Abstract Book

AIDS 2018

22ND INTERNATIONAL AIDS CONFERENCE
AMSTERDAM, NETHERLANDS
23-27 JULY 2018

BREAKING BARRIERS • BUILDING BRIDGES

Scientific Programme Committee

Co-Chairs
James Hakim, Zimbabwe
Sheena McCormack, UK
Wafaa El Sadr, USA

Members

Track A: Basic and Translational Research
Huldrych Günthard, Switzerland
Sharon Lewin, Australia

Track B: Clinical Research
Karine Lacombe, France
Roy Gulick, USA

Track C: Epidemiology and Prevention Research
Caroline Sabin, UK
Nittaya Phanuphak, Thailand

Track D: Social and Political Research, Law, Policy and Human Rights
Catherine Hankins, the Netherlands
Maksut Kulzhanov, Kazakhstan
Morenike Ukpong-Folayan, Nigeria

Track E: Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors
Charlotte Watts, UK
Jonathan Gunthorp, South Africa

Scientific Programme Track Committees

Track A: Basic and Translational Research

Co-Chairs
Huldrych Günthard, Switzerland
Sharon Lewin, Australia

Committee members
Galit Alter, USA
Peter Hunt, USA
Javier Martinez Picado, Spain
Monique Nijhuis, the Netherlands
Sandhya Vasan, Thailand
Reena Rajasuriar, Malaysia
Jo-Ann Passmore, South Africa
Cecile Tremblay, Canada
Lara Vojnov, WHO

Track B: Clinical Research

Co-Chairs
Karine Lacombe, France
Roy Gulick, USA

Committee members
Judy Currier, USA
Beatriz Grinstzejn, Brazil
Andrew Kambugu, Uganda
N Kumarasamy, India
Noel Magloire Manga, Senegal
Cristiana Oprea, Romania
Reinout Van Crevel, the Netherlands
Geraldina Dominguez, USA
Dorothy Mbori-Ngacha, UNICEF

Track C: Epidemiology and Prevention Research

Co-Chairs
Caroline Sabin, UK
Nittaya Phanuphak, Thailand

Committee members
Nelly Rwamba Mugo, Kenya
Kevin M. De Cock, Kenya
Frances Cowan, Zimbabwe
Evgeny Voronin, Russia
Kimberly Green, Vietnam
J. Peter Figueroa, Jamaica
Julia del Amo Valero, Spain
Peter Godfrey-Faussett, UNAIDS

Track D: Social and Political Research, Law, Policy and Human Rights

Co-Chairs
Catherine Hankins, the Netherlands
Maksut Kulzhanov, Kazakhstan
Morenike Ukpong-Folayan, Nigeria

Committee members
Michaela Clayton, Namibia
Anya Sarang, the Netherlands
Richard Elliott, Canada
Prince Bahati Ngongo, Kenya
John de Wit, the Netherlands
Kate Shannon, Canada
Jonathan Cohen, USA
Ilya Zhukov, UNFPA
Andrew Ball, WHO

Track E: Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors

Co-Chairs
Charlotte Watts, UK
Jonathan Gunthorp, South Africa

Committee members
Ade Fakoya, Switzerland
Idrissa Ba, Senegal
Ashley John Duits, Curaçao
Gabriela Gomez, United Kingdom
Jacquelyne Alesi Mugenyi, Uganda
Souhaila Bensaid, Tunisia
Tigran Yepoyan, UNESCO
Miriam Rabkin, USA

Abstract Mentor Programme

The Abstract Mentor Programme (AMP) was introduced at the 15th International AIDS Conference (AIDS 2004), with the objective to help young or less experienced researchers improve their abstracts before submitting them, in order to increase the chance of their work being presented at conferences. Over the years, the AMP has proven to increase the motivation of early career researchers, as well as the number of abstract submissions received from resource-limited countries.

This year, 202 mentors reviewed 309 draft abstracts submitted by 219 researchers.
195 of the reviewed abstracts were submitted to AIDS 2018 and the following were selected:

- 3 Oral Abstracts
- 1 Poster Discussion Session
- 63 Poster Exhibition

We would like to thank all volunteer abstract mentors, listed below, who supported early-career HIV researchers improve the quality of their abstracts.

Abiodun Egbetokun, Nigeria
Abiola Ajibola, Nigeria
Adebola Adedimeji, United States
Adedotun Ogunbajo, United States
Ali Judd, United Kingdom
Alinda Vos, Netherlands
Allison Carter, Canada
Amos Laar, Ghana
Anam Nyembezi, South Africa
Andrea Low, Canada
Andrew Etsetowaghan, Nigeria
Andrew Mujugira, Uganda
Andy Guise, United Kingdom
Anita De Rossi, Italy
Anna Grimsrud, Canada
Archana Sud, Australia
Ashley Lacombe-Duncan, Canada
Assane Diouf, Senegal
Barbara Burmen, Kenya
Barbara Castelnuovo, Italy
Beatrice Wamuti, Kenya
Bharat Negi, Nepal
Brandon Brown, United States
Brenda Crabtree- Ramirez, Mexico
Brendan Maughan-Brown, South Africa
Bright Drah, Ghana
Carlos Brites, Brazil
Carmen Logie, Cape Verde
Carmen Figueroa, Dominican Republic
Caspian Chouraya, Zimbabwe
Catherine Todd, United States
Chandrakant Lahariya, India
Charles Van Der Horst, United States
Chen Zhang, China
Chien-Ching Hung, Taiwan, China
Chioma Daisy Onyige, Nigeria
Christina Psomas, Canada
Christinah Mukandavire, Zimbabwe
Christy Ekerete Udofia, Nigeria
Chunyu Li, United States
Clotilde Allavena, France
Collins Iwuji, United Kingdom
Darshini Govindasamy, South Africa
David Hanna, United States
David Lubogo, Uganda
David Dunn, United Kingdom
David Moore, Canada
Deborah Brickley, United States
Deborah Jjones Weiss, United States
Degu Jerene Dare, Ethiopia
Dimitrios Paraskevis, Greece
Dominicus Husada, Indonesia
Elie Kasindi Kabululu, The Democratic Republic of the Congo
Elijah Paintsil, United States
Elisa De Castro Alvarez, Spain
Elisabete Cristina Morandi Dos Santos, Brazil
Elona Toska, Albania
Elvis Temfack, Cameroon
Elvis Enowbeyang Tarkang, Cameroon
Emilio Letang, Spain
Emily Hyle, United States
Emma Sacks, United States
Emmanuelle Papot, France
Ernest Ekong, Nigeria
Neema Makyao, United Republic of Tanzania
Ethan Morgan, United States
Francis Ogirima, Nigeria
Fred Collins Semitala, Uganda
Ganesh Shanmugasundaram Anusuya, India
Genaro Castro-Vazquez, Mexico
Gift Kamanga, Malawi
Grace Mchugh, Ireland
Grace John-Stewart, United States
Guillermo Teran-Angel, Venezuela
Guinevere Lee, Canada
Gulden Ersoz, Turkey
Halima Dawood, South Africa
Hanna Tessema, United States
Heather Bailey, United Kingdom

Xiaoming Li, United States
Yuntao Wu, Canada

International Abstract Review Committee

The The 22nd International AIDS Conference received more than 7,800 abstract submissions, which went through a blind, peer-reviewed process carried out by an international panel of reviewers who play a critical role in designing a strong scientific programme.

More than 950 specialists from around the world volunteered their time and expertise to serve as peer reviewers, helping to ensure that the abstracts presented were selected on the basis of rigorous review and were of the highest scientific quality.

We extend our special thanks to the large pool of abstract reviewers for the time they dedicated to the success of the conference:

Lisa Abuogi, United States
Jeffry Acaba, Philippines
Sylvia Adebajo, Nigeria
Carlos Adon, Dominican Republic
Kawango Agot, Kenya
Allison Agwu, United States
Ali Ahmad, Canada
Atsushi Ajisawa, Japan
Ajaz Akhtar, Pakistan
Nazmul Alam, Canada
Jose Alcami, Spain
Anna Aldovini, United States
Grace Aldrovandi, United States
Jacquelyne Alesi Mugenyi, Uganda
Robert Allard, Canada
Todd Allen, United States
Galit Alter, United States
Marcus Altfeld, Germany
Dennis Altman, Australia
Ugo Amanyeiwe, United States
Rama Rao Amara, United States
Atul Ambekar, India
K. Rivet Amico, United States
Jintanat Ananworanich, Thailand
Petronela Ancuta, Canada
Jonathan Angel, Canada
Brian Angus, United Kingdom
Cristian Apetrei, United States
Victor Appay, France
Chris Archibald, Canada
Roberto Arduino, United States
Gabriele Arendt, Germany
Radka Argirova, Bulgaria
Nathalie Arhel, France
Emily Arnold, United States
Jose Arribas, Spain
Judith Auerbach, United States
Matt Avery, Thailand
Santiago Avila-Rios, Mexico
Nwe Nwe Aye, Myanmar
Olubukola Oyeyinka Ayinde, Nigeria
Helen Ayles, Zambia
Yusef Azad, United Kingdom
Tasnim Azim, Bangladesh
Iskandar Azwa, Malaysia
David Back, United Kingdom
Abdallah Badahdah, Qatar
Andrew Badley, United States
Jared Baeten, United States
Rachel baggaley, Switzerland
Prince Bahati, Kenya
Andrew Ball, Switzerland
Stephen Banspach, United States
Stefan Baral, Canada
Giuseppe Barbaro, Italy

Table of Contents

Tuesday Oral Abstract Sessions

TUAA01 From conception to delivery: The vaccine discovery pipeline 1
TUAA02 Strategies for cure: Pitfalls, possibilities and promise 3
TUAB01 Antiretroviral strategies 4
TUAB02 HIV and TB: Double challenge 6
TUAC01 Forging new pathways towards HIV elimination 10
TUAC02 It's raining men: Key statistics for engagement 12
TUAC03 Diversities in delivery: PrEP from home to clinic 14
TUAD01 Harm reduction: I can't get no satisfaction 16
TUAD02 The defence does not rest: Resisting the criminalization of HIV 18
TUAD03 Lost in transition: Challenges in domestic financing for HIV and human rights 20
TUAD04 Time for transformation: Listening to trans voices 22
TUAE01 Taking testing to the next level 24

Tuesday Oral Poster Discussions

TUPDA01 Besieging the reservoir and kicking it where it hurts 27
TUPDB01 Neuro HIV: Cognition, complications and ART toxicity 29
TUPDC01 Mortality trends in the ART era 33
TUPDD01 #UsToo: Violence against key populations 35
TUPDD02 Active engagement or missing in action: Community voices in HIV research 38
TUPDE01 Geomapping to enhance equitable access 40
TUPDX01 PrEP in the real world: What are we learning? 43

Tuesday Poster Exhibition

Track A > Track A - Basic and Translational Research

PEA001-A006 Viral origins, evolution and diversity 47
PEA007-A008 Viral fitness and resistance 49
PEA009 Entry (attachment, receptors and co-receptors, penetration and tropism) 50
PEA010-A011 Viral replicative cycle (reverse transcription, integration, viral assembly and maturation) 51
PEA012-A013 Transcriptional and gene expression regulation (including regulatory genes) 51
PEA014-A018 Innate immunity 52
PEA019-A024 Humoral immunity (including broadly neutralizing antibodies) 54
PEA025-A031 Cellular immunity 56
PEA032-A034 Mucosal immunity 59

Track B > Track B - Clinical Research

PEB035-B039 HIV testing and retesting (e.g. point of care diagnostics) 60
PEB040 CD4 measurement (e.g. point of care diagnostics) 62
PEB041-B044 Viral load measurement (e.g. point of care diagnostics) 63
PEB045-B046 Measuring ART adherence (drug levels, dried blood spots, hair sampling) 64
PEB047-B053 Drug resistance testing 65
PEB054-B062 Diagnostics of co-infections and comorbidities 68
PEB063-B066 Biomarkers for the prediction of morbidity and mortality 71
PEB067-B072 Neurologic disorders 73
PEB073-B079 Depression and other psychiatric manifestations 76
PEB080-B083 Malignancies (AIDS and non-AIDS) 78
PEB084-B107 Cardio-vascular disease 80
PEB108-B112 Bone disease 90
PEB113-B115 Renal disease 92
PEB116-B126 Metabolic, lipid and endocrine complications, including obesity and lipodystrophy 94
PEB127-B131 Hepatic complications (e.g. NASH) 99
PEB132-B138 Ageing with HIV (including polypharmacy and frailty) 101
PEB139 Immune reconstitution disorders / immune reconstitution inflammatory syndrome (IRIS) 105
PEB140-B147 Other non-communicable diseases 105
PEB148-B151 Other ART complications and adverse reactions 109

Track C > Track C - Epidemiology and Prevention Research

PEC152-C156 Natural history, morbidity patterns and survival 111
PEC157-C166 Epidemiology of HIV in the general population 114
PEC167-C195 Epidemiology of HIV in MSM 118
PEC196-C205 Epidemiology of HIV in infants, children and adolescents 130
PEC206-C233 Epidemiology of HIV in other key vulnerable populations (e.g. PWID, women, TGW, sex-workers, prison populations, older groups) 135
PEC234-C262 Risk factors for acquisition, infectivity and transmission of HIV 146
PEC263-C267 Epidemiology of AIDS events (e.g. AIDS-related opportunistic infections and cancers) 158
PEC268-C275 Epidemiology of non-AIDS infections and communicable diseases (e.g. viral hepatitis, STIs) 161
PEC276-C287 Epidemiology of non-AIDS non-communicable diseases (e.g. non-AIDS cancers, CVD) 164
PEC288-C290 Describing the spread of HIV through molecular epidemiology 169
PEC291-C300 Modelling the potential impact of prevention strategies on the HIV epidemic 170
PEC301-C303 Modelling the evolution of the HIV epidemic through behavioural and PrEP studies 175
PEC304 Modelling attempts to end HIV 176
PEC305-C310 The role of social and sexual networks in the spread of HIV 177
PEC311-C316 The role of syndemics 180
PEC317-C321 The role of political and structural factors 182
PEC322-C328 Understanding the spread of HIV through behavioural studies 184
PEC329-C333 Modelling future healthcare needs 187
PEC334-C339 Identifying optimal service models 189

Track D > Track D - Social and Political Research, Law, Policy, and Human Rights

PED340-D348 Social and behavioural concepts and theories 191
PED349 Strengthening social and behavioural data collection and analysis 195
PED350-D351 Mixed methods, integrated approaches and synergies in HIV research and intervention 196

PED352-D362 Qualitative and ethnographic methods in HIV research 196
PED363-D366 Knowledge translation and dissemination of research and programme outcomes 201
PED367-D375 Community engagement in research and research dissemination 202
PED376 Role of social and behavioural science in biomedical responses 206
PED377 Research data disaggregation by factors such as sex, age, race/ethnicity, sexual orientation, etc.) 207
PED378-D411 Positive health, dignity, psychological well-being, and mental health 207
PED412-D415 Adaptation to living with HIV for individuals, families, and communities 220
PED416 Living with HIV and co-infections and/or co-morbidities 221
PED417-D419 Adaptation to living with HIV for individuals, families, and communities 222
PED420-D425 Experiences and impacts of antiretroviral therapy 223
PED426-D435 Growing up with HIV: specific needs and interventions for children and adolescents 225
PED436-D438 Ageing with HIV: evolving and additional needs and responses 229
PED439-D440 Prevention interventions and their effects on the lives and relationships of people living with HIV 230
PED441-D446 Sexual and reproductive health, fertility, family planning, pregnancy, and abortion 231
PED447-D454 Living with HIV and co-infections and/or co-morbidities 233
PED455-D480 Human rights of people living with HIV and key and vulnerable populations 236
PED481 Gender equity 245
PED482-D491 Sexual and reproductive health and rights 246
PED492 Children's rights and HIV 249
PED493-D501 Stigma and discrimination regarding people from key populations 250
PED502-D521 Stigma and discrimination in specific settings, including family, community, work place, education, and healthcare settings 253
PED522-D525 Representations of stigma: social attitudes, media, and public debate 262
PED526-D529 Experiences and impacts of homophobia and transphobia 263
PED530-D537 Laws and policies regarding access to HIV treatment and medical devices, including Intellectual property and trade regimes, competition law, price regulation, etc. 265
PED538-D545 Human rights programmes 268
PED546-D556 Legal advocacy tools and strategies 270
PED557-D564 Ethical aspects and standards in research, including clinical trials 275
PED565-D566 Ethical aspects and standards in prevention programmes 278

Track E > **Track E - Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors**

PEE567-E577 National financing analyses and initiatives 278
PEE578-E581 Transitional financing 282
PEE582-E588 International assistance, frameworks, and funding mechanisms 284
PEE589 Financing HIV within UHC frameworks 286
PEE590-E607 Approaches to achieving sustainability 287
PEE608-E616 Economic evaluation and affordability assessments 293
PEE617 Supporting sustainable financing for civil society 296
PEE618-E620 Financing HIV drug access: the economics of generics and differential pricing structures 297
PEE621-E626 HIV and universal health coverage 298
PEE628-E630 Evidence from integration of health services 301
PEE631 Evidence from cross-sectoral programming 302
PEE632 Approaches to financing across sectors 302
PEE633-E644 Combination programming on social drivers of HIV (including education; violence; & workplaces) 303
PEE645-E648 Delivering gender transformative programmes and tackling violence against women and girls: programmatic lessons 307
PEE649-E657 Social protection: new evidence and programmatic lessons 308
PEE658-E660 Innovations in behavioural data collection and use 311
PEE661-E662 Big data: an untapped opportunity? 313
PEE663-E665 Innovative approaches to track individuals 314
PEE666-E687 Innovative uses of data to strengthen systems and programmes 315
PEE688-E708 Approaches to using data to improve programming 324
PEE709-E711 Evaluating large scale programmes: approaches to rigorous evaluation 333
PEE712-E718 Implementation science: lessons from researcher / programme partnerships 335
PEE719-E732 Effective approaches to linking population and programme data, to inform HIV programming 338
PEE733-E735 Data and accountability and transparency 343
PEE736-E737 Monitoring and reporting in the SDG era 345

Wednesday Oral Abstract Sessions

WEAA01 Poking, prodding and purging the final reservoir frontier 346
WEAA02 Killers or helpers: The double life of T cells 348
WEAB01 Keep your eyes on OIs and STIs 350
WEAB02 ART in infants and children 352
WEAC01 The new high risk populations: Who are they? 355
WEAD01 Justice on the margins: Legal strategies to address barriers to HIV services 357
WEAD02 Time for a youthquake in HIV prevention and treatment 358
WEAD03 Treatment politics and financing in 2018 360
WEAE01 Reaching men: Yes we can! 362
WEAE02 Tough choices, smart decisions, maturing responses 364
WEAE03 Money, money, money: Dynamic financing solutions 366
WEAE04 PrEP: Work in progress 368
WEAE05 I want you back: Improving retention on HIV programmes 370

Wednesday Oral Poster Discussions

WEPDA01 All fired up: Tackling inflammation 373
WEPDB01 Acute infection and viral reservoir 375
WEPDB02 Antiretrovirals: Pharmacokinetics and generics 377
WEPDC01 From online to IRL: Social media, sex apps and surfing to enhance cascades 379
WEPDC02 Sex and drugs: Ongoing syndemics in the PrEP and treatment era 382
WEPDD01 Occupy the epidemic: Economic inequality and HIV 385
WEPDE01 Keeping it up: National ownership and financial sustainability 387

Wednesday Poster Exhibition

Track A > **Track A - Basic and Translational Research**

PEA001-A004 Systemic immune activation and inflammation 390
PEA005 T cell depletion and reconstitution, and immune ageing 391
PEA006 Microbiomes and microbial translocation 392
PEA007-A011 Correlates of HIV susceptibility, disease progression, (biomarkers and genetics) 392
PEA012-A017 HIV co-morbidities 394
PEA018-A020 Systems biology approaches to HIV infection 396
PEA021 Neurodegeneration 398
PEA022 Biomarkers and imaging 398
PEA023-A024 Viral mechanisms of HIV/SIV persistence and latency 399
PEA025-A026 Host cellular factors and latency 400
PEA027-A029 Cellular and tissue reservoirs of HIV/SIV 401
PEA030-A032 Quantifying HIV/SIV reservoirs and rebounding virus 402

Track B > **Track B - Clinical Research**

PEB033-B036 Impact of co-factors (e.g. viral clade, tropism, genetic factors) on disease progression 403
PEB037-B038 Morbidity, mortality and life expectancy in clinical research 405
PEB039-B040 Opportunistic infections (excluding TB) 406
PEB041-B073 Tuberculosis 406
PEB074-B077 Bacterial, non TB mycobacterial, viral and parasitic infections 419
PEB078-B081 Viral hepatitis B and D 421
PEB082-B099 Viral hepatitis C 423
PEB100 Other viral hepatitis (e.g. A and E) 432
PEB101-B110 STI's including HPV 432
PEB111-B114 Sex-specific issues of ART efficacy, adverse reactions and complications 436
PEB115-B124 Pregnancy (clinical management issues and pharmacokinetics) 438
PEB125-B127 Contraception 442
PEB128-B129 Menopause 444
PEB130 Clinical issues in men who have sex with men 445
PEB131-B138 Clinical issues in people who use drugs 445
PEB139-B140 Clinical issues in transgender and non-binary populations 448
PEB141 Clinical issues in migrants 449
PEB142-B148 Clinical issues in other vulnerable populations 449

