engage participants and text messaging programs like WhatsApp to engage participants asynchronously. Additional HIV ECHO programs are in development in several more African countries, Asia and Latin America.
Conclusions/Next steps: Successful implementation of the ECHO model to strengthen HIV programs in seven countries supported by Ministries of Health, academic institutions, laboratories, and foundations improves access to high quality, cost-effective HIV care in low resource settings. Accelerated dissemination of national guidelines and best practices helps countries build the workforce needed to attain epidemic control of HIV.

THPEE755

Adaptation, implementation and evaluation of a tele-mentoring program for the Namibian HIV health workforce

L. Bikinesi[1], N. Hamunime[1], A. Mengistu[1], T. Mekonen[1], C. Roscoe[2], N. Shoopala[2], S. Sawadogo[2], S. Agolory[2], G. Mutandi[2], V. Garises[3], L. Tison[4], R. Pati[4], E. Rodriguez[4], T. Ellerbrock[4], L. Brandt[5], N. Forster[5], J. Scott[6], B. Wood[6], K. Unruh[6], S. Arora[7], M. Iandiorio[7], S. Kalishman[7], S. Zalud-Cerrato[7], J. Lehmer[7], C. Ramers[7], B. Struminger[7], G. O'Bryan[8], G. O'Malley[8]
[1]Namibia Ministry of Health and Social Services, Directorate of Special Programs, Windhoek, Namibia, [2]U.S. Centers for Disease Control and Prevention, Windhoek, Namibia, [3]Namibia Institute of Pathology, Windhoek, Namibia, [4]U.S. Centers for Disease Control and Prevention, Atlanta, United States, [5]International Training and Education Center for Health, Windhoek, Namibia, [6]University of Washington, Division of Allergy and Infectious Diseases, Department of Medicine, Seattle, United States, [7]University of New Mexico Health Sciences Center, ECHO Institute, Albuquerque, United States, [8]International Training and Education Center for Health, Seattle, United States

Background: Namibia experiences critical shortages of healthcare workers caring for the 14% of the adult population living with HIV. In 2015, the Namibia Ministry of Health and Social Services (MoHSS) adapted, piloted and evaluated a tele-mentoring platform for case-based learning in virtual communities of practice called Project ECHO® (Extension for Community Health Outcomes) to address challenges in HIV care. Goals of this first ECHO adaptation in Africa included assessing feasibility and acceptability, strengthening workforce capacity, improving provider satisfaction, and reducing isolation.
Description: Best practices for adapting an evidence-based HIV ECHO program were applied, a 9-month curriculum was developed, and Continuing Professional Development (CPD) accreditation obtained.
A virtual community of practice using weekly video-teleconference sessions with didactic training and patient case presentations was established; participants included national experts, regional clinical mentors, doctors, nurses, pharmacists, laboratorians, and health assistants. Between 50 and 120 individuals participated per session, learning from didactics and de-identified patient case discussions. A mixed-methods assessment of the first 34 sessions included process evaluation, pre/post questionnaires (knowledge, satisfaction, self-efficacy, CPD credits), qualitative interviews, and focus group discussions.
Lessons learned: To optimize ECHO in Namibia, MoHSS adapted a model that included leveraging of centralized and decentralized Ministry leadership and expertise, rotating session facilitation, disseminating new guidelines (e.g. PrEP, community adherence clubs, etc.), and empowering lower-level cadres to differentiate aspects of HIV care that could be task-shifted. Over 50% of participants are nurses. During the pilot, knowledge of clinical HIV improved 17.8% overall and 22.3% for nurses ($p < 0.01$). Self-reported clinical professional satisfaction increased 30%. Most participants (66%) reported reduced professional isolation, and 57% reported improved access to CPD credits. Following the pilot, increased demand and popularity of ECHO led to expansion from 10 to 23 spoke sites.
Conclusions/Next steps: Namibia's HIV ECHO improved knowledge and provider satisfaction and has demonstrated the ability to adapt to evolving needs in an African context. MoHSS will increase ECHO to 36 sites and expand focus areas beyond HIV in 2018. This first successful ECHO implementation in Africa encountered minimal barriers and has catalyzed development of several additional ECHO programs across Africa and Central Asia.

THPEE756

Health system strengthening in rural Nigeria: Focus on HIV programmes

O.B. Onokala[1], G. Abiaziem[2], F. Oluwasina[3]
[1]AIDS Healthcare Foundation, Treatment, Abuja, Nigeria, [2]AIDS Healthcare Foundation, Treatment, Makurdi, Nigeria, [3]AIDS Healthcare Foundation, Monitoring and Evaluation, Abuja, Nigeria

Background: Some rural populations are often excluded in interventions against HIV/AIDS. In order to effectively reduce the global HIV burden, underserved rural communities need to be prioritized. Health System Strengthening (HSS) is pivotal for sustaining HIV programmes dedicated to reaching underserved communities. The study describes interventions made to strengthen health systems for HIV programmes in underserved rural communities in Nigeria.
Methods: The longitudinal cohort study was done at HIV treatment facilities in 24 randomly selected underserved communities in rural Nigeria. HIV programme interventions were designed to bridge specific gaps identified in health systems according to the World Health Organization-accepted core HSS functions. Human resources interventions incorporated trained local indigenes into community health systems. Health information was optimized by efficient monitoring and evaluation of health system data. Health governance interventions included engagement of community gate-keepers. Service delivery interventions included rural decentralization of Anti-Retroviral Therapy (ART), differentiated HIV care, standardization and integration of HIV services. Interventions for health finance and availability of medicines involved private-public partnerships. The pre- and post-intervention assessment of HSS functions were done in October 2012 and October 2017 respectively. Chi-square was applied as inferential statistics; $P < 0.05$ indicated statistical significance.
Results: Interventions increased HIV services from 10% pre-intervention to 80% post-intervention. The interventions increased HIV treatment facilities from 7 (pre-intervention) to 63 post-intervention. Subsequently, the cumulative number of adult ART patients increased from 2,393 pre-intervention to 10,609 post-intervention, while the cumulative number of pediatric ART patients increased from 104 pre-intervention to 817 post-intervention. Optimization of human resources for health improved the quality of patient care from 30% pre-intervention to 90% post-intervention. Health information system strengthening enabled efficient monitoring and evaluation of HIV services and outcomes. Interventions in health governance ensured sustenance of HIV services to displaced persons at 3 facilities affected by rural conflict within the period. The private-public partnership enabled pooling of resources to eliminate user fees at the facilities.
Conclusions: The interventions significantly improved core HSS functions in human resources for health; health finance; health governance; health information; medicines; and service delivery. The interventions are recommended for strengthening health systems for HIV programmes in underserved rural communities in Nigeria.

THPEE757

Reaching underserved populations living with HCV: Pairing treatment with intensive navigation to improve adherence and completion of HCV treatment during and after incarceration in San Francisco Jails

M. Yoshida[1], J. Hilton[2], L. Pratt[1], S. Aggarwal[1], J. McDonald[1], S. Halliwill[1], A. Luetkemeyer[3]
[1]San Francisco Department of Public Health, Jail Health Services, San Francisco, United States, [2]University of California, Epidemiology & Biostatistics, San Francisco, United States, [3]University of California, Medicine, San Francisco, United States

Background: The availability of all oral HCV regimens creates an important opportunity to cure HCV in the most vulnerable populations, including incarcerated patients who are highly impacted by this disease, yet have substantial barriers to initiating treatment both during and after incarceration. San Francisco Jail Health Services assessed the feasibility of initiating HCV treatment during incarceration, coupled with intensive, short-term case management to promote adherence, treatment completion, and linkage to care post-discharge.

Methods: Between 3/2017 and 12/2017, HCV-positive patients incarcerated in the San Francisco County Jail were enrolled and given 12 weeks of 100 mg velpatasvir/400 mg sofosbuvir (Epclusa®), plus intensive navigation if discharged before treatment completion. The primary objective was to achieve ³70% sustained virologic response after completing treatment (SVR12) among inmates initiating HCV treatment.
Results: 100 participants enrolled; median age, 39(range, 23-67); male, 84%; Hispanic ethnicity, 10%; race: White 50%, African-American 26%, and multiracial/other 14%. Prior incarceration 95%, HCV treatment-naïve 96%, APRI of ≥1 suggesting F4 fibrosis 13%, HIV co-infected 6%, and self-reported history of IDU 86%. HCV genotypes: GT1 81%, GT2 6%, GT3 10%, and 3 without GT available.
As of January 2018, 70 completed treatment (27 completed following release), 10 remain on treatment (7 on treatment following release), 16 prematurely discontinued treatment following release, 3 discontinued due to reported side effects, 1 participant spontaneously cleared prior to starting study therapy. 50 participants were still on HCV treatment at time of release, with a median treatment remaining of 4.6 weeks (range, 0.43-11.14 weeks). Among 70 who completed treatment, 35 attained SVR12 to date. Of those who reached the SVR12 time point, 37/51 (72.5%) attained SVR12, including 2 who prematurely discontinued treatment. Complete treatment and SVR12 data will be presented.
Conclusions: Initiation of HCV treatment in jail is an effective approach to reach this high-risk population, with 78.7%(70/89) able to complete a full 12 weeks of therapy thus far, despite half being released during treatment, and over 70% with SVR12 to date. Jail-based HCV treatment initiation should be paired with short-term intensive case management services post-release given the high risk for premature treatment discontinuation.

THPEE758

The Grantee as an essential public health service manager in collaborative governance for care and treatment of target populations

J. Agbodzakey
Nova Southeastern University, H.W. Huizenga College of Business and Entrepreneurship, Fort Lauderdale, United States

Background: This study utilizes the emergent collaborative governance framework to examine ongoing HIV/AIDS care and treatment efforts by two Eligible Metropolitan Areas (EMAs) in South Florida with the Grantee as a critical variable in health service delivery and management. The purpose is to ascertain the Grantee's role as it relates to helping engage infected and affected populations, service providers, and non-elected community leaders in collaborative governance for collective problem solving as part of national measures to fulfill established legislative intents.
Methods: The study relies on a qualitative methodology, specifically, in-depth interviews, extensive observations and review of documents to generate needed data for analysis and interpretation. Thirty-one (31) key leaders and members (including three Grantees) of the health services planning councils at both EMAs were interviewed in 2016-2017. Furthermore, the interview data was complemented by observation of forty (40) various committees and general meetings in 2013-2014, and various relevant documents (minutes, reports, integrated plans etc.) were reviewed. The data was coded and analyzed in compliance with qualitative research protocols, which helped to derive relevant concepts and themes for interpretation purposes.
Results: The results reveal the Grantee's pivotal role in judicious resource allocation for various service categories to enhance care and treatment of HIV/AIDS infected and affected, effective management of existing human and service network capacity, strategic engagement of core groups in the collaborative process, and responsiveness to key county/community, state, and federal stakeholders as it relates to established performance expectations.
Conclusions: The findings accentuate viability of collaborative governance framework in addressing a complex problem, which in this case is the HIV/AIDS conundrum with the Grantee serving as an essential public service manager to promote effective service delivery to target populations and to ensure sustainable resource management. It is apparent that collaborative governance involving affected populations, service providers, and non-elected community leaders enhances health equity in terms of care and treatment. Understanding the contributions and impacts of Grantees' in all twenty-four (24) EMAs in the U.S. and its territory, which is the next phase of this research will foster creative and comprehensive narrative on care and treatment system and attendant implications for policy, research and praxis.

THPEE759

Barriers to delivering HIV treatment services to internally displaced persons in Nigeria

R.C. Abah, I. Atta, C. Ojeonu
National Agency for the Control of Aids Nigeria, Abuja, Nigeria

Background: There are over 2.1 million internally displaced persons (IDPs), representing more than 300,000 households in various parts of northern Nigeria. It is necessary to ensure that most of the IDPs, having stayed in temporary shelters under pressure, and may have been exposure to risky behaviour, have access to medical services. This will assist many IDPs to know their general health status including HIV. Identifying the barriers to delivering HIV services to internally displaced persons will improve efficiency and effectiveness of interventions.
Methods: A review of secondary data sources of HIV interventions and IDP management in parts of Nigeria between 2016 and 2017 was reviewed. Using qualitative deductive approach and quantitative statistical analysis, relevant information on the population, demographic structure, health status, and available services, and challenges were clearly summarized and presented.
Results: The IDPs were identified in Adamawa, Bauchi, Benue, Borno, Gombe, Taraba, Yobe, Nasarawa, Plateau, Kaduna, Kano, Zamfara states. The total number of IDPs identified was 2,066,783 (344,564 households). A total of 1, 777, 434 (86%) IDPs are in host communities with relation and friends while 14% (289,350) are located in camp sites around these states. A total of 1,136, 731 (55%) of the IDPs are Children and 53% of all IDPs are females. A total of 24, 216 IDPs in camps lack access to Health services, and over 70% of IDPs outside camps lack access to health services such as HIV testing, treatment services, and PMTCT. Barriers identified included inadequate health commodities, weak management structure for temporary shelters, corrupt practices by some camp officials, the dwindling economy of states, weak central coordination, local human resource gaps, continued insurgent attacks along supply routes, inadequate information of interventions by local authorities, poor community sensitization.
Conclusions: Nigeria has witnessed a sustained number of IDPs mainly due to conflicts. Barriers to HIV services for non-camp IDPs can be bridged by community consultation, building capacity and incentivising community health workers for door-to-door sensitisation, and leveraging on polio vaccination volunteers. Distribution of commodities can be safer using established routes and security escort, helicopter drop-offs, and the proximity hub and spoke model to reduce travel over long distances.

THPEE760

Assessment of an enhanced linkage to care model: Promising results from a pilot project in two New York City HIV clinics

Y. Salazar[1], C. Ferraris[2], J. Fefer[3], D. Nurutdinaova[3]
[1]*Waterbury Hospital, Infectious Diseases, Waterbury, United States,* [2]*St Lukes Mount Sinai West Hosptial, Infectious Diseases, New York, United States,* [3]*St Lukes Mount Sinai West, Infectious Diseases, New York, United States*

Background: Linking HIV positive individuals to care and initiating ARVs not only has individual and clinical implications but also reduces HIV transmission rates. Despite the need to quickly engage newly-diagnosed persons in care, data show that only about 72% have that receipt of care with even less being retained and prescribed ARVs. More data are needed from clinical settings in the real-world to identify and scale-up successful models in HIV care cascade.

Methods: Newly diagnosed patient data was obtained through a retrospective chart review of Electronic Medical Records (EMR) at two outpatient HIV care sites in New York City within a 1-year period. In this analysis, risk factors, socio-demographics, linkage to care, prescribing of antiretrovirals (ARVs) were analyzed. During this period an expedited linkage to care model was implemented to ensure an initial medical assessment to newly diagnosed individuals within 72 hours. This model included the designation of a linkage to care specialist within the clinical team, and a rapid course through wraparound and medical services.
Results: From April of 2015 to April of 2016, the study team identified a total of 21 patients who were referred to care with a new HIV diagnosis. All 21 patients were connected to HIV services within the clinical setting. The median age was 32 (range) years, 90% were male, and 71% were Hispanic/Black.
The main risk factor for HIV acquisition was MSM (90%) while 42% of all patients were co-infected with other sexually transmitted infections at the time of HIV diagnosis. 52% of the sample reported prior or current use of recreational drugs, the most common being cannabinoids and amphetamines.
Of the sample, 90% presented to care with no health coverage. There was a median of 9 days (range) between the HIV diagnosis and initial visit to the HIV clinic. While the majority of patients had multiple visits over a 12 months period, 33% were lost to follow-up.
Conclusions: This expedited model was successful in a real-world clinical setting in demonstrating high rates of linkage to care and ARV initiation among key populations despite preexisting limitations in health coverage, and high rates of underlying substance use.

THPEE761

Cascade model of mentorship for mixed cadre HIV prevention outreach teams to enhance health services among female sex workers in East Central Uganda, process, achievements, lessons and conclusions

J. Muhumuza[1], J. Mugweri[2], P. Odeke[2], S. Kiirya[2], A. Muhwezi[2], N. Tumwesigye[2], HIV-Prevention Team
[1]University Research Co., LLC, HIV Prevention, Kampala, Uganda, [2]University Research Co., LLC, Kampala, Uganda

Background: To achieve the fast track initiatives to end HIV/AIDS by 2030, World Health Organization and international community recommends accelerated technical and programmatic innovations. However, in sub Saharan Africa, particularly in Uganda, despite many governmental and non-governmental HIV Prevention interventions designed to increase health service uptake among key populations (Female sex workers (FSWs), Men having sex with men, people living with HIV etc), outcome results remain sub-optimal.
USAID's RHITES-EC project under University Research co. LLC (URC); implemented HIV prevention interventions targeting FSWs through a cascade model of mentor-ship for mixed local cadre staff using outreaches. Though it was successful, little is known about the process and what characteristics of HIV Prevention outreach teams are essential for effective delivery of services among FSWs.
Description: HIV Prevalence in East central Uganda reduced from 5.8% in 2011 to 4.7% in 2017, however, the AIDS Assessment report 2017, indicated that high HIV positivity rates still existed among key populations with FSWs most affected. The project scaled up HIV prevention interventions targeting FSW between June to September 2017 prioritizing on-job mentor-ship of mixed cadre staff at all levels on the HIV Prevention minimum package followed by mentorships for HIV prevention outreach teams composed of FSW peers, Bio-medical staff, and community social workers. Contrary, previous HIV prevention programs relied only on medical staff from health facilities and Community Health workers (CHW) to mobilize FSWs.
Lessons learned: The number of female sex workers reached increased from 5.9% (n=311) in June to 72.4% (n=3828) in September 2017 with an HIV positivity rate of 8.0%. Linkage to care for new HIV positives increased from 55.2% in June to 78.7% in September 2017 among other services. The increase in services uptake was due to change in working with acceptable demand creation agents coupled with well supported mixed professionals at the supply end.

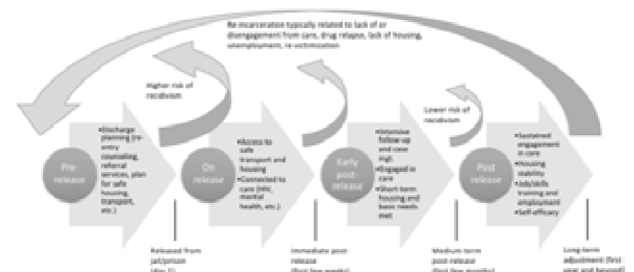
Conclusions/Next steps: The cascade model of mentorship for mixed cadres proved to be successful in improving health services uptake among FSWs; specific issues related to demand creation approaches, Human resources diversification and on-job support were highlighted for scale up and inform future HIV Prevention framework strategies.

THPEE762

A conceptual model for linking and transitioning previously incarcerated women with HIV in the US South to clinical and social services to support post-release adjustment

C. Sprague[1,2,3], M.L. Scanlon[1], S. Brown[1,4], B. Radhakrishnan[1], D.W. Pantalone[5,6]
[1]University of Massachusetts Boston, Department of Conflict Resolution, Human Security & Global Governance, Boston, United States, [2]University of Massachusetts Boston, Department of Nursing, Boston, United States, [3]University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [4]Boston University, Department of Health Sciences, Sargent College of Rehabilitation and Health Sciences, Boston, United States, [5]University of Massachusetts Boston, Department of Psychology, Boston, United States, [6]The Fenway Institute, Fenway Health, Boston, United States

Background: Due to the disproportionate burden of HIV among incarcerated, socially-marginalized populations in the US and globally, jails and prisons are key sites for HIV service delivery. While the numbers of incarcerated women are growing, women remain under-researched. Moreover, recidivism remains high, which may reflect unmet mental health and social service needs for this population, especially post-release. Little published research has investigated this possibility directly, however. The study objective was to investigate unmet mental health and social service needs of previously incarcerated HIV-positive women in the US South, specifically Alabama.
Methods: We collected data from three sources for triangulation purposes, using semi-structured, in-depth qualitative interviews with: (1) 25 previously incarcerated HIV-positive women participants in two cities; and (2) 16 key informants who provide health and social services to the study population; combined with (3) service availability mapping. We analyzed the data using conventional content analysis. We grouped codes into categories and organized them by stage: pre-release, on-release and post-release. We conducted multiple, independent coding passes, then cross-checked and verified the emerging themes across the main categories and against the original transcripts. Final themes, and a novel conceptual framework, emerged iteratively.
Results: Participants reported particular unmet needs, captured in four findings by stage:
(1) *Pre-release*: discharge planning and linkage to support services to successfully manage high-risk environments were absent, demonstrating the importance of removing women from triggers (harmful environments);
(2) *On-release:* services were concentrated among few community-based organizations that secured participants' trust and linked them to mental health and social services;
(3) *Early-post-release:* mental health and substance abuse treatment during re-entry were essential to avoid relapse;
(4) *Long-term-post-release*: social support was crucial in fostering post-release adjustment, revealing the interplay between types of services and support, longer-term.



[Figure 1. Conceptual model for linking and transitioning previously incarcerated women living with HIV to clinical and social services]

Conclusions: Safe, stable housing support, substance abuse treatment, human connection, restoration of dignity and love were central to women's wellness. This emphasizes the need for more comprehensive and gender-responsive services to support this underserved, socially-marginalized population. We propose an original conceptual model (Fig. 1), with key steps to establish continuous linkage to services for previously incarcerated women—to address unmet needs and support women´s long-term post-release adjustment.

Evidence on making task shifting work

THPEE763
Task shifting for point-of-care early infant diagnosis testing: Comparison of error rates between nurses and specialized laboratory trained personnel

F.M. Simmonds[1], A. Chadambuka[2], B. Mutede[2], A. Mahomva[2], J. Cohn[3]
[1]*Elizabeth Glaser Pediatric AIDS Foundation, Harare, Zimbabwe,* [2]*Elizabeth Glaser Pediatric AIDS Foundation, Technical, Harare, Zimbabwe,* [3]*Elizabeth Glaser Pediatric AIDS Foundation, Geneva, Switzerland*

Background: Point-of-care (POC) early infant diagnosis (EID) of HIV allows for sample analysis at peripheral health facility. Unlike conventional testing that requires specialized laboratory personnel, POC EID is nearfully automated and may be operated by non-specialized laboratory personnel. POC EID technologies include internal error controls that detect user errors. High rates of error may suggest inadequate user capacity. To decentralize POC EID, task-shifting to cadres such as nurses is important. We used data from a POC EID project in Zimbabwe to compare the error rates and result return to caregivers for samples run on a POC EID technology (Alere q HIV 1/2 Detect) between nurses and lab personnel (MLSc/Techs) to assess user competence.
Methods: All ten sites in Zimbabwe providing POC EID for routine clinical use were enrolled. Two sites are operated by MLSc/Techs, six by nurses, and two by both cadres. Data from December 2016 to June 2017 were reviewed. Error rates were downloaded from each POC EID machine and exported to excel to analyze errors by type of operator. Turnaround time (TAT) from sample collection to issuing of results to caregiver was extracted from the EID test request form and uploaded into an Excel-based database for analysis.

Error Category	Testing Cadre	Error Rate	P-Value
General Errors	MLSc/Techs	7.69%	**0.36**
General Errors	Nurse	9.24%	
End User Errors	MLSc/Techs	5.22%	**0.38**
End User Errors	Nurse	6.41%	

[Table 1: Comparison of error rates in the use Alere Q platform for POC EID by type of operator in Zimbabwe, 2017]

[Figure 1: Error rates by type of operator over the data collection period]

Results: A total of 1,847 tests were conducted by 45 testers (12 MLSc/Techs and 33 nurses), including 165 errors. Overall error rate was 8.93% (7.69% vs. 9.24%, for MLSc/Techs and nurses, respectively, p=0.36). User error rate was 6.17% (5.22% vs. 6.41%, for MLSc/Techs and nurses, respectively, p=0.38). There was no statistical difference between error rates for MLSc/Techs and for nurses. Over time, both cadres' error rates decreased. 98.75% of results were issued to clients versus 98.92% for MLSc/Techs and nurses, respectively. Overall median TAT was same day (Q_1=0.5, Q_3=2). Tests processed by MLSc/Techs had a TAT of one day (Q_1=0.5, Q_3=3.5) versus same day (Q_1=0.5, Q_3=2.5) for nurses.
Conclusions: Similar error rates and TATs between nurses and lab-tech-operators suggest that non-specialized laboratory trained personnel can perform POC EID equally well as specialized laboratory personnel. Nurse-operated POC EID testing will ensure decentralization and timely return of test results without compromising the quality of testing.

THPEE764
Expert clients are associated with improved client tracing among HIV-positive adults who struggle to engage in ART under Test and Treat in Malawi

K. Phiri[1], P.C. Kalande[1], M. Mphande[1], E. Chikuse[2], M. Samuko[2], K. Dovel[1,3], EQUIP-Innovations for Health
[1]*Partners in Hope Malawi, Implementation Science, Lilongwe, Malawi,* [2]*Partners in Hope Malawi, Care and Treatment, Lilongwe, Malawi,* [3]*University of California, Division of Infectious Diseases, Los Angeles, United States*

Background: Tracing is an important strategy for promoting ART retention and re-engaging clients into HIV care. However, tracing activities are difficult and time-consuming. The most efficient models for tracing are still unclear. As part of a larger study to examine the impact of the new universal treatment policy (Test and Treat) in Malawi, we examined the effectiveness of client tracing using two cadres: expert clients (ECs; HIV-positive client volunteers), and Health Surveillance Assistants (HSAs; community health workers in Malawi).
Methods: Study staff reviewed medical records at 4 rural sites to identify clients who failed to take-up ART (did not return for their 4-week appointment or non-initiates), and clients who initiated ART but poorly engaged in care (^{3}14 days late for an ART appointment). From November 2016 - May 2017, HSAs traced identified clients to encourage re-engagement in care. HSAs are community health workers primarily responsible for child immunization, disease surveillance, and tracing activities. Expert clients were introduced to sites in May 2017. Expert clients are HIV-positive community volunteers who successfully engage in care and are responsible for assisting with ART appointments, promoting demand-creation for HIV-testing, and client tracing. From June 2017 onward, ECs became the primary cadre responsible for HIV-related tracing. We collected anonymized medical records between November 2016-September 2017 to determine the proportion of clients successfully traced over time. Wilcoxon ranksum tests were conducted to determine if a greater proportion of clients were traced after the introduction of ECs.
Results: A total of 205 and 127 clients were given to HSAs and ECs, respectively. HSAs successfully traced 41% of clients versus 62% by ECs, resulting in a 51% increase with the introduction of ECs (p< 0.01) (Table).

Facility	Type of facility	ART cohort size	Number of HSAs	Number of ECs	Number of clients given to HSAs for tracing	n (%) of clients successfully traced by HSAs	Number of Clients given to ECs for tracing	n (%) of clients successfully traced by ECs	p-value*
Facility 1	Rural Cham	1430	30	4	41	21 (51%)	32	23 (71%)	0.08
Facility 2	Rural hospital	1431	56	8	89	27 (30%)	47	24 (51%)	0.02
Facility 3	Rural Health centre	603	37	4	49	25 (51%)	13	7 (54%)	0.86
Facility 4	Rural Health centre	177	32	4	26	11 (42%)	35	25 (71%)	0.02
Males traced	-	-	-	-	82	38 (46%)	56	36 (64%)	0.04
Females traced	-	-	-	-	123	46 (37%)	71	43 (60%)	0.002
Total	-		155	20	205	84 (41%)	127	79 (62%)	<0.001

[Facility characteristics and successful tracing outcomes using Health Surveillance Assistants versus Expert Clients in four facilities in Malawi]

Similar improvements were seen across gender: HSAs traced 46% of males and 37% of females compared to 64% of males and 60% of females by ECs.
Conclusions: The introduction of expert clients is an effective way to improve successful tracing of HIV-positive clients. Future cost-benefit-analyses are needed to guide decision making about integrating a new cadre of ECs across the HIV service delivery system.

THPEE765

Acceptability and effectiveness of lay provider HIV testing among key populations in Vietnam: Results from an intervention evaluation

B. Vu Ngoc[1], K. Green[1], H. Phan Thi Thu[2], M. Tran Hung[3], H. Ngo Van[1], S. Vo Hai[1], T. Ngo Minh[4], A. Doan Hong[1], A. Bao[1], L. Dang Hong[3], G. Ha Thi Tra[1]
[1]PATH, Mekong Regional Program, Hanoi, Vietnam, [2]Ministry of Health, Vietnam Administration for HIV/AIDS Control, Hanoi, Vietnam, [3]Center for Creative Initiatives in Health and Population, Hanoi, Vietnam, [4]U.S. Agency for International Development, Office of Health, Hanoi, Vietnam

Background: Achieving the first 90 of the 90-90-90 HIV target depends upon successfully reaching undiagnosed people. To meet this goal, Vietnam implemented lay provider HIV testing services (HTS), using the "test for triage" approach through community-based organizations and village health workers. However, local acceptability and effectiveness of this new approach are unknown.
Methods: We conducted operations research involving a cross-sectional survey and analysis of routine program data in two cities of Hanoi and Ho Chi Minh City and two rural mountainous provinces of Nghe An and Dien Bien from October 2015 - September 2017. Acceptability of lay provider HTS was defined as proportion of first-time HIV testers, and effectiveness was measured by HIV positivity and antiretroviral therapy (ART) initiation rates. Univariate and multivariate analyses were used to determine lay provider HTS preference and factors associated with that preference.
Results: Among 1,230 lay provider HTS clients recruited for a face-to-face interview in the survey, 74% belonged to key populations, including people who inject drugs, men who have sex with men, and female sex workers. Most clients (67%) reported being first-time testers, and the majority (87.5%) preferred lay provider HTS over facility-based HTS. Multivariate analysis found that clients who were from urban areas, i.e. Hanoi (OR = 2.89, 95% CI 1.01-8.29) or Ho Chi Minh City (OR = 2.96, 95% CI 1.28-6.85) and had a university or higher education (OR = 1.84, 95% CI 1.00-3.38) were more likely to prefer lay provider HTS. Lay provider HTS yielded a higher HIV positivity rate (4.1%) compared to facility-based HTS (1.6%) and had a high ART initiation rate (91%).
Conclusions: Our findings suggest that lay provider HTS is a highly acceptable approach to reach first-time testers and can be effective at reaching undiagnosed people in Vietnam. This will be a critical addition to accelerating achievement of the 90-90-90 target.

THPEE766

Task shifting and mobile technology for HIV drug-drug interaction screening in Uganda

K. Seden[1,2], D. Kiiza[2], E. Laker[2], J.W. Arinaitwe[2], C. Waitt[1,2,3], M. Lamorde[2], S. Khoo[1,3]
[1]University of Liverpool, Liverpool, United Kingdom, [2]Infectious Diseases Institute, Makerere University, Kampala, Uganda, [3]Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Drug-drug interactions (DDIs) in patients taking antiretrovirals (ARVs) are prevalent globally (14-41%), though types of interaction and ability to manage DDIs differ between settings. Data from Uganda show a prevalence of clinically significant DDIs (CSDDIs) of 18.9%. However, assessing DDIs through prescription review alone may underestimate burden. We report on both the prevalence of DDIs in Ugandan outpatients taking ARVs using screening of complete medication history, and on prescriber acceptability and clinical utility of a novel medication safety feedback loop.
Methods: As part of an ongoing longitudinal study (SAPU), trained pharmacy technicians at two diverse clinics obtained detailed medication histories using patient report, clinical notes and prescriptions. Prescribed and purchased medicines from any source were included. Information was transferred via secure mobile upload with tablet devices to an ARV information resource (AIDS Treatment Information Centre), who screened for DDIs using www.hiv-druginterctions.org, and generated medication safety feedback for prescribers. Prescribers documented at baseline whether they were aware of DDIs for each patient. At the next patient clinic visit, prescribers assessed acceptability and clinical utility of the medication safety feedback via anonymous questionnaire.
Results: Of 300 patients, 296(98.7%) had ≥1 potential DDI, with 610 potential DDIs detected. Of these, 119(19.5%) were CSDDIs, affecting 83(27.6%, 95%CI 22.7-33.1%) of all patients. At the baseline visit prior to DDI screening, prescribers reported being aware of only 6(5%) CSDDIs. For 249(83%) of the 300 patients, prescribers gave feedback on the medication safety report. Prescribers reported that DDI checks provided new information in 152(61%) cases. Prescribers changed their clinical management for 199(56.1%) DDIs, as a result of the medication safety report. DDI screening saved prescribers time in 164(65.9%) cases and added benefit in 179(71.9%, 95%CI 65.9-77.4%) cases. A full-time pharmacy technician and pharmacist could screen >3000 Ugandan patients in 12 months, at a cost of 7500 USD
Conclusions: The novel DDI screening and feedback loop was feasible, acceptable to prescribers and added benefit in >70% of cases. DDI screening using patient interview showed CSDDI prevalence ~10% higher than observed with prescription review alone. Longitudinal follow up will inform whether the DDI feedback loop can improve patient outcomes and demonstrate cost-benefit.

Can oral fluid based rapid HIV test facilitated by Frontline health workers provide a feasible option for screening among pregnant women in rural India?

S. Khan[1], P. Sharma[1], J. Behera[1], P. Verma Shivkumar[2], S. Mehra[3]
[1]MAMTA- Health Institute for Mother and Child, Research & Evidence Building, New Delhi, India, [2]Mahatma Gandhi Institute fo Medical Sciences, Obstetrics and Gynecology, Wardha, India, [3]MAMTA- Health Institute for Mother and Child, New Delhi, India

Background: The importance of knowing HIV status is a key strategy for HIV response and development of effective treatment services. Evidence suggest that introduction of rapid oral based non-invasive HIV testing in community settings is a feasible approach for reaching the vulnerable populations. Shifting the task of HIV testing services aided by FLWs have potential for increased coverage and uptake of HIV screening among pregnant women. Hence, the current study explored the feasibility and acceptability of rapid oral fluid-based HIV testing using the OraQuick® kits conducted by frontline workers (FLWs) among pregnant women living in rural districts of India.
Methods: A feasibility study, using cross sectional design was conducted among 900 pregnant women from two rural districts of India, who consented to be screened for HIV using OraQuick® HIV test. The screening was assisted by trained FLWs and subsequently, participants were sent to the existing government system for confirmatory HIV testing. Information was gathered through a structured questionnaire on the acceptability of oral fluid based HIV testing from 479 pregnant women, on their availability and willingness to participate. The descriptive statistics was used to analyze the quantitative data. Thematic content analysis was used to analyze the qualitative in-depth interviews.
Results: Of the 947 pregnant women who were offered to get screened for HIV using OraQuick® saliva based test, 95% (n=900) accepted to undergo the test. Of the total 479 pregnant women interviewed, 91.2% liked the OraQuick® kit for HIV screening. The key motivators of accepting the test are easy procedure (43%), non-invasiveness (29%) and quick access to results (18%). Of the total, 900 pregnant women screened by rapid HIV test- OraQuick®, nine women were found to be HIV positive, which later corresponded with confirmatory test results. Qualitative data provided further insights into the FLWs to understand their views regarding the current situation on HIV testing as well as the services available to the pregnant women.

Conclusions: With an urgent need to improve access to HIV screening at the grass root level, an oral based HIV rapid testing mechanism can provide a reasonable solution for improving early detection of HIV among the under-served pregnant women.

Systems to deliver effective, long term chronic care

THPEE768

Predictors of controlled CD4 count and blood pressure in an integrated chronic disease management model in a rural South African setting

S. Ameh[1,2,3], K. Klipstein-Grobusch[4], K. Kahn[3], S. Tollman[3], F. Gómez-Olivé[3]
[1]University of Calabar, Community Medicine, Calabar, Nigeria, [2]Harvard University, Global Health and Population, Boston, United States, [3]University of the Witwatersrand, Medical Research Council/Wits University Rural Public Health and Health Transitions Research Unit (Agincourt), Johannesburg, South Africa, [4]University Medical Center, Julius Global Health, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands

Background: South Africa is undergoing an epidemiological transition with a dual burden of chronic communicable and non-communicable diseases. A pilot Integrated Chronic Disease Management (ICDM) model was initiated in 2011 by South Africa´s National Department of Health in selected primary health care (PHC) facilities. The aim of the ICDM model is to leverage an established HIV treatment programme for non-communicable diseases (NCDs) for better health outcomes of patients with chronic diseases.

This study determined predictors of controlled CD4 count and blood pressure (BP) in hypertension and HIV patients receiving antihypertension medication and antiretroviral drugs, respectively in PHC facilities in the Bushbuckridge sub-district of Mpumalanga province, South Africa.

Methods: This was a panel study to assess the effectiveness of the ICDM model in controlling patients' CD4 count and BP. Patients ≥ 18 years were recruited through a three-step sampling process into the ICDM model facilities (n=435) and comparison facilities (n=443) in the Bushbuckridge sub-district. Health outcome data (BP and CD4 counts) for each patient were retrieved from health facility records over 30 months (January 2011 to June 2013). Control of BP and CD4 counts were defined as BP < 140/90 mmHg and CD4 counts >350 cells/mm³, respectively. Multilevel logistic regression analyses were conducted to determine predictors of controlled CD4 count and controlled hypertension. Data were analysed using Stata 14 statistical software.

Results: The odds of controlling CD4 count were increased by reception of care at the ICDM model facilities (OR=4.05, 95% CI: 2.77-5.92), but decreased by male gender (OR=0.52, 95% CI: 0.34-0.80). The odds of controlling hypertension were higher with increasing age: 40-49 years (OR=6.02, 95% CI: 2.07-17.57); 50-59 years (OR=23.17, 95% CI: 7.46-72.16); ≥ 60 years (OR=77.48, 95% CI: 25.03-82.26), but decreased by male gender (OR=0.38, 95% CI: 0.21-0.69).

Conclusions: Application of the ICDM model appeared effective in controlling patients' CD4 counts, but not their BP; hence, the HIV programme should be more extensively leveraged for hypertension treatment in health facilities in the study setting. Health education programmes to improve HIV treatment outcomes should focus on males. Hypertension educational programmes should target younger males in the study setting.

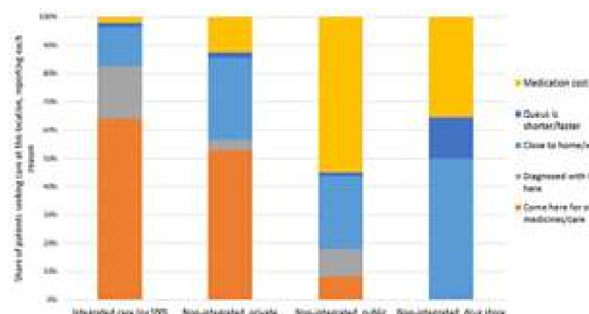
THPEE769

Substantial hypertension care-seeking costs for patients on ART in Malawi: A survey of patients receiving treatment for HIV at an integrated care site

C. Moucheraud[1], M. Hing[2], J. Seleman[3], K. Phiri[3], F. Chibwana[3], D. Kahn[2], A. Schooley[2,3], A. Moses[3], R. Hoffman[2], EQUIP Innovation for Health
[1]University of California, Fielding School of Public Health, Los Angeles, United States, [2]University of California, David Geffen School of Medicine, Los Angeles, United States, [3]Partners in Hope, Lilongwe, Malawi

Background: There is mounting evidence about the clinical and epidemiological connections between HIV and non-communicable diseases like hypertension — yet little is known about the health care experiences of patients with both conditions, particularly in high dual-burden settings where health systems may be ill-equipped to effectively and efficiently provide ongoing care for multiple conditions. This study aimed to quantify the costs of care-seeking for people receiving treatment for both HIV and hypertension in Malawi.

Methods: Data were collected at an urban, PEPFAR-USAID supported HIV treatment site in Malawi that also provides hypertension care, but charges for antihypertensive medicines (ART is provided for free). Adult patients on ART who were taking at least one antihypertensive were invited to participate in a survey. Data were collected between June and December 2017. Questions included experiences with hypertension care including locations and frequencies of visits, and costs of refills (direct medicine and transport costs, as well as indirect costs such as lost wages).



[Reported reasons for care-seeking at different locations]

		Integrated care (n=100)	Non-integrated care (n=98)	p-value for t-test of difference
HTN medicine expenditures	Zero annual expenditure on HTN medicines, % (n)	6.0% (6)	33.3% (33)	< 0.001
	Among those with HTN medicine expenditure: Annual mean (range)	$20.80 (2.52-86.52)	$23.55 (4.20-92.40)	0.24
Refill visit transportation	Zero annual expenditure on refill visit transportation, % (n)	n/a	48.5% (48)	.
	Among those with transport expenditure: Annual mean (range)	.	$6.15 (1.28-28.39)	.
Refill visit lost wages	Zero annual lost wages due to refill visit, % (n)	n/a	53.1% (52)	.
	Among those with lost wages: Annual mean (range)	.	$106.45 (3.41-851.67)	.
Total HTN careseeking costs*	Zero annual HTN careseeking expenditure/costs, % (n)	6.0% (6)	6.1% (6)	0.99
	Among those with any expenditure/cost: Annual mean (range)	$20.80 (2.52-86.52)	$90.28 (1.70-871.83)	< 0.001

These are marginal costs: for people receiving integrated care, "total costs" represents the additional buden of HTN treatment, i.e., the medicines (since transport, lost wages and other costs would be expended regardless for the HIV visit).

[Hypertension (HTN) medicine refill costs (US$)]

Results: There were 199 survey respondents, of whom 65% were female. The median age was 53, and median duration on hypertension treatment was 4 years. On average, patients reported taking 2 antihypertensive medicines, and making 8-9 refill visits each year. Half of respondents (50.3%) received integrated hypertension-ART care (i.e., medicines refilled simultaneously) at the study site. Among non-integrated patients,

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

the most common refill locations were drug shops and public-sector health facilities (37% and 32%, respectively) - most often selected due to cost and convenience (Figure 1). Patients receiving non-integrated care reported paying approximately 4 times more each year for their antihypertensive refill visits ($90 versus $21/year for patients with integrated care) (Table 1). No significant sex differences were found for refill patterns or costs in this study population.

Conclusions: We found substantial access barriers - including expensive medicines and high transaction costs - in this population of patients with hypertension who receive free ART care in Malawi. Despite the lower cost of integrated care, half of respondents opted to go elsewhere for antihypertensives. More research is needed to understand patient preferences for non-communicable disease care, and to study efficient and cost-effective care models.

THPEE770

Evaluating the impact of community-based adherence clubs on the clinical outcomes amongst ART patients in the Cape Winelands district of Western Cape Province of South Africa

S.-A. Meehan[1], D. Wademan[1], G. Hoddinott[1], R. Holtman[2], N. Grobbelaar[3], J. Kruger[2], L. Maschilla[4], B. Yang[1], V. Naidoo[1], P. Bock[1], C. Gunst[4]
[1]*Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa,* [2]*Western Cape Government, Department of Health, Cape Town, South Africa,* [3]*ANOVA Health Institute, Cape Winelands Health District, South Africa,* [4]*Western Cape Government, Department of Health, Cape Winelands District and Drakenstein sub-District, South Africa*

Background: South Africa has 7.1 million individuals living with HIV. Implementing WHO recommendation for lifelong ART regardless of CD4 count for all HIV positive individuals, has resulted in increasing numbers of individuals on ART and increased client burden at health facilities. One consequence has been worse clinical outcomes. Referring stable HIV positive individuals to adherence clubs (differentiated model of care) is one strategy to manage increased numbers of HIV-positive individuals. This study aimed to evaluate the impact of adherence clubs on the clinical outcomes amongst ART patients.

Methods: This retrospective cohort study was conducted in one high HIV burdened health facility in the Cape Winelands district, South Africa. It included individuals aged ≥18 years, who started ART between January 2014 and December 2015. Routine data was extracted from electronic datasets for analysis. Participants were followed up until December 2016. Descriptive statistics and multivariate analysis was used to determine viral load suppression, factors associated with referral to a club and loss to follow up (LTFU).

Results: 465 individuals were included in the study. At baseline, the majority (64.3%) were women, median age was 32 years and median baseline CD4 count was 375cells/µL. Overall, 184 (39.6%) of participants had a viral load reported, of which 162 (88%) were virally suppressed. Median time to referral to the adherence club was 14.1 months (IQR 9.9-19.1). Individuals with baseline CD4 > 500 (aHR =1.86, 95% CI 1.13-3.08) and women pregnant at initiation of ART (aHR =1.70, 95% CI 1.07-2.68) were more likely to be referred to an AD club. LTFU over time was lower in individuals referred to adherence clubs (P=0.002) compared to those who remained in the health facility.

Conclusions: Participants were more likely to be retained in care if referred to an adherence club. This suggests that health workers are referring the correct clients to clubs (more stable patients as per guidelines). Although the large proportion of missing data regarding viral load reporting needs further investigation, viral load suppression remained high for those reported. Adherence clubs are one strategy to manage increasing numbers of HIV-positive individuals outside of healthcare facilities.

THPEE771

Implementing community-based adherence clubs for stable HIV-infected patients in South Africa. Lessons learned from patient and health worker experiences

S.-A. Meehan[1], D. Wademan[1], G. Hoddinott[1], R. Holtman[2], N. Grobbelaar[3], J. Kruger[2], M. Leonard[4], B. Yang[1], V. Naidoo[1], P. Bock[1], C. Gunst[4]
[1]*Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa,* [2]*Western Cape Government, Department of Health, Cape Town, South Africa,* [3]*ANOVA Health Institute, Cape Winelands Health District, South Africa,* [4]*Western Cape Government, Department of Health, Cape Winelands District and Drakenstein Sub-District, South Africa*

Background: South Africa has the largest burden of HIV globally; 7.1 million people living with HIV, 3.9 million on ART. Implementation of the WHO guidelines; offering ART to everyone living with HIV, has resulted in increased burden on health facilities with longer patient waiting times. Referring stable HIV positive individuals to community-based adherence clubs is one strategy to manage increased numbers of HIV-positive individuals. This study aimed to generate lessons learned on the implementation of community-based adherence clubs from patient and health worker perspectives.

Description: The Cape-Winelands Health district (South Africa) have implemented community-based adherence clubs (outside of health facilities) since 2012 according to department of health guidelines. 'Clubs' are supported by non-governmental organizations. Stable HIV-positive patients are referred to clubs to collect pre-packed medication, but return to the health facility for a clinical visit every six months. This study enrolled 59 patients and 20 health workers from two 'clubs'. An electronic self-administered questionnaire comprising closed- and open-ended questions was used to collect data. Descriptive statistics and thematic analysis was used to analyse data.

Lessons learned: The majority of participants reported that 'clubs' are best led by counselors, should have ≥20 patients and take place in a community hall or church.

From the patient perspective, 'clubs' (Table 1):
· provide group identity (not alone in living with HIV)
· are empowering (motivated to stay adherent)
· are less time consuming (short queues)

From the health worker perspective, 'clubs':
· are effective at decongesting health facilities
· reduce the burden of work for facility staff
· empower health workers to tailor their support to individual needs

Health workers highlighted that 'clubs' are labour intensive and teamwork between stakeholders is critical. Good communication between NGO and facility personnel is vital when dealing with challenges e.g. individual patient non-compliance or non-collection of medication.

	Club A (n=37)				Club B (n=22)

Overall is a good way to deliver high quality services for people living with HIV	23 (62.16)	14 (37.84)	0 (0)	0 (0)	11 (50.0)	10 (45.45)	0 (0)	1 (4.55)

[Patient experiences of community-based adherence clubs in Winelands district, Western Cape Province, South Africa]

Conclusions/Next steps: Community-based adherence clubs are a good way to deliver high quality health services for people living with HIV. Implementation of 'clubs' is not simple. Optimal functioning is reli-

ant on strong co-ordination of a multidisciplinary team with clear roles and responsibilities with standardized strategies that are specific to the needs and resources of the community.

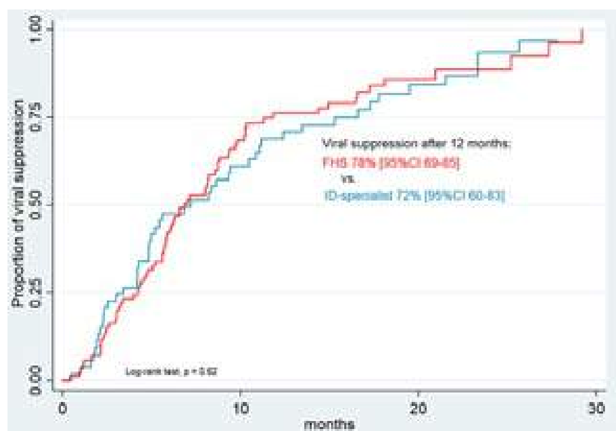
THPEE772

Decentralization of antiretroviral therapy to the family health strategy: Effectiveness of a new delivery strategy for HIV care in Rio de Janeiro, Brazil

R. Castro[1,2], M. Ribeiro-Alves[1], L. Lauria[3], R. Polari[3], P. Santos[4], S. Manzi[5], R.G. Correa[6], A.C.G. Ferreira[1], S.W. Cardoso[1], B. Grinzstejn[1], V.G. Veloso[1], Rede de Políticas Públicas e Modelo de Atenção à Saúde - PMA Fiocruz Network
[1]Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, [2]Universidade Federal do Estado do Rio de Janeiro, Instituto de Saúde Coletiva, Rio de Janeiro, Brazil, [3]Secretaria Municipal de Saúde, Coordenação de Área Programática 2.1, Rio de Janeiro, Brazil, [4]Secretaria Municipal de Saúde, Coordenação de Área Programática 3.3, Rio de Janeiro, Brazil, [5]University of Exeter Medical School, National Institute for Health Research Collaboration for Leadership in Applied Health Research and Care South West, Exeter, United Kingdom, [6]Ministério da Saúde, Departamento de Vigilância Prevenção e Controle das IST, do HIV/Aids e das Hepatites Virais, Brasília, Brazil

Background: In Brazil, antiretroviral therapy (ART) has been historically prescribed by infectious diseases (ID) specialists. In 2014, a new strategy was implemented in the city of Rio de Janeiro to decentralize HIV-care from specialized care to the family health strategy (FHS) in primary care units. HIV-specialists and activists do not fully agree with this decentralized approach. This study aimed to compare the effectiveness of the two ART delivery strategies (FHS versus ID-specialists-based) in primary care units of Rio de Janeiro.

Methods: All adult individuals initiating ART between 2014-2016 in any primary care unit of two administrative regions in Rio de Janeiro were included. Electronic medical records were retrospectively reviewed to (1) check patient eligibility; (2) assess the implemented HIV-care strategy (FHS or ID-specialist-based); and, (3) collect patient data. Lymphocytes CD4+ T cell counts, HIV-1 viral loads (VL), and ART dispensation longitudinal information was retrieved from SISCEL and SICLOM (Brazilian Ministry of Health´s information systems developed to monitor laboratory tests and control the logistic of ART delivery, respectively). Kaplan-Meier survival curves and Cox Proportional-Hazard models were employed, considering the time until viral suppression as the outcome.



[Kaplan-Meier viral suppression estimates by ART delivery strategy in Rio de Janeiro, Brazil]

	aHR (95% CI)	p-value
	age in years	
30-49 vs. <30	1.10 (0.72 - 1.69)	0.63
>= 50 vs. <30	1.87 (1.06 - 3.30)	**<0.05**
	baseline CD4+ T cell counts	
200-500 vs. <200	1.32 (0.81 - 2.16)	0.26
>500 vs. <200	1.70 (1.04 - 2.78)	**<0.05**
	ART delivery strategy	
FHS vs. ID-specialist	0.94 (0.64 - 1.38)	0.75

[Adjusted hazard ratios (aHR) of multivariate Cox Proportional-Hazard model with viral suppression as outcome in Rio de Janeiro, Brazil]

Results: Overall, 421 HIV-1-infected individuals were included, 211 (50.1%) had ART prescribed by the ID-specialist-based strategy and 210 (49.9%) by FHS. Mean age (SD) was 36.6 (13.1) and 35.3 (10.8); males were 135 (64.0%) and 152 (72.4%); black or mixed race/ethnicity individuals were 119 (56.4%) and 142 (67.6%), considering ID-specialist and FHS-based strategies, respectively. The log-fold-change of HIV-1 VL before and after ART was not different between strategies. Log-rank test of Kaplan-Meier estimated average time to viral-suppression between strategies was not significant. Viral suppression adjusted hazard-ratios (95% confidence intervals) [aHR (95% CI)] estimated after a multivariate Cox Proportional-Hazard model fitting were not significant between ART delivery strategies, aHR: 0.94 (0.64-1.38), but were significant between age >= 50 and < 30 years, aHR: 1.87 (1.06-3.30), and baseline CD4 > 500 and < 200, aHR: 1.70 (1.04-2.78).

Conclusions: In real-world settings of primary care units in Rio de Janeiro, FHS and ID-specialist-based ART delivery strategies did not have different virologic outcomes. This finding supports the ongoing process of decentralization of HIV-care.

THPEE773

Certification of HIV-care to improve structural and process components in 25 HIV treatment centres in the Netherlands

J. Branger[1], W. Kortmann[1], A. Vollaard[1], G. ter Beest[2], M. van der Valk[1]
[1]Dutch Society of HIV Treating Physicians (NVHB), Amsterdam, Netherlands, [2]Dutch Society of Nursing Professionals HIV (V&VN), Amsterdam, Netherlands

Background: In the Netherlands, anonymized patient data collected in a national monitoring system provide data on the cascade of care and health outcomes. The medical care for HIV infected patients is concentrated in 26 HIV treatment centres (HIV-tc). In order to measure and improve the quality of care, the Dutch society of HIV treating physicians (NVHB) decided in 2015 to implement a mandatory nationwide certification programme for HIV-tc.

Methods: Up to now twenty five out of 26 Dutch HIV-tc have been audited by an independent external certification organisation (DNV) in a period of three years (2015-2017) to obtain a HKZ certificate. Quality indicators were described by the NVHB. The audit was performed by an independent external audit leader (DNV), together with an infectious diseases medical specialist and a HIV-nurse who had been trained as auditors. After one year, centres were re-audited to verify whether shortcomings had been addressed.

Results: Thirteen indicators of procedural content and 5 of medical content were evaluated (table 1). Concerning the 5 medical quality indicators, all HIV-tc met the medical criteria. In contrast, procedural criteria were partially met. Especially describing and yearly evaluating goals for improvement of HIV care using a plan-do-check-act (PDCA) cycle was present in a minority of HIV-tc (6/25; 24%). Results did not differ between large, small, academic or non academic treatment centres. Recertification one year later showed a robust improvement in meeting certification criteria (18/21; 86%).

quality indicator	criteria met by % HIV-tc (N=25) at audit	criteria met by % HIV-tc (N=25) at re-audit
mission and vision HIV-tc described	88	100
concrete goals described	24	90
organisational structure HIV-tc described	100	100
job and tasks physicians and nurses HIV-tc described	80	100
regular multidisciplinary consultation present	100	100
≥90% HIV-RNA < 400 cp/ml after 6 mo of cART	100	100
yearly evaluation all quality indicators by HIV-tc	28	86
improvements in response to evaluating yearly indicators using PDCA	24	90
symptomatic client seen within 5 working days as recorded	96	100

[Table 1.percentage of Dutch HIV-tc that met 18 different quality criteria as evaluated at a certification audit and a re-audit one year later]

Conclusions: All HIV treatment centres provide the required clinical care shown by an external certification programme. Self-evaluation using procedural indicators such as planning and evaluating measures to improve quality of care were largely not met at start of the program. The certification program helped to promote clinical organisation as witnessed by near universal improvements in process indicators in 1 year.

THPEE774

Community HIV care and treatment for female sex workers in Ethiopia: Successful service provision through drop in centers

S. Ejigu[1], E. Workalemahu[2], I. Lemma[3], G. Mamo[2]
[1]Population Services International (PSI), MULU/MARPs, Addis Ababa, Ethiopia, [2]PSI, MULU/MARPs, Addis Ababa, Ethiopia, [3]PSI, Addis Ababa, Ethiopia

Background: Female sex workers in Ethiopia are disproportionately affected by HIV, with a prevalence of 23% (national MARPs survey, 2013, EPHI), compared to a national prevalence of 1.2% (EPHI-2017 national estimates). Linkage to treatment and early ART initiation remains a challenge; only 72% of HIV positive patients are put on treatment.
These challenges are magnified among FSW, who face additional barriers to treatment such as stigma and discrimination, and have initiation rates as low as 26%.
Description: To improve uptake of ART among FSW living with HIV, the USAID-funded MULU/MARPs project began offering ART in 25 FSW-friendly drop-in-centers (DICs) in October, 2016. DICs are safe hubs for FSW located in hot-spots, and providing integrated behavioural and clinical services including peer support in a "one-stop-shop" format.. Along with friendly staffs, these social and integrated clinical services make the DICs friendly, and were hypothesized to reduce the barriers to ART uptake among FSWs.
Lessons learned: In the 12 months prior to the roll-out of DIC-based ART delivery, 573 HIV positive female sex workers were identified, of which 510 (89%) were successfully linked to treatment at public health facilities but only 133 (26%) patients were initiated on ART.
Between ART roll-out in October 2016 and December 2017, total of 1282 FSWs were identified and out of these 1232 (96%) were linked to treatment at DIC. Including those who are referred from other testing sites A total of 1,612 FSW were enrolled to care, of which 42 (2.6%) transferred out. From the remaining 1570 patients and 1,506 (96%) started treatment immediately at 25 DICs. Among the 305 patients with viral load test results available, 92% had VL < 1000 copies/ml. 12 month retention rate is 92%.
Conclusions/Next steps: Providing community ART service at DICs tailored to the needs of FSWs improves linkage, initiation to treatment and viral suppression compared to referral to public health facilities. These improvements contribute to progress in achieving the second and third 90s in Ethiopia.
Convenient, confidential, and FSW-friendly services such as those offered in the DICs are a successful strategy for implementing community ART service provision.