Track C > **Track C - Epidemiology and Prevention Research**

PEC149-C151 New PrEP products (e.g. TAF and other antiretrovirals, long acting oral and injectable drugs, topical PrEP/microbicides) 452
PEC152-C155 Other new prevention tools 454
PEC156-C172 Reaching and recruiting key populations for HIV services (online, offline, online-to-offline) 455
PEC173-C199 Innovative HIV testing strategies (peer-led testing, peer-mediated testing, self-testing with and without online/offline support, use of fourth generation and recency assays) 461
PEC200-C203 Rapid/Same-Day ART initiation 472
PEC204-C224 Demonstration and pilot projects for PrEP, PEP, male circumcision 474
PEC225-C262 Scale-up of PrEP, PEP, male circumcision 482
PEC263-C272 Integrating STI, sexual and reproductive health, HBV and HCV services in HIV prevention programs 497
PEC273-C301 Developing tailored and comprehensive services for specific key and vulnerable populations 501
PEC302-C305 Male and female condom use 511
PEC306-C309 Access to harm reduction interventions 513
PEC310-C316 Novel research designs for epidemiology and surveillance 515
PEC317-C318 Novel research designs for HIV prevention in the era of PrEP/PEP 518
PEC319 Capacity building for epidemiological and prevention research 518
PEC320-C324 Community involvement and good participatory practice in epidemiological and prevention research 519
PEC325 Harnessing big data for epidemiological research/digital epidemiology 521
PEC326 Utilising clinical data systems for epidemiological and behavioural research 521

Track D > **Track D - Social and Political Research, Law, Policy, and Human Rights**

PED327-D355 Conceptualizing social and structural factors and their impacts 522
PED356-D361 Socio-economic differences: poverty, wealth, and income inequalities 533
PED362-D368 Dynamics of social status and power: sex, gender, age, race/ethnicity, sexual orientation, disability 535
PED369-D370 Economic transitions and social and cultural changes affecting HIV and the HIV response 538
PED371-D375 Intergenerational and/or transactional sex 539
PED376-D381 Migration and HIV 541
PED382-D394 Violence and conflict: political, social, structural, interpersonal, and family-based 543
PED395-D398 Humanitarian crises and HIV 548
PED399-D405 Sexuality- and/or gender-based violence and exploitation, including in conflict settings 550
PED406-D414 Prisons and other closed settings 553
PED415-D419 Media, cultural and religious representations of HIV and of key populations 556
PED420-D443 Gay, bisexual, and other men who have sex with men 558
PED444-D467 People who use drugs (including by injection) 568
PED468-D502 Sex workers 576
PED503-D522 Transgender people 588
PED523-D551 Other populations vulnerable in specific contexts 596
PED552-D555 Sexualities and sexual cultures: meanings, identities, norms, and communities 605
PED556-D567 Adolescents, sexuality, and relationships 607
PED568 Same-sex-attracted, bisexual, and queer people 612
PED569-D580 Gender issues and gendered relationships 612
PED581-D583 Sexual concurrency and sexual networks 616
PED584-D588 Sexuality, gender, and prevention technologies (including condoms, treatment as prevention, male circumcision, pre-exposure prophylaxis) 618

Track E > **Track E - Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors**

PEE589-E623 Approaches to scale and the optimisation of service delivery 619
PEE624-E641 Methods to improve service quality, support and tailoring of services 633
PEE642 Approaches to scale and the optimisation of service delivery 641

PEE643-E649	Methods to improve service quality, support and tailoring of services	641
PEE650-E657	Prep: lessons learned from delivery	644
PEE658-E679	Testing and treatment at scale : issues and lessons	647
PEE680-E686	HIV self-testing for HIV and linkages to prevention and care	656
PEE687	Ensuring continuity of services for mobile populations	659
PEE688-E698	Approaches to viral load monitoring at scale	659
PEE699-E706	Innovations and lessons for supporting adherence	664
PEE708-E734	Adolescent and youth programming	667
PEE735-E737	Delivering in services in and around conflict settings	678
PEE738-E739	HIV service delivery in conflict affected and humanitarian settings	679
PEE740-E742	Adapting HIV programmes to systems with severe resource constraints	680
PEE743-E745	Key populations in humanitarian settings and fragile contexts	681
PEE746	Integrating HIV and other health programming in migrant or refugee settings	682
PEE747-E769	Delivering differentiated care	682
PEE770-E779	Strategies to Increase Uptake of retention in HIV Services	691

Thursday Oral Abstract Sessions

THAA01	Building the wall: On a mission to block transmission	696
THAB01	Non-communicable diseases: Continued challenges	698
THAB02	HIV and the liver	701
THAB03	Pregnancy: Pre, peri, and post	703
THAC01	New tools, old tricks: Innovative methods for understanding the epidemic	706
THAC02	Testing for 2030: Novel strategies for the home stretch	708
THAC03	Better care: Enhancing mother and child outcomes	710
THAC04	Pedal to the metal: Accelerating the cascade	712
THAC05	I want your sex: Sexual health in the PrEP era	714
THAD01	Creating danger: Impact of end-demand laws and policing of sex work	717
THAD02	Dignity has no nationality: HIV and migrants' rights	719
THAD03	Community system strengthening = Sustainable HIV response	720
THAE01	Confronting violence against women	722

Thursday Oral Poster Discussions

THPDA01	Restoring immunity and ageing gracefully	725
THPDB01	Antiretroviral drug resistance	727
THPDC01	From online to door-2-door: expanding access to HIV self-testing	729
THPDD01	Knowing and resolving stigma	732
THPDD02	Falling off the HIV cascade: Autonomy as a determinant of ART retention among sex workers	734
THPDE01	#NextGeneration: Programming for adolescents	736
THPDE02	Meeting the challenge: Community financing for a sustained response	739

Thursday Poster Exhibition

Track A > Track A - Basic and Translational Research

PEA001-A004	Eliminating/Silencing latency	742
PEA005-A006	Immunotherapy	743
PEA007	Vaccines	744
PEA008-A009	Genetherapy	744
PEA010	HIV controllers (including post-treatment controllers) and long term non-progressors	745
PEA011-A012	Founder viruses/transmission bottleneck	746
PEA013-A015	Preclinical drug development, including prophylactic drug and microbicide development	746
PEA016	Immunotherapy (including broadly neutralizing antibodies)	747
PEA017	Adjuvants	748
PEA018	Novel vectors and strategies	748
PEA019-A022	Antibodies	748
PEA023	Correlates of immune protection	750
PEA024	Co-infection: TB and other mycobacteria	750
PEA025	Co-infection: Viral hepatitis	750
PEA026-A028	Novel assays of immune responses	751
PEA029-A032	Novel approaches to assess viral load and ARV resistance/tropism	752
PEA033	In-vitro activity	754
PEA034	Tissue penetration	754

Track B > Track B - Clinical Research

PEB035	ART in acute infection	754
PEB036-B043	ART in first- and second-line therapies	755
PEB044-B046	ART in highly treatment-experienced persons	759
PEB047-B058	Regimen simplification and switch studies	760
PEB059-B062	Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring	766
PEB063-B064	Drug interactions	768
PEB065-B078	Antiretroviral drug resistance	769
PEB079-B092	Adherence	774
PEB093-B094	Ethical issues in clinical trials and treatment strategies	780
PEB095	Immune-based therapy trials	781
PEB096-B100	Cure interventions	782
PEB101	Nutrition	784
PEB102-B110	Diagnosis of HIV disease in paediatric and adolescent populations	784
PEB111	Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring in paediatric and adolescent populations	789
PEB112-B113	Drug formulations for infants and children	789
PEB114-B118	Clinical trials in paediatric and adolescent populations	790
PEB119-B122	ARV management strategies in paediatric and adolescent populations	793
PEB123-B124	Cure strategies in paediatric and adolescent populations	795
PEB125-B133	Adherence in paediatric and adolescent populations	796
PEB134-B139	HIV complications and comorbidities in paediatric and adolescent populations	799
PEB140-B141	HIV-associated co-infections and malignancies in paediatric and adolescent populations	802
PEB142-B144	Behavioural health outcomes in paediatric and adolescent populations	803
PEB145-B154	Mental health and neuro-cognition in paediatric and adolescent populations	804
PEB155-B158	HIV-exposed uninfected children	809
PEB159-B163	Transition of adolescents into adult care	811

Track C > Track C - Epidemiology and Prevention Research

PEC164-C193	Surveillance in key population groups	813
PEC194-C196	Determining the incidence of HIV	825
PEC197-C200	Novel methods/algorithms for detecting acute and recent HIV infections	826
PEC201	Monitoring acute HIV infections	828
PEC202-C204	Novel studies to measure HIV incidence	829
PEC205-C214	Measuring the epidemic through population-based surveys, including the undiagnosed fraction	830
PEC215-C225	Measuring the population impact of prevention and treatment interventions	834
PEC226-C230	Measuring the population-level impact of policy-level HIV interventions	840
PEC231-C243	Monitoring and evaluation of health systems along the HIV cascade	842
PEC244	Estimating the need for ART and other clinical services	848
PEC245-C255	Expanding the HIV care cascade	848
PEC256-C259	Surveillance of drug resistance	853
PEC260-C263	Describing the spread of HIV through geographical information systems	854
PEC264-C274	Optimizing vertical transmission prevention programs	856
PEC275-C299	Combination prevention strategies	861
PEC300-C314	Innovative behavioural interventions	872
PEC315-C317	Structural interventions	877
PEC318-C343	Measuring and enhancing retention and adherence in HIV prevention programs	879
PEC344-C362	Key population-led prevention programs (from reach, recruit, test, treat, prevent, and retain)	890
PEC363-C366	Public-private partnerships	897

Track D > Track D - Social and Political Research, Law, Policy, and Human Rights

PED367-D389	Awareness, information, and risk perception regarding HIV transmission and prevention	898
PED390-D402	HIV services in healthcare settings	907
PED403-D414	HIV services in community settings	912
PED415	Sero-adaptive behaviours: preference, practice, and impact	916
PED416-D419	Voluntary medical male circumcision	916
PED420-D431	Antiretroviral therapy, including treatment as prevention	918
PED432-D448	Pre-exposure prophylaxis	923
PED449	Risk compensation: conceptualisation, assessment, and mitigation	930
PED450-D451	Combination HIV prevention	930
PED452-D458	School-based sexual education, life skills and gender equality education	931
PED459-D491	Community-based approaches, including empowerment, outreach, and service delivery	934
PED492-D497	Social, political, and legal advocacy	946
PED498-D508	Community mobilization and demand creation	949
PED509-D515	Couples- or family-centred approaches	952
PED516-D521	Prevention of vertical transmission	956
PED522-D523	Financial incentives, micro-finance, and other economic approaches	958
PED524-D525	Safe housing, social protection and other care and support for people affected by HIV	959
PED526-D527	Development and poverty alleviation	960
PED528-D536	Interventions to reduce stigma and discrimination	960
PED537-D539	Harm reduction	964
PED540-D542	Traditional and complementary health care approaches	965
PED543-D552	Access to appropriate healthcare services, including for co-infections and co-morbidities	966
PED553-D570	Policies regarding HIV services and programmes	970
PED571	Policies addressing social and economic determinants of vulnerability	977
PED572-D574	Policies addressing HIV in the workplace and/or educational institutions	977
PED575-D581	Policies related to treatment access, including intellectual property policy	978
PED582-D586	Policy analysis and indicators of policy effectiveness	981
PED587-D604	Monitoring and evaluation of policies and their impact on people living with HIV and key populations	983
PED605-D626	Interventions to increase demand, uptake, and retention of key populations for HIV services and programmes	990
PED627-D633	Funding for HIV programmes and services	998
PED634-D637	Integration of HIV and sexual and reproductive health services	1001

Track E > Track E - Implementation Research, Economics, Systems and Synergies with other Health and Development Sectors

PEE638-E647	Assessments of cost-effectiveness : provider and community perspectives	1002
PEE648-E657	Economics of affordability	1006
PEE658-E664	Supporting effective linkages between Maternal and HIV services	1010
PEE665	Approaches to effective HIV/SRH integration	1013
PEE666-E674	Approaches to effective HIV/TB service delivery	1014
PEE675-E677	Supporting resilient health systems	1017
PEE678-E689	Making health systems work for adolescents	1018
PEE690-E707	Community participation in systems for health	1024
PEE709-E721	Delivering paediatric HIV services	1030
PEE722-E732	Approaches to minimising loss in the prevention/treatment cascade	1036
PEE733-E742	Getting policies into practice	1040
PEE743-E762	Systems serving underserved populations	1044
PEE763-E767	Evidence on making task shifting work	1053
PEE768-E774	Systems to deliver effective, long term chronic care	1055
PEE775-E778	Integrating mental health and wellness in HIV programming	1058
PEE779-E789	Partnerships involving donors, NGOs, and government	1060
PEE790-E800	Public-private partnerships	1063
PEE801-E805	Partnerships across HIV and other vertical programmes, e.g., tuberculosis, sexually transmitted infections, drug treatment, family planning	1068

Background: The development of soluble native-like HIV-1 envelope trimers (SOSIP trimers) has enabled the induction of neutralizing antibodies against neutralization-resistant (Tier-2) primary HIV-1 strains in several animal models. However, these neutralizing antibody responses are relatively weak, short-lived, and narrow in specificity. Displaying antigens in a multivalent fashion on nanoparticles or virus-like particles is a well-established strategy to increase their immunogenicity. Here, we present the design and characterization of two-component protein nanoparticles displaying twenty SOSIP trimers.

Methods: Using computational protein structure prediction the trimeric component of a two-component self-assembling protein nanoparticle (I53-50NP) was redesigned to allow SOSIP trimer fusion. The resulting fusion proteins (SOSIP-I53-50A) were expressed in 293F cells and affinity purified with the trimer-specific antibody PGT145 to obtain native-like trimers. To obtain SOSIP-presenting I53-50NPs, fusion proteins where mixed in vitro with the other component of the two-component nanoparticle, I53-50B.

Results: The nanoparticles self-assemble with high efficiency into stable, monodisperse and well-ordered icosahedral particles as observed by, size-exclusion chromatography, negative-stain electron microscopy, cryo-EM and dynamic light scattering. The protruding SOSIP trimers maintain their antigenic integrity as observed by surface plasmon resonance and, in contrast to their soluble counterparts, induce strong activation of cognate B cells in vitro. Rabbits immunized with these nanoparticles induced significantly higher levels of neutralizing antibodies than the corresponding soluble SOSIP trimers (~50-fold higher median titer after one immunization) or SOSIP trimers presented on other nanoparticle platforms.

Conclusions: The design of the SOSIP-I53-50NP allows for selection of native-like trimers prior to nanoparticle assembly. This may provide a considerable advantage over particles that are assembled intracellularly (i.e. ferritin particles and VLPs) which may naturally present a significant population of non-native trimers. Two-component I53-50 self-assembling nanoparticles represent a versatile platform for vaccine strategies aimed at increasing and broadening neutralizing antibody responses against viral envelope proteins.

TUAA0102

A CD4-mimetic compound enhances vaccine efficacy against stringent immunodeficiency virus challenge

Background: Preventing sexual transmission of human immunodeficiency virus (HIV-1) is a global priority. HIV-1 envelope glycoproteins (Env) mediate virus entry through a series of conformational changes triggered by binding to the receptors, CD4 and CCR5/CXCR4. Broadly neutralizing antibodies that recognize conserved elements of the closed Env are potentially protective, but are elicited inefficiently during natural HIV-1 infection or by vaccination. Small-molecule CD4-mimetic compounds (CD4-mc) engage the CD4-binding pocket on the gp120 exterior Env, directly inactivate HIV-1, and induce Env epitopes that are highly sensitive to neutralization by vaccine-induced antibodies.

Methods: For cell culture studies, viruses containing primary HIV-1 Envs were incubated with the different concentrations of BNM-III-170, a CD4-mc. Virus neutralization by various antibodies or sera was tested in the presence or the absence of CD4-mc. Three groups of monkeys were used in the present study. The monkeys were boosted with human serum albumin (HSA) (Group 1) or HIV-1_{CH505} gp120 (Groups 2 and 3) either two weeks (Challenges 1 and 2) or four weeks (Challenge 3) before the SHIV-C5 challenge. Group 1 and 3 were also treated with 300 uM CD4-mc.

Results: Small-molecule CD4-mimetic compounds (CD4mc) bind the HIV-1 gp120 Env and promote conformational changes similar to those induced by CD4, exposing conserved Env elements to antibodies. Our results show that a CD4mc synergizes with antibodies elicited by monomeric HIV-1 gp120 to protect monkeys from multiple high-dose intrarectal challenges with a heterologous simian-human immunodeficiency virus (SHIV). The protective immune response persists for at least six months after vaccination.

Conclusions: CD4-mimetic compounds directly interrupt HIV-1 infection and dramatically enhance the neutralizing activity of antibodies that can be elicited in monkeys with currently available Env immunogens. CD4mc should increase the protective efficacy of any HIV-1 Env vaccine that elicits antibodies against CD4-induced conformations of Env. Based on these results, macaque-sized intravaginal rings for sustained-release topical delivery of CD4-mc are being developed and evaluated in vitro in preparation for pharmacokinetics and efficacy studies in a macaque model. Used as microbicides, CD4-mimetic compounds might increase the protective efficacy of HIV-1 vaccines. Our results set the stage for clinical studies in humans at risk of sexually acquired HIV-1 infection.

Background: In the immediate hours and days post mucosal transmission, HIV-1 is considered to be at a vulnerable state due to localized replication and low or unestablished viral reservoirs. Thus, HIV vaccines should induce a strong and long-lasting mucosal immune response and mucosal vaccination would be an ideal route to achieve this. Here we evaluate the immunogenicity and efficacy of oral vaccination and compare it with systemic vaccinations in rhesus macaques (RM).
Methods: For oral vaccination, we immunized a group of RM (n=5) via sublingual and buccal tissue (SL/B) routes using a modified needle-free injector. Animals were immunized twice with modified vaccinia Ankara (MVA) expressing HIV-1 Gag, Pol and envelope antigens, followed by two immunizations with a recombinant trimeric gp120 immunogen along with the mucosal adjuvant dmLT. A second group (n=6) received the immunizations via the conventional intradermal (MVA) and subcutaneous (protein) routes (ID/SC). All animals were challenged intrarectally at around 5 months after the final immunization with a pathogenic SHIV162P3 for a maximum of 6 challenges.
Results: Systemic immunization (ID/SC) induced strong IgG responses in serum and mucosal secretions (rectal, vaginal, and salivary secretions) but failed to induced IgA responses. Impressively, needle-free oral immunization generated a robust HIV Env-specific IgG and IgA antibody response both in blood and mucosal compartments that are at least 10-fold higher compared to responses in ID/SC immunized animals. The vaccine induced IgG responses showed a strong cross-reactivity to a global panel of gp70-V1V2 scaffolds. Following intrarectal challenge, all 5 controls became infected by 3 challenges and we observed a significant delay in acquisition of infection in both vaccinated groups (p= 0.02 for oral, p= 0.007 for ID/SC and p= 0.002 for combined) compared to unvaccinated controls. Two of the six ID/SC animals remained uninfected at the end of 6 challenges.
Conclusions: Our results show that needle-free injection of the sublingual and buccal tissues acts as an effective and practical route to generate both systemic and mucosal antibodies via vaccination. They also show that MVA prime followed by a gp120 trimer boost can provide a significant protection against intrarectal SHIV challenges.

TUAA0104

Long-term data from APPROACH: Phase 1/2a randomized, double-blind, placebo-controlled study evaluating safety/tolerability and immunogenicity of vaccine regimens using combinations of Ad26.Mos.HIV, MVA-mosaic and gp140 envelope protein

F. Tomaka[1], D. Stieh[2], D. Barouch[3], M. Robb[4,5], N. Michael[4], G. Tomaras[6], G. Alter[7], J. McElrath[8], L. Lavreys[9], S. Nijs[9], K. Callewaert[2], J. Hendriks[2], Z. Euler[2], M. Pau[2], H. Schuitemaker[2]

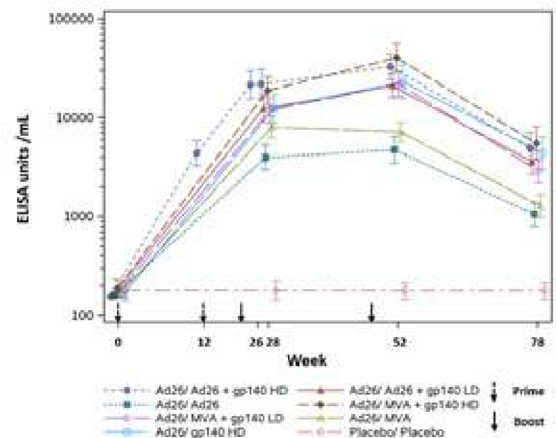
Background: Globally, 1.8 million new HIV infections in 2016 demonstrate the need for a prophylactic HIV vaccine, but none currently exist. APPROACH (NCT02315703) investigates various vaccine regimens (comprising viral vectors with global mosaic HIV-1 Env, Gag and Pol transgenes and a soluble clade C gp140 trimeric envelope protein), that aim to elicit protective immunity against multiple clades of HIV-1. Week 28 and 52 data showed Ad26.Mos.HIV double prime, and Ad26.Mos.HIV or MVA-Mosaic boost regimens combined with gp140 Env protein were immunogenic and well tolerated. We here present data on durability of immune responses.
Methods: Healthy, uninfected participants were randomized into seven vaccine regimens, or a placebo and administered Ad26.Mos.HIV double prime (Weeks 0 and 12) and a double boost of either Ad26.Mos.HIV or MVA-Mosaic, with high- or low-dose aluminium-phosphate adjuvanted gp140 Env protein (Weeks 24 and 48). Vaccine responders were participants exhibiting an immunological response >LLOQ (if baseline is <LLOQ/missing) or 3-fold increase from baseline (if ≥LLOQ). Week 78 and 96 endpoints were immunogenicity and safety/tolerability.