Integrating mental health and wellness in HIV programming

THPEE775

Barriers and facilitators to implementation of trauma-informed care services at a large, urban HIV treatment center in the Southern United States

A. Kalokhe[1], K. Piper[2], C. Riddick[2], J. Lucas[2], J. Schiff[3], B. Getachew[2], C. Escoffery[2], J. Sales[2]
[1]Emory University, Rollins School of Public Health, Global Health, Atlanta, United States, [2]Emory University, Rollins School of Public Health, Behavioral Sciences and Health Education, Atlanta, United States, [3]Emory University, School of Medicine, Atlanta, United States

Background: The high prevalence of trauma and its negative impact on health and health-promoting behaviors in HIV-infected populations underscore the need for tailored, integrated trauma screening and management within HIV services ("trauma-informed care" or TIC) to improve retention, adherence to therapy, and overall physical and mental well-being. Little is known about provider and staff attitudes towards implementation of TIC in HIV services.
Methods: To gather information on the current level of TIC services and barriers and facilitators to enhancing TIC delivery, survey assessments (N=31) and in-depth interviews (N=19) were conducted with staff and providers, between March-August 2017, at a large urban HIV treatment center that serves a largely uninsured, low-socioeconomic population in the southern US. The assessment included 8 items on current TIC services. On a scale of 0-3 (strongly disagree to strongly agree), mean item scores ≥2 indicated strong consensus about the availability of this service and mean item scores < 2 indicated consensus on its absence. Interviews were coded using NVivo.
Results: Staff scored ≥2 for 8/8 survey items, indicating high perceived availability of TIC services, while providers scored < 2 for 5/8 survey items, indicating perceived gaps in current TIC services (see Table).
Interviews highlighted the availability of several trauma-related services, including counselling, support groups, and educational courses, but also described the lack of an overarching TIC framework at the center. Providers and staff received little to no training on how to understand, recognize, and respond to patient-reported trauma.
Further, providers and staff supported implementation of organization-wide TIC procedures and employee trainings to improve the delivery of services to patients with trauma histories, and believed the center had capacity to provide TIC, but were concerned time and resource constraints could hinder implementation.
Other concerns voiced by providers included personal discomfort with discussing trauma, limited knowledge regarding support service offerings, and skill deficiencies in responding to trauma.

Availability of TIC Services Survey Items	Provider (N=14) Mean	Staff (N=17) Mean
1. The center provides opportunities for care coordination for services not provided within that organization.	1.7	2.5
2. The center educates patients about traumatic stress and triggers.	0.9	2.3
3. The center has access to a clinician with expertise in trauma and trauma-related interventions (on-staff or available for regular consultation).	1.7	2.5
4. The center provides opportunities for patients to receive a variety of services (e.g., housing, employment, legal and educational advocacy, and health, mental health and substance abuse services).	2.4	2.6
. When mental health services are needed (i.e. individual therapy, group therapy and/or family therapy), the center refers patients to counseling.	2.4	2.6
6. The center provides opportunities for patients to express themselves in creative or nonverbal ways (i.e. art, theater, dance, movement, music).	2.1	2.3
7. Written safety plans (i.e. what a patient and staff members will do if the patient feels threatened by another person outside of the center) are incorporated into patients' individual goals and plans.	0.9	2.3
8. Each patient has an individualized written crisis prevention plan (i.e. for how to help manage stress and feel supported) which includes a list of triggers, strategies and responses which are helpful and those that are not helpful and a list of persons the patient can go to for support.	0.8	2.1

[Table 1.]

Conclusions: This comprehensive assessment revealed strong staff and provider support for strengthening TIC within HIV treatment services. Future implementation efforts should address service gaps, overcome identified barriers to TIC, and equip staff and providers with the knowledge and skills to better respond patients' trauma needs.

THPEE776

Empowerment is a key factor in wellness and healing for women living with HIV who have experienced lifetime trauma

C. Dawson-Rose[1], Y.P. Cuca[1], M. Shumway[2], N. Khanna[3], K. Davis[4], J. Cocohoba[4], E.L. Machtinger[4]
[1]University of California, School of Nursing, San Francisco, United States, [2]University of California, Department of Psychiatry, San Francisco, United States, [3]University of California, San Francisco, United States, [4]University of California, School of Medicine, San Francisco, United States

Background: Lifetime trauma (child abuse, gender based violence, poverty, racism, and other forms of structural violence) can drive women's risk for acquiring HIV, and for poor health outcomes among women living with HIV (WLHIV), even in the setting of viral suppression. As part of a project to integrate a response to trauma and promote healing for WLHIV, we conducted an exploratory analysis to identify factors that may be amenable to interventions to improve the lives of WLHIV who have experienced trauma.
Methods: We enrolled 104 WLHIV in a prospective study and measured structural and demographic factors (Adverse Childhood Experiences, trauma history, housing, and food insecurity); factors that could change with intervention (PTSD, anxiety and depression symptoms, prescribed and illicit substance use, stigma, and empowerment), and biological outcomes-abstracted from medical record (viral load). Focusing on two main outcomes of interest (quality of life/wellness and undetectable viral load), we conducted hierarchical regression analyses in two blocks: structural/demographic factors and factors amenable to intervention.
Results: Almost all (97%) participants had experienced trauma. Women with higher empowerment scores had significantly better quality of life (coef 5.71, 95% CI 1.68, 9.76, p=0.006), while those with higher depression scores had significantly worse quality of life (coef -0.70, 95% CI -0.89, -0.51, p< 0.0001). White women (AOR 15.5; 95% CI 1.5, 165.6, p=0.02) and women with stable housing (AOR 7.4; 95% CI 1.7, 31.5, p=0.01) were significantly more likely to have an undetectable VL, while women with higher stigma (AOR 0.3; 95% CI 0.1, 0.8, p=0.01) and with positive drug abuse screens (AOR 0.4; 95% CI 0.2, 0.8, p=0.008) were significantly less likely to have an undetectable viral load.
Conclusions: These data suggest that integrating trauma-informed approaches that increase empowerment and reduce depression symptoms could improve quality of life and wellness for WLHIV. While having an undetectable viral load is significantly affected by structural factors such as race and stable housing, it may also be amenable to change through clinical interventions that address substance use and stigma. Implementing trauma-informed primary care may help HIV clinics better address factors such as stigma, substance use, depression, and empowerment for WLHIV.

THPEE777

How does disclosure of parental HIV impact children in sub-Saharan Africa?

M. Lightfoot[1], G. Kumalo-Sakutukwa[2], L. Pollack[2], A. Chingono[3]
[1]University of California, San Francisco, Medicine, San Francisco, United States, [2]UCSF, San Francisco, United States, [3]University of Zimbabwe, Harare, Zimbabwe

Background: In Western countries, children who do not know their parent's HIV positive status experienced increased problem behaviors and negative mood over time. However, the robustness of the finding between disclosure and family outcomes has not been established in sub-Saharan Africa where the largest number of families living with HIV resides. This study examines the mental health and risk outcomes for the children in these families.
Methods: A total of 332 families were recruited from 18 medical and ARV clinics in rural Zimbabwe. Families included one HIV positive primary guardian and one child 10 - 17 years of age who is unaware of the parent's HIV states. Families were randomized to receive an intervention that encouraged disclosure or control group. Parent and child completed culturally appropriate surveys in their local language that included emotional distress, depression, anxiety, family relationships, and risk behaviors at baseline, 3-, 6-, 12- and 18-months. Using mixed effects regression models, we compared family outcomes for all families in which a parent disclosed their status by the 3-month follow-up to families where disclosure did not occur.
Results: Parents were mostly biological parent (76%; 18% were grandparent), were a mean age of 43.64 years (SD = 9.99), 80% female, mostly married (55%) or widowed (35%), with a mean of 2.83 children (SD = 1.32). Children were 54% boys and a mean age of 12.73 (SD = 1.89). At 3 months, 71% of intervention and 29% of control parents had disclosed their HIV status. Children who were disclosed to reported significantly fewer delinquent behaviors and more family openness. For parents who disclosed, they reported significantly higher social support, lower mental health symptoms, lower distress, lower anxiety, and lower depression.
Conclusions: Parental disclosure appears to be a healthy choice for families with adolescent children. Disclosure likely provides opportunity for children to support their parent's health care needs and supports a climate of open discussions within the family. Unlike prior studies, children who are unaware of their parent's HIV status do not report high levels of mental health problems, negative externalizing behaviors or risky sexual and substance use behaviors.

THPEE778

Impact of male involvement beyond PMTCT: Male partner practical support improves maternal mental health in rural Zimbabwe

L. Comrie-Thomson[1,2,3], Z. Kapamurandu[4], P. Wata[4], B. Madzima[5], J. Davis[1,2], M.-A. Nicholas[1], D. Patel[4], S. Luchters[1,2,6], K. Webb[4]
[1]Burnet Institute, Melbourne, Australia, [2]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia, [3]Ghent University, Department of Obstetrics and Gynecology, Ghent, Belgium, [4]Organization for Public Health Interventions and Development, Harare, Zimbabwe, [5]Ministry of Health and Child Care, Government of Republic of Zimbabwe, Harare, Zimbabwe, [6]Ghent University, International Centre for Reproductive Health (ICRH), Department of Obstetrics and Gynecology, Ghent, Belgium

Background: Zimbabwe has an HIV prevalence among women in antenatal care of 16.1% and HIV is the leading cause of maternal death. Male partner involvement during pregnancy is associated with improved PMTCT uptake and outcomes. While there is evidence that male involvement is associated with improved maternal mental health, this is rarely a focus of male involvement strategies. Our objective was to examine the influence of male partner practical support upon maternal mental health outcomes.
Methods: A cross-sectional baseline survey was conducted June-August 2016 for a community-based health program in rural Mutasa District, Zimbabwe. Trained non-clinical female enumerators administered the survey in eight health facility catchments with women who had given birth in the previous six months. The questionnaire included a Shona-language Edinburgh Postnatal Depression Scale (EPDS), previously validated in Zimbabwe, and questions about male partner practical support during pregnancy, birth and after birth. Survey data was analysed with Stata 13.0, adjusted for clustering effects.
Results: Among 459 women enumerated, mean age was 25.5 years and mean number of children 2.4. Using the validated EPDS cut-off of 11, 28.8% (95%CI:24.6-32.9) of women reported symptoms of clinically significant depression and anxiety, while 18.7% (95%CI:14.0-23.4) reported thoughts of self-harm. Mean EPDS score was 7.6 (95%CI:7.1-8.2) out of 30. Across the items of male partner practical support assessed, there was no difference in level of support provided to HIV positive and HIV negative women.
However, multiple items of practical support from male partners including assistance with food preparation, household chores, and childcare were significantly associated with improved maternal mental health out-

comes related to postnatal depression and anxiety, and recent suicidal ideation among all women (Table 1).
Conclusions: Male involvement in maternal and child health is increasingly recommended as a PMTCT strategy in high prevalence settings, with a focus on increasing couples' uptake of HIV testing during pregnancy. We demonstrate that among vulnerable, rural women in a high prevalence setting, male involvement also improves mental health outcomes. Investment into programs that meaningfully engage men in maternal, newborn and child health, including PMTCT, can benefit maternal mental health as well as HIV outcomes.

Male partner support item	Clinically significant symptoms of depression and anxiety, OR (95% CI)	Recent suicidal ideation, OR (95% CI)
Helped to obtain or prepare special foods in pregnancy	0.61 (0.45, 0.83)**	0.45 (0.27, 0.75)**
Encouraged woman to rest in pregnancy	0.45 (0.32, 0.66)**	0.30 (0.19, 0.48)**
Accompanied woman to ANC clinic	0.69 (0.45, 1.06)	0.75 (0.46, 1.23)
Accompanied woman to place of birth	0.56 (0.29, 1.06)	0.69 (0.39, 1.23)
Financial support for birth	0.34 (0.19, 0.59)**	0.21 (0.12, 0.34)**
Assists with bathing, dressing, holding or playing with the baby	0.67 (0.47, 0.95)*	0.54 (0.37, 0.78)**
Assists with household chores	0.61 (0.44, 0.85)**	0.45 (0.33, 0.62)**
Encourages breastfeeding	0.63 (0.44, 0.90)*	0.37 (0.21, 0.68)**
* Significant at p<0.05 ** Significant at p<0.01

Partnerships involving donors, NGOs, and government

THPEE779

Lahore first MSM organization get recognition with National AIDS control program of MSM issues in HIV epidemic

S.R.H. Tirmizi[1,2], A. Apcom[3]
[1]*Dostana Male Health Society, Program Monitoring and Evaluation, Lahore, Pakistan,* [2]*Dareecha Male Health Society, Rawalpindi, Pakistan,* [3]*APCOM, Equity Dignity & Social Justice, Bangkok, Thailand*

Background: Homosexuality is breach of Law and Illegal in Pakistan. If some male is engaged in male to male sex can result up to 100 lashes, and imprisonment up to 10 years. MSM/Gay are hidden. Extremely stigmatized in Pakistan. Up till now there are very few HIV prevention programs for MSM in Pakistan and there is no recognition on National and Provincial levels of MSM people.as a result in recent IBBS report the HIV infection among MSM sex workers is 3.2%.
Description: Under Global funds R9 south Asia regional project developed Dostana in 2012. Dostana is the first community based organization in Lahore Pakistan providing Technical, institutional support for improving health and human rights of MSM in Lahore Punjab. And providing HIV testing services, Behavior change communication and STI diagnosis and treatment in Lahore for MSM community. Dostana provides a strong platform for MSM population in Lahore through advocacy with Government bodies like Punjab AIDS control program, National AIDS control program in their HIV response. Dostana Male Health Society registered more than 35,000 MSM since July-2012, and distributed more than 550,000 condoms & Lubricants and tested HIV MSM more than 9000 and Diagnosed & Treated more than 6400 cases of sexually transmitted infections in community led Clinic, Organized training´s and trained more than 75 health care providers during 2016 & 2017.and been a part of with GOVT to propose community based testing and prevention of HIV programs in Pakistan in National concept note.
Lessons learned: Working with MSM population in Lahore Pakistan is a difficult & challenging task, Dostana staff in office and field work has been harassed, discriminated and beaten by the public by police and other people. Several times Dostana office is raided by police.
Conclusions/Next steps: Dostana provide services via personal networks in MSM community and referrals.by advocating with National AIDS control program and Provincial AIDS control program & Civil society Dostana will be able to provide more suitable environment for MSM population to learn more about HIV, sexual health and human rights issues in Islamic republic of Pakistan by doing reduce the impact of HIV.

THPEE780

Innovative grant governance mechanism: Civil society ensuring transparency & accountability

J.C. Gomes[1], J. Waters[2], I. Cruickshank[3], M. de Bruin[4]
[1]*Caribbean Vulnerable Communities Coalition, Management, Kingston, Jamaica,* [2]*Caribbean Vulnerable Communities, Programmes, Santo Domingo, Dominican Republic,* [3]*Caribbean Vulnerable Communities, Administration and Finance, Kingston, Jamaica,* [4]*University of the West Indies HIV/AIDS Response Programme, Kingston, Jamaica*

Background: In 2016 the Global Fund (GF) approved a Concept Note by Caribbean Civil Society (CSO) partners led by Caribbean Vulnerable Communities (CVC). As a regional organization CVC was not required by the GF to establish a Regional Coordinating Mechanism (RCM) for grant oversight, however, CVC did set up a Technical Advisory Group (TAG), and empowered it to function as an RCM to ensure accountability.
The TAG was designed to embody "the core principles of good governance" of the GF and to "ensure participation of multiple stakeholders". The TAG governance manual was developed to conform with GF guidelines for CCMs. Members include regional KP networks, CSO and academic partners, PANCAP representing the governments of the region, and UN Agencies.
Description: With its funding approved in the grant, the TAG became operational in February 2017, electing a Chair and Vice-Chair, developing and approving a Governance Manual and nominating members. CVC Board's approved the manual, the selection of officers and confirmed the TAG's legal status as a Sub-Committee of CVC's Board.
The TAG has organized itself into different working groups including a Transition Working Group overseeing a responsible transition of PR from UNDP to a regional CSO entity. An Oversight and Monitoring Committee ensures accountability for all grant related activities from the PR and SRs. The CSO and regional network TAG members have made significant input into meetings and have worked hard to ensure that GF principles are brought to bear on the delivery and oversight of the grant.
Lessons learned: The TAG's role as primary accountability mechanism to which the Principal Recipient (PR) would report faced stiff initial resistance from the PR, the UNDP. With support from the GF FPM, the grant owners and TAG members insisted on recognition of its accountability role, and the TAG's inclusion in decision making for the grant is now accepted by the PR.
Conclusions/Next steps: The TAG is currently overseeing the first proposed transition of a PR from an International Development Partner to an indigenous Caribbean CSO. We believe that the TAG could serve as an innovative, effective and sustainable model of grant governance, ensuring oversight and accountability for regional grants.

THPEE781

Towards resilient health systems through government centred partnerships using a culture change model: A paradigm shift in the Malawi southern region

C. Mupure[1], N. Nyathi[1], R. Chivaka[1], D. Midiani[2]
[1]*Spark Health, Cape Town, South Africa,* [2]*Malawian Ministry of Health, HIV and AIDS Department, Lilongwe, Malawi*

Background: The Malawi public healthcare landscape is characterised by a multiplicity of challenges, chief being the high burden of disease, high attrition of skilled healthcare professionals, ill-equipped leadership at district and zonal levels and increased pressure on limited resources. Focus of interventions has been mainly biomedical, with little emphasis placed on developing public sector managers' leadership and management capabilities.

Malawi Ministry of Health responded to the disappointing and unsustainable results of an exclusive focus on biomedical and technical skills interventions, by partnering with Spark Health to co-design and implement a culture change program in the Southern region which leveraged existing implementing partners.
Description: A transformational leadership didactic session introduced managers to team based, collaborative problem-solving based on systematic root case analysis, and data driven decision-making. Culture change was developed through rigorous on-the-job mentorship sessions. Quarterly meetings were held to foster accountability and encourage cross fertilization of ideas.
Through this partnership in Malawi South, Spark Health demonstrated that culture change through cultivating transformational leadership competencies results in significant improvements in health outcomes. Early infant diagnosis of HIV at 2 months increased from 25.1% (Q1 2016) to 72.4% (Q3-2017) while diagnosis at 24 months increased from 58.8% (Q1 2016) to 70.6% (Q3-2017). Vertical transmission of HIV at 12 months was reduced from 4.1% (Q1 2016) to 2.6% (Q3 2017).
Lessons learned: Strengthening the healthcare system to produce measurable and sustainable results requires:
· Human asset development that shifts emphasis from hard skills (technical) to the so-called soft skills (human)
· Shifting mind-sets from deficit to asset based thinking
· A recognition that healthcare professionals are the most important asset in the system
· A culture for creative use of existing resources given the resource-constrained Africa governments
· The culture of 'home-grown' innovations that are based on people's way of life.
Conclusions/Next steps: The Malawi Ministry of Health is working towards full coverage of the Spark Health philosophy in the country by introducing the new way of thinking in the remaining Northern region.

THPEE782

Redefining partnership: The importance of coordination in HIV implementation programs

J. Mwangi, J. McCutcheon, C. Barbo, E. Easley, F. Harris
JSI Research & Training Institute, Inc. (JSI), Boston, United States

Background: When determining whether to bid on an HIV program, organizations consider factors such as feasibility and scope alignment with their mission. Organizations often overlook the appropriateness and sustainability of their approach, likelihood of buy-in, and resources necessary to coordinate effectively within existing national structures.
Description: Under the US Department of State/PEPFAR-funded DREAMS Innovation Challenge Funds Manager grant, JSI Research & Training Institute, Inc. (JSI) supports 46 implementing partners (IPs) across ten African countries to decrease vulnerability of adolescent girls and young women to HIV. JSI has learned several lessons about the importance of prioritizing local, national, and international stakeholder coordination as a key determinant of programmatic success. JSI´s practical experience in HIV programming, stakeholder management, and system strengthening has value for donors, implementers, and other stakeholders.
Lessons learned: JSI found several areas to be critical for success of IPs working in these countries. Key considerations will be identified related to: priorities of various sectors and levels of government; donor landscape and priorities; existing local IPs (public, private, NGO); and formal and informal referral systems. Our multi-country experience enables us to present comparisons and contrasts across and within countries. Specific lessons that should be considered include the need to share work plans and budgets with national, and often subnational governments; regularly participate and contribute to technical forums and annual country operating plans; and report into existing government and donor reporting systems, requiring IP indicators to be established to meet donor, government and IP specifications. For example, in Kenya, where the governance system is devolved, reporting and attendance at coordination meetings is required both at national level and in every county that DREAMS was operating; whereas the IPs in Uganda report into one platform which is accessible to national and regional governments.
Conclusions/Next steps: This presentation will illustrate the ongoing evolution from donor- and IP -focused approaches, to ones centered on beneficiary needs and filling gaps in existing country systems. The information will be useful in rethinking what partnerships mean and building more sustainable and effective models.

THPEE783

Providers in private practices are indispensable to achieving the targets for triple 90 in HIV epidemic control: Experiences from Private Health Sector Project in Ethiopia

A.G. Woldegiorgis[1], P. Mitiku[1], E. Gezahen[1], T. Tasew[1], G. Habte[1], A. Mekonnen[1], A. Nuru[1], M. Teferi[1], M. Eshetu[1], M. Tilaye[2], Y. Vartanova[3]
[1]Abt Associates Inc, Private Health Sector Project in Ethiopia, Addis Ababa, Ethiopia, [2]USAID, Ethiiopia Mission, Addis Ababa, Ethiopia, [3]Abt Associates, Cambridge, United States

Background: In Ethiopia, only 60% of people living with HIV (PLWH) know their HIV status and 62% of PLWH are receiving anti-retroviral treatment (ART). To address these gaps and achieve UNAIDS 90-90-90 targets, the government is implementing a catch-up initiative. To support this initiative, the USAID-funded Private Health Sector Project (PHSP) is engaging private health facilities to deliver quality affordable HIV services in seven regions throughout Ethiopia using Public-Private Mix (PPM) approaches. The purpose of this review is to share experiences and outcomes in scaling up HIV services in private health facilities over the past year.
Description: PHSP provides technical assistance, including training, mentoring, supportive supervision, quality assurance including monthly performance monitoring, and ensuring supply of commodities and tools to 242 private health facilities. 75/242 of the facilities provide ART and 167/242 of the facilities refer diagnosed HIV clients to facilities where ART is provided.
Lessons learned: From October 2016 to September 2017, the facilities provided HIV Testing Service (HTS) to 270,274 (59.1% female) people and identified 7,233 (56.1% female) new HIV clients. The HIV positivity was 2.7% (2.5% in female vs 2.9% in male, $p < 0.0001$). The contribution of PITC, VCT, PMTCT, and TB to HTS were 58%, 32%, 10% and 1%, respectively. The HIV positivity was 3% from PITC, 2.5% from VCT, 1.1% ANC/PMTCT, and 13.2% from TB. HIV positivity by age categories were 2% (< 15yr), 1% (15-24 yr), 3.4% (25-49 yr.) and 4.1% (>=50 yr.). Only 25.8%, (1,864/7,233) HIV-infected clients were initiated on ART and the rest (74.2%) were referred to public health facilities. PHSP introduced a linkage confirmation mechanism to help providers confirm linkage to ART through telephone calls to clients and health facility staff or by receiving written referral feedback. This strategy improved the linkage confirmation rate from 54% at the end of September 2016 to 89% by September 2017.
Conclusions/Next steps: Based on these findings, engaging private health facilities is essential to achieve 90-90-90 targets to reach HIV epidemic control. Furthermore, the high positivity rate indicates that high-risk populations may prefer private health services and requires further analysis to better understand preferences for accessing HIV care and treatment.

THPEE784

In-service biomedical training in Kenya: Upskilling technicians on lab equipment critical to the HIV clinical cascade

S. Goldfrank[1], P. Anyango[2], W. Arneson[3], V. Freeman[3]
[1]American International Health Alliance, Washington, United States, [2]American International Health Alliance, Nairobi, Kenya, [3]University of Texas Medical Branch, Galveston, United States

Background: Kenya has a national HIV prevalence rate of 5.6% with prevalence in select counties as high as 24.8%. Kenya's network of 2,500+ public health labs plays a key role in the country's efforts to address HIV/AIDS. Most Kenyan biomedical engineers and technicians (biomeds) lack capacity to conduct routine equipment maintenance and repair, which impedes accuracy of lab diagnostic services necessary for effec-

tive HIV/AIDS care and treatment. Limited workforce capacity also hinders the country's efforts to increase its number of accredited labs and their diagnostic capabilities.
Description: American International Health Alliance (AIHA), the Kenya Ministry of Health's (MOH) National Public Health Laboratory Services (NPHLS), and the University of Texas Medical Branch are implementing an in-service training program designed to upskill biomeds in equipment maintenance and repair targeting laboratory equipment supporting HIV diagnostics. With support from President's Emergency Plan for AIDS Relief (PEPFAR) and U.S. Centers for Disease Control and Prevention in Kenya, the project focuses on NPHLS labs and 17 county/sub-county facilities in 10 high HIV burden counties. AIHA trained 19 biomeds and 6 TOTs to step down training to new counties as the project expands to ensure sustainability and increased local capacity.
Lessons learned: In 2017, NPHLS conducted a rapid response intervention (RRI) to prepare 43 labs for accreditation. Biomeds trained in the initial project counties performed routine servicing and verification of 385 pieces of equipment in labs, a function formerly outsourced at high cost. At the beginning of the RRI, 24 labs scored ≤1star rating using the WHO SLIPTA checklist; at the end of the RRI process, 18 advanced to ≥2 star rating. At the beginning of the RRI, only 7 target labs were at ≥3 star rating, but at the end of the RRI 12 labs scored ≥3 star rating with a big component on equipment management.
Conclusions/Next steps: Biomeds play a vital role in Kenya's sustainable approach toward attaining laboratory accreditation and reaching global 90-90-90 targets. This comprehensive program has built Kenya's lab capacity, decreased costs, increased quality of labs across the country, and can be readily replicated in other countries.

THPEE785

Nutrition status of PLHIV in drought-affected regions of Kenya

M. Josephine Muthoni[1], C. Ouma[2], M. Mumma[3]
[1]UN World Food Programme, VAM, Nairobi, Kenya, [2]UN WFP, Nairobi, Kenya, [3]UN World Food Programme Regional Bureau Nairobi, Nutrition, Nairobi, Kenya

Background: With Kenya classified as a UNAIDS fast track country and with the fourth largest HIV burden globally, progress has been made in reversing the HIV trend in Kenya but new HIV infection still occurs among young people and key populations. HIV response in ASAL areas remains a concern due to the paucity of information on the impact of drought-related shocks on PLHIV. Gaps persist in the prevention of mother to child transmission, antiretroviral treatment coverage, coverage, distribution of health facilities and personnel. The study aimed to establish the effects of drought on nutrition and wellbeing of PLHIV.
Methods: A mixed methods research approach was used in data collection Kilifi, Kitui, and Turkana. Three comprehensive care clinics (CCCs) from each county were selected as the entry point. The study population comprised of children aged 2 to 14 years and adult men and women. the sample size was 424 for each county. The levels of malnutrition were assessed using BMI and Z scores. Data analysis was conducted using SPSS v24.
Results: Global and Severe Acute Malnutrition were 24.3% and 8.3% respectively. underweight and stunting was 35.4% and 45.8% respectively. A significant change was observed in nutritional status of children from enrolment to the present. The mean (SD) stunting Z score increased from -1.34 (2.09) to -1.75 (2.12); underweight reduced from -1.73 (1.46) to -1.60 (1.40) while wasting mean Z score reduced from -1.37 (1.86) to -0.83 (1.81). Prevalence of underweight in children aged 2-14 years was 25%. BMI for age score was -1.4 (1.6). Prevalence of underweight in adults was 30.2%. More males (41.7%) were underweight compared to females (26.1%).
Conclusions: Acute Malnutrition is highly prevalent among PLHIV in drought-affected semi-arid and arid lands. Programmatic gaps in nutrition and food support between humanitarian and HIV sectors exist. Family food support in PLHIV households should be planned for and costed as part of HIV programming during a drought in ASAL areas. The CCCs should mimic the humanitarian response during drought to achieve treatment goals for PLHIV.

THPEE786

CheckME™: An integrative Smartphone app for HIV/STI prevention and sexual health promotion tailored for MSM in Portugal

C. Farinha[1], R. Freitas[1], L.M. Carvalho Rocha[1,2]
[1]GAT - Grupo de Ativistas em Tratamentos, CheckpointLX, Lisbon, Portugal, [2]Coalition PLUS Community-Based Research Laboratory, Paris, France

Background: Smartphone apps for HIV/STI prevention in MSM are promising yet scarce, hence the recommendation from ECDC to its development and use. CheckME™ is an app tailored for MSM in Portugal, including for PLHIV, and aims to increase their sexual health literacy and health-seeking behavior.
Description: CheckME™ integrate services such sexual health info, HIV risk self-assessment tool, HIV/STI prevention and harm reduction services map, health-related checkups reminders, sexual partners record, partner notification and venues map. It was developed by GAT in partnership with AHF and Coalition Plus with the support of the Directorate-General of Health. Critical steps: MSM-led project, focus groups to assess acceptability and added value services, benchmarking of related apps, content development linking health professionals and peers, app for both iOS and Android Smartphone´s system, MSM app ß-testers group and marketing plan connecting community and institutional partnerships.
Lessons learned: From July to December 2017, CheckME™ counted 4303 downloads. It can promote health information-seeking behavior (310 did an HIV risk self-assessment) and health-seeking behavior (456 click in the prevention map to call testing/harm reduction sites) and it offer an acceptable venue to store sexual health self-management data (169 used the calendar for medical appointments and/or medication).
Conclusions/Next steps: CheckME™ followed existing recommendations and acceptability data, promoted community participation and partnerships. CheckME shows potential for high uptake in the MSM community, and the wide array of functionalities makes it an easily accessible prevention, personal health monitoring and health connection tool. Community involvement in the design of the app facilitates uptake by providing a mix of health related functions and community suggested functionalities, and should be considered when developing similar tools. Continuous feedback will allow the app to maintain its relevance and foster further adoption by the community.

THPEE787

Building effective partnerships to achieve the 90-90-90 treatment targets: Lessons in advocacy from Uganda

M. Dombo[1], W. Kidega[1], K. Gray[2], J. Gaberu[3]
[1]PATH, Kampala, Uganda, [2]PATH, Washington, D.C., United States, [3]PATH, Advocacy for Better Health, Kampala, Uganda

Background: Uganda was one of the first countries to register significant achievements against the HIV/AIDS epidemic—but there are still thousands of new infections each year. The 90-90-90 treatment targets provide a framework for realizing the Presidential Commitment to end HIV/AIDS by 2030, yet gaps in human resources for health (HRH) and inadequate funding threaten progress. USAID Advocacy for Better Health (ABH), implemented by PATH and Initiatives Inc., has built successful partnerships to advocate for increased domestic financing and retention of skilled workers—both essential in meeting 90-90-90 targets.
Description: In 2017, the Ministry of Finance proposed a 30% cut to the national health budget. ABH convened more than 20 civil society partners to highlight expected impacts on service delivery, develop a position paper, and host discussions with the Parliamentary Committee on Health. With the support of Parliament, cuts were averted. ABH has also forged partnerships to protect the health workforce. Advocates realized the HRH gap—estimated at 25,000—would be exacerbated if government failed to absorb 2,000 PEPFAR-contracted staff into public service. ABH and IntraHealth convened six government ministries, Parliamentarians, hospital directors, donors, and civil society organizations to form a

multi-sectoral task force, chaired by the Ministry of Health (MOH). The task force completed a detailed analysis of PEPFAR staff and developed a roadmap for absorption, to which the MOH committed.
Lessons learned: Through partnership, ABH has turned policymakers into champions. The project has spent significant time cultivating relationships with Parliamentary caucuses and committees and has become a trusted source on health issues. ABH also provides platforms for civil society and people living with HIV to engage in national-level policy conversations, whose voices can galvanize policymakers. Finally, complex policy problems often require action from a number of government ministries. ABH was able to accelerate HRH solutions by establishing a coordinating mechanism and facilitating joint planning.
Conclusions/Next steps: The partnerships advanced by ABH demonstrate the importance of demand-side interventions—namely advocacy and accountability efforts—in addition to service delivery. Both are required to realize the goal of an AIDS-free Uganda. ABH will continue to work with partners and champions to hold government accountable for meeting 90-90-90 treatment targets.

THPEE788

Effectiveness of synergy of HIV prevention and National Hepatitis C Elimination programs in Georgia

M. Gogia[1], K. Stvilia[2], K. Kutateladze[1], I. Khonelidze[3], G. Jikia[1], A. Asatiani[3]
[1]Georgian Harm Reduction Network, Tbilisi, Georgia, [2]National Center for Disease Control and Public Health, HIV Managment, Tbilisi, Georgia, [3]National Center for Disease Control and Public Health, Tbilisi, Georgia

Background: HIV and HCV remain significant public health challenges in Georgia. The most affected risk groups for both infections are PWIDs. Prevalence of HCV in PWIDs that varies between 50-92% illustrates high magnitude of the problem. HCV screening was accessible in harm reduction program since 2006, but due to high cost the treatment was not affordable, especially for key populations. Accordingly no diagnostic and linkage to care services existed in harm reduction program. Government with support of Gilead Pharma and CDC Atlanta started National HCV elimination program in 2015. Strict drug policy represented additional barrier for the program.
Description: In order to react proactively towards its new role for the hepatitis C elimination, GHRN has developed new targeted interventions which were aligned with HIV prevention interventions supported by the GFATM HIV program. The emphasis was placed on increased HIV/HCV tandem screening of PWID population through expanding outreach capacities of the program. For avoiding stigma and self-stigma factors HCV testing was offered to general population as well. Mobile ambulatories expanded the program coverage to 55 cities allowing testing of additional 7,536 PWIDs in 2017. Case managers that were mostly people living with viral hepatitis were ensuring linkage of screening positive PWIDs to HCV treatment sites.
Lessons learned: New model practices allowed 2 times increasing the number of PWIDs tested for HCV in 2016 (26,025) in comparison to 2014 (12,410). 42.6% of testing was conducted through outreach testing by mobile ambulatories. 10,926 PWIDs were referred to HCV treatment sites, HCV education module was included to existing Peer Driven educational program, flyers and brochures about HCV were delivered. At harm reduction sites more emphasize was done on increasing HCV disease awareness, delivering free RNA diagnostic and treatment adherence support.
Conclusions/Next steps: Capacities of the harm reduction programs can effectively be used for early detection, linkage to treatment services for HCV positive PWIDs. Strong Integration between HCV and HIV programs ensures cost-effectiveness of both interventions. Unified screening and treatment databases are critical for success of the elimination program. Besides, initiation of HCV national program enabled initiation dialogue with Police officials to smooth attitude to harm reduction program.

THPEE789

Methadone maintenance therapy uptake, retention, and linkage for people who inject drugs transitioning from prison to the community in Kyrgyzstan: Evaluation of a national program

C. Bachireddy[1], A. Kurmanalieva[2], L. Azbel[3], N. Shumskaia[4], J. Rozanova[5], J. P. Meyer[5], F. Altice[5]
[1]National Clinician Scholar Program, Veterans Affairs Medical Center, University of Pennsylvania, Philadelphia, United States, [2]AFEW Kyrgyzstan, Research Department, Bishkek, Kyrgyzstan, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]AIDS Foundation East - West in the Kyrgyz Republic, Chairperson, Bishkek, Kyrgyzstan, [5]Yale University School of Medicine, New Haven, United States

Background: In Eastern Europe and Central Asia (EECA) the HIV epidemic is accelerating, fueled by people who inject drugs (PWID) and concentrated in prisons. In Kyrgyzstan, 35% of prisoners are PWID, and 10% have HIV. Kyrgyzstan was the first country in EECA to provide methadone maintenance therapy (MMT) in prisons for HIV prevention. Official criteria for MMT prescription in prisons were: being 18yo+, having an opioid dependence diagnosis (consistently having ≥ 3 ICD10 symptoms like injection marks, opioids in urine during the previous year), and willing to participate. We assessed this program for: 1) MMT uptake and retention in prison; and 2) linkage to MMT upon release.
Description: Patients initiating MMT must be ≥18 years and opioid dependent. De-identified administrative data for PWID in Kyrgyzstan who had ever initiated MMT in prison from 2008-2014 were analyzed for MMT dosing, and correlates of linkage to community MMT post-release (for those who were released to the community).
Lessons learned: From 2008-2014, 916 prisoners initiated MMT. At end-of-year 2014, 19% (498) of the estimated (by biobehavioral survey) 2,670 prisoners PWID (before/during prison) were receiving MMT. Most MMT clients were men (97%) in their late 30s (Mean=38 years). Mean daily maximum (72mg) and last (43mg) MMT dose was low with mean treatment duration=8 months. Almost half (46%) discontinued prison MMT voluntarily or because they violated the MMT contract in-prison. Over the six years of observation, 22% (n=198) of prison MMT participants were released from prison, of whom 26% (n=52) and an additional 30% (n=59) linked to community MMT within 7 days and 90 days, respectively. Pre-release MMT dose ≥80mL/day was an independent correlate of linking to community MMT post-release (aOR=1.9; 95%CI=1.1-3.3).
Conclusions/Next steps: In the only evaluation of MMT within prison in EECA, MMT coverage and retention on treatment should be increased for HIV prevention needs with considerable room for improvement. Interventions to increase coverage should include behavioral interventions like screening, brief intervention and immediate treatment (modified SBIRT) with MMT to improve uptake (i.e., acceptability) and quality prescribing of higher MMT doses to improve retention, especially to ensure better continuity of treatment and HIV prevention post-release.

Public-private partnerships

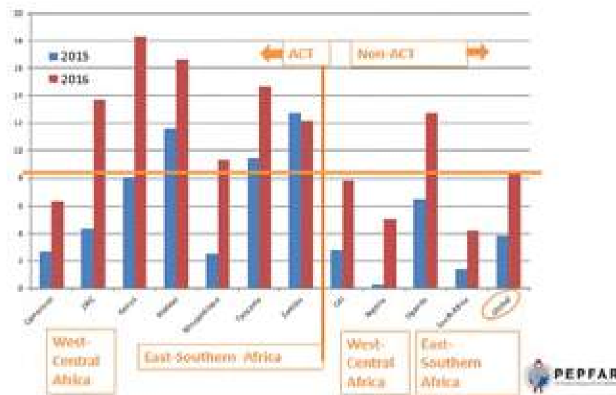
THPEE790

Role of partnership in the Accelerating Children's HIV/AIDS Treatment (ACT) initiative

L. Marks[1], J. Robinson[2], K. Harrison[3]
[1]Office of U.S. Global AIDS Coordinator and Health Diplomacy, Washington, United States, [2]Children's Investment Fund Foundation (UK) (CIFF), London, United Kingdom, [3]Avert, Brighton, United Kingdom

Background: Partnership between funders plays a vital role in tackling the AIDS epidemic. But how do partnerships form, how is value leveraged and maximized, and how can partnerships achieve policy change? These questions will be explored through the specific example of the Accelerating Children's HIV/AIDS Treatment Initiative (ACT), an ambitious public private partnership which successfully scaled up access to pediatric treatment in nine African countries over two-years.

Description: The abstract considers how the PEPFAR/CIFF partnership formed, and the differing styles and contributions both organizations brought to the ACT Initiative. ACT enabled 561,000 children to receive ART, Pediatric ART coverage increased by 10% or more from 2014-2015 in most of the ACT countries, and PEPFAR now supports nearly 1.1 million children on ART globally. The partnership also influenced policy at the global and national level. The abstract reflects on whether working in partnership was more or less effective than independent funding, with some reflections on the values and challenges of collaboration.
Lessons learned: Both PEPFAR and CIFF entered the ACT partnership with the belief that they could achieve more by working together than by working alone. Part of the success of ACT achieving results over an expedited time frame was achievable precisely because of joint planning and collaboration between the partners. Not only did this partnership demonstrate programmatic results; it also justified that the value proposition of working in partnership superseded the transaction costs. As a result of working in partnership, PEPFAR and CIFF were able to reach more pediatric patients in a quicker manner, better grounded in technical learnings across partners, and with greater chance of long-term systemic change.
Conclusions/Next steps: Partnerships clearly bring a combination of challenges and opportunities. Wise funders will work together to clarify the type of partnership they want to engage in, and will undertake a robust cost-benefit analysis before collaborating. They must be prepared to invest additional time and funding to service the partnership itself. The ambition of the ACT initiative, and the commitment of both funders and all their partners, led to broader gains than might have been expected, with global improvements in pediatric ART coverage and policy changes.



[Increment in % ART coverage (from 2014)]

THPEE791

Dating app and HIV - making possible an international partnership within the Brazilian government

J.G. Netto[1], J.A. Paz Paz[1], D. Callisto[1], V. Araujo Rocha[2], A. Schwartz Benzaken[1]
[1]*Ministry of Health of Brazil, STI, AIDS and Viral Hepatites, Brasilia, Brazil,* [2]*Global e-Network of People Living with HIV, Brasilia, Brazil*

Background: The Ministry of Health of Brazil (MoH) was contacted by the international dating app Hornet, focused on gay, bisexual, and other men who have sex with men (MSM), and this initiative resulted in the Close Certo project - a no-costs partnership during Rio2016 (Olympics and Paralympics games), that included UNAIDS and UNESCO also. Along with the reached goals, many lessons from this were left in terms of how to make an international partnership with dating apps possible.
Description: The project involved 18 young gay men volunteers. They labeled their online profiles on Hornet to chat on HIV prevention, diagnosis and treatment - some of them opened up their serostatus. MoH remotely coordinated all meetings with Hornet and volunteers through Skype, WhatsApp Messenger and chats that often occurred late night. It also provoked a discussion within the volunteers on news fields and forms for activism. For the Brazilian MoH, it was an unprecedented international partnership, and provoked an internal discussion in depth in different hierarchical levels.
Lessons learned: The volunteer's autonomy was discussed in depth in the MoH, for example, whether the volunteers should meet the users in person, as global Hornet users do. Hornet supported a more flexible approach, with more autonomy.
Similar experiences with governments had not involved online chat and it was not necessary to sign a term of partnership, as the Brazilian policy demanded. Around 1,000 messages were exchanged and the most common subjects was PrEP, PEP, testing and life after HIV diagnosis.
This experience created an "e-health culture" within the MoH, and made possible to develop ongoing projects. A working group is currently discussing eHealth strategies to support PrEP as a public policy.
Conclusions/Next steps: eHealth strategies can be part of international partnerships with governments, international organizations and civil society activists; however, the traditional way in which partnerships are usually developed in governments need to be updated to follow the new trends in tech partnerships.
UN organizations played a crucial role: they raised the voice against prejudice when the project was criticized for being focused on gay, bisexual and MSM, under an approach that the government was not able to.

THPEE792

Increasing the pool of health workers available for HIV care and treatment services in Kenya through sustainable financing—the Afya Elimu Fund

P. Milo[1], I. Wanyoike[1], J. Gachari[2]
[1]*IntraHealth International, Nairobi, Kenya,* [2]*Higher Education Loans Board, Nairobi, Kenya*

Background: Kenya has a health workforce-to-population ratio of 1.3:1000, far below the World Health Organization recommendation. Access to training fees is a challenge for qualified high school students interested in pursuing medical education. For many families in Kenya, the USD 4,280 required for a nursing diploma program is beyond reach.
Description: In 2013, USAID, through IntraHealth International, and in partnership with the Ministry of Health (MOH), Higher Education Loans Board, and the private sector, established the Afya Elimu Fund (AEF). AEF is a revolving fund that offers tuition fee loans (4% interest rate, compared to 14% for commercial loans) to health professional students, including critical cadres for HIV services. Loan eligibility criteria consider student's family income, orphaned status, gender, disability status, and county of origin (e.g., hardship; high HIV disease burden). A technical working group spearheading AEF implementation and an oversight committee chaired by MOH enhance operational efficiency and prudent governance. Resource mobilization strategies and appropriate financial management systems are in place to raise funds as well as monitor fund performance.
Lessons learned: As of December 2017, 12,607 beneficiaries (51% female) that include nurses, clinicians, medical laboratory technologists, pharmacists and health records officers, had accessed tuition fee loans from 47 counties. 10,359 (82%) of beneficiaries were from 27 high HIV-burden counties. 4,105 beneficiaries have graduated and were available for employment, of which 776 [18.9%] (F-52%; M-48%) are employed in public, private and faith-based health facilities that offer HIV services including testing and counseling, care and treatment, prevention of mother-to-child transmission and laboratory investigation.

[Afya Elimu Fund resource mobilization per academic year 2013-2017]

USAID has provided USD 3.492 million, while resource mobilization efforts from private corporations, national and county governments have raised an additional USD 5.237M, for a total of USD 8.729M in the fund. AEF fundraising strategies targeting private sector and government ensure alignment with shared values and corporate social responsibility initiatives. Stakeholder buy-in was critical in setting up AEF as a vehicle for medical education financing.
Conclusions/Next steps: AEF is positioned to increase medical education access through sustainable public-private partnership financing, thereby increasing the number of graduating health workers for HIV services in Kenya.

THPEE793

Creating open public-private forums can ensure the success of private sector HIV/AIDS service delivery in Côte d´Ivoire

A. Kouakou[1], S. Hefner[2]
[1]Abt Associates, Abidjan, Cote D'Ivoire, [2]Abt Associates, Rockville, United States

Background: With a generalized HIV epidemic and total adult (15-49 years) prevalence rate of 2.7%, Côte d´Ivoire contends with one of the highest HIV prevalence rates in West Africa. Although the private health sector accounts for 40% of total health care service provision (EU 2008), there has been limited public-private collaboration in national HIV policy development and coordination of health activities. Strengthening the private sector's ability to deliver quality HIV and ART services could be a powerful way to accelerate the national HIV response.
Description: From 2013 to present the Strengthening Health Outcomes through the Private Sector (SHOPS) and then the Private Sector Health Project (PSHP) worked with a broad range of public and private partners to advance multi-sectoral collaboration in Côte d'Ivoire's HIV response. Nationally, SHOPS worked with government and private sector umbrella bodies to agree upon and formalize the legal and regulatory permissions required for the private sector to offer HIV care and treatment in accordance with national policy. At the district level, the projects established 12 public-private HIV and AIDS fora involving 150 private clinics in 16 health districts.
Lessons learned: By creating an open forum for stakeholders the projects established a strong legal, regulatory, and operational platform for private health sector provision of HIV and AIDS services. In 2013 the Minister of Health released a memo allowing private health clinics to offer government-provided ARVs for free to their clients, for a truly multisectoral HIV response. SHOPS created and PSHP supports a public-private steering committee that regularly discusses service provision challenges and opportunities. District-level fora operationalized these new permissions and now support 150 clinics in regularly reporting their data into the district and national HMIS, a first for the private sector. The private and public sectors are willing to collaborate, however a neutral outside facilitator needs to steward the process and support all stakeholders in taking joint action to achieve HIV and AIDS priorities.
Conclusions/Next steps: PSHP will scale the public-private fora approach to additional high-prevalence districts. With sustainability in mind, PSHP has begun building ACPCI's technical and managerial capacity to ensure private sector clinics will be supported after PSHP ends in 2020.

THPEE794

Collaborative efforts for improving TB services: A case of PS Kenya in Nyanza region of Kenya, private sector

C. Kanari
Population Services Kenya, HIV/TB, Nairobi, Kenya

Background: Despite evidence that close to 50% of the Kenyan population, including those from the poorest quintile, seek health services in private facilities (Marek et al 2005), only 18% and 8.2% of private providers provide TB diagnostic and treatment services respectively (NTLD, 2011). Key bottlenecks to increasing case detection in the small-medium private sector include ; low capacity of providers to screen TB patients; inadequate infrastructure with poorly ventilated facilities; lack of lab facilities; and low motivation due to the additional effort and resources needed to manage TB patients. With funding from TB Reach, PS Kenya targeted to increase TB case finding and management in private clinics. Nyanza has the highest number of notified TB cases in the country (21,185 cases in 2009) largely driven by a high HIV/AIDS prevalence of 15% (KAIS 2014) but coincidentally lower than average notification rates 325/100,000 against a national average of 338/100,000. One main challenge in the program was the insistence by MOH that TB services in the private sector should be offered for free, as they received drugs and some lab commodities from the government. Providers argued they needed to charge a service fee to cover their time and overheads. In addition, MoH claimed that private providers are only motivated by money and often have poor quality services due to minimal oversight from the MoH.
Description: Health care providers and laboratory staff from 48 health facilities underwent training on early case detection and management in collaboration with MOH and follow up was done via joint support supervision and mentorship. Community engagement was with community health volunteers both for demand creation of TB services, community screening and referral to health facilities and community follow up including defaulter tracing.
Lessons learned: There was an increased 53% private health facilities accredited by the MOH to carry out TB services.
Conclusions/Next steps: In TB service provision it is imperative to collaborate with all health care providers including private sector providers. There is however need to Advocate for policy reviews to support delivery of TB services through the private sector especially around cost of services will be important for continued sustainable provider involvement.

THPEE795

How to make men test early for HIV?

S.M. Afsar, S. Olney
ILO, Geneva, Switzerland

Background: According to the UNAIDS report 2017 - Blind Spot - health systems are failing to reach men.
There is limited HIV testing/treatment coverage amongst men even in developed countries. There is a need to look into the low health seeking behaviour for men and create synergies between health and labour sector.
Description: Out of 4 million workers who took the HIV test from July 2013 to December 2016 under the ILO's global voluntary counselling and testing for workers (VCT@WORK) Initiative, nearly 70% were men. Carefully crafted strategies addressed the reasons that stop men from visiting the health facilities.
The main reasons stopping workers to go for HIV testing were: stigma and discrimination (fear of losing the job in case they were found HIV positive); low risk perception/ lack of information about testing facilities; and the opportunity costs of accessing the services (a daily wage worker may end up losing at least half a day's wage due to travel and waiting time even if the testing is free).
VCT@WORK was implemented within the framework of human rights - in workplaces which had a HIV workplace policy in place. Emphasis was given on dissemination of the policy and reassuring messages by the management as well as union leaders. Communication was built around "the benefits of testing early"; and HIV testing services were taken to workers in order to reduce the opportunity cost for workers. The Initiaive focussed on selected economic sector such as mining, transport, construction, and tourism which engage a high number of mobile and migrant workers.
Lessons learned:
- Workplaces have a huge potential of enhancing access to health information and HIV-TB services to men. This calls for building synergies between the health and labour sector.
- VCT@WORK facilitated results-based public-private partnerships and resulted in covering hard- to- reach groups such as mobile and migrant workers.

- A conducive policy environment needs to be created and gender norms need to be addressed for the success of the initiative.

Conclusions/Next steps:

- Dissemination of good practices and lessons learned under the VCT@WOPK in order to scale up the initiative.
- Pre-test the idea of self-testing with the involvement of trade unions.

THPEE796

Utilizing helpline toll free to support KVP on HIV prevention, testing and treatment - Tanzania case

E. Ndakidemi[1,2], P. Masika[1], B. Luvanda[1], B. Mpora[2]
[1]Tanzania Youth Alliance, Dar es Salaam, Tanzania, United Republic of, [2]Ministry of Health, Community Development, Gender, Elderly and Children, National AIDS Control Program (NACP), Dar es Salaam, Tanzania, United Republic of

Background: Tanzania data shows that the proportion of female and male population groups with comprehensive knowledge about HIV transmission and prevention is 42% for female and 50% for male. Social or cultural norms, stigma and lack of appropriate information remain the challenge that prevents the uptake of treatment and prevention services posing a challenge in reaching 90-90-90 goal. The growing use of mobile phones and text messaging in Tanzania encouraged TAYOA to develop helpline toll free to increase HIV/AIDS knowledge and service uptake. Currently helpline supports core components of HIV/AIDS including counseling and testing, prevention and treatment. The main target are Key and Vulnerable population especially young people and key population.

Description: Helpline is a toll free is a national service providing HIV/AIDS related information including referral to services. The services can be accessed country wide with the support of all mobile companies in Tanzania. Airtime cost is covered by mobile companies to make it free for callers. The free helpline operates from noon to midnight, with 16 lines with trained counselors, it also have an interactive voice response (IVR) that operates 24/7, a referral database with facilities per ward, a cheat sheet to support counselors with guidelines updates. Counselors are trained as per national guidelines and all information in the helpline is approved by the ministry of health. Helpline receive an average of 2000 calls per day, with an average of 300 people speaking directly to the counselors and other listening to IVR.

Lessons learned: 93% of all callers concerted for their information to be recorded, among those 71% of all callers were male. Common subjects includes ART including adherence (29%), Sexual reproductive health information for people living with HIV (18%) Care and support for people who are living with HIV (9%), Counseling and testing (9%), myths and misconception (9%) and PMTCT (4%). 47% are repeated callers, 37% callers reported to seek services after talking to a counselor

Conclusions/Next steps: Helpline is useful source of HIV related information among key and vulnerable population with limited access to health services. NGOs and profit companies can work together to fight HIV.

THPEE797

We "BELIEVE" in responsible community engagement: Overview of structure and outcomes in the BELIEVE collaboratory for HIV cure research at the GWU Milken Institute School of Public Health, Washington, DC

C. Boone[1,2], A.T. Young[1,3], J. Fenech[1], M. Magnus[4], A. Castel[4], D. Nixon[5], R.B. Jones[5], R. Furler[5], R. Strange[1], R. Swanda[1], T.J. Villa[1], E. Sarkodie[1], T. Howard[1], E. Rodriguez Estrada[1], A. Ceranto[1], D. Barros[1]
[1]The George Washington University, BELIEVE Collaboratory for HIV Cure Research, Milken Institute School of Public Health, Washington, United States, [2]The George Washington University, Department of Psychology, Applied Social Psychology Program, Washington, United States, [3]Executive Director - Community Education Group, Washington, United States, [4]The George Washington University, Milken Institute School of Public Health, Department of Epidemiology and Biostatistics, Washington, United States, [5]The George Washington University, School of Medicine and Health Sciences, Washington, United States

Background: In 2011, the National Institute of Allergy and Infectious Diseases at the National Institutes of Health sponsored a five-year program designed to facilitate public- and private-sector collaborative cure research. The Martin Delaney Collaboratory (MDC): Towards an HIV-1 Cure supports emerging curative strategies across key areas of basic and clinical research. As part of this work, in 2016, the NIH funded the "Bench to Bed Enhanced Lymphocyte Infusions to Engineer Viral Eradication" (BELIEVE) Collaboratory site. BELIEVE includes twenty-two collaborating institutions from Brazil, Canada, Mexico, and the U.S.

Methods: Robust community engagement is integral to implementing cure research protocols. This presentation will focus on details of BELIEVE's community engagement efforts, focusing on:

(a) Community Advisory Board (CAB) member recruitment, developing infrastructure for incorporating international partnerships, and organizing annual meetings to build capacity and develop scientific literacy;

(b) integrating input from ongoing community stakeholder appraisals of research protocols;

(c) launching a global survey assessing knowledge, attitudes, and perceptions among seropositive and seronegative people about cure research; and

(d) collaboration with other MDC sites to address ethical and regulatory considerations of developing cellular and genetic therapies toward a functional and/or sterilizing cure.

Results: Complex, novel HIV cure strategies constitute an extraordinary case of research which merits efforts that transcend traditional cooperative structures, that involve more than methodological bench-to-bedside investigation, and more than merely creating a CAB. Educational activities that raise awareness and explain cure research require leveraging networks and grassroots collaboration expertise of BELIEVE's community engagement partners. Successful implementation of cure research requires intentional and extensive collaborations among basic and sociobehavioral scientists; global communities of persons living with HIV and their caretakers; people at highest risk for contracting HIV; clinicians, government, health agencies, and private partners.

Conclusions: Rather than being disconnected from its base communities, BELIEVE has established a global coordinated community with real-time connectivity between stakeholders, ensuring they are effectively engaged throughout discovery, development, and diffusion of ultimately produced therapies. Next steps include ongoing explanation of HIV cure research, harnessing unique opportunities to increase cure awareness and reduce mistrust among communities that may be early testers of innovative cure strategies.

THPEE798

Integrating public-private partnerships in development of youth friendly service in Thailand

W. Pumpradit[1,2,3], V. Danthamrongkul[4], K. Pongpirul[5], P. Srisoontornthai[6], P. Wienrawee[6]
[1]Bumrungrad, Bangkok, Thailand, [2]Bangkok Health Hub, Bangkok, Thailand, [3]PATH, Thailand, Bangkok, Thailand, [4]Chulalongkorn University, Bangkok, Thailand, [5]Bumrungrad Hospital, Bangkok, Thailand, [6]Path2Health Foundation, Bangkok, Thailand

Background: Given escalating sexual health threats and a lack of youth friendly service, we initiated a model of the voucher scheme, community based youth friendly sexual health service in Bangkok since 2007. In addition to a service provider network composed of city community health centers, private clinics, mobile clinic, and private pharmacies in Bangkok metropolitan area, demand promotion strategies including "online clinic" were also introduced. The program aimed to identify features which are able to promote the uptake of sexual health service by youth and to evaluate the utilization of our program.
Description: Focus group discussions were conducted on general youth in 10 schools and 10 Young Key Affected Population (YKAP) groups e.g. MSM, TG, and CSW. Analysis of the service registry during July 2008 December 2010 was performed. Approval from Society for AntiAIDS danger and Life Quality Development for the evaluation was obtained the confidentiality of all study participants was strictly protected. Thematic content analysis and descriptive statistics were used to analyze qualitative and qualitative findings, respectively.
Lessons learned: Findings from the focus group discussions suggested that youth friendly service must be confidential, stigma free, respectful, comprehensive, convenient, free of charge, and with tailor-made promotional strategies. At program inception, 9 city health centers, 13 private clinics, 1 mobile clinic, and 100 private pharmacies joined our program. A total of 17,299 clients (46.11% were younger than 24 years) used the clinics (23,450 visits) during the study period. Of 7,978 youths, 49.56% were female, and 26.50% were still in school. The ratio of a number of youths who utilized private clinics vs city health centers were approximately 40:60. Some challenges encountered during the program implementation were shared.
Conclusions/Next steps: Youth friendly service carefully designed based on inputs from selected youth groups and services provided by a network of public-private providers was well utilized.