[ELISA - Total IgG gp140 Env Clade C]

Results: 393 participants from the US, East-Africa, South Africa and Thailand were randomised and received ≥1 dose of study vaccine (n=48-50/group; see figure for regimens). Median age 29 years; 54% male; 54% Black, 27% White and 16% Asian.
Participants in all vaccine regimens showed humoral response rates >92% at Week 78 (30 weeks after fourth dose). Rates of antibody decay after the fourth vaccination exhibited regimen-independent decrease in magnitude. Groups boosted with Ad26.Mos.HIV+gp140 Env (high- or low-dose) maintained 100% response rate (high-dose [n=44]; 95% CI=91.96%-100%; low-dose [n=39]; 95% CI=90.97%-100%).
Bridging with a parallel non-human primate (NHP) challenge study showed for Ad26.Mos.HIV+gp140 Env high-dose boost group, autologous ELISA responses at Week 78 were 4.3-fold higher in humans than in partially protected NHPs at time of challenge.

During the post-fourth vaccination period, safety appeared to remain favorable for all groups.

Conclusions: All participants in Ad26.Mos.HIV prime with Ad26.Mos.HIV+gp140 Env (high- and low-dose protein) groups achieved high and persistent immune responses that were maintained until Week 78 (30 weeks after fourth dose). Follow-up of participants that received Ad26+gp140 Env boosted regimens will continue (5-year).

TUAA0105

HPX1002/IPCAVD010: A randomized controlled trial evaluating the safety and immunogenicity of shorter and simpler vaccine schedules using Ad26.Mos.HIV combined with gp140 Env protein

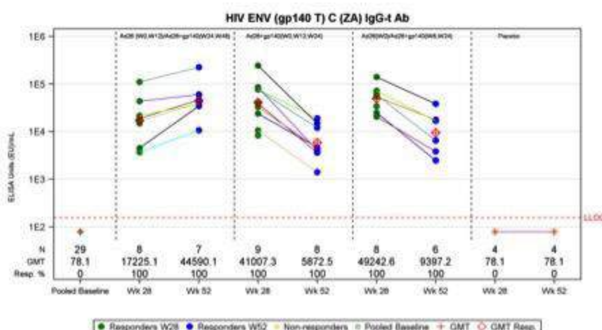
K. Stephenson[1,2], J. Ansel[1], S. Walsh[1], C.S. Tan[1], D. Ananos[1], A. Yanez[2], L. Peter[1], F. Tomaka[3], D. Stieh[3], J. Hendriks[3], S. Nijs[3], C. Truyers[3], M. Grazia Pau[3], M. Seaman[1], B. Walker[2], H. Schuitemaker[3], D. Barouch[1,2]
[1]BIDMC/Harvard, Center for Virology & Vaccine Research, Boston, United States, [2]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [3]Janssen Vaccines AG, Bern, Switzerland

Background: A large Phase 2b proof-of-concept study called "Imbokodo" was initiated in 2017 to assess the preventive vaccine efficacy of a prime/boost regimen using mosaic antigens encoded by Ad26 and gp140 Env protein in HIV-uninfected women in sub-Saharan Africa. The vaccine schedule in Imbokodo involves 4 vaccination visits over 48 weeks, a long regimen that may be a factor in limiting adherence. We explored in HPX1002/IPCAVD010 whether shorter, simpler regimens might be equally immunogenic to an Imbokodo-like regimen.

Methods: HPX1002/IPCAVD010 was a randomized, placebo-controlled, double-blind Phase 1 study in 36 HIV-uninfected adults (12 per arm) to evaluate the safety and immunogenicity of 3 different vaccine regimens with Ad26 vectors expressing mosaic Env and Gag/Pol antigens (Ad26.Mos.HIV) and aluminium-phosphate adjuvanted Clade C gp140 trimeric envelope protein (gp140 Env). Group 1 received Ad26 double prime at Weeks 0 and 12 and a double boost with Ad26+gp140 at Weeks 24 and 48. Group 2 received Ad26+gp140 at weeks 0, 12 and 24. Group 3 received Ad26 at Wk 0, and Ad26+gp140 at weeks 8 and 24. The study was conducted at Beth Israel Deaconess Medical Center in Boston, MA, USA. Data from Baseline, 28 and 52 were analyzed.

Results: All vaccine regimens appeared to be well tolerated. Pain and fatigue were the most frequently reported solicited events. The shortened regimens (Groups 2 and 3) elicited equivalent antibody titers against autologous Clade C Env at peak immunity to the Imbokodo-like regimen (41,007 and 49,243 GMT vs. 44,590 GMT, respectively), with this peak occurring earlier in the shortened regimens. Antibody responses remained elevated (>5,000 GMT) in Groups 2 and 3 at week 52. ADCP, Env-specific IgG3, tier 1A neutralizing activity and broad cellular immune responses were detected in all groups.

Conclusions: In this Phase 1 study, we demonstrate that Ad26.Mos.HIV combined with gp140 Env protein can elicit HIV-specific immune responses in shortened, 24 week vaccine schedules that appeared to be similar to responses elicited in a longer, 48 week vaccine schedule that is currently being evaluated in a clinical efficacy study. Further studies are required to test the protective efficacy of these shortened vaccine regimens.



[Antibody Titers Against Autologous Clade C Env in IPCAVD010]

TUAA02 Strategies for cure: Pitfalls, possibilities and promise

TUAA0203

Dominant HIV DNA populations present in different T-cell subsets before stem cell transplantation persist in tissues early after transplantation with CCR5Δ32 stem cells

Background: Cure of HIV infection was observed in the Berlin patient following stem cell transplantation (SCT) with homozygous CCR5Δ32 donor cells. In contrast, in the Boston patients, transplanted with cells from regular CCR5WT donors, HIV rebound occurred after treatment interruption despite loss of detectable HIV-DNA in PBMCs. It is unknown which reservoir fueled HIV rebound.

Methods: IciStem is an International collaboration to guide and investigate the potential for HIV cure in stem cell transplantation. In IciStem patient #5 SCT was performed using homozygous CCR5Δ32 cord blood combined with a third party donor. Before SCT we performed: 1) Phenotypic and genotypic coreceptor tropism analysis, 2) HIV reservoir quantification using ddPCR and viral characterization using deep-sequencing of PBMCs, $CD4^+$-T-cell subsets (Tn, Tcm, Ttm, Teff) and bonemarrow, 3) Single copy assay (SCA) on plasma. Post-SCT viral dynamics were analyzed using ddPCR and SCA. The post-mortem viral reservoir was quantified using ddPCR and characterized using deep-sequencing.

Results: Patient #5 was on effective cART for 5 years harboring subtype B CCR5-tropic HIV-1 (FPR: 68.8-96.2%). Before SCT, HIV-RNA could be detected in plasma (15 c/mL). HIV-DNA LTR copies were detected in PBMCs (1967 c/10^6), Tn cells (1270 c/10^6), all memory T-cells (Tcm, Ttm and Teff, 3074, 5564 and 6924 c/10^6) and bonemarrow (1130 c/10^6). Deep-sequencing revealed that two viral variants dominate all T-cell populations and bonemarrow (variant 1: FPR 87.2%; variant 2: 89.7%). Four weeks post-SCT, complete donor chimerism was observed in PBMC, HIV-DNA diminished to undetectable levels (< 1 c/10^6) and no HIV-RNA could be detected in plasma. Ten weeks post-SCT patient #5 deceased. Post-mortem analysis revealed presence of HIV-DNA LTR copies in ileum (549 c/10^6), liver (54 c/10^6), spleen (44 c/10^6) and lung (62 c/10^6), whereas no HIV-DNA LTR copies could be detected in PBMCs (< 7 c/10^6). HIV-sequences obtained from ileum and lung revealed the dominance of sequence variant 2 in both tissues.

Conclusions: In the neutropenic phase early post-SCT, HIV-DNA could no longer be detected in PBMCs. In contrast, dominant HIV-DNA populations as present in different T-cell subsets before SCT persisted in tissues indicating that tissue reservoirs may play an important role as long-standing viral reservoirs.

TUAA0204

Rapid rebound of a highly replication competent preexisting CXCR4-tropic HIV variant after allogeneic stem cell transplantation with CCR5Δ32 stem cells

J. Verheyen[1,2], A. Thielen[2], N. Lübke[3], M. Dirks[1], M. Widera[1], U. Dittmer[1], L. Kordales[4], M. Däumer[2], D. de Jong[5], A. Wensing[5], R. Kaiser[6], M. Nijhuis[5], S. Esser[7]
[1]*University of Duisburg-Essen, University Hospital, Institute of Virology, Essen, Germany,* [2]*Institute of Immunology and Genetics, Kaiserslautern, Germany,* [3]*Heinrich-Heine-University, University Hospital, Institute of Virology, Düsseldorf, Germany,* [4]*University Hospital, University of Duisburg-Essen, Department of Bone Marrow Transplantation, Essen, Germany,* [5]*University Medical Center Utrecht, Medical Microbiology, Utrecht, Netherlands,* [6]*University of Cologne, Institute of Virology, Cologne, Germany,* [7]*University Hospital, University of Duisburg-Essen, Clinic for Dermatology, Essen, Germany*

Background: To date, the case of the Berlin patient provides the only evidence of an intervention that has been able to cure HIV infection. The procedure involved an allogeneic stem cell transplantation (SCT) with donor cells lacking the CCR5 coreceptor (CCR5Δ32). Interestingly, in the Berlin patient no viral rebound was observed despite the fact that cART was stopped at the day of transplantation. In a similar setting in the Essen patient, cART was stopped before initiation of myeloablative therapy and a rapid viral rebound was observed after SCT. To fully understand the underlying mechanism of viral breakthrough in the Essen patient we retrospectively analyzed the genotypic and phenotypic characteristics of the viral population.
Methods: RNA was isolated from plasma and total DNA was isolated from PBMCs at different time points before (-287d: RNA, -103d: RNA/DNA, -18d: DNA) and after (+20d: RNA, +373d: RNA/DNA) SCT. HIV coreceptor tropism was genotypically assessed (geno2pheno) after deep-sequence analysis of the viral envelope (gp120-V3). The observed gp120-V3 sequences were cloned in our shuttle vector pHXB2-Δgp120-V3 and chimeric viruses were tested for replication capacity and coreceptor usage in primary cells (PBMCs).
Results: Viral breakthrough was observed three weeks after SCT. Every single viral RNA sequence detected with deep-sequence analysis at time of breakthrough was predicted to be CXCR4-tropic (FPR: 0.2%-0.7%). These sequences are genetically distinct from the pre-SCT viral variants predicted to be CCR5-tropic (FRP: 8.5%-10.5%). Interestingly, the most dominant viral variant rebounding after SCT (FPR 0.4%) could already be detected as a minority variant in the proviral DNA 103 days before transplantation. This dominant variant, once cloned in our HIV shuttle vector, demonstrated a high replication capacity in primary cells and is completely dependent on the alternative CXCR4 coreceptor for replication.
Conclusions: In this study we demonstrate that the rapid rebound after SCT was related to a highly replicative CXCR4-tropic HIV variant, which was already present prior to SCT. These data indicate that in-depth HIV coreceptor analysis is essential for future CCR5-based stem cell transplantation and gene therapy studies.

TUAA0205

Modular gene therapy vectors for gene therapy cure in resting immune cells

A. Wong[1], A. Aggarwal[1], O. Atthi[1], B. Hao[1], H. Macrae[1], M. Churchill[2], A. Kelleher[1], S. Turville[1]
[1]*University of New South Wales, Kirby Institute, Sydney, Australia,* [2]*RMIT University, School of Health and Biomedical Sciences, Melbourne, Australia*

Background: Conventional gene therapy vectors warrant extensive cellular activation of the target population (defined as resting CD4 T cells, and macrophages) to increase gene delivery outcomes. However, cellular departure from the resting state lowers stemness and therefore long-term therapeutic potential. There are two barriers to the genetic modification of target cells: particle delivery/fusogenicity, and ability to perform reverse transcription/integration. We designed a platform where vectors are customised to overcome these limitations.
Methods: To increase lentiviral vector fusion into CD4 T cells, over 1000 envelopes were surveyed, yielding a shortlist of one dozen candidate pseudotypes. These pseudotypes were previously characterised by the HIV Affinofile assay and distinguished by an ability to attain cellular entry despite low CD4 levels. For the enhancement of gene delivery, over 200 Vpx variants were surveyed, creating a shortlist of 37 candidate variants. These variants were validated by firstly determining their capacity to enhance HIV NL43 infection, before further measurement of gene delivery enhancement using lentiviral vectors.
Results: From the many prospective pseudotypes, one lead candidate was identified. This pseudotype consistently enabled cellular entry in greater than 95% of untouched resting CD4 T cells. Six lead Vpx variants were identified that enhanced gene transfer up to 20-fold and 10-fold in macrophages and T cells, respectively. Combining both approaches resulted in an excess of 95% and 45% gene delivery in macrophages and T cells, respectively, accomplished using low MOIs (0.04). Whilst a majority of Vpx variants still enhanced gene delivery for greater than two weeks, we identified variants that possessed contracted enhancement durations in T cells (< 2 weeks). This would alleviate cellular vulnerabilities to HIV upon reinfusion into hosts.
Conclusions: We have designed a lentiviral vector platform that targets resting cell types by leveraging the fusogenic potential of the lead pseudotype and enhancing potential of Vpx. We achieved gene delivery into a challenging cell type using limited inocula, and benchmarked at levels conducive to clinical applications.

Comparative effectiveness of first-line antiretroviral therapy regimens: Results from a large real-world cohort in Brazil after the implementation of Dolutegravir

M.V. Meireles[1,2], A.R. Pascom[1], F. Perini[1], F. Rick[1], A. Benzaken[1]
[1]*Ministry of Health of Brazil, Department of STI, AIDS and Viral Hepatitis, Brasilia, Brazil,* [2]*University of Brasilia, Faculty of Medicine, Brasilia, Brazil*

Background: In early 2017, the Ministry of Health of Brazil (MoH) released new antiretroviral treatment (ART) guidelines, which set Lamivudine+Tenofovir+Dolutegravir as the preferred first-line regimen for HIV treatment. In this study, we used real-world programmatic data from Brazil aiming to describe the observed effectiveness of different regimens in the initial response to ART, using the six-month viral load (VL) count.
Methods: Programmatic data from two information systems from the MoH were used; they gather data on every VL and CD4 counts performed within the country's public health system, and on every ART dispensation. Patients aged 15 and over, who started ART from January 2014 to June 2017 and had a 6-month VL (180±90 days after treatment initiation) were included. The outcome was failure to achieve initial virologic suppression (VS), defined as presenting the 6-month VL above 50 copies/mL. Univariable and multivariable analyses were performed, with unconditional logistic regression models assessing the likelihood of the outcome according to the initial ART regimen, controlling for adherence level, sex, age and CD4 and VL at treatment initiation. Adherence level was calculated using pharmacy refill data.
Results: Of the 103,240 patients included in the analysis, 67.6% were male; median values of age, baseline CD4, baseline VL and adherence were 34 years old, 394 cells/mm^3, 38,057 copies/mL and 96.2%, respectively. Overall, 76.9% achieved a VL< 50 copies/mL. The most common regimens were 3TC+TDF+EFZ (74.0%), 3TC+TDF+DTG (7.2%), 3TC+AZT+LPV/r (4.9%), 3TC+TDF+ATV/r (4.6%), 3TC+AZT+EFZ (3.5%) and 3TC+TDF+LPV/r (2.0%). VS ranged from 63.7% with 3TC+TDF+LPV/r to 85.2% with 3TC+TDF+DTG. In the multivariable analysis, with 3TC+TDF+DTG as the reference, aOR (95%CI) of failing to achieve VS were 1.42 (1.32-1.52) for 3TC+TDF+EFZ, 1.51 (1.35-1.68) for 3TC+AZT+EFZ, 2.11 (1.91-2.32) for 3TC+TDF+ATV/r, 2.41 (2.18-2.66) for 3TC+AZT+LPV/r and 2.62 (2.32-2.95) for 3TC+TDF+LPV/r.

Conclusions: The observed effectiveness of 3TC+TDF+DTG was markedly superior after controlling for possible confounders, with all other regimens showing 42%-162% higher odds of not achieving initial virologic suppression. Our results support the decision made by the MoH to switch its recommendations for preferred first-line ART from Efavirenz to Dolutegravir-containing regimens.

Baseline characteristics			Multivariable analysis	
		%	aOR	95% CI

TUAB0102

Simplification to dolutegravir monotherapy is non-inferior compared to continuation of combination antiretroviral therapy in patients who initiated combination antiretroviral therapy during primary HIV infection: A randomized, controlled, non-inferiority trial

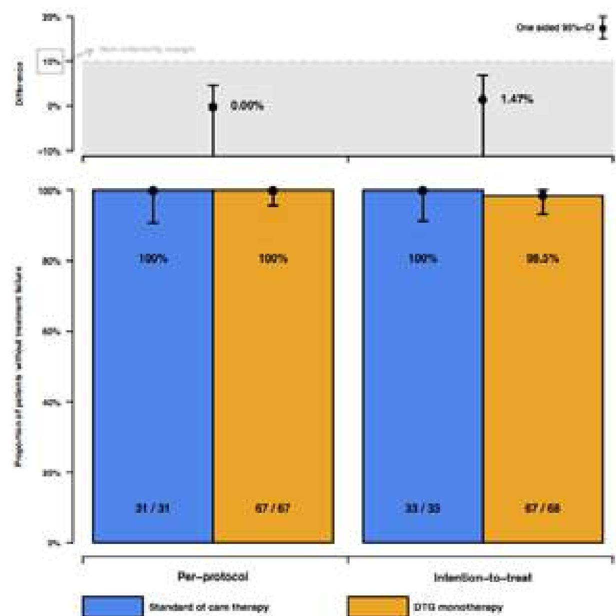
D.L. Braun[1,2], T. Turk[1], B. Hampel[1,2], C. Grube[1], P. Schreiber[1], M. Greiner[1], D. Steffens[1], F. Tschumi[1], C. Bayard de-Torronté[1], C. Depmeier[1], K. Metzner[1,2], B. Bertisch[3], J. Böni[2], R. Kouyos[1,2], H. Günthard[1,2], for the Zurich Primary HIV Infection Study
[1]University Hospital Zurich, Division of Infectious Diseases and Hospital Epidemiology, Zurich, Switzerland, [2]Institute of Medical Virology, University of Zurich, Zurich, Switzerland, [3]Checkpoint Zurich, Zurich, Switzerland

Background: Patients who started combination antiretroviral therapy (cART) during primary HIV-1 infection (PHI) show a smaller HIV-1 reservoir size compared to patients who started cART during chronic infection. Thus, we hypothesized that a smaller HIV-1 reservoir size translates in sustained virological suppression after simplification of cART to dolutegravir monotherapy.

Methods: In this randomized, open-label, non-inferiority trial, we recruited patients >18 years with documented PHI who started cART < 180 days after estimated date of infection (EDI) and were fully suppressed for > 48 weeks. Exclusion criteria were previous virological failure or treatment interruption and major resistance associated mutations (RAM) to integrase inhibitors. We randomly assigned patients 2:1 to monotherapy with dolutegravir 50 mg once daily or to continuation of cART. Primary endpoint was virological response, defined as HIV-1 RNA < 50 cp/mL plasma at week 48, in the per-protocol-population, with a non-inferiority margin of 10% (NCT02551523).

Results: Between 11/2015-3/2017, we randomly assigned 101 patients (68 to dolutegravir monotherapy, 33 to continuation of cART). At week 48 in the per-protocol-population, 67/67 (100%) had virological response in the dolutegravir monotherapy group versus 31/31 (100%) in the cART group (difference 0%, 95%-CI [-1, 0.047]), showing non-inferiority at the prespecified level (Figure1). In the intention-to-treat population, 1 patient in the dolutegravir monotherapy group experienced viral failure at week 36 (viral load 382 cp/mL) and 2 patients in the cART group left the study before week 48 because they moved abroad. The patient who experienced viral failure was found to be chronically infected at the start of first cART and therefore violated entry criteria. Resistance test at time of viral failure revealed no RAMs and he was re-suppressed on cART. Overall, 14 severe adverse events occurred (dolutegravir monotherapy 10 [15%]; cART 4 [12%]), none related to study-drugs.

Conclusions: In our randomized simplification trial, monotherapy with once daily dolutegravir was effective, safe, and non-inferior to cART in patients with a documented PHI who initiated cART < 180 days after EDI and were virologically suppressed for at least 48 weeks. Our results suggest that future simplification studies should use a stratification according to time of infection at start of first cART.



[Figure 1: HIV-1 RNA <50 copies per mL plasma at week 48 for the per-protocol and intention-to-treat populations. Error bars are 95% CI.]

TUAB0103

Dolutegravir monotherapy versus dolutegravir/abacavir/lamivudine for HIV-1-infected virologically suppressed patients: Results from the randomized non-inferiority MONCAY trial

L. Hocqueloux[1], C. Allavena[2], T. Prazuck[1], L. Bernard[3], S. Sunder[4], J.-L. Esnault[5], D. Rey[6], G. Le Moal[7], M. Roncato-Saberan[8], M. André[9], E. Billaud[2], V. Avettand-Fènoël[10], A. Valéry[11], F. Raffi[2], J.-J. Parienti[12], MONCAY Study Group
[1]CHR d'Orléans - La Source, Infectious and Tropical Diseases, Orléans, France, [2]CHU de Nantes, Infectious Diseases, Nantes, France, [3]CHU de Tours, Infectious Diseases, Tours, France, [4]CHG, Infectious Diseases, Niort, France, [5]CHD, Infectious Diseases, La Roche sur Yon, France, [6]CHU de Strasbourg, Infectious Diseases, Strasbourg, France, [7]CHU de Poitiers, Infectious Diseases, Poitiers, France, [8]CHG, Infectious Diseases, La Rochelle, France, [9]CHU de Nancy, Infectious Diseases, Nancy, France, [10]CHU Necker - Enfants Malades, APHP, Virology, Paris, France, [11]CHR d'Orléans - La Source, Biostatistics, Orléans, France, [12]CHU de Caen, Clinical Research and Biostatistics, Caen, France

Background: We investigated whether dolutegravir alone was able to maintain virological suppression in HIV-1-infected patients on a successful dolutegravir-based standardized triple-therapy.

Methods: MONCAY was a 48-week multicentric, randomized, open-label, 12% non-inferiority margin study. Inclusion criteria were: age ≥18 years, CD4 nadir >100/µl, no previous AIDS event, plasma HIV-RNA (pVL) <50 copies/ml for ≥12 months, stable regimen with once daily dolutegravir/abacavir/lamivudine (DTG/ABC/3TC) and no failure or resistance to any integrase inhibitor (INI). Patients were 1:1 randomized to continue DTG/ABC/3TC or to simplify to DTG monotherapy. The primary endpoint was the proportion of patients with pVL <50 copies/ml at week (W) 24 in intention-to-treat (ITT), missing or switch equals failure (M=F); modified ITT (mITT) excluding patients who had non-inclusion criteria; Per-protocol (PP) excluding from mITT patients with major protocol deviation. Virologic failure (VF) was defined as two consecutive pVL >50 copies/ml within 2 weeks apart.
Results: Seventy-eight patients were assigned to DTG and 80 to continue DTG/ABC/3TC. Of these 158 patients, 3 had non-inclusion criteria and 6 had major protocol deviation in the DTG arm; 2 had non-inclusion criteria and 1 had major protocol deviation in the DTG/ABC/3TC arm. By W24, 2 patients in DTG group experienced VF (both at W24) without resistance to the INI class; 1 patient stopped DTG/ABC/3TC due to adverse event (at W4). In ITT (n=158), the success rate was 73/78 (93.6%) in the DTG arm and 77/80 (96.3%) in the DTG/ABC/3TC arm; difference 3.9%, 95%CI: -5.0 to 10.8. This figure was 1.4%; 95%CI: -4.5 to 8.1 in mITT (n=153) and 1.6%; 95%CI: -4.5 to 8.8 in PP (n=146). During subsequent follow-up, 3 additional patients in the DTG arm experienced VF (2 at W36 and 1 at W48) with emerging resistance mutations to INI in 2 cases, whereas none occurred in the DTG/ABC/3TC group (difference 6.5%, 95%CI: -1.8 to 15.6). The DSMB recommended to re-intensify the DTG arm with standardized triple-therapy.
Conclusions: Although non-inferior to DTG/ABC/3TC at W24, DTG monotherapy was not a valid option to maintain virological suppression overtime in HIV-1-infected patients on a successful DTG/ABC/3TC triple-therapy and favoured emergence of INI resistance.

TUAB0104

A phase 3b, open-label, pilot study to evaluate switching to elvitegravir/cobicistat/emtricitabine/tenofovir alafenamide (E/C/F/TAF) in virologically-suppressed HIV-1 infected adult subjects harboring the NRTI resistance mutation M184V and/or M184I (GS-US-292-1824)

I. Perez Valero[1], J.M. Llibre[2], A. Lazzarin[3], G. Di Perri[4], F. Pulido[5], J.-M. Molina[6], S. Esser[7], I. McNicholl[8], R.-P. Lorgeoux[9], N. Margot[8], Y. Shao[8], D. Piontkowsky[8], M. Das[8], R. Haubrich[8]
[1]*Unidad VIH - Hospital Universitario La Paz, Madrid, Spain,* [2]*Fundación Lucha contra el SIDA, Barcelona, Spain,* [3]*Fondazione IRCCS San Raffaele del Monte Tabor, Milan, Italy,* [4]*Dipartimento di Malattie Infettive e Tropicali, Turin, Italy,* [5]*Unidad VIH, Hospital Universitario 12 de Octubre, imas12, UCM, Madrid, Spain,* [6]*Department of Infectious Diseases, Saint-Louis Hospital and University of Paris, Paris, France,* [7]*Universitätsklinikum Essen, Essen, Germany,* [8]*Gilead Sciences, Inc, Foster City, United States,* [9]*Gilead Sciences, Inc, Montreal, Canada*

Background: Treatment with once-daily E/C/F/TAF in HIV-1-infected therapy-naïve patients was shown to be effective and safe through 144 weeks in two randomized, double-blinded trials, which excluded participants whose HIV-1 harbored the M184V and/or M184I mutation.
Methods: This ongoing, prospective open-label, single arm, multicenter, 48-week trial is evaluating the efficacy and safety of switching suppressed participants to E/C/F/TAF from a stable regimen (≥6 months) of a third agent plus either F/tenofovir disoproxil fumarate or abacavir/lamivudine. Participants had a historical genotype report showing M184V and/or M184I and no evidence of previous virologic failure (VF) or resistance to boosted PIs or INSTIs.
At screening, HIV-1 RNA < 50 c/mL was required as well as absence of additional NRTI or PI resistance mutations based on sequencing of integrated HIV DNA (GenoSure Archive, Monogram Biosciences).
The primary objective is to evaluate the efficacy of switching to E/C/F/TAF in maintaining HIV-1 RNA < 50 c/mL at Week 12 using pure virologic response (PVR). Participants with discontinuation or missing values were considered responders if they never had HIV-1 RNA ≥50 c/mL at 2 consecutive visits and the last HIV-1 RNA was < 50 c/mL. This report presents the Week 24 data.
Results: Thirty-seven participants were enrolled and switched to E/C/F/TAF. Mean age was 50 years(range 22-76), 73% White, 19% Black, 22% women, median CD4 count 724 cells/µL and 100% HIV RNA < 50 c/mL at baseline. Through Week 24, all 37 participants(100%) had HIV-1 RNA < 50 c/mL based on PVR(Table). Three participants who discontinued prior to Week 24 with last recorded HIV-1 RNA < 50 c/mL were not considered VF.
Four serious adverse events occurred (none were study drug-related): 1 each of squamous cell carcinoma, acute kidney injury (with poorly controlled hypertension and diabetes), transient proteinuria (resolved on study drug) and pulmonary embolism.
Twenty-two percent (8/37) of participants experienced a study drug-related AE (grade 1 or 2); one participant discontinued due to grade 2 muscle spasms.
Conclusions: E/C/F/TAF offers an effective, well tolerated switch option for patients with pre-existing M184V and/or M184I mutations. These data on continued virologic suppression despite resistance are encouraging though longer term data are needed.

Baseline Characteristics	
Presence of M184V, M184I or both mutations, screening historic genotype	100% (37/37)
Baseline Archive DNA Mutations: M184V/I, M184V/I + NNRTI, NNRTI only, none	22%, 22%, 5%, 51%
Regimen prior to switching:	
2 NRTI + PI + ritonavir or cobicistat	54%
2 NRTI + INSTI, 2 NRTI + INSTI + NNRTI	32%, 3%
2 NRTI + NNRTI	11%
Results	
Week 24 HIV-1 RNA <50 c/mL (PVR)	100% (37/37)
Week 24 HIV-1 RNA <50 c/mL (missing=failure)	92% (34/37)
Week 24 HIV-1 RNA <50 c/mL (missing=excluded)	100% (34/34)
Virological failures or emergent resistance	0

[Table]

TUAB02 HIV and TB: Double challenge

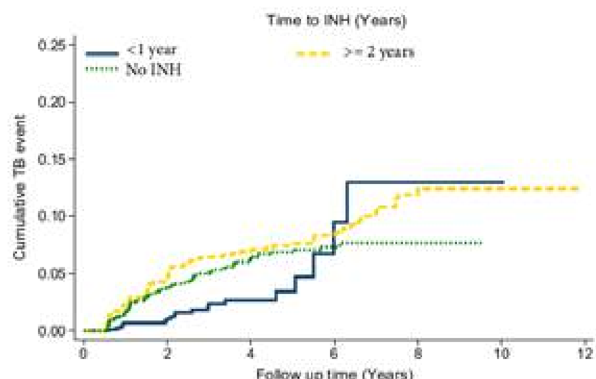
TUAB0201

Durability and effectiveness of isoniazid preventive therapy in Lesotho, southern Africa

E. Mugomeri[1], D. Olivier[2], W.M.J. van den Heever[2]
[1]*National University of Lesotho, Department of Pharmacy, Maseru, Lesotho,* [2]*Central University of Technology, Department of Health Sciences, Bloemfontein, South Africa*

Background: The southern African country of Lesotho, which has the highest tuberculosis (TB) incidences in the world, is facing a catastrophic syndemic of HIV and tuberculosis. In 2011, the government of Lesotho launched isoniazid preventive therapy (IPT) as a once-off intervention with no follow-up booster doses, to reduce the occurrence of TB in people living with HIV (PLHIV). However, the effectiveness and durability of this intervention remains obscure in this setting. This study evaluated the effectiveness of IPT and the durability of its protection in Lesotho.
Methods: The study was based on 2 955 records which met the inclusion criteria out of 4 122 HIV-positive medical records randomly sampled from eight health institutions in six districts of Lesotho. Univariate Kaplan-Meier function, Wilcoxon's log-rank test and Cox regression analyses were used to select factors into the model. Cox's proportional hazards regression analysis was performed, with data formatted as discrete-time survival data with interval date as the time variable and the occurrence of TB as the 'failure' outcome.
Results: The overall TB incidence rate was 2.0 per 100 person-years in 12 208 person-years. Thirty-nine (15.9%, *n* = 246) patients developed TB after IPT. TB incidences per 100 person-years by timing of IPT were as follows: (a) IPT before ART (1.7); (b) IPT after ART (1.8); (c) no IPT (2.6); (d) IPT within one year of ART commencement (1.3) and (e) IPT 3-5 years after ART initiation (2.3). IPT effectiveness rapidly deteriorated after four years

in patients given IPT within one year of ART commencement (Figure 1). Gender, baseline WHO clinical stage, district category and time to IPT relative to ART commencement emerged as significant predictors of TB occurrence. Increasing time to IPT by one six-month interval increased the risk of contracting TB by between 6% and 59%, depending on the cohort.



[Figure 1]

Conclusions: While IPT significantly reduces the risk of TB, delayed IPT after ART commencement significantly affects the effectiveness of this intervention. The apparent loss of protection four years after IPT indicates the need for booster doses of IPT in this population. Patient characteristics significantly associated with higher risk of TB are important for policy making.

TUAB0202

Drug susceptibility testing, HIV-coinfection and outcomes in patients treated for tuberculosis in low- and middle-income settings

Background: Drug resistance and HIV-coinfection are major challenges for the global control of tuberculosis (TB).

Methods: We collected *Mycobacterium tuberculosis (Mtb)* isolates from adult TB patients in Côte d'Ivoire, Democratic Republic of the Congo, Kenya, Nigeria, South Africa, Peru, and Thailand, stratified by HIV status and TB drug resistance. Drug susceptibility testing (DST) was performed locally (Xpert MTB/RIF, line probe assay or culture) and at the Swiss National Center for Mycobacteria (MGIT liquid culture). We categorized drug regimens into adequate treatment, under-treatment and over-treatment, based on WHO and local guidelines. We used multivariate logistic regression adjusted for age, sex, sputum microscopy, HIV status, and treatment adequacy, accounting for clustering at site-level, to examine mortality during treatment according to DST results and treatment adequacy.

Results: 634 TB patients were included; 272 (42.9%) were HIV-positive, with a median CD4 cell count at TB treatment start of 192 cells/µl (IQR 78-369 cells/µl). 175 (64.3%) of HIV-positive patients were on ART at the start of TB treatment or initiated ART within 3 months. Based on reference MGIT DST, 394 (62.2%) isolates were pan-susceptible, 45 (7.1%) mono-resistant, 163 (25.7%) multidrug-resistant (MDR-TB), and 30 (4.7%) pre-extensively or extensively drug-resistant (pre-XDR/XDR-TB). In 126 (19.9%) patients, local and reference DST results were discordant. For any drug resistance, the sensitivity of local DST was 84% (95% CI 80%-88%); specificity was 89% (95% CI 84%-92%).Treatment was inadequate (under-/over-treatment) in 25/126 (19.8%) patients with discordant DST results, and 16/508 (3.1%) with concordant DST (P< 0.001). Mortality was 13.6% (24/176) if DST results were concordant, but 26.6% (17/64) if DST results were discordant (P=0.019). The corresponding risk ratio was 1.95 (95% CI 1.12-3.38), and the population attributable fraction 20.2%. In multivariate logistic regression, mortality was determined by TB drug resistance and adequacy of treatment, but not by HIV status, gender or sputum positivity.

	No. of patients (n=542)	No. of deaths (%)	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Sex female	206	19 (9.2)	1	1
male	336	45 (13.4)	1.52 (0.86-2.68)	1.40 (0.75-2.59)
Age (per 1 year increase)	542	64 (11.8)	1.03 (1.01-1.05)	1.04 (1.02-1.06)
HIV status negative	326	41 (12.6)	1	1
positive	216	23 (10.7)	0.82 (0.48-1.42)	1.15 (0.50-2.67)
Treatment adequacy Pan-susceptible adequate	319	19 (6.0)	1	1
Pan-susceptible inadequate	24	4 (16.7)	2.36 (0.64-8.65)	2.75 (0.46-16.47)
Any resistance adequate	180	36 (20.0)	3.93 (2.18-7.10)	4.82 (2.40-9.64)
Any resistance inadequate	19	5 (26.3)	7.26 (2.28-21.23)	7.40 (2.57-21.33)

[Factors associated with mortality during treatment in patients diagnosed with tuberculosis complete case analysis.]

Conclusions: Inaccurate DST testing leading to inappropriate treatment, but not HIV infection, contributed to mortality during treatment of drug-resistant TB. Increasing capacity for DST and adequate drug-resistant TB treatment is a priority in low- and middle-income countries with high TB burden.

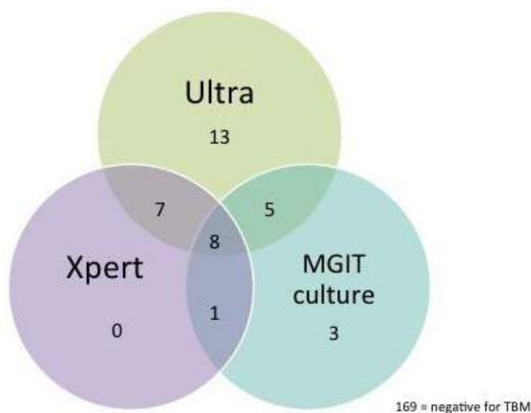
TUAB0203

Xpert MTB/Rif Ultra for earlier diagnosis of TB meningitis in HIV-positive adults

F. Cresswell[1,2], N. Bahr[3], A. Bangdiwala[4], A. Akampuria[5], K. Ssemambulidde[5], J. Rhein[4,5], D. Williams[4,5], R. Kwizera[6], E. Nuwagira[7], P. Orikiriza[7], C. Muzoora[7], D. Meya[1,6], D. Boulware[4], A. Elliott[8]
[1]Infectious Diseases Institute, Clinical Research, Kampala, Uganda, [2]London School of Hygiene and Tropical Medicine, Infectious and Tropical Diseases, London, United Kingdom, [3]University of Kansas, Kansas City, United States, [4]University of Minnesota, Minneapolis, United States, [5]Infectious Diseases Institute, Kampala, Uganda, [6]Makerere University, Kampala, Uganda, [7]Mbarara University of Science and Techology, Mbarara, Uganda, [8]London School of Hygeine and Tropical Medicine, London, United Kingdom

Background: TB meningitis (TBM) mortality is 40-60% in HIV-positive individuals, in part due to diagnostic delay. Earlier diagnosis and initiation of treatment are needed to improve outcomes. The re-engineered Xpert Ultra (Ultra) has an eight-fold lower limit of detection than Xpert (Xpert) and requires evaluation in clinical settings.

Methods: We obtained samples of cerebrospinal fluid (CSF) from HIV-positive adults presenting with suspected meningitis to Mbarara (since Feb 2015) and Mulago Hospitals (since Dec 2016), in Uganda. CSF was tested for cryptococcal antigen, then if negative, centrifuged and tested with Xpert, Ultra and culture. The performance of Ultra was measured against:
1) Composite reference standard of any positive CSF test
2) Uniform case definition of 'probable' or 'definite' TBM.
Results: CSF was collected from 406 patients. After exclusion of cryptococcal meningitis (57%, 231/406), CSF from 206 patients was tested for TBM, of which 37 (18.0%) patients had microbiologically confirmed TBM (33 Ultra, 16 Xpert and 17 culture positive, **Fig 1**). 47 met the criteria for 'probable' or 'definite' TBM by the uniform case definition.
Against composite reference standard the sensitivity of Ultra was 89% (33/37), versus 43% (16/37) for Xpert and 46% (17/37) for culture. Against uniform case definition sensitivity of Ultra was 70% (33/47), versus 34% (16/47) for Xpert and 36% (17/47) for culture.
Specificity of Ultra was 100% and negative predictive value was 98% [95%CI 94-99%] against the composite reference standard and was 91% against then uniform case definition.
13 were positive only by Ultra, of which we tested 10/13 samples with a multiplex meningoencephalitis PCR assay and did not identify other potential aetiology. In these HIV-positive adults with meningitis we believe these are true positive results. 4 patients were negative by Ultra but positive on culture.
Conclusions: Ultra detected significantly more cases than either Xpert or culture in this HIV-positive population. A diagnostic test with ~90% sensitivity and a 90 minute turnaround time holds the potential to improve early diagnosis. Whilst 98% NPV in microbiologically proven TBM is an vast improvement, the NPV of 91% against uniform case definition means that Ultra cannot be used as a stand-alone rule-out test for TBM.



[Venn diagram illustrating the method of diagnosis of the 36 microbiologically confirmed cases of TBM in HIV-positive Ugandan adults]

TUAB0204

Risk factors of recurrent TB disease in a setting of high HIV prevalence

S. Hermans[1,2], N. Zinyakatira[3,4], J. Caldwell[5], F. Cobelens[1,6], A. Boulle[3,4], R. Wood[2,7]
[1]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, [2]Desmond Tutu HIV Centre, Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Cape Town, South Africa, [3]School of Public Health and Family Medicine, University of Cape Town, Cape Town, South Africa, [4]Western Cape Government Health, Cape Town, South Africa, [5]City Health, Department of Health, Cape Town, South Africa, [6]KNCV Tuberculosis Foundation, The Hague, Netherlands, [7]Department of Medicine, University of Cape Town, Cape Town, South Africa

Background: The incidence of retreatment tuberculosis (TB) disease in high-prevalence settings such as Cape Town is very high. We previously showed that risk of recurrence increases with every subsequent episode. It is unclear what mechanisms underlie this increasing risk over time. We evaluated the risk factors of recurrent TB disease after previous TB treatment completion by subsequent episode.
Methods: All recorded TB episodes from January 2003 to April 2016 in the City of Cape Town were included, and linked to individuals by deterministic linkage of personal identifiers. Among a cohort of individuals whose first episode was notified in Cape Town we calculated recurrence rates after previous treatment completion which were adjusted to population HIV- and non-HIV associated mortality rates sourced from the THEMBISA HIV model of the Western Cape. We used multivariable Cox proportional hazards regression to estimate risk factors of recurrent TB disease per subsequent episode.
Results: A total of 245,533 individuals experienced 21,297 episodes of recurrent disease. The rate of recurrent TB after previous treatment completion was 14.5 (95% CI 14.2-14.7) per 1000 person-years of follow-up and increased per subsequent episode: the HIV-negative rate increased 7-fold from episode 2 to episode 5 (from 11.3 (95% CI 11.0-11.7)/1000 to 84.1 (95% CI 62.4-113.5)/1000 respectively), and the HIV-positive rate increased 6-fold (from 22.1 (95% CI 21.6-22.6)/1000 to 123.7 (95% CI 99.5-153.8)/1000). HIV infection was the strongest risk factor for recurrence, reducing per subsequent episode (Table 1). Other factors identified were male gender and older age. Antiretroviral treatment (ART) use was associated with a reduced rate of recurrence for a second episode but not for subsequent episodes. CD4 count was not associated with recurrence.
Conclusions: We identified very high TB recurrence rates after successful previous treatment in Cape Town, especially after multiple episodes. As expected, HIV was the strongest risk factor and ART had a protective effect. However, the importance of HIV as a risk factor declined over subsequent episodes, suggesting additional mechanisms underlying the escalating rate of TB recurrence. Further investigation into increased risks of reinfection or progression to disease through clinical, microbiological, immunological and socio-economic factors is warranted.

Episode		2	3	4	5
Gender	Female	1	1	1	1
	Male	1.35 (1.30-1.40)	1.15 (1.06-1.26)	0.99 (0.83-1.20)	0.66 (0.45-0.98)
Age	Per 10 years´ increase	1.02 (1.01-1.04)	1.04 (1.00-1.07)	0.97 (0.89-1.05)	1.15 (0.95-1.39)
HIV status	Negative	1	1	1	1
	Positive	1.89 (1.82-1.96)	1.44 (1.31-1.57)	1.26 (1.04-1.52)	1.37 (0.92-2.04)
CD4 count	<200/ul	1	1	1	1
	>=200/ul	1.03 (0.95-1.12)	1.00 (0.85-1.18)	0.90 (0.65-1.25)	1.18 (0.60-2.31)
ART use at previous episode	No	1	1	1	1
	Yes	0.84 (0.74-0.95)	1.10 (0.85-1.18)	1.46 (1.04-2.04)	1.47 (0.74-2.90)

*[Adjusted hazard ratios (95% confidence intervals) per subsequent episode of TB recurrence. *Among HIV-positives only (adjusted for age and gender)]*

TUAB0205

Clinical outcomes with bedaquiline use when substituted for second-line injectable agents in multidrug resistant tuberculosis: A retrospective cohort study

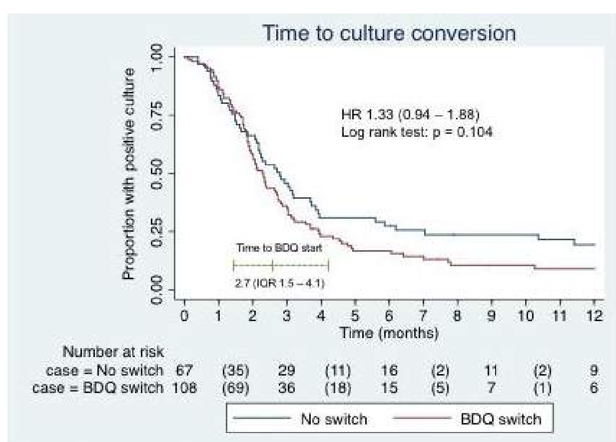
Y. Zhao[1], K. Manning[1], A. Stewart[2], T. Fox[1], N. Tiffin[3], A. Boulle[3], V. Mudaly[4], Y. Kock[4], G. Meintjes[5], S. Wasserman[5]
[1]University of Cape Town, Department of Medicine, Cape Town, South Africa, [2]University of Cape Town, Clinical Research Centre, Cape Town, South Africa, [3]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, [4]Provincial Government of the Western Cape, Department of Health, Cape Town, South Africa, [5]University of Cape Town, Wellcome Centre for Infectious Diseases Research in Africa, Department of Medicine, Cape Town, South Africa

Background: Second-line injectable drugs (SLIs), core agents in the treatment of multidrug resistant tuberculosis (MDR-TB), are associated with substantial toxicity and treatment discontinuations. Bedaquiline is being widely used as a substitute in MDR-TB regimens for patients unable to tolerate SLIs, but the efficacy and safety of this strategy is unknown.