THPEE799

Private sector opportunities to deliver oral PrEP to women

K. Muther[1], N. Bhavaraju[2], L. Bernicker[2], P. Jeckonia[3], I. Mahaka[4], S. Mullick[5], E. Gardiner[6], C. Saade[7], K. Torjesen[7]
[1]Last Mile Health, Boston, United States, [2]FSG, Washington DC, United States, [3]LVCT Health, Nairobi, Kenya, [4]Pangaea Zimbabwe AIDS Trust, Harare, Zimbabwe, [5]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [6]AVAC, New York, United States, [7]FHI 360, Durham, United States

Background: Introduction of oral PrEP in Africa has primarily focused on public sector delivery channels. However, a significant number of women and girls at risk for HIV access health services through the private sector. Rapid market assessments can help governments, donors and implementers quickly understand opportunities and considerations for private sector oral PrEP delivery.
Description: We analyzed existing publications, HIV incidence and health services utilization data, and conducted 30 interviews with implementers, donors and policy experts in Kenya, South Africa and Zimbabwe. We developed a framework to prioritize delivery channels based on accessibility and capacity factors.
Lessons learned: Private sector healthcare is widely used by women and girls at risk for HIV driven by convenience, quality, confidentiality and the ability to consistently see a single provider. Utilization is highest in urban areas where HIV incidence is high. Using contraceptive price as a benchmark, private sector healthcare clients may be able to afford an oral PrEP price of ~$5.50/month.
Four private delivery channels were identified for potential delivery of oral PrEP:
· Private doctors due to affordability, reach and capacity to deliver confidential, quality care consistently over time with the same individual.
· Social franchises/NGOs due to their ability to reach lower-income women with high-quality, subsidized care.
· Faith Based Organizations due to their ability to reach rural populations in some countries.
· University clinics due to extensive HIV testing and family planning services for difficult-to-reach populations.
Cost, prescription and testing requirements for oral PrEP likely limit near-term efforts in pharmacies to information dissemination. A mix of private and public channels could reach populations that would otherwise be missed and provide greater confidentiality and privacy. Potential challenges to private sector delivery include limited ability to track patients, affordability and lack of provider HIV specialization.
Conclusions/Next steps: Market assessments of Kenya, South Africa and Zimbabwe found that many women access, prefer and can afford private services. Private sector delivery could help channel public sector resources to those who cannot pay. Governments, donors and implementers should consider a portfolio of private sector channels to expand oral PrEP access and should explore cost-sharing public-private partnerships.

THPEE800

Increased HIV testing and case finding in diverse clinical settings targeting young men who have sex with men in Bali

H. Luis[1], N. Adnyana[2], S. Wignall[1]
[1]Bali Peduli, Denpasar, Indonesia, [2]Sayan Ubud II Government Health Center, Ubud, Bali, Indonesia

Background: Indonesia is one of the few countries in the Asia Pacific region where HIV infections continue to rise. Among MSM in Indonesia, the rates of HIV have increased from 5.35% in 2007 to 25.8% in 2015, with HIV prevalence reaching 36 % among MSM in Bali.
HIV testing and care services in Indonesia have barriers such as cost, inconvenient clinic hours, stigma, confidentiality, discriminatory from health care workers, unsupportive cultural and religious values.
Description: Integrated clinical services for predominantly young MSM Bali were developed in a physician's private practice and in a government health facility. Services provided are free included HIV rapid tests with confirmation, syphilis testing, simple lab for rectal and urethral samples, hemoglobin, blood chemistry, CD4 testing, viral load and PCR for chlamydia/gonorrhea (Xpert). HIV+ clients initiated ART on the same week (Rapid ART). An SMS reminder system supported adherence and follow-up testing for negatives. Staff were trained to provide non-judgmental services regardless of sexual orientation/practices. Clients were encouraged to refer friends to the clinic and services were marketed through websites and social media.
Lessons learned: Clinic attendance remains high with over 200 new predominantly young MSM clients testing monthly. From September 2011 to December 2017, 11,115 patients enrolled with 33,895 visits (include follow up visits) documented. 12,333 clients were tested HIV, of which 1,140 were diagnosed HIV+ (9.24%). 891 patients were started on ARV. Total 9,667 Syphilis serological screening test were performed, 679 (7.02%) were early syphilis & 221 (2.28%) were latent syphilis. 2,827 cases of other STIs were diagnosed and treated. Most clients reported attending via peer and friend referrals, not through a paid peer outreach worker.
Conclusions/Next steps: Free, friendly, efficient, one-stop services can create demand and attract high numbers of young MSM, even in settings where social and religious norms are not conducive to overt community mobilization. Demand-generating characteristics were shown to be successful in a variety of clinical settings such as a private doctor's clinic and a government health facility. Such settings can provide youth-friendly MSM services by following a recipe of stigma-free and convenient services coupled with cost-efficient peer referral and use of social media.

Corrections to community care: An innovate partnership to ensure HIV linkage to care and viral suppression for incarcerated individuals in New York state prisons

R. Cook[1], C. Koenigsmann[2], C. Marra[2], R. Riordan[2], B. de Leon-Stevens[1]
[1]New York State Department of Health, AIDS Institute, Albany, United States, [2]New York State Department of Corrections and Community Supervision, Albany, United States

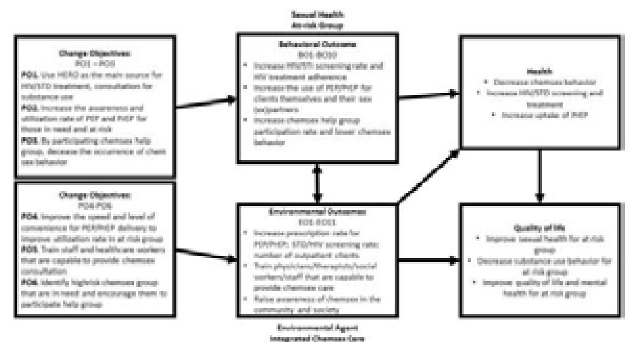
Background: The NYS Department of Health (DOH) and NYS Department of Corrections and Community Supervision (DOCCS) Corrections to Community Care model offers a public health opportunity to proactively engage incarcerated individuals and provide education, facilitate HIV testing and disclosure of HIV status, and support continuous care for individuals living with HIV both during incarceration and following community reentry.
Moreover, it serves as a pathway to assist incarcerated individuals living with HIV as they prepare to transition into the community and support positive health outcomes and self-sufficiency. They gain the knowledge and skills necessary to effectively self-manage and navigate the full continuum of HIV care and support that is available in the correctional facility and, once released/discharged, in the community.
Description: Incarcerated individuals and individuals being released from correctional settings who are living with HIV are offered increased access to care to improve the overall coordination of health and support services including behavioral health services, health care coverage, social and support services such as housing, substance use treatment, education, mentoring and employment assistance programs, with services and interventions being provided using comprehensive systems navigation in a client-centered manner. Individuals are screened for eligibility, given a readiness and comprehensive behavioral risk and needs intake assessment and then enrolled into an individual-level, multi-session service. A Linkage Action Plan is developed with every enrolled individual that includes appointments to medical care, entitlements, housing arrangements, an HIV/STD/HCV risk reduction plan, and goal setting worksheets to build self-sufficiency.
Lessons learned: Incarcerated individuals and reentrants who are living with HIV experienced improved continuity of care when additional support, coaching and resources are provided that empowers them to disclose their HIV status, engage in medical care and treatment, and achieve and maintain viral suppression.
Conclusions/Next steps: Outcome tracking methods include the completion of client linkage reports that compile referral source, engagement in care, release dates, treatment adherence and viral suppression for each client. Next steps include annual reviews of the reports to guide future service delivery, track viral suppression and retention in care successes, and improve referral and linkage processes for incarcerated and formerly incarcerated persons living with HIV.

THPEE802

An integrated chemsex care and HIV prevention service in Taiwan: The HERO healing, empowerment, recovery of ChemSex model

C. Strong[1], A.-C. Chung[2,3], W.-S. Li[3,4], C.-Y. Pan[5], Y.-J. Chang Chien[5], H.-J. Wu[1], S.-T. Hsu[3,6], N.-Y. Ko[1,2,7], HERO-Taiwan
[1]National Cheng Kung University, Department of Public Health, Tainan, Taiwan, Province of China, [2]Taiwan Love and Hope Association, Kaohsiung, Taiwan, Province of China, [3]Healing, Empowerment, Recovery of ChemSex Health Center, Kaohsiung, Taiwan, Province of China, [4]Kaohsiung Chang Gung Memorial Hospital, Division of Infectious Diseases, Department of Internal Medicine, Kaohsiung, Taiwan, Province of China, [5]Kaohsiung City Government, Division of Disease Control, Department of Health, Kaohsiung, Taiwan, Province of China, [6]Kaohsiung Municipal Kai-Syuan Psychiatric Hospital, Department of Psychiatry, Kaohsiung, Taiwan, Province of China, [7]National Cheng Kung University, Department of Nursing, Tainan, Taiwan, Province of China

Background: The rising trend of combining use of recreational drugs during sex (ChemSex) in Taiwan has become a critical contributor in the HIV epidemic. The existing health care model that tackles substance abuse, sexual health and HIV prevention independently is no longer desirable. A model of integrated health services that simultaneously addresses these health issues and provides a safe environment for people under the influence of ChemSex may effectively improve HIV prevention and quality of life.
Description: We established HERO integrated service (Healing, Empowerment, Recovery of ChemSex) in Southern Taiwan in 2017 to cope with ChemSex epidemic and sexual health problems for at risk population, inspired by the 56 Dean Street model in London. The main services HERO provided include HIV/STI testing and rapid link to treatment, consultation and prescription for pre-exposure prophylaxis (PrEP), and ChemSex support group. To evaluate the effectiveness of the integrated service, we developed an evaluation plan based on the logic model of change at both individual and health service levels. Clients visited the service were asked to fill out an online survey after providing consent. Administrative data were collected to measure changes toward the expected program goals.
Lessons learned: Since HERO opened in November 25 in 2017, there has been 65 clients visited, while 93.8% used HIV screening service, 7.7% received PrEP consultation and 10.8% joined ChemSex support group. The average age was 29.0 years and the majority were males (87.8%) and self-identified as homosexual or bisexual (83.1%). Among all, 38.5% reported having ChemSex in the past month, 23.1% scored moderate anxiety or higher and 6.2% scored moderate depression or higher. Out of five people receiving PrEP consultation, 60% started using PrEP. For the ChemSex support group, 28.6% set their goal to be abstinent, 28.6% would like to stop using substance temporarily and 42.9% not sure what their goals were.
Conclusions/Next steps: HERO as the first integrated service for sexual health in Asia, our experiences and evaluation will provide insight on the development and implementation of integrated health care model for HIV and ChemSex prevention for people under the influence of drugs that engaged in HIV/STI transmission risk behavior.



[Evaluation plan for HERO based on the logic model of change]

THPEE803

Increasing HIV case identification and linkage to antiretroviral therapy through nutrition screening: Lessons learned from the Cote d'Ivoire nutrition and community-facility linkages activity

A. Rurangwa[1,2], E. Kouassi[3], D. N'Dabian[3]
[1]FHI 360, Global Health, Nutrition and Population, Washington DC, United States, [2]FHI 360, Food and Nutrition Technical Assistance Project, Washington, DC, United States, [3]FHI 360 Cote d'Ivoire, Food and Nutrition Technical Assistance, Abidjan, Cote D'Ivoire

Background: Increasing HIV case identification and linkage to antiretroviral therapy through nutrition screening: Lessons learned from the Cote d'Ivoire Nutrition and Community-Facility Linkages Activity.
Description: FANTA led the establishment of partnerships between service providers at 11 health facilities, and 8 social centers and 14 community-based organizations (CBOs), which provide services to orphans and vulnerable children and their caregivers in 8 districts around Abidjan. Health workers screened clients seeking psychosocial support at social centers and CBOs for nutritional status using mid-upper arm circumference. Individuals identified with moderate- or severe-acute malnutrition were referred to a health facility, Nutrition focal points were assigned at each location, registries and forms were developed to facilitate and document referrals between locations. HIV seropositive clients were managed through a case management system, followed for malnutrition treatment, and enrolled in HIV treatment and other support services. A client list, HIV patient appointment schedules and care plans were shared among service providers who communicated to ensure clients received services. Clients lost to follow up were contacted by phone or home visit and counseled to re-engage in care.
Lessons learned: Malnutrition can signal the presence of an HIV infection. Between January 2015 and December 2017, 25,000 clients received psychosocial support at the social centers and community-based organizations, 42% of whom (10,493) were screened for malnutrition. Among those screened, 11% (1,144) had moderate- or severe- acute malnutrition and referred to the health facility. Of those referred, 49% (563) were tested for HIV; 63% (354) of those tested were HIV-positive. 98% of the HIV-positive individuals were initiated on antiretroviral therapy. 116 HIV seropositive individuals lost to follow up were re-engaged in care. The integration of NACS and HIV care delivery and the facility and community partnerships developed through the NCFLA increased HIV case identification and facilitated enrollment into the HIV services, including ART initiation, adherence and retention counseling.
Conclusions/Next steps: NACS services and partnerships developed through the NCFLA in Cote d'Ivoire provided a new gateway to HIV case identification and enrollment into the HIV treatment cascade. Integrated service delivery and context-appropriate community-facility linkages are recommended as part of the response to end the HIV epidemic by 2030.

THPEE805

Early retention in a newly established Medically-Assisted Therapy Clinic in Kenya

D. Naitore[1], A. Ngulu[1], K. Ndede[1], A. Howard[2], M. Mugambi[3], H. Musyoki[3], D. Onyango[4], J. Otieno[5], M. Hawken[1], R. Fayorsey[2], E. Abrams[2]
[1]Columbia University, Mailman School of Public Health, ICAP-Kenya, Nairobi, Kenya, [2]ICAP at Columbia University, Program, New York, United States, [3]National AIDS and STI Control Programme, Ministry of Health, Kenya, Key Populations, Nairobi, Kenya, [4]Kisumu County, Health Department, Kisumu, Kenya, [5]Jaramogi Oginga Odinga Teaching and Referal Hospital, Health Department, Kisumu, Kenya

Background: It is estimated there are 18,347 people who inject drugs (PWID) in Kenya, of whom approximately 1,000 live in the Nyanza region. The HIV prevalence amongst PWID is estimated to be 18%, which is three times that of the general population[1]. This epidemic is driven by unsafe drug injecting practices and risky sexual behaviour. Medically-Assisted Therapy (MAT) is the supervised use of methadone replacement therapy for PWID to treat drug addiction, and is an important risk reduction strategy for HIV.
Methods: In March 2017, a MAT clinic was established at the Jaramogi Oginga Odinga Teaching and Referral Hospital (JOOTRH) in the Nyanza region, Kenya. The clinic adopted a one stop shop model offering integrated HIV, TB and methadone treatment services. Clients are referred from a community drop-in center and screened for suitability for MAT. The MAT clinic offers HIV testing and counseling, Hepatitis B and C screening, STI screening, psychosocial support, ART for those who are HIV-positive, and TB screening and treatment. Staff were trained on national guidelines and clinic standard operating procedures.
Results: During a 10-month period from March to December 2017, 83 adults were screened for eligibility and 70 eligible patients were identified and initiated on MAT. Among the 70 who initiated MAT, 7 (10%) were female and 63 (90%) were male. Ten (14%) tested HIV-positive of which 100% were initiated on ART, and 7 (10%) were Hepatitis B surface antigen positive. One client had MDR-tuberculosis and was started on directly-observed therapy. Amongst the 53 clients who were receiving MAT services for 6 months or more, the 6-month retention rate for methadone treatment was 79% (42/53).
Conclusions: ICAP successfully established the first MAT clinic, with integrated HIV services at JOOTRH in western Kenya. The majority of clients served were men, and initial retention rates in methadone treatment have been good. Going forward strategies to further increase clinic referrals and uptake of MAT services should be explored.

FRAD01 Bound and gagged: Exposing the impact of the expanded Mexico City policy

FRAD0101

The Mexico City Policy and PEPFAR: Estimating the impact on NGOs and funding

K. Moss, J. Kates
Kaiser Family Foundation, Washington, United States

Background: In January 2017, President Trump reinstated and expanded the Mexico City Policy. In the past, it had required foreign non-governmental organizations (NGOs) to certify that they would not "perform or actively promote abortion as a method of family planning" using funds from any source as a condition for receiving U.S. family planning assistance. In a significant expansion, it now applies to almost all U.S. global health bilateral assistance, including PEPFAR. Among the many questions about the policy's impact is its effect on HIV programs and services. This study sought to estimate the number of NGO recipients of PEPFAR funding who could be subject to the policy as well as the amount of funding they receive.
Methods: We analyzed data from ForeignAssistance.gov over the most recent three-year period for which such data were available (FY 2013 - FY 2015) to identify NGO recipients of bilateral HIV assistance as a proxy for the current number of recipients. We also calculated the amount of funding they receive and number of countries they work in. We further stratified these countries by the legality of abortion.
Results: We identified 470 foreign NGO prime recipients of PEPFAR bilateral HIV funding, who received $873 million. In addition, we identified 274 U.S. NGO prime recipients, accounting for $5.5 billion, who would be required to ensure that any foreign NGO sub-recipients were in compliance. Overall, this funding supported programs in 61 countries. Of these, 36 allow for legal abortion in at least one case not permitted by the policy and 24 do not; one country was not classifiable. These estimates should be considered minimums since we were unable to identify NGO sub-recipients of HIV support, who represent a much greater number and are also affected by the policy.
Conclusions: The expansion of the Mexico City Policy to encompass almost all U.S. bilateral global health assistance, including PEPFAR, greatly extends its reach. While it is still too early to know its ultimate impact on the ground, our analysis indicates that the expanded policy will likely affect hundreds of NGO recipients of PEPFAR support.

FRAD0102

Understanding the global gag rule: How to sustain global health progress amidst the new U.S. policy environment

C. Cooney[1], T. Coenen[2], J. Rucks[3]
[1]*Planned Parenthood Federation of America, Washington, United States,* [2]*Rutgers, Utrecht, Netherlands,* [3]*PAI, Washington, United States*

Background: The global gag rule (also known as the Mexico City Policy) is affecting the global fight against HIV/AIDS on an unprecedented scale by directly applying to PEPFAR-funded programs for the first time ever.
Description: This session will provide conference participants a comprehensive review of the global gag rule, experiences with the policy, expert guidance for implementers, and advocacy opportunities. The presenters will offer a variety of perspectives from both policy experts and implementing organizations and will specifically focus on the expansion to U.S.-funded HIV/AIDS programs and the disproportionate impact the policy will have on women and girls and integrated service provision. Session co-sponsors include: amfAR, AVAC, Center for Health and Gender Equity (CHANGE), Marie Stopes International (MSI), PAI, Planned Parenthood Federation of America, Rutgers, and Stop AIDS Alliance.

Lessons learned: Under previous iterations of the global gag rule from 2001-2009, the policy resulted in a number of harmful impacts, including:
- USAID had to end condom shipments to Lesotho at a time when one in four women in the country was infected with HIV because the Lesotho Planned Parenthood Association, the primary conduit for condoms in the country, could no longer receive U.S. funding under the global gag rule; and
- Between 2002-2006 in Kenya, the global gag rule led to the termination of critical activities run by the Family Planning Association of Kenya and Marie Stopes International (MSI) Kenya—the leading providers of health care to people living in poor and rural communities in the country

This session will highlight these and other examples of the global gag rule's impact, with a focus on both historical and emerging evidence where HIV/AIDS programs and providers are seeing the impact of the policy.
Conclusions/Next steps: This comprehensive review of the global gag rule will provide new insight into the harmful impact of the policy on HIV/AIDS programs and engage participants in a dynamic discussion with policy and program experts on the impact of the policy and implications for future HIV/AIDS policy and programs.

FRAD0103

A model of dis-integration: Unpacking the impact of the global gag rule on HIV-SRHR linkages

L. Orza[1], L. Stackpool-Moore[2], E. Restoy[3], J. Davis[3]
[1]*International HIV/AIDS Alliance, Bridport, United Kingdom,* [2]*Watipa, London, United Kingdom,* [3]*International HIV/AIDS Alliance, Brighton, United Kingdom*

Background: The HIV community has expressed grave concern for what the expanded Global Gag Rule (GGR) could mean for the health and rights of people most affected by HIV. While the impact of the GGR on the provision of reproductive health services is beginning to be understood, little has been done to document the impact of the rule on communities most impacted by HIV, especially on HIV prevention. The International HIV/AIDS Alliance, with support from Sida, has undertaken research in Ethiopia and Zimbabwe to project the potential impact of the GGR on HIV and key population services, and on HIV-SRHR integration.
Methods: This is a mixed methods study combining desk research, statistical forecasting and community engagement (focus groups, stakeholder meetings and semi-structured interviews). It has involved the participation of civil society organizations - including those representing key populations - working on HIV, including through delivering a comprehensive, integrated SRHR agenda.
Results: Preliminary findings forecast that loss of funding to civil society partners implementing integrated HIV/SRHR programmes in all study sites will result in:
- Reduction in access to HIV prevention, testing and treatment services caused by the disintegration of HIV/SRHR services
- Denial of life-saving treatment and essential services to people living with HIV
- The health of people from key and vulnerable populations being jeopardised by restrictions to the package of services they can receive
- Fear that advocacy efforts to maintain or liberalise laws which allow access to safe abortion will be stifled due to confusion, uncertainty, and fragmentation of civil society; however, there is also evidence of civil society seeking creative opportunities for new advocacy collaborations

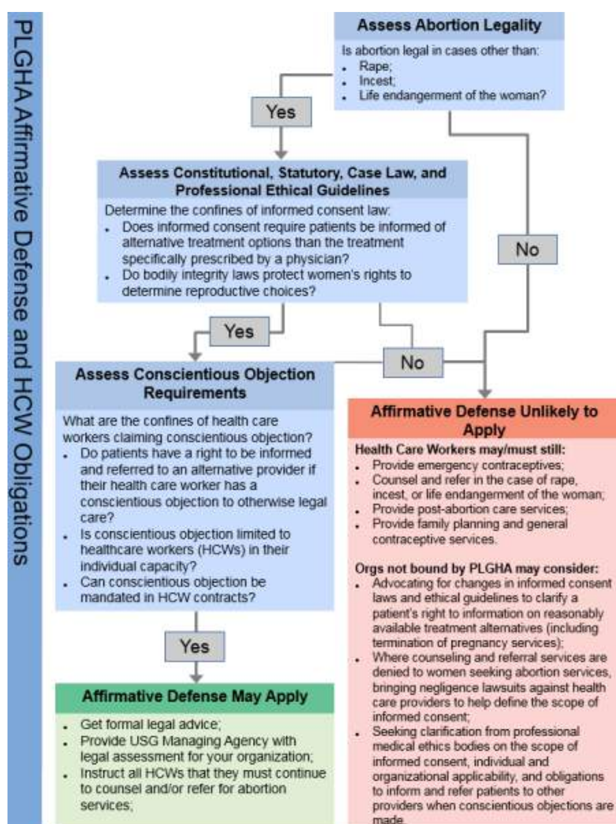
Conclusions: Non-GGR compliant HIV organizations implementing comprehensive integrated SRHR programming have lost tens of millions of dollars in funding. These translate into: cuts to prevention programming for key populations; denial of treatment to people living with HIV; the un-doing of decades of progress to integrate SRHR and HIV programmes, including for adolescents and young people; and a silencing of civil society on issues of individual choice, rights and agency. Despite additional barriers to accessing HIV and SRHR services, examples of community resilience, partnership, and solidarity were identified.

FRAD0104

Caught by ideology: HIV providers in the era of the protecting life in global health assistance policy (AKA Mexico City Policy)

B. Honermann[1], B. Roose-Snyder[2], T. Gonese[3], A. Sharp[1], J. Sherwood[1]
[1]amfAR, Public Policy Office, Washington, United States, [2]Center for Health and Gender Equity (CHANGE), Public Policy, Washington, United States, [3]Southern Africa Litigation Centre, Johannesburg, South Africa

Background: On 15 May, 2017, the US government formally announced the introduction of the Protecting Life in Global Health Assistance Policy (The Policy) - formerly known as the Mexico City Policy (MCP) or the Global Gag Rule (GGR). The Policy prohibits any foreign-NGO receiving Global Health Assistance funding to certify that it will not "perform or actively promote abortion as a method of family planning [...] or provide financial support to to any foreign-NGO that conducts such activities". This includes what an organization is able to do with non-USG funding. Distinct from the MCP, however, was a new affirmative defense against the Policy that states: "[...] in the event of a conflict between [the Policy] and an affirmative duty of a healthcare provider required under local law to provide counseling about and referrals for abortion [...], compliance with such law shall not trigger a violation of [the Policy]."
Description: The expansion of the Policy has significant implications for organizations delivering HIV services globally. For organizations funded for prevention of mother-to-child transmission services, community health worker engagement, and those with integrated family planning and HIV services - most of whom have no prior experience with the MCP - incorporating the Policy is legally complex and ethically dubious. We conducted a legal assessment of the applicability of the affirmative defense in several African countries.



[PLGHA Affirmative Defense and HCW Obligations]

Lessons learned: South Africa has particularly strong Constitutional protections for reproductive rights (sections 12(2)(a) and 27(1)(a)), strong informed consent requirements in the National Health Act and ethical guidelines, and robust case law that compel healthcare providers - including PEPFAR partners - to continue counseling about and referring for abortion services that cannot be circumvented by the Policy. Evaluations in Mozambique, Zambia, and Zimbabwe have found differing levels of protections.

Conclusions/Next steps: The legal and ethical obligations of HIV providers requires assessing the legal landscape in which they are operating and standing up for women's reproductive health choices. South Africa in particular has provided a template that advocates should utilize in pressing for legislation that enables healthcare providers to mitigate some of the substantial harms created by the Policy.

FRAD0105

The impact of the USG Policy Protecting Lives in Global Health Assistance (PLGHA) on Sida's SRHR-HIV partnerships

P. Engstrand[1], M. Hildebrand[2], S. Thomsen[3], Å. Andersson[4], M.-T. Bejarano[5]
[1]Sida, Lead Policy Specialist Health & SRHR, Stockholm, Sweden, [2]Embassy of Sweden / Lusaka, Regional SRHR Team, Lusaka, Zambia, [3]Sida, Senior Policy Advisor Health, Stockholm, Sweden, [4]Sida, Senior Programme Specialist, Health, Stockholm, Sweden, [5]Sida, Research Advisor, Stockholm, Sweden

Background: In January 2017, the USG reinstated the Mexico City Policy (MCP) expanding its scope beyond Family Planning Assistance to include US Global Health Assistance (US GHA). In short, MCP/PLGHA prohibits foreign NGOs receiving US GHA to perform or promote abortion, regardless of funding source. Subsequently, Sida adopted a position and guidance on MCP/PLGHA to assist staff to identify potential risks to Sida-supported SRHR programmes should partners decide to comply with MCP/PLGHA.
Description: Between August-September 2017, Sida undertook a portfolio assessment to understand the implications of MCP/PLGHA on 30 of Sida's NGO-partners receiving funding for SRHR incl. HIV. Data was analyzed using descriptive statistics and qualitative thematic analysis.
Lessons learned: One third of Sida's SRHR partners had ongoing US GHA agreements. Of those, two US based NGOs indicated intent to comply with MCP/PLGHA. Six Foreign NGOs choose not to comply with MCP/PLGHA; for these, US GHA contributed between 5 to 60 percent of their total budget. At least ten of Sida's partners had sub-grantees that received US GHA and were considering complying with MCP/PLGHA. In one case a national member association took over program implementation, and will not be required to comply with MCP/PLGHA. HIV organizations providing integrated SRH-HIV services including some level of counselling and referrals for safe abortion care, but that do not provide abortion services or advocacy, were for the first time affected by the expanded scope of the policy. The potential impact and loss of funding led to uncertainties and confusion for the sector which Sida has had to mitigate choosing various strategies including re-programming of agreements.
Conclusions/Next steps: The assessment found that the MCP/PLGHA may potentially cause disintegration of SRH-HIV services and systems, jeopardizing gains made in recent decades for comprehensive SHR-HIV services for adolescent girls and young women who are disproportionate at risk of HIV. MCP/PLGHA may also have a 'silencing effect' on broader SRHR policy reform linked to gender equality and the SDGs. Discontinuation of services compounds the vulnerability of those who are already left behind such as the poorest and marginalised people, people in rural areas, LGBT-communities and people living with HIV, adolescent girls and young women.

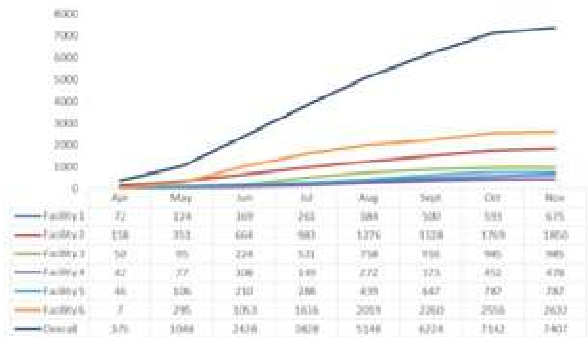
FRAE01 Differentiated treatment models

FRAE0101

Implementation of appointment spacing model of differentiated care in Ethiopia-successes and challenges

T. Assefa[1], Z. Melaku[1], W. Amdino[1], A. Abebe[2], M. Rabkin[3], K. Hartsough[3], R. Fayorsey[3]
[1]ICAP Ethiopia, Addis Ababa, Ethiopia, [2]Federal Ministry of Health, Disease Prevention and Control Directorate, Addis Ababa, Ethiopia, [3]Columbia University, Mailman School of Public Health, New York, United States

Background: There are over 420,645 people living with HIV on antiretroviral therapy (ART) in Ethiopia. This number is expected to increase by 30% with the adoption of Test and Treat by the Federal Ministry of Health (FMOH) in 2016. This poses a challenge to the Ethiopian health system, where shortage of clinical staff is a recurring problem.
Description: To address this issue, ICAP, in collaboration with the FMOH and the Centers for Disease Control and Prevention conducted a pilot of a differentiated service delivery (DSD) six-month appointment spacing model (ASM). ICAP established a technical working group on DSD and developed supplemental guidelines, monitoring framework, provider support tools, and training curriculum for regional and facility service providers. Six high-volume health facilities were included in an ASM pilot, which began in April 2017. Eligible non-pregnant adult patients (stable per World Health Organization criteria) were enrolled in the pilot, which included six- months medication supply, biannual clinical visit, annual viral load testing, psychosocial support, counseling, and encouragement to participate in peer support groups.
Lessons learned: Of the 24,657 clients that were currently on ART at the 6 pilot facilities, 12,649 clients (51%) were eligible for ASM, of whom 49% were enrolled by the 6th month of the pilot. Among the 51% who declined participation, the major reasons cited for refusal to participate in the ASM were fear of inadvertent disclosure due to having a large volume of medication and concerns regarding safety and storage of medication for prolonged periods at home. ASM has been scaled-up to 765 facilities, with 57,000 clients enrolled as of November 2017.
Conclusions/Next steps: Implementation of the ASM in the Ethiopian context demonstrated rapid enrollment of a large number of clients within a short period, and acceptance of the model by clients and service providers. Future work is needed to increase acceptance of ASM model and address common concerns cited by those who declined to take part in pilot. Additionally, work will be needed to evaluate retention on ART and healthcare worker and client satisfaction at 1.5 years on ASM.



[Cummulative ASM enrollment at the six pilot hospitals, Apr-Nov, 2017]

Quick & cheaper: A comparison of patient costs and distance to access care through differentiated models of antiretroviral treatment delivery in Zimbabwe

F. Chirowa[1], N. Ngorima-Mabhena[1], O. Mugurungi[2], I. Mlingo[1], T. Makuve[1], B. Ndidzano[1], E. Tarowera[1], G. Fatti[3], A. Grimwood[3], S. Rosen[4]
[1]Khethimpilo, Harare, Zimbabwe, [2]Ministry of Health & Child Care, Aids and TB, Harare, Zimbabwe, [3]Khethimpilo, CapeTown, South Africa, [4]HE2RO, Johannesburg, South Africa

Background: .Patient transport costs are a significant barrier to accessing antiretroviral treatment (ART), particularly for those living in rural areas of sub-Saharan Africa. As part of a pragmatic cluster-randomized trial to assess the effectiveness of differentiated models of ART delivery for stable ART patients, we compared patient-level costs and travel distance for participants accessing ART at health facilities vs. participants expected to access ART in community ART refill groups (CARGs) in Zimbabwe.
Methods: Patient-level cost data of trial participants were collected at 26 health facilities in both urban and rural areas of five districts between July 2017 and December 2017, using a standardized questionnaire administered by study nurses. At 10 facilities, participants accessed ART directly from the facility, while for the remainder participants were patients in newly formed CARGs, which are groups of 6-12 participants who meet in the community for drug pick-up; patients in CARGs were asked their expectations in joining groups. The average visit cost of accessing care, mean travel distance and time spent per visit were compared. Costs included both direct costs and the opportunity cost of attending the appointment, both to the patient and an accompanying person.
Results: Amongst 473 respondents, 260 (55%) received ART at the health facility and 213 (45%) received ART in CARGs. CARG participants had a 89% shorter travel distance to the selected meeting place for a drug pick-up. (0.9 km; 95% CI: 0.8-1.0 km) compared to facility-based participants (8.4 km, 95% CI: 6.8-9.9 km); p< 0.00. The average visit cost for CARG participants is 69.5% lower than facility-based patients (US$1.24 vs. US$4.06, two-way respectively. Travel time to the drug pick up point is lower for CARG participants: 178 (91%) reported travel time for < 30 minutes, while 100% of facility-based patients travelled >30 minutes.
Conclusions: Collecting ART from CARGs has lower visit costs, and patients travel substantially shorter distances with reduced travel times to access care, compared to participants collecting ART from facilities. CARGs are a differentiated model of care offering important benefits to stable ART patients.

Decentralizing and differentiating HIV care for men who have sex with men living with HIV in Guatemala City: Acceptability and retention in care

C. Barrington[1], M.I. Loya Montiel[2], S. Northbrook[3], J.K. Williams[4], J.P. Alvis[2], R. Santa Luce[2], K. Guzman Guerrera[2], R. Pinzon Meza[5], M.E. Anton Urbina[6], M.R. Calderon[2]
[1]University of North Carolina at Chapel Hill Gillings School of Global Public Health, Health Behavior, Durham, United States, [2]Universidad del Valle de Guatemala, Guatemala, Guatemala, [3]Centers for Disease Control, Guatemala, Guatemala, [4]Centers for Disease Control, Atlanta, United States, [5]Hospital Roosevelt, Guatemala, Guatemala, [6]Ministerio de Salud Publica y Asistencia Social, Programa Nacional de Prevención y Control de ITS, VIH y SIDA, Guatemala, Guatemala

Background: Centralized HIV care causes social, time, and cost burdens, which can threaten achieving optimal HIV clinical outcomes and well-being. We conducted the first decentralization pilot in Central America among men who have sex with men (MSM) living with HIV and assessed acceptability, retention in care, and satisfaction.
Methods: This is a longitudinal, intervention study with mixed-methods assessments at baseline, 6 months, and 12 months. We recruited participants consecutively from January to May 2017. Eligibility criteria included $\geq$18 years old, male, self-reported sex with men, diagnosed with HIV, enrolled in care for $\geq$one year without interruption, viral load $\leq$1000 copies/mL, and on first-line treatment. Eligible participants were offered the option to decentralize to one of 3 clinics with tailored services for

key populations (2 NGO and one governmental). Retention in care was defined as attending at least 3 quarterly appointments during 9 months of follow-up. Evaluation methods included socio-behavioral surveys, in-depth interviews, and clinical chart review. Thematic qualitative analysis and descriptive statistics were used to assess indicators and processes related to acceptability and retention in care.

Results: Nearly half (47%) of the 276 participants voluntarily decentralized while 53% opted to stay, with no significant differences between the two groups. Among those who decentralized, 51% (n=66) chose a gay health NGO, 41% (n=53) chose an NGO with a history of HIV prevention and care with key populations, and 8% (n=11) chose a governmental STI clinic. Motivators for decentralization included schedule, location, and type of organization. Only 1 participant opted to re-centralize due to schedule issues and 98% of decentralized participants were retained in care at the third clinic visit during study follow-up. Median duration of the decentralized consult was 30 minutes, compared to 4-5 hours at the centralized clinic. Over 90% of participants across the 3 clinics considered the care they received to be "excellent".

Conclusions: Decentralization to key population-friendly clinics with flexible schedules is acceptable and feasible for MSM. Retention was not negatively affected and participants were highly satisfied with the services provided in the decentralized clinics. These findings are informing policy and practice throughout Central America to differentiate care and improve quality.

Urban adherence clubs in Zambia: Findings from model implementation

M. Roy[1], C. Bolton[2,3], I. Sikazwe[2], M. Mukumbwa-Mwenechanya[2], E. Efronson[2], P. Somwe[2], E. Kalunkumya[2], M. Lumpa[2], A. Sharma[2], J. Pry[2,4], N. Padian[5], E. Geng[1], C. Holmes[6,7]

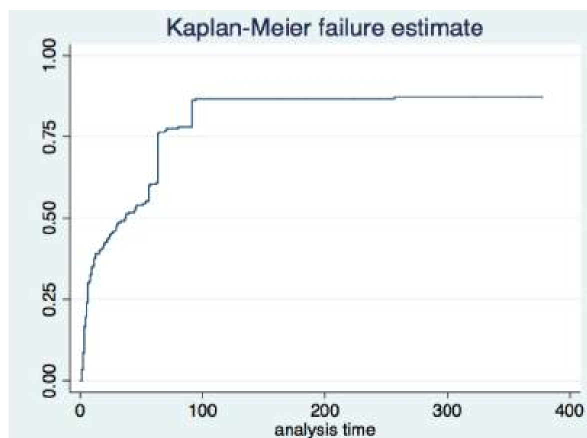
[1]University of California San Francisco, San Francisco, United States, [2]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [3]University of Alabama, Birmingham, United States, [4]University of California Davis, Sacramento, United States, [5]University of California Berkeley, Berkeley, United States, [6]Georgetown University, Washington DC, United States, [7]Johns Hopkins University, Baltimore, United States

Background: The urban adherence club (UAC) model is a differentiated service delivery (DSD) model designed to improve on-time drug pickup and retention in HIV care through off-hours facility access and group drug distribution. Successes during scale-up in South Africa have been tempered by a recent report of high loss to follow-up and transfers back to facility-based care. We sought to characterize retention among patients enrolled in UACs at five urban health facilities in Zambia to evaluate model implementation outside of South Africa.

Methods: As part of a cluster randomized trial, a systematic sample of eligible patients (HIV+, on ART > 6 months, not acutely ill, CD4 >=200/µl) were enrolled in UACs between May 19 & July 29, 2016. Patients were scheduled for bimonthly group drug-pick up meetings in the first six months and every 3-month meetings thereafter. Clinical and pharmacy visit data were obtained through the existing electronic medical record. UAC meeting visit attendance, transfer-outs, and deaths were collected prospectively through October 31, 2017.

Results: Among 592 intervention patients, median age was 41 yrs (IQR: 35-48), 371 (63%) were female, median CD4 count was 411 /µl (IQR: 273 - 559), and median time on ART was 4.0 yrs (IQR: 2.0 -7.2). Out of 3,756 scheduled UAC visits, 685 (18%) were not attended. In 204 (30%) of the unattended visits, patients still obtained medication on the same day: either via a buddy (151(74%)) or same day drug-pick up at the facility outside of the UAC meeting (53 (26%)). Among the 481 (70%) unattended visits where patients did not receive same-day medication, cumulative incidence of drug-pick up after a missed UAC visit was 27% at 14 days and 32% at 28 days (Figure 1). At 12 months, cumulative incidence of treatment interruption (> 14 days late for drug pick-up) was 9.8%, transfer out of UAC was 6.8%, and death was 0.51%.

Conclusions: Group meetings were generally well-attended and in nearly one third of missed meetings patients accessed timely drug pick-up via other means. These findings suggest that group-based care is a viable model of care, although adaptation and patient-centeredness should be prioritized in DSD model implementation.



[Figure 1. Kaplan-Meier survival curve of time to drug pick-up after first unattended group visit]

FRAE0105

The impact of community delivery of antiretroviral therapy on viral load suppression: Findings from a pragmatic randomized non-inferiority trial in Dar es Salaam, Tanzania

J. Francis[1], P. Geldsetzer[2], N. Ulenga[1], D. Sando[2], I. Lema[1], E. Mboggo[1], M. Vaikath[2], S. Lwezaula[3], H. Koda[1], J. Hu[4], R. Noor[2,5,6], I. Olofin[2], W. Fawzi[2,5,7], G. Asmus[8], T. Bärnighausen[2,8,9]

[1]Management Development for Health, Dar es Salaam, Tanzania, United Republic of, [2]Harvard T.H. Chan School of Public Health, Global Health and Population, Boston, United States, [3]National AIDS Control Program, Dar es Salaam, Tanzania, United Republic of, [4]Duke University, School of Medicine, Durham, United States, [5]Harvard T.H. Chan School of Public Health, Department of Nutrition, Boston, United States, [6]Africa Academy for Public Health (AAPH), Dar es Salaam, Tanzania, United Republic of, [7]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [8]Institute of Public Health, Heidelberg University, Heidelberg, Germany, [9]Africa Health Research Institute, Mtubatuba, South Africa

Background: Delivering antiretroviral therapy (ART) to patients' homes and other meeting points in the community using community health workers (CHWs) could reduce patient volumes at healthcare facilities, improve ART adherence and retention, and decrease patients' out-of-pocket healthcare expenditures. This randomized trial in Dar es Salaam aimed to assess whether community delivery of ART is non-inferior to the standard of care in achieving viral suppression.

Methods: We randomized 48 healthcare facilities in Dar es Salaam to either the standard of care (facility-based ART care) or CHW-led ART community delivery. The CHW cadre is a long-standing public sector cadre in Dar es Salaam, called home-based carers. Patients had to be clinically stable on ART to be eligible for ART community delivery. The primary endpoint was the proportion of ART patients in viral failure (viral load >1,000 copies/ml) at the end of the study period. We fitted log-binomial models clustering standard errors at the facility level and computed p-values through randomization inference.

Results: We recruited 1,174 participants at intervention and 998 at control facilities. 521 participants received CHW-led ART community delivery. Mean follow-up was 321 days. 24.5% of participants in the intervention and 18.5% in the control arm were lost to follow-up. The risk ratio (RR) for viral failure in the intervention compared to the control arm was 0.91 (95% CI: 0.72 - 1.12). The p-value for the observed RR being below the margin of non-inferiority (RR=1.45) was < 0.001. Participants' healthcare expenditures over the last six months were not significantly different between intervention and control facilities.

Conclusions: Community delivery of ART by CHWs in Dar es Salaam did not result in inferior viral suppression compared to the standard of care. While ART community delivery did not reduce participants' healthcare expenditures by a substantial amount, it is likely to save ART patients substantial amounts of time and may improve long-term retention in care.

TUAB0106LB

Non-inferior efficacy of dolutegravir (DTG) plus lamivudine (3TC) versus DTG plus tenofovir/emtricitabine (TDF/FTC) fixed-dose combination in antiretroviral treatment-naïve adults with HIV-1 infection - 48-week results from the GEMINI studies

P. Cahn[1], J. Sierra Madero[2], J. Arribas[3], A. Antinori[4], R. Ortiz[5], A. Clarke[6], C.-C. Hung[7], J. Rockstroh[8], P.-M. Girard[9], C. Man[10], J. Sievers[11], A. Currie[12], M. Underwood[10], A. Tenorio[10], K. Pappa[10], B. Wynne[10], M. Gartland[10], M. Aboud[11], K. Smith[10]
[1]Fundación Huésped, Buenos Aires, Argentina, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [3]Hospital La Paz, Madrid, Spain, [4]Istituto Nazionale per le Malattie Infettive Lazzaro Spallanzani, Rome, Italy, [5]Bliss Healthcare Services, Orlando, United States, [6]Royal Sussex County Hospital, Brighton, United Kingdom, [7]National Taiwan University Hospital, Taipei, Taiwan, Province of China, [8]Rheinische Friedrich-Wilhelms Universität, Bonn, Germany, [9]Hôpital Saint Antoine, Paris, France, [10]ViiV Healthcare, Research Triangle Park, United States, [11]ViiV Healthcare, Brentford, United Kingdom, [12]GlaxoSmithKline, Stockley Park, United Kingdom

Background: The requirement for life-long antiretroviral therapy of HIV infection has highlighted interest in 2-drug regimens (2DRs) to minimise cumulative drug exposure. DTG´s potency, safety and resistance barrier make it an optimal core agent for 2DRs while 3TC´s safety, tolerability and efficacy make it an attractive partner for initial HIV-1 treatment.
Methods: GEMINI-1 and GEMINI-2 are two identical global double-blind, multicentre Phase III studies evaluating efficacy and safety of DTG+3TC once daily in treatment-naïve HIV-1-infected adults with Screening HIV-1 RNA ≤500,000c/mL (ClinicalTrials.gov: NCT02831673/NCT02831764). Participants were randomised 1:1 (stratified by Screening plasma HIV-1 RNA and CD4+ cell count) to treatment with DTG+3TC or DTG+TDF/FTC. The primary endpoint is the proportion of participants with plasma HIV-1 RNA < 50c/mL at Week 48 (Snapshot algorithm).
Results: 714 and 719 adults were randomised and treated in GEMINI-1&2, respectively. Participants were well matched for demographic/baseline characteristics. Overall, 20% of participants had baseline HIV-1 RNA >100,000c/mL; median CD4+ was 432 cells/mm³. Based on a 10% non-inferiority margin, DTG+3TC was non-inferior to DTG+TDF/FTC at Week 48 in both GEMINI-1&2 and in the pooled analysis [Table]. Response rates in subjects with baseline HIV-1 RNA >100,000 c/mL were high and similar between arms. Across both studies, 6 participants on DTG+3TC and 4 on DTG+TDF/FTC met protocol-defined virologic withdrawal criteria through Week 48; none had treatment-emergent primary integrase-strand transfer inhibitor or NRTI resistance mutations. Overall rates of AEs were similar between arms, with low rates of withdrawals due to AEs for both DTG+3TC and DTG+TDF/FTC. More drug related AEs were reported with DTG+TDF/FTC. Post baseline changes in markers of bone and renal function favoured DTG+3TC through week 24.

		GEMINI-1	GEMINI-2	Pooled
Snapshot responders	DTG+3TC	320/356 (90%)	335/360 (93%)	655/716 (91%)
	DTG+TDF/FTC	332/358 (93%)	337/359 (94%)	669/717 (93%)
Adjusted Difference (95% CI)		-2.6 (-6.7, 1.5)	-0.7 (-4.3, 2.9)	-1.7 (-4.4, 1.1)

[Proportion of Participants with Plasma HIV-1 RNA <50 c/mL at Week 48: Snapshot Analysis - ITT-E population]

Conclusions: In GEMINI-1&2, DTG+3TC demonstrated non-inferior efficacy to DTG+TDF/FTC in treatment-naïve adults with Screening HIV-1 RNA ≤500,000c/mL at Week 48. Both regimens were well tolerated. Biomarkers of bone turnover and renal function favoured DTG+3TC. The results suggest DTG+3TC is an option for initial treatment of HIV-infected patients.

TUAB0107LB

Non-inferior efficacy for darunavir/ritonavir 400/100 mg once daily versus lopinavir/ritonavir, for patients with HIV RNA below 50 copies/mL in South Africa: The 48-week WRHI 052 study

F. Venter[1], M. Moorhouse[1], S. Sokhela[1], E. Maharaj[1], G. Akpomiemie[1], B. Simmons[2], C. Serenata[1], A. Hill[3]
[1]University of Witwatersrand, WITS Reproductive Health and HIV Institute, Johannesburg, South Africa, [2]Imperial College, Faculty of Medicine, London, United Kingdom, [3]Liverpool University, Pharmacology, Liverpool, United Kingdom

Background: Darunavir/ritonavir (DRV/r) is the most widely recommended protease inhibitor in treatment guidelines. The approved dose of DRV/r is 800/100 mg once daily (QD) for patients with no PI resistance. In the POWER studies, patients treated with a lower dose - 400/100mg QD - showed similar reductions in HIV RNA to the standard dose, with consistent results shown in other pilot studies (DARULIGHT, DRV600). Reductions in the dose of DRV/r could improve safety and lower costs of mass treatment in low- and middle-income countries. Low cost generic DRV/r is becoming available in many countries as patents expire.
Methods: In this study in Johannesburg, South Africa, 300 patients previously stable on 2NRTI+LPV/r with HIV RNA < 50 copies/mL were randomised to 2NRTI+DRV/r 400/100 mg QD (n=148) or continued 2NRTI+LPV/r (n=152). Treatment success was defined as HIV RNA < 50 copies/mL at Week 48 (FDA snapshot). Treatment arms were compared using the new FDA non-inferiority (NI) margin of -4% for switch studies, using the Intent to Treat (ITT) population.
Results: Patients were 68% female and 99.7% Black, with mean age 42 years, CD4 count 621 cells/µL, body weight 72 kg. In the primary efficacy analysis, HIV RNA < 50 copies/mL by Week 48 (ITT) was 143/148 (96.7%) in the DRV/r arm versus 145/152 (95.4%) in the LPV/r arm (Difference = +1.2% (95% CI = -3.7% to +6.2%). Of the 12 patients with failure, 7 had low-level viraemia (50-199 copies/mL), 2 had transient high-level viraemia at Week 48 which resolved after adherence counselling; 3 had missing data. Summary safety data is shown in the table below.
Conclusions: In this study for patients with HIV RNA < 50 copies/mL at baseline, switching to 2NRTI+DRV/r 400/100 mg once daily showed non-inferior efficacy versus 2NRTI+LPV/r in the primary efficacy analysis (96% versus 95%), within the -4% FDA non-inferiority margin for switch studies. For stable patients, switching from LPV/r to DRV/r 400/100 QD would improve convenience and could lower long-term costs. New clinical trials are required to evaluate DRV/r 400/100 mg after first-line treatment failure, where this PI is most widely used.

Treatment arm	2NRTI + DRV/r	2NRTI + LPV/r
Sample size	148	152
HIV RNA <50 copies/mL	143 (96.7%)	145 (95.4%)
Grade 1-4 adverse events	101 (68.2%)	108 (71.1%)
Grade 3-4 adverse events	7 (4.7%)	5 (3.3%)
Serious adverse events	5 (3.4%)	4 (2.6%)
Discontinuation for adverse events	3 (2.0%)	0 (0.0%)

[WRHI 052 trial - 48 week results (n=300)]

To give birth and die: The needs of HIV-positive mothers for retention in longer-term HIV care and treatment in Russia

E. Shastina[1,2], J. Godunova[3], A. Yakovleva[4], E. King[5], I. Evdokimova[3], N. Sukhova[3], E. Titina[6], D. Legchilova[7]
[1]The Association 'E.V.A.', Orenburg, Russian Federation, [2]Autonomous Nonprofit Organization for Prevention of Socially Significant Diseases 'New life', Orenburg, Russian Federation, [3]The Association 'E.V.A.', St. Petersburg, Russian Federation, [4]Sociological Institute of Russian Academy of Sciences, St. Petersburg, Russian Federation, [5]University of Michigan School of Public Health, Ann Arbor, United States, [6]The Association 'E.V.A.', Samara, Russian Federation, [7]The Association 'E.V.A.', Khanty-Mansi Autonomous Ddistrict, Russian Federation

Background: The feminization of the HIV epidemic continues in Russia. PMTCT offers the opportunity to engage women in treatment but Option B+ is not commonly accepted. Little is known about HIV care and treatment retention among women after pregnancy. Our research objective was to identify factors influencing postpartum retention in treatment in Russia.

Methods: We conducted mixed-methods, community-based participatory research in 7 regions across Russia. In phase one, we conducted in-depth interviews with WLHIV and service providers in order to explore and identify factors related to HIV care and treatment among HIV-positive mothers. In phase two, we administered a survey to 200 HIV-positive mothers in order to identify the most salient factors and measure the strength of their association with postpartum treatment. We triangulated study results across sites and sources to draw conclusions. WLHIV played an active role in study design, data collection and interpretation of findings.

Results: 1. The majority of women don't connect ARV with their own health but rather with the goal of PMTCT. Health care providers frequently hold the idea that ARV use is solely to protect the future child and don't encourage women's longer-term use.

2. Psychosocial support is devastatingly low. Lack of counseling has adverse effects on HIV treatment retention. Only 27% received post-test counseling. 80% of women not receiving pre-test counseling during pregnancy reported skipping doses or stopping ARVs postpartum.

3. Every third woman experienced a change in dosage or treatment plan. Taking pills twice daily and side effects were especially difficult postpartum. 25% lacked provider support when experiencing harsh side effects.

4. Single mothers, mothers afraid to disclose their serostatus, and mothers married to AIDS denialists are especially vulnerable to stopping treatment.

5. The majority of women expressed grave financial need -lacking money for food or housing. Financial hardship was associated with poor ARV adherence.

Conclusions: Programs to support HIV-positive mothers are needed across Russia that incorporate education on the benefits of ARV, emphasize valuing one's own health, promote skills (nutrition, lifestyle, sobriety), strengthen social support, and focus on families. Structural issues need to be addressed: including, economic opportunities and availability of quality ARVs.

TUAA02 Strategies for cure: Pitfalls, possibilities and promise

TUAA0202LB

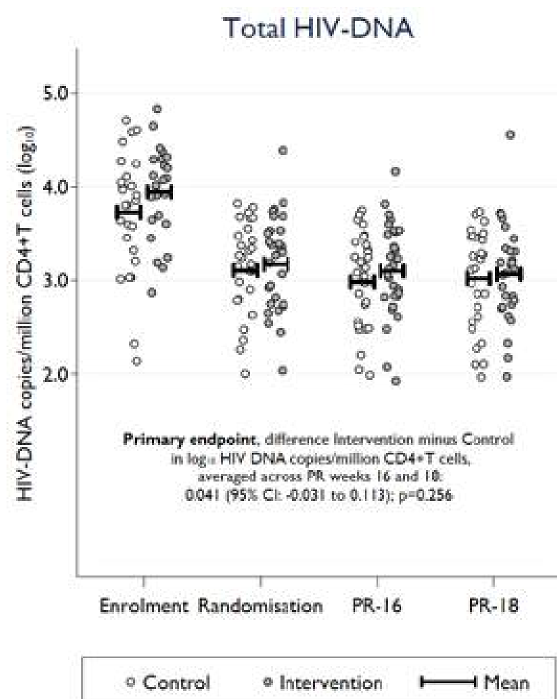
A randomised controlled trial comparing the impact of antiretroviral therapy (ART) with a 'Kick-and-Kill' approach to ART alone on HIV reservoirs in individuals with primary HIV infection (PHI); RIVER trial

S. Fidler[1], W. Stohr[2], M. Pace[3], L. Dorrell[3], A. Lever[4], S. Pett[2], S. Kinloch[5], J. Fox[6], A. Clarke[7], M. Nelson[8], M. Khan[9], A. Fun[4], D. Kelly[10], J. Kopycinski[3], M. Johnson[5], T. Hanke[3], H. Yang[3], B. Howell[11], S. Kaye[9], M. Wills[4], R. Barnard[11], A. Babiker[2], J. Frater[12],
On Behalf of the RIVER trial investigators
[1]Imperial College London, Medicine, London, United Kingdom, [2]University College London, MRC CTU, London, United Kingdom, [3]University of Oxford, NDM, Oxford, United Kingdom, [4]University of Cambridge, Cambridge, United Kingdom, [5]University College London, Royal Free Hospital, London, United Kingdom, [6]Kings College London, Guys & St Thomas Kings, London, United Kingdom, [7]Univeristy of Brighton, Medicine, Brighton, United Kingdom, [8]Chelsea & Westminster Hospital, Medicine, London, United Kingdom, [9]Imperial College London, London, United Kingdom, [10]Patient advocacy Alliance CIC, Manchester, United Kingdom, [11]Merck MSD, Pennsylvania, United States, [12]University of Oxford, Peter Medwar, Oxford, United Kingdom

Background: ART alone is unable to cure HIV because of an inaccessible pool of latently infected cells, the HIV reservoir. In the first randomised controlled trial (RCT) of a 'kick-and-kill' strategy, amongst participants with PHI on ART, we investigated the impact of HIV-specific T-cell vaccines and a latency reversing agent (vorinostat) on the HIV reservoir.

Methods: Individuals who started ART within 4 weeks of confirmed PHI diagnosis with suppressed plasma HIV-RNA were randomised to either ART plus vaccination with ChAdV63.HIVconsv prime < 1 week post-randomisation (PR) and MVA.HIVconsv boost (8 weeks later) followed by 10 doses of 400mg oral vorinostat taken every 3 days (intervention) or ART alone (control).

The two arms were compared for the primary outcome ($\log_{10}$ total HIV-DNA copies/million from CD4+ T-cells at weeks PR-16&18) using analysis of covariance adjusted for baseline level. Secondary endpoints included quantitative viral outgrowth measuring replication-competent HIV-1 reservoir at week PR-16, HIV-specific CD4+ and CD8+ T-cell responses by intracellular cytokine staining at weeks PR-9&12, histone acetylation pre&post vorinostat and adverse events.



[Figure of total HIV DNA by arm]

Results: 60 male participants were randomised at 6 UK sites (30 intervention, 30 control), with median: age 32 years, 26 weeks since ART start and CD4+ count 708 cells/mm³. All participants completed follow-up. There was no difference between the arms in the primary outcome (intervention versus control: 0.041 (95%CI -0.031, 0.113) log10 HIV-DNA copies/million CD4+ T-cells p=0.256), or in the proportion with undetectable viral outgrowth (0.42 (95% CI 0.13, 1.37) p=0.151) Participants with undetectable viral outgrowth had significantly lower total HIV-DNA. Participants in the intervention arm showed significantly higher HIV-specific CD4+ (IFNg/IL2/TNFa/CD154) and CD8+ (IFNg/TNFa) T-cell responses post vaccination than control. Histone acetylation increased 3.2-fold two hours post-vorinostat (p<0.001). There was no virological failure or intervention-related SAE. More clinical adverse events were reported in the intervention arm, all were mild/moderate.
Conclusions: In the first 'kick-and-kill' RCT in PHI, despite evidence of robust vaccine-induced HIV-specific T-cell immunity and vorinostat activity, there was no impact on measures of HIV reservoir compared to ART alone. Vaccination and vorinostat did not raise any safety concerns. Further analyses are ongoing to explore mechanisms to explain these findings.

Evaluation of an antibody to Alpha4Beta7 in the control of SIV infection

M. Di Mascio[1], J.J. Lifson[2], S. Srinivasula[3], P. Degrange[4], B. Keele[2], Y. Wang[1], P. Lusso[1], M. Proschan[1], H.C. Lane[1], A.S. Fauci[1]
[1]National Institute of Allergy and Infectious Diseases, Bethesda, United States, [2]AIDS and Cancer Virus Program, Frederick National Laboratory for Cancer Research, Frederick, United States, [3]Leidos Biomedical Research, Inc, Frederick, United States, [4]Battelle/Charles River-Integrated Research Facility, NIAID Frederick, Frederick, United States

Background: It was recently reported that treatment with an antibody to the a4b7 integrin in rhesus macaques infected with SIVmac 239 having a stop codon in nef (SIVmac239nefstop) was associated with prolonged post-treatment suppression of viremia. The present study was undertaken to try to confirm and extend those observations.
Methods: Twenty-two Mamu-A001, Mamu-B008 and Mamu-B017 negative juvenile to adult Indian rhesus macaques (>4 kg or 3 yrs; mixed sex) were infected intravenously with 200 $TCID_{50}$ SIVmac239nefstop (courtesy F. Villinger). At 5 weeks post-infection (wpi), combination antiretroviral therapy (cART) was started with tenofovir, emtricitabine and L-870812. After 4 weeks of cART, animals received a total of 8 infusions every 3 weeks of primatized anti a4b7 antibody (n=12) or control antibody (n=10); cART was stopped at 18 wpi (after the fourth antibody infusion). Plasma SIV RNA levels had been monitored through at least 33 wpi at the time of abstract submission.
Results: Peak plasma SIV RNA levels averaged ~10^6 copies/ml in both groups. Sequencing confirmed the presence of the expected stop codon in nef in the challenge virus, with restoration to nef open by 5 wpi in all animals. Four weeks after cART initiation plasma SIV RNA levels were < 100 copies/ml in 10/12 experimental group animals and 10/10 controls. Three weeks following discontinuation of cART, plasma SIV RNA levels rose to above 100 copies/ml in 10/12 a4b7-treated animals and 8/10 controls. Fifteen weeks following cART interruption (33 wpi) mean plasma SIV RNA levels were ~ 10^4 copies/ml in both groups and not significantly different
Conclusions: In the present study, administration of an antibody to the a4b7 integrin in conjunction with short term cART was not associated with control of SIV replication following treatment cessation. Follow up studies to explore potential reasons for differences between the present findings and published results will focus on potential antidrug antibody responses and other possibilities.

TUAC02 It's raining men: Key statistics for engagement

TUAC0207LB

Integrated biological and behavioural surveillance (IBBS) survey among men who have sex with men in South Sudan

M. Solangon[1], K. Kriitmaa[2], S. Taher[1], V. Achut[3], A.J. Nyniyal[3], H.D. Awongo[4], G. Atillio[4], P. Moyo[5], P. Jasi[6]
[1]International Organization for Migration (IOM), Juba, South Sudan, [2]International Organization for Migration (IOM), Geneva, Switzerland, [3]Republic of South Sudan, Ministry of Health (MoH), Juba, South Sudan, [4]Republic of South Sudan, South Sudan HIV/AIDS Commission (SSAC), Juba, South Sudan, [5]Consultant, East London, South Africa, [6]International Organization for Migration (IOM), Dhaka, Bangladesh

Background: South Sudan has a 2.6% HIV prevalence rate and is regarded as low and generalized with pockets of high concentration among key populations (KPs). Female sex workers (FSW), their clients and men who have sex with men (MSM) account for 63% of new adult HIV infections. No research has been done to date on MSM risk behaviours, limiting development of evidence-based interventions. This first ever IBBS survey among MSM aimed at establishing HIV and syphilis prevalence and risk behaviours to better inform policy and programming.
Methods: The IBBS study was conducted in six sites in South Sudan. MSM is a criminalised behaviour in South Sudan, thus the study utilized non-probability sampling techniques including purposive and snowball sampling. Data collection methods used included electronic structured questionnaires, key informant interviews and focus group discussions. Respondents were tested for HIV and syphilis, using national testing algorithms.
Results: A total of 165 MSM participated in this survey. About 92% (n=152) were South Sudanese, and 87% (n=143) were under 28 years old. The HIV prevalence among MSM was 3.3% (N=152), higher than the 2.6% national average. The syphilis prevalence was also 3.3% (N=152). About 36% (n=59) of the MSM had a relationship with a female, which shows that sexual partners of MSM are not only same-sex but also heterosexual. About 26% (n=43) used condoms with non-regular partners every time and 12% (n=20) had a sexually transmitted infection (STI) during the past 12 months preceding the survey. Only 5% (n=8) had ever disclosed that they are MSM to health care workers, 22% (n=36) had avoided health services due to stigma and discrimination, while 26% (n=43) had access to HIV and AIDS programmes.
Conclusions: The preliminary results provide the first ever baseline data on the sexual behaviours, HIV and syphilis prevalence for MSM in South Sudan. Results show higher HIV prevalence than the national average, presence of high-risk sexual behaviours, limited access to tailored HIV and AIDS programmes and high levels of stigma and discrimination towards MSM. These findings illustrate the need to strengthen the country's policies and KP-focused interventions.

TUAC03 Diversities in delivery: PrEP from home to clinic

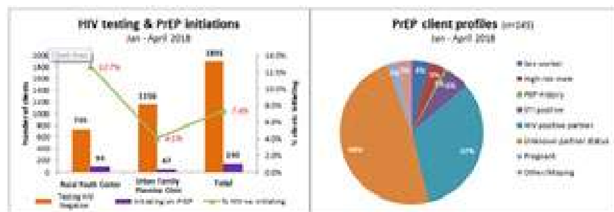
Integrating oral HIV pre-exposure prophylaxis (PrEP) in a public family planning facility and youth center to inform national roll out in Zimbabwe

M.M. Gombe[1], Y. Mangwendeza[2], G. Ncube[3], N. Zwangobani[4], M. Prust[5], B. Cakouros[5], A. Svisva[2], A. Mangwiro[2], M. Murwira[4], A. Mkwamba[1], A. Erlwanger[2], 3DE CHAI
[1]Clinton Health Access Initiative, Demand Driven Evaluations for Decisions, Harare, Zimbabwe, [2]Clinton Health Access Initiative, Harare, Zimbabwe, [3]Ministry of Health and Child Care, HIV prevention, Harare, Zimbabwe, [4]Zimbabwe National Family Planning Council, Harare, Zimbabwe, [5]Clinton Health Access Initiative, Boston, United States

Background: There is limited information on the process of offering oral PrEP to the general at-risk population in resource-limited public sector settings globally. Programming has been limited to private sector demonstration projects targeting key populations. This study aims to provide operational guidance to the Zimbabwe Ministry of Health on national public sector integration of oral PrEP as part of combination HIV prevention.

Description: PrEP was piloted in an urban family planning clinic and a rural youth center, integrating it into existing HIV prevention and reproductive health services and activities. 150 HIV negative clients screened as being at high risk of HIV infection were offered PrEP between January and April 2018, primarily through provider initiative. Demand generation included group client education and in-facility posters and pamphlets; community leader sensitization was also conducted at the rural center. Semi-structured interviews on PrEP experiences were conducted with five healthcare workers (HCWs) and 37 clients who agreed to be followed up (7 decliners and 30 accepters).



[Graph showing percentage uptake of PrEP and risk status of clients]

Lessons learned: PrEP risk assessment can be integrated into existing routine family planning and HIV testing and counselling services. Differences in facility enrollment data and interviews with study participants indicate that HCW knowledge and attitudes, and client awareness, affect whether PrEP is offered and/or accepted. PrEP uptake is driven by partner's risky behaviour or positive HIV status; this did not vary by population group. Female uptake, retention and adherence is largely determined by family or partner support. Male PrEP clients were primarily in polygamous marriages where one wife is HIV positive. Male decliners prefer condoms. Females in sero-discordant marriages report decreased condom use after PrEP initiation. This is driven by their male HIV positive partners.

Conclusions/Next steps: PrEP demand generation strategies should address HCW knowledge and client awareness. National clinical training tools for HCWs should emphasize client education and counselling on PrEP as part of combination of HIV prevention options. The national HIV Communication Strategy should focus on increasing general awareness of how PrEP works in order to increase uptake and reduce stigma associated with use. Adjustments to national PrEP target-setting will be informed by study findings on PrEP uptake among those testing HIV negative.

Engagement in methadone maintenance therapy associated with less time with plasma HIV-1 RNA viral load above 1500 copies/mL among a cohort of HIV-positive people who use drugs in Vancouver, Canada

B. Barker[1,2], C. Fairgrieve[1], K. Ahamad[1,3,4], T. Kerr[1,5], J. Shoveller[6], J. Montaner[5,7], E. Wood[1,5], M.-J. Milloy[1,5]
[1]BC Centre on Substance Use, Vancouver, Canada, [2]University of British Columbia, Interdisciplinary Studies Graduate Program, Vancouver, Canada, [3]Providence Health Care, Department of Family and Community Medicine, Vancouver, Canada, [4]University of British Columbia, Department of Family Medicine, Vancouver, Canada, [5]University of British Columbia, Department of Medicine, Division of AIDS, Vancouver, Canada, [6]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [7]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

Background: It is well established that elevated plasma HIV-1 RNA viral load (VL) drives the risk of onward viral transmission. Despite being a key population living with HIV, people who inject drugs continue to experience individual, social and structural barriers in accessing and being retained in HIV treatment and care. In the present study, we sought to longitudinally examine the relationship between engagement in a low-threshold methadone maintenance therapy (MMT) program and amount of person-time with heightened HIV transmission risk (i.e., VL >1500 copies/mL plasma) among HIV-positive people who use drugs (PWUD).

Methods: Data were derived from the AIDS Care Cohort to evaluate Exposure to Survival Services (ACCESS), a community-recruited prospective cohort of HIV-positive PWUD in Vancouver, Canada. Longitudinal cohort data was confidentially linked to comprehensive HIV clinical monitoring records in a setting of universal no-cost HIV treatment and care. We used generalized estimating equation analyses to assess the impact of engagement in low-barrier MMT on the number of days with an HIV-1 RNA VL above 1500 c/mL in the previous 180 days.

Results: Between 5 December 2005 and 29 November 2017, 867 HIV-seropositive antiretroviral therapy-exposed PWUD were recruited and contributed 4531 person-years of observation time. Among these, 522 (60.2%) were engaged in MMT at least once during follow-up. In a multivariable model, periods of MMT were independently associated with fewer days with a VL above 1500 c/mL (Adjusted Rate Ratio=0.70, 95% Confidence Interval: 0.60-0.81), after controlling for demographics, drug use patterns, and CD4 count.

Conclusions: We observed that engagement in MMT was associated with significantly less person-time with a VL above 1500 copies/mL among a large and long running cohort of PWUD. These findings suggest that low-threshold MMT is an effective intervention in lowering the risk of onward viral transmission among this key population. Further, these findings demonstrate the important role of evidence-based addiction treatment in optimizing individual and community-level impacts of antiretroviral therapy among HIV positive patients with comorbid opioid dependence. Efforts to address barriers to the use and availability of MMT will likely improve HIV outcomes and reduce new infections among this population and should therefore be prioritized.

	Unadjusted Rate Ratio		Adjusted Rate Ratio	
Characteristic	RR (95% CI)	p-value	ARR (95% CI)	p-value
MMT	0.81 (0.69 – 0.96)	0.013	0.70 (0.60 – 0.81)	<0.001

Universal test and treat (UTT) versus standard of care for access to antiretroviral therapy in HIV clients: The MaxART stepped-wedge randomized controlled health systems trial in Swaziland

S. Khan[1], D. Spiegelman[2], F. Walsh[3], S. Mazibuko[4], M. Pasi[4], B. Chai[2], R. Reis[5,6,7], K. Mlambo[1], W. Delva[8,9,10], G. Khumalo[11], M. Zwane[12], Y. Fleming[13], E. Mafara[1], A. Hettema[1], C. Lejeune[1], T. Bärnighausen[2,14], V. Okello[4]

[1]Clinton Health Access Initiative (CHAI), Mbabane, Swaziland, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]Clinton Health Access Initiative (CHAI), Boston, United States, [4]Ministry of Health, Mbabane, Swaziland, [5]Leiden University, Leiden University Medical Center, Leiden, Netherlands, [6]University of Amsterdam, Amsterdam Institute for Social Science, Amsterdam, Netherlands, [7]University of Cape Town, Children's Institute, Cape Town, South Africa, [8]Stellenbosch University, The South African Department of Science and Technology - National Research Foundation (DST-NRF) Centre of Excellence in Epidemiological Modelling and Analysis (SACEMA), Stellenbosch, South Africa, [9]Hasselt University, Center for Statistics, Diepenbeek, Belgium, [10]Ghent University, Ghent, Belgium, [11]Swaziland National Network of People Living with HIV/AIDS (SWANNEPHA), Mbabane, Swaziland, [12]SAfAIDS, Mbabane, Swaziland, [13]aidsfonds, Amsterdam, Netherlands, [14]Heidelberg Institute of Public Health, University of Heidelberg, Heidelberg, Germany

Background: The World Health Organization recommends offering antiretroviral treatment (ART) to all HIV-positive individuals regardless of CD4 count or disease stage, known as "universal test and treat" (UTT). However, the health systems effects of UTT implementation are unknown. We investigated the effect of UTT on retention and viral suppression in the world's first UTT implementation trial in a government-managed health system.

Methods: In this stepped-wedge randomized controlled trial, fourteen public sector health facilities in Swaziland were paired and randomly assigned to transition in four-month steps from implementing the current national standard of care (SoC) to providing ART under UTT. ART-naïve clients ≥ 18 years who were not pregnant or breastfeeding were eligible for enrollment. We used Cox proportional hazard models with censoring of follow-up at clinic transition to measure the effects of UTT on our two primary endpoints: retention and viral suppression after ART initiation. The trial is registered with clinicaltrials.gov (NCT02909218).

Results: Between September 2014 and August 2017, 3405 clients (62% women, median age 33 years (IQR:28-42)) were enrolled. Under SoC, 12-month retention and post ART initiation viral load suppression rates were 80% (95% CI): 77-83) and 4% (95% CI: 2-7), respectively, compared to 86% (95% CI: 83-88) and 79% (95% CI: 75-83) under UTT. 75% of clients were missing viral load at the 6-month time window following ART initiation; they were considered unsuppressed. Compared to SoC, UTT had a modest effect on retention (hazard ratio (HR) 1.60, 95% CI 1.15-2.21) and a large effect on viral suppression among those retained 6 months after ART initiation (HR: 14.51, 95% CI: 7.31-28.79) (Table 1). The UTT effect on the combined endpoint of retention and viral suppression was also substantial (HR 4.88, 95% CI 2.96-8.05).

Conclusions: Adopting UTT improves the performance of the health system in providing ART to people living with HIV. The observed improvement in retention and viral suppression, key indicators of ART success, provides an important co-benefit of UTT. Our results from this "real world" health systems trial strongly support the scale-up of UTT in Swaziland and countries with similar HIV epidemics and health systems.

Endpoint	Crude HR (95%CI)	p-value	Adjusted HR (95%CI)	p-value
Retention	1.60 (1.15-2.21)	0.005	1.94 (1.33-2.82)	0.0006
Viral suppression	14.51 (7.31-28.79)	<0.0001	22.08 (7.91-61.59)	<0.0001
Combined endpoint (retention and viral suppression)	4.88 (2.96-8.05)	<0.0001	6.90 (3.11-15.31)	<0.0001

Men's HIV risk profiles in South African DREAMS sites: Using latent class analysis for more strategic, context-specific programming and evaluation

A. Gottert[1], C.J. Heck[2], S. Mathur[1], J. Pulerwitz[3]

[1]Population Council, HIV and AIDS Program, DREAMS IS, Washington, DC, United States, [2]Population Council, Poverty, Gender, and Youth Program, New York, United States, [3]Population Council, HIV and AIDS Program, Washington, DC, United States

Background: There is a critical need to reach high-risk men with HIV prevention, care, and treatment services. Latent class analysis (LCA) can generate context-specific profiles based on demographic, attitudinal, and behavioral indicators—which can then be used to refine program targets and assess service uptake.

Methods: From May to September 2017, we conducted surveys with 962 men ages 20-40 in informal settlements in Durban, South Africa where the DREAMS Partnership is being implemented. Using LCA, we identified classes based on sociodemographics, normative gender attitudes, and HIV risk behaviors. We then assessed associations between class membership and HIV service use.

INDICATORS	Younger moderate risk (35.8% of sample)	Younger high risk (24.7% of sample)	Older low risk (19.5% of sample)	Older high risk (20.1% of sample)	Full sample
Sociodemographic					
Age (mean)	22.5 years	27.2 years	29.5 years	35.9 years	27.7 years
Married/cohabiting	3.9%	7.5%	26.0%	35.7%	15.5%
Educ. (last compl.)					
Some second or less	16.5%	20.0%	24.9%	35.3%	22.8%
Secondary	51.3%	66.3%	60.1%	47.6%	56.0%
Tech college/Univ	32.2%	13.6%	15.0%	17.1%	21.2%

High-end	6.0%	17.3%	9.8%	19.6%	12.3%
Hazardous drinking[d]	41.0%	72.0%	39.9%	58.5%	51.8%
HIV SERVICE UPTAKE, by latent class membership	**Younger moderate risk**	**Younger high risk**	**Older low risk**	**Older high risk**	**Overall p-value**[f]
Tested for HIV in last 12 months	74.7%	69.6%	67.4%	70.2%	>0.05
Received VMMC in last 5 years	42.6% (ref)	18.8%***	13.1%***	8.6%***	<0.001
HIV treatment literacy score (range 0-5)[e]	3.57	3.36**	3.70 (ref)	3.57	<0.01
Currently taking antiretroviral therapy (n=84)	90.1%	89.5%	94.7%	90.6%	>0.05

Fit statistics for this LCA model: AIC=22,122; BIC=22,478
[a]Measured by a 19-item Gender Equitable Men's (GEM) Scale (Cronbach's alpha=0.87), with binary cut-point at midpoint of range
[b]Mean number of years up to last three partners were younger than respondent
[c]Low-end transactional relationships include providing various low-cost goods or services like cash, food, or transportation mainly to start or stay in a relationship; high-end transactional relationships include paying for things like housing, debt or school fees mainly to start or stay in a relationship
[d]Assessed by AUDIT-C measure
[e]Composite score of 5 items assessing correct knowledge about the attributes and benefits of HIV treatment
[f] p-value represents overall statistical significance of difference between groups, based on Pearson's chi-square test
*p<0.05, **p<0.01, ***p<0.001; significance of pairwise comparisons with the reference category (ref)

[HIV risk profiles among men (n=962)]

Results: We identified four latent classes (Table 1), with good model fit statistics. The **younger moderate-risk class** (36% of the sample; mean age 23) were largely unmarried, recent technical college/university graduates, unemployed, and moderately gender-inequitable. They had high numbers of same-age partners, low-end transactional relationships, and some hazardous drinking. The **younger high-risk class** (25%; mean age 27) were unmarried, employed secondary graduates with the highest number of partners and the most inequitable gender views,

hazardous drinking, and low-end transactional relationships. The **older low-risk class** (20%; mean age 30) were largely married/cohabiting, employed secondary graduates and were the most gender-equitable, with few partners, limited transactional sex and relatively low hazardous drinking. Finally, the **older high-risk class** (20%; mean age 36) were largely married/cohabiting, employed secondary graduates, and moderately gender-inequitable. They had highly age-disparate partners and substantial high-end transactional relationships and hazardous drinking. High-risk men tended to be taxi drivers, factory/construction workers, or small business owners/entrepreneurs. Uptake of voluntary medical male circumcision was much higher among the younger moderate-risk class than the others (all p< 0.001). The older low-risk class had higher HIV treatment literacy than the younger high-risk class (p< 0.01). HIV testing and current use of antiretroviral therapy did not differ across the classes.

Conclusions: We identified distinct HIV risk profiles among men in Durban. Interventions should focus on reaching the highest-risk profiles who, despite their elevated risk, were less likely or no more likely than the lower-risk to use HIV services. LCA has the potential to enable more strategic, data-driven programming and evaluation.

WEAX0104LB

Risk of HIV transmission through condomless sex in MSM couples with suppressive ART: The PARTNER2 Study extended results in gay men

A. Rodger[1], V. Cambiano[1], T. Bruun[2], P. Vernazza[3], S. Collins[4], G.M. Corbelli[5], O. Degen[6], V. Estrada[7], A.M. Geretti[8], A. Beloukas[8], A.N. Phillips[1], J. Lundgren[2], for the PARTNER Study Group

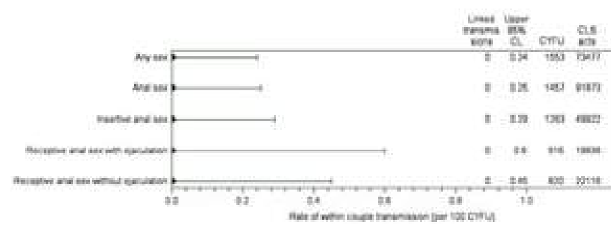
[1]University College London, London, United Kingdom, [2]University of Copenhagen, Copenhagen, Denmark, [3]Cantonal Hospital, St. Gallen, Switzerland, [4]HIV i-Base, London, United Kingdom, [5]European AIDS Treatment Group, Bruxelles, Belgium, [6]University Medical Center, Hamburg, Germany, [7]Hospital Clinico San Carlos & Universidad Complutense, Madrid, Spain, [8]University of Liverpool, Liverpool, United Kingdom

Background: Although zero cases of HIV transmission in gay men have been reported in observational studies (PARTNER1 and Opposites Attract) of serodifferent couples where the positive person was on suppressive ART, the level of evidence for gay men remained less than for heterosexual couples. The aim of PARTNER2 was to provide more precise estimates of transmission risk through condomless-sex in serodifferent gay male couples where the HIV-positive partner was on suppressive ART.

Methods: The PARTNER Study was a prospective observational study in 14 European countries. Phase 1 (Sep 2010-May 2014) recruited both heterosexual and gay male couples, and Phase 2 (to April 2018) recruited and followed gay couples only. Study data, collected at baseline and every 6 -12 months, included sexual behaviour questionnaires with HIV testing (HIV-negative partner) and HIV-1 viral-load (HIV-positive partner). Eligibility criteria for CYFU inclusion were condomless sex, no reported PEP or PrEP use, and most recent plasma HIV-1 RNA load < 200 copies/mL in the last year. If a seroconversion occurred, anonymised phylogenetic analysis compared HIV-1 polymerase and envelope sequences in both partners to identify linked transmissions.

Results: Between Sep 2010 and July 2017, 972 gay couples were enrolled. Of these, 779 couples provided 1561 eligible CYFU over a median of 1.6 years [IQR 0.8-2.8]. At baseline, mean age was 40 years [IQR 33-46] and couples reported condomless-sex for a median of 1.0 years (IQR 0.4-2.9). During eligible CYFU, a total of 74,567 condomless-sex acts were reported, a median of 42 times per couple year (IQR 19-74). Condomless-sex with other than the main partner was reported by 285 HIV-negative men (37%). There were 17 new HIV infections, but none were phylogenetically linked transmissions, giving a precise rate of within-couple HIV transmission of zero, with a narrow upper 95% confidence limit of 0.24/100 CYFU. This upper-limit for condomless anal sex with ejaculation was 0.59/100 CYFU.

Conclusions: Despite almost 75,000 condomless-sex acts in gay serodifferent couples where the positive partner was on suppressive ART, we found zero cases of within couple HIV transmission. PARTNER2 provides a similar level of confidence for gay men as for heterosexual couples in PARTNER1.



[Figure 1: Rate of HIV Transmission According to Sexual Behavior Reported by the HIV-Negative Partner]

[1]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]Bennett Statistical Consulting, Inc., Ballston Lake, United States, [4]Goodtables Data Consulting, LLC, Norman, United States, [5]Botswana Ministry of Health, Gaborone, Botswana, [6]Centers for Disease Control and Prevention, Gaborone, Botswana, [7]Massachusetts General Hospital, Boston, United States, [8]Brigham and Women's Hospital, Boston, United States, [9]U.S. Centers for Disease Control and Prevention, Atlanta, United States, [10]The Wharton School, University of Pennsylvania, Philadelphia, United States

Background: Antiretroviral therapy(ART) markedly reduces incidence in known HIV-discordant relationships. However, the impact of expanded access to HIV testing/counseling(HTC), ART, and male circumcision(MC) on community HIV incidence is unknown, particularly in settings with both high HIV prevalence and high baseline ART coverage such as Botswana.

Methods: The Ya Tsie Botswana Prevention Project was a pair-matched community-randomized trial that evaluated the impact of prevention interventions on HIV incidence in 30 rural/semi-urban communities throughout Botswana, from 2013-2018.

Fifteen communities were randomized to receive community-wide HTC, linkage-to-care, earlier ART initiation, and enhanced MC services, and 15 communities received standard of care. Universal ART became standard of care in both arms mid-2016.

A random sample of ~20% of households in each community was selected, and HIV-uninfected 16-64 year-old residents of these households enrolled in a longitudinal HIV incidence cohort (HIC) that underwent ~annual HTC. We compared HIV incidence by randomized arm over ~30 months. The pre-specified primary analysis used a permutation test of inverse variance weighted average of log- transformed incidence ratios from pair-specific, interval-censored Cox proportional hazards models (PHM); 95% CIs were obtained using standard pair-stratified Cox PHM for interval censored data. P-values are two-sided.

Results: Among 12,610 participants, at baseline 29% were HIV-infected, 72% of whom were already on ART (97% of individuals on ART had HIV-1 RNA< 400copies/mL). We enrolled 8,974 HIV-uninfected individuals in the HIC (4,487/arm), with median age 29 years (60% female).

The median duration of follow-up was 29 months, and 95% of participants in each arm re-tested for HIV at ≥1 follow-up visit. 57 HIC participants in the intervention arm (annualized HIV incidence: 0.59%) and 90 in the control arm (annualized HIV incidence: 0.92%) acquired HIV.

The HIV incidence ratio was 0.69 (*P*=0.09) in intervention vs. standard-of-care communities in the primary weighted-average Cox PHM. The pair-stratified Cox PHM produced 95%CI of 0.46-0.90 (incidence ratio=0.65, *P*=0.01).

Conclusions: We observed a 30% reduction in community HIV incidence with expanded HTC, linkage, ART, and MC campaigns. Importantly, our findings demonstrate that it is possible to reduce HIV incidence in high-HIV-prevalence settings that have already approached the ambitious UNAIDS 90-90-90 targets, by further increasing coverage.

Figure 1.A. Estimated survival curve (95% confidence interval, CI) for time to HIV seroconversion according to randomization arm.

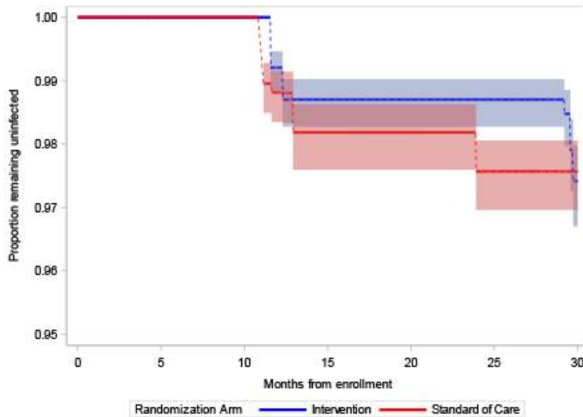

Figure 1.B. Map of annualized HIV incidence among communities randomized to intervention (blue circles) and standard of care (red circles).

Bacon[8], M. van der Laan[6], C. Cohen[1], E. Bukusi[4], M. Petersen[6], M. Kamya[3], SEARCH Collaboration
[1]University of California, San Francisco, Department of Medicine, San Francisco, United States, [2]University of Massachusetts, Amherst, Amherst, United States, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]Kenya Medical Research Institute, Nairobi, Kenya, [5]University of Pennsylvania, Philadelphia, United States, [6]University of California, Berkeley, Berkeley, United States, [7]Gilead Sciences, Foster City, United States, [8]National Institutes of Health, Bethesda, United States

Background: SEARCH (NCT:01864683) is a community-cluster randomized study in rural Uganda and Kenya evaluating whether a multi-disease, streamlined-care approach to HIV "test and treat" reduces HIV incidence and improves community health, compared to a national guideline approach augmented with baseline HIV and NCD (hypertension and diabetes) testing.

Methods: We randomized (2013-2014) 32 pair-matched communities in 3 regions (Uganda- West, Uganda-East, Kenya) to an active control with baseline HIV/NCD testing and ART/NCD care by national guidelines or an intervention with additional annual population HIV/NCD testing, rapid-start ART for all HIV+, and patient-centered, streamlined ART/NCD care. In all communities, population-level testing was delivered through multi-disease health fairs; non- participants were tested at home/in community. In the control arm, ART eligibility expanded during the study from CD4+< 350 to CD4+< 500 to all HIV+. Three-year HIV cumulative incidence, HIV viral suppression, mortality, HIV-TB, and hypertension control were compared between arms using targeted maximum likelihood estimation.

Results: At baseline, 335,005 persons (150,395 adults ≥15 years) were enrolled; 90.1% of adults were HIV-tested. HIV prevalence was 6.6%, 3.5%, and 19.3%, and HIV viral suppression was 47.5%, 43.0%, and 52.8% in Uganda-West, Uganda-East, and Kenya, respectively. Population-level viral suppression increased to 73.0% by year 1 in the intervention arm; at year 3, suppression was higher in intervention (79.7%) vs. control (68.4%) (RR:1.17; 95%CI:1.11,1.22; P< 0.001). At year 3, the intervention arm had 21% lower mortality among HIV+ (RR:0.79; 95%CI:0.65,0.96; P=0.02), 59% lower annual TB incidence among HIV+ (RR:0.41; 95%CI:0.19,0.86; P=0.02), and 16% less uncontrolled hypertension (RR:0.84; 95%CI:0.79,0.90; p< 0.001) compared to control. Annual HIV incidence in the intervention arm decreased from year 1 to year 3 by 30% (RR:0.70; 95%CI:0.57,0.86; P< 0.001); incidence decreased by 45% in Kenya (RR:0.55; 95%CI:0.40,0.76; P< 0.001). Three-year cumulative HIV incidence did not differ between intervention (0.77%) and control (0.81%) (RR:0.95; 95%CI:0.77,1.17; P=0.60).

Conclusions: A multi-disease disease approach using streamlined care rapidly achieved UNAIDS 90-90-90 targets, improving community health (HIV mortality, HIV-TB, hypertension control). Annual HIV incidence decreased by 30% during the study; however, three-year cumulative HIV incidence did not differ between arms.
Continued investment and innovation in HIV treatment and prevention are needed for HIV elimination.

WEAA01 Poking, prodding and purging the final reservoir frontier

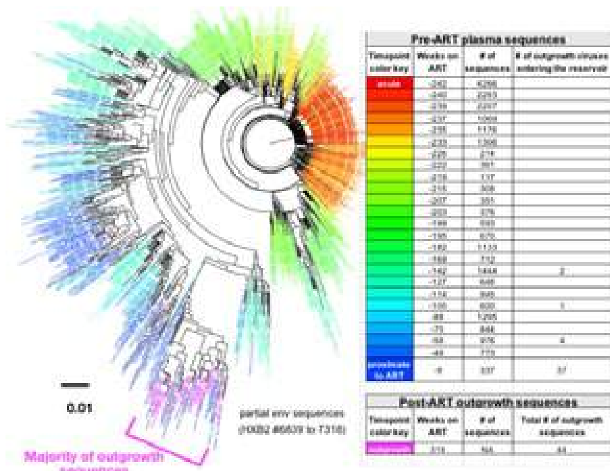
WEAA0108LB

The majority of the replication-competent virus in the latent reservoir originates from viruses circulating near the time of ART initiation

S.B. Joseph[1], M.-R. Abrahams[2], N. Garrett[3], S. Zhou[4], M. Moeser[4], W. Burgers[2], L. Tyers[2], D. Matten[5], C. Anthony[2], O. Council[1], N. Archin[6,7], D.M. Margolis[6,7], S. Abdool Karim[3,8], R. Swanstrom[4,9], C. Williamson[2,3]
[1]University of North Carolina at Chapel Hill, Department of Microbiology and Immunology, Chapel Hill, United States, [2]University of Cape Town Faculty of Health Sciences, Division of Medical Virology, Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa, [3]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [4]University of North Carolina at Chapel Hill, UNC Center for AIDS Research, Chapel Hill, United States, [5]University of Cape Town Faculty of Health Sciences, Division of Medical Virology, institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa, [6]University of North Carolina at Chapel Hill, Division of Infectious Diseases, School of Medicine, Chapel Hill, United States, [7]University of North Carolina at Chapel Hill, UNC HIV Cure Center, Chapel Hill, United States, [8]Columbia University, Department of Epidemiology, New York City, United States, [9]University of North Carolina at Chapel Hill, Department of Biochemistry and Biophysics, Chapel Hill, United States

Background: HIV-1 persists during suppressive therapy in latently infected cells. These cells have been observed in all HIV-infected people even if treated very early, but little is known about when viruses enter the latent reservoir. Such knowledge would inform our understanding of the dynamics of this reservoir.

Methods: Plasma samples were collected longitudinally from 9 HIV-infected, ART-naive women enrolled in the CAPRISA 002 acute infection cohort who initiated therapy when CD4+ T cell count dropped below 500 cells/µl (mean = 4.5 yr p.i.). After prolonged ART (mean= 5.1 yr), resting CD4+ T cells were isolated from blood and cultured in a quantitative viral outgrowth assay (QVOA) to sample virus in the latent reservoir. vRNA from plasma collected longitudinally pre-ART was analyzed by MiSeq deep sequencing across the genome, and PacBio was used to analyze vRNA from p24+ QVOA outgrowth wells to generate near full-length sequences. Phylogenetic analyses were performed to compare these two types of sequences.



[Representative example of the phylogenetic relationship between pre-ART plasma sequences and sequences from the replication-competent reservoir]

Results: Of the genetically unique outgrowth viruses sampled from each participant, 60 to 100% were related most closely to virus circulating in the year prior to ART initiation, and 0 to 22% to virus circulating during the first two years of infection.

This suggests that the start of therapy is associated with the formation of the majority of the persistent reservoir. In sampling 6-44 outgrowth viruses per person, between 0 and 50% of these viruses were genetically identical indicating they were derived from clonally expanded cells, with half arising well before ART initiation and the other half proximal to the start of ART.

Conclusions: We used virus evolution off therapy as a molecular clock to date formation of the latent reservoir. Unexpectedly, the majority of the viruses that we detected entered the reservoir near the time of therapy. Our results support several models including ones in which ART-induced changes to the host immune environment promote latency in HIV-infected cells and/or increase the half-life of latently infected cells. These findings provide unique insights into the formation of the latent reservoir and suggest that interventions at the time of ART initiation may significantly reduce the size of the latent reservoir.

WEAE04 PrEP: Work in progress

Background: On-demand PrEP with TDF/FTC has been recommended as an alternative to Daily PrEP for MSM by the European AIDS Clinical Society following the results of clinical studies but data are limited on real-world experience.

Methods: The ANRS Prevenir study is an ongoing prospective cohort study in the Paris region enrolling high risk individuals willing to/or using PrEP. Both daily and On-demand PrEP were offered to eligible individuals. At baseline, month 1 and every 3 months thereafter subjects were tested for HIV using a 4th generation combined ELISA test and other STIs and creatinine plasma levels were monitored. At each visit participants provided information regarding sexual behaviour and adherence using computer assisted self-interviews. Analysis of HIV incidence was assessed to provide additional data on the efficacy and safety of the two PrEP dosing regimens.

Results: From May 3rd 2017 to May 1st 2018, 1435 subjects were enrolled across 22 sites, 59% being PrEP experienced for a median of 10 months. Median age was 37 years (IQR: 30-44), 98.7% were MSM. At enrolment, PrEP was used Daily in 44% and On-demand in 53% of participants. Median number of partners in the 3 months before enrolment was 15 (IQR: 7-25) in the Daily group and 10 (5-15) in the On-demand group (P< 0.001). Median number of condomless sex in the prior 4 weeks was 3 (1-8) and 2 (0-4), respectively, P< 0.001. The current follow-up lasted 302 and 361 person-years (PY) in the Daily and On-demand groups, respectively. The incidence of HIV-1 infection was 0 (95% CI: 0-1.2) per 100 PY and 0 (95% CI: 0-1.0) in the Daily and On-demand groups respectively (P=1.00) and the incidence of study discontinuation was 3.0 and 3.6 per 100 PY

(P=0.674) respectively, including 1.3 and 1.1 per 100 PY drop out of PrEP because participants no longer feel at risk. No participant discontinued PrEP for drug-related adverse events.

Conclusions: In this ongoing PrEP cohort in Paris region, enrolling mainly MSM at high risk of HIV-acquisition, no breakthrough HIV-infection was reported so far with either daily or on-demand PrEP, supporting continuing use of both dosing regimens in this population.

WEAD02 Time for a youthquake in HIV prevention and treatment

WEAD0208LB

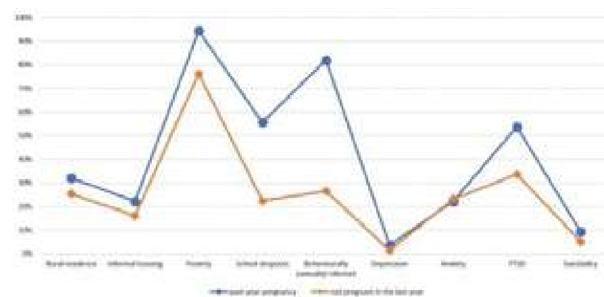
The third generation of HIV: World first longitudinal study of pregnancy in adolescents living with HIV

E. Toska[1,2], L. Sherr[3], L. Cluver[2,4], S. Zhou[1], Mzantsi Wakho Cohort Study
[1]University of Cape Town, AIDS and Society Research Unit, Cape Town, South Africa, [2]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [3]University College London, London, United Kingdom, [4]University of Cape Town, Dept of Psychiatry and Mental Health, Cape Town, South Africa

Background: Nearly 1.7 million HIV-positive adolescent girls in Southern Africa experience high rates of pregnancy, poor birth outcomes, and AIDS-related mortality. Option B+ has dramatically reduced the overall rates of paediatric HIV-infections, but the legacy of adolescents living with HIV persists. HIV-positive adolescent mothers have exceptionally high rates of mortality, morbidity, and onwards vertical HIV transmission. Their HIV-exposed children face increased risk of delayed HIV-testing and ART initiation, worse retention in care, poorer health and higher mortality. The study of the syndemic of adolescent pregnancy and HIV is urgently needed. This study presents the first data on rates of incident and repeated pregnancies among adolescent girls living with HIV and factors shaping early motherhood.

Methods: All HIV-positive adolescent from 52 clinics in a health district in South Africa were approached (90.1%), resulting in n=563 HIV-positive adolescent girls. Two interviews were conducted 18-months apart, following voluntary consent from adolescents and caregivers. Data collection tools were piloted with n=25 HIV-positive adolescents. Analyses investigated factors longitudinally associated with incident and repeated pregnancies: socio-demographic, family, mental health, mode of infection and HIV-related factors using STATA25.

Results: N=98/563 (17%) reported lifetime pregnancy, with N=54 (9.6%) becoming pregnant between the interviews (incident pregnancy) and 37 (6.6%) reporting multiple pregnancies. The majority (n=76, 82.6%) reported knowing their children's HIV-status, with n=4 (4.35%) reporting having at least one HIV-positive child. HIV-positive adolescents who were pregnant were more likely to be older, from poor households, not enrolled in school, suicidal, and sexually infected (Fig 1).



[Fig 1. Socio-demographic and mental health among HIV+ adolescent girls (N=583)]

Three factors were longitudinally associated with both incident and repeated pregnancy: age >15 years-old (OR10.7, CI3.6-31.9, p< 0.001), not being enrolled in school at baseline (OR4.2, CI2.0-9.6, p< 0.001), and being sexually/ behaviourally infected (OR10.9, CI4.9-24.0, p< 0.001).

Conclusions: The next generation of HIV infection dawns. Factors which result in HIV infection in young people may have long-term ramifications for HIV-positive young mothers and the next generation - their HIV-exposed/ infected children. Adolescent pregnancy (and multiple pregnancy) is an issue, with cycles of disadvantage clustering in terms of poverty, school dropout and mental health. Breaking the cycle of onward transmission to their children is an urgent intervention gap.

WEAB02 ART in infants and children

WEAB0208LB

Impact of late *versus* early antiretroviral therapy on PBMC-associated HIV-1-DNA levels and the percentage of naive T lymphocytes in HIV-1 infected children and adolescents - The ANRS-EP59-CLEAC study

P. Frange[1,2], V. Avettand-Fenoel[1,2], J. Le Chenadec[3], C. Dollfus[1], L. Nailler[3], O. Dialla[3], T. Montange[4], D. Batalie[4], M. Fillion[2], I. Leymarie[3], L. Ait Si Selmi[3], T. Wack[3], J. Warszawski[3], F. Buseyne[4], ANRS-EP59-CLEAC Study Group
[1]AP-HP, Paris, France, [2]Université Paris Descartes, EA7327, Paris, France, [3]INSERM, Le Kremlin-Bicêtre, France, [4]Institut Pasteur, Unité d'Epidémiologie et Physiopathologie des Virus Oncogènes, Paris, France

Background: Early combined antiretroviral therapy (cART) initiation reduces progression to AIDS and death and decreases the cell-associated viral reservoir in children infected with HIV-1 during the perinatal period. Little data are available on the benefit of early cART initiation for children over five years of age and adolescents. The ANRS-EP59-CLEAC study aimed to assess the immunological and virological characteristics of HIV-1-infected children and adolescents who achieved initial virological suppression, according to age at cART initiation (< 6 months *vs.* ≥ 24 months of age).

Methods: Patient recruitment was conducted in the Paris area between 2016 and 2018. Total cell-associated HIV-1 DNA was quantified in the blood using ultrasensitive real-time PCR (adapted from Biocentric, Bandol, France). CD4 and CD8 CD45RA+CCR7+ naive T lymphocytes were quantified in fresh blood by flow cytometry. The Kruskal-Wallis test was used to compare the parameters of early/late treated children (5-12 years) and adolescents (13-17 years).

Results: We prospectively enrolled 27 children (E-Ch) and nine adolescents (E-Ado) in the early-cART group, and 19 children (L-Ch) and 21 adolescents (L-Ado) in the late-cART group. The patients were mainly girls (54%), born in mainland France (60%) to mothers originating from Sub-Saharan African countries (74%). At the time of the study, all patients were receiving ART, 76% had undetectable plasma HIV-1 RNA, and the median (interquartile range) CD4 T-cell count was 824 [660; 1167] cells/µl. HIV-1 DNA levels were lower in the early-cART than late-cART groups for both children and adolescents (medians were 2.2 (E-Ch), 2.9 (L-Ch), 2.3 (E-Ado), and 3.0 (L-Ado) log_{10} copies/10^6 PBMCs, $P < 0.0001$). Data on the percentage of naive CD4 and CD8 T lymphocytes were available for 58 subjects. We observed the highest percentages in E-Ch (medians in the E-Ch, L-Ch, E-Ado, and L-Ado groups were respectively 61, 54, 36, and 55% for CD4, $P = 0.02$; and 50, 33, 29, and 29%, for CD8, $P = 0.004$).

Conclusions: Early cART initiation during infancy is associated with lower short- and long-term PBMC-associated HIV-1 DNA levels, as targeted in HIV-1 remission strategies. An immunological benefit of early cART initiation on naive T lymphocytes was suggested in children from this study.

WEAE05 I want you back: Improving retention on HIV programmes

WEAE0508LB

Taking biometric coding and the patient-linkage and retention system to scale: Game changers for improving patient tracking and reducing loss to follow-up (LTFU) among PLHIV in Haiti

L. Hall[1], M.P.J.S. Valles[2], R. Jean-Francois[3], P. Joseph[2], M. Antoine[2], N. Celestin[2], G. Perrin[4], S. Morisseau[3], A. Leggoe[3]
[1]Centers for Disease Control and Prevention, Atlanta, United States, [2]Centers for Disease Control and Prevention, Port-au-Prince, Haiti, [3]United States Agency for International Development, Port-au-Prince, Haiti, [4]Centers for Disease Control and Prevention, Port-au-Prince, Heard Islands and McDonald Islands

Background: In 2015, after identifying an alarming rate of LTFU (15% for FY14) among PLHIV enrolled on treatment, the PEPFAR Haiti program implemented a multi-faceted intervention to improve patient tracking, LTFU retrieval, adherence, and retention: fingerprint-based Biometric Coding (BC) and the Patient Linkage and Retention (PLR) System.
Methods: PLR encompasses tracking of patients at the community level, including HIV+ patients never linked to care, LTFU, and active patients at risk of being LTFU. PLR is optimized with GPS and BC, allowing for a unique identifier for HIV+ patients, improved estimates of the never-diagnosed PLHIV, and identification of silent transfers and medical shopping. Details of eligible patients are provided to community health workers (CHWs) who conduct home visits.
Results: To date, PLR and BC have been rolled-out in 90% of clinical facilities, covering 72% of PLHIV enrolled on ART. 55% of LTFU have been brought back to care with 57% of retention. The overall annual LFTU rate has decreased from 15% in FY14 to 9% in FY17. Barriers to retention, documented through the PLR tool, have been incorporated to address programmatic gaps in patient linkage and retention. Moreover, GPS and BC facilitate data quality assurance by identifying duplicate patients and medical shopping across Haiti. BC, PLR and the CHW network also facilitate data-driven partne
Conclusions: While the validity of BC connected to patient tracking has been shown effective at improving HIV treatment outcomes in other geographically limited settings, PEPFAR-Haiti is demonstrating that BC taken to scale in a resource-constrained setting and applied at the national level, improves clinical outcomes, de-duplicating national figures of PLHIV on ART and tracking patterns of LTFU and re-entry across Haiti. BC and PLR are an important factor in decreasing LTFU. PEPFAR-Haiti will continue to take this innovation to scale to all supported facilities for improved program management to achieve epidemic control in Haiti.

Chan School of Public Health, Statistical & Data Analysis Center, Boston, United States, [6]Frontier Science & Technology Research Foundation, Inc., Amherst, United States, [7]National Institutes of Health, Division of AIDS, Therapeutics Research Program, Washington DC, United States, [8]Kamuzu Central Hospital, Lilongwe, Malawi, [9]Parirenyatwa CRS, Harare, Zimbabwe, [10]Blantyre CRS, John Hopkins Research Project, Blantyre, Malawi, [11]Moi University Clinical Research Center, Oncology, Eldoret, Kenya, [12]Tygerberg Hospital, Family Clinical Research Unit, Cape Town, South Africa, [13]Instituto de Pesquisa Clinica Evandro Chagas, Rio de Janeiro, Brazil, [14]Kenya Medical Research Institute, Kericho, Kenya, [15]Uganda Cancer Institute, Kampala, Uganda, [16]National Cancer Institute, Bethesda, United States, [17]Kisumu Clinical Research Site, Kisumu, Kenya, [18]Durban International CRS, Enhancing care foundation, Durban, South Africa, [19]AIDS Malignancy Consortium, New York, United States

Background: Advanced Kaposi sarcoma (KS) is a potentially life-threatening complication of HIV infection where access to chemotherapy is limited and HIV and KS herpesvirus coinfection rates are high. No evidence-based standard of care (SOC) guideline for advanced KS exists in settings where resources for safe preparation and administration of intravenous (IV) chemotherapy are scarce.
Methods: Participants at 11 ACTG sites in 5 sub-Saharan African countries and Brazil with measurable, previously-untreated, biopsy-proven, advanced (T1 stage) AIDS-related KS, adequate organ function and performance status, and limited (≤42 days) or no ART exposure were prospectively randomized 1:1:1 to receive oral etoposide plus ART (ET+ART), IV bleomycin and vincristine+ART (BV+ART), or IV paclitaxel+ART (PTX+ART). Randomization was stratified by CD4 count (< 100 or ≥100 cells/mm³) and country. PTX+ART, a standard regimen in resource-rich settings, was considered the active control. The trial was designed to evaluate whether ET+ART (an oral regimen affording significant logistical advantages in resource-limited settings [RLS]) and/or BV+ART (a commonly-used regimen in RLS) were noninferior to PTX+ART. Noninferiority was defined as a week-48 progression-free survival (PFS) rate within 15% of the PFS rate of the PTX+ART arm, projected at 65% and based on Kaplan-Meier methods.
Results: Entry and on-study characteristics are shown in Table 1. An interim Data and Safety Monitoring Board (DSMB) review in 3/2016 found the ET+ART arm inferior to the PTX+ART arm. The ET arm was closed; accrual continued for the two remaining arms. A subsequent interim DSMB review in 3/2018 found the BV+ART arm inferior to the PTX+ART arm; further accrual was halted. PTX was offered to all remaining eligible study participants. Week-48 PFS rates (95% CI) at the time each study arm was closed were 19% (8,35), 43% (34,53) and 63% (54,72), respectively for the ET+ART, BV+ART and PTX+ART arms (Fig.1). There were no safety concerns about any of the treatment regimens; ~90% had HIV VL < 400c/mL by week 12.
Conclusions: These findings establish PTX+ART as a SOC for initial treatment of advanced AIDS-KS, and underscore both the urgent need to improve the cancer therapeutic infrastructure and the accessibility of essential chemotherapeutic agents in RLS.

THAC01 New tools, old tricks: Innovative methods for understanding the epidemic

THAC0108LB

Using a social networking "app" to establish an open cohort for assessing HIV incidence among men who have sex with men in Beijing, China

Z. Chen[1], X. Chu[2], F. Yu[1], Y. Ma[1], X. Xu[3], J. McGoogan[3], G. Mi[1,3], Z. Wu[3]
[1]Blued, Beijing, China, [2]Langfang CDC, Langfang, China, [3]National Center for AIDS/STD Control and Prevention, Beijing, China

Background: HIV infection is spreading quickly among men who have sex with men (MSM) in China. Yet, MSM continue to be difficult to reach, and as a result, creating and maintaining a cohort by traditional methods is challenging. Blued is a gay social networking application ("app") with over 40 million users worldwide and 480,000 monthly active users in Beijing. We aimed to develop an innovative new method using Blued to estimate HIV incidence among MSM.

Methods: All Blued users in Beijing who obtained rapid HIV screening tests via Blued (ie, online appointment booking through Blued and attendance at one of four Blued-designated voluntary counseling and testing [VCT] clinics in Beijing)) from 21st June, 2017 to 31st March, 2018 were eligible for the study. Before testing, users provided inform consent electronically and completed an online survey, which collected demographic and sexual health and behavior information, through Blued. After testing, results (negative or reactive) were recorded. Users who tested more than once had their testing records linked automatically by Blued UID and the time intervals between tests were captured. Attendances with reactive results were referred to local CDC for confirmatory testing by Western blot, and all confirmed diagnoses were counted as seroconversions. All those recruited into the cohort and followed were censored at seroconversion or study end date, whichever came first, and observed time and HIV incidence rate were calculated.

Results: A total of 4808 HIV screening tests were taken by 3766 Blued users, among whom 168 were HIV-reactive and received confirmed diagnoses of HIV infection, for a point prevalence of 4.5%. The remaining 3598 were followed, among whom 673 (18.7%) accessed HIV screening again via Blued. Ten HIV seroconversions were observed during 827.7 person-years (PY) of follow-up time, for an incidence rate of 1.21 per 100 PY.

Conclusions: Our study demonstrates that use of social networking apps such as Blued provide a promising new method for evaluating and monitoring HIV incidence. Although further study is required, this method may have great potential for nationwide scale-up to monitor HIV incidence in this important key population

THAE01 Confronting violence against women

THAE0106LB

Integration of GBV into HIV/STI services increases uptake of post GBV care services among key populations, lessons learned from Papua New Guinea, 2015-2017

I.U. Mogaba[1], R. Nopa[2], W. Yeka[3], M. Dogimab[4], D. Tesfaye[1], E. Valaun[3], M. Ramsey[5]
[1]FHI 360 (Family Health International), Papua New Guinea, Program Management (Country Office), Port Moresby, Papua New Guinea, [2]FHI 360 (Family Health International), Papua New Guinea, Programs, Port Moresby, Papua New Guinea, [3]FHI 360 (Family Health International), Papua New Guinea, M&E, Port Moresby, Papua New Guinea, [4]Cardno, Papua New Guinea, Formerly with FHI 360 (Family Health International), Papua New Guinea, Port Moresby, Papua New Guinea, [5]FHI 360 (Family Health International), Headquarters, Global Health Population and Nutriontion, Port Moresby, Papua New Guinea

Background: Overall adult HIV prevalence in Papua New Guinea (PNG) is 0.9% (UNAIDS, 2016), higher (1.1%--1.68%) among key populations (KPs), including female sex workers (FSW) (14.9%), men who have sex with men (MSM)/transgender women (TG) (8.5%) (NDoH, 2017). Two-thirds of women experienced gender-based violence (GBV) (Darko et al., 2015), and 41%-45% of FSW and MSM/TG reported sexual violence in the last 12 months (Kelly-Hanku et al., 2017). GBV increases HIV risk yet decreases service utilization. Sociocultural factors inhibit GBV disclosure and service uptake for all survivors; laws criminalizing sex work and sodomy heighten this inhibition for KPs. In 2015, FHI 360 began integrating gender and GBV interventions into its USAID-funded Strengthening HIV/AIDS for KPs in PNG project (2012-2018) to prevent GBV and to increase post-GBV service uptake. Initial interventions prepared service providers to offer KP-friendly, comprehensive post-GBV clinical services and then moved to GBV prevention, awareness and referral among KP, communities and other service providers.

Description: Interventions implemented in five health facilities and the outcomes are listed below. Disaggregated descriptive and trends analyses were conducted using health facility program monitoring data (fiscal year (FY) 2015-2017) to understand results from routine GBV screening and post-GBV care uptake.

Lessons learned: The number of GBV-screened individuals among clients accessing HIV/STI services increased from 718 (2015) to 8,426 (2017). The percentage of individuals screened and identified as GBV-survivors remained low compared to survey results (Darko et al., 2015). The number of GBV cases expanded exponentially. The percentage of survivors seen (including walk-ins/referrals) receiving post-GBV care for both sexes increased sharply before a 2017 slight decline. The percentage of GBV survivors among KPs who received care increased sharply (2015-2017) (MSM/TG: 0% to 86.1%, FSW: 33.3% to 86.5%).

Conclusions/Next steps: In this context, increasing the number of service points, providing integrated KP-friendly and comprehensive GBV services combined with community GBV awareness and referral had a dramatic impact on post-GBV care uptake. However, proactive screening did not increase the proportion of GBV survivors identified by much, suggesting other factors exist affecting GBV survivors' disclosure.

Interventions implemented	Outputs/outcomes
KP sensitization trainings for service providers (health care workers and GBV hotline counsellors).	Service providers: • Understand KPs' vulnerability to violence, their rights to live lives free from violence and to access friendly and welcoming services should they experience GBV. • Become more receptive to KPs accessing GBV and other services.
Development of a GBV screening protocol; Implementation of routine GBV screening among clients accessing HIV/STI services; Introduction of a minimum package of post-GBV care at health facilities with onward referral for non-health services.	The 5 participating health facilities (1 in Madang Province and 4 in the National Capital District) have: • Simple one page GBV screening protocol available to all HIV service providers • The ability to provide the minimum 5 essential post-GBV services (psychological first aid, emergency contraceptives, post-exposure prophylaxis, prophylaxis for STIs and vaccination against tetanus and HepB). First sites offering GBV services specifically for KP. Number of all-population GBV service sites in Port Moresby increased from 1 to 5, and from 1 to 2 in Madang Province, increasing access in a community where travel between and among neighborhoods can be dangerous.
Training of HIV/STI service providers on the GBV screening protocol and the post-GBV care minimum package.	Health care workers screen all clients accessing STI, HIV testing and ART services and provide the minimum post-GBV care package.
Sensitization of communities on GBV prevention/bystander interventions and post-GBV services. Strengthening post-GBV care referral linkages between communities and health facilities.	Community leaders aware of GBV and its relationship to HIV, and where and how to access post-GBV care. Telephone counsellors working with GBV hotline counselling service became conversant with the referral pathways for post-GBV services and make referrals. Increase in number of referrals (including self-referrals) from the community.
Inclusion of GBV empowerment and safety planning in the community outreach minimum HIV prevention package. Training KP peer educators and GBV hotline counsellors towards engaging clients on GBV/post-GBV care referral pathways.	Peer educators provide education to KPs on GBV, GBV prevention and identification and referral of survivors for post-GBV care. A standard operating procedure on GBV prevention, recognition and referral, and GBV safety planning tool kit developed. More KPs reached with GBV prevention and post-GBV care.
Revision of HIV data collection and reporting tools to capture relevant data on GBV screening and post-GBV care.	Program monitoring data on GBV screening and uptake of post-GBV care available (disaggregated by sex, KP type, KP/general population, year), including: • Number of individuals screened for GBV • Number and proportion of GBV-survivors among those screened • Number of self-referred GBV-survivors • Number and proportion of GBV-survivors receiving post-GBV care.