Methods: We conducted a retrospective cohort study to evaluate outcomes at 12-months for MDR-TB patients who substituted bedaquiline for SLIs. We included consecutive adult MDR-TB patients who had bedaquiline substitutions in the Western Cape Province of South Africa between May 2015 and May 2016, as well as MDR-TB controls who did not receive bedaquiline, matched for location and time of treatment initiation. Data were extracted from the electronic TB register. The composite primary outcome measure was the proportion of patients with death, loss to follow up, or failure to achieve sustained culture conversion at 12 months of treatment.

	Bedaquiline (n = 162)	Control (n = 168)
Age, years	42 (35-49)	35 (28-42)
Male sex	93 (57.4)	97 (58.1)
Weight, kg	54 (45.3-61.6)	No data
HIV positive	110 (67.9)	94 (74.0)
CD4 count, cells/mm3	92.5 (46-185)	222.5 (54-375)
HIV viral load lower than detectable limit	46 (63.0)	50 (72.5)
Previous TB (any)	88 (63.3)	95 (56.6)
Extra-pulmonary TB	18 (11.4)	13 (7.8)
Sputum smear positivity	98 (60.5)	112 (66.7)

[Table 1. Baseline Demographic and Clinical Characteristics]



[Figure 1. Time to sputum culture conversion]

Results: Data from 330 patients with laboratory-confirmed pulmonary MDR-TB were analyzed; 162 with bedaquiline substitution and 168 controls. Baseline characteristics were similar between the groups, except for CD4 cell count which was lower in the bedaquiline group (Table 1). SLIs were stopped at a median of 54 days (interquartile range, IQR 25 - 82), with a 44 day (IQR 29 - 71) delay to starting bedaquiline. The primary outcome, ascertained in 200 individuals, occurred in 63 (55.3%) patients in the bedaquiline group versus 54 (62.8%) patients in the control group (odds ratio, 0.73; 95% confidence interval [CI], 0.41 to 1.23; P = 0.285). Rates of sustained culture conversion (48.6% vs. 47.8%), loss to follow up (10.5% vs. 12.5%), and death (6.8% vs. 6.6%) at 12 months were similar between the groups. There was a trend towards earlier sputum culture conversion in the bedaquiline group (hazard ratio, 1.33; 95% CI, 0.94 to 1.88; P = 0.104; Figure 1).

Conclusions: Substituting bedaquiline for SLIs in the treatment of MDR-TB does not result in inferior outcomes at 12 months compared with patients who remain on SLIs, supporting the use of this strategy in MDR-TB therapy. The substantial delay between interrupting SLIs and initiating bedaquiline needs to be addressed.

TUAB0206

Safety and efficacy of dolutegravir-based ART in TB/HIV co-infected adults at week 48

K. Dooley[1], R. Kaplan[2], T. Mwelase[3], B. Grinsztejn[4], E. Ticona[5], M. Lacerda[6], O. Sued[7], E. Belonosova[8], M. Ait-Khaled[9], K. Angelis[10], D. Brown[11], R. Singh[12], C. Talarico[13], A. Tenorio[13], M. Keegan[9], M. Aboud[9]
[1]Johns Hopkins University School of Medicine, Baltimore, United States, [2]Desmond Tutu HIV Foundation, Cape Town, South Africa, [3]Clinical HIV Research Unit, Johannesburg, South Africa, [4]4Instituto de Pesquisa Clinica Evandro Chagas FIOCRUZ, Rio de Janeiro, Brazil, [5]Hospital Dos de Mayo, Lima, Peru, [6]Fiocruz/Tropical Medicine Foundation Dr Heitor, Manaus, Brazil, [7]Fundación Huésped, Buenos Aires, Argentina, [8]Regional Center For Prevention and Treatment of AIDS and Infectious Diseases, Moscow, Russian Federation, [9]ViiV Healthcare, Brentford, United Kingdom, [10]GlaxoSmithKline, Stockley Park, United Kingdom, [11]ViiV Healthcare, Melbourne, Australia, [12]GlaxoSmithKline, Upper Merion, United States, [13]ViiV Healthcare, Research Triangle Park, United States

Background: Concurrent treatment of tuberculosis (TB) and HIV is challenging owing to drug interactions, overlapping toxicities, and immune reconstitution inflammatory syndrome (IRIS). The efficacy and safety of dolutegravir (DTG) in adults with HIV/TB co-infection was assessed.

Methods: INSPIRING (NCT02178592) is a Phase 3b, non-comparative, active control, randomised, open-label study in HIV-1-infected ART-naïve adults (CD4+ ³50 cells/µL) with drug-sensitive TB. Subjects on rifampicin-based TB treatment ≤8 weeks were randomised (3:2) to receive DTG (50mg twice daily during and 2 weeks post-TB therapy, followed by 50mg once daily) or EFV (600mg once daily), with two NRTIs for 52 weeks. The Week 48 primary endpoint was the proportion of DTG subjects with plasma HIV-1-RNA < 50c/mL (responders) using the FDA Snapshot algorithm (intent-to-treat exposed [ITT-E] population). An independent committee adjudicated IRIS episodes. The study was not powered to show a difference between arms; no formal statistical hypothesis was tested.

Results: Subjects were randomised to DTG (n=69) or EFV (n=44). Median baseline HIV-1-RNA and CD4+ counts were 5.10 $\log_{10}$c/mL and 208 cells/µL for DTG and 5.24 $\log_{10}$c/mL and 202 cells/µL for EFV. The proportions of Week 48 responders (ITT-E) were 52/69 (75%) (95%CI: 65%, 86%) for DTG and 36/44 (82%) (95%CI: 70%, 93%) for EFV. The DTG non-response rate was primarily driven by non-treatment-related discontinuations: eleven subjects (16%) for DTG and three (7%) for EFV discontinued due to non-treatment-related reasons whilst suppressed (mainly loss to follow-up). There were two protocol-defined virological failures (PDVF) and no treatment-emergent resistance-associated mutations (RAMs) for DTG and one PDVF in EFV with NRTI and NNRTI RAMs. Week 48 median CD4+ increases were 220 cells/µL (IQR: 111, 271) for DTG and 190 cells/µL (IQR: 104, 252) for EFV. Two EFV subjects discontinued due to AEs. TB-associated IRIS rates were low (DTG, n=4[6%]; EFV, n=4[9%]). No subjects discontinued due to IRIS or liver events. TB treatment success was 61/69 (88%) and 39/44 (89%) in DTG and EFV, respectively. Median DTG trough concentrations during twice daily dosing with rifampicin was like that with DTG once daily without rifampicin.

Conclusions: These results show that DTG is effective and well-tolerated in HIV/TB co-infected adults receiving rifampicin-based TB treatment.

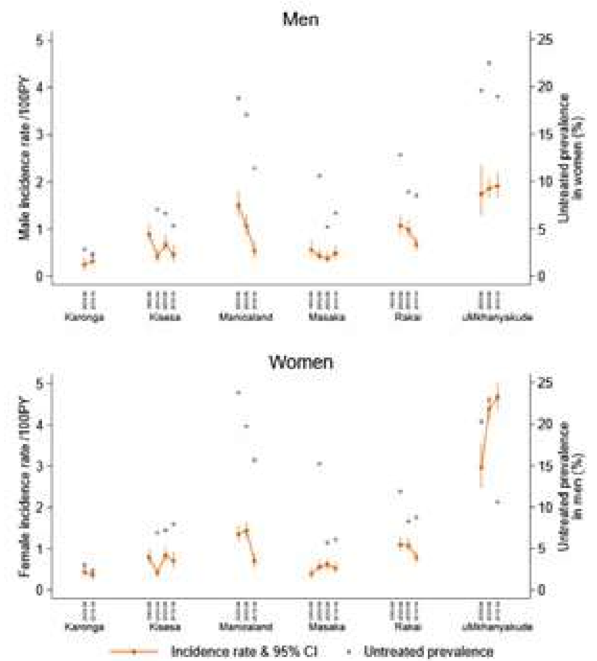
TUAC01 Forging new pathways towards HIV elimination

TUAC0101

HIV incidence trends among the general population in Eastern and Southern Africa 2000-2014

E. Slaymaker[1], J. Todd[1], M. Urassa[2], A.J. Herbst[3], N. McGrath[3,4], R. Newton[5,6], D. Nabukalu[7], A. Crampin[8,9], C. Nyamukapa[10,11], K. Tomlin[1], K. Risher[1], G. Reniers[1], M. Marston[1], B. Zaba[1]
[1]London School of Hygiene & Tropical Medicine, Population Health, London, United Kingdom, [2]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [3]Africa Health Research Institute, Durban, South Africa, [4]University of Southampton, Southampton, United Kingdom, [5]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, [6]University of York, York, Uganda, [7]Rakai Health Sciences Project, Entebbe, Uganda, [8]Malawi Epidemiology and Intervention Research Unit, Lilongwe, Malawi, [9]London School of Hygiene & Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom, [10]Imperial College, London, United Kingdom, [11]Biomedical Research and Training Institute, Harare, Zimbabwe

Background: Studies from Kenya, Malawi, Tanzania, South Africa, Uganda and Zimbabwe comprise the Network for Analysing Longitudinal, Population-based HIV/AIDS data on Africa (ALPHA). We used data from 6 studies to assess whether HIV incidence has changed over time.
Methods: Individual participants consented to research HIV tests at regular intervals, typically around 2 years apart. Person-time under observation started at the first HIV negative test recorded while resident in the study area. Participants were followed until study exit or seroconversion. Seroconversion dates were estimated using multiple imputation assuming a uniform distribution of seroconversion dates between the last negative and first positive study test result.
We estimated incidence rates and Poisson confidence intervals, by study, sex and age (15-19,20-24, 25-29,30-34,35-39 and 40-49) and calendar year between 1995 to 2014. We fitted piecewise exponential models for 2000 to 2014 to estimate age-adjusted hazard ratios for non-linear change in HIV incidence over time with random intercepts for study and individual and a random slope for change over time by study.
To acount for exposure to infection we estimated age, sex and period-specific untreated HIV prevalence among potential heterosexual partners using observed data on age-mixing between sexual partners and HIV status and treatment status among the opposite sex. We included this in the regression model as an explanatory variable.
Results: There were 1475 seroconversions among 163,613 male person-years of observation and 3302 among 218,233 female person-years. Men and women aged 15-49 experienced clear incidence rate declines in Rakai and Manicaland; elsewhere women's incidence appeared stable or rising whilst men's was stable or declining (Figure 1).
Adjusted for age, men's incidence declined between 2000-04 and 2010-14 (HR 0.78,Table 1). Adjusting for untreated opposite sex prevalence decreased the effect of calendar year.
Female incidence trends diverged so three models were fitted showing: decline in Manicaland and Rakai, increase in uMkhanyakude and stable elsewhere (Table 1). Trends over time were greater after adjusting for untreated prevalence.
Conclusions: Incidence has declined among men, but not among women in all studies, most probably due to higher treatment coverage among women reducing their infectivity to men but not vice versa.



[Crude incidence rates by site, sex and calendar year period and the estimated mean untreated prevalence among sexual partners of the opposite sex.]

Population viral load and recent HIV-1 infections: Findings from population-based HIV impact assessments (PHIAs) in Zimbabwe, Malawi, and Zambia

M. Farahani[1], E. Radin[1], S. Saito[1], K. Sachathep[1], J. Manjengwa[1], S. Balachandra[2], A. Low[1], Y. Duong[1], S. Jonnalagadda[2], H. Patel[2], D. Voetsch[2], W. Hladik[2], A. Hakim[2], N. Ahmed[1], G.N. Musuka[1], B.A. Tippett Barr[2], N. Wadonda-Kabondo[2], A.F. Auld[2], A. Jahn[2], D.B. Williams[2], D. Barradas[2], D. Payne[2], G. Bello[3], O. Mugurungi[4], B. Parekh[2], D. Hoos[1], J. Justman[1]
[1]Columbia University, ICAP, New York, United States, [2]U.S. Centers for Disease Control and Prevention (CDC), Atlanta, United States, [3]International Training and Education Center for Health (I-TECH), Lilongwe, Malawi, [4]Zimbabwe Ministry of Health and Child Care, Harare, Zimbabwe

Background: Population viral load (PVL) reflects antiretroviral therapy (ART) program effectiveness and transmission risk in a population. Using nationally representative data from household surveys conducted in

Zimbabwe, Malawi and Zambia in 2015-16, we examined the association between PVL and viral load suppression (VLS) and the probability of at least one recent HIV-1 infection in the surveys' smallest geographic sampling unit, an enumeration area (EA).

Methods: Viral load (VL) and limiting-antigen avidity enzyme immunoassay (LAg-Avidity EIA) testing were performed on all HIV-1 positive (+) samples. Recent HIV cases were defined by World Health Organization criteria (LAg-Avidity EIA < 1.5 ODn and HIV RNA > 1000 c/mL), and VLS as HIV RNA < 1000 c/mL. PVL was defined as the arithmetic mean of $\log_{10}$ HIV RNA of HIV+ individuals in the EA, and ART coverage as prevalence of self-reported current ART use. We used logistic regression adjusted for EA-level variables, e.g., HIV prevalence, population size and mean age of the female population, to estimate the probability of one recent HIV-1 infection.

Results: Among 1,510 EAs across the three surveys, a total of 58,366 adults aged 15-59 years resided in 1,374 (91%) EAs that had at least one HIV+ adult consenting to an interview and blood draw. Among the 1,374 EAs, 92.65%, 6.99% and 0.04% had 0, 1 and 2 recent HIV-1 cases, respectively. Mean VLS prevalence across these EAs was 63.5% (95% confidence intervals (CI) 62-65%).

In multivariable analysis, PVL, particularly among those unaware of their HIV+ status, was associated with a recent HIV-1 case in that EA (adjusted odds ratio [AOR]: 1.44, 95% CI 1.22-1.70, p < 0.001). VLS prevalence was inversely correlated with recent infections (AOR: 0.17, 95% CI 0.08-0.37, p < 0.001). On average, every 1% increase in VLS in an EA decreased the predicted probability of one recent infection by 8%.

Conclusions: We found a strong association between PVL and VLS prevalence with recent HIV-1 infection at the EA level in three southern African countries with generalized HIV epidemics. These results suggest expanding and maintaining high levels of VLS may be key to HIV epidemic control in these three countries.

TUAC0103

Temporal trends of population viral suppression in the context of Universal Test and Treat: Results from the ANRS 12249 TasP trial in rural South Africa

J. Larmarange[1,2], M.H. Diallo[1], N. McGrath[3,4,5], C. Iwuji[2,5,6], M. Plazy[7], R. Thiébaut[7], F. Tanser[3], T. Bärnighausen[2,8,9], J. Orne-Gliemann[7], D. Pillay[2,10], F. Dabis[7], TasP ANRS 12249 Study Group

[1]Ceped, Institut de Recherche pour le Développement (IRD), Université Paris Descartes, Inserm, Paris, France, [2]Africa Health Research Institute, Mtubatuba, South Africa, [3]Africa Health Research Institute, University of KwaZulu-Natal, School of Nursing and Public Health, Durban, South Africa, [4]Faculty of Medicine and Faculty of Social, Human and Mathematical Sciences, University of Southampton, Southampton, United Kingdom, [5]Research Department of Infection and Population Health, University College London, London, United Kingdom, [6]Department of Global Health & Infection, Brighton and Sussex Medical School, Brighton, United Kingdom, [7]Bordeaux University, School of Public Health (ISPED), Inserm, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, France, [8]Department of Global Health & Population, Harvard School of Public Health, Harvard University, Boston, United States, [9]Heidelberg University, Institute of Public Health, Faculty of Medicine, Heidelberg, Germany, [10]University College London, Division of Infection and Immunity, London, United Kingdom

Background: The universal test-and-treat strategy (UTT) aims to maximize the proportion of all people living with HIV (PLWHIV) on antiretroviral treatment (ART) and virally suppressed in a community, i.e. to reach population viral suppression (PVS). The ANRS 12249 TasP trial did not demonstrate an impact of universal ART on HIV incidence at population level (Lancet HIV 2017). Here, we investigated whether PVS improved during the course of the trial: differentially by arm, according to trial interventions or contextual changes.

Methods: The TasP cluster-randomized trial (2012-2016) implemented six-monthly repeated home-based HIV counselling and testing (RHBCT) and referral of PLWHIV to local HIV clinics in 2×11 clusters opened sequentially. ART was initiated according to national guidelines in control clusters vs. regardless of CD4 count in intervention clusters.

Test results, clinic visits, ART prescriptions, viral loads, CD4 counts, migrations and deaths were used to produce information on residency status, HIV status and HIV care status for each participant. PVS was computed daily and per cluster among all resident PLWHIV (≥16, including those not in care). We used a mixed linear model to explore the relation between PVS with calendar time, time since cluster opening, trial arm and interaction between arm and time since cluster opening, adjusting on sociodemographic changes at cluster level.

Results: 8,646 PLWHIV were observed. Between January 1st, 2013 and January 1st, 2016, PVS increased significantly in both arms (intervention: 29.0% to 46.2%, +17.2, p< 0.001; control: 32.4% to 44.6%, +12.2, p < 0.001), but difference in temporal variation (+5.0%) was not significant (p=0.175).

According to adjusted model (figure) this increase was mainly attributable to RHBCT (measured by time since cluster opening). They were also some effect due to contextual changes (measured by calendar time). The effect attributable to universal ART (interaction term) was limited.

Conclusions: Although suboptimal, the UTT strategy implemented in TasP trial improved PVS over time. As it was mainly due to RHBCT rather than universal ART, it did not induce differences between arms, explaining the null effect observed on cumulative incidence, the main trial finding. Changes in ART initiation guidelines alone are not enough to significantly increase PVS.

TUAC0104

Trends in percent time spent viremic among persons newly diagnosed with HIV, San Francisco, CA, USA, 2008 - 2016

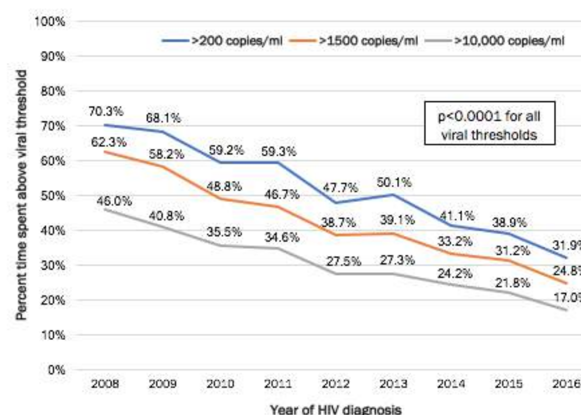
A. Hughes, L. Hsu, S. Scheer

San Francisco Department of Public Health, San Francisco, United States

Background: The risk of sexual HIV transmission increases when HIV viral load (VL) is above 1500 copies/mL. As such, persons newly diagnosed with HIV are at greater risk of transmission until they initiate ART and achieve sustained viral suppression. We sought to examine trends in time spent above three viral thresholds among persons newly diagnosed with HIV in San Francisco (SF).

Methods: We analyzed data from the HIV surveillance registry. Persons were included if they were diagnosed with HIV during 2008-2016, were SF resident at time of diagnosis, alive 12 months after HIV diagnosis and had ≥2 VL tests within 12 months after diagnosis. Consecutive VL pairs were used to calculate percent of person-time (pPT) spent above 200 copies/mL (pPT>200), 1500 copies/mL (pPT>1500) and 10000 copies/mL (pPT>10000) for the 12 months after HIV diagnosis. Multivariate zero-inflated negative binomial regression was used to assess trends in year of diagnosis and time spent above each viral threshold, while controlling for covariates (gender, transmission category, race/ethnicity, age, housing status, CD4+ lymphocyte count, health insurance type, and time from HIV diagnosis to ART initiation).

Results: Of the 3336 new HIV diagnoses from 2008-2016, 2556 (77%) met inclusion criteria for analysis. Overall, persons newly HIV diagnosed spent 53.6% of pPT>200, 44.1% pPT>1500, and 31.7% pPT>10000. By year, pPT>200 decreased from 70.3% in 2008 to 31.9% in 2016, pPT>1500 decreased from 62.3% in 2008 to 24.8% in 2016 and pPT>10000 decreased from 46.0% in 2008 to 17.0% in 2016 (p< 0.0001 for each threshold; see Figure).



[Percent time spent above each viral threshold during 12 months after HIV diagnosis by year of HIV diagnosis, San Francisco, CA, 2008-2016.]