Let's Stick Together: community empowerment approach significantly impacts multiple HIV and sexual and reproductive health outcomes among female sex workers in Tanzania

D. Kerrigan[1,2], J. Mbwambo[3], S. Likindikoki[3], W. Davis[4], A. Mantsios[2], S. Beckham[2], A. Leddy[5], S. Aboud[3], N. Galai[2]

[1]American University, Sociology, Washington, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [3]MUHAS, Dar es Salaam, Tanzania, United Republic of, [4]American University, Washington, United States, [5]UCSF, San Francisco, United States

Background: Female sex workers (FSW) are 13.5 times more likely to be HIV-infected than other women. They are also at risk for a number of other negative health outcomes and conditions, including gender-based violence and unintended pregnancies.

Methods: We conducted a community-randomized trial of a community empowerment model of combination prevention (Project *Shikamana/* Let's Stick Together) among FSW in Iringa, Tanzania. We used time-location-sampling to enroll a cohort of 496 women, collecting survey data and conducting HIV screening and viral load assessments at 0 and 18 months. The intervention, targeting both HIV-infected and uninfected women, was anchored around the promotion of social cohesion and mobilization to address socio-structural constraints such as stigma, discrimination, violence and financial insecurity. We conducted an intent-to-treat analysis with logistic and GEE Poisson regression.

Results: Project *Shikamana* peer educators conducted 7,677 outreach sessions and distributed 81,463 condoms during the 18-month intervention period. Even without PrEP, participants in the intervention were significantly (62%) less likely to become infected with HIV at follow-up (OR .38; p=0.05); with an HIV incidence of 5.0% in intervention vs. 10.4% in control. Consistent condom use increased significantly in the intervention (RR 1.50; p=0.01) vs. the control (RR .97; NS). The intervention also had a significant impact on reductions in gender-based violence (RR: 0.80; p=0.05) and increases in modern family planning methods at follow-up (RR=1.48; p=0.02). The *Shikamana* women's group has now been formally registered, established a community savings group, and started a local business to continue to support mobilization activities.

Conclusions: Project *Shikamana* is one of the first comprehensive models of community empowerment implemented and evaluated among FSW in Africa, which if taken to scale, holds significant promise to generate and sustain improvements in HIV-related outcomes, sexual and reproductive health, and the human and labor rights of this key population.

THAB03 Pregnancy: Pre, peri, and post

THAB0307LB

DolPHIN-1: Randomised controlled trial of dolutegravir (DTG)- versus efavirenz (EFV)-based therapy in mothers initiating antiretroviral treatment in late pregnancy

C. Orrell[1], K. Kintu[2], J.A. Coombs[1], A. Amara[3], L. Myer[4], J. Kaboggoza[2], B. Simmons[5], L. Else[3], C. Heiberg[1], C. Waitt[3], S. Walimbwa[2], E.M. Hodel[3], A. Hill[3], S. Khoo[3], M. Lamorde[2], DolPHIN-1 Study Group
[1]Desmond Tutu HIV Foundation, Cape Town, South Africa, [2]Infectious Diseases Institute, Kampala, Uganda, [3]University of Liverpool, Liverpool, United Kingdom, [4]University of Cape Town, Cape Town, South Africa, [5]Imperial College, London, United Kingdom

Background: ART initiation in the 3rd trimester of pregnancy is associated with failure to achieve viral suppression (VS) by delivery and increased transmission of HIV. We randomised 60 treatment naïve pregnant women at 28-36w gestation in Uganda and South Africa 1:1 to receive EFV or DTG+2NRTIs. The primary endpoint was pharmacokinetics (PK) of DTG in women and breastfed infants; secondary endpoints included VS.
Methods: To comply with national guidelines, EFV+2NRTI was initiated on referral, with subjects randomized to DTG switched within 7 days. Viral load (VL) was collected at every visit; intensive maternal PK sampling (0-24h) was performed at 14 days on DTG, and 2 weeks post-partum, with paired sampling between maternal plasma and cord blood, breastmilk and infant plasma. All infants were exclusively breastfed.
Results: There was no significant pre-ART differences between DTG (n=29) and EFV (n=31) arms in maternal age, gestation at treatment initiation (30.8w), weight, obstetric history, VL (log 4 copies) and CD4 count (394 cells/mm^3). Third trimester DTG exposures were low with C_{trough} at or below target (MEC 324ng/mL) in 9/28 (32%) mothers. DTG transfer across the placenta (122%) and in breast milk (3%) coupled with delayed elimination resulted in significant infant exposures potentially persisting during breast-feeding. Both regimens were well-tolerated. A total of 10 SAEs were reported in 5 mothers and 3 infants, with no significant differences between arms.
Superior VS was observed with DTG (Table 1) at the 2w post-partum visit (P=0.005). However, VL>1000 copies/mL near delivery was still observed with both DTG (3.7%) and EFV (7.4%). No HIV transmissions were observed
Conclusions: HIV RNA suppression < 50 copies/mL was more rapid with DTG (despite low DTG exposures when started in the third trimester) which may translate to improved PMTCT for ART initiation in late pregnancy. The impact of significant infant DTG exposures related to intra-uterine transfer, continued breastfeeding and delayed elimination is being evaluated in the DolPHIN-2 study.

	DTG N (%)	EFV N (%)	Fisher's exact P value
Screening (pre-ART) (N)	29	31	
<50 copies/mL	-	-	
50-199 copies/mL	-	-	1.00
200-999 copies/mL	1 (3.4%)	2 (6.5%)	
1000+ copies/mL	28 (96.6%)	29 (93.5%)	
Day 14 (N)	29	27	
<50 copies/mL	11 (37.9%)	2 (7.4%)	
50-199 copies/mL	10 (34.5%)	8 (29.6%)	0.021
200-999 copies/mL	5 (17.2%)	10 (37.0%)	
1000+ copies/mL	3 (10.3%)	7 (25.9%)	
Day 28 (N)	27	25	
<50 copies/mL	15 (55.6%)	7 (28.0%)	
50-199 copies/mL	9 (33.3%)	9 (36.0%)	0.101
200-999 copies/mL	2 (7.4%)	7 (28.0%)	
1000+ copies/mL	1 (3.7%)	2 (8.0%)	
Post-partum (N)	27	27	
<50 copies/mL	20 (74.1%)	10 (37.0%)	
50-199 copies/mL	5 (18.5%)	5 (18.5%)	0.005
200-999 copies/mL	1 (3.7%)	10 (37.0%)	
1000+ copies/mL	1 (3.7%)	2 (7.4%)	
Note: at Day 14 and Day 28, (N) does not equal total as some mothers delivered prior to reaching timepoint for evaluation. At post-partum, five individuals are still waiting HIV RNA results or withdrew prior to evaluation.

Sachathep[4], J. Justman[7], B. Haufiku[1]
[1]Namibia Ministry of Health and Social Services, Windhoek, Namibia, [2]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [3]University of California in San Francisco, Institute for Global Health Sciences, San Francisco, United States, [4]ICAP at Columbia University, New York, United States, [5]Namibia Statistics Agency, Windhoek, Namibia, [6]Namibia Institute of Pathology, Windhoek, Namibia, [7]Columbia University, Epidemiology and Medicine, Hastings-on-Hudson, United States

Background: In 2015, Namibia implemented an Acceleration Plan rapidly scaling up HIV testing and treatment services with the goal of reaching the UNAIDS 90-90-90 targets by 2020. In 2017, Namibia conducted the Namibia Population-based HIV Impact Assessment (NAMPHIA) to estimate HIV viral load suppression (VLS) and progress toward the 90-90-90 targets.
Methods: NAMPHIA was a cross-sectional household-based survey conducted between June and December, 2017; analyses were weighted to account for complex survey design. Eligible adults aged 15-64 years who consented were interviewed and offered HIV rapid testing according to national guidelines. All HIV-seropositive (HIV+) samples were tested for viral load at a central laboratory. The 90-90-90 targets were defined as: (1st 90) the proportion of people living with HIV (PLHIV) who reported knowing their HIV+ status; (2nd 90) the proportion of PLHIV who knew their status and reported being on antiretroviral therapy (ART); and (3rd 90) the proportion of PLHIV who reported being on ART who had measured VLS (HIV RNA < 1,000 copies/ml).
Results: Of 16,939 participants, 2,446 tested HIV+ (Overall/Total HIV prevalence=12.6%; female=15.7%, male= 9.3%). Among all PLHIV, irrespective of knowledge of HIV+ status and reported ART status, 77.4% had VLS (female VLS=81.7%, male VLS=69.6%) [Table]. Among PLHIV, 78.8% reported knowing that they were HIV+ (female=83.1%, male=71.1%). Among PLHIV who reported knowing their HIV+ status, 95.3% reported being on ART, (female ART=96.0%, male ART=93.8%). Among PLHIV who reported ART use, 91.5% had VLS (female VLS=92.2%, male VLS=89.9%). (Table)
Conclusions: Namibia is the first country in Africa to have reached and surpassed at a national level the UNAIDS 2020 goal of having at least 73% of all people living with HIV be virally suppressed. NAMPHIA data also show that once diagnosed, a high proportion (≥ 90%) of both male and female PLHIV initiated ART and achieved VLS. While this is a remarkable accomplishment, 21.2% of PLHIV are unaware of their HIV+ status, including almost 30% of men. Strategies to improve HIV testing, particularly for men, are urgently needed to ensure Namibia's continued progress towards HIV epidemic control.

	Females % [95% CI]	Males % [95% CI]	Total % [95% CI]
HIV prevalence among adults	15.7 [14.5–16.8]	9.3 [8.5–10.1]	12.6 [11.7–13.5]
Prevalence of overall VLS among HIV+ adults, irrespective of awareness of diagnosis or ART status	81.7 [79.1–84.3]	69.6 [65.2–74.0]	77.4 [74.8–80.0]
90-90-90 Target Indicators			
HIV+ adults who report knowing their HIV+ status (1st 90)	83.1 [80.7–85.4]	71.1 [67.4–74.8]	78.8 [76.6–81.1]
Self-reported ART use among HIV+ adults who report knowing their HIV+ status (2nd 90)	96.0 [94.5–97.5]	93.8 [90.8–96.8]	95.3 [93.6–97.0]
VLS among HIV+ adults 15-64 who report ART use and knowing their HIV+ status (3rd 90)	92.2 [90.4–94.0]	89.9 [86.7–93.2]	91.5 [89.8–93.2]

Empowerment clubs did not increase PrEP continuation among adolescent girls and young women in South Africa and Tanzania - Results from the EMPOWER randomised trial

S. Delany-Moretlwe[1], M. Chersich[1], S. Harvey[2], A. Stangl[3], D. Baron[1], M. Columbini[2], F. Scorgie[1], N. Naicker[1], S. Kapiga[2,4], EMPOWER study group

[1]University of the Witwatersrand, Wits RHI, Johannesburg, South Africa, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]ICRW, Washington DC, United States, [4]Mwanza Intervention Trials Unit, Mwanza, Tanzania, United Republic of

Background: Background: Adolescent girls and young women (AGYW) are likely to benefit from PrEP. Strategies to support PrEP uptake and address barriers to consistent use are urgently needed. We conducted a randomised controlled trial to evaluate whether empowerment clubs increase PrEP uptake and continuation among AGYW.

Methods: Methods: We enrolled sexually active, HIV-negative women into an open-label PrEP study. Participants were randomised to standard of care (SOC), which included comprehensive sexual and reproductive health care, with counselling and SMS reminders for PrEP users, or to empowerment clubs plus SOC. A standardised four-session curriculum developed to support safe introduction of PrEP within relationships was delivered at monthly facilitator-led, small group sessions. Clinic follow-up visits were scheduled at months 1, 3 and quarterly thereafter, for up to 15 months. We used pharmacy records to measure PrEP continuation. We assessed differences in PrEP continuation using Kaplan-Meier survival analysis, by log-rank test.

Results: Results: From October 2016 to July 2017, 619 women were screened, 431 women enrolled (SA n=379, Tz n=52) and 213 randomised to clubs. Participants were mostly unmarried (90%), 27% had >1 partner in the past 6 months, 39% used a condom at last sex and 33% had a curable STI; most (84%) believed PrEP could prevent HIV. Of these, 408 initiated PrEP at, and 8 after, enrolment (97%) (SA n=364, Tz n=52). Participants completed a median of 3 follow up visits (range 0-6) and one club session (range 0-7); 48% did not attend any club sessions. In the ITT, PrEP continuation did not vary significantly by study arm (p-value =0.31); PrEP continuation was 73% at M1, 61% at M3 and 34% at M6 (Figure 1). There was also no difference in PrEP continuation when comparing those that attend ≥1 club session compared to none (p-value =0.12).

Conclusions: Conclusions: While PrEP uptake was high in this at-risk population, use diminished with time. Empowerment club participation was low and did not enhance PrEP continuation, contrary to experiences in the HIV treatment field. Ongoing analyses will elucidate barriers to club participation and reasons for PrEP discontinuation and inform the development of future tailored PrEP support packages for adolescents.

Ixazomib reduces HIV-1 reservoir size in a Casp8p41-dependent manner

N. Cummins[1], S. Natesampillai[1], Z. Nie[1], R. Sampath[1], J. Baker[2], K. Henry[3], M. Pinzone[4], U. O'Doherty[4], E. Polley[5], G. Bren[1], D. Katzmann[5], S. Rizza[1], A. Tande[1], M. Mahmood[1], J. Zeuli[5], C. Rivera[5], S. Kumar[5], A. Badley[1]
[1]*Mayo Clinic, Infectious Diseases, Rochester, United States,* [2]*University of Minnesota, Minneapolis, United States,* [3]*Hennepin County Medical Center, Minneapolis, United States,* [4]*University of Pennsylvania, Philadelphia, United States,* [5]*Mayo Clinic, Rochester, United States*

Background: The main barrier to HIV-1 cure is the latent reservoir that persists despite suppressive ART. Following reactivation from latency, HIV-infected cells generate protease and the HIV-specific cell death stimulus, Casp8p41, yet resist Casp8p41-mediated apoptosis through neutralization by Bcl2. Since proteins that have been inactivated are often degraded by the proteasome, we investigated whether the Casp8p41-Bcl2 complex was as well using *in vitro* and *ex vivo* models.
Methods: Polyubiquitination of Casp8p41 and the Casp8p41-Bcl2 complex was assessed by immunoprecipitation and immunoblot. Expression of Casp8p41 was assessed in the presence of ixazomib by flow cytometry. Apoptosis in HIV-1 infected cells in response to ixazomib was assessed in chronically infected J-Lat 10.6 cells, acutely infected primary CD4 T cells, and *ex vivo* CD4 T cells from HIV-1 infected patients. HIV reactivation was assessed in J-Lat 10.6 cells and HIV LTR activation assessed using HIV-LTR luciferase reporter. We have obtained an FDA IND for use of ixazomib in HIV infected patients and are enrolling a Phase 1b/2a clinical trial of ixazomib in ART-suppressed HIV-1 positive patients (NCT02946047).
Results: Casp8p41 bound to Bcl2 is polyubiquitinated and degraded by the proteasome. Ixazomib directly (a) induces HIV reactivation in an NFkB dependant manner, (b) increases Casp8p41 and induces apoptosis of infected but not uninfected cells, and (c) decreases viral replication. *Ex vivo* treatment of CD4 T cells from ART suppressed, HIV-1+ patients with a single dose of ixazomib reduces total cell associated HIV DNA by a median of 35% [IQR 7%, 42%] (P=0.007) and integrated HIV DNA by a median of 69% [IQR 58%, 89%] (P< 0.001). Preliminary clinical trial results indicate that ixazomib doses of 1-2mg weekly are safe and well tolerated.
Conclusions: The FDA-approved proteasome inhibitor ixazomib reactivates HIV-1, blocks degradation of HIV specific death stimulus Casp8p41, and reduces HIV reservoir size *ex vivo*. Enrollment of a Phase 1b/ 2a clinical trial of ixazomib is ongoing to evaluate the primary outcome of safety and tolerability, and secondary outcomes of HIV reservoir size and immunologic status.

Diagnostic accuracy, feasibility and acceptability of HIV oral fluid rapid tests among hard-to-reach key populations in Latvia, the country with highest infection rates in Europe

A. Kivite[1], R. Kaupe[1,2], I. Linina[1], I. Upmace[1,3], HERMETIC study group
[1]*Riga Stradins University, Riga, Latvia,* [2]*NGO "DIA+LOGS", Riga, Latvia,* [3]*NGO "Baltic HIV Association", Riga, Latvia*

Background: In Europe, Latvia has the highest rate of new HIV diagnoses and one of the lowest HIV testing rates. Half of the HIV cases are estimated to be undiagnosed and the proportion of late diagnoses is high (>50%). Thus, new strategies to promote HIV testing are of utmost priority.
Methods: For the first time oral fluid rapid tests (OraQuick®) were used to promote HIV testing outside clinical settings and stationary harm reduction sites. Between September 2017 and February 2018, 310 people who inject drugs (PWID) were tested via mobile van services and 205 men who have sex with men (MSM) via outreach work in night clubs. Participants were also tested with a capillary blood rapid test (CHIL®) to compare the two methods. Diagnostic accuracy of OraQuick® was assessed against the HIV positive serostatus, which was defined by either having a positive capillary blood rapid test or participants' self-reported positive HIV serostatus. Acceptability of the oral fluid tests was assessed through mixed methods, i.e. quantitative questionnaires (n=515), 3 focus groups and 7 in-depth interviews. Chi square or Fisher exact test were employed to analyze quantitative data, qualitative data were analyzed inductively adopting thematic analyses.
Results: OraQuick® tests had 84.4% sensitivity, 99.1% specificity, 94.2% positive and 97.3% negative predictive value. No significant differences were identified in accuracy measures between PWID and MSM. Contradictory test results occurred mostly among participants on anti-retroviral therapy. MSM's awareness of the oral fluid test before the study was greater compared to PWID (32.0% vs 21.8%, p< 0.001). Acceptability was higher among MSM. They had greater trust in the validity of the test (p< 0.001) and recommended the test more often to others (p=0.08). PWID trusted the capillary blood test more than the oral fluid test (p< 0.001). Qualitative results showed that mistrusting oral fluid test results was due to scepticism about new interventions in general and by confusion about the fact that HIV cannot be transmitted via saliva.
Conclusions: Accuracy of the oral fluid test was high in Latvia. Oral fluid tests were more accepted by MSM than PWID. Educational interventions should clarify the existing target-group specific misconceptions.

* Measures of OraQuick® validity and performance were calculated compared to HIV positive serostatus, which was defined by either having a positive capillary blood rapid test or when the patient self reported a positive HIV serostatus prior to testing.

[Diagnostic accuracy and acceptability of oral fluid test vs capillary blood test]

THPDD01 Knowing and resolving stigma

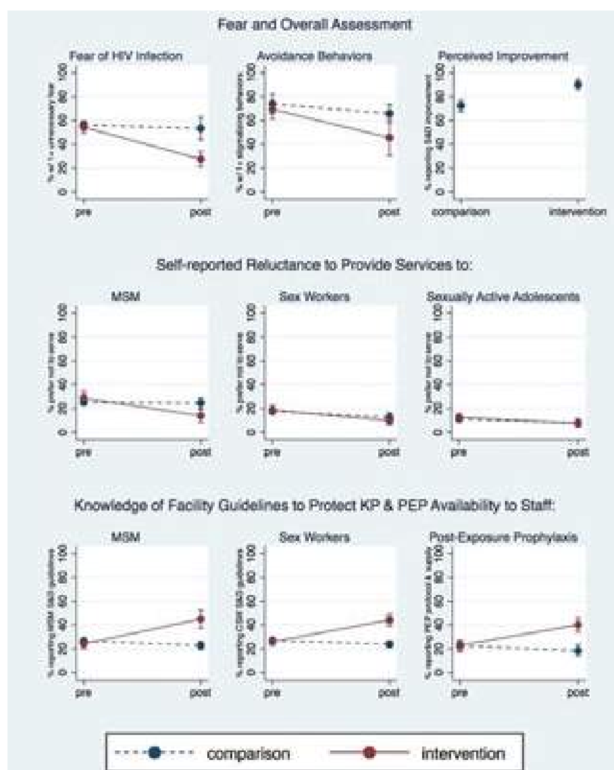
THPDD0108LB

Reducing health worker stigma and discrimination is critical to reaching 90-90-90 targets and is possible: Evaluation results of a whole-facility approach in Ghana

L. Nyblade[1], N.A. Addo[2], K. Atuahene[3], E. Gyamera[2], C. Stewart[1], S. Jacinthe[4], E. Essandoh[4], N. Alsoufi[4], R. Vormawor[2], J. Kraemer[5]
[1]HP+/RTI International, Washington, United States, [2]Educational Assessment and Research Center, Accra, Ghana, [3]Ghana Aids Commission, Accra, Ghana, [4]United States Agency for International Development, Accra, Ghana, [5]Georgetown University, Washington, United States

Background: Achieving 90-90-90 targets requires addressing structural factors to reach people who are hidden due to stigma and discrimination(S&D) from HIV, key population or other marked status. S&D in health facilities are particularly detrimental, yet their reduction is not a standard or scaled practice in most HIV interventions or health systems. Lack of evaluated S&D-reduction interventions is a contributing factor. The USAID-and-PEPFAR-funded Health-Policy-Plus project has partnered with the Ghana AIDS Commission and the Educational Assessment Research Center, with support from The Global Fund, to test a whole-facility approach to S&D-reduction.

Methods: Representative baseline (n=717 females/432 males; August 2017) and endline (n=778 females/371 males; April 2018) surveys capturing stigma-drivers and manifestations from health facility staff (HFS) in 10 high-HIV caseload facilities (5 intervention matched with 5 comparison), in five regions of Ghana. Endline data was collected six months after starting the still-ongoing intervention. We estimated before-after trends and differences-in-differences by fitting generalized linear models with identity link functions and binomial error distributions. Standard errors were clustered by facility. Interventions included: capacity building for facility-based S&D-reduction training teams (health workers+clients); 2-day participatory training for all staff levels (clinical+non-clinical), targeting 70% of all facility staff; facility-based S&D-reduction champion teams that led onsite activities. All 10 facilities received baseline data collection and participatory data validation that included action planning.



[Changes in Fear, Care Willingness, and Knowledge of Policy]

Selected Difference-in-Differences (change) in pre-post data collection, comparing intervention (n=1,198) to comparison (n=1,110) health facilities							
S&D indicator	% difference in change between intervention and comparison facilities in non-stigmatizing direction	Significance (P-value)	95% Confidence Interval	S&D indicator	% difference in change between intervention and comparison facilities in non-stigmatizing direction	Significance (P-value)	95% Confidence Interval
Fear of HIV transmission during routine care for people living with HIV				*Routinely engaging in unnecessary and stigmatizing avoidance behaviors with clients living with HIV*			
Touching clothing of a client living with HIV (n= 1,848)	11.25%	0.037	7.0, 21.8	Avoid physical contact (n=1,827)	1.7%	0.367	-2.0, 5.42

Drawing blood from a client living with HIV (n=1,588)	23.29%	<0.001	14.53, 32.04	Wear gloves during all aspects of the patient´s care (n=1,698)	4.2%	0.320	-3.92, 11.97
Taking the temperature of a client living with HIV (n=1,613)	6.7%	0.184	-3.21, 16.67	Use extra precautionary measures only with clients living with HIV (n=1,678)	24.67%	<0.001	17.46, 31.88
Composite: at least one of the above (n=1,958)	**23.86%**	**<0.001**	**10.69, 37.04**	**Composite: usually engage in at least one of the avoidance behaviors (n=1,940)**	**15.65%**	**0.011**	**3.61, 27.70**
Own preference to not treat men who have sex with men				*Own preference to not treat sex workers*			
Men who have sex with men (n= 2,275)	14.2%	0.001	5.71, 22.59	Sex workers (n= 2,274)	3.8%	0.238	-2.51, 10.08

[Selected Difference-in-Differences (change) in pre-post data collection, comparing intervention (n=1,198) to comparison (n=1,110) health facilities]

Results: There were statistically significant before-after improvements in most outcome domains in intervention facilities (Table 1/Figure 1), and smaller improvements in comparison facilities. We observed statistically significant difference-in-differences in reductions in unnecessary fear (23.9%; p< 0.001), stigmatizing avoidance behaviors (15.7%; p=0.011), preferences not to treat MSM (14.2%; p=0.001), as well as several facility policies. Intervention facilities' staff were 21.5% (p=0.019) more likely to report that behavior toward patients was much better at follow-up than comparison staff. Key intervention ingredients include: data to define the problem and catalyze action; building facility ownership and facility-led response; participatory training; empowered HFS champions.

Conclusions: S&D-reduction interventions targeting the whole facility are feasible, welcomed, and stimuli for change in a short time frame (6-months). Reducing S&D in health facilities is critical to improving quality of care to ensure equitable access to services for all.

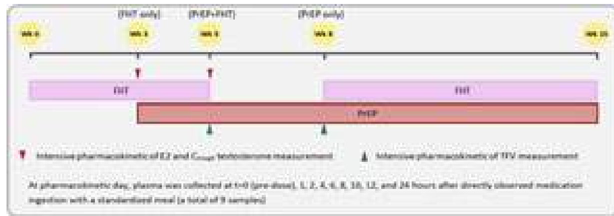
Drug-drug interactions between the use of feminizing hormone therapy and pre-exposure prophylaxis among transgender women: The iFACT study

A. Hiransuthikul[1], K. Himmad[1], S. Kerr[2,3], N. Thammajaruk[2], T. Pankam[1], R. Janamnuaysook[1], S. Mills[4], R. Vannakit[5], P. Phanuphak[1], N. Phanuphak[1], iFACT study team
[1]The Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [3]Kirby Institute, University of New South Wales, Sydney, Australia, [4]LINKAGES Thailand FHI 360, Bangkok, Thailand, [5]Office of Public Health, United States Agency for International Development, Bangkok, Thailand

Background: Concerns about potential drug-drug interactions (DDI) between feminizing hormone therapy (FHT) and pre-exposure prophylaxis (PrEP) have hampered uptake and adherence of PrEP among transgender women (TGW). To determine DDI between FHT and PrEP, we measured pharmacokinetic parameters of blood plasma tenofovir (TFV), estradiol (E2), and testosterone.

Methods: Twenty TGW who never underwent orchiectomy and had not received injectable FHT within 6 months were enrolled between January and March 2018. FHT (estradiol valerate 2 mg and cyproterone acetate 25 mg) were prescribed to participants at baseline until week 5, and week 8 until the end of study. PrEP (tenofovir disoproxil fumarate 300 mg/emtricitabine 200 mg) was initiated at week 3 and continued without interruption. Intensive E2 pharmacokinetic parameters and trough serum testosterone concentration (C_{trough}) were measured at weeks 3 and 5 (assessing DDI between PrEP and FHT), and intensive TFV pharmacokinetic parameters were measured at weeks 5 and 8 (assessing DDI between FHT and PrEP).



[iFACT study scheme]

E2 pharmacokinetic parameter	Week 3 (FHT only)	Week 5 (PrEP+FHT)	GMR (95%CI)	p-value
AUC_{0-24} (pg*h/mL)	775.13 (26.2)	782.84 (39.6)	1.01 (0.89 - 1.15)	0.88
C_{max} (pg/mL)	51.47 (26.9)	55.76 (32.9)	1.08 (0.94 - 1.24)	0.25
C_{24} (pg/mL)	15.15 (42.0)	14.32 (67.4)	0.95 (0.75 - 1.19)	0.63
Half-life (h)	11.25 (32.6)	11.83 (50.9)	1.05 (0.87 - 1.27)	0.60
TFV pharmacokinetic parameter	Week 5 (PrEP+FHT)	Week 8 (PrEP only)	GMR (95%CI)	p-value
AUC_{0-24} (mg*h/L)	2.28 (26.2)	2.63 (26.9)	0.87 (0.78 - 0.96)	0.009
C_{max} (mg/L)	0.36 (34.8)	0.32 (25.3)	1.10 (0.95 - 1.28)	0.2
C_{24} (mg/L)	0.04 (28.8)	0.05 (28.0)	0.83 (0.76 - 0.90)	<0.001
Half-life (h)	15.19 (15.4)	15.69 (23.0)	0.97 (0.88 - 1.07)	0.53

[Summary of E2 and TFV pharmacokinetic parameters; data are presented in geometric mean (%CV)]

Results: Median (IQR) age, BMI, and CrCl were 21.5 (21-26) years, 20.6 (19.0-22.4) kg/m², and 0.86 (0.75-0.94) mL/min, respectively. The geometric mean (%CV) of area under curve from time zero to 24 hr (AUC_{0-24}), maximum concentration (C_{max}), and concentration at 24 hr (C_{24}) of E2 at weeks 3 and 5 were 775.13 (26.2) pg*h/mL, 51.47 (26.9) pg/mL, and 15.15 (42.0) pg/mL; and 782.84 (39.6), 55.76 (32.9), and 14.32 (67.4), respectively. The geometric mean (%CV) of TFV AUC_{0-24}, C_{max}, and C_{24} at weeks 5 and 8 were 2.28 (26.2) mg*h/L, 0.36 (34.8) mg/L, and 0.04 (28.8) mg/L; and 2.63 (26.9), 0.32 (25.3), and 0.05 (28.0), respectively. The geometric mean of AUC_{0-24} and C_{24} of TFV at week 5 were significantly less than that at week 8 by 13% (p=0.009) and 17% (p< 0.001), respectively. There were no significant changes in E2 pharmacokinetic parameters and median (IQR) C_{trough} of bioavailable testosterone between week 3 and 5.

Conclusions: Our study demonstrated lower plasma TFV exposure in the presence of FHT, suggesting that FHT may potentially affect PrEP efficacy among TGW; but E2 exposure was not affected by PrEP. Further studies are warranted to determine whether these reductions in TFV are clinically significant.

Surface signature of HIV latently-infected cells revealed using direct hybridization-based digital counting

H.S. Sperber[1,2], L.R. Chavez[1,3], S.K. Pillai[1,3]
[1]*Blood Systems Research Institute, San Francisco, United States, [2]Free University of Berlin, Biochemistry, Berlin, Germany, [3]University of California, San Francisco, United States*

Background: The main obstacle to a cure for HIV infection is a population of long-lived HIV latently-infected cells that persist during antiretroviral therapy (ART). Upon cessation of ART, remaining latently-infected cells typically undergo reactivation and reinitiate spreading of viral infection. Identification of a reliable surface biomarker of HIV latently-infected cells will be critical to eradicating the latent reservoir. We implemented a direct hybridization-based digital counting approach to identify a cellular transcriptomic and proteomic signature of latent HIV infection.
Methods: We infected fresh primary CD4+ T cells collected from healthy donors with a specialized dual-reporter virus that enables isolation and characterization of HIV latently-infected, productively-infected, and uninfected cells. We then implemented the nanoString nCounter platform, a direct hybridization-based, nucleic acid counting technology enabling simultaneous detection and quantification of 770 mRNA and 30 surface protein targets. Expression patterns were compared between the populations using t-tests with a p< 0.01 cutoff.
Results: Virus-unexposed control cells exhibited a dramatically different expression pattern compared to virus-exposed, uninfected cells, indicative of bystander effects or effects of abortive infection. Virus-exposed uninfected and HIV productively-infected cells exhibited a similar surface protein expression pattern, except for a specific downregulation of CD4 and upregulation of GITR protein on the surface of productively infected cells. The expression of 6 mRNAs (*CCL5*, *IL2RA*, *CCL3L1*, *BCL2L1*, *CSF1*, *CD80*) and one surface protein (IL2R) target was significantly elevated in productively infected cells as compared to uninfected cells. HIV latently-infected cells featured a distinct surface protein expression signature with respect to both uninfected and productively infected cells; expression of nine targets (HLA-DRA, CD28, NT5E, CD27, CD8A, CD163, NKP46, CTLA-4, CD45) was specifically elevated on the surface of HIV latently-infected cells.
Conclusions: The application of direct hybridization-based digital counting to primary cell-based models of HIV latency is a promising approach to simultaneously discover intracellular and extracellular biomarkers of latent infection. Surface expression of TNF receptor superfamily members associates with HIV transcriptional states; therefore, the TNF superfamily may include pharmacologic targets for eradication efforts. Our results warrant validation using clinical samples from ART-suppressed HIV-infected individuals.

LBPEA002

Characterization of the HIV-1 reservoir in $CD32^+$ $CD4^+$ T cells

G. Darcis[1,2], N. Kootstra[3], B. Hooibrink[4], T. van Montfort[1], S. Jurriaans[5], M. Bakker[1], C. van Lint[6], B. Berkhout[1], A. Pasternak[1]
[1]*University of Amsterdam, Laboratory of Experimental Virology, Amsterdam, Netherlands, [2]Liège University Hospital, Infectious Diseases Department, Liège, Belgium, [3]University of Amsterdam, Department of Experimental Immunology, Amsterdam, Netherlands, [4]University of Amsterdam, Department of Cell Biology, Amsterdam, Netherlands, [5]University of Amsterdam, Laboratory of Cinical Virology, Amsterdam, Netherlands, [6]Université Libre de Bruxelles, Service of Molecular Virology, Bruxelles, Belgium*

Background: CD32 was reported to mark the HIV-1 reservoir harboring replication-competent proviruses, but several recent reports challenged this finding. We aimed to confirm or deny the usefulness of CD32 as a marker of the latent reservoir and to further characterize the phenotype of these $CD32^+$ $CD4^+$ T-cells, as well as the transcriptional activity of HIV-1 residing in this reservoir.
Methods: CD32 expression was measured by flow cytometry on PBMCs from ART-treated HIV-1 infected patients (n=18) and uninfected controls (n=3). Co-expression of HLA-DR, immune checkpoint receptors (PD-1, TIGIT, LAG-3) and CD2 was measured by flow cytometry. HIV-1 DNA and unspliced RNA were quantified in bulk PBMC samples and in $CD32^+$ and $CD32^-$ fractions sorted with magnetic beads.
Results: The median frequency of $CD32^+$ $CD4^+$ T-cells in HIV-infected individuals was 0.07% (range 0.0078%-0.87%), which was significantly higher than in the controls (0.01%, p=0.0158). Overall, $CD32^+$ $CD4^+$ T-cells were not enriched for HIV-1 DNA or RNA compared with $CD32^-$ $CD4^+$ cells (n=18). However, in a subgroup of patients with smaller $CD32^+$ $CD4^+$ T-cell fractions (n=9), we observed a significant enrichment for HIV-1 DNA in this fraction compared to the corresponding $CD32^-$ $CD4^+$ fraction (average of 5.7-fold, p=0.012).
We also found a positive correlation between the percentage of $CD32^+$ $CD4^+$ T-cells and total HIV-1 DNA load in PBMCs (rho=0.58; p=0.012). $CD32^+$ $CD4^+$ T-cells demonstrated increased expression of LAG-3 (p=0.0156), TIGIT (p=0.0156) and HLA-DR (p<0.0001) compared with $CD32^-$ $CD4^+$ T-cells in HIV-infected patients. We did not observe a statistically significant change in PD-1 and CD2 expression between the $CD32^+$ or $CD32^-$ $CD4^+$ T-cell populations.
Conclusions: We confirmed that $CD32^+$ $CD4^+$ T-cells are enriched for HIV-1 DNA, although the level of enrichment was less pronounced than previously reported. Our results suggest that the CD32 expression level in the $CD32^+$ $CD4^+$ T-cell fraction correlates with the level of HIV-1 enrichment in this fraction, which underscores the importance of using highly CD32-expressing cells for analysis and might explain the negative results obtained by others. Our data further indicate that these $CD32^+$ $CD4^+$ T-cells are active, rather than resting cells, and that they often co-express the immune checkpoint receptors TIGIT and LAG-3.

LBPEA003

ART does not inhibit antigen presenting cell-mediated HIV *trans* infection

G. Rappocciolo[1], D. Delucia[1], N. Sluis-Cremer[1,2], C. Rinaldo[1]
[1]*University of Pittsburgh, Infectious Diseases and Microbiology, Pittsburgh, United States, [2]University of Pittsburgh, School of Medicine, Pittsburgh, United States*

Background: Professional antigen presenting cells (APC; dendritic cells [DC], macrophages, B cells) mediate highly efficient HIV *trans* infection of CD4+ T cells, which could contribute to the persistent HIV reservoir during ART. We evaluated *trans* infection by APC from HIV-infected individuals on suppressive ART in the Multicenter AIDS Cohort Study (MACS) to define the role of APC-T cell virus spread in HIV persistence.
Methods: HIV R5-tropic Bal-loaded APC from 10 chronic HIV-infected MACS participants (PR) before and after initiation of ART, and APC from 5 seronegative controls (SN) treated with ART *in vitro* (CCR5 agonist, NRTI, PI and NNRTI, alone or in combination), were mixed with autologous or heterologous CD4+ T lymphocytes to assess *trans* infection. To control

for the effect of residual ART, APC *trans* infection was also tested with both autologous and heterologous SN CD4+ T cells. Virus replication was measured by p24 ELISA
Results: APC from all 10 HIV-infected PR *trans* infected CD4+ T cells with equivalent efficiency either prior to or after initiation of ART *in vivo*. In sharp contrast, their CD4+ T cells were resistant to direct, *cis* infection, showing >90% inhibition compared to pre-ART susceptibility. APC from 5 SN exposed in vitro to 4 different classes of ART alone or in combination at physiological concentrations, maintained their ability to *trans* infect CD4+ T cells, while *cis* infection of their CD4+ T cells was inhibited (>90%). *Trans* infection was only inhibited when DC and/or CD4 T cells from SN were exposed *in vitro* to the CCR5 antagonist maraviroc (25-75% inhibition through 12 days of culture) or the NNRTI rilpivirine (90% inhibition by day 12). Strikingly, when B cells were used, none of the drugs tested *in vitro* inhibited *trans* infection.
Conclusions: We show for the first time that APC from PR on ART maintain their ability to *trans* infect CD4+ T cells, which was confirmed *in vitro* in APC from SN. This supports a central role for APC-mediated *trans* infection in maintaining the HIV reservoir despite virus-suppressive ART.

LBPEA004

Evidence of HIV replication in tissue samples at autopsy from donors on cART with undetectable HIV RNA in blood

V. Natarajan[1], Y. Badralmaa[1], H.C. Lane[2]
[1]Leidos Biomedical Research Inc, Frederick, United States, [2]National Institute of Allergy and Infectious Diseases, Clinical and Molecular Retrovirology Section, Laboratory of Immunoregulation, Bethesda, United States

Background: When antiviral therapy is interrupted in HIV patients with prolonged viral suppression, invariably viral rebound occurs suggesting potential viral reservoirs. Source of the viral rebound is thought to be either the activation of latently infected cells or from tissues that had low antiviral drug penetrance. To investigate the potential tissue reservoir, samples obtained at autopsy from patients with suppressed viremia were analyzed for viral DNA and RNA.
Methods: Autopsy samples were collected from donors who were compliance with antiviral therapy and died from causes unrelated to HIV. The following samples were obtained from donors within 24 h after their death: Frontal cortex, parietal cortex, temporal cortex, brain-white matter, lymph node, liver, spleen, terminal ilium, transverse colon, sigmoid colon, esophagus-Mucosa, pancreas, stomach, heart, kidney and tonsil. HIV DNA and RNA levels in purified nucleic acids from blood and different tissues were estimated using two different primers and probes from the gag region to increase the sensitivity of detection. Quality of the RNA from the tissues was monitored by spiking the samples with Rous sarcoma virus (RSV) and estimating the RSV RNA recovered.
Results: Even though the blood sample from five donors had HIV DNA, viral RNA was undetectable in all of them indicating the suppression of viral replication. HIV DNA was found in many of the tissue samples examined. Additionally, HIV RNA was found in lymph node (1/5), colon (4/5), spleen (3/5), brain (3/5), kidney (1/5), and liver (3/5). Interestingly, three of these patients were diabetic with kidney disease and the highest level of HIV DNA was found in their kidney.
Conclusions: Presence of HIV RNA in tissue samples from all patients with "undetectable" viral RNA in their blood indicates ongoing transcription of proviral DNA. This may represent persistent viral replication and/or transcripts from "defective" proviruses in those organs.

LBPEA005

Single-cell RNA-seq reveals a distinct transcriptomic signature of CD32+ CD4+ T cells from HIV+ individuals on suppressive therapy

M. Abdel-Mohsen[1], A. Kossenkov[1], C. Tomescu[1], S. Vadrevu[1], L. Giron[1], K. Lynn[2], K. Mounzer[3], P. Tebas[2], L. Montaner[1]
[1]The Wistar Institute, Philadelphia, United States, [2]University of Pennsylvania, Philadelphia, United States, [3]Jonathan Lax Center, Philadelphia FIGHT, Philadelphia, United States

Background: CD32 was suggested as a marker of the replication-competent HIV reservoir. However, we recently reported that CD32 is expressed on cells with transcriptionally active HIV but does not enrich for HIV DNA in resting T cells [PMID 29669853; *Sci Transl Med*. 2018]. CD32 may represent a tool to better understand persistent HIV transcription during suppressive antiretroviral therapy (ART). We used single-cell RNA-sequencing to characterize the transcriptomic signature of CD32+ CD4+ T cells from HIV+ individuals on ART.
Methods: CD32+ CD4+ and CD32- CD4+ T cells were sorted from HIV+ ART-suppressed individuals using Fluorescence-activated cell sorting (FACS). The nanowell-based single-cell RNA-sequencing system, ICELL8, was used to characterize the single-cell transcriptomes of 151 CD32+ CD4+ T cells and 186 CD32- CD4+ T cells. Only cells with >100,000 reads were considered for subsequent analysis (131 CD32+ CD4+ T cells and 66 CD32- CD4+ T cells). False discovery rates (FDR) were calculated to account for multiple comparisons in statistical analyses. Ingenuity pathway analysis (IPA) was used to evaluate the functional significance of differentially expressed genes.
Results: All sorted cells expressed CD3 transcripts, suggesting a T cell lineage, as expected. 17.6% of CD32+ CD4+ T cells expressed CD32b transcripts compared to only 3% of CD32- CD4+ T cells. Out of the 17.6%, 9.2% also expressed transcripts of non-T cell markers (CD14, CD19, CD86, CD68, CD79A, or CD79B). We compared the transcriptomic profile of CD4+ T cells express CD32b but not any of the non-T cell markers to CD4+ T cells express neither CD32b transcripts nor any non-T cells markers. 20 genes were differentially expressed between CD32+ CD4+ T cells and CD32- CD4+ T cells (FDR < 0.05), including genes associated with protein ubiquitination, IL-10, Toll-like Receptor, PI3K/AKT, TNFR1, and IL-6 signaling pathways (FDR< 20%).
Conclusions: Our analysis identified several transcriptomic pathways that are differentially expressed in the CD32+ CD4+ T cells and may contribute to the higher HIV transcriptional activity we previously observed in this population. Our transcriptomic signatures highlight host factors and pathways that may be targeted to manipulate the levels of latent HIV transcription during suppressive ART.

FDA-approved chemotherapeutic drugs that inhibit VEGF, RAF-1, B-RAF and the proteosome reverse HIV latency without global T cell activation

I. Munoz-Arias[1], E. Gibson[2], E. Hanhauser[3], G. Wu[4], C. Thanh[5], M.A. Mohsen[5], L. Hogan[6], K. Hobbs[5], B. Howell[7], S. Pillai[8], S. Deeks[5], T. Henrich[5]
[1]University of California at San Francisco, Department of Experimental Medicine, San Francisco, United States, [2]University of Califronia at San Francisco, San Francisco, United States, [3]MIT, Boston, United States, [4]Merck & Co, Department of Infectious Diseases, West Point, United States, [5]University of California at San Francisco, San Francisco, United States, [6]Trinitinity College, Dublin, United Kingdom, [7]Merck, Readington Township, United States, [8]University of California at San Fracisco, San Francisco, United States

Background: Drugs that reactivate latent HIV-1 reservoirs without global CD4+ T cell activation are urgently needed. Novel cancer therapeutic drugs are promising given the ability to target specific cell signaling pathways that may directly reverse HIV latency.
Methods: A panel of small-molecule chemotherapeutic compounds were screened for their capacity to reactivate HIV-1 from cART-suppressed HIV-1 infected patient-derived CD4+ T cells. To estimate reac-

tivation, increased cell-associated unspliced HIV-1 Gag RNA was measured by qPCR. To determine the frequency of individually HIV-1 reactivated cells, a novel single-cell-in-droplet (scd) PCR method was used. Viral production was measured by testing cell lysates and supernatant using the ultrasensitive Simoa p24 ELISA. Cells were also treated with Romodepsin and Bryostatin for comparison. Uninfected CD4+ T cells treated with drugs of interest were then analyzed for expression of surface activation markers, NF-B or NFAT target transcription and translation. The drug screen was then expanded to other compounds that target similar pathways.
Results: We identified several major cellular pathways whose inhibition leads to HIV reactivation. Bortezomib (26s proteosome), Sorafenib (VEGF/RAF-1/B-RAF), and Sunitinib (VEGFR) induced HIV-1 transcription from cART suppressed patient derived CD4+ T cells. In addition, after 6 days of culture, Bortezomib treatment led to increased HIV p24 detection in supernatant whereas Sunitinib and Sorafenib treatment resulted in greater p24 production in cell lysates.
None of these drugs induced global cell activation or production of the NFkB/NFAT targets tested. Single-cell ddPCR testing showed that these drugs led to a higher frequency of individual HIV Gag RNA+ cells, even when compared to Romodepsin (HDAC inhibitor) and Bryostatin (PKC agonist).
Of note, sunitinib-dependent HIV reactivation was muted by concurrent treatment with the mTOR inhibitor, PP242. To confirm that the inhibition of these pathways is involved in HIV reactivation, we identified four additional drugs that target these pathways (Axitinib, Cabozantinib, Regorafenib, Carfilzomib) and led to HIV-1 reactivation in primary CD4+ T cells.
Conclusions: We identified and characterized, for the first time, seven FDA approved chemotherapeutic drugs targeting VEGFR, BRAF/RAF-1 and the proteosome that induce HIV-1 reactivation from cART-suppressed patient CD4+ T cells with minimal CD4+ T cell activation or cytotoxicity.

LBPEA007

Broadly neutralizing antibodies reduce latent HIV infection in a primary T_{CM} model of latency

R.S. Resop, G. Mantus, A.B. Macedo, R. Lynch, A. Bosque
George Washington University, Microbiology, Immunology and Tropical Medicine, Washington, United States

Background: Broadly neutralizing antibodies (bNAbs) that target key epitopes on the HIV-1 Env protein, including the CD4 binding site, V1V2-apex and gp41, are of great interest as avenues for eradication of HIV. Although much literature exists on how bNAbs affect productive infection of HIV, less is known about how they impact establishment of latency. To address this question, we investigated whether bNAbs prevent establishment of latent HIV infection using our primary T central memory (T_{CM}) model of latency.
Methods: Briefly, we isolated naïve CD4+ T cells, activated and expanded them, and infected with NL4-3. Following infection, we crowded to allow cell-to-cell transmission, viral replication and establishment of latency, introducing bNAbs at this time point. We then treated with antiretroviral therapy and isolated CD4+ cells to eliminate productively infected cells. To assess levels of HIV latency, we reactivated for 48 hours with IL-2, CD3/28, or media-only control. Using this in vitro protocol, we examined whether administration of various bNAbs during the crowding phase of our model would 1) Reduce cell-to-cell transmission of virus and 2) Translate to reduced latent virus upon reactivation. We tested three bNAbs: 10E8, VRC-PG04 and PG09, in addition to an isotype control (C10).
Results: We first characterized the effect of bNAbs on productive infection by measuring intracellular p24 via flow cytometry. We found that for all three bNAbs we tested, cell-to-cell transmission was inhibited. We determined IC50 and IC90s for VRC-PG04 and 10E8 by 8-point titration in primary cells. Because VRC-PG04 was the most effective antibody (IC50 of 2.45 μg/mL vs. 14.85 μg/mL for 10E8), we further tested this bNAB over the full course of the model and found that treatment with VRC-PG04 can also prevent the establishment of latency. Interestingly, latent infection appeared more sensitive to inhibition by bNAbs than productive infection.
Conclusions: We demonstrate that broadly neutralizing antibodies may be effective at reducing not only productive HIV infection but also establishment of latent infection in a primary T_{CM} model of latency. These results indicate that the T_{CM} model of latency may be a valuable tool to investigate the role of VRC-PG04 and other bNAbs in preventing establishment of latency.

Dendritic cells drive antigen-specific exposure and immune elimination of HIV latently infected CD4+ T cells

J. Kristoff[1], N. Sluis-Cremer[2], M. Palma[1], T. Garcia-Bates[1], P. Gupta[1], C. Rinaldo[1], R. Mailliard[1]
[1]*University of Pittsburgh, Infectious Diseases and Microbiology, Pittsburgh, United States,* [2]*University of Pittsburgh, Microbiology and Medicine, Pittsburgh, United States*

Background: Exposing the latent reservoir of replication-competent HIV in ART-suppressed individuals is a major barrier to a cure. While dendritic cells (DC) have safely induced T cell responses in clinical trials of HIV, their HIV latency reversal (LR) potential has been underexplored. Here we investigate the use of type-1 polarized DC (DC1) to drive both antigen-specific HIV LR and CTL targeting of the exposed autologous HIV cellular reservoir.
Methods: Monocyte-derived DC1 were generated from chronic HIV-infected Multicenter AIDS Cohort Study participants on ART and tested for inducing HIV LR in naturally infected autologous CD4+ T cells, with or without HIV, CMV, or Flu antigens. CD3/CD28 activation served as the positive LR control. LR was determined by quantifying HIV RNA and intracellular expression of p24. DC1-induced HIV-specific CTL were used as autologous effectors against the DC-activated CD4+ T cells in cytotoxicity and viral outgrowth assays.
Results: DC1 induced both antigen-specific HIV LR and CTL capable of effectively killing the exposed HIV-infected targets. Importantly, the DC1-mediated latency reversal was antigen dependent, with CMV and HIV antigen having notable LR activity, while Flu antigen did not. Moreover, DC1 LR activity was sharply diminished with CD40L/CD40 blockade (94.1% ± 6.1% and 85.3% ± 13.2% inhibition of RNA and p24 expression, respectively), supporting the required involvement of cognate antigen-driven bidirectional signaling events between the DC1 and the antigen-responsive CD4+ T cells. Importantly, the DC1 LR activity exposed those targets harboring replication-competent virus, which were efficiently controlled by broadly reactive, DC1-induced HIV-specific CTL in respective short- and long-term cytotoxicity (75.4% ± 14.3% killing) and viral outgrowth (85.4% ± 13.5% suppression of p24) assays.
Conclusions: DC1 are uniquely capable of both activating HIV in latently infected CD4+ T cells and promoting their immune targeting by HIV-specific CTL. Inclusion of common MHC class II viral epitopes in DC1-based HIV immunotherapies, such as those derived from CMV, could promote sufficient CD4+ T cell ‚help' to support CTL induction, while serving as a safe and effective targeted means to unmask the latent HIV reservoir in antigen-specific CD4+ T cells.

ABX464, by binding the CBC 80/20 complex, enhances pre-mRNA splicing, resulting in the generation of novel HIV-derived RNA species and in increased expression of the anti-inflammatory miR124

J. Tazi[1], A. Vautrin[2], L. Manchon[3], A. Garcel[2], N. Campos[2], K. Chebli[3], D. Scherrer[2], J.-M. Steens[4], H. Ehrlich[4]
[1]*University of Montpellier, Montpellier, France,* [2]*ABIVAX, Montpellier, France,* [3]*University of Montpellier, CNRS, Montpellier, France,* [4]*ABIVAX, Paris, France*

Background: ABX464 is a first-in-class, clinical stage small molecule with at least three biological effects when given to HIV patients: 1) an antiviral effect, 2) a reduction in HIV-DNA in PBMCs, and 3) an anti-inflammatory effect through increased expression of miR-124 in rectal tissue.

In earlier studies, the antiviral effect was shown to be mediated through enhanced splicing of viral mRNA, while there was only a negligible effect on pre-mRNA splicing of cellular genes.
Methods: Using customized library probes targeting HIV sequences, cDNAs were prepared from infected PBMCs (+/- ABX464) of 6 donors. Given that the target of ABX464, the CBC complex, is also involved in the biogenesis of small non coding RNA including microRNAs, we also performed a microarray analysis of these RNAs from 6 healthy donors.
Results: In all samples treated with ABX464, 90% of assembled contigs corresponded to spliced RNA.In contrast, in untreated samples, >90% of the viral RNA is full length and unspliced. After filtering and analysis of splicing events in treated samples, 3 novel species of spliced RNA were identified. The capacity of these novel RNAs to generate immunogenic peptides is currently being tested.
While infection leads to large variations in the expression of small non coding RNAs, ABX464 induced a reproducible upregulation of a single microRNA, i.e. miR124, in both infected and non infected cells. This upregulation was only observed with locus miR124.1, which happens to have different long non coding transcripts that could be responsible for the biogenesis of miR124. ABX464 enhanced the splicing of a single long non coding RNA in this locus.
Conclusions: Our findings substantiate a mechanism of action of ABX464 that starts with CBC 80/20 binding, leading to a conformational change of this regulatory protein and enhanced splicing of a viral as well as a non coding RNA. HIV viral load reduction and, via upregulation of miR124, the generation of a therapeutic anti-inflammatory response are direct consequences of this mechanism. We are currently studying whether the observed reduction of HIV reservoir cells could be caused by the initiation of an immune response, e.g. through novel peptides/proteins generated by the modulation of splicing.

Background: HIV controllers, who spontaneously contain HIV replication to very low levels, develop particularly efficient antiviral T cell responses. To gain insights into the contribution of the CD4 helper subset to HIV control, we characterized the differentiation status of HIV-specific CD4+ T cells at the single cell level.
Methods: CD4+ T cells reactive with MHC-II tetramers specific for the most immunodominant HIV epitope (Gag293) were analyzed by multiplexed real-time qPCR (Biomark, Fluidigm) combined with multiparametric flow cytometry. HIV controllers from the ANRS CODEX-CO21 cohort with a viral load < 50 copies/mL were compared to efficiently treated patients with an equivalently low viral load.
Results: Gag293-specific cells from HIV controllers proved to express lower levels of CCR5 and PD-1 than those of treated patients, while CCL5 and TRBV2 expression were increased. As low expression of the HIV coreceptor CCR5 may inhibit HIV entry, we tested the susceptibility of Gag293-specific CD4+ T cells to fusion with an HIV-1 JRFL-BlaM-Vpr reporter virus. HIV controller specific cells proved less susceptible to HIV fusion than those of treated patients (P=0.017). Moreover, CCR5 expression in specific cells correlated with HIV fusion (R=0.83, P< 0.005). CCR5 expression in total CD4+ T cells did not reveal significant differences between groups. However, a negative correlation was observed between CCR5 expression in total CD4+ T cells and the frequency of Gag293-specific cells, indicating that the subset of controllers with low CCR5 expression maintained strong CD4 responses. Genetic analysis of one controller with particularly low fusion susceptibility uncovered biallelic mutations that impaired CCR5 expression.
Conclusions: Taken together, these findings reveal a lower susceptibility of HIV controller specific CD4+ T cells to HIV entry, and point to a role for low CCR5 expression in promoting spontaneous HIV control.

Autophagy suppresses mucosal HIV-1 replication and improves clinical outcomes for HIV-1 infected individuals

A. Cloherty, N. van Teijlingen, J. van Hamme, R. Sarrami-Forooshani, N. Kootstra, T. Geijtenbeek, C. Ribeiro
Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background: Contemporary HIV-1 antiretroviral therapy is highly effective, however, treated HIV-1 patients suffer from severe comorbidities due to persistent viral replication and immune dysfunction. There is thus an urgent need to identify therapeutic targets to enhance antiviral immunity and restore immune function in treated HIV-1 patients. Autophagy functions as an antiviral defense mechanism by degrading viruses and instructing adaptive antiviral T-cell responses. We were the first to show that autophagy inhibits mucosal HIV-1 infection, and to identify the molecular mechanism. Human TRIM5 mediates assembly of an autophagy-activating scaffold to HIV-1 components, which targets HIV-1 for degradation and potently restricts infection of human mucosal dendritic cell (DC) subsets. In this study, we aimed to define the *in vivo* relevance of these autophagy mechanisms in the disease progression of HIV-1 infected individuals. Furthermore, we identified autophagy-enhancing drugs that boost HIV-1 degradation at mucosal sites.
Methods: To this end, we analysed the effect of autophagy polymorphisms on the clinical course of HIV-1 infection in participants of the Amsterdam Cohort studies on HIV-1/AIDS (ACS). Furthermore, we investigated the impact of autophagy-enhancing drugs in HIV-1 infection and transmission using human primary mucosal DCs and *ex vivo* mucosal explant tissue models.
Results: Here, we show a novel protective role for autophagy machinery in HIV-1 infected individuals. Recently, we identified a gene polymorphism in a regulator of TRIM5-mediated autophagy that is associated with decreased plasma viral load, delayed disease progression and improved survival in HIV-1 infected individuals from the ACS. We demonstrated that donors homozygous for this autophagy polymorphism display increased autophagy levels and heightened CD8+T-cell effector responses *in vitro*, indicating a novel link between TRIM5-mediated autophagy and antiviral T-cell immunity. Notably, we have further shown that targeting autophagy with clinically approved drugs everolimus and carbamazepine decreased susceptibility to HIV-1 infection of emigrated DC subsets in *ex vivo* explant models.
Conclusions: Our data strongly suggest a pivotal role for TRIM5-mediated autophagy in limiting mucosal HIV-1 replication and boosting antiviral T-cell immunity. These recent findings underscore the *in vivo* relevance of autophagy mechanisms and the therapeutic potential of autophagy-targeting strategies to intervene in acute and chronic HIV-1 infections.

LBPEA012

Susceptibility to anti-HIV broadly neutralizing antibodies is concordant in plasma vRNA and PBMC proviral DNA compartments and supports potential utility of screening prior to therapy

J. Reeves[1], Y. Zheng[2], Y. Lie[1], L. Burke[3], B. Taiwo[4], C. Petropoulos[1], P. Tebas[5], M. Caskey[6], K. Bar[5], AIDS Clinical Trials Group
[1]Monogram Biosciences, San Francisco, United States, [2]Harvard University, Cambridge, United States, [3]Cornell University, New York, United States, [4]Northwestern University, Chicago, United States, [5]University of Pennsylvania, Philadelphia, United States, [6]The Rockefeller University, New York, United States

Background: Pre-existing resistance is a potential barrier to the efficacy of broadly neutralizing antibodies (bnAbs) for treatment and cure of HIV infection. We tested a panel of clinical samples to determine the range of baseline susceptibilities to bnAbs in clinical development and to assess the PhenoSense HIV Neutralizing Antibody Assay's (PS.HIV.nAb) predictive capacity.

Methods: Three samples (pre-ART plasma and PBMCs from 1 and 3 years of ART) from each of 65 chronically HIV-infected participants of the ART naïve trial A5257 were tested for neutralization sensitivity to seven bnAbs (VRC01, VRC07.523LS, 3BNC117, N6, 10-1074, CAP256-VRC26.25, 10E8) using the PS.HIV.nAb platform, which generates pseudovirions representing plasma vRNA or PBMC proviral DNA envelope quasispecies *(PMCID:PMC153062)*. PBMCs from 9 participants at entry to trial A5340, which evaluated VRC01 during ART interruption, were tested and compared with published plasma neutralization titers and time to rebound *(PMCID:PMC5292134)*. Rank-based Spearman Correlation and Fisher's exact tests were used for statistical analyses.

Results: The participants were 88% were male, 63% white, with median age of 37 years. Baseline viral load was >100,000 copies/ml in 40% of individuals and median CD4 count was 353 cells/mm^3. 50% inhibitory concentrations (IC50s) for the 3 samples are shown in Table 1. IC50s ranged between 1,000-10,000-fold for each bnAb, but pre-ART plasma, year 1 and 3 PBMC values were highly correlated (P< 0.001 for all comparisons). Among the A5340 samples, VRC01 IC50s from entry PBMCs correlated with published pre-ART plasma IC50s available for 5 participants (Spearman r=0.9, P=0.04). In 9 participants with entry PBMCs, VRC01 IC50s did not significantly correlate with time to rebound (Spearman r=0.35, P=0.36), but IC50< 0.5 µg/mL was associated with delayed time to rebound (>8 weeks) and IC50>0.5 µg/mL was associated with rapid rebound (2-5 weeks)(P=0.0278).

Conclusions: We found a wide range in baseline neutralization susceptibilities to clinically relevant bnAbs with highly correlated values across plasma and PBMC-derived pseudovirions over 3 years of ART. PS.HIV.nAb susceptibilities were similar to published values and IC50< 0.5 µg/mL was associated with delayed rebound. Results support the utility of screening for neutralization susceptibility prior to therapeutic bnAb use and suggest PS.HIV.nAb PBMC testing may be a valid approach.

Long-term immunologic responses to treatment among HIV-1, HIV-2 and HIV-1/2 dually infected patients in Côte d'Ivoire

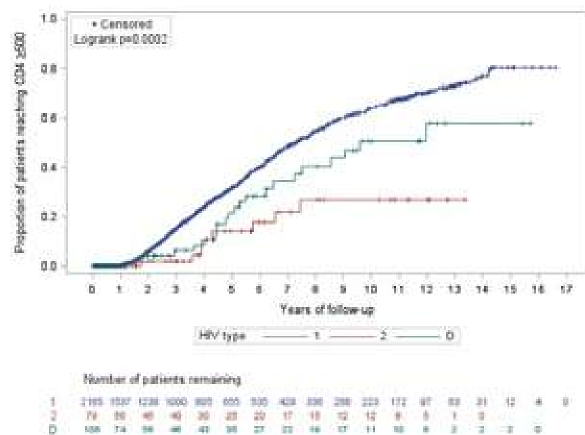
C. Adje epse Toure[1], P. Minchella[2], M. Aka Kouakou Adade[1], G. Zhang[2], K. Diallo[2], J. Hedje[1]
[1]CDC, DGHT, Abidjan, Cote D'Ivoire, [2]CDC, DGHT, Atlanta, United States

Background: HIV-2 accounts for an estimated one to two million people living with HIV worldwide, yet responses to antiretroviral therapy (ART) for individuals infected with HIV-2 or dually infected with HIV-1 and HIV-2 (HIV-D) are poorly understood. We aimed to characterize long-term immunological responses to ART among patients infected with HIV-1, HIV-2, and HIV-D in Côte d'Ivoire

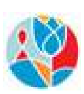
Methods: We analyzed longitudinal data recorded in a laboratory information system for 3,922 adults (≥15 years) attending two HIV clinics in Abidjan, Côte d'Ivoire between 1998 and 2016. Data included demographic information, ART regimens, CD4 counts, and the results of tests for renal, hepatic and hematological abnormalities. Patients were categorized according to their HIV types and stratified by their baseline CD4 cell counts. Kaplan-Meier (KM) methods and Cox regression models were used to assess time to achieving CD4 count ≥500 cells/µl across HIV types and baseline CD4 strata

Results: Patients had a median of 7 recorded visits and 3.9 years of follow-up; 83% had at least one documented ART regimen during follow-up and 53% received ART for >75% of follow-up time. 3,594 (91.68%) patients were infected with HIV-1, 144 (3.67%) with HIV-2, and 182 (4.64%) with HIV-D. Among all patients with baseline CD4 < 200, KM estimates for the likelihood of CD4 ≥500 after ≈6 years were 40% for HIV-1, 18% for HIV-2, and 31% for HIV-D (log-rank p< 0.001). In adjusted Cox regression models both HIV-1 and HIV-D patients with baseline CD4 < 200 were more likely to achieve CD4 ≥500 during follow-up than HIV-2 patients in the same CD4 stratum (HIV-1 vs. HIV-2: adjusted hazard ratio (aHR)= 2.60, 95% CI: 1.29-5.22; HIV-D vs. HIV-2: aHR=2.22, 95% CI=0.99-4.99)

Conclusions: Among patients with low baseline CD4 counts, those with HIV-1 and HIV-D were more likely to have robust immunological responses to ART than those with HIV-2. It is likely that the use of inappropriate and/or ineffective ART regimens among patients with HIV-2 were at least partly responsible for the differential responses. Further studies to identify optimal ART regimens for patients with HIV-2 and low CD4 counts are needed



[Figure 1. Time to achieving CD4 ≥500 cells/µl among adult patients with baseline CD4 <200 cells/µl, by HIV type, 1998 - 2016 (N=3,922)]



LBPEB014

Systematic empirical versus test-guided anti-tuberculosis treatment impact in severely immunosuppressed HIV-infected adults initiating antiretroviral therapy with CD4 cell counts < 100/mm³: Final results from the STATIS (ANRS 12290) randomized trial

F.X. Blanc[1], A.D. Badje[2], M. Bonnet[3], D. Gabillard[2], E. Messou[4], C. Muzoora[5], S. Samreth[6], D.B. Nguyen[7], L. Borand[8], A. Domergue[7], N. Natukunda[9], S. Juchet[4], S. Eholie[10], S. Domoua[10], X. Anglaret[2], D. Laureillard[11]

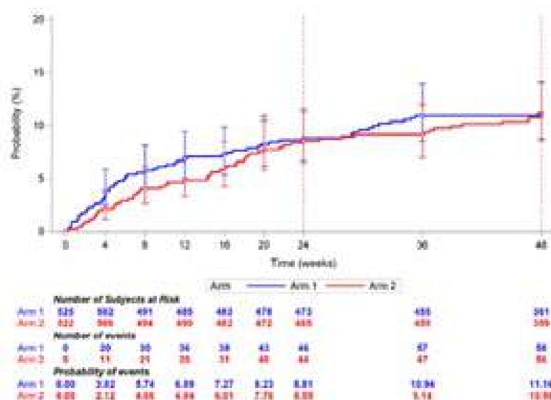
[1]L'Institut du Thorax, CHU de Nantes, Université de Nantes, Respiratory Medicine Dpt, Nantes, France, [2]INSERM, Bordeaux, France, [3]IRD, Montpellier, France, [4]INSERM, Abidjan, Cote D'Ivoire, [5]Mbarara University of Science and Technology, Mbarara, Uganda, [6]National Centre for HIV/AIDS Dermatology and STDs, Phnom Penh, Cambodia, [7]Pham Ngoc Thach Hospital, Ho Chi Minh City, Vietnam, [8]Institut Pasteur du Cambodge, Phnom Penh, Cambodia, [9]Epicentre, Mbarara, Uganda, [10]Université Félix Houphouët-Boigny, Abidjan, Cote D'Ivoire, [11]CHU de Nîmes, Department of Infectious Diseases, Nîmes, France

Background: Despite increasing access to ART in low-income settings, many HIV-infected adults still present for care with severe immunosuppression. In such late presenters, mortality following ART initiation is high and tuberculosis (TB) or invasive bacterial diseases (IBD) remain major causes of death. Here, we report the final results of the STATIS trial (NCT02057796) comparing the efficacy and safety of two strategies aiming at decreasing mortality and IBD in late presenters in Côte d'Ivoire, Uganda, Cambodia and Vietnam.

Methods: From September 2014 to May 2017, ART-naive HIV-1 infected adults with CD4< 100/mm³ were randomly assigned to ART/extensive TB screening (arm 1) or ART/systematic empirical TB treatment (arm 2). In arm 1, TB screening included Xpert MTB/RIF on sputum and urine lipoarabinomannan. ART was initiated immediately in patients who did not start TB treatment at baseline (arm 1 patients with negative TB screening) and two weeks after starting TB treatment in others (arm 1 patients with positive TB screening and arm 2 patients). Primary outcome was the occurrence of death or IBD at week 24. Follow-up lasted 48 weeks (last visit of the last patient: April 2018).

Results: 1047 participants (arm 1: 525, arm 2: 522; Africa: 583, Asia: 464; males: 611, females: 436) were analyzed. At baseline, mean (SD) age was 36 (9) years, BMI 20.1 (3.5) kg/m², CD4 36 (27) /mm³, viral load 5.4 (0.6) $\log_{10}$ copies/ml (no difference between arms). As previously reported, there was no difference between arms regarding the primary outcome. During follow-up, 45 participants died in each arm (p=0.9773); there were 20 IBD in arm 1 and 22 in arm 2 (p=0.7337). The rate of documented or presumptive TB was 14.4 (11-8-17.0) per 100 person-years [arm 1: 26.1 (21.0-31.3); arm 2: 4.2 (2.5-6.6), p< 0.0001]. The rate of grade 3-4 drug-related toxicity was 15.7 (12.9-18.4) per 100 person-years (arm 1: 8.7 (5.9-11.6); arm 2: 23.4 (18.6-28.3), p< 0.0001).

Conclusions: Systematic TB treatment is not superior to extensive TB screening and targeted TB treatment to decrease the risk of mortality or IBD in ART-naive adults with CD4< 100/mm³. It is associated with a lower risk of TB but higher drug-related toxicity.



[Kaplan-Meier probability of first invasive bacterial disease or death during the STATIS trial (log-rank test: p=0.85).]

LBPEB015

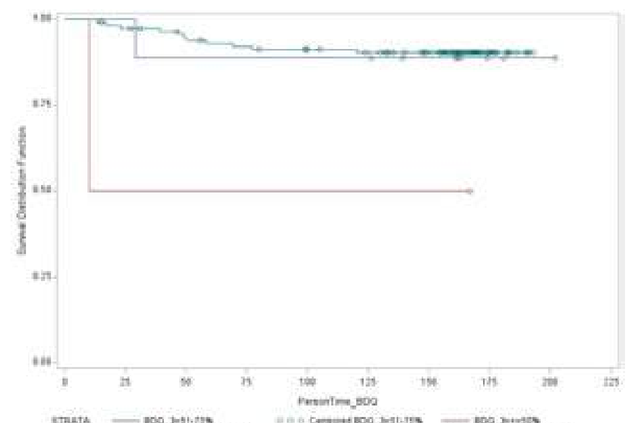
Adherence to Bedaquiline and antiretroviral therapy predicts mortality in the treatment of multi- and extensively drug-resistant tuberculosis (M/XDR-TB) HIV co-infected patients in KwaZulu-Natal, South Africa

C. Hwang[1], G. Friedland[2], R. Amico[3], A. Daftary[4], J. Zelnick[5], B. Seepamore[6], A. Wolf[1], R. Boodram[7], B. Maharaj[7], C. Orrell[8], N. Padayatchi[7], M. O'Donnell[1,7], PRAXIS Study Group

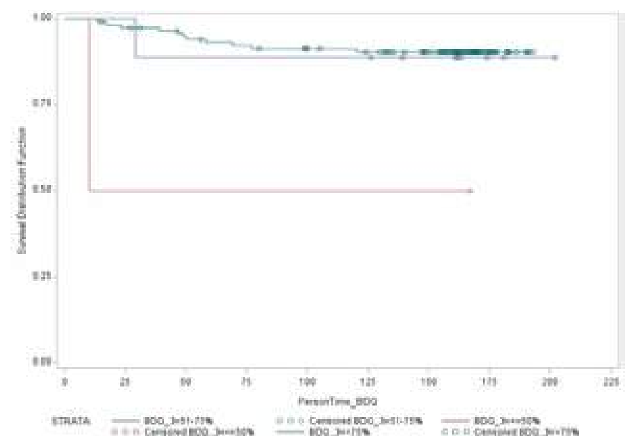
[1]Columbia University, New York City, United States, [2]Yale School of Medicine, New Haven, United States, [3]University of Michigan, Ann Arbor, United States, [4]McGill University, Montreal, Canada, [5]Touro College, New York City, United States, [6]University of KwaZulu-Natal, Durban, South Africa, [7]Centre for AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [8]University of Cape Town, Cape Town, South Africa

Background: Medication adherence is critical to successful treatment but is poorly characterized in TB/HIV treatment. Bedaquiline is the first new medication licensed for drug-resistant TB treatment in over 40 years. Using next-generation electronic pill boxes (Wisepill RT2000), PRAXIS aims to concurrently measure adherence to Bedaquiline and antiretroviral therapy (ART) in the treatment of multi- and extensively drug resistant tuberculosis (M/XDR-TB) HIV.

Methods: Prospective observational cohort study of adult M/XDR-TB HIV patients initiating treatment on Bedaquiline-containing regimens and on antiretroviral therapy (ART). Medication adherence was assessed in real-time using Wisepill devices separately for Bedaquiline and ART through 6 months. Percent adherence was calculated as observed versus expected doses. Patients were censored at loss to follow up, death or study withdrawal. Patients were assessed clinically in monthly study visits. Primary outcome was all cause mortality at 6 months. Secondary outcomes were changes in HIV viral load, sputum TB culture conversion, and differential adherence to Bedaquiline and ART through 6 months.



[Kaplan Meier Survival Curves; Stratified by Bedaquiline Adherence (<50%, 51-75%, >75%)]



[Kaplan Meier Survival Curves; Stratified by Bedaquiline Adherence (<50%, 51-75%, >75%)]

Results: From November 2016 through February 2018, 200 M/XDR-TB HIV patients were enrolled. 156 had sufficient follow up time (≥6 months) to be included in the primary analysis. Overall patients achieved an average of 92% (SD 11.7) adherence to Bedaquiline and 81% (SD 21.8) to ART (p< 0.0001). Mortality through 6 months was 16/153 (10.4%). In patients with < 50% adherence to Bedaquiline 6-month survival was 50% while in the highest quartile of adherence survival was 100%. Bedaquiline adherence >85% compared to ≤85% was associated with increased TB culture conversion at 6 months (80.5% vs. 65%; p< 0.0001). Differential adherence was observed between Bedaquiline and ART (primarily Nevirapine). A decrease in adherence to Bedaquiline was noted from inpatient treatment (96%) to outpatient treatment (91%) (P=0.002). Self-reported, 7-day recall of Bedaquiline and ART non-adherence was poorly sensitive (11% and 5%) but specific (100%) with Wisepill adherence as reference standard.
Conclusions: Adherence is a key indicator of mortality for patients with MXDR-TB and HIV. Next generation e-pill boxes to measure adherence may provide real-time feedback on adherence practices. Supporting optimal adherence may be an important intervention to improve mortality in M/XDR-TB HIV treatment.

LBPEB016

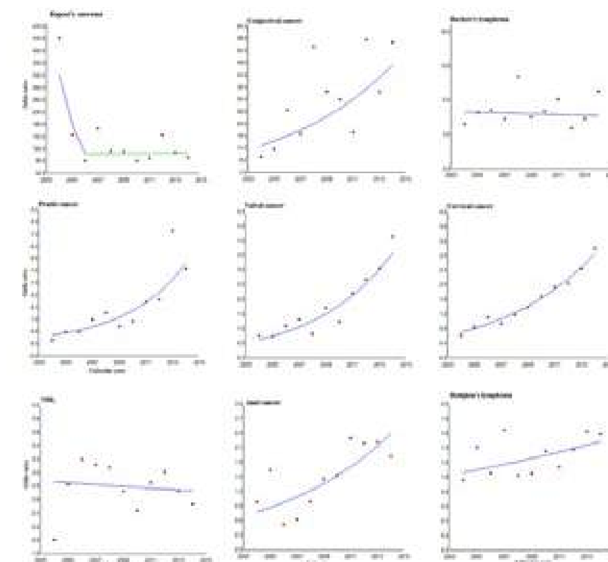
Trends in cancer risk in HIV-infected people in South Africa (2004 - 2014)

T. Dhokotera[1,2], J. Bohlius[3], A. Spoerri[3], M. Egger[3,4], J. Ncayiyana[2,5], V. Olago[1,2], E. Singh[1,2], M. Sengayi[1,2]
[1]National Health Laboratory Service, National Cancer Registry, Johannesburg, South Africa, [2]University of the Witwatersrand, School of Public Health, Division of Epidemiology and Biostatistics, Johannesburg, South Africa, [3]University of Bern, Institute of Social and Preventive Medicine (ISPM), Bern, Switzerland, [4]University of Cape Town, School of Public Health and Family Medicine, Centre for Infectious Disease Epidemiology and Research (CIDER), Cape Town, South Africa, [5]University of Cape Town, School of Public Health and Family Medicine, Division of Epidemiology and Biostatistics, Cape Town, South Africa

Background: The impact of South Africa's high HIV burden on cancer risk is not fully understood particularly in the context of antiretroviral treatment (ART) availability. The National Health Laboratory Service (NHLS) serves 80% of the South African population allowing for the first national evaluation of HIV-related cancers in the era of ART. We examined national cancer trends and excess cancer risk in people living with HIV (PLHIV) compared to those who are HIV-negative.
Methods: We assigned HIV status to cancer cases diagnosed in the South African public sector between 2004-2014 through probabilistic linkage of records from the National Cancer Registry (NCR) with HIV data from the NHLS. We also used text search of specific HIV terms from the clinical section of pathology reports to determine HIV status of cancer patients. We used logistic and Joinpoint regression models to evaluate the risk and trends in cancers in PLHIV across the 11-year period adjusting for age, gender, race and year of cancer diagnosis. In sensitivity analysis, we used inverse probability weighting (IPW) to correct for possible selection bias.
Results: A total of 329 208 cancers were reported to the NCR from the public sector from 2004-2014 with the HIV status known for 95 279 (28.9%) cancer records. 50.4% (30 486) of all females and 47.3% (16 443) of all males with a known status were HIV-positive. PLHIV were at higher risk of AIDS-defining cancers (Kaposi sarcoma [adjusted OR 134.01 (111.20-161.50)], non-Hodgkin lymphoma [2.73 (2.56-2.91)] and, cervix [1.7 (1.63-1.77)]), conjunctival cancer [21.51 (16.28-28.41)] and human papilloma virus (HPV) related cancers (including; penis [2.35 (1.85-2.99)], vulva [1.94 (1.67-2.25)] and, anus [1.63 (1.33-2.00)]) (Table 1). Analysis using the IPW population yielded comparable results. The risk of conjunctival, cervical, anal, penile, and vulvar cancers continued to rise in the ART era (Figure 1).
Conclusions: Cancer risk in PLHIV continues to rise despite widespread ART availability, specifically for conjunctival cancer and HPV-associated cancers. There is need for improved awareness and screening of these cancers at HIV care centres. Further research and discussion is warranted on inclusive HPV vaccination in PLHIV.

Cancer	Complete Case Analysis OR(95% CI)	Weighted Analysis OR(95% CI)
Kaposi	134.01 (111.20-161.50)	98.8 (80.93-120.61)
Cervix	1.7 (1.63-1.77)	1.68 (1.60-1.76)
NHL	2.73 (2.56-2.91)	2.89 (2.71-3.08)
Anus	1.63 (1.33-2.00)	1.61 (1.30-1.99)
Hodgkin´s lymphoma	1.22 (1.09-1.37)	1.43 (1.27-1.61)
Vulva	1.94 (1.67-2.25)	1.82 (1.58-2.10)
Penis	2.35 (1.85-2.99)	2.06 (1.63-2.61)
Conjunctiva	21.51 (16.28-28.41)	20.84 (15.24-28.50)
NHL=non-Hodgkin's lymphoma. OR= Odds ratios determined using logistic regression models adjusting for age, gender, race and year of cancer diagnosis. The weighted analysis included inverse probability weights estimated from known HIV status age, gender, cancer diagnosis and cancer diagnosis year.		

[Table 1: Odds ratios for cancer in PLHIV by complete case analysis and by weighted analysis]



[Trends in cancer risk for selected cancers]

LBPEB017

Doravirine (DOR) versus ritonavir-boosted darunavir (DRV+r): 96-week results of the randomized, double-blind, phase 3 DRIVE-FORWARD Noninferiority trial

J.-M. Molina[1], K. Squires[2], P. Sax[3], P. Cahn[4], J. Lombaard[5], E. DeJesus[6], M.-T. Lai[2], X. Xu[2], A. Rodgers[2], L. Lupinacci[2], S. Kumar[2], P. Sklar[2], B.-Y. Nguyen[2], G. Hanna[2], C. Hwang[2], E. Martin[2]
[1]University of Paris, Paris, France, [2]Merck & Co., Inc., Kenilworth, United States, [3]Brigham and Women's Hospital, Boston, United States, [4]Fundación Huesped, Buenos Aires, Argentina, [5]Josha Research, Bloemfontein, South Africa, [6]Orlando Immunology Center, Orlando, United States

Background: DOR is a novel non-nucleoside reverse transcriptase inhibitor (NNRTI) with once-daily dosing and potent *in vitro* activity against the most common NNRTI resistant variants (K103N, Y181C, G190A). The 48-week results of the phase 3, DRIVE-FORWARD trial showed that DOR was noninferior to DRV+r in treatment-naïve adults, with a superior lipid profile for fasting LDL-C and non-HDL-C. Herein we present the 96-week data.
Methods: HIV-1 infected, treatment-naïve adults were randomized to DOR (100 mg/d) or DRV+r (800/100 mg/d) with investigator-selected nucleoside reverse transcriptase inhibitors (NRTI): tenofovir/emtricitabine (TDF/FTC) or abacavir/lamivudine (ABC/3TC). Resistance-associated mutations to NNRTIs or NRTIs was an exclusion factor. Study was double-blinded until week 96. Participants were stratified by baseline HIV-1 RNA (≤ or >100,000 copies/mL) and background NRTI therapy. The proportion of participants achieving HIV-1 RNA < 50 copies/mL (FDA Snapshot Approach), adverse events (AEs), and fasting serum lipids effects at week 96 were assessed.

Author Index

Results: Of 769 participants randomized, 766 (383 in each group) received study drug and were included in the analyses (mean age 35.2 years, 84% male, 73% white, 87% on TDF/FTC). At 96 weeks, DOR demonstrated higher efficacy versus DRV+r: 73.1% and 66.0% in the DOR and DRV+r groups, respectively, achieved HIV-1 RNA < 50 copies/mL; treatment difference 7.1% (95% CI: 0.5, 13.7), and responses were similar regardless of baseline characteristics (Table). Treatment-emergent resistance to any study drug occurred in 0.5% and 0.1% of DOR and DRV+r groups, respectively. AE rates (overall, serious, drug related, and leading to treatment discontinuation) were similar across groups. The most common AEs (>5%, week 0-96) were diarrhea (DOR 17.0%, DRV+r 23.8%), nausea (11.7%, 13.6%), headache (14.9%, 12.0%), and upper respiratory tract infection (13.3%, 7.8%). Pronounced differences between treatment arms in mean changes from baseline in LDL-C (DOR -0.44 mg/dL, DRV+r +14.0 mg/dL) and non-HDL-C (-0.48 mg/dL, +17.7 mg/dL) were seen in favor of DOR.
Conclusions: Through 96 weeks of therapy, DOR demonstrated greater antiviral activity versus DRV+r, was well tolerated, and exhibited a more favorable lipid profile in treatment-naïve adults with HIV-1 infection. DOR in combination with NRTIs provides an attractive alternative for the treatment of HIV-1 in treatment-naïve adults.

LBPEB018

The effect of delayed switch to second-line ART and confirmed failure monitoring on mortality among South African adults

H. Bell Gorrod[1], A. Boulle[2], M. Fox[3], R. Wood[2], H. Prozesky[4], F. Tanser[5], M.-A. Davies[2], M. Schomaker[2]
[1]University of Sheffield, School of Health and Related Research (ScHARR), Sheffield, United Kingdom, [2]University of Cape Town, Cape Town, South Africa, [3]Boston University, Boston, United States, [4]Stellenbosch University, Stellenbosch, South Africa, [5]Africa Centre, Mtubatuba, South Africa

Background: HIV treatment guidelines in South Africa recommend that patients should switch to second-line antiretroviral therapy (ART) after first-line treatment has failed. Treatment failure is confirmed when two consecutive viral load (VL) measurements exceed 1000 copies/ml. Previous studies have shown that delays in the time-to-switch are associated with increased death. However, the impact of duration between the first and second VL measurements of confirmed failure have not been considered in detail. This is important to consider given the recent push for increased VL monitoring.
Methods: We included 7,255 adult patients, from 8 South African treatment programs, with confirmed virological failure (2 consecutive VL >1000 copies/ml, ≥4 weeks apart) from 2004 onwards. A switch from first- to second-line was defined as a switch from a regimen composed of nucleoside reverse transcriptase inhibitors (NRTI) and non-nucleoside reverse transcriptase inhibitors (NNRTIs), to a regimen containing at least 1 protease inhibitor (PI). We compared the hazards of death for 6 different time-to-switch categories vs no switch using inverse probability weighting (IPW) of marginal structural models, which adjusted for measured time-dependent confounding of CD4 count and VL. Analyses were performed using the time of the second VL measure of confirmed failure as baseline, and repeated with the baseline at the time of first VL measure of confirmed failure.

Baseline	Second VL measurement of Confirmed failure		First VL measurement of Confirmed failure	
Time from baseline to switch*	HR	95% CIs	HR	95% CIs
No switch (reference category)	1.00	-	1.00	-
Less than 30 days	0.45	(0.35 -0.59)	0.32	(0.19 -0.56)
Greater than or equal to 30 and less than 60 days	0.52	(0.41 -0.65)	0.49	(0.35 -0.68)
Greater than or equal to 60 and less than 120 days	0.56	(0.47 -0.66)	0.54	(0.44 -0.66)
Greater than or equal to 120 and less than 180 days	0.67	(0.57 -0.78)	0.59	(0.49 -0.72)
Greater than or equal to 180 and less than 360 days	0.70	(0.63 -0.79)	0.66	(0.58 -0.76)
Greater than or equal to 360 days	0.85	(0.82 -0.89)	0.85	(0.82 -0.89)
*Note that in the first VL measurement analysis, an additional 30 days from baseline to the upper and lower limits of each delay category were included to account for the fact that patients in our sample were not permitted to switch until 4 weeks after first VL measure >1000copies/ml.				

[Table 1: Estimates of delay in switch vs no switch on mortality]

Results: 3,765 (52%) patients switched to second-line treatment with a median time from failure to switch of 121 (IQR: 49-288) days. Median time from first to second VL measurement of confirmed failure was 115 (IQR: 83-190) days. Table 1 shows the results of the IPTW adjusted analyses for each time-to-switch category vs no switch.
Conclusions: Delays in switch from first-line to second-line ART after confirmed failure result in increased risk of death. In addition, the results indicate an increased risk of death as the length of delay from first VL measure of confirmed failure to switch increases. This implies that efforts should be made to reduce monitoring delays between the first failing VL measurement and confirmed failure, to accelerate the time from first failing VL measure to switching treatment.

LBPEB019

Preliminary virologic outcomes and prevalence of integrase strand transfer inhibitor resistance mutations among highly treatment experienced patients receiving dolutegravir in Botswana

K.K. Seatla[1,2,3], A. Avalos[2,4,5], T. Mphoyakgosi[4], S. Moyo[2,6], M. Mogwele[7], M. Mine[2,8], W. Choga[1,2], C. Petlo[4], D. Ramaabya[4], T. Gaolatlhe[2,9], I. Kasvosve[10], J.N. Jarvis[2,11], S. Gaseitsiwe[1,2,6]
[1]SANTHE, Gaborone, Botswana, [2]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [3]University of Botswana, Department of Medical Laboratory Sciences, Gaborone, Botswana, [4]Ministry of Health and Wellness, Gaborone, Botswana, [5]Careena Centre for Health, Gaborone, Botswana, [6]Harvard T.H. Chan School of Public Health, Department of Immunology & Infectious Diseases, Boston, United States, [7]University of Botswana, Department of Biological Sciences, Gaborone, Botswana, [8]Ministry of Health and Wellness,Botswana, Gaborone, Botswana, [9]University of Botswana, Faculty of Health Sciences, Gaborone, Botswana, [10]Faculty of Health Sciences, University of Botswana, Department of Medical Laboratory Science, Gaborone, Botswana, [11]London School Hygiene and Tropical Medicine, London, United Kingdom

Background: Botswana became the first country in Sub-Saharan Africa to implement the wide spread use of dolutegravir (DTG) in their public national antiretroviral therapy (ART) programme in January 2016. Approximately 60,000 patients were receiving DTG as part of their first, second, third and salvage ART regimens, as of 31st March 2018. As part of HIV-1 drug resistance (HIV-DR) surveillance, genotypic resistance testing (GRT) is available for all patients who present with virologic treatment failure on DTG. To date, no naïve patients initiated on a DTG containing regimens has developed integrase strand inhibitor (INSTI) resistance mutations. We report preliminary findings from the Botswana Epidemiological ART Treatment Cohort Study, which monitors virologic outcomes and the development of HIV-DR in highly treatment experienced (HTE) patients on DTG containing regimens.
Methods: GRT was performed for patients with confirmed virologic failure (two consecutive viral loads (VL) > 400 copies/ml) while on DTG containing regimens. We sequenced protease (PR), reverse transcriptase (RT) and INSTI genes using ViroSeq™ HIV-1 standard protocols. Mutational profiles were interpreted using the Stanford HIV Drug Resistance Database. Complete clinical histories were obtained from electronic and manual chart reviews. Patients defined as HTE were those who had failed 3 or more ART regimens.

Patient/ Gender	Year of ART initiation	No of ART treatment regimens	Months on DTG containing regimens	RT mutations	PR mutations	INSTI mutations	Latest viral load (copies. ml) as of 31 March 2018
1/F	2004	5	16	Unknown	Unknown	Q148R	<400
2/M	2004	4	27	Unknown	Unknown	G118R, E138K	<400
3/M	2002	10	24	K65R, D67N, K70R, M184V, Y181C, K219N	V32I, I47V, I54L, I84V, V32I	T97A, E138K, G140A, S147G, Q148R	5,971
4/M	2004	8	22	A62V, K65R, A98G, M184V	I50V, I54V A71V, V82M, L90M	A128T, E138K, G140A, Q148K	642

[Mutational profiles of 4 HTE patients receiving DTG]

Results: Out of 93 HTE placed on DTG containing regimens, 20 were identified with VL >400 copies/ml, 74/93 (79.5 %) achieved VL < 400 copies/ml. Four patients were identified with extensive INSTI mutations (Table 1). Patients 1, 3 & 4 failed Raltegravir (RAL) containing regimens prior to treatment with DTG (patient 2 never received RAL). Patients 1 & 2, with major INSTI resistance mutations, achieved VL < 400copies/ml. Patients 3 & 4, despite having accumulated extensive mutations to all ART classes, have remained clinically stable on DTG with low grade viremia, both harbouring K65R mutations.
Conclusions: There is limited data on DTG related resistance in HIV-1C virus in real-world settings in Sub-Saharan Africa, particularly among HTE patients. At 2 years of implementing DTG into regimens of HTE patients, clinical outcomes and the low prevalence of INSTI resistance mutations in Botswana are encouraging.

LBPEB020

Preliminary virologic outcomes of patients switched to dolutegravir containing regimens for toxicities, treatment failures and regimen optimization at a large urban hospital in Botswana

A. Avalos[1,2,3], T. Gaolathe[2,4], R. Mokgwathise[2], D. Ramaabya[3], K. Lesego[2], M. Zwinila[2], M. Kapanda[3], C. Petlo[3], K. Seatla[2], S. Gaseitsiwe[2], The Botswana Epidemiological ART Treatment Cohort Study
[1]*Careena Centre for Health, Gaborone, Botswana,* [2]*Botswana Harvard Partnership, Gaborone, Botswana,* [3]*Botswana Ministry of Health and Wellness, Department of HIV/AIDS Prevention & Care, Gaborone, Botswana,* [4]*University of Botswana, Meidicne, Gaborone, Botswana*

Background: Botswana became the first country in Sub-Saharan Africa to implement the use of Dolutegravir (DTG) in their National public antiretroviral (ART) programme in January 2016. Approximately 60,000 patients were receiving DTG by 31 March 2018, with approximately 10,000 patients switched to DTG from their previous regimens. We report the preliminary findings from the Botswana Epidemiological ART Treatment Cohort Study, which monitors real-world outcomes of patients switched to DTG regimens for toxicities, treatment failure and regimen simplification.
Methods: Switch patients were identified from electronic and manual patient medical records. All patients that were switched to DTG containing regimens beginning 1 January 2016, were included in the analysis. Viral loads were recorded at 6 and 12 months post initiation of DTG, frequencies of toxicities requiring switch to DTG were also recorded.
Results: A total of 341 patients were switched to DTG containing regimens. Table 1 outlines the viral load results of switch patients at 6 and 12 months post initiation. There were 173 patients switched to DTG for toxicities from previous regimens: 78/173 (45%) due to NRTI induced lipodystrophies, 22/173 (12.7%) for GI disturbance due LPV/r use,11/173 (6%) due to CNS effects of EFV. Additional toxicities included gynecomastia, skin discoloration, renal and liver dysfunction. Treatment simplification occurred in 33 patients and 135 patients were switched to DTG for treatment failure.

Reason for Treatment Switch to DTG (n)	Viral load <400 copies/mL at 6 months, n(%)	Viral load <400 copies/mL at 12 months, n(%)
Toxicities (173)	85/87 (97.7%)	85/86 (98.8%)
Virologic Failure (135)	27/37 (72.9%)	94/98 (95.9%)
Treatment Simplification (33)	10/11 (90.9%)	20/22 (90.9%)

[Viral load outcomes of patients switched to DTG containing regimens]

There were a total of 52 patients failing TRU/ALU (26) and TRU/ATA/r (26) regimens when they were switched to TRU/DTG regimens, 45/52 (86.5%) achieved VL < 400 copies/mL at 6 months. Of the 8 patients failing TRU/EFV (4) and TRU/NVP (4) containing regimens that were switched to TRU/DTG, 6 out of 8 achieved VL < 400 copies/ mL by 12 months
Conclusions: In this real world setting, regardless of the reason for switching patients to DTG containing regimens, the majority of patients displayed excellent virologic outcomes at 6 and 12 months. Patients previously failing ART often took longer to achieve full viral load suppression. It is important to note that a significant number of patients previously failing TRU containing regimens before switching to TRU/DTG containing regimens also achieved full virologic suppression by six months.

LBPEB021

Administration of CC-11050, a phosphodiesterase 4 inhibitor, is well tolerated but does not significantly decrease immune activation in treated HIV+ persons

A. Boulougoura[1], E. Gabriel[1], E. Laidlaw[1], A. Pau[1], A. Poole[1], J. Higgins[2], A. Rupert[2], A. Kibiy[1], V. Khetani[3], K. Arakawa[3], P. Kumar[4], I. Sereti[1]
[1]*NIH, NIAID, Bethesda, United States,* [2]*Leidos Inc, Frederick, United States,* [3]*Celgene Global Health, Summit, United States,* [4]*Georgetown University, Washington, United States*

Background: Phosphodiesterase 4 inhibitors (PDE4i) are novel anti-inflammatory medications that block degradation of cAMP and decrease productions of inflammatory cytokines. Apremilast and roflumilast are PDE4i approved for treatment of psoriasis and COPD respectively. PDE4i are also being tested as host-directed therapy (HDT) in TB. In the current study, we examined the safety of CC-11050 in HIV+ people with suppressed viral load on ART and hypothesized that CC-11050 would also decrease inflammation.
Methods: Phase 1, placebo-controlled, double-blinded study to examine safety of CC-11050 administered over 12 weeks in HIV+ persons on ART for at least 1 year with plasma HIV viremia (VL) < 50 c/mL. Eligible patients were randomized 2:1 to CC-11050 200 mg BID or placebo. Plasma cytokines were measured at weeks 0, 2, 4, 8 and 12. Monocyte and T-cell activation profile was assessed by flow cytometry. For comparisons between time points T-test or Wilcoxon rank sum tests were used for comparison of continuous variables. To compare biomarker levels over all treatment time points, linear generalized estimating equations (GEE) were used. All analyses were performed in R.
Results: 45 persons were screened and 30 were randomized (19 active drug and 11 placebo) as planned, 20% of whom were women and 43% African American. The median age was 49.5 years (44-55), median BMI 26.8 and median Hemoglobin 13.5. 53% were on NNRTI and 47% on ISTI regimens. The median CD4 at baseline was 459 cells/μL and CD8 712 cells/μL. Most frequent AEs (grade 1 and 2 only) in active drug recipients were headache (8/19), diarrhea (5/19), cough (2/19), nasal congestion (2/19) and restlessness (2/19). There were no statistically significant changes in CD4 or CD8 T cell counts and no changes in VL. Efavirenz levels were not affected significantly. There were no significant differences between the two randomization groups in the average level over the treatment weeks, in the unadjusted or adjusted GEES models, for TNF-a, IL-6, IL-8, IL-10, IFN-g, sCD14, CRP, D-dimer.
Conclusions: Administration of CC-11050 in suppressed HIV-infected patients is well tolerated and can be co-administered with efavirenz, but at the studied dose has minimal effect on systemic inflammatory markers or immune activation.

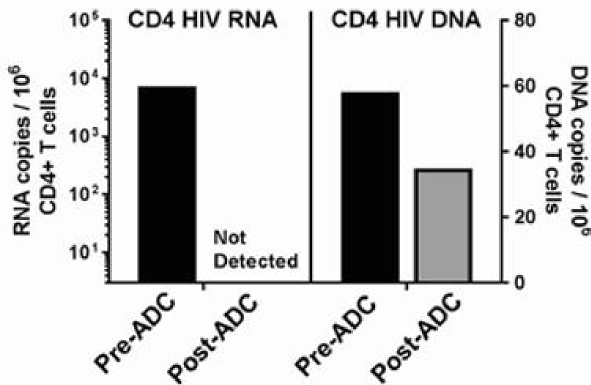
LBPEB022

Loss of detectable HIV CD4+ T cell RNA following single-dose brentuximab vedotin anti-CD30 therapy for Hodgkin lymphoma

C.-C. Wang[1], C. Thanh[1], E. Gibson[1], M. Ball-Burack[1], L. Hogan[1], B. Descours[2], N. Jones[1], A. Carvidi[1], J. Milush[1], S. Deeks[1], T. Henrich[1]
[1]*University of California, San Francisco, San Francisco, United States,* [2]*Human Genetic Institute, Molecular Virology unit, CNRS, Montpellier, France*

Background: We previously reported that CD4+ T-cells expressing the tumor marker, CD30, were enriched in HIV RNA, and that CD30 mRNA and HIV RNA colocalized in gut tissue from ART suppressed individuals. *Ex vivo* treatment of PBMC from ART-suppressed individuals with the anti-CD30 antibody-drug conjugate, brentuximab vedotin, led to a significant decrease in HIV DNA levels. However, the direct, longitudinal impact of bretuximab vedotin therapy on HIV persistence *in vivo* is not known. We studied the impact of brentuximab vedotin therapy for Hodgkin lymphoma on HIV persistence in a newly identified HIV-infected individual on ART
Methods: In depth characterization of CD4+ T cell-associated HIV-1 unspliced RNA and total DNA, and immune phenotyping of CD30 expression on PBMC were determined prior to and 3 weeks following brentuximab vedotin therapy in an HIV-infected individual.

Results: The male participant was on long-term suppressive ART and was diagnosed with stage IV Hodgkin lymphoma in 2014. He received doxorubicin/bleomycin/vinblastine/dacarbazine therapy and went into complete remission. In 2017 he was treated with salvage chemotherapy (ifosfamide/carboplatin/etoposide) for recurrence, and again went into remission. Brentuximab vedotin was started as bridging therapy prior to planned autologous hematopoietic stem cell transplant. Prior to brentuximab vedotin, CD4+ T-cell-associated HIV RNA and DNA levels were 7,359 and 58 copies/10^6 CD4+ T-cells, respectively. Three-weeks following a single 1.8 mg/kg dose, no HIV RNA could be detected in CD4+T-cells (>3-$\log_{10}$ reduction), and total cell-associated HIV DNA levels decreased by 42% (**Figure**). A concomitant 4-fold decrease in the frequency of CD4+ T-cells expressing CD30 was observed (2.26% to 0.54%).
Conclusions: A single dose of the anti-CD30 antibody-drug conjugate, brentuximab vedotin reduced the number of circulating CD30+CD4+ T cells and led to a major decrease in circulating cell-associated HIV RNA and a modest reduction in total cell-associated HIV DNA. These data and our prior observation of the loss of HIV DNA and RNA following multi-cycle brentuximab vedotin therapy suggest that targeting CD30 may reduce the pool of transcriptionally active HIV-infected cells that persist on suppressive ART. Longitudinal sampling of blood and tissues is underway to determine the longer-term effect of anti-CD30 therapy on the total HIV reservoir.



[Reduction in Cell-Associated HIV RNA and DNA Following Single Dose Brentuximab Vedotin Anti-CD30 Antibody-Drug Conjugate (ADC)Therapy]

Pharmacokinetic and 4-week safety/efficacy of dolutegravir (S/GSK1349572) dispersible tablets in HIV-infected children aged 4 weeks to < 6 years: Results from IMPAACT P1093

T. Ruel[1], E. Acosta[2], R. Singh[3], C. Alvero[4], T. Fenton[4], K. George[5], S. Popson[5], E. Townley[6], R. Hazra[7], C. Brothers[3], C. Vavro[3], A. Buchanan[3], A. Wiznia[8], IMPAACT P1093 Team
[1]University of California, San Francisco, Pediatrics, Division of Infectious Disease and Global Health, San Francisco, United States, [2]University of Alabama at Birmingham, Birmingham, United States, [3]ViiV Healthcare, Research Triangle Park, United States, [4]Harvard School of Public Health, Boston, United States, [5]FHI 360, Amherst, United States, [6]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Division of AIDS, Bethesda, United States, [7]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, United States, [8]Albert Einstein College of Medicine, Bronx, United States

Background: Dolutegravir (DTG) is recommended for first-line treatment of HIV-1 infected adults due to its potency, high barrier to resistance, and tolerability. A 5mg dispersible tablet (DTG-DT) pediatric formulation is being evaluated in IMPAACT P1093, an ongoing phase 1/2 open-label pharmacokinetic (PK), safety, and dose-finding study. Here we present the intensive PK, 4-week safety (primary outcome) and efficacy data of the first doses of DTG-DT tested in the youngest age-defined cohorts (V: ≥4 weeks to < 6 months, IV: ≥6 months to < 2 years, III: ≥ 2 to < 6 years).

Methods: On enrollment, children received DTG-DT as monotherapy, or added to stable-failing or empiric initial background regimens and dosed using weight-band tables. Intensive 24-hour PK sampling was completed between days 5-10 with fasting (2 hours prior/1 hour after), after which background regimens were optimized based on enrollment HIV genotypes. Safety, tolerability, and plasma HIV-1 RNA levels were assessed through 4 weeks. From adult data, targets (range) for geometric mean (GM) exposures were AUC_{24h} 46 (37-86) mgxh/L and C_{24h} 750 (500-2260) ng/mL.
Results: Thirty-two children enrolled to achieve 30 (10 per cohort) with evaluable data, of whom 17/30 (57%) were female; 27/30 (90%) had CD4% >14, with baseline median (range) HIV-1 RNA of 4.9 (2.8-7.0) $\log_{10}$ (copies/ml). The GM AUC_{24h} and C_{24h} of each cohort were within target ranges (Table). However, DTG C_{24h} demonstrated moderate inter-subject variability; 8/10 in each of cohorts V and IV achieved C_{24h} above the lower acceptable limit (>500 ng/mL), but only 4/10 achieved the lower limit in cohort III (Figure). DTG-DT was well-tolerated, with no Grade 3 or 4 adverse events or study drug discontinuations. At 4 weeks, 23/30 (76.7%) subjects had attained HIV-1 RNA of < 400 copies/ml or a >2 $\log_{10}$ decrease.
Conclusions: In P1093, once daily dosing of DTG-DT at median dose of ~ 1.2 mg/kg was well-tolerated, achieving mean AUC_{24} and C_{24h} results within target range with universal declines in plasma HIV-1 RNA. Given the moderate inter-subject PK variability, higher doses are likely needed for children 2 to < 6 years of age to reliably achieve a C_{24h} within the acceptable range.

Cohort (n=10 each)	Age (yrs)^	Dose(mg/kg)^	AUC24h (mgxh/L)*	C24h (ng/mL)*
≥2 years to <6 years (Cohort III)	4.0 (2.1-5.9)	1.1 (0.8-1.6)	40 (36%)	461 (59%)
≥6 months to <2 years (Cohort IV)	1.2 (0.9-1.9)	1.2 (1.0-1.4)	51 (38%)	711 (60%)
≥4 weeks to <6 months (Cohort V)	0.34 (0.28-0.39)	1.2 (0.9-1.7)	61 (44%)	1207 (55%)
^ Median (range); * Geometric mean (arithmetic CV%); Targets (range): AUC24h 46 (37-86) mg x h/L and C24h 750 (500-2260) ng/mL

Prevalence and correlates of HIV infection among men who have sex with men in Hanoi, Vietnam

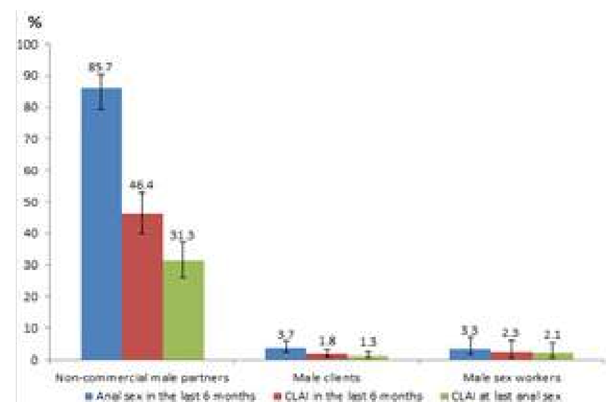
H. Bui[1,2], G. Le[3], D. Vu[4], L. An[2], P. Truong[5], R. Shiraishi[6], I. Zablotska-Manos[7], J. Blandford[4], A. Abdul-Quader[4], H. Van[2], L. Maher[1]
[1]The Kirby Institute for Infection and Immunity, UNSW Sydney, Sydney, Australia, [2]Center for Research and Training on HIV/AIDS (CREATA), Hanoi Medical University, Hanoi, Vietnam, [3]Institute of Preventive Medicine and Public Health, Hanoi Medical University, Department of Global Health, Hanoi, Vietnam, [4]Centers for Disease Control and Prevention (CDC) Vietnam, Hanoi, Vietnam, [5]Bach Mai Hospital, Department of Microbiology, Hanoi, Vietnam, [6]Centers for Disease Control and Prevention (CDC) Atlanta, Atlanta, United States, [7]Sydney Medical School-Westmead, University of Sydney, Sydney, Australia

Background: Despite advances in HIV biomedical prevention, men who have sex with men (MSM) remain at high risk of HIV infection globally. In Vietnam, where there are concerns that HIV in MSM is increasing, estimates of prevalence and understanding of risk factors in this population remain limited.

Methods: Health in Men (HIM) - Hanoi is a prospective observational study designed to estimate HIV prevalence, incidence and associated risk factors among MSM in Hanoi. The first wave of the baseline survey was conducted in late 2017 using Time Location Sampling. Participants (n=800) completed an audio computer-assisted self-interview and provided biological samples. Data were weighted using the inverse of individual selection probabilities with weights adjusted for individual and cluster non-response. All analyses accounted for the complex design of the survey and were performed using Stata 14.0. Log-binomial regression was used to identify risk factors for HIV infection.

Results: Participants had a mean age of 24.3 years (range: 16 - 66), 87.5% had ≥ 12 years of schooling and 46.4% reported condomless anal intercourse (CLAI) with non-commercial male partners, 1.8% with male clients, and 2.3% with male sex workers, in the last six months. HIV testing uptake was low with 40.8% tested in the last six months and 33.1% never tested. HIV prevalence was 10.9% (95%CI 7.4%-15.8%) and 42.1% tested positive for any non-HIV STI, including infectious syphilis (18.9%), Chlamydia (23.9%), Gonorrhoea (13.9%) and HSV-2 (3.6%). HIV infection was independently associated with lifetime sex with male clients (adjusted prevalence ratio (APR)=1.92, 95%CI 1.09-3.39), ≥ 3 non-commercial anal sex male partners in the last month (APR=2.15, 95%CI 1.20-3.83), group sex with non-regular male partners while using party drugs in the last six months (APR=1.67, 95%CI 1.03-2.72), STI symptoms in the last six months (APR=1.56, 95%CI 1.04-2.36), testing positive for infectious syphilis (APR=1.93, 95%CI 1.17-3.20), and past hepatitis B infection (APR=1.86, 95%CI 1.09-3.15).

Conclusions: The young age, high prevalence of HIV infection and observed associations with STIs and sexual risk behaviour in this sample indicate an urgent need for targeted STI screening and biomedical approaches, including HIV PrEP, to control transmission among MSM in Vietnam.



[Figure 1: Risky sexual behaviour with different types of male sexual partners (n=800)]

LBPEC025

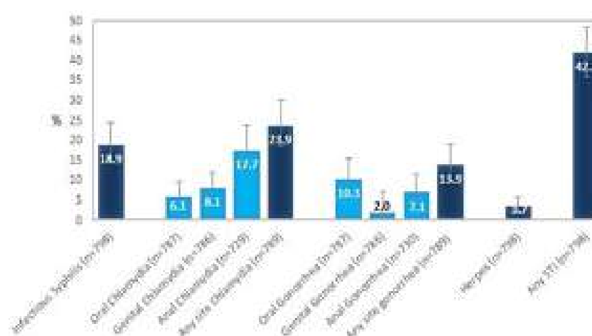
High prevalence of sexually transmitted infections (STIs) among men who have sex with men (MSM) in Vietnam and the need of STIs interventions

D. Vu[1], G. Le[2,3], H. Bui[3,4], L. An[2,3], H. Van[2,3], P. Truong[5], L. Maher[4], R. Shirayshi[6], H. Bui[1], A. Abdul-Quader[1], J. Blandford[1]
[1]US Centers for Disease Control and Prevention, DGHT, Hanoi, Vietnam, [2]Hanoi Medical University, Institute of Preventive Medicine and Public Health, Hanoi, Vietnam, [3]Hanoi Medical University, Centre for Research and Training on HIV/AIDS, Hanoi, Vietnam, [4]University of New South Wales, The Kirby Institute for Infection and Immunity, Sydney, Australia, [5]Bach Mai Hospital, Dept. Microbiology, Hanoi, Vietnam, [6]U.S. Centers for Disease Control and Prevention, DGHT, Atlanta, United States

Background: Globally, men who have sex with men (MSM) are at high risk of STIs. This risk is potentially increased in the era of HIV Pre-Exposure Prophylaxis (PrEP). In 2017, the Health in Men-Hanoi study launched its baseline survey to measure prevalence of HIV and STIs among a representative sample of MSM in Hanoi, Vietnam.

Methods: The first stage of recruitment for this prospective observational study consisted of a cross-sectional survey using venue-based time-location sampling to recruited 800 MSM. Audio computer-assisted self-interviewing was used to collect demographic and risk behaviour data. Blood, oral, urine and anal specimens were collected for HIV, Hepatitis and STI testing. All analyses accounted for the complex design of the survey and were performed using Stata 14.0. Log-binomial regression was used to identify risk factors for STIs.

Results: The majority of MSM attending venues in Hanoi were aged < 25 years (72.7%) and had college/university education (73.0%). Only 44.4% reported consistent condom use with male partners, 46.2% reported at least one STI symptom in the last 6 months and 42.1% of MSM tested positive for at least one STI, including 18.9% with infectious syphilis (Figure 1).



[Figure 1: Prevalence of STIs among MSM in Hanoi, Vietnam in 2017]

Variables	Categories	Frequency STIs / row N	Weighted % positive with STIs [95%CI]	Unadjusted weighted prevalence ratio [95%CI]	Adjusted weighted prevalence ratio [95%CI

[Table 1: Factors associated with STI infection among MSM in Hanoi, Vietnam, (n=799)]

Higher STI prevalence was associated with age (20-24 years) (APR 1.61, 95% CI: 1.00-2.60), inconsistent condom use (APR 1.64, 95% CI: 1.19-2.24), history of diagnosed STIs (APR 2.09, 95% CI: 1.41-3.08) and stimulant use at moderate or high level (APR 2.24, 95% CI: 1.02-4.90). STI prevalence did not correlate with recent STI symptoms (Table 1).

Conclusions: High STI prevalence among this young MSM cohort requires effective measures to break transmission chains. Condom use and frequent STI testing, especially in the context of the aggressive scale-up of PrEP planned for Vietnam can prevent STIs spreading among MSM. As the Vietnam HIV program routinely screens MSM bi-annually, integrating STI screening and treatment into HIV testing services would result to positive outcomes. As self-reported STI symptoms are not reliable predictors of STI infection, laboratory confirmed diagnoses need to be used to identify treatment needs.

Occupational hazards of traditional healers in rural South Africa: Bloodborne pathogen exposures and risk of HIV transmission

C. Audet[1], S. Ngobeni[2], M. Mkansi[2], F. Wafawanaka[2], M. Aliyu[1], K. Kahn[2,3], R. Wagner[2,3]

[1]Vanderbilt University Medical Center, Health Policy, Nashville, United States, [2]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Johannesburg, South Africa, [3]Umeå University, Umeå Centre for Global Health Research, Umeå, Sweden

Background: Occupational hazards associated with traditional healer practices in sub-Saharan Africa (SSA) are not well studied. Similar to allopathic health care workers, healers are exposed to blood borne pathogens through a widespread practice of traditional "vaccination". This involves dozens of subcutaneous cuts in the shoulders, back and chest to rub herbs directly into the bloodied skin. The risk of exposure to patient blood by traditional healers remains unknown; however, previous work has shown that personal protective equipment (PPE), such as gloves, are not always available.

Methods: From December 2017 to May 2018 we conducted 126 surveys and community-based point-of-care HIV counseling and testing with a simple random sample of traditional healers living in rural northeast South Africa. Healers with an initial positive test immediately underwent confirmatory testing before referral to the nearest health facility for care and treatment.

Results: Healers were mostly female (76%), older (median age: 57.0 years; interquartile range [IQR]: 47-67), with low levels of formal education (median: 0 years; IQR: 0-5). Healers had practiced for a median of 19 years (IQR: 7-34) and treated a median of 2 patients (IQR: 0-5) in the past month. Fourteen healers (11%) reported at least one unprotected exposure event to source blood in the past month. Among all healers who tested (95% uptake), HIV prevalence was 29.2% (CI: 21.6%-38.0%). HIV prevalence was 71.4% (CI: 40.0%-90.4%) among healers with blood exposure compared to 23.6% (CI: 16.4%-32.7%) among those with no blood exposure. Controlling for age, sex, education level, years practicing as healer, and any previous blood transfusion, healers who were exposed to patient blood had 10.4 times higher odds (CI: 2.74, 39.6; p=0.001) of being HIV-positive than non-exposed healers.

Conclusions: Traditional healers have a higher prevalence of HIV than adults of similar age (>40 years) in the same setting (29.2% vs. 23.0%, respectively). Among our participants, blood exposure was significantly associated with a positive test. Interventions to educate traditional healers on the risk of blood exposure and provide appropriate PPE are urgently required to prevent HIV acquisition amongst this neglected high risk group.

LBPEC027

Progress towards achieving HIV epidemic control among people who inject drugs in Myanmar: Findings from the 2017-18 bio-behavioral survey among PWID

S. Hone[1], M.Y. Aung[1], S. Phyu[2], R. Sutton[3], K.M. Tun[3], M. Jacobs[2], Y. Wu[3], M. Lahuerta[3,4]

[1]National AIDS Programme, Nay Pyi Taw, Myanmar, [2]Joint United Nations Programme on HIV/AIDS (UNAIDS), Yangon, Myanmar, [3]ICAP at Columbia University, New York, United States, [4]Mailman School of Public Health, Department of Epidemiology, New York, United States

Background: In Myanmar, with an HIV prevalence of 0.6%, an estimated 29% of new infections occur among people who inject drugs (PWID). Identifying gaps in the HIV prevention and treatment cascade among PWID is crucial to understanding and controlling the epidemic.

Methods: From October 2017-January 2018, we conducted a cross-sectional bio-behavioral survey (BBS) among PWID using respondent driven sampling (RDS) in eleven townships and two cities in Myanmar. Eligibility criteria included age ≥15 years, having injected drugs in the past month, and having lived in the township or city for ≥6 months. Participants completed an interview and were counseled and tested for HIV, hepatitis B, hepatitis C and syphilis. HIV prevalence data was compared with the 2014 BBS conducted in eight townships and two cities among 3,275 PWIDs. Weighted data analysis was conducted with RDS Analyst and SAS.