In adjusted regression, significant differences for all three pPT thresholds were found by transmission category, age, CD4 count, and time from HIV diagnosis to ART initiation. PWID (including MSM-PWID) and younger age were associated with increased pPT viremic. Persons with lower CD4 count and shorter time to ART initiation had decreased pPT viremic.
Conclusions: The percent time spent above each viremic level decreased significantly among newly diagnosed persons from 2008 to 2016. Thus, the possibility that persons with a recent HIV diagnosis could transmit HIV in more recent years decreased and likely contributed to the decreased HIV incidence observed in SF.

TUAC0105

HIV prevention in a Fast Track City: Trends in time-dependent HIV cascade indicators among gay and bisexual men attending high HIV caseload testing services in Melbourne, Australia

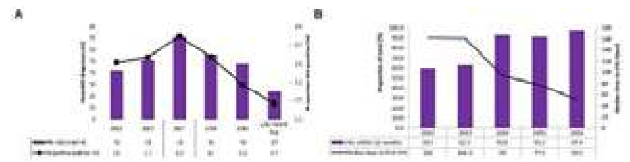
[1]Burnet Institute, Disease Elimination Program, Public Health Discipline, Melbourne, Australia, [2]Monash University, School of Population health & Preventive Medicine, Melbourne, Australia, [3]Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [4]The Peter Doherty Institute for Infection and Immunity, University of Melbourne, Melbourne, Australia, [5]International Council Of AIDS Service Organizations, Toronto, Canada, [6]The Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia, [7]Victorian AIDS Council, Melbourne, Australia, [8]Burnet Institute, Melbourne, Australia, [9]North-West Melbourne Public Health Network, Melbourne, Australia, [10]Victoria Department of Health and Human Services, Melbourne, Australia, [11]Cancer Council Victoria, Melbourne, Australia, [12]Kirby Institute, University of New South Wales, Sydney, Australia, [13]Prahran Market Clinic, Melbourne, Australia, [14]Centre Clinic, Victorian AIDS Council, Melbourne, Australia, [15]Northside Clinic, Melbourne, Australia

Background: The Fast-Track Cities partnership focuses on translating global HIV goals into local strategies, with progress towards 90-90-90 targets used as key indicators. Melbourne is Australia's only Fast Track City and, alongside Amsterdam, has reported achieving 90-90-90 targets. Sentinel surveillance in Melbourne also enables monitoring of individuals' progress through the HIV cascade, producing indicators highly sensitive to change. With 78% of HIV diagnoses in Melbourne occurring among gay and bisexual men (GBM), we present trends in HIV testing, diagnosis rates, and time to viral suppression among GBM attending three general practices specialising in GBM health and one GBM peer-led testing service in Melbourne.
Methods: HIV testing data was extracted from patient management systems through the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance (ACCESS) between Jan 2012-Sep 2017. Using anonymised unique identifiers, ACCESS prospectively links data on individuals' clinic attendances and laboratory test results. We calculated annualised trends in repeat testing (follow-up tests within three, six and 12-months), HIV positivity, the proportion of GBM with undetectable viral loads (<200 copies/ml) within 12 months of diagnosis and median time between diagnosis and undetectable viral load.
Results: 11,607 GBM received 47,722 HIV diagnostic tests between 2012 and 2017. There were significant increases in 12-month (56% to 63%; p<.01), six-month (28% to 44%; p<.001) and three-month (10% to 22%; p<.001) repeat testing. Between 2012 and 2017, 292 GBM were newly diagnosed with HIV; HIV positivity was 1.5% in 2012, peaked at 2.2% in 2014 then declined significantly to 0.4% in 2017 (p<.001). Among GBM newly diagnosed between 2012 and 2016, the percentage with undetectable viral loads (<200 copies/ml) within 12 months of diagnosis increased from 59% to 97% (p<.001) and the median time between diagnosis and undetectable viral load declined from 162 days to 50 days (p<.001).
Conclusions: Considerable declines in time between HIV diagnosis and viral suppression among GBM attending specialist HIV testing services in Melbourne have coincided with substantial declines in HIV diagnosis rates at these services. The most recent declines in diagnoses also coincided with a substantial scale up of PrEP among GBM in 2016-17 as part of a multi-site implementation project.



[Figure 1. HIV diagnoses and proportion of positive tests (A) and undetectable viral load (UVL) within 12 months of HIV diagnosis and median days to viral suppression (B) among GBM attending specialist services in Melbourne, 2012-17]

TUAC02 It's raining men: Key statistics for engagement

TUAC0201

Impact of HIV combination prevention in men who have sex with men, Bangkok, Thailand

S. Pattanasin[1], B. Cadwell[2], D.K. Smith[2], W. Sukwicha[1], P.A. Mock[1], W. Wimonsate[1], C. Ungsedhapand[1], P. Sirivongrangson[3], M.C. Thigpen[1,2], E.F. Dunne[1,2]
[1]Thailand MOPH-U.S. CDC Collaboration, Nonthaburi, Thailand, [2]Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, United States, [3]Ministry of Public Health, Department of Disease Control, Nonthaburi, Thailand

Background: PrEP is recommended for HIV prevention among at risk men who have sex with men (MSM) in Thailand. Anticipated PrEP impact on reduction of HIV infections would support the expansion of programs implementing PrEP in combination with consistent condom use. We used a deterministic model to assess PrEP and condom use and estimated HIV infections among MSM in Bangkok, Thailand using different adherence attributes.
Methods: For this deterministic model previously developed by Smith et al, we used three parameters from published data: 1) PrEP effectiveness from the iPrEx international clinical trial among MSM having < 50% adherence and ≥90% adherence based on self-reported medication adherence and pill counts 2) condom effectiveness from self-reported condom use during anal sex among MSM reporting at least one HIV-positive partner in two prospective HIV prevention trials and 3) annual HIV incidence in the absence of PrEP from the Bangkok MSM Cohort study, overall and stratified by characteristics. Among different age groups and risk behaviors, and adherence categories, the number of HIV infections per 10,000 MSM each year was calculated. The estimates assumed that PrEP and condom use efficacy were independent.
Results: Among MSM who had ≥90% PrEP adherence, an estimated 46 (19-110) HIV infections would occur among those who used condoms consistently; and an estimated 590 (520-680) HIV infections would occur among those not taking PrEP and not using condoms (a reduction of 544 HIV infections). Among MSM who had < 50% PrEP adherence, an estimated 116 (52-260) HIV infections would occur if condoms were used consistently. Combination HIV prevention used in MSM who were ages 18-21 years, or who engaged in sex parties, or who used club drugs with sex resulted in the greatest reduction of HIV infections (a reduction of 811, 922, and 1493 HIV infections) compared to those not using PrEP and condoms.
Conclusions: Models predict an estimated >10 fold reduction of HIV infections each year for MSM using PrEP and condoms in Bangkok, Thailand. Adherent combination prevention strategies in the highest risk MSM could result in the most substantial reductions in HIV infection.

Changes in rectal STI incidence and behavioral HIV risk before, during, and after PrEP in a national sample of gay and bisexual men in the United States

J. Parsons[1], H.J. Rendina[1], T. Whitfield[2], C. Grov[3]
[1]Hunter College-CUNY, Psychology, New York, United States, [2]Center for HIV Educational Studies and Training, New York, United States, [3]CUNY School of Public Health, New York, United States

Background: There has been mixed evidence about the extent to which gay and bisexual men (GBM) who use PrEP engage in greater condomless anal sex (CAS) and acquire STIs more frequently. Many studies rely on between-group comparisons of PrEP users and non-users or lack longitudinal data before and after PrEP initiation. The current study sought to examine within-person changes among men who electively initiated—and in some cases, discontinued—PrEP while enrolled in an observational study.

Methods: Data were taken from a longitudinal study of 1,071 HIV-negative GBM from across the U.S. Participants were tested annually for rectal gonorrhea and chlamydia and reported on PrEP use and CAS. We examined the odds of diagnosis with a rectal STI, number of CAS acts with casual male partners, and receptive CAS acts with serodiscordant casual male partners by PrEP status using general estimating equations; models were adjusted for visit year, relationship status, and race.

Results: We analyzed all data from the 281 (26.2%) GBM reporting PrEP use at one or more visits—1012 person-visits of data were examined, of which 517 (51.1%) were prior to initiation, 406 (40.1%) were while on PrEP, and 89 (8.8%) were after discontinuation. Overall prevalence of rectal STIs was 8.6%, with no significant changes in the odds while on PrEP (AOR = 1.28, $p = 0.36$) or after discontinuing (AOR = 0.28, $p = 0.08$) compared to pre-uptake. There were significant increases in CAS with casual male partners (AOR = 2.49, $p < 0.001$) and receptive CAS with serodiscordant male partners (AOR = 8.02, $p < 0.001$) while on PrEP compared to before uptake; no significant differences were observed in CAS comparing pre-PrEP and post-PrEP assessments.

Conclusions: Despite substantial within-person increases in CAS, including receptive CAS with serodiscordant partners, we failed to observe statistically significant increases in rectal STI incidence. It is likely that the desire for CAS was a motivator for initiating PrEP and GBM feel more comfortable having CAS while on PrEP. At discontinuation, however, CAS returned to pre-PrEP use levels, suggesting GBM are quite capable of other HIV prevention strategies when no longer on PrEP.

TUAC0203

Reducing risk of male sex partners: HIV testing, treatment, and VMMC of men in PEPFAR-supported DREAMS districts

C. Cooney[1], K. Sato[2], S. Allen[1], N. Toiv[1], D.H. Watts[1], J. Saul[1]
[1]U.S Department of State, Office of the U.S. Global AIDS Coordinator and Health Diplomacy, Washington, D.C., United States, [2]U.S. Peace Corps, Washington, D.C., United States

Background: The U.S. President's Emergency Plan for AIDS Relief's (PEPFAR) launched the Determined, Resilient, Empowered, AIDS-Free, Mentored and Safe (DREAMS) Public-Private Partnership in 2014 with the goal of preventing HIV in adolescent girls and young women (AGYW) in ten high HIV burdened African countries. PEPFAR complemented DREAMS activities for AGYW with increased funding to ensure saturation of HIV services for young adult men in DREAMS districts, including HIV testing (HTS), treatment, and voluntary medical male circumcision (VMMC).

Here we compare DREAMS and similar non-DREAMS districts in five countries to examine changes in HTS, VMMC, and treatment results after two years of DREAMS implementation (2015-2017).

Methods: Countries were selected for inclusion if they met the following criteria: there were comparable non-DREAMS districts that were originally considered for DREAMS or will begin DREAMS implementation in 2018; and districting remained consistent from 2015-2017.

PEPFAR indicators were used to analyze total number of VMMCs completed, clients tested, and new clients on treatment for males 15-49 years in DREAMS and non-DREAMS districts. Annual results from 2015 and 2017 were compared and a percent change was calculated. A series of generalized linear mixed models, based on a Poisson distribution, were used to assess the difference between DREAMS vs. non-DREAMS districts. We controlled for false discovery rate for multiple hypothesis testing.

Results: The generalized linear mixed models showed significant positive differences (p-value < 0.001) between DREAMS vs. non-DREAMS districts in three countries for an increase in new on treatment, three countries for increase in total number tested, and two countries for an increase in VMMCs supported. Results are shown in the table.

Conclusions: Change in VMMC, HTS, and treatment results for men ages 15-49 in DREAMS vs. non-DREAMS districts varied. In DREAMS districts that showed a greater percent increase vs. non-DREAMS districts in testing and treatment indicators, data suggest that focusing on treatment as prevention for male partners during DREAMS implementation may be associated with an increase in these services. Variation in results emphasizes the need for continued efforts in reaching young adult men and in reaching AGYW with structural and combination prevention to interrupt the cycle of heterosexual HIV transmission.

Profile of adverse events in a national VMMC program in Mozambique (2009-2017): Reduction in AE with a national scale-up, but three events require further attention

H. Muquingue[1], S. Ndimande[2], E. Necochea[2], S. Wei[3], R. Frescas[2], I. Malimane[3], A. Jaramillo[2], M. Mahomed[4], C. Lee[5], M. Canda[3]
[1]Jhpiego Mozambique, MER, Maputo, Mozambique, [2]Jhpiego Mozambique, Maputo, Mozambique, [3]CDC Mozambique, Maputo, Mozambique, [4]Jhpiego South Africa, Durban, South Africa, [5]Jhpiego, Baltimore, United States

Background: Adverse events (AE) in male circumcision are "any injuries, harm, or undesired outcomes occurring during or following male circumcision (MC) that would not have occurred if the client had not undergone the procedure" (USAID). AEs are categorized by severity (mild, moderate and severe), timing (intra or post-operative), nature (bleeding, etc), and surveillance (passive or active). AE occurrence is a proxy for quality management and provision, and influences MC acceptability. Thus, efforts try to both understand the program- and beneficiary-related etiologies of AE and monitor AE, particularly in large scale MC programs, given the potential risks involved.

Methods: We report on AE identified within males circumcised in Mozambique by Jhpiego, from 2009-2017 with more than 700,000 VMMC procedures provided through a national program. Data on AE events in Mozambique VMMC program were analyzed, using descriptive statistics and trends. AEs were calculated per age group and severity (moderate or severe).

Results: Out of 718,090 procedures, there were 1,826 moderate and severe AEs (0.25% rate, peaking at 2.3%, in the first month), with 1,650 moderate (90.4%) and 176 severe (9.6%). The three most common AEs (80% of AE) were infection (41%), hematoma (23%) and excessive bleeding (16%). Damage to the penis and pain accounted for 6% each. Most moderate AEs were infections (44.2%), and most severe AE were hematomas (59.1%). The most affected age was 10 to 14 years, with 40% of the AEs, followed by 15 to 19, and 20 to 24 years, with 24% each. By age strata, AE were 0.2% (10-14), 0.22%(15-19; 35-49), 0.8% (50+); 0.29%(30-34); 0.37%(25-29); 0.57%(20-24).

Conclusions: A high volume VMMC program has the potential to dramatically reduce AE occurrence, overtime. The high prevalence of infection as an AE may be related to both client and provider factors, which require further consideration; parents and caregivers need to understand proper wound care; providers need to assure proper technique during MC procedures. A challenging limitation is that AE reporting depends on providers recognizing, documenting and addressing adverse events, therefore results should be carefully backed by an active surveillance system to improve the reliability of data and seek those opportunities for quality improvement.

TUAC0205

Results from a cluster-randomized trial to evaluate a microfinance and peer health leadership intervention for HIV and intimate partner violence prevention among social networks of young Tanzanian men

S. Maman[1], M. Mulawa[2], P. Balvanz[1], H.L. McNaughton-Reyes[1], M. Kilonzo[3], T. Yamanis[4], B. Singh[5], L. Kajula[3]
[1]University of North Carolina at Chapel Hill Gillings School of Global Public Health, Health Behavior, Chapel Hill, United States, [2]Duke University, Global Health Institute, Durham, United States, [3]Muhimbili University of Health and Allied Sciences, Department of Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of, [4]American University, School of International Service, Washington, United States, [5]Medical University of South Carolina, Department of Psychiatry and Behavioral Sciences, Charleston, United States

Background: Despite calls to engage men in HIV and intimate partner violence (IPV) prevention efforts, effective approaches to reach and engage men in low-resource, high-HIV prevalence settings are limited. We identified and engaged social networks of mostly young men, locally referred to as "camps," in Vijana Vijiweni II, a cluster-randomized trial to evaluate the efficacy of a combined microfinance and peer health leadership intervention for HIV and IPV prevention among 59 camps in Dar es Salaam, Tanzania.

Methods: Thirty camps (n=621 men) were randomly assigned to the two-year intervention condition and 29 camps (n=628 men) were randomized to the control. Behavioral assessments were conducted at baseline and 30-months post-intervention launch, with biological samples drawn at 30-months to test for sexually-transmitted infections (STIs). Primary outcomes included prevalence of STIs and past-year IPV perpetration. Secondary outcomes included STI sexual risk behaviors and past-year HIV testing. Proximal intervention targets included inequitable gender norm attitudes and hope. We compared outcomes among intervention vs. control participants by computing covariate-adjusted risk ratios (aRR) with robust confidence intervals (CI) using an intention-to-treat approach.

Results: Of 1,249 men enrolled in the trial, 1,029 (82.4%) completed the 30-month follow-up. There was no evidence that the intervention reduced STI prevalence (aRR 1.05, 95% CI 0.86-1.29), IPV perpetration (aRR 1.15, 95% CI 0.91-1.44), or STI risk behaviors. Men in the intervention condition reported greater levels of past-year HIV testing, controlling for HIV testing status at baseline, (aRR 1.13, 95% CI 1.00-1.28, p=.04) as well as significantly lower levels of inequitable gender norm attitudes at the 30-month follow-up (adjusted effect -0.11, 95% CI -0.21-0.00, p=.04), while there was no significant difference in hope across condition.

Conclusions: We successfully engaged and retained social networks of men in this multilevel HIV and IPV prevention study. The combined microfinance and peer health leadership intervention successfully improved HIV testing and reduced inequitable gender norm attitudes. We did not see an effect on the primary outcomes or STI sexual risk behaviors. Additional analyses will examine whether there were effects for particular subgroups and whether there were differential effects as a function of intervention exposure.

TUAC03 Diversities in delivery: PrEP from home to clinic

TUAC0301

Retention in care for HIV pre-exposure prophylaxis (PrEP) among sex workers of four public health centers in Senegal

O. Diouf[1], M. Sarr[2], D. Gueye[1], M. Mane[1], A. Mboup[1], C. Toure Kane[1], S.E. Hawes[3], C. Suarez[2], M.D. Bousso Bao[1], F. Jones[2], J. Presley[4], G. Gottlieb[3], S. Mboup[1]
[1]IRESSEF : Institut de Recherche en Santé, de Surveillance Epidemiologique et de Formations, Dakar, Senegal, [2]Westat, Rockville, United States, [3]University of Washington, Seattle, United States, [4]Bill and Melinda Gates Foundation, Seattle, United States

Background: Recent breakthroughs in antiretroviral (ARV)-based prevention provide new opportunities to rethink HIV prevention strategies, especially for key populations such as female sex workers (FSWs). As pre-exposure prophylaxis (PrEP) demonstration projects are increasingly initiated, more information is needed about the correlates of PrEP retention when implemented in Ministry of Health (MoH)-run clinics such as in Senegal.

Methods: The Senegal PrEP Demonstration Project is a prospective, open-label cohort study assessing the delivery of oral Truvada (emtricitabine/tenofovir DF) PrEP to FSWs in 4 Ministry of Health (MoH)-run clinics in Dakar, Senegal. We assessed retention in PrEP care at 6 and 12-months follow-up. Repeated measures analysis using Generalized Estimating Equation (GEE) models were used to identify the predictors of PrEP retention.

Results: Overall, out of 325 eligible FSWs, 271 (83.4%) were initially enrolled at baseline. The average age of those enrolled was 38 years (STD=8.7). Most FSWs were Senegalese (96.7%), and approximately half of them never attended school (44.8%). Among the 267 participants who were prescribed PrEP, 70.4% were retained in care at six months (Pikine: 68.5%, Mbao: 78.8%, Rufisque: 71.2%, Diamniadio: 65.8%; p=0.439) and 67% were retained in PrEP care at twelve months (Pikine: 69.9%, Mbao: 61.5%, Rufisque: 72.7%, Diamniadio: 63.2%; p=0.483). Older age among FSW was found to be a significant predictor of higher PrEP retention (P = 0.0012). Compared to the 18-24 year age group, the 25-34 (OR= 2.53, 95%CI=1.22-4.99), 35-44 (OR= 3.24, 95%CI=1.57-6.23), and 45+ year age groups (OR= 3.85, 95%CI=2.13-10.27) were significantly more likely to be retained in PrEP. We did not find significant differences in retention by site, education, registration as sex worker status, condom use or HIV risk perception.

Conclusions: Our results showed evidence of good PrEP retention rates among FSWs at 12-months follow-up when offered in Ministry of Health (MoH)-run clinics in Dakar, Senegal, with older age as the only significant predictor of higher PrEP retention. Further research is needed to identify the factors that may optimize retention in PrEP care in public health settings.

TUAC0302

Key population-led health services (KP-LHS) critical to PrEP introduction among MSM and TG in Thailand

R. Vannakit[1], M. Kim[1], S. Charoenying[2], S. Mills[2], M. Avery[2], N. Phanuphak Pungpapong[3], P. Phanuphak[3], D. Rinjongrat[4], S. Janyam[5], P. Chanlearn[6], S. Sittikarn[7], T. Nakpor[8]
[1]Office of Public Health, U.S. Agency for International Development, Regional Development Mission Asia, Bangkok, Thailand, [2]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [3]Thai Red Cross Aids Research Center, Bangkok, Thailand, [4]Rainbow Sky Association of Thailand, Bangkok, Thailand, [5]Service Workers in Group, Bangkok, Thailand, [6]Mplus Foundation, Chiang Mai, Thailand, [7]Caremat, Chiang Mai, Thailand, [8]Sisters Foundation, Pattaya, Thailand

Background: PrEP is a necessary component of a national AIDS program in many settings, but particularly in countries with concentrated epidemics among key populations (KPs). There are to date only a few countries who have approved PrEP and even fewer who have attempted rapid scale-up for epidemic control.

Methods: PrEP is available through multiple providers in Thailand, including 13 government hospitals, 5 public- and private-sector clinics, and 7 community-based organizations working under a key population-led health services (KP-LHS) model. We examined data from sites to assess the contribution of KP-LHS as part of a national strategy to increase PrEP uptake.