Results: Overall, 6,061 PWIDs were enrolled (98.5% male; median age of 30 years). The majority (83.0%) reported injecting more than once a day. Only 5.9% reported that they had used a needle or syringe used previously by someone else at last injection. One-third (35.1%) had received drug treatment to stop drug use and 17.4% had received methadone treatment in the past 12 months. Among the 76.6% that had sexual intercourse in the last month, condom use was low (21.3%). Less than half (47.8%) had ever been tested for HIV and only 51.2% of these were tested in the past year. HIV prevalence among PWID was 34.9% (range 7.6-60.9%) and six townships had an increase in HIV prevalence since the 2014 BBS. Among the HIV-positive, 38.8% were aware of their status; and of these 67.0% were currently on antiretroviral treatment (ART). ART coverage was 34%. Prevalence of hepatitis B, hepatitis C, and syphilis was 7.7%, 56% and 1.5%, respectively.

	Population %	95% Confidence Interval (CI)	Range by Site (N=13)
% Male	98.5	98.0, 98.9	93.2 - 100.0
Median age in years, interquartile range (IQR)	30 (25, 37)	N/A	25 - 33
Ever taken an HIV test	47.8	45.9, 49.8	24.4 - 73.5
HIV prevalence	34.9	33.0, 36.8	7.6 - 60.9
1st 90: Known HIV status	38.8	35.6, 42.0	20.7 - 73.8
2nd 90: On ART	67.1	61.4, 72.8	47.7 - 89.4
Hepatitis B Prevalence	7.7	6.7, 8.8	4.3 - 10.6
Hepatitis C Prevalence	56.0	54.0, 57.9	27.4 - 84.5
Syphilis Prevalence	1.5	1.1, 1.9	0 - 5.7

[Table 1. 2017 BBS Results among PWID in Myanmar]

Conclusions: Our results highlight the critical gaps in controlling the HIV epidemic among PWID in Myanmar. The low proportion aware of their HIV status as well as the low ART coverage emphasizes the need for increased interventions, policies and resources to improve coverage and effectiveness of HIV prevention and treatment services for PWID.

Background: Awareness of HIV-positive status, effective linkage to and retention on antiretroviral (ARV) treatment and viral load suppression (VLS) are key to epidemic control. We analyzed data from the 2016-17 Tanzania HIV Impact Survey (THIS) to describe the status of the UNAIDS 90-90-90 indicators among PLHIV in Tanzania.

Methods: THIS was a two-stage cluster survey of randomly selected households in all 31 administrative regions of Tanzania. Consenting adults, 15-64 years, self-reported their HIV status and ARV use. The survey involved home-based counseling and testing using the national HIV rapid test (RT) algorithm consisting of SD Bioline HIV ½ (screening RT) and UniGold (confirmatory RT). Those testing positive on both RTs were confirmed using BioRad Geenius™ HIV-1/HIV-2 Supplemental Assay. VLS was defined as < 1,000 HIV RNA copies/mL. Progress towards the 90-90-90 targets was described using weighted percentages, after accounting for non-response, to achieve population representativeness. Jackknife replication method was used to calculate 95% confidence intervals (95%CI).

Age group (years)	Percentage of PLHIV who self-reported their HIV positive status (95% CI)			Percentage who self-reported ART use of those who self-reported their HIV positive status (95% CI)			Percentage who are virally suppressed, of those who are on ARVs (95% CI)		
	Males	Females	Total	Males	Females	Total	Males	Females	Total
15-24	35.1 (11.5-58.7)	40.6 (29.1-52.0)	39.1 (27.2-51.0)	*	88.2 (77.5-99.0)	87.7 (77.4-98.0)	*	90.6 (79.1-100.0)	82.3 (66.3-98.2)
25-34	24.6 (13.5-35.6)	49.6 (41.5-57.8)	42.0 (35.2-48.9)	66.0 (41.6-90.4)	86.9 (78.8-95.0)	83.2 (75.5-90.9)	*	88.0 (80.6-954)	87.4 (80.3-94.5)

15-64	**45.3 (39.0-51.6)**	**55.9 (51.4-60.3)**	**52.2 (48.3-56.2)**	**86.1 (80.6-91.7)**	**92.9 (90.4-95.4)**	**90.9 (88.4-93.4)**	**84.0 (77.2-90.9)**	**89.2 (85.9-92.5)**	**87.7 (84.7-90.8)**

*[90-90-90 Estimates by Age and Sex among PLHIV in Tanzania, THIS 2016-17 (* Estimates were suppressed because denominator was <25)]*

Results: Of 29,369 eligible persons ages 15-64 years interviewed and tested, 1,778 were HIV-positive, resulting in an adult prevalence of 5% and an estimated 1.4 million adults living with HIV (PLHIV) in Tanzania. Approximately half 52.2% [95% CI: 48.3-56.2] of PLHIV reported knowledge of their HIV-positive status. Of these 90.9% [95% CI: 88.4-93.4] reported current use of ARVs. Of those reporting ARVs, 87.7% [95%CI: 84.7-90.8] had achieved VLS. Awareness of HIV-positive status was ≤40% in males and females ages 15-24 years (Table). Among all PLHIV, irrespective of knowledge of HIV and ART status, 52.0% [95%CI: 48.6-55.4%] were virally suppressed; this was higher among women (57.5% [95% CI: 54.0-61.1%]) than men (41.2% [95% CI: 35.7-46.7%]).

Conclusions: THIS is the first national survey in Tanzania to provide direct measurement of the 90-90-90 targets. Our results indicate that the national program has succeeded in initiating and retaining the majority of HIV-positive adults who report knowledge of their diagnosis. Targeted testing, however, must identify those unaware of their HIV-positive status, especially among adolescents and young people, in both men and women.

LBPEC029

Factors associated with viral load suppression among PLHIV in Tanzania; Results from Tanzania HIV Impact Survey (THIS) 2016-17: Implications to the ART programs

C. Makafu[1,2,3], J. James[2], E. Karugendo[3], R. Mdodo[4], E. Gummerson[5], G. Mgomela[4], A. Ramadhani[6], J. Mushi[6], S. Jonnalagadda[7], K. Lavilla[8], J. Zelothe[1], G. Somi[6], E. Luaula[3], C. Vesper[9], B. Simpoli[10], V. Mugisha[11], K. Jackson[7], R. McCree[8], O. Malewo[8], W. Nega[1], J. Justman[12]

[1]ICAP, Dar es Salaam, Tanzania, United Republic of, [2]Ministry of Health, National AIDS Control Program, Dar es Salaam, Tanzania, United Republic of, [3]National Bureau of Statistics, Dar es Salaam, Tanzania, United Republic of, [4]CDC, Tanzania, Dar es Salaam, Tanzania, United Republic of, [5]ICAP, NY, New York, United States, [6]NACP, Dar es Salaam, Tanzania, United Republic of, [7]CDC, Georgia, United States, [8]CDC, Dar es Salaam, Tanzania, United Republic of, [9]ICAP, Pretoria, South Africa, [10]NBS, Dar es Salaam, Tanzania, United Republic of, [11]ICAP, Kigali, Rwanda, [12]ICAP, New York, United States

Background: WHO recommends early initiation of antiretroviral drugs (ARV) to provide better clinical outcomes among People Living with HIV (PLHIV) and prevent progression to AIDS. Viral Load Suppression (VLS) has recently been globally adopted as universal approach in monitoring the effectiveness of antiretroviral treatments (ART). We analyzed data from the 2016-17 Tanzania HIV Impact Survey (THIS) to establish the prevalence and describe the factors associated with VLS among PLHIV age 15+ years

Methods: The THIS was a cross-sectional, household survey using two-stage stratified cluster sampling. The sample was powered to obtain VLS estimates at 95% CI of +/- 10% based on the surveyed number of HIV+ individuals. HIV status awareness and ARV use were both self-reported. Blood samples tested using the national HIV Rapid Test (RT) algorithm consisting of SD Bioline HIV 1/2 (screening RT) and Uni-Gold™ (confirmatory RT). Those testing positive on both RTs were confirmed using BioRad Geenius™ HIV-1/HIV-2 Supplemental Assay. VLS was defined as <1,000 HIV RNA copies/mL and described using weighted percentages; odds ratios (ORs) were estimated to determine co-factors associated with viral suppression

Results: Of the 31,579 eligible persons of ages 15+ years interviewed and tested; 1,831 were HIV-positive. Among all PLHIV, 51.82% (95% CI: 48.74, 54.88) were virally suppressed; 41.14% among males (95% CI: 36.23, 46.5) and 57.15% among females (95% CI: 53.79, 60.45). Factors independently associated with VLS included; female gender, Index (respondent) awareness of their HIV+ status, urban residence, age, widowed marital status, disclosure of HIV+ status [i.e. Index (respondent) HIV+ status known to partner, Index (respondent) knows HIV+ status of partner], higher CD4 counts, and number of sexual partners in the past 12 months

Conclusions: VLS is an effect of interaction amid diverse dynamics, besides central ARV administration. Consequently, ART programs should consider strategizing for efficient interplay between the personal, clinical, social and demographic VLS influences

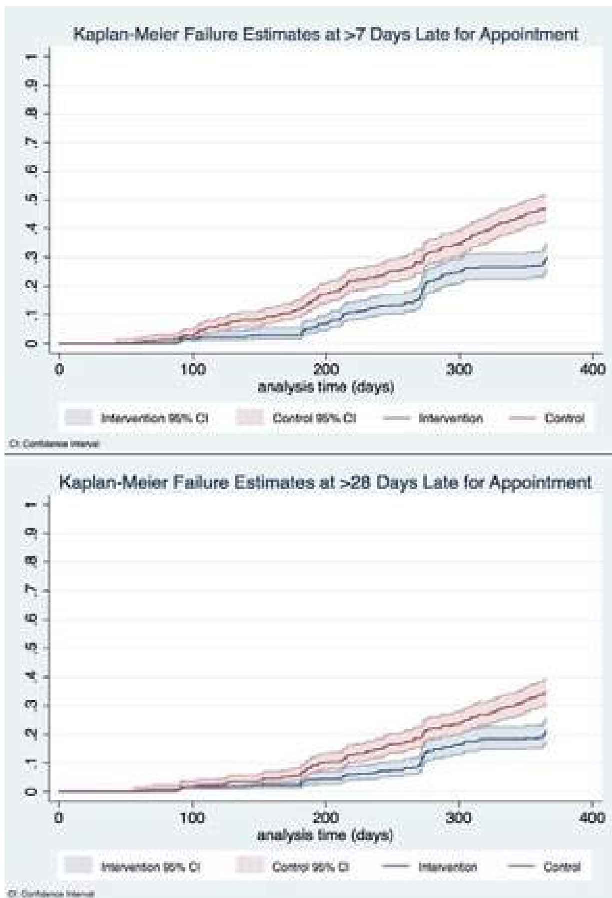
Does faster service equal better retention: Assessing fast track services in Lusaka, Zambia

J. Pry[1,2], M. Roy[3], I. Sikazwe[1], M. Mukumbwa-Mwenechanya[1], P. Somwe[1], E. Kalunkumya[1], M. Lumpa[1], A. Sharma[1,4], N. Padian[5], E. Geng[3], C. Holmes[6], C. Bolton[1,7]
[1]*Centre for Infectious Disease Research Zambia, Lusaka, Zambia,* [2]*University of California, Davis, United States,* [3]*University of California, San Francisco, United States,* [4]*University of Washington, Seattle, United States,* [5]*University of California, Berkeley, United States,* [6]*George Washington University, Washington D.C., United States,* [7]*University of Alabama, Birmingham, United States*

Background: As part of a larger differentiated service delivery (DSD) study in Lusaka, 2 urban sites where selected for a FAST-TRACK (FT) intervention to decrease waiting times and overall time spent at the clinic. The model included a dedicated clinic room staffed by a pharmacy technician (to dispense drugs) and two lay health care workers (to provide brief symptom screening to identify patients in need of higher-level care). Patients were required to visit the clinic every three months to receive ART supply and every 6 months for a clinical examination. Our primary outcome was retention at 12 months.

Methods: A systematic sample of eligible patients (HIV+, on ART > 6 months, not acutely ill, CD4 >=200/µl) were enrolled in FT between March 17 and August 31, 2016. Patients were scheduled for 3-month antiretroviral therapy (ART) pick-ups. Clinical and pharmacy visit data were obtained through existing electronic medical records. Our outcomes included clinic visit attendance, transfer-outs, and death. Kaplan-Meier failure estimates were calculated for 7, 14, 28 and 90 days late for a pharmacy visit. Significance was assessed at the 95% confidence level using the log-rank test.



[Figure 1: Kaplan-Meier Curves for >7, >14, >28, and >90 Days Retention at One Year]

Results: Among 905 patients, median age was 40 years (IQR: 34-46), 607 (67.1%) were female, median CD4 count was 499 cells/mm³(IQR: 354-691), and median time on ART was 5 years (IQR: 3-7). The intervention participants had a significantly lower rate of >7 and >14 days late compared to the control group at six (p-value: 0.003 and < 0.001, respectively) and twelve (p-value: 0.0255 and < 0.001, respectively) months of follow-up. In addition, the intervention participants had a significantly lower rate of > 28 days late at twelve months (p-value: < 0.001) of follow-up (figure 1). The median visit spacing for pharmacy visits was 90 days for the intervention and 89 for the control.

Conclusions: Compared to our controls, FT had a significant effect on improving retention at six and twelve months. The standard of care, as represented by the control participants, did not show a significantly different ART refill schedule indicating that reduced wait time can increase retention.

LBPEC031

Digital pre-exposure prophylaxis (PrEP): Near real-time remote capture of medication ingestion for clinical use in trials and adherence support

S.H. Browne[1], N.J. Hanan[2], T.F. Katsivas[1], A.J. Tucker[2], A. Umlauf[2], F. Vaida[2], J.F. Rooney[3], C.A. Benson[2], T.F. Blaschke[4]
[1]*University of California San Diego, Department of Medicine, La Jolla, United States,* [2]*University of California San Diego, La Jolla, United States,* [3]*Gilead Sciences, Foster City, United States,* [4]*Stanford University, Stanford, United States*

Background: Medication adherence is critical to PrEP prevention of HIV infection. An FDA approved & CE marked Digital Health Feedback System (DHFS) consisting of an edible ingestion sensor (IS), external wearable patch and paired mobile device, can detect and record the timing of ingestion events that are automatically uploaded to a secure Internet server, allowing for near-real time remote confirmation and adherence support. We developed Digital PrEP byco-encapsulating Truvada with an IS to generate precise ingestion records. Prior to general clinical use, equivalence of Digital PrEP (IS-Truvada) must be assessed with respect to the native formulation. We report the in vivo equivalence of IS-Truvada to native Truvada, demonstrate its use and acceptability for longitudinal adherence monitoring.

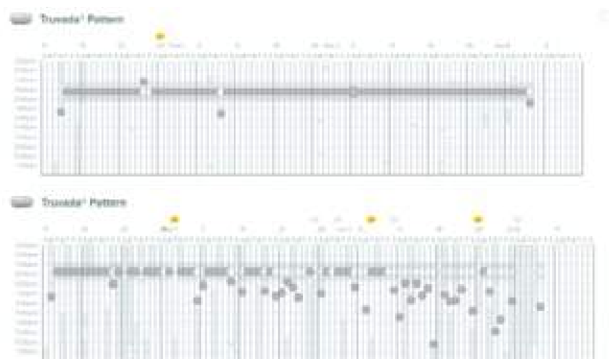
Methods: Sixty adult HIV-seronegative participants desiring PrEP were enrolled in a prospective single arm open label intervention study over 12 weeks assessing the DHFS. Twelve participants taking IS-Truvada underwent pharmacokinetic sampling of tenofovir (TFV) and emtricitabine (FTC) on day 14 at 0, 2, 4, 6, 8, & 24-hours post-dose, and on Day 15 at 2 & 4 hours post-dose following crossover to the native formulation.
Plasma specimens were analyzed using a validated LC-MS/MS assay. Pharmacokinetic parameters for TFV & FTC were calculated by non-compartmental methods. IS-Truvada formulation equivalence was assessed by comparing peak FTC and TFV concentrations (C2) and concentrations sampled 4 hours post-dose (C4) following IS-Truvada and native Truvada ingestion using the geometric mean ratio (GMR) test at a 90% confidence level. Subsequently the acceptability of the DHFS was evaluated.

	FTC-Steady-State PK		TFV-Steady-State PK	
PK Parameter	IS-Truvada Mean (CV%)	Truvada1 Mean (CV%)	IS-Truvada Mean (CV%)	Truvada1 Mean (CV%)
Cmax (ng/mL)	1679 (27)	1650 (18)	263 (39)	288 (22)
Tmax (hr)	2 (0)	2.98 (20)	2 (0)	2.4 (38)
Cmin (ng/mL)	97 (48)	75 (22)	59 (49)	54 (20)
AUC(0-24)	10916 (29)	10700 (11)	2706 (42)	2800 (18)
CL/F (L/hr)	195 (24)	190 (12)	59 (41)	50 (18)
T1/2 (hr)	6.7 (11)	10.7 (16)	17 (53)	15 (24)

[Table 1. Steady-State pharmacokinetics of FTC & TFV for IS-Truvada & native Truvada; 1. J Clin Pharmacol. 2007 Jun;47(6):751-9]

Results: Participant demographics were: mean age 37, 100% Male (83.3% White, 33.3% Hispanic ethnicity), mean CDC risk score 21.5. The GMRs (90% CI) at C2 & C4 (IS-Truvada/native Truvada) for TFV were 1.04 (0.89, 1.16) and 0.99 (0.87, 1.12), and for FTC were 0.96 (0.87, 1.12) and 0.94 (0.90, 1.04). IS-Truvada pharmacokinetics were comparable to literature values (Table 1.) Figure 1 demonstrates DHFS records. Ninety two percent of participants reported a positive experience with the DHFS.

Conclusions: Pharmacokinetic equivalence enables clinical use of IS-Truvada for remote capture of precise dosing histories. Acceptable, easy, real-time adherence monitoring is available for PrEP clinical trials and adherence support.



[Fig 1: Online platform displays date and time stamped ingestions differentiating PrEP adherence patterns (Subject 1 highly regular, Subject 2 erratic).]

LBPEC032

Use of geolocation-based push messaging from a social media platform to promote HIV testing among MSM - Beijing, China, 2015-2016

D. Podson[1], Y. Ma[2], F. Yu[2], Z. Chen[2], G. Mi[2], L. Wang[3]
[1]Public Health Institute, US CDC DGHT China Office, Beijing, China, [2]Blued, Beijing, China, [3]Beijing Ditan Hospital, Capital Medical University, Beijing, China

Background: Men who have sex with men (MSM) disproportionately bear the highest burden for new human immunodeficiency virus (HIV) infections in China. Estimates of the size of the population of MSM in China range from 4 - 20 million, and 50-75% of those HIV-infected are unaware of their HIV status. Since 2013, "Blued" emerged as the most popular social media platform for Chinese MSM, with over 40 million cumulative users. They currently operate 4 drop-in HIV testing sites in Beijing.
Methods: On March 16, 2015, in order to improve the uptake of HIV testing at its drop-in HIV testing sites, all Blued users who opened the location-enabled mobile app while located within the Beijing city limits were sent a private text message to the number they had registered with Blued. The message had language encouraging HIV testing as a way to preserve health and well-being, and offered the opportunity to follow an embedded link to an online appointment system for HIV testing sites.
Results: Volume at the 4 sites increase markedly following the push messaging effort. In the two weeks prior to the effort, a total of 45 persons were tested at the 4 sites, while in the two weeks including and following the effort, a total of 151 persons tested at the same sites. In 2015 there were 3,086 persons tested versus 388 persons total in 2014 - a sevenfold increase in testing. 41% of persons testing for HIV at the sites in 2015 arranged their testing through the text's provided link. Over 150 persons were diagnosed with HIV at the testing sites in 2015 and more than 60% of them were 30 years or younger.
Conclusions: GPS push messaging to Beijing users in 2015 coincided with an increase in HIV testing uptake soon after the start of the campaign, suggesting that this technique is effective in reaching a traditionally "hard to reach" population, specifically young, well-educated MSM. More information is needed to understand the impact of geo-location push-messaging, whether it retains utility after repeated use, and how to optimize efficiency to achieve sustained levels of testing among MSM.

LBPEC033

Impact of a digital HIV self-testing strategy on referrals, new infections and linkage to care: Results from a transition to scale cohort study in South Africa

N. Pai[1], A. Esmail[2], G. Marathe[1], S. Oelofse[2], M. Pretorius[2], M. Fadul[2], M. Smallwood[1], J. Daher[1], R. Janssen[3], P. Saha-Chaudhuri[4], N. Engel[3], K. Dheda[2]
[1]McGill University / Research Institute of the MUHC, Department of Medicine, Division of Clinical Epidemiology, Montreal, Canada, [2]University of Cape Town and UCT Lung Institute, Lung Infection and Immunity Unit, Division of Pulmonology, Department of Medicine, Cape Town, South Africa, [3]Maastricht University, Department of Health, Ethics & Society, Research School for Public Health and Primary Care, Maastricht, Netherlands, [4]McGill University, Department of Epidemiology, Biostatistics & Occupational Health, Montreal, Canada

Background: Although HIV self-testing (HIVST) offers a promising solution for expanded test access, challenges remain in operationalizing rapid linkages to care. In participants presenting to test for HIV in community clinics in South Africa, we investigated whether an offer of a personalized, digital HIVST strategy (a choice of: a) take home unsupervised HIVST, or b) a clinic based supervised HIVST) improved outcomes (i.e., test referrals, new infections, and rapid linkages to counseling/care). The digital strategy consisted of a choice of phone/tablet app with a connected, online cloud web platform and counsellors offering 24/7 linkages to care.
Methods: In an ongoing transition-to-scale cohort study (n=2500), we recruited 1250 participants in HIVST cohort up to March 2018. In geographically separated community clinics, we observed and compared outcomes in 1250 participants opting for conventional HIV testing (ConvHT cohort). Test referrals were defined as the total number of participants referred by all index testers. Linkages (a proportion) were defined as the number of consenting participants linked to care (numerator), over the total number of recruited participants (denominator).
Results: Of 1250 participants recruited in the HIVST cohort, 760 (60.8%) opted for unsupervised HIVST, and 490 (39.2%) for supervised HIVST. Participants (HIVST vs. ConvHT) were young (mean age 28.2 (SD=8.8) vs. 29.1 (SD=8.6)); female (65.0% vs. 75.3%); and poor, monthly income < 3,000 RAND ($253 USD) (80.5% vs. 75.8 %).
There were many more referrals (RR 5.3 [95% CI: 3.7-7.5]) in HIVST; break up (HIVST 14.8% (12.9-16.9) vs. ConvHT 2.8% (1.9-3.9)). Many new HIV infections (RR 1.5 [95% CI: 1.1-1.9]) in HIVST, 120 (9.6% (8.0-11.4)) vs ConvHT 80 (6.4 % (5.1-7.9)) were documented. New infections identified: 64 (53.3%) in unsupervised HIVST vs. 56 (46.7 %) in supervised HIVST.
Linkages were set up for many HIVST participants (99.7% unsupervised HIVST, 99.8% supervised HIVST), with no difference between the two cohorts HIVST vs ConvHT (RR 1.005 [95% CI: 0.99-1.01]).
Conclusions: We conclude that a personalized, connected digital HIVST strategy successfully documented many referrals, detected many new infections, and linked almost all participants to counselling and care. This strategy offers a promising HIVST scale up solution for all digitally savvy populations worldwide.

LBPEC034

Different PrEP modalities for different people: switches between daily and event-driven PrEP among MSM and TGP

E. Hoornenborg[1], L.N. Coyer[1], R.C.A. Achterbergh[1], M.F. Schim van der Loeff[1,2], U. Davidovich[1], H.J.C. de Vries[1], M. Prins[1,2], on behalf of the Amsterdam PrEP Project team in the HIV Transmission Elimination AMsterdam Initiative (H-TEAM)
[1]Public Health Service of Amsterdam, Amsterdam, Netherlands,
[2]Academic Medical Center, Amsterdam, Netherlands

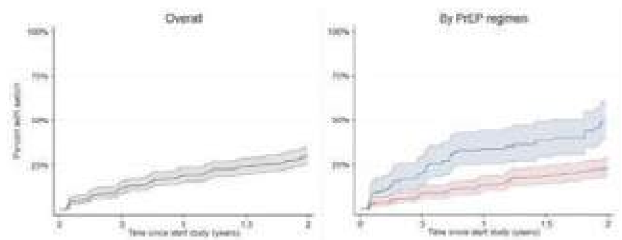
Background: To meet individual HIV prevention needs for people whose risk may vary over time, daily (one tablet emtricitabine-tenofovir daily) and event-driven (2 tablets before, and 2 times 1 tablet after sex) pre-exposure prophylaxis (dPrEP and edPrEP, respectively) can be offered at choice of the user. We assessed user-initiated switches and factors associated with switches during the first two years of follow-up.

Methods: HIV-negative MSM (n=370) and TGP (n=2) participated in the Amsterdam PrEP project at the Public Health Service of Amsterdam. Participants chose a dPrEP or edPrEP regimen and could switch regimen at quarterly visits. We analyzed data from study start (August 2015) through March 2018. We evaluated time-to-first-switch overall and by PrEP regimen using Kaplan-Meier plots. With Cox regression we assessed the association of baseline characteristics with time to switch, in separate models for dPrEP and edPrEP.

Results: At baseline, 270 (73%) people chose dPrEP and 102 (27%) edPrEP. Medium follow-up time was 2 years [IQR 1.8-2.2]. In total, 106 (28%) participants switched regimen 154 times; 37/106 (35%) switched more than once. 78 (51%) switches were from dPrEP to edPrEP, and 76 (49%) from edPrEP to dPrEP. The cumulative proportion of participants that switched two years after PrEP start was 30% (95% CI 25-35%). Over time, the cumulative proportion that switched was higher among those who started edPrEP compared to those who started dPrEP (log rank test, p< 0.001) (Fig).

Higher age was associated with switching (Table) for both PrEP regimens. Among those who started edPrEP, a higher number of sex acts with casual partners (reported at baseline) was associated with a higher switch hazard. Other baseline variables were not significantly associated with the switch hazard, including ethnicity, STI at baseline, and chemsex (Table).

Conclusions: A substantial proportion of MSM switch between daily and event-driven PrEP regimens if allowed to do so. Some participants may have switched without reporting, suggesting possible underreporting. The high number of switches, in addition to 27% initiating event-driven PrEP, clearly indicates the varying needs and added value of a client-centered approach in PrEP regimen provision.



[Time to first switch to another PrEP regimen since start PrEP, (a) overall and (b) by PrEP regimen]

	Switch dPrEP --> edPrEP Hazard ratio (a) (95% CI)	Switch edPrEP --> dPrEP Hazard ratio (a) (95% CI)
Age in years at baseline	0.30 (0.11-0.77) (b)	0.24 (0.07-0.81) (b)
Ethnicity (white)	0.96 (0.47-1.97)	1.74 (0.57-5.37)
No. of anal sex partners in 3 months before PrEP start	0.71 (0.37-1.36) (b)	0.54 (0.27-1.09) (b)
No. of anal sex acts with casual partners in 3 months before PrEP start	1.20 (0.66-2.19) (b)	2.31 (1.14-4.67) (b)
Chemsex in 3 months before baseline	1.10 (0.59-2.05)	0.82 (0.37-1.82)
Any STI at baseline	0.53 (0.23-1.19)	1.59 (0.65-3.88)
Possible drug-related problem (DUDIT≥8) at baseline	1.08 (0.56-2.07)	1.65 (0.73-3.71)
Possible alcohol-related problem (AUDIT≥8) at baseline	1.06 (0.59-1.89)	0.72 (0.33-1.57)
(a) Adjusted for all other variables in the model; (b) Per increase in natural log. Abbreviations: AUDIT, alcohol use disorders identification test; DUDIT, drug use disorders identification test; IQR, interquartile range; PrEP, pre-exposure prophylaxis; STI, sexually transmitted infection

Syphilis acquisition and dosing schedule for pre-exposure prophylaxis (PrEP) users in Taiwan PrEP demonstration project

H.-J. Wu[1], C. Strong[1], S.W.-W. Ku[2], C.-W. Li[3], C.-Y. Cheng[4], H.-C. Tsai[5], C.-Y. Lee[6], S.-T. Huang[7], N.-Y. Ko[8], Y.-F. Huang[7], TW-CDC

[1]Department of Public Health, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan, Province of China, [2]Division of Infectious Diseases, Taipei Veterans General Hospital Hsinchu Branch, Hsinchu, Taiwan, Province of China, [3]Division of Infectious Diseases, Department of Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan, Province of China, [4]Department of Infectious Diseases, Taoyuan General Hospital, Ministry of Health and Welfare, Taoyuan, Taiwan, Province of China, [5]Department of Medicine, Division of Infectious Diseases, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, Province of China, [6]Division of Infectious Diseases, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, Province of China, [7]Centers for Disease Control, Ministry of Health and Welfare, Taipei, Taiwan, Province of China, [8]Department of Nursing, College of Medicine, National Cheng-Kung University and Hospital, Tainan, Taiwan, Province of China

Background: Efficacy of daily and on-demand pre-exposure prophylaxis (PrEP) has been well established among men who have sex with men (MSM) in clinical trials. Yet the experience of both schedules in real life is still lacking. The first government-led demonstration project in Asia, providing daily or on-demand PrEP, was launched by Taiwan CDC in November, 2016. The aim of this study were to investigate characteristics associated with PrEP dosing schedule and examine whether dosing schedule was associated with syphilis incidence up to one year follow-up.

Methods: HIV-negative adult individuals with risk factors were eligible and enrolled in the demonstration project. After PrEP initiation, self-reported side effects, adherence, and risk behaviors were collected every 3 months, last updated in March, 2018. The latest dosing schedule of the participants was categorized in three types: daily, on-demand, or mixed (switching between daily and on-demand). Participants were tested for syphilis every 3 months. Multivariable logistic regression was used to determine factors at baseline associated with dosing schedule (daily vs. on-demand or mixed). Cox proportional hazard regression model was used to determine risk factors for incident syphilis.

Results: A total of 302 participants initiated PrEP; 92.1% were MSM and 3.6% were women. Overall, 24.5% used daily PrEP, while 75.5% used on demand or mixed. More than half of women (72.7%) and people infected with hepatitis B virus (58.8%) used PrEP on demand or mixed. Daily PrEP was associated with using recreational drug in last 3 months (aOR 2.36, 95% CI 1.27-4.38) and having PrEP-related stigma (aOR 2.02, 95% CI 1.11-3.70). There was no difference in syphilis incidence between different dosing schedule.

Conclusions: Only a quarter of participants in the Taiwan CDC demonstration project took PrEP daily, and at-risk populations recommended to use only daily PrEP were reported to use PrEP on demand in real life. The dosing schedule does not appear to be associated with syphilis acquisition up to one year follow-up. Contextual and individuals factors that contribute to using PrEP on demand should be further examined and be considered for interventions to improve adherence.

	Univariable analysis	Multivariable analysis	
	OR [95% CI]	aOR [95% CI]	p-value
Age	1.03 [0.99-1.07]	1.02 [0.98-1.06]	0.441
HBsAg	2.30 [0.84-6.28]	1.61 [0.53-4.93]	0.403
Northern Taiwan vs. Southern Taiwan	1.17 [0.68-2.02]	0.85 [0.47-1.52]	0.584
Male vs. Female	0.86 [0.22-3.33]	0.62 [0.16-2.50]	0.497
Consistently condom use in the last 3 months	0.79 [0.44-1.41]	0.72 [0.40-1.29]	0.271
Agreed/ Strongly agreed with PrEP-related stigma	1.81 [1.04-3.14]	2.02 [1.11-3.70]	0.022
Recreational drug use in the last 3 months	2.70 [1.52-4.77]	2.36 [1.27-4.38]	0.007
Knowing someone using PrEP	1.98 [1.11-3.51]	1.87 [1.00-3.52]	0.051

[Factors associated with daily PrEP dosing schedule in Taiwan PrEP demonstration project.]

LBPEC036

The impact of pre-exposure prophylaxis with TDF/FTC on HIV diagnoses, 2012-2016, United States

P.S. Sullivan[1], D.K. Smith[2], R. Mera-Giler[3], A. Siddiqi[2], B. Gunnels[2], N. Harris[2], X. Hu[2], L. Waller[2], S. McCallister[3]
[1]Emory University Rollins School of Public Health, Epidemiology, Atlanta, United States, [2]Centers for Disease Control and Prevention, Atlanta, United States, [3]Gilead Sciences, Foster City, United States

Background: Pre-exposure prophylaxis (PrEP) reduces the risk of HIV infection in those at risk for acquiring HIV. TDF/FTC was approved for PrEP in the United States (US) in 2012; 147,000 people had initiated PrEP through 2016.
Methods: We analyzed HIV diagnoses among persons ≥ 13 years old, and viral suppression, from the National HIV Surveillance System and national pharmacy data on prevalence of TDF/FTC use, for PrEP /1,000 persons with PrEP indications. We described changes in rates of HIV diagnoses and PrEP users, from 2012-2016, for 50 states and DC using estimated annual percent change (EAPC). We calculated EAPC and 95% confidence intervals (CI) for HIV diagnoses for states by quintiles of PrEP use. To evaluate the independence of the effect of PrEP uptake from the effect of treatment as prevention, we used data from a subset of 38 states and DC (39 jurisdictions) with viral suppression data (averaged for available years from 2012-2014) among those living with diagnosed HIV, and examined whether the association of PrEP uptake and HIV diagnoses changed when controlling for state-specific level of viral suppression.
Results: The overall US rate of HIV diagnoses decreased significantly from 15.7 (2012) to 14.5 (2016)/100,000 (EAPC: -1.6, CI: -1.9, -1.3). PrEP use prevalence increased from 7.0 (2012) to 68.5 (2016)/1,000 (EAPC: +78.0%, CI: +77.3%, +78.7%). The pooled unadjusted EAPC of HIV diagnoses for states in the highest quintile of PrEP use was -4.7% (CI: -5.4%, -3.9%) and for states in the lowest PrEP use quintile was +0.9% (CI: +0.2%, +1.7%) (Figure). The average prevalence of PrEP users in 2016 was 110/1,000 (11%) in the highest quintile, and 33/1000 (3.3%) in the lowest. Among the 39 jurisdictions with viral suppression data, rate of PrEP uptake remained significantly associated with declines in new HIV diagnoses after controlling for state-level viral suppression.
Conclusions: PrEP uptake was significantly associated with declines in HIV diagnoses in the US, and this association is independent of levels of viral suppression. US states should take steps to increase the coverage of PrEP among persons with indications in the current context of increasing HIV viral suppression for people living with HIV.

LBPEC037

A cost-effective strategy to reach WHO hepatitis C virus elimination targets in men who have sex with men in the UK : 90% decrease in hepatitis C incidence by 2030

L. MacGregor[1], Z. Ward[1], N. Martin[1,2], F. Hickson[3], P. Weatherburn[3], M. Hickman[1], P. Vickerman[1]
[1]University of Bristol, Bristol, United Kingdom, [2]Division of Global Public Health, University of California San Diego, San Diego, United States, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Routine pre-exposure prophylaxis (PrEP) and post-HIV diagnosis appointments provide low-cost HCV-screening opportunities amongst men who have sex with men (MSM), providing a route towards achieving WHO elimination targets of reducing hepatitis C (HCV) incidence by 90% by 2030.
Methods: We developed a deterministic model of HCV/HIV transmission, incorporating biological and behavioural heterogeneities (serosorting, injection drug use and fisting). Our model was parameterised with UK data, calibrated to UK prevalence of HIV (5.9%), active HCV infection among HIV-positive MSM (10.0%) and HIV-negative MSM (1.6%). We assessed the effect of scaling up PrEP to 12.5% coverage amongst HIV-negative MSM (versus no PrEP) on HCV incidence over 2018-2030, assuming 86% HIV-efficacy. We then evaluated the impact over 2018-2030 of enhanced HCV screening with rapid HCV treatment within 6-months of diagnosis versus baseline of 28-months. Enhanced screening strategies included 3, 6 or 12-monthly (versus symptomatic after 10-years) in PrEP users, 6-monthly (versus 12-monthly) in HIV-diagnosed MSM and symptomatically in remaining MSM. The mean incremental cost-effectiveness ratio (ICER) was estimated for each strategy up to 2030 compared to status quo screening. We incorporated HCV screening costs for antibody (£10.22) and RNA tests (£45.57) and HCV treatment drug costs (£15,000) plus other diagnostics (£807.80), staff (£57.09) and necessary additional HCV-care costs.
Results: PrEP scale-up decreases HCV incidence by 13.3% due to reduced prevalence of HIV (by 23.2%), thus reducing HIV/HCV co-infection. When rapidly treating and screening PrEP users for HCV 12, 6 or 3-monthly, overall HCV incidence decreases by 42.6%, 46.0% or 47.8%, respectively. If this is combined with rapid treatment and 6-monthly screening in HIV-diagnosed MSM then HCV incidence deceases further, by 77.9%, 81.1% and 82.7%. If rapid treatment also occurs in other MSM (but no enhanced screening), then HCV incidence declines by 90.3%, 91.4% and 92.0% for 12, 6 or 3-monthly screening in PrEP users, respectively, with mean ICERs of £7,200, £8,200 and £10,300 per quality adjusted life year (QALY); highly cost-effective compared to UK thresholds (£20,000/QALY).
Conclusions: Increased screening in PrEP users and HIV-diagnosed MSM plus universal rapid linkage to HCV treatment is highly cost-effective and could achieve the WHO elimination target for MSM.

LBPEC038

Three-fold increases in population-level HIV viral-load suppression among men and young adults in a mixed urban-rural Tanzania lake-zone community: Intervention outcomes of the Bukoba Combination Prevention Evaluation (BCPE)

C. Steiner[1], D. MckKellar[2], H. Cham[2], H. Maruyama[1], O. Rwabiyago[3], G. Kundi[1], O. Msumi[1], R. Weber[4], J. Byrd[2], E. Churi[1], S. Pals[2], C. Madevu-Matson[5], K. Kazaura[3], D. Mbilinyi[6], F. Morales[1], J. Justman[5], A. Rwebembera[7]
[1]ICAP at Columbia University, Dar es Salaam, Tanzania, United Republic of, [2]Centers for Disease Control and Prevention, Atlanta, United States, [3]Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [4]Centers for Disease Control and Prevention, Yaounde, Cameroon, [5]ICAP at Columbia University, New York, United States, [6]United Nations Children's Fund, Dar es Salaam, Tanzania, United Republic of, [7]National AIDS Control Program, Dar es Salaam, Tanzania, United Republic of

Background: BCPE interventions aimed to increase population HIV viral-load suppression (VLS) in Bukoba Municipal Council (BMC), a Tanzania Lake-zone community of ~150,000, by increasing uptake of antiretroviral therapy (ART) during a period of expanding ART-eligibility. We compare estimated population prevalence of VLS before (pre) and after (post) the 2.5-year BCPE intervention phase.
Methods: BCPE facility- and community-based HIV testing and counseling (HTC), linkage-case-management (LCM), and defaulter-tracing (DT) interventions were implemented during three ART-eligibility periods: CD4< 350 (10/2014-11/2015); CD4< 500 (12/2015-09/2016); and Test & Start (T&S)(10/2016-03/2017). Pre- and post-intervention population-based surveys were conducted in 53 and 47 enumeration areas (EAs), respectively, randomly selected in proportion to the estimated population in 14 BMC wards. In sampled EAs, survey participation was offered to all contacted household members aged 18-49 years. VL quantification was performed at the national laboratory on plasma specimens of participants who tested HIV-positive. Pre- and post-intervention, survey-weighted prevalence of VLS (HIV RNA < 1,000 copies/ml) was estimated for HIV-infected participants.
Results: During the BCPE intervention phase (10/2014-03/2017), 133,695 HIV tests were conducted and 4,134 persons were newly HIV diagnosed. Of 4,206 total LCM clients, 93% enrolled in HIV care, and 47% (n=1057) were initiated on ART during CD4< 350, 67% (n=815) during CD4< 500, and 86% (n=649) during T&S periods. Of 859 contacted DT clients who reported not being in care, 604 (70%) returned to care, and 573 started or re-started ART. Compared with the pre-intervention survey, estimated

VLS prevalence among HIV-positive post-intervention survey participants increased two-fold overall (28.6% vs. 64.9%) and among females (33.3% vs. 68.0%), and approximately three-fold among males (20.5% vs. 59.1%), and young adults aged 18-24 (14.2% vs. 51.4%) and 25-29 (16.6% vs. 61.2%) years (Table).

Conclusions: After a 2.5-year combination-prevention intervention implemented during a period of expanding ART-eligibility policies (6 months under Test & Start), prevalence of VLS increased substantially among HIV-positive adults in Bukoba, particularly among men and young adults, two groups with consistently low ART coverage. BCPE facility-based testing and LCM interventions were approved in 2017 as new service delivery models and are being adopted by three non-governmental organizations in Tanzania for implementation in 2018.

Ninajiamini (I have confidence): Understanding the transformative effects of a participatory intervention in the Maisha Intimate Partner Violence (IPV) Trial in Tanzania

S. Lees[1], G. Mshana[2], V. Selestine[2], M. Marchant[3], S. Harvey[1], S. Kapiga[1,2], C. Watts[1]
[1]London School of Hygiene and Tropical Medicine, PHP, London, United Kingdom, [2]Mwanza Intervention Trials Unit, Mwanza, Tanzania, United Republic of, [3]UZIKWASA, Pangani, Tanzania, United Republic of

Background: A cluster randomized trial conducted among women in 66 microfinance groups in Tanzania, evaluated a 10-session participatory intervention (MAISHA) aimed at empowering women, preventing IPV and promoting healthy intimate partner relationships. Over two years, the intervention significantly reduced physical violence. Drawing on qualitative data, we sought to understand women's experiences of the intervention and, drawing on their narratives, how the intervention was transformative.

Methods: A longitudinal qualitative study was conducted alongside the trial. Eighteen in-depth interviews and 9 focus groups were conducted, in Swahili, with women at three time points: baseline; immediately post-intervention; and two years post-intervention. Interviews were transcribed and translated into English and uploaded to NVIVO 11. A framework analysis approach was taken.

Results: Baseline interviews revealed women's past and present struggles for access to education, income earning opportunities and rights to land and other assets. Women's discussion of intimate partner relationships highlighted experiences of violence for some, especially physical and economic abuse. However, none of the women articulated these experiences in terms of gender inequalities. During post-intervention interviews,most of the women did not remember details of individual sessions but were very positive about the sessions as a whole. They interpreted concepts of gender and power in terms of traditional gender norms and authority. In challenging tradition they did not extend fully to notions of equality. However, sessions involving skills development, such as communication in relationships, as well as knowledge about intimate partner violence, built women's confidence to challenge norms of male authority. One woman commented "I have been taught to communicate with confidence, maybe to protect the boundaries".

Conclusions: Andrea Cornwall (2016) notes that ‚where empowerment initiatives include a dimension to actively engage women in critical, conscious, reflection on their own circumstances ...there can be a marked enhancement of a programme or project´s transformative effects'. This research revealed that transformation in this participatory intervention allowed women to consciously engage in understandings of gender and power. Whilst such concepts remain, to some extent, abstract, women's awareness of the realities of their lives and intimate partner relationships meant that skills and knowledge building were the most tangible aspects of transformation.

I have made friends with whom we remind and encourage each other: Youth perspectives on and access to a *WhatsApp*-based HIV treatment support tool in Nairobi, Kenya

K. Ronen[1], C. Mugo[2], A. Muriithi[2], D. Seeh[2], C. Akinyi[2], H. Moraa[2], M. Nduati[2], B. Guthrie[1], M. Moreno[3], G. John-Stewart[1], I. Inwani[2]
[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya, [3]University of Wisconsin, Madison, United States

Background: Adolescents and young adults (AYA) are disproportionately affected by HIV infection and experience poor treatment outcomes. Mobile health strategies show promise in improving ART adherence but studies in AYA have been limited. In 2014, HIV-infected AYA in Nairobi spontaneously established peer support groups using the mobile social media application, WhatsApp. We conducted a mixed-methods analysis of group messages, perspectives on the groups, and technology access among HIV-infected AYA in Nairobi.

Methods: The study was conducted at two HIV clinics in Nairobi in December 2017-April 2018. The study joined two WhatsApp groups and recorded 6 weeks' messages. In-depth interviews were conducted with 35 HIV-infected AYA (age 14-24): 14 members of WhatsApp peer support groups and 21 non-members. Transcripts and messages were translated and analyzed inductively and deductively. Two-hundred HIV-infected AYA attending study clinics completed a technology access questionnaire. Correlates of smartphone access were identified by ^{2}-test.

Results: WhatsApp groups included 250 and 60 members each, with 378 and 714 messages shared during the 6-week observation period respectively. Messaging was unstructured and included encouragement, ART reminders, and entertainment. Members viewed groups as providing companionship, instrumental support, emotional support and behavioral modeling. Barriers to group participation included lack of smartphone and unawareness of the group. Members and non-members endorsed using WhatsApp for peer treatment support. Desired group characteristics included ^{3}20 members, mixed gender, and age segregation. Desired content included unstructured discussion, ART reminders, and advice on status disclosure and HIV prevention. Some respondents desired healthcare worker involvement; others opposed it. Technology survey respondents had median age 17(16-20) and 99(50%) had ^{3}1 deceased parent. One-hundred-forty (70%) had access to a mobile phone; 112(56%) to a smartphone; 123(62%) had used WhatsApp. Smartphone access was higher in young adults (age 20-24) than adolescents (age 14-19) (86% vs. 44%, p< 0.0001), but did not differ by gender, orphanhood or parental financial support (p>0.05 for all).

Conclusions: Mobile social media offer a feasible and acceptable platform to support HIV treatment in Kenyan AYA. Access to smartphones and familiarity with social media is substantial, particularly among older youth. These findings offer guidance for development and evaluation of virtual peer support interventions.

LBPED041

A comparison of clinical characteristics and behavioral risks between HIV-infected and non-infected older adults in Northern Thailand

A. Tangmunkongvorakul[1], P. Musumari[2], K. Srithanaviboonchai[1,3], W. Sitthi[1], K. Rerkasem[1,3]
[1]Chiang Mai University, Research Institute for Health Sciences, Chiang Mai, Thailand, [2]Kyoto University School of Public Health, Department of Global Health and Socio-epidemiology, Kyoto, Japan, [3]Chiang Mai University, Faculty of Medicine, Chiang Mai, Thailand

Background: There is a shift in the demographic profile of people living with HIV toward older age groups. Little is known whether the clinical characteristics and pattern of alcohol use, smoking and physical exercise are different in older adults living with HIV compared to non-infected older adults. The present study addresses this research gap.
Methods: This cross-sectional study was conducted in 2017 and analyzed in 2018. It enrolled two groups of participants aged 50 years and above, including older adults living with HIV (OALHIV) and age-and-gender-matched comparison group of non-infected older adults. Participants were recruited from 12 community hospitals in Chiang Mai Province, Northern Thailand. Behavioral information was collected through face-to-face interviews and clinical data were retrieved from the medical records.

AUDIT: The Alcohol Use Disorders Identification Test

[Behavioral characteristics of HIV-infected and non-infected older-adults in Chiang Mai, Thailand]

Results: We recruited a total of 728 participants, 364 participants in each of the groups. The proportion of participants with chronic kidney disease (14.0% versus 2.2%; $P< 0.001$) and dyslipidemia (or history of treatment with lipid modifying agents) (41.2% versus 13.7%; $P< 0.001$) was higher in OALHIV than in the comparison group. The proportion of underweight (BMI< 18.5) was significantly higher among HIV-infected participants than in the comparison group (21.7% versus 10.4%; $P< 0.001$).
However, alcohol use was less common (18.7% versus 28.0%; $P=0.003$) and physical exercise more common (59.1% versus 36.3%; $P< 0.001$) in the group of OALHIV than in the comparison group. OALHIV were less likely to report ever drank alcohol in the past year (AOR, 0.55; CI, 0.34-0.89, $P=0.015$) and more likely to report being currently engaged in physical activities (AOR, 2.58; CI, 1.77-3.76, $P< 0.001$). There was no difference between the two groups in terms of the "current smoking status".
Conclusions: OALHIV drank less but were more engaged in physical exercise than the non-infected older adults. The awareness of being sick and necessity to adhere to healthier lifestyle recommendation to control the disease, and the concerns over the consequences of alcohol on the effectiveness of antiretroviral drugs are possible reasons for lower prevalence of alcohol use in HIV-infected individuals compared to non-infected individuals. There is however need for continued monitoring of socio-behavioral risk factors in this population of OALHIV.

LBPED042

Treatment team model for HIV, aging and long-term survivors

C. Hutchinson, M. Adams, L. Angus, M. Beckles, D. Butler, J. Brooks, N. Collins, C. Fammons, D. Georgetti, J. Gorge, D. Ronning, S. Russo, B. Summer, M.A. Jones
Westside Community Services, AIDS Case Management and Home Care Program, San Francisco, United States

Background: With the advent of highly active ART, persons with HIV are living longer, and those aged 50 and older comprise a larger proportion of HIV cases over time. Those 50 years and older now represent more than 50% of the living HIV cases in San Francisco. Between 2010 and 2014, the number and proportion of living HIV cases aged 50 and older increased from 6,455 (44%) to 9,202 (58%).
In 1988, Westside Community Services began addressing the needs created by this devastating illness by increasing fragmentation of the health care delivery system, Westside instituted a comprehensive case management system to coordinate and monitor patient care.
Description: Westside Community Services, AIDS Case Management Program primarily serves an aging population; 77% of our clients are above the age of 50. Among our aging clients, we are seeing elevated levels of depression, loneliness, and suicidal tendencies. We also see multiple forms of trauma in this population, and often consequent post-traumatic stress disorder among older HIV-positive men.
Lessons learned: The management of HIV-infected patients is a highly specialized area of practice, often requiring use of complex medication regimens for reduction of HIV-associated morbidity and mortality prophylaxis and treatment of opportunistic infections, and prevention of HIV transmission. To maximize the effectiveness and safety of treatment with antiretroviral agents and associated pharmacotherapies, an interdisciplinary team often is involved in patient care. At Westside, the AIDS Case Management has long worked with an interdisciplinary care team including Social Workers Case Managers, Registered Nurse Case Managers and Home Care Attendants to care for patients with HIV infection. Specialty and other support services, include: medication education, assistance with prescription fulfillment, assistance with medication access, treatment monitoring, and enhancing linkage with primary care providers and other specialty providers and appointment and diagnostic testing compliance.
Conclusions/Next steps: The partnership between the Westside's Social Workers Case Managers, Registered Nurse Case Managers and Home Care Attendants is important for the care and treatment of this population. Broadening access to health, education to ensure prevention and treatment of the additional needs of long term survivors is critical to the epidemic response.

Non-disclosure of Middle East-returned expatriates has led to the extraordinary high transmission of HIV in AJK, Pakistan

A.R. Janjua[1], N. Shafi[2], J. Khurshid[2], S.A. Kazmi[2], M. Khalid[3]
[1]University of Azad Jammu and Kashmir, Department of Zoology, Muzaffarabad, Pakistan, [2]University of Azad Jammu and Kashmir, Zoology, Muzaffarabad, Pakistan, [3]University of Azad Jammu and Kashmir, Biotechnology, Muzaffarabad, Pakistan

Background: AIDS is a growing public health concern in Pakistan due to increasing prevalence particularly in high risk groups where HIV incidence has escalated from 66, 000 to 130,000 during last six years. Current study was aimed to screen the family members of the HIV positive individuals of Azad Jammu and Kashmir and to analyze the potential transmission routes of HIV in these patients.
Methods: A total of 134 AIDS patients (49 females and 85 males), registered at Pakistan Institute of Medical Sciences Islamabad were approached for the HIV screening of their family members. 300 family members, (162 females and 138 males) of these HIV positive patients, were screened for HIV by ELISA and further confirmed by PCR. Risk factors were evaluated by using a structured questionnaire.
Results: A total of 177 (59%) individuals were found positive for HIV, of which, 25 (14%) were children. Of the HIV positive individuals, 57.6% and 42.4% were males and females respectively. Analysis of risk factors in the previously diagnosed HIV positive individuals revealed that HIV was transmitted to all the 49 females by their spouses.
Among HIV positive males, 65.8 % had a boarding history of Middle East with unprotected sexual exposure while 22 % of the infected males had history of unprotected sexual practices in other cities of Pakistan whereas 11.2% were exposed to unhygienic shaving tools. About 7 % were found to be Injection drug users and 2.4% males were found to be homosexuals.
Conclusions: Our study revealed that non- disclosure of HIV carriers has led to transmission of HIV to their spouses ultimately resulting in its vertical transmission to their children. HIV-associated stigma and lack of reproductive freedom for females in a man dominating society renders females engaged in unprotected sexual practices making them vulnerable for high transmission risks of HIV. In this scenario coherent interventions are direly needed to control HIV spread in high risk groups by disseminating preventive awareness, disclosure of disease status, reproductive freedom encouraging the safe sexual practices with pregnancy management among HIV positive spouses and mandatory HIV screening of all incoming populaces at airports

Young female sex workers and men who have sex with men in Cameroon: Unmet need for HIV prevention and treatment services

S. Ketende[1], A.L. Bowring[1], M. Njindam[1,2], G. Fako[2], A. Rao[1], C. Lyons[1], M. Decker[1], G. Turpin[1], G. Fouda[3], F. Ndonko[3], D. Levitt[4], U. Tamoufe[2], S. Billong[5], Z.-K. Bissek[6], O. Njoya[7], S. Baral[1]
[1]Johns Hopkins School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Metabiota, Yaounde, United States, [3]CARE Cameroon, Yaounde, Cameroon, [4]CARE USA, New York, United States, [5]Groupe Technique Central (CNLS), Yaounde, Cameroon, [6]Ministry of Health, Department of Operational Research, Yaounde, Cameroon, [7]Yaounde University Hospital Centre, Department of Internal Medicine, Yaounde, Cameroon

Background: In Cameroon female sex workers (FSW) and men who have sex with men (MSM) are key populations (KP) for HIV prevention. While there are limited data, young KP may be additionally vulnerable to HIV infection due to ongoing sexual risks in the context of compounded legal and social challenges to effective service provision.
Methods: In 2016, FSW and MSM aged 18+ years were recruited through respondent-driven-sampling (RDS) for a biobehavioural survey carried out in five Cameroonian cities. Prevalence of HIV, risk, stigma, and service access were compared between young (<25 years) and older (25+ years) KP. Multivariate Poisson regression models for various HIV prevention outcomes were used to estimate prevalence ratios (PR) comparing young KP to older KP.
Results: Among 2,255 FSW, 724(32%) were aged < 25 years. The median age of first transactional/compensated sex was 22 years(IQR:19-28). Among 1,323 MSM, 839(63%) were aged < 25 years. The median age of first anal sex with men was 18 years(IQR:17-21).
In both populations, condom use, recent experience of physical violence and forced sex were similar between age groups. Lifetime experience of stigma was lower among young than older KP but remained high.
HIV prevalence was 7.9% and 32.2% in young and older FSW, respectively, and 14.3% and 32.1% in young and older MSM, respectively.
Compared to older KP, young KP in both populations were less likely to have tested for HIV in the past year (FSW PR:1.05[0.94-1.17]; MSM PR:0.85[0.76-0.95]), participated in peer education session in the past three months (FSW PR: 0.59[0.43-0.79]; MSM PR: 0.71[0.57-0.88]), received free condoms in the past six months (FSW PR:0.75[0.63-0.90]; MSM PR: 0.73[0.64-0.85]), and be members of FSW/MSM CBO (FSW PR:0.60[0.48-0.75]; MSM PR: 0.58[0.40-0.83]).
Conclusions: Behavioural and structural risks are consistent across age groups, while biomedical risks-including untreated STIs-are higher among young KP. Further, young KP have lower access to HIV prevention services. Given significant changes in HIV prevalence between age groups, these data suggest high HIV incidence among younger KP in Cameroon, consistent with global findings.
Thus, while social and legal systems affecting young KP are complex, achieving an AIDS-Free generation necessitates addressing the specific HIV prevention and treatment needs among youth.

LBPED045

Bringing CSE in the era of #digitalization: Comprehensive sexuality education advocacy through innovative online evidence-based approach

P. Mladenov
CSE Hub, Sofia, Bulgaria

Background: Global Online Hub for Advocacy on Comprehensive Sexuality Education (CSE) was an outcome recommendation by youth advocates, including from key populations, who were part of a global technical meeting of 50 global CSE experts. It is based on the need of an innovative instrument for communication and working on joint advocacy initiatives.
Description: In 2016 the first version of the Hub was tested during the AIDS2016. It was developed based on an extensive need assessment and research activity. Since 2017 it provided access to 200 publications, 187 news, 30 advocacy stories, and 270 registered users.
The platform has been recognized as a key in providing opportunity for building effective advocacy strategies especially around high level inter-

national forums and regional conferences, etc. The analysis shows that the platform has been highly welcomed by the registered users as useful instrument in their work, especially on providing evidence-based advocacy practices which are further supported by qualitative and quantitative results in the field.
The user satisfaction report shows that through the platform and related social media accounts, the average amount of outreached people is 6000 and the read articles/publications via the Hub is between 650-800 unique checks (natural, no artificial boosting). People are more likely to register and benefit from the daily news section and they state that the Hub is one of the main channels they are using for getting informed on specialized topics such as CSE and SRHR. More than 85% of the users highlight that using innovative tools is welcomed by experts on CSE/SRHR due to its time and cost efficiency. Lastly it proves that advocacy around CSE could be implemented via online methods that involve qualitative and quantitative data analysis.
Lessons learned: The Hub is an example of how to use innovative methods and digitalization as a cost-effective instrument in community outreach focusing on key populations but also in building successful advocacy and legal strategies.
Conclusions/Next steps: The Hub will be further advanced and it will serve as the online platform for governments as well in information and policy exchange on the upcoming Global Summit on CSE with a clear focus on young key populations.

LBPED046

HIV pre-exposure prophylaxis (PrEP) roll out at the National Program in Brazil

T. Meireles D. Alencar[1], A.R. Pati Pascom[1], M. T. Santos Christ[1], I. Ornelas Pereira[1], C. H. Dutra Barros[2], M. Veloso Meireles[1], C. Pimenta[1], F. M. Rick[1], A. Schwartz Benzaken[1]
[1]Brazilian Ministry of Health, Brasilia, Brazil, [2]Brazilian Ministry of Health, Department of Surveillance, Prevention and Control of IST, HIV/AIDS and Viral Hepatitis, Brasilia, Brazil

Background: Since December 2017, Brazil's response to the HIV epidemic includes free access to pre-exposure prophylaxis (PrEP) for populations at substantial risk for HIV infection (men who have sex with men (MSM), sex workers and transgender persons), and serodiscordant couples. We used national health system data to monitor the first quarter of PrEP implementation, from January 1st to March 31st 2018.
Description: Brazilian National Health System is providing PrEP, free of charge at point of care, in 11 states, comprising 22 different municipalities and 36 health services. National monitoring system has been used to track 20 different indicators, such as PrEP user profile, sexual practices, adverse events, adherence, seroconversion, PrEP interruption, STIs and health service network.
Lessons learned: During the first quarter of PrEP deployment, 1,758 TDF/FTC were dispensed for 1,120 PrEP users. 83% of them were gay men/MSM, 11% cis women, 4.9% heterosexual men, 1% transgender women (TGW) and 0.2% transgender men. Among gay/MSM, 8% declared themselves as sex workers, equal percentage observed among cis women and 25% of TGW. The age group between 30-39 years presented the highest number of PrEP users. Figure 1 presents age data by key population. Regarding schooling, the vast majority declared 12 or more years of study (76.9%). The mean number of sexual partners, in three months, was higher among the age groups of 18-24yrs. (18.4) and 25-29yrs. (18.8). Thirty days after the first TDF/FTC prescription, 57.7% of users reported no adverse events related to PrEP use, and 7.7% reported having missed 5 or more tablets. With regard to STIs, 22.1% reported symptoms or had a diagnosis in the six months prior to PrEP initiation.
Conclusions/Next steps: The initial profile of PrEP implementation points to new challenges: offer PrEP to those who can most benefit from it and are at greater risk for HIV, especially low-income, less educated, non-white ethnic groups of transgender, young gay men and sex workers. Yet, it is clear that offering PrEP at public health services, free of charge at point of care, can reach and retain high numbers of users and provide the opportunity to diagnose and treat STIs.

LBPED047

EQUIP Khethimpilo: Rapid scale up of viral load testing in an area previously challenged by access to viral lab support in Urban Setting in Zimbabwe: Lessons learnt

E. Mothibi[1], A. Grimwood[1], C. Chikanda[2], J. Mangoma Chaurura[1], N. Nhando[3], N. Mabhena[1], B. Makumbe[1], F. Chirowa[3]
[1]Khethimpilo, Cape Town, South Africa, [2]Pulse, Midrand, South Africa, [3]Khethimpilo, EQUIP, Harare, Zimbabwe

Background: By the end of 2015, VL coverage of the 1 1103 000 on ART in Zimbabwe was 3%. The government is committed to aggressively scaling-up VL testing to cover 90% of people on ART by 2018. Despite this goal Chitungwiza VL coverage < 2% in 2016.
Description: The Chitungwiza Viral Load Acceleration project is delivered in partnership with Ministry of Health and Child Care (MoHCC) and Population Services International (PSI). Khethimpilo EQUIP supported efficiencies in specimen collection, transport systems and storage. The overall goal was to ensure 90% of eligible patients have a VL done and results received, documented and acted upon. EQUIP supported commissioning and automating the PSI lab's viral load machine.
Lessons learned: Coverage of VL testing in Chitungwiza facilities increased from a baseline of < 2% to 14.4% in October, 27% in December 2017 and 47% in March 2018. A total of 22 493 VL samples overall were processed by March 2018, with 22 432 VL (99%) results received and 20 187 VL (90%) suppressed with little gender difference. VL tests turnaround time reduced from 3 months to 48 hours for plasma and 3-5 days for DBS samples. Locally accessible lab reduced travel time and patients saved $60 per test, the cost in private laboratories.Demand creation at facility and community level are key for increased VL uptake. The involvement of local health facilities in sample transportation systems improved efficiencies. Workflow optimization is critical to achieving efficient intra-lab processing. Training on sample collection results in low rejection rate< 2%.
Conclusions/Next steps: The demonstration project improved VL coverage in Chitungwiza assisting the Zimbabwe government in reaching their UNAIDS 3rd 90 global target. Scaling up of the Chitungwiza VL Demonstration project to other districts in Zimbabwe will increase coverage rapidly and assist with the decanting of stable patients to multi month dispensing groups as either part of facility based adherence clubs or community based antiretroviral support groups (CARGS) currently evaluated for 3or 6m ART supply. VL outcomes will assist HCWs in detecting and addressing early warning indicators of treatment failure.

HIV investment case report for Ukraine: Evaluation of program costs, service quality, and resource allocation for HIV expenditures

N. Avaliani[1], A. Latypov[1], M. Duda[1], R. Dierst-Davies[2], C. Kerr[3], J. Pearson[4], I. Kuzin[5]
[1]Deloitte Consulting, LLC, USAID HIV Reform in Action Project, Kyiv, Ukraine, [2]Deloitte Consulting, LLC, San Francisco, United States, [3]Optima Consortium for Decision Science, Sydney, Australia, [4]Deloitte Consulting, LLC, Arlington, United States, [5]Public Health Center of Ministry of Health of Ukraine, Kyiv, Ukraine

Background: Countries globally set ambitious goals to achieve 90-90-90 targets by 2020. Optimized resource allocation and cost-effective interventions are the key to achieve success within the limited resource constraints. USAID HIV Reform in Action Project studied the cost drivers of HIV services in Ukraine to identify the most cost-effective mix of services within existing budget constraints to guide HIV resource allocations.
Methods: The 57-facility study was conducted in three regions of Ukraine - Mykolayiv, Poltava and Zhytomyr and focused on: (1) Unit Cost Analysis for multiple cost types (staffing, commodities, overhead, medications, laboratory), across nine services (HCT, needle and syringe

program, opioid substitution therapy, condom distribution, case management, psychosocial services, TB Co-infection, opportunistic infection treatment, and antiretroviral therapy); (2) Client Satisfaction Study measuring correlations between the cost of services and their perceived quality among clients, (3) Extrapolation Analysis - expanding service and cost study results to non-sampled facilities in three regions, (4) Resource Allocation and Epidemic Forecasting - identifying more efficient funding mixes for HIV prevention, care, and treatment services for the three regions utilizing the Optima Consortium for Decision Science's model
Results: Results: Key cost drivers identified were low patient/high expenditure ratios and inflated overhead expenditures; user-friendliness and accessibility were key drivers of overall client satisfaction. At current funding levels, the total cost of services will be US$115.1M between 2016 and 2030. Using the current funding mix, the 90-90-90 goals can be achieved by 2020, and sustained through 2030, in the three regions with a total budget of US$184.5M. Using a more cost-effective mix of funding, 90-90-90 goals can be achieved in the three regions for US$155.9M. Shifting resources away from certain prevention services (e.g., condom distribution and HCT) to NSP and ART programs (as they are the most cost effective) will help achieve the 90-90-90 benchmarks faster and save US$ 28.6M over 15 years.
Conclusions: Results indicate that Ukraine can achieve the 90-90-90 goals by 2020, and effectively sustain them through 2030, which will avert and halve the estimated new infections and deaths, through a reallocation of services to the most cost-effective programs and US$40.8 million in additional funding.

LBPEE049

Same-day ART initiation without laboratory tests is safe and effective: Primary outcomes of the SLATE trial in South Africa

S. Rosen[1,2], M. Maskew[2], A.T. Brennan[1], M. Fox[1], L. Vezi[2], B. Larson[1], I. Tsikhutsu[3], M. Bii[3], W.D. Venter[4]
[1]Boston University, Department of Global Health, Boston, United States, [2]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]KEMRI, Walter Reed Projects, Kericho, Kenya, [4]University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa

Background: The WHO recommends same-day ART initiation for patients who are eligible and ready and ART initiation ≤7 days of diagnosis for all patients. Identifying efficient operational procedures for determining same-day eligibility and readiness is now a priority. The Simplified Algorithm for Treatment Eligibility (SLATE) trial tested a clinical algorithm that allows nurses to determine eligibility for immediate ART dispensing at a patient's first clinic visit, without laboratory results or delays for other reasons.
Methods: SLATE was an individually randomized trial at public outpatient clinics serving informal settlements in Johannesburg, South Africa. Patients presenting for an HIV test or HIV care but not yet on ART were randomized to the intervention or standard care. The intervention arm was assessed with a symptom self-report, medical history questionnaire, brief physical examination, and readiness questionnaire to distinguish between patients eligible for immediate ART dispensing and those who should have further care, tests, or counseling before initiation. Follow-up was by passive record review. We report the proportion in each arm initiated ≤28 days and retained at 8 months ("28d/8m") after study enrollment.
Results: From 3/7/17-7/28/17, we enrolled 600 adult, HIV+, non-pregnant patients (median [IQR] age 34 [29-40]; 63% female; median CD4 count 288 [140-487]). Eight-month follow up was completed in April 2018. In the intervention arm, 68% of patients initiated ≤7 days, compared to 40% in the standard arm (risk difference [95% CI] 28% [20-35%]; relative risk (RR) 1.68 [1.43-1.98]). After 8 months' follow-up, 53% of the intervention arm and 50% of the standard arm achieved 28d/8m outcomes (RR 1.06 95% CI 0.90-1.25) (Table), with no difference in viral suppression rates. Many patients in both arms were > 1 month late for their routine 6-month visit and/or missing viral load results.
Conclusions: The SLATE algorithm, comprising a simplified set of steps for ART initiation, demonstrates that same-day ART initiation for both new and established HIV patients can be offered safely and effectively at primary health centers without delays for laboratory results, additional education or counseling, or other services. It offers a practical model of same-day treatment initiation that can be widely implemented by existing providers.

Outcome	Control arm	Intervention arm	Crude risk difference (95%CI)*	Crude relative risk (95% CI)*
N enrolled	302	298		
Days from enrollment to ART initiation				
≤ 28 (protocol primary outcome)	204 (72%)	232 (82%)	10% (2-16%)	1.13 (1.03-1.24)
≤7 ("rapid" initiation)	114 (40%)	193 (68%)	28% (20-35%)	1.68 (1.43-1.98)
0 (same-day initiation)	33 (12%)	161 (56%)	45% (38-52%)	4.84 (3.46-6.78)

LBPEE050

Effectiveness of a community-based model of HIV care in western Kenya

S. Goodrich[1], A. Siika[2], A. Mwangi[3], T. Spira[4], M. Bateganya[4], C. Toroitich-Ruto[5], B. Otieno-Nyunya[5], V. Naanyu[3], K. Wools-Kaloustian[1]
[1]Indiana University School of Medicine, Medicine - Infectious Diseases, Indianapolis, United States, [2]College of Health Sciences, Moi University, Department of Medicine, Eldoret, Kenya, [3]College of Health Sciences, Moi University, Department of Behavioral Sciences, Eldoret, Kenya, [4]Centers for Disease Control and Prevention (CDC), Atlanta, United States, [5]Centers for Disease Control and Prevention (CDC), Nairobi, Kenya

Background: The Kenya Ministry of Health recommends differentiated models of care for clinically stable HIV clients. We evaluated the effectiveness of a model of differentiated care that utilizes peer-group meetings (ART Co-ops) led by lay health workers in lieu of clinic visits.
Methods: HIV-positive patients with no acute illnesses, receiving health services at the Academic Model Providing Access to Healthcare (AMPATH) HIV clinic in Kitale, Kenya, who were ≥ 18 years of age, had a CD4 ≥200 cells/mL, viral load (VL) < 40 copies/mL at enrollment and living in one of 30 surrounding sub-locations were eligible. Sub-locations were randomized to standard of care (clinic visits every 3-4 months) or intervention (ART Co-ops with 6-15 members meeting every 3 months in their community for adherence checks, symptom screen, ART delivery and subsequent annual clinic visits). Patients were enrolled from October 2016-March 2018 and followed for 12 months. Data on patient sociodemographic characteristics were collected and outcomes assessed at 12 months, including: CD4 count, VL, durability of ART regimen, and vital status. Descriptive statistics, Chi-square tests and Fisher's exact test were used.
Results: A total of 420 patients were enrolled and randomized to the standard of care (213) or intervention (207); 77% were female and the median age was 46 years. There were no significant differences in the socio-demographic characteristics between the two groups. The 12 month outcomes, including proportion with viral suppression and ART durability were similar between the standard of care and intervention groups (see table); however, a greater proportion of patients in the intervention group withdrew (17.4% vs. 0.94%; p-value < 0.001). The most common reasons

for withdrawal were relocation (31%), perceived stigma associated with attending meetings (17%) and patient request to discontinue participation (14%). The death in the intervention group was unrelated to the study.
Conclusions: Based on VL and ART durability criteria, no difference was found between patients receiving the standard of care (regular clinic visits) and those receiving differentiated care (community-based care; once a year clinic visit). Withdrawals from the intervention highlight issues related to patient mobility and stigma, which warrant further evaluation.

	Intervention (N=207) (%/IQR)	Standard of Care (N=213) (%/IQR)	p-value
Completed Study	167 (80.7%)	206 (96.7%)	<0.0001
Withdrawn	36 (17.4%)	2 (0.94%)	<0.0001
Deceased	1 (0.48%)	0	0.493
Lost to follow-up	3 (1.4%)	5 (2.39%)	0.724
Changed ART regimen	0	0	
Median exit CD4 (cells/µL)	557 (420-701)	522 (408-666)	0.156
VL undetectable (<40 copies/mL)	153 (91.6%)	194 (94.2%)	0.327
VL >1,000 copies/mL (failure)	0	3 (1.5%)	0.248

[Patient Outcomes by Study Arm]

LBPEE051

HIV testing in TB treatment clinic as an effective testing modality for identification of HIV positive individuals: Results from CDC supported health facilities, Nigeria, 2017

B. Odume, C. Meribe, H. Debem, I. Mgbakor, D. Onotu, J. Gwamna, A. Mukhtar, I. Dalhatu, M. Swaminathan
US Centers for Disease Control and Prevention, CDC, Division of Global HIV/AIDS and TB, Abuja, Nigeria

Background: The HIV epidemic has impacted on the burden of tuberculosis in Nigeria. The WHO estimate ranks Nigeria amongst the 30 countries with the highest TB burden in the world with a projected 219 incident TB cases per 100,000 population and TB/HIV co-infection rate of 16% in 2016. HTS (HIV Testing Services) as an entry point to the HIV program, is implemented widely across most TB treatment clinics (DOTS Centers) in supported sites. The identification of effective strategies for increasing overall yield of HIV positive persons in Nigeria as the first step to reaching the first 90 of the UNAIDS 90-90-90 target, will require an in-depth analysis of specific HIV epidemiology, HTS coverage, and yield by various testing modalities, thereby, increasing program efficiency
Methods: In 2016, CDC-funded implementing partners were guided to implement and optimize approaches that improve HTS yield within testing streams in the facilities. HTS implementation was monitored to determine yield by testing streams and the streams were to be prioritized for scale-up based on patterns of HIV yield, available resources and programme cost effectiveness.
Results: HIV testing in TB treatment clinics was the second highest yielding of the 6 facility HTS streams/modalities analyzed (Table 1). HTS at TB treatment clinics had a high-yield (5.3% HIV+), but currently low patient volume. Increasing TB screening in health facilities for presumptive TB identification and testing them for HIV can increase the number of identified PLHIV in supported facilities.

Facility Testing Modality	facility Index	TB treatment Clinic	Inpatient Clinic	VCT	Pediatric Clinic	PMTCT-ANC
Total # Tested	8,038	86,616	134,884	1,134,117	20,698	909,298
# HIV +Ve	742	4,583	4,824	39,834	231	7,274
% HIV +Ve	9.2	5.3	3.6	3.5	1.1	0.8

[Table 1: HTS testing streams and yield; CDC supported sites in Nigeria Oct 2016-Sept 2017]

Conclusions: The HTS testing stream data informed decisions on testing services optimization and scale up in TB treatment clinics and other high yield testing streams/modalities through support for training, commodity supplies and human resources. Continued support for and scale-up of HTS in TB treatment clinics and for Presumptive TB within health facilities will be key to meeting the first 90 of the UNAIDS 90-90-90 targets.

LBPEE052

Concurrent implementation of targeted and routine provider-initiated-testing and counseling of HIV among children and adolescents: Evidence from the Active Search for Pediatric HIV/AIDS (ASPA) study in Cameroon

H.A. Yumo[1,2], C. Kuaban[3], I. Sieleunou[2,4], M. Beissner[5], D. Nash[6]
[1]Ludwig Maximilian University, Center for International Health (CIH), Munich, Germany, [2]R4D International Foundation, Yaounde, Cameroon, [3]Bamenda University, Faculty of Health Sciences, Bamenda, Cameroon, [4]University of Montreal, School of Public Health, Montreal, Canada, [5]Ludwig Maximilian University, Department of Infectious Diseases and Tropical Medicine, Munich, Germany, [6]City University of New York (CUNY), School of Public Health, New York, United States

Background: This study assessed the effectiveness of the concurrent implementation of the targeted (tPITC) and the routine provider-initiated-testing and counseling (rPITC) in HIV testing, case detection and linkage to HIV care and treatment among children and adolescents in Cameroon.
Methods: During a 6-month period, the ASPA study was conducted by introducing the tPITC strategy in three hospitals in Cameroon. This novel approach was implemented by inviting HIV positive parents receiving HIV care in these hospitals to have their biological children (6 weeks-19 years) tested for HIV either in the hospital or at home. At the same time, the study systematically offered HIV testing to all children attending the outpatient department (OPD) of the same three hospitals (rPITC). We collected prospectively and retrospectively the numbers of: children tested for HIV, children tested HIV positive and children enrolled on ART. We compared the means of these numbers before and after the intervention.
Results: Before the implementation of rPITC, 5891 children consulted at the OPD, 1338 tested for HIV, 63 tested HIV+ and 44 enrolled on ART. After the implementation of rPITC, 4643 children consulted at the OPD, 2090 tested for HIV, 58 tested HIV+ and 38 enrolled on ART. While the HIV testing uptake was significantly higher after rPITC implementation compared with before (223.0 vs 348.3, p< 0.0001), the HIV case detection was significantly lower (10.5 vs 9.7, p< 0.0001) and there was no significant difference on ART enrolment (7.3 vs 6.3, p= 0.1368). During the concurrent implementation of tPITC and rPITC, the HIV testing uptake increased significantly by 143% compared with before (223.0 vs 542.2, p< 0.0001). Likewise, the HIV case detection also increased by 93.7% (10.5 vs 20.3, p< 0.0001) and the ART enrolment by 65.9% (7.3 vs 12.2, p=0.0001).
Conclusions: The tPITC was associated with an increase in HIV testing uptake, a doubling of HIV case detection, and a significant increase on ART enrollment. This highly effective strategy yielded more newly HIV cases and increased significantly ART initiation. It could be used to fast-track the achievement of the 90-90-90 targets by 2020 among children and adolescents, especially in West and Central Africa Region.

LBPEE053

Right people in the right place: Aligning investments in health workers to achieving PEPFAR program targets

V. Vasireddy[1], Y. Obeng-Aduasare[2], T. Lim[3], C. Hall[4], A. Herman-Roloff[4], T. Mah[5], D. Sedlacek[5], A. Schubert[5], M. Glenshaw[4]
[1]US Department of State/ PEPFAR, Office of the Global AIDS Coordinator, Washington, United States, [2]Peace Corps, Interagency Collaborative for Program Improvement (ICPI)/ PEPFAR, Washington, United States, [3]Centers for Disease Control and Prevention (CDC), Interagency Collaborative for Program Improvement (ICPI)/ PEPFAR, Washington, United States, [4]Centers for Disease Control and Prevention (CDC), Pretoria, South Africa, [5]United States Agency for International Development (USAID), Pretoria, South Africa

Background: PEPFAR is the largest bilateral funder of global HIV programs and supports an increasing number of human resources for health (HRH) in partner countries to deliver HIV services. PEPFAR's HRH strategy is to ensure that health workers with the right skills are placed in priority facilities and communities to scale up HIV services and achieve the UNAIDS 95-95-95 goal.

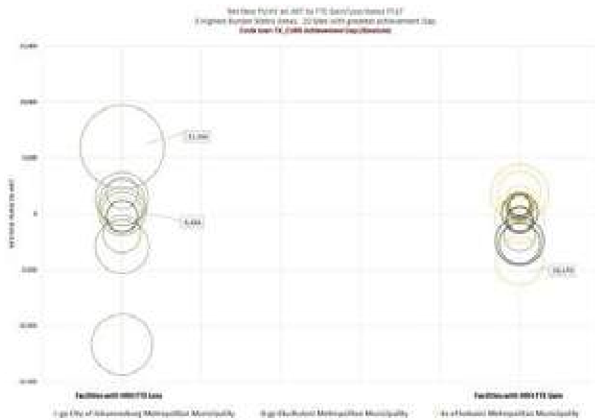
Description: PEPFAR provides direct support for HIV services to patients through remuneration to health workers via implementing partners (IP). Relevant indicators reported by IP track the number of full-time equivalents (FTE) currently supported to implement facility and community programs (HRH_CURR), and total number of PLHIV currently on ART (TX_CURR). We examined data from these indicators in South Africa to describe PEPFAR HRH targets and achievements.

	City of Johannesburg Metropolitan Municipality	eThekwini Metropolitan Municipality	Ekurhuleni Metropolitan Municipality	City of Johannesburg Metropolitan Municipality	eThekwini Metropolitan Municipality	Ekurhuleni Metropolitan Municipality	Total
	ART Gain | FTE Gain, FY16-FY17			ART Loss | FTE Gain, FY16-FY17			FTE Gain Facilities
Number of facilities	58	100	72	7	6	4	247
All Cadre FTE Change (% Clinical Cadre)1	798 (39%)	362 (41%)	112 (13%)	78 (41%)	22 (32%)	7 (51%)	1,379 (39%)
Net New** PLHIV on ART	35,583	58,038	34,076	(2,706)	(7,330)	(6,068)	111,593
	ART Gain | FTE Loss, FY16-FY17			ART Loss | FTE Loss, FY16-FY17			FTE Loss Facilities
Number of facilities	60	20	26	9	1	2	108
All Cadre FTE Change (% Clinical Cadre)1	(184) (16%)	(14) (33%)	(63) (51%)	(92) (43%)	(6) (12%)	(6) (27%)	(365) (7%)
Net New** PLHIV on ART	38,927	5,721	15,215	(20,979)	(239)	(359)	38,286
**Net New is the difference between Fiscal Years (FY) 2016 and 2017 TX_CURR values. Net New changes are influenced by PLHIV newly initiating on ART, PLHIV re-initiating treatment, patients lost to follow up, and death rates. For this analysis All Clinical cadres are defined as clinical and clinical support cadres. Other cadres include: management, social service, and other cadres such as data capturers.				1 Percentage (%) of HRH FTEs per ART/FTE gain/loss category that are clinical cadre			

[Table 1: Changes in PEPFAR-supported HRH_CURR and Net New PLHIV on ART/FTE gain or loss status, 3 highest burden metropolitan areas - US FY2017]



[Figure 1: Distribution of NET NEW PLHIV on ART in relation to changes in HRH_CURR by magnitude of TX_CURR Target Achievement Gap, U.S. FY2017]

Lessons learned: In US fiscal year 2017, PEPFAR supported 4302 FTEs in the priority metropolitan areas of Johannesburg, eThekwini, and Ekurhuleni. From April to September 2017, targeted HRH was provided to 355 facilities: 65% with roving teams, 27% with secondment, and 7% with temporary surge support. Data in Table 1 suggests that while HRH might be a contributing factor to increasing new patients on ART across a majority (62%) of facilities, a quarter (26%) of facilities gained patients despite losing HRH. Figure 1 shows the facility achievement of treatment targets in relation to changes in HRH_CURR across 30 sites. There is not a strong association between achievement of treatment targets and changes in HRH_CURR. To ensure impact and efficient resource management, data suggests that PEPFAR consider allocating HRH using multiple factors, such HIV burden, existing HRH, facility-level performance and needs.

Conclusions/Next steps: Programmatic shifts are critical to increase and/or realign HRH investments to maximize impact and ensure implementation fidelity. PEPFAR programs recently implemented site assessments to understand the HRH context and re-allocate workers based on results rather than a "one size fits all" staffing norms model. PEPFAR is implementing HRH recruitment and allocation models based on a variety of factors such as People Living with HIV (PLHIV), TX_CURR, and program performance. PEPFAR South Africa is developing a business portal linking site-level performance, HRH assessments, and workforce allocation for optimal results.

LBPEE054

I-Surge: Scale-up of HIV programs in Zambezia (ZM) province, Mozambique (MZ)

S. Michaels-Strasser[1], M. Vitale[2], B. Chilundo[2], R. Sutton[1], M. de Frietas[2], E. Pimentel De Gusmao[1], S. Dane[1], A. Mussa[2], W. El Sadr[1]
[1]ICAP at Columbia University, New York, United States, [2]ICAP at Columbia University, New York, Mozambique

Background: MZ has a severe generalized HIV Epidemic. Confronting the HIV epidemic in MZ requires accelerating the identification of HIV-positive (HIV+) persons, enabling them to initiate and remain on antiretroviral therapy (ART).with sustained viral load suppression (VLS). To achieve such ambitious goals, we embarked on a comprehensive surge in ZM.
Methods: Since January 2018, ICAP at Columbia University developed and implemented, in collaboration with Ministry of Health and CDC, with funding from PEPFAR, a surge strategy at 26 clinics in ZM. The ICAP surge (I-surge) uses a hyper-focused strategy to eliminate missed opportunities to test, treat and retain HIV+ patients. Community health workers (CHWs) drive *Push* activities generating demand for HIV services and efforts to track patients who missed visits and to motivate retention and adherence. Clinic staff implement *Pull* strategies, focusing on increased coverage for HIV testing, ART initiation, VL testing and VLS. Daily reporting of data elements by facility focal points to supervisors allowed for performance review, addressing gaps and re-allocation of resources. Use of WhatsApp® messages facilitated sharing of lessons learned and solutions across facilities and staff members.
Results: As presented in the Table, coinciding with I-surge, consistent increase in achievement of key targets was noted in testing, ART initiation and VLS. A 26% increase was noted in HIV testing with more than 1000% increase in index case testing and an 11% increase in linkage to care. A 54% and 43% increase in number of adults and children, respectively, who newly initiated ART was noted and there was a 117% increase in number of VL tests done with a 120% increase in VLS. Most substantial progress was noted in index case testing and viral load testing.

TARGET		Q1 (before surge)	Q2 (with surge)	Change n (%)
HIV Testing	Number of persons tested for HIV	61,185	77,253	+16,068 (26%)
	Number of persons testing positive for HIV	3,734	5,236	+1,502 (40%)
	Number of persons tested for HIV via index case testing (ICT)	290	5,574	+5,284 (1,822%)
ART Initiation	Number of HIV+ adults newly initiated ART	3,014	4,648	+1,634/ (54%)
	% Linkage to ART	86%	97%	+11%
	Number of HIV+ children <15 years newly initiated on ART	243	348	+105 (43%)
Number active on ART by age category	adults/children<15 years	39,634/ 2,808	42,785/ 3,033	+3,151(8%)/ +225 (8%)
Viral Load Testing	Number of Viral Load (VL) Tests done	4,843	10,523	+5680 (117%)
Viral Load Suppression (VLS)	Number of patients with VLS/ % of HIV+ persons with VLS	3,605 (74%)	7,944 (75%)	+4339 (120%)

[Table: Comparison of target achievement between Q1 and Q2 of FY18 following I-Surge Implementation at 26 clinics in ZM]

Conclusions: Reaching epidemic control requires a focused and nimble approach. Complementary facility and community activities are necessary, with intensive follow-up, data use and supervision. Maintaining this momentum requires sustaining staff motivation and intensive oversight.

LBPEE055

The implementation of Universal Test and Treat Programs: one-year experience from *Test & Treat Project* in Shinyanga and Simiyu Regions, Tanzania

P. De Nardo[1], T. Rinke de Wit[2], A. Bortolani[1], R. Mfaume[3], G. Pellizzer[1], M. Kihulya[4], B. Desderius[5], A. Pozniak[6], T&T Study Group
[1]Doctors with Africa - CUAMM, Padova, Italy, [2]Amsterdam Institute for Global Health & Development, Amsterdam, Netherlands, [3]Ministry of Regional Administration and Local Government, Shinyanga Regional Commissioner Office, Shinyanga, Tanzania, United Republic of, [4]Ministry of Regional Administration and Local Government, Simiyu Regional Commissioner Office, Bariadi, Tanzania, United Republic of, [5]Bugando Consultant and Teaching Hospital, Mwanza, Tanzania, United Republic of, [6]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom

Background: The *Test&Treat Project* in Shinyanga and Simiyu Regions, where HIV prevalence is estimated at 5.9% and 3.9% respectively, aims to implement a community model of HIV care encompassing both Universal Test and Treat and Differentiated Care based out of four Care and Treatment Centres (CTC). Here we report twelve-month data on HIV testing, linkage to care and viral suppression.
Description: Community-based HIV testing services and sensitization campaigns were implemented in public areas, factories, schools, and places of worship based on a "hamlet-testing" strategy. HIV testing was also offered routinely to all clients reporting to health facilities (HFs). All people tested HIV+ were referred to a CTC through community health workers who represented a key component in the linkage to care.
Lessons learned: From May 2017 to April 2018, 86,744 clients were tested through the testing campaigns (TC), while 25,944 were tested at the project's HFs. More men were tested in the TC compared to HFs (56% *vs* 44%; *p*< 0.0001). Overall 2,021 (1.8%) HIV+ clients were detected (male 39%). Of these, 953 (47%) were identified by TC and 1,068 (53%) by HFs. 15,554 (14%) children < 15 years were tested; of these, 65 (0.4%) were HIV+. Among the HIV+ clients detected in the TC, 138 (13%) were already aware of their HIV status. By 31st March 2018, 352 (43%) newly diagnosed clients identified in TC were linked to a CTC. More women were linked than men (45% *vs* 40%). Linkage was higher in Shinyanga than Simiyu (47% *vs* 38%; *p*=0.003). Among 3,014 patients on ARV at the project CTCs, viral load (VL) data were available for 1,745 (58%). Of these, 1,592 (91%) had VL < 1,000 cp/ml, while 1,440 (82%) being < 50 cp/ml.
Conclusions/Next steps: One-year data of a Tanzanian *Test&Treat Project* demonstrate the potential of TC to increase overall testing coverage in a short time frame and preferentially include male clients. Linkage to care remained a challenge. Viral suppression was achieved in majority of those on treatment. Determinants that underlie these first results are being studied with the aim to develop a sustainable Tanzanian blueprint for the UNAIDS 90-90-90 goals.

LBPEE056

Identifying gaps in viral load monitoring: Results from an evaluation of viral load reporting at primary health care facilities in South Africa

S. Pascoe[1], A. Huber[1], J. Murphy[1], W. Macleod[1,2], J. Bor[1,2,3], C. White[4], M. Fox[1,2,3]
[1]Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [2]Boston University School of Public Health, Department of Global Health, Boston, United States, [3]Boston University School of Public Health, Department of Epidemiology, Boston, United States, [4]Clinton Health Access Initiative, South Africa National Department of Health, Pretoria, South Africa

Background: While rates of viral load (VL) testing for HIV patients on treatment vary widely across facilities and districts in South Africa (SA) the reasons are unclear. We set out to assess prevalence of missing VL measures for HIV patients receiving care in the SA public health sector.
Methods: We used a retrospective design conducted at 24 facilities. Patients with a VL due (based on ART guidelines) between 1/10/2016-31/12/2016 were identified from SAs electronic HIV register, TIER.Net, and followed through electronic records to determine whether a VL was done within the scheduled window (Table). For patients with no VL on TIER.Net within the window, up to 300 paper clinic files per facility were randomly selected and reviewed. Proportion suppressed among those with a VL was reported.
Results: We identified 15,437 patients (68% female) with a VL due (Table). Of those, 69% had a VL captured on TIER.Net and 84% of those were suppressed. Of the remaining 4,748 files, we found and reviewed 2914 paper files (68% of 4308 selected). Almost 25% had a blood draw captured on file and just over 15% had a VL result (of which 68% were supressed). Females had slightly higher testing and suppression than males and the proportion with a VL done and suppressed did vary by previous suppression status. Of 1360 previously unsuppressed (VL>400 copies/ml), 32% had a follow-up VL in TIER.Net (37% suppressed) vs. 73% of those newly initiated/previously suppressed (of which 86% were suppressed), 16% of those previously unsuppressed and not found in TIER.Net (n=581) had a result on paper file (19% were suppressed).
Conclusions: A high proportion (31%) of ART patients had no VL recorded when one was due. Gaps in electronic data capture accounted for a minority of these missing results, suggesting most results were missing because VLs were not conducted - a failure to follow national guidelines for lab monitoring. Very large gaps in monitoring were observed following an unsuppressed viral load, precisely the group at highest risk for HIV morbidity, mortality and onward transmission. Interventions (e.g. intensified tracing) should be targeted to improve VL monitoring among patients with previous unsuppressed viral load.

	Total patients with a VL due on TIER.Net	Patients with VL due with VL captured on TIER.Net during scheduled window*				Patients with no VL captured on TIER.Net in window*	Patients with VL due with no VL captured on TIER.Net in scheduled window* where patient file was reviewed							Total VL suppressed among those with VL captured in window* on TIER.Net or file

Provision of comprehensive HIV/AIDS and TB services in protection of civilian (PoC) sites in South Sudan

B. Gikundi[1], M. Solangon[1], K. Kriitmaa[2], P. Jasi[3], F. Makonese[4], B. Otieno[5], S. Akandwanaho[6], A. Nur Hussein[7], S. Taher[7]
[1]International Organization for Migration, Migration Health Unit (MHU), Juba, South Sudan, [2]International Organization for Migration, Geneva, Switzerland, [3]International Organization for Migration, Dhaka, Bangladesh, [4]International Organization for Migration, Bentiu, South Sudan, [5]International Organization for Migration, Malakal, South Sudan, [6]International Organization for Migration, Wau, South Sudan, [7]International Organization for Migration, Juba, South Sudan

Background: The protracted conflict in South Sudan, the food insecurity, economic deterioration, and disease outbreaks continue to drive internally displaced persons (IDPs) into Protection of Civilian (PoC) sites across the country. Data from health facilities revealed that 1,140 HIV cases have been lost to follow up, either to neighbouring countries or to PoCs. There are currently 265,209 people residing inside the PoCs. In 2016, HIV/AIDS and tuberculosis (TB) were the leading causes of mortality in PoCs with IDPs unable to access treatment outside due to insecurity. Despite the challenging operating environment, IOM initiated provision of comprehensive HIV and TB services in three PoC sites in South Sudan.
Description: Since 2015, IOM had been providing HIV services only to pregnant mothers in the PoCs. Given the high rates of morbidity and mortality from HIV and TB, IOM expanded programming in 2016 to provide TB testing and treatment, and in 2017 to provide comprehensive HIV services in the three PoC sites. The services include voluntary counselling and testing (VCT), provider-initiated testing and counselling (PITC), and antiretroviral (ART) treatment. In addition, all TB confirmed

cases are screened for HIV and positive patients are initiated on ART. Health education sessions on HIV and AIDS and TB are conducted to raise awareness on services and treatment adherence.

Lessons learned: By 2018, 12,365 individuals have been counselled and tested for HIV in the three PoCs, 262 tested positive and 259 have been initiated on ART. Mortality rates due to HIV/AIDS and TB have decreased in the three PoCs from 107 (23% of the total deaths) in 2016 to 31 deaths in 2017 (12% of the total deaths), a 71% decrease in the mortality rate. This corroborates longitudinal studies showing decrease in AIDS-related deaths due to free access to HIV services[1].

[1] Lima et.al. AIDS incidence and AIDS-related mortality in British Columbia, Canada, between 1981 and 2013: a retrospective study. The Lancet HIV, Vol.2, 2015

Conclusions/Next steps: The provision of comprehensive HIV and TB prevention, testing, and treatment services to displaced populations in camp-based settings is essential in reducing morbidity and mortality from HIV, and in ensuring the 90-90-90 global targets are achieved.

LBPEE058

Establishing a digital OVC case management system in the DRC: New potential for innovation in OVC M&E systems

A. Keirstead[1], S. Reier[2], J. Bakua Mushitu[2], N. Do Nascimiento[3], J. Mwanza[3], A. Mafwila[4]

[1]Education Development Center (EDC), Washington, United States, [2]Education Development Center (EDC), ELIKIA Project, Lubumbashi, Congo, Democratic Republic of the, [3]The Palladium Group, Washington, United States, [4]The Palladium Group, ELIKIA Project, Lubumbashi, Congo, Democratic Republic of the

Background: The ELIKIA project is a five-year PEPFAR-funded project implemented in the DRC's Haut-Katanga province. The consortium is led by Education Development Center (EDC), and implemented in partnership with Catholic Relief Services, The Palladium Group, three local NGO partners, and the Haut-Katanga Division of Social Affairs. ELIKIA supports HIV-affected OVC and their caregivers through a combination of case management and psychosocial support; linkages to HIV testing, care, and treatment; household economic strengthening and parenting education; health and social service referrals; and strengthening child protection systems. Household support is coordinated through a cadre of 60 case managers from the Congolese government and civil society partners.

Description: ELIKIA developed a digital case management system for case managers to track their portfolio of OVC households. The project provided a total of 15 days of foundational training in the project case management approach, household support and referral strategies, and data collection and management procedures. Using programmed tablets, case managers record household vulnerability information; HIV risk, knowledge of HIV status, testing results, and ART initiation/adherence; service referrals and counter-referrals; and participation of caregivers in household economic strengthening and parenting education activities. Tablets sync daily with ELIKIA's DHIS2-based project database, enabling performance tracking and results capture in real-time. Database dashboards provide project managers with data on performance by implementing partner, health zone, program component, and individual case manager.

Lessons learned: By the end of its second year of implementation, 100% of ELIKIA case managers were using the digital system to track and provide support to 11,557 OVC and primary caregivers from 1,804 households. The system is increasingly effective in supporting analysis of case manager performance, ensuring continuous service delivery to retain households in the project, reducing double-counting of OVC supported by multiple project interventions, and demonstrating program results in alignment with PEPFAR reporting standards.

Conclusions/Next steps: Digital case management systems have the potential to facilitate improved case management and offer substantial improvements to OVC program monitoring and evaluation, avoiding several common challenges with tracking and reporting. Case managers with a university-level education or a high-school education and some prior social work experience can effectively use digital systems to manage data.

PUB001

Efficiency of two-drug combination of dolutegravir and rilpivirine when compared to triple and quadruple combinations

R. Dhani[1], S. Patro[2], G. Manavalan[1], D.D.R. Harish Kumar[3], D. Rajamanickam[3]
[1]Ratnam Institute of Pharmacy, Pharmaceutical Chemistry, Nellore, India, [2]Ratnam Institute of Pharmacy, Pharmaceutical Analysis, Nellore, India, [3]M.S. Ramaiah University of Applied Sciences, Faculty of Pharmacy, MSR Nagar, Bangalore, India

Background: The importance of two-drug combination in viral suppression of HIV is to simplify dosing regimen and reduce pill burden for patients with HIV. Reducing the number of drugs in a regimen reduces long term drug exposures and potential drug toxicity or drug interaction as well as protecting the activity of drugs spared for the future. Subjects switching to this two-drug regimen experienced a significant benefit in bone biomarkers.
Methods: Several clinical trials are performed for DTG+RPV they demonstrate NON INFERIORITY in two phase -3 switch studies known as sword - 1 and sword - 2 with 95% efficacy at 48 weeks. (LLIBRE is the lead author on sword - 1 and sword - 2 the studies referenced above). Sub studies evaluating bone, kidney, lipid profile, cardio vascular health and health related quality of life are ongoing.
Results: During clinical studies on these two- drug combination of dolutegravir and rilpivirine, the virologic suppression rates were similar between two-drug combination and triple and quadruple combination. The virologic failure rates were >1% in DTG+RPV and 1% in the three or four antiretroviral drug. In DTG+RPV no integrase strand inhibitor resistance(INSTI) - associated mutations were reported.
Conclusions: Life long HIV antiretroviral therapy has prompted an interest in two-drug regimen to minimize cumulative drug exposure and toxicity. The safety, tolerability and efficacy of dolutegravir and rilpivirine suggest potential comapatability and effectiveness as a two-drug regimen.

Track B

PUB002

Correlates of mortality among HIV patients following completion of standard Cryptococcal meningitis treatment in Uganda

J. Kitonsa[1], N. Kiwanuka[2], J. Kiwanuka[3], J. Namutundu[2], Z. Anywaine[1], A.-B. Ggayi[1], F. Kibengo[1], P. Kaleebu[1]
[1]Medical Reseach Council / Uganda Virus Research Institute Research Unit on AIDS, Kampala, Uganda, [2]Makerere University School of Public Health, Kampala, Uganda, [3]AIDS Healthcare Foundation, Kampala, Uganda

Background: Cryptococcal meningitis (CCM) remains a leading cause of mortality amongst HIV patients in Uganda. When patients receive recommended therapy, mortality in various clinical trials has been reported to vary between 20 to 35%. Patients may remain at risk of mortality after completing treatment due to complications, immune reconstitution syndrome and relapse. However, mortality rate and factors affecting time to mortality after completing recommended therapy are not well known. We investigated the mortality rate, and factors affecting time to mortality at 2 years following completion of recommended CCM therapy in South Western Uganda.
Methods: A retrospective non-comparative cohort study was conducted among HIV patients that had completed 10 weeks of recommended treatment for CCM (2 weeks of amphotericin B 1mg/kg and 10 weeks of Fluconazole 800mg) in the CryptoDex trial (ISRCTN59144167) between 2013 and 2015. Data was collected using semi structured questionnaires. Survival analysis applying cox regression was used to evaluate the mortality rate and factors affecting time to mortality at 2 years.
Results: This study followed up 112 participants for 2 years. Median age was 34 years (IQR, 29-40) with 57.1% female while 74.5% had been on ART for less than 1 year. At 2 years, overall mortality was 30% (1.7 per 100 person months). Majority of deaths (63.4%) occurred during the first 6 months whereas only 36.6% occurred in the remaining 18 months. At multivariate analysis, mortality was associated with discontinuation of ART at time of evaluation or prior to death (aHR=4.6, 95%CI: 1.1-19.0), p=0.038; and continuation of fluconazole (aHR=4.9, 95%CI: 2.4-10.1), p< 0.001; whereas never being re-admitted (aHR=0.140, 95%CI: 0.07-0.28), p< 0.001; and >50% quality of life (aHR=0.320, 95%CI: 0.13-0.76), p=0.01 were associated with reduced mortality.
Conclusions: There remains a considerable burden of mortality in the first two years after completing standard therapy for CCM in resource-limited settings. This burden is highest during the first 6 months. We recommend maintenance of close patient follow up during this period. Re-admitted patients and those with poor quality of life need to be followed up more closely while continuation of ART needs to be emphasized to reduce mortality.

PUB003

Predictors of intention to use condom among adolescents living with HIV and AIDS in Botswana

O. Rapinyana[1], R. Kubanji[2]
[1]University of Botswana, School of Nursing, Gaborone, Botswana, [2]University of Botswana, Population Studies, Gaborone, Botswana

Background: Adolescent HIV prevalence in Botswana is estimated at 5 % (3.6% males and 6.2% females). Youth in Botswana use condoms inconsistently. Among HIV positive youth aged 15 - 24years consistent condom use with non-regular partners was 57.2%. This clearly calls for programmes that reduce risky sexual behaviours among adolescent living with HIV and AIDS (ALWHA).
Methods: The study utilised a cross sectional quantitative survey of 98 ALWHA aged 15 to 19 years, recruited from child care and infectious disease control clinics managing HIV and AIDS clientele. The Theory of Reasoned Action was used to predict intentions, attitudes and beliefs that influence ALWHA's intention to use condoms. A univariate Generalised Estimation Equations (GEE) model in which a clinic was used as a cluster, with an exchangeable correlation matrix was employed in analysing the correlates between intention to use condom and explanatory variables loaded individually into the model.
Results: Reaction, normative beliefs, prevention beliefs, control belief technical and hedonistic beliefs had higher mean scores (above 3), while control belief negotiation had less than 2.5. Reaction, normative, prevention, control belief technical and hedonistic beliefs had higher scores in explaining condom use intention among ALWHA.
The results show that prevention belief and control belief negotiation significantly affected one's intention to use condom while reaction and normative beliefs did not, for both the adjusted and the unadjusted models. The models were adjusted for age and gender.The survey enrolled 98 ALWHA aged 15 - 19 years, about 56 %(n=55) females and 44% (n= 43) males. The mean age was 15.80 (SD = 0.21) for females and 15.73(SD = 0.14) for males. Self-reported sexual behaviour indicates that 17% had ever had sexual intercourse, 9% had experienced unprotected sex (males- 7.7%; females -10.0%). Generally ALWHA exhibited higher intentions to use condoms (mean=3.90; males-3.93 compared to females 3.88).
Conclusions: Overall, the results suggest that interventions that equip ALWHA with skills to use condoms correctly and consistently and negotiate for safer sex will not only benefit ALWHA but will also curb the spread of HIV.

Detection of infectious agents of cervicitis among young & adolescent female sex workers by multiplex real time PCR in Dhaka, Bangladesh

S. Paul[1], S. Ahmed[1], S. Anwar[1], K. Achabe[2], L. Rahman[2], Z. Shams[2]
[1]Bangabandhu Sheikh Mujib Medical University (BSMMU), Microbiology, Dhaka, Bangladesh, [2]Save the Children, Dhaka, Bangladesh

Background: The prevalence of STIs related cervicitis in Bangladesh among female sex workers (FSWs) is quite high and among them young (≤ 24 years) FSWs are more sufferers. The aim of this study was to detect infectious agents of cervicitis including *Chlamydia trachomatis, Neisseria gonorrhoeae, Trichomonas vaginalis, Mycoplasma genitalium, Mycoplasma hominis, Ureaplasmaurealyticum*and *Ureaplasmaparvum* in SWs of aged 10-24 years from endocervical swabs by multiplex real time PCR.
Methods: A cross sectional study was done in collaboration with department of Microbiology, BSMMU and Save the Children, Bangladesh between March to December 2017 among sex workers enlisted to receive HIV prevention services at different drop in centers (DICs) in Dhaka. Total 105 SWs of aged between 10-24 years and clinically suspected as cervicitis, were enrolled for the study. Endo-cervical swabs were collected during examination and testedby multiplex PCR and other tests for aforementioned pathogens.Data were collected by face to face interview using semi-structured questionnaire and clinical examinations were done using Casco's vaginal speculum. Data analysis was done using SPSS (Version-20).
Results: Among the study population, 87(82.9%) were between 20-24 years followed by 15-19 years(15.2%).On examination,out of 105, 67 (63.8%) patientshad no cervical discharge,60(57.1%) had friablecervix and only 8(7.6%)had muco-purulent discharge. Out of total,95(90.5%) patients were mPCR positive for at least one pathogen and only 3(2.9 %) N gonorrhoeae isolated by culture, 8(7.6%) cases of C trachomatis were detected by DFA and 8(7.6%)cases of T vaginalis were detected by wet film. Among the mPCR positive (95) cases, 63(66.3%) patients had mixed infections and among them,*M hominis* was the highest(76.2%) followed by*U urealyticum*(49.2%).In the patients having ,no'(67) cervical discharge, 32(48%) had *M hominis*followed by*Uparvum*(40%).
Conclusions: Results revealed that majority of FSWs had no cervical discharge though it is one of the diagnostic criteria for cervicitis in current syndromic management and high number of patients had mixed infection. In comparison to other available diagnostic tests, organisms were detected efficiently by multiplex PCR and could be advised routinely in such cases of mixed infection.

Organisms detected by mPCR								
	Total (%)	CT(24) n(%)	NG(18) n(%)	TV(25) n(%)	MG(16) n(%)	MH(53) n(%)	UU(34) n(%)	UP(43) n(%)
Mixed infection	63 (66.3)	22 (35)	17 (27)	22 (35)	15(23.8)	48(76.2)	31(49.2)	26(41.3)
No cervical discharge	67 (63.8)	18 (26.9)	11 (16.4)	14 (21)	8(12)	32(48)	22(32.8)	27(40.2)

The factors associated with high-risk behavior among labor migrants, Uzbekistan

S. Umarkhojaev[1], G. Rajabov[2]
[1]Republican AIDS Center, Prevention, Tashkent, Uzbekistan, [2]Republican AIDS Center, Tashkent, Uzbekistan

Background: The HIV epidemic in the Republic of Uzbekistan is in its concentrated stage and spreads primarily among MARPs. However, routine surveillance data shows that in recent years there has been an increased incidence of HIV infection among labor migrants and their sexual partners in the country. If the proportion of HIV infected migrants among newly registered cases in 2002 was 0.9%, so in 2015 this figure increased to 13.6%. This study aimed to identify risk factors of HIV infection and assess the effectiveness of prevention programs among labor migrants.
Methods: From July to September 2015 in 16 sentinel sites of the republic was conducted a cross-sectional study. Data were collected through an anonymous structured questionnaire, blood samples by „Dried Blood Specimen" (DBS) methodology. All DBS specimens were tested for HIV, HCV and syphilis antibodies by ELISA. The criteria for including to the study were: people in the age of 18-49 that were employed or self-employed outside of Uzbekistan during the last 5 years. 5450 respondents were recruited into the study. The data were analyzed in Epi-Info 3.5. Logistic regression was used to assess the factors associated with HIV infection.
Results: Of the participants, 69.9% were males; 80.6% had secondary education; 19.6% were single and 13.1% separated.The mean age of the participants was 34.3 years.
4.5% participants had ever taken drugs, 0.6% reported having sexual partner who inject drugs. 57.5% consumed alcohol in migration. 32.0% respondents reported having sexual intercourse in migration. 37.3% of migrants had irregular and commercial sex partners in migration, 40.8% of them used a condom during their last sexual intercourse. 7,0 % reported that they had symptoms of STDs, only 40,6% of them went to health care facilities.
49,5% had misconceptions about HIV transmission and prevention. Prevalence´s of HIV, HCV and syphilis among migrants were 0.8%, 3.8% and 1.1%, respectively. Not sufficient educational level and risky sexual behavior were associated with HIV serostatus in the multivariate analysis.
Conclusions: The results of study confirms that the increasing of the number of HIV cases among labor migrants is urgent as the insufficient awareness, high risky behavior and restricted access to health services.

PUB006

Low risk perception about safe motherhood negatively impact on health seeking behaviour during antenatal period among female sex workers (FSWs) in Bangladesh

Z. Shams[1], K. Achabe[2], S. Jahan[1], L. Rahman[3], S. Sultana[1], T. Wahed[4]
[1]Save the Children, Bangladesh, Dhaka, Bangladesh, [2]Save the Children,USA, Washington,DC, United States, [3]Save the children, Bangladesh, Dhaka, Bangladesh, [4]Research to Policy Limited, Dhaka, Bangladesh

Background: In Bangladesh, Maternal mortality ratio (MMR) declined significantly from 322 (2001) to 194 (2010) per 100,000 live births. This was linked to fertility reduction; increased access & use of services in the antenatal, delivery, and postpartum periods; and socioeconomic improvements [i] However, The Bangladesh Demographic and Health Survey (BDHS) 2014 demonstrated that 10.5% of urban women did not seek for antenatal care (ANC).[ii] Among the vulnerable women, female sex workers (FSWs) are at high risk of becoming pregnant because of their reproductive age, poor negotiation power for condom use, and the high number of client. It is essential to understand the risk perception regard-

ing pregnancy to fill up need. This study looked at sexual and reproductive health (SRH) practices among FSWs including pregnancy and use of maternal healthcare services.

Methods: A cross-sectional descriptive study was conducted in 2015 among FSWs in Dhaka based 3 drop- in centers (DICs) using stratified random sampling. About 731 FSWs from residence, hotel, and street participated in the study. They received HIV preventive services from Save the Children and partner organizations with support from the Global Fund. A quantitative survey was done and analyzed by SPSS (version 20).

Results: Only 9% (66) of FSWs were pregnant during study (p< 0.006) where 24% of them were pregnant for the first time. The majority (75.8%) of pregnant FSWs planned to continue the pregnancy. However, about one-fourth (26%) of them did not visit a healthcare provider. Moreover, almost half of pregnant FSWs were continuing their sex trade despite of their current pregnancy because of regular income source. Around 38% of current pregnant FSWs had 1-3 times sex act /day which increased their health risk. About 25% of current pregnant had already history of abortion once or more.

Conclusions: Because of commercial sex practice and low level of knowledge about safe motherhood, FSWs were at risk of STI including HIV, spontaneous abortion, or even preterm birth, or low birth weight baby. To increase self-risk perception, it is essential to raise awareness on pregnancy care, safe delivery and STI prevention. Strong integrated HIV-SRH services free or at lower rate can be offered.

PUB008

The exploring the vulnerability of the deaf community in Ghana to HIV infections

W.K. Mprah
Kwame Nkrumah University of Science and Technology, Community Health, Kumasi, Ghana

Background: HIV/AIDS is major public health issue in Ghana and the Government of Ghana has initiated several measures to curb HIV infections. However, deaf people are unlikely to benefit from these initiatives and may be at high risk for HIV infections. This study investigated the vulnerability of deaf people in Ghana to HIV infection.

Methods: This study was quantitative and targeted deaf people who communicate in the Ghanaian Sign Language (GSL) and resident in Ghana. Questionnaires were administered to a total of 304 deaf respondents, made up of 130 females and 174 males.

Results: The findings of the study indicated that majority of respondents in the study lacked basic knowledge on HIV; they had not discarded misconceptions about HIV/AIDS and had difficulty identifying methods for preventing HIV infection. Although this study is limited in scope, because it focused only on deaf people who use the GSL, the findings provide insights into deaf people's level of knowledge on HIV/AIDS.

Conclusions: The findings suggest that the situation could be more serious among deaf people who do not use the GSL and are unable to use sign language interpreters to access information and services on HIV/AIDS. It is therefore recommended that more studies should be conducted on the general deaf population in Ghana to identify the needs of the different categories of deaf people so that these could be captured in HIV/AIDS interventions.

PUB007

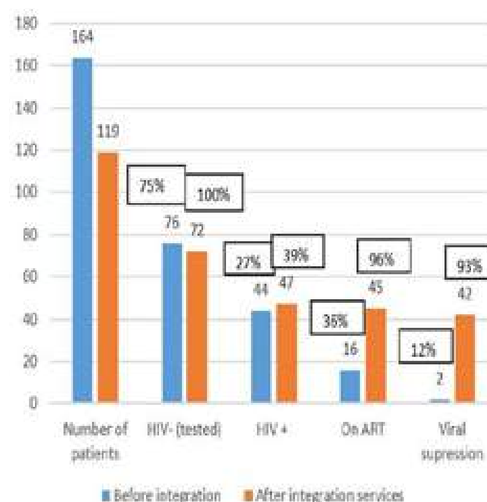
Integration of HIV services for PWID and navigator involvement improves HIV cascade of care in PWID in Tajikistan clinic

N. Malikov, I. Kim
Republican Center of Narcology, Opioid Substitution Treatment, Dushanbe, Tajikistan

Background: In the Republic of Tajikistan, providing preventive and curative services to people who inject drugs (PWID) is hampered by poor integration of HIV services within drug treatment centers and non-governmental organizations. To tackle this problem and work towards achieving the UNAIDS 90-90-90 goals, the RNC in Dushanbe has integrated HIV services within its medicated assisted treatment (MAT) program for PWID. In this study we investigated the effectiveness of this integrated approach, initiated in November 2014, combined with navigator-provided support.

Methods: This prospective study analyzed patient medical records from November 2014 through to November 2017 in terms of the following: (1) HIV testing, (2) administration of antiretroviral therapy (ART), (3) viral load (VL).

Results: In November 2014, there were 164 (147 male; 17 female) patients in care at the MAT site, 44 of whom were people living with HIV (PLHIV) (m=34;f=10; [27%]). Of these 44 PLHIV, 16 (m=13;f=3; [36%]) were on ART, 2 (m=2;[12%]) of whom had a suppressed VL. Of the remaining 102 HIV-negative patients, 76 (75%) had been tested for HIV. As of December 1, 2017, 119 (m=107;f=12) patients had been enrolled in the integrated service program and were supported by a navigator. All 119 (100%) of these patients had been tested for HIV and were aware of their status. Patients with a positive HIV test subsequently underwent timely testing of ELISA, CD4, and VL. Of the 119 patients, 47 (m=38;f=9;[39%]) were found to be HIV-positive, of whom 45 had initiated ART (m=36;f=9;[96%]). Of these 45 individuals on ART, 42 (m=35;f=7;[93%]) achieved viral suppression. The remaining 72 patients tested for HIV were found to be HIV-negative.



[Figure. Continuum of HIV care for PWID before and after integration of HIV and MAT services]

Conclusions: Following integration of HIV services within the MAT program for PWID and provision of navigator support, the rate of HIV-positive individuals on ART and achieving viral suppression has increased markedly at the RNC. It would appear that such integration of services facilitates timely testing, initiation of ART and suppression of the HIV VL. The resulting improvement achieved in the 90-90-90 cascade of care for RCN suggests the model would also be effective in other MAT sites in Tajikistan and elsewhere.