Results: Between October 2016 and January 2018, the cumulative number of reported PrEP users in Thailand from all sources increased by more than 200%. PrEP uptake as a percentage of all clients tested HIV-negative was slightly higher at government facilities than through community-based providers (7% versus 5%) but the total number of KP clients receiving PrEP under the KPLHS model was six times higher (1,299 versus 183). PrEP uptake at a private-sector clinic targeting men who have sex with men was significantly higher (1,205 PrEP clients, 16%) but PrEP clients at that clinic were significantly more likely to be non-Thai clients compared with clients at community-based services (88% versus 8%). Over the 15-month period, none of the clients who accessed PrEP through hospital services seroconverted; four clients who accessed community-based PrEP later tested HIV-positive (0.2%), though it is impossible to ascertain whether these clients were actively using PrEP at the time of infection.

Conclusions: Our study on the scale-up of PrEP showed that the most significant increase of clients requesting PrEP were at KP-LHS sites as well as private clinics whose services are provided by KPs. These organizations appear to be the most critical for rapid scale-up, particularly where epidemic growth is concentrated among KPs. Government health facilities are still needed for sustainability and coverage. However, our data suggest that in the early stages of introduction, KP-LHS can quickly add new products such as PrEP and obtain high uptake through their trusted relationships with KPs.

TUAC0303

Comparison of measures of adherence to HIV pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) and transgender women (TGW): Results from the PrEP Brasil study

L.M.S. Marins[1], T.S. Torres[1], I. Costa Leite[2], R.I. Moreira[1], B. Hoagland[1], E.G. Kallas[3], J.V. Madruga[4], P.L. Anderson[5], A.Y. Liu[6], B. Grinsztejn[1], V. Veloso[1], PrEP Brasil Study Team
[1]Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, [2]Fundação Oswaldo Cruz, Escola Nacional de Saúde Pública, Rio de Janeiro, Brazil, [3]Universidade de São Paulo, School of Medicine, São Paulo, Brazil, [4]Centro de Referência e Treinamento em DST/AIDS, São Paulo, Brazil, [5]University of Colorado, Skaggs School of Pharmacy and Pharmaceutical Sciences, Denver, United States, [6]San Francisco Department of Public Health, Bridge HIV, San Francisco, United States

Background: Adherence is a critical factor for efficacy of daily emtricitabine/tenofovir (FTC/TDF) for PrEP. We examined the concordance between three adherence measures contrasted to protective drug levels among participants retained through 48 weeks in the PrEP Brasil Study.

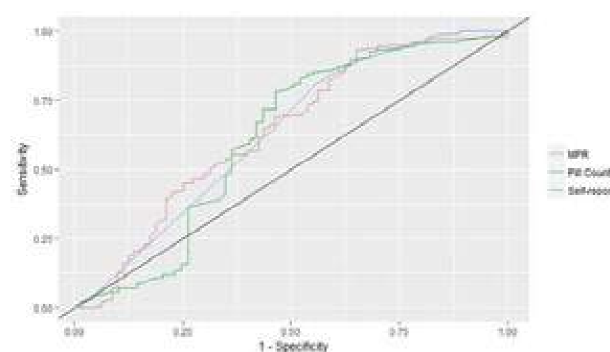
Methods: PrEP Brasil was a prospective, multicentre, open-label demonstration project assessing PrEP delivery for MSM and TGW at higher risk for HIV infection in the context of the Brazilian Public Health System. Three adherence measures were obtained at week 48: Self-report (in-person interview; 30-days recall), Pill count (tablets dispensed in prior visit minus tablets returned at week 48, divided by the days between the two visits) and Medication possession ratio (MPR) (ratio between tablets dispensed in prior visit and days between the two visits). TFV-DP was measured using LC-MS/MS at week 48. Areas under the ROC curve (AUC) were used to evaluate the concordance between achieving protective drug levels (TFV-DP≥700fmol/punch) and the adherence measures. The optimal cut-off points for discriminating between those with/without protective drug levels were found based on Youden index and distance to corner. Sensitivity, specificity, negative (NPV) and positive (PPV) predictive values for the cut-off points were calculated. Finally, we carried out the DeLong test to verify whether the curves are different from each other.

Results: From April/2014 to July/2016, 450 participants initiated PrEP, 375(83.3%) were retained through 48 weeks. Of these, FTC/TDF was provided to 354(94.4%) in the previous 3 months and those participants were included in this analysis. Median age was 30 years (IQR: 25-35); 84(23.7%) were aged 18-24 years, 19(5.4%) TGW, 41(11.8%) black and 83(24.5%) had < 12 years of education. At week-48, 77.4%(274/375) had TFV-DP ≥700fmol/punch. All adherence measures were able to discriminate between participants with and without protective drug levels (AUC>0.5) (Table 1).

Adherence measures	Median adherence (IQR)	AUC (95%CI)	P-value	Cut-off point	Sensitivity	Specificity	PPV	NPV
MPR	1.16 (1.00-1.31)	0.64 (0.56-0.71)	<0.001	1.07	0.69	0.54	0.84	0.34
Pill count	96.82 (88.15-100.00)	0.62 (0.53-0.70)	0.01	90.24	0.77	0.54	0.86	0.38
Self-report	100.00 (96.67-100.00)	0.64 (0.56-0.71)	<0.001	100.00	0.65	0.54	0.84	0.29

[Table 1. Association between adherence measures and protective drug levels]

High recorded adherence was predictive of protective drug levels (PPV>0.8) while low recorded adherence was fairly predictive of lack of protective drug levels (NPV< 0.4). No statistical differences were found between the adherence methods curves (p=0.38) (Figure 1).



[Figure 1. ROC Curves for protective drug level vs adherence measures.]

Conclusions: Low-burden measurements such as MPR and self-report can be used to predict PrEP adherence in a public health context in Brazil.

TUAC0304

Uptake of PrEP within clinics providing integrated family planning and PrEP services: Results from a large implementation program in Kenya

K. Mugwanya[1], J. Pintye[1], J. Kinuthia[1,2], F. Abuna[3], H. Lagat[3], M. Serede[3], J. Sila[3], G. John-Stewart[4], J.M. Baeten[4], PrEP Implementation for Young Women and Adolescents (PrIYA) Program
[1]University of Washington, Department of Global Health, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya, [3]University of Washington-Kenya, Nairobi, Kenya, [4]University of Washington, Departments of Global Health, Epidemiology and Medicine, Seattle, United States

Background: Integrating PrEP within family planning (FP) clinics could serve as a platform for reaching young women at-risk for HIV in high burden settings. The PrEP Implementation for Young Women and Adolescents (PrIYA) Program is conducting real-world delivery of PrEP to at-risk women seeking routine FP services in Western Kenya.
Methods: PrIYA is part of the DREAMS Innovation Challenge funded by PEPFAR managed by JSI Research & Training Institute, Inc. We approached HIV-uninfected women seeking routine FP services at 16 clinics in Kisumu County, Kenya from June to December 2017. At each encounter, women were screened for behavioral risk factors and willingness to consider PrEP following the national PrEP guidelines. Eligible women who were interested in PrEP were offered PrEP at the same visit.
Results: Overall, we conducted 493 assessments among FP clients for behavioral risk factors and willingness to consider PrEP. Among all women, median age was 25 years (IQR 21-29); 78% were married and 39% did not know their male partner's HIV status. The most frequently used FP methods were injectables (53%), implants (32%) and oral contraception (7%); 4% used intrauterine devices (IUDs), 4% used condoms alone and 3% used other methods.
Overall, 110 (22%) of encounters led to PrEP initiation. Frequency of PrEP initiation differed by male partner HIV status (HIV-negative 11%, unknown 30%, HIV-positive 82%, p< 0.001). Younger women were as likely to initiate PrEP as older women (< 24 vs ≥24 years, OR=1.53, 95% CI 0.93-2.51, p=0.09). Initiating PrEP was associated with having an STI (OR=5.33, 95% CI 1.28-22.09, p=0.021) and experiencing intimate partner violence in the last 6 months (OR=3.17, 95% CI 1.27-7.88, p=0.01).
Likelihood of PrEP initiation did not differ between women using a non-barrier FP method (hormonal contraception or IUDs) and women using condoms alone (OR=2.02, 95% CI 0.43-9.48, p=0.37). Frequently reported reasons for declining PrEP included the perception that HIV risk was low (30%) and the partner was HIV-negative (30%).
Conclusions: Among FP clinic attendees in Kenya, PrEP initiators were more likely to have HIV risk factors and just as likely to use FP methods other than condoms as those who declined PrEP.

TUAC0305

Adolescent use of Truvada (FTC/TDF) for HIV pre-exposure prophylaxis (PrEP) in the United States (2012-2017)

D. Magnuson[1], T. Hawkins[2], R. Mera[1]
[1]Gilead Sciences, Epidemiology, Foster City, United States, [2]Gilead Sciences, Medical Affairs, Foster City, United States

Background: Truvada (FTC/TDF) for PrEP has been approved for use in adults (≥18 years of age) at high risk of sexually acquired HIV infection in the US, EU, and other countries. Regulatory reviews are ongoing to expand the indication to include adolescents.
There are limited data on the efficacy of FTC/TDF for PrEP in adolescents and there are no data on drug utilization in US or EU.
This study describes FTC/TDF for PrEP use in adolescents in US from January 2012 through September 2017.
Methods: We used a nationally representative sample of de-identified data from a US prescription claims database to quantify the number of unique individuals who received a FTC/TDF for PrEP prescription, representing >80% of retail pharmacies in the US. Data included medical claims, diagnosis, diagnostic procedures and both patient and provider demographics. A validated algorithm was used to exclude FTC/TDF for non-PrEP use (e.g. chronic HIV treatment, post-exposure prophylaxis and chronic Hepatitis B treatment).
Results: From January 2012 to September 2017, 148,147 unique individuals began FTC/TDF for PrEP: 2,388 (1.6%) were 12-17 yrs; 20,409 (13.8%) were 18-24 yrs; 114,279 (77.1%) were 25-54, and 11,071 (7.5%) were ≥ 55 yrs. The total number of adolescents increased annually from 266 in 2012 to 805 in 2015, but decreased to 216 in 2016. Females given FTC/TDF for PrEP accounted for 86.0% of adolescents while comprising only 18.4% of adults given prescriptions (p < 0.0001). Medicaid provided coverage for FTC/TDF in 59.1% of adolescents as compared to 13.5% of adults. Adolescents received FTC/TDF for PrEP prescriptions most commonly from pediatricians (31.6%), emergency medicine (22.6%), and family medicine physicians (12.3%).
Conclusions: While adolescent use of FTC/TDF for PrEP is not approved in the US, 1.6% of FTC/TDF PrEP users were < 18 years of age. In contrast to adults on FTC/TDF for PrEP, adolescents on FTC/TDF for PrEP were predominantly female and commonly used Medicaid coverage. Pediatricians and emergency medicine doctors were most common prescribers in adolescents. Adolescents and young adults are disproportionately affected by HIV and efforts to increase access to PrEP for adolescents at high risk are important, including expanding the indication.

TUAD01 Harm reduction: I can't get no satisfaction

TUAD0101

Study on drug consumption rooms on current practice and future capacity to address communicable diseases like HCV

E. Schatz[1], V. Belackova[2]
[1]De Regenboog Groep, Correlation Network, Amsterdam, Netherlands, [2]Uniting MSCI, Sydney, Australia

Background: Drug consumption rooms (DCRs) target the most vulnerable people who inject drugs (PWID). While decreases in risky injecting behaviours are an outcome of DCR use, specific HCV prevention & treatment in these settings haven't been described. There are no international DCR standards for HCV practice and research is yet to address sero-prevalence status of DCR clients and their access to HCV prevention, treatment or supportive services.
Methods: An online survey providing a 'snapshot' of DCR clients' HCV status, their access to HCV services and the needs in expanding these was conducted in 2016. 49 of the 91 DCRs from Australia, Canada, Denmark, France, Germany, Luxembourg, Netherlands, Norway, Spain and Switzerland participated in the survey (54%). Each country where a DCR operates was represented.
Results: An estimate of clients ration that were tested for HCV (mean=72%) and that were HCV positive (mean=60%) was provided by 39 DCRs. Most DCRs provided HCV testing onsite (n=30) via blood samples (n=19) or finger prick/saliva (n=10). Also, several DCRs referred clients offsite for testing (n=23).
Only three European DRCs provided HCV treatment onsite; one providing DAAs. Several offered disease self-management support (n=21) or monitoring of liver health (n=10). Overall, HCV support (n=41) as well as new treatment (n=42) or interferon (n=24) were available to DCR clients offsite, and the majority of DCRs referred their clients into that treatment (n=35).
To provide further HCV-related services, DCRs would need more staff time (n=23) and training (n=21), expanded staff qualifications (n=13) and funding for equipment and services (n=18). A change in national HCV treatment guidelines for active drug users was also identified as a need (n=11).
Conclusions: DCR involvement in HCV prevention and treatment is crucial. With access to most marginalised populations, DCRs staff need to be supported to provide an entry point to HCV treatment.

TUAD0102

You don´t feel freedom inside: Causes and factors influencing the adherence to the substitution therapy program in Khujand, Tajikistan

N. Ilhomjon[1], A. Sarang[2]
[1]NGO Khujand, Khujand, Tajikistan, [2]SKOSH, Amsterdam, Netherlands

Background: The substitution therapy program in Khujand (Tajikistan) started in 2011 with the support of UNDP/GFATM. 345 PWID passed through the program, however, during six years 283 patients (82%) have fallen out. Currently, 62 clients are enrolled, or 6% or PWID registered in the region - coverage far below the targets recommended by WHO for universal access to HIV prevention, treatment and care for PWID. Low coverage and high drop out rate undermine the program effectiveness in preventing HIV. Our qualitative study aimed to identify the factors that influence adherence.
Methods: In 2017 we carried out in-depth interviews with twelve men and six women aged between 34 and 46 who used to participate in the program (15) or are current clients (3). We also interviewed two doctors.
Results: Analysis revealed the factors that affect low retention:
1) The discrepancy between expectations and reality: many participants said they expected the program to be a short-term intervention that would fully rid them of dependency.
2) Neglect: respondents felt the program failed to consider their needs and fully excluded them from decision making regarding own treatment, in particular concerning the dosage, their psychological needs were not addressed.
3) Stringent rules and insufficient information. Often patients signed their contract without understanding the terms and regulations.
4) Loss of control. The patients are required to visit OST daily which impedes resocialization and employment. Many withdrew from the program as they felt lack of personal freedom and control. In general, people felt disempowered by the program even more than by their previous drug addiction and wanted the exit to regain control over their lives.
Conclusions: To make the program an empowering environment for people to regain control over their lives, not visa versa we need to:
- Ensure more patient involvement in decision making regarding the overall program design and individual treatment plans;
- Allow take-home methadone, subject to individual conditions;
- Make methadone available at pharmacies, hospitals and penal institutions;
- Include patient representatives in the program governance and staff;
- Give more attention to patient expectations before admission and ensure more psychosocial support in achieving their goals.

TUAD0103

Increased methadone dose reduces illicit drug injection among HIV negative methadone clients in Myanmar

S. Tun[1,2], V. Balasingam Kasinather[2], D. Singh Mahinder Singh[2]
[1]Myanmar Medical Association, Yangon, Myanmar, [2]University Sains Malaysia, University of Science, Centre for Drug Research, Penang, Malaysia

Background: HIV prevalence rate among People who inject drugs (PWID) in Myanmar is high at 28.5%. The transmission of HIV can be reduced by reducing unsafe needle sharing among injecting drug uses and Opioid substitution. National Drug Abuse Prevention and Control Programme in Myanmar has increased financial and programmatic support for Methadone Maintenance Therapy as an Opioid Substitution Therapy (OST), paralleling with Needle Syringes Exchange Programme (NSEP). Out of 83,000 estimated people who inject drugs, more than 12,550(15%) had taken methadone for Opioid substitution in 2017. Evaluation of methadone programme is vital for the efficient service delivery.
Methods: A cross-sectional study was conducted in five cities with stratified random sampling from all State/ Regions of Myanmar, where methadone services delivered. A sample of 42 persons from each site with minimum 6-month duration on methadone, total 210 respondents were recruited to answer survey questionnaires relating to methadone profile, drug use history for 30 days and urine sample collection for methadone and illicit drug use detection (Morphine, Cannabis, Methamphetamine, Amphetamine, Benzodiazepam).
Results: Findings showed that 93 (44.5%) didn't inject within 30 days and 116 (55.5%) admitted that they injected heroin. Those respondents had average methadone dose of 83 mg ranging from 20 to 300mg and reported HIV is 74 out of 200, 37% of who answered. An increase in methadone dose proved that reduced in the reported drug injection within 30 days especially among HIV negative respondents (P= 0.00) in Cox regress analysis. This finding is also consistent with less use of Morphine in the urine samples (P=0.034) and less use of Cannabis in the urine findings (P=0.032). However, there is association of methadone dose and Benzodiazepam in the urine (P=0.014).
Conclusions: High dose of methadone maintenance therapy more than 80mg is crucial in reducing of illicit drug injection among HIV negative individuals which can subsequently reduce the unsafe practice of sharing needle among injecting drug uses. The increased methadone dose can further prevent HIV transmission among people who inject drugs. This methadone evaluation finding from Myanmar will be useful for other similar settings where methadone is used for Opioid substitution worldwide.

TUAD0104

Reducing harm caused by drugs: HIV prevention among people who inject drugs in South Africa

E.M. Sibanda
Right to Care, Global Fund, Pretoria, South Africa

Background: The overall aim of the Global Fund (GF) prevention programme is to reduce the number of new HIV infections and further spread of HIV among people who inject drugs (PWID). This was necessitated by rapid escalation of injection drug use which coincided with synergistic rise in HIV prevalence. A 2013, UNODC study in major metropolitan cities to assess HIV prevalence and risk practices among PWID found that 1 in 6 (14%) PWID where HIV infected. National prevalence rate is estimated at 19%. When comparing PWID to people in the general population from similar socio-economic contexts (using race as a proxy), the HIV burden among PWID is between two and ten times higher, (Scheibe et al 2014).
Description: The programme is guided by WHO comprehensive package of services for PWID and utilises combination prevention methods that include behavioural, biomedical and structural interventions. Peer outreach workers act as a link to biomedical services and conduct community awareness around drug use. Key interventions include HIV Testing Services (HTS), Antiretroviral therapy (ART), Opioid Substitution Therapy (OST), and Needle and syringe programme (NSP). Of the WHO comprehensive package the GF programme doesn't support diagnosis and treatment of Hepatitis C virus (HCV), a common occurrence among PWID due sharing of drug paraphernalia. A study by Semugona et al 2017 showed a 27% HCV positivity rate among men who have sex with men and injecting drugs in Cape Town. The programme is implemented in 4 cities, namely, Durban, Cape Town, Port Elizabeth and Johannesburg by Right to Care partners, Anova and TB HIV Care Association under Global Fund.
Lessons learned: Attainment of results was necessitated by stakeholder engagement in planning, community mapping, and implementation. From April 2016 to date the programme achieved the following;
Programme Results

Intervention	Output	Comment
PWID reached with comprehensive prevention package	2,349	Harm reduction messaging, information, education and communication
PWID tested for HIV and know their status	2,410	Positives referred for onward management
PWID HIV+	449	Denotes 19% positivity rate
Needles and syringes distributed	542,634	To minimise sharing and re-use of needles
PWID initiated on Opioid Substitution Therapy (OST)	63	17 lost to follow up denoting about 30% - in line with global trends

[Programme results]

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

· HIV Positivity rate is in line with previous studies results.
· Use of peer outreach workers from target population helps in mapping areas and roll-out of interventions.
· Need to include Hepatitis C in programmes for PWID as co-infection is common

Conclusions/Next steps: Results show increased access to HIV prevention services and early enrolment in HIV care and treatment including medically assisted therapy (OST).

TUAD0105

Combatting the HIV epidemic among people who inject drugs in ground zero of the war on drugs - the Afghan experience

A.R. Rejaey
Bridge Hope and Health Organisation, Programme Director, Kabul, Afghanistan

Background: Afghanistan is at a cross-roads; the country is emerging from more than twenty years of political and social unrest as the leading global producer of opium in a geographic region widely affected by drugs and HIV. The number of drug users in Afghanistan is growing and currently is estimated at between 1.3 and 1.6 million. Drug treatment capacity in Afghanistan still covers only 7.8 per cent of opium and heroin users. The community consultation identified the rapid increase in the use of methamphetamine and overall drug-related risks being compounded by low knowledge levels.

Description: Bridge was formed by people who use drugs in 2014, and over time PLHIV and other key populations have mobilised together under the Bridge banner.

Bridge's team of peer advocates and peer educators have skilled up to undertake a number of different activities including:

Peer research
Peer education
Wound care management
Outreach
Multi and social media advocacy
High level advocacy

All this has been set against working in a very high risk context where people who use drugs face daily beatings, extortion, heavy criminalisation and the threat of being rounded up and forced in to a compulsory detox centre. The drug scene is also extremely volatile and only Bridge is prepared to undertake outreach in the midst of the open drug scenes.

Lessons learned: Peer workers can take harm reduction commodities and life saving settings where traditional harm reduction and HIV NGOs fear to tread.

Bridge has the ability to identify and respond to changing drug trends with creativity and applying international best practice

Bridge is able to identify failings in service provision from traditional providers including highlighting corruption, poor quality services and human rights abuses.

Bridge has been unable to secure sustainable funding as an HIV representative organisation or as a harm reduction provider despite repeatedly demonstrating its unique ability and capacity.

Conclusions/Next steps: There is an urgent need for international donors to step up and support Bridge so it can realise its potential and support the urgent scale up in the quality and coverage of the HIV response with PWID.

TUAD02 The defence does not rest: Resisting the criminalization of HIV

TUAD0201

The new AIDS denialism: How criminal courts' dismissal of modern science perpetuates HIV stigma, discrimination and criminalisation

E.J. Bernard, S. Cameron
HIV Justice Network, Brighton, United Kingdom

Background: People living with HIV continue to be charged with HIV-related offences, often in cases where the likelihood of transmission is remote or transmission is not possible.

Methods: The HIV Justice Network undertook a global audit of HIV-related arrests, investigations, prosecutions and convictions on behalf of HIV Justice Worldwide (October 2015 to September 2017: with final data to April 2018 to be presented).

Results: More than 200 prosecutions were identified. The vast majority related to a perceived risk of HIV acquisition associated with sexual activity, with a minority relating to biting, spitting and breastfeeding. Convictions were common, usually resulting in incarceration, including in cases where no harm was intended, where HIV transmission did not occur, and/or where HIV transmission was extremely unlikely or not possible. Often courts doubted or ignored contemporary scientific evidence of the preventative effectiveness of condoms, antiretroviral treatment and low viral load. (Non-transmission) cases include: incarceration for a single instance of breastfeeding; incarceration and sex offender registration for consensual sex with a low viral load; and denial of an appeal against a 30-year sentence for consensual sex, using a condom while having a low viral load. Disaggregated data showed gendered and heteronormative values strongly influence prosecutions, as do issues of race and social marginalisation.

Conclusions: Courts' dismissal of scientific evidence and corruption of legal principles has resulted in overt miscarriages of justice and the perpetuation of HIV-related stigma. Not only have individuals received long jail terms where HIV exposure was not possible, the ongoing application of HIV exceptionalism in courts of law undermines the human rights of all people living with HIV. Despite remarkable scientific advancements, many people living with HIV remain vulnerable to the risk of unjust prosecutions because up-to-date science on HIV-related risks and harm has not been effectively and/or consistently recognised in criminal law and associated policy. This issue requires the development of new strategies including greater involvement of HIV-expert scientists in structural interventions, and training and support of expert witnesses, defence lawyers and judges in their analysis of modern HIV science.

TUAD0202

Decriminalizing HIV: How people living with HIV translated quantitative research into community action and legislative transformation

H. Turk[1,2], A. Ochoa[3], A. Hasenbush[4]
[1]*L.A. HIV Law & Policy Project, Los Angeles, United States,* [2]*UCLA School of Law, Los Angeles, United States,* [3]*UCLA, Luskin School of Public Affairs, Los Angeles, United States,* [4]*UCLA School of Law, Williams Institute, Los Angeles, United States*

Background: On January 1, 2018, four HIV-specific criminal statutes were repealed or modified, making California the third state in the U.S. to transform and reduce the harsh impact of criminal laws targeting people living with HIV. This victory hinged on the strategic dissemination by PLWH of quantitative research and their role in effectively communicating the disparate impact of HIV criminalization on sex workers, women, and people of color.

Description: Beginning in 2015, The Williams Institute and the California HIV/AIDS Policy Research Center issued findings from California statewide data on the use of criminal laws targeting PLWH. The Los Angeles HIV Law and Policy Project and their collaborative partners trained and

engaged PLWH to present these data. Working in partnership with academic researchers, HIV-positive activists translated quantitative figures into compelling evidence demonstrating that HIV-specific laws were disparately enforced against HIV-positive women and people of color, especially those engaged in commercial sex work. At every step throughout the movement, the experiences of PLWH were centered not just in the data but also, and most importantly, in the voices of the HIV-positive leaders who shaped the movement.

Lessons learned: An important best practice underscored by this successful decriminalization is the meaningful involvement of and engagement with PLWH. Throughout the multi-year campaign, HIV-positive people of color, women, and current and former sex workers were authentically engaged in the work, thereby providing a uniquely qualitative aspect to an otherwise quantitative presentation of facts and figures. And as a direct result of their engagement throughout this movement, and scaffolding provided to ensure their success, PLWH engaged in this work were able to further develop their individual and collective capacities to shape and direct the future of HIV-specific policies.

Conclusions/Next steps: HIV criminalization remains the norm across the United States and in many parts of the world. Where it is safe to do so, PLWH are uniquely positioned to lead and facilitate transformative conversations with community members as well as lawmakers. Beyond the decriminalization movement, the California example shows that people living with HIV are best positioned to reform policies and laws that impact them most.

TUAD0203

Step by step: Ending unjust HIV criminalization in Canada through community advocacy based on science and rights

R. Elliott[1,2], N. Caivano[1,2], C. Kazatchkine[1,2], A. McClelland[2,3], C. Clarke[4], L. Pelletier-Marcotte[5,6], N. Self[7,8], V. Nicholson[7,8]
[1]*Canadian HIV/AIDS Legal Network, Toronto, Canada,* [2]*Canadian Coalition to Reform HIV Criminalization, Toronto, Canada,* [3]*Concordia University, Montreal, Canada,* [4]*Canadian Coalition to Reform HIV Criminalization, London, Canada,* [5]*Coalition des Organismes Communautaires Québécois de lutte contre le Sida, Montreal, Canada,* [6]*Canadian Coalition to Reform HIV Criminalization, Montreal, Canada,* [7]*Positive Living Society of British Columbia, Vancouver, Canada,* [8]*Canadian Coalition to Reform HIV Criminalization, Vancouver, Canada*

Background: Canada has the third-largest number of recorded criminal prosecutions for alleged HIV non-disclosure in the world. There is no HIV-specific criminal law. *Aggravated sexual assault* is the charge most commonly laid; conviction carries a maximum penalty of life imprisonment and mandatory registration as a sex offender. In cases where no transmission has occurred, people have been convicted even when they used a condom or had an undetectable viral load, or solely on the basis of oral sex.

Description: Canadian advocates have long pursued multiple strategies to combat unjust prosecutions, including court interventions, lobbying for prosecutorial guidelines, mobilizing scientific experts, and building feminist critiques of HIV criminalization. In 2015, the country-wide Canadian Coalition to Reform HIV Criminalization (CCRHC, www.HIVcriminalization.ca) was created, including advocates with lived experience of HIV criminalization. In May 2017, CCRHC organized a think tank to discuss pros and cons of *Criminal Code* amendments as a strategy in a legal context of no HIV-specific law and the wide interpretation of sexual assault law. CCRHC developed a Community Consensus Statement on HIV criminalization through a countrywide consultation process. Endorsed by over 150 organizations, the statement was released shortly before World AIDS Day 2017.

Lessons learned: Engaging in multiple strategies, adapting advocacy to the changing political landscape and involving people with lived experience are essential. On December 1, 2017, the Ontario Attorney General issued a directive to prevent prosecutions in that province in cases where a person accused of non-disclosure had a "suppressed viral load" (< 200 copies/ml) for six months. The federal Justice Minister issued a report going further, recommending the criminal law should also not apply when people are on ARV treatment, use condoms, or engage only in oral sex (unless aware of other risk factors present).

Conclusions/Next steps: Although significant, these steps are insufficient to end unjust criminalization in Canada. Advocates must continue to seek concrete actions from both levels of government to implement the Community Consensus Statement recommendations. These include: amending the *Criminal Code* to remove or limit the use of sexual assault charges; better prosecutorial guidelines; and training for judges and other actors in the criminal justice system.

TUAD0204

Marginalized women living with HIV at increased risk of viral load suppression failure: Implications for prosecutorial guidelines regarding criminalization of HIV non-disclosure in Canada and globally

A. Krüsi[1,2], K. Deering[1,2], F. Ranville[1], L. Gurney[1], M. Braschel[1], B. Simpson[1], M. Kestler[3], K. Shannon[1,2], SHAWNA Project Team
[1]*Gender and Sexual Health Initiative, Vancouver, Canada,* [2]*University of British Columbia, Faculty of Medicine, Vancouver, Canada,* [3]*Oak Tree Clinic, BC Women's Hospital, Vancouver, Canada*

Background: The criminalization of HIV non-disclosure continues to supersede human rights and public health imperatives in many settings globally. Canada stands out in its assertive approach to criminalizing HIV non-disclosure, despite recent recommendation by the Federal Government to limit prosecution of HIV non-disclosure cases. In some jurisdictions, such as Ontario, Canada, prosecutorial guidelines limiting prosecution to people living with HIV who do not have a sustained suppressed viral load for six months have been implemented.

We examined factors correlated with not meeting this legal test of achieving sustained viral suppression for 6 months among women living with HIV (WLWH) in Vancouver, Canada.

Methods: Prospective data (2010-2016) were drawn from SHAWNA (**S**exual health and **H**IV/**A**IDS: **W**omen´s Longitudinal **N**eeds **A**ssessment). SHAWNA is a community-based participatory open cohort study with WLWH (cis and trans women) who access HIV services in Metro Vancouver; the cohort includes data linkages to comprehensive HIV clinical monitoring. Participants completed semi-annual interviewer administered questionnaires and visits with a study nurse. Multivariable logistic regression using generalized estimating equations (GEE) was used to prospectively model correlates of viral load suppression failure over a seven-year period.

Results: Of 277 WLWH (Median age 43) 61% would not meet the legal test of achieving sustained viral suppression for at least one six-month period over the seven year follow up. Over half of participants (58%) identified as Indigenous, 33% identified as White and 9% identified as African/Caribbean/Black. In multivariable GEE analyses, younger age (AOR:0.97 per year older, 95%CI:0.95-0.99), recent homelessness (AOR:1.89,95%CI:1.30-2.75), recent sex work (AOR:1.88,95% CI:1.38-2.55) and recent incarceration (AOR:2.17,95%CI:1.15-4.10) were correlated with increased odds of viral load suppression failure.

Conclusions: These findings highlight that approaches exempting people from criminal liability for HIV non-disclosure, conditional on maintaining an undetectable viral load for 6 months, continue to put a large proportion of WLWH in Canada at risk for criminal prosecution. Those at highest risk of prosecution are the most marginalized WLWH, including those who are younger, unstably housed, sex workers and those who have been recently incarcerated. Further action to limit the criminalization of HIV non-disclosure is urgently needed.

TUAD0205

How punitive laws have encouraged human rights violations and increased HIV/AIDS transmission among gays and other men who have sex with men in Nigeria

C. Chiaha
International Centre for Advocacy on Right to Health, Human Rights Unit, Abuja, Nigeria

Background: HIV infection has been on the increase among gays and other men who have sex with men (MSM) in Nigeria where same sex relationships are criminalised. Gays and MSM encounter legal barriers to access healthcare due to discrimination in healthcare facilities forcing many of them to go underground to save their faces, resulting in the spread of HIV/AIDS and STIs.
Again, organisations rendering services to this vulnerable groups reduced there publicity and stopped having group meetings but instead engaged in interpersonal one-on-one meetings with the target group for fear of being prosecuted under the Same Sex Marriage Prohibition Act (SSMPA) 2013, which prohibits same sex relationships including civil union/partnerships and even criminalises activities of organisations rendering any form of services to same sex persons in Nigeria, as provided in sections 4 and 5 of the Act.
Methods: The international Centre for Advocacy on Right to Health (ICARH) carried out documentation of cases of Human rights violations of LGBTI persons in ABUJA Nigeria from March 2011 till December 2017. ICARH also recorded data of Gays and MSM clients' inflow in its clinic within the same period. A total of 160 of these clients were interviewed at the entry phase using a structured questionnaire. These data were analysed using both descriptive and inferential methods to arrive at the results shown below.
Results: : ICARH recorded 160 cases of human rights violation from 2011 till date. These are: denial of medical services, forced HIV test, disclosure of HIV status, wrongful termination of employment arbitrary arrest. Of the 160 cases, 18 occurred between 2011 and 2012 while the most occurred between 2013 to 2017 when SSMPA was passed and signed into law. Analysis shows that 90% of the clients experienced denial of medical services in public healthcare facilities. New HIV infections among gays and MSM increased after the passage of the law. Clinical data from 2011 to 2012 shows only 30% of the clients tested positive while from 2013 to 2017 80% tested positive.
Conclusions: Need for high level stakeholders advocacy on the effect of discriminatory laws against sexual minorities in the fight against HIV/AIDS.

TUAD03 Lost in transition: Challenges in domestic financing for HIV and human rights

TUAD0301

How loss of PEPFAR support for outreach puts the 90-90-90 targets at risk: Results from a mixed methods evaluation in Kenya and Uganda

M. Qiu[1], L. Paina[2], D. Rodriguez[2], J. Wilhelm[2], H. Zakumumpa[3], C. Mackenzie[4], F. Ssengooba[3], E. Eze-Ajoku[2], S. Bennett[2]
[1]Johns Hopkins Bloomberg School of Public Health, International Health, Washington, United States, [2]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [3]Makerere University, School of Public Health, Kampala, Uganda, [4]Ipsos Kenya, Nairobi, Kenya

Background: PEPFAR recently implemented Geographic Prioritization (GP), where support for HIV services was prioritized according to disease burden at sub-national level. Central support (CS) units, due to lowest burden and prevalence, were intended to transition to government support. We share findings from a mixed methods evaluation of the GP in CS facilities in Kenya and Uganda, focusing on the implications for outreach and the 90-90-90 targets.
Methods: Our study draws from national level stakeholder interviews, longitudinal, in-depth case studies, and a cross-sectional facility survey. Qualitative respondents included government officials, facility staff, district/county health staff, implementing partners, and patients. Qualitative data were analyzed in Atlas.ti. Facility surveys were conducted in 230 facilities in Kenya and 262 facilities in Uganda. Each country's survey data were analyzed in Stata to compare facilities that report transition from PEPFAR support to those maintained.
Results: Findings indicate that outreach-related services in CS facilities in both Kenya and Uganda largely ceased due to loss of PEPFAR support at a high proportion of affected facilities. In Uganda, survey results found that the odds of discontinuing outreach was 26.3 times higher in CS facilities than in Maintenance. In Kenya, 39% of CS facilities and 36% of Maintenance reported discontinuing outreach services. Case study respondents in both countries frequently discussed loss of support for conducting community-based HIV testing (1st 90), loss of support for informal health workers to link new patients into care (2nd 90), and support for tracing defaulters (3rd 90). Respondents described various avenues of adapting, including piggybacking HIV-related outreach onto other funded outreach activities such as immunization, while noting that government support has not been forthcoming.
Conclusions: Early results indicate that loss of PEPFAR support for outreach-related services may be hindering efforts across the treatment cascade in CS regions in both Kenya and Uganda. Despite low prevalence and burden of HIV, decreased outreach may compound local contextual factors such as poor infrastructure and high stigma that limit access to care. Decreasing outreach across facilities raises concern for countries' ability to reach their 90-90-90 goals as health facilities' links into communities are lost.

TUAD0302

What shall be done if donor funding to fight HIV drastically decreases. Transition to sustainable funding of social care services for PLHIV through regional budgets in Ukraine

I. Kovalchuk
All-Ukrainian Network of PLWH, Advocacy, Kyiv, Ukraine

Background: From 2004 to 2015, social care services for over 60,000 people living with HIV (PLHIV) in Ukraine have been funded by the Global Fund to Fight AIDS, Tuberculosis and Malaria (GF) and other donors. State and regional budgets did not provide funding for social care services for PLHIV. As donor funding is projected to decrease drastically in 2020 according to the agreement between the GF and Ukrainian government, ways and mechanisms of funding of essential social services had to be developed and implemented to allow for domestic funds from state and regional budgets to substitute donor funds.
Description: In 2017 All-Ukrainian Network of PLHIV has designed a portfolio of interventions aimed at creating environment for regional budgets funding of social care services for PLHIV.
Those interventions included development of regional policies to include funding for social services for PLHIV in regional targeted and integrated programs covered by regional budgets. This allowed development of mechanisms for direct purchases of social care services from regional NGOs through the system of electronic public procurement. The first group of services to benefit from this mechanism is social support for PLHIV.
Lessons learned: Proactive role of NGOs can ensure sustainability of vital social care services for PLHIV and implement the plan for the transition from donor funding to domestic regional funding. Direct purchasing is the optimal mechanism to be used by the government sector to procure social care services as it allows engaging NGOs.
In 2017, after new regional policies introduction, 10 regions allocated funding in amount of $60.251 in total from regional budgets for purchases of social care services for PLHIV delivered by regional NGOs.
Funding in amount of $126,423 for procurement of social care services for PLHIV in 7 regions is already allocated in 2018.
Furthermore, approx. $143,857 in 8 regions are planned in 2018 as well.

Conclusions/Next steps: Interventions made by All-Ukrainian Network of PLHIV allowed creating environment for transition to sustainable funding of social care services for PLHIV through regional budgets.
Final target is to cover 100% of regions of Ukraine and provide funds needed for social care services for PLHIV from state and regional budgets.

TUAD0303

Development of impactful advocacy arguments for domestic investments in HIV response among key population: Experience from EECA region

I. Varentsov[1], G. Dovbakh[1], L. Serebryakova[2]
[1]Eurasian Harm Reduction Association, Vilnius, Lithuania, [2]Caucasus University, Tbilisi, Georgia

Background: Donors funding for HIV in low and middle-income countries is decreasing, especially in EECA region. Governments are more likely to invest in HIV drugs procurement, than in prevention services. The following trends have been observed: funding for HIV programs was reduced, share of NGO-based services for key populations was decreased and overall, meaningful involvement of the communities was diminished. Disruptions in services became common. Role of communities to advocate for domestic funding is vast and information about arguments that work or fail in this process is important to multiply the effect.
Description: Based on the systematic analysis of case studies, experiences and data accumulated as a result of regional advocacy programs Eurasian Harm Reduction Association has developed a systematic approach to arguments used for national and sub-national advocacy. Each sub-group of arguments has different research data requirements and can be used to plan effective advocacy campaigns for domestic investment in HIV.
Lessons learned: Advocacy arguments and their impact for HIV investments can be grouped as following:
- Services for key populations as basic human rights: this argument in EECA does not work because of low political support to human rights values.
- Service funding gap and other cost estimation exercises: is often requested, but rarely used for public budgeting proposes, which are constructed using historical costing models. However, availability of arguments strengthened by budget/cost figures positively impacts the image of the community and gives them access to policy discussions of HIV program budgeting.
- International or donor requested commitments/conditionality for domestic funding: those prove to be effective only in case of strong watchdoging from local communities.
- Potential cost saving impact of prevention versus treatment: there is a limited local data to strengthen arguments, and health authorities are more favourable and trustful towards funding services in healthcare facilities (often publicly owned), rather then hard-to-measure prevention activities.
Conclusions/Next steps: Regional and national advocacy for sustainable HIV funding from domestic sources lacks not only capable and trained advocates, but also a systematic approach to advocacy argument and targeted evidence-collection.

TUAD0304

Challenges in implementing domestic funding policies for HIV prevention for key populations

S. Talawat[1], R. Rahman[2], P. Panitchpakdi[2]
[1]Raks Thai Foundation, Program, Phayathai, Thailand, [2]Raks Thai Foundation, Bangkok, Thailand

Background: The policy of domestic funding for HIV prevention for key populations in Thailand aims to strengthen the national AIDS strategies for ending AIDS by 2030 by using RRTTR approaches. It began in the fiscal year of 2016. The funding allocates 200 million baht per year.
Description: In 2016, the domestic fund was mainly allocated to health care services nationwide though it intended to engage CSOs & NGOs in the response. The fund could not be given to CSO due to the limitations of the National Health Security Act. However, with the Article 44 of the National Council for Peace and Order (NCPO), CSOs were made eligible to access this fund to implement HIV prevention services in 2017. As it is the first year that the NHSO can directly signed contact with CSOs, there were many challenges and lessons learned in establishing a well-functioning system for the country. Through this process, all gaps and barriers were reflected to the policy makers as well as the recommendations for further improvement.
Lessons learned: Clear guidelines of fund management, financial regulation, and the sharing of information is very important in bridging policy to practice. Close monitoring networks with tangible collaboration of key stakeholders can shape meaningful policy.
Conclusions/Next steps: The challenges of 2017 serve as good guidance for establishing a mechanism for domestic funding of HIV prevention initiatives. NHSO has developed a manual for implementing and managing the HIV Prevention Fund.

TUAD0305

Assessing and overcoming human rights-related barriers to HIV in 20 countries

R. Jürgens[1], H. Lim[1], A. Iovita[1], D. Burrows[2], R. Armstrong[3], A. Stangl[4], S. Gruskin[5], L. Ferguson[5], S. Baral[6], C. Lyons[6], N. Poku[3], C. Schutte[3]
[1]The Global Fund to Fight AIDS, TB and Malaria, Community, Rights and Gender Department, Geneva, Switzerland, [2]APMG Health, Sydney, Australia, [3]HEARD, Johannesburg, South Africa, [4]ICRW, Washington DC, United States, [5]University of Southern California, Institute for Global Health, Los Angeles, United States, [6]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States

Background: Stigma and discrimination, gender inequality and other human rights-related barriers continue to impede access to HIV services and attainment of global HIV goals. Despite UN member states´ commitments to support programs known to reduce these barriers, the programs have nowhere been sufficiently scaled up. A five-year initiative of the Global Fund to Fight AIDS, TB and Malaria aims to change this, first by assessing human rights-related barriers to HIV services and then supporting and evaluating the scale-up of evidence-based programs to reduce those barriers.
Description: An extensive consultation identified 20 countries for this effort - Benin, Botswana, Cameroon, Côte d'Ivoire, DR Congo, Ghana, Honduras, Indonesia, Jamaica, Kenya, Kyrgyzstan, Mozambique, Nepal, Philippines, Senegal, Sierra Leone, South Africa, Tunisia, Uganda and Ukraine. In each country, research teams assessed existing barriers to HIV services and effectiveness of programs to address them, but also what programs and interventions will be required over a five-year period to comprehensively address barriers. Retrospective costs of existing services were estimated, as were prospective costs of the proposed comprehensive response.
Lessons learned: Results of the assessments confirmed that human rights-related barriers continue to impede access to services for many. Few effective programs are being funded to address these barriers, undermining access to services and representing a serious gap in the HIV response. Even where laws and policies on the books seemingly protect key and vulnerable populations, practices by law enforcement agents and health care providers continue to subject people to discrimination and violence. There is an urgent need to significantly scale up UNAIDS' seven key interventions to reduce stigma and discrimination and increase access to justice, which, when implemented strategically, will increase uptake of and retention in services. Substantially larger investment in these programs will be needed, but the expected benefits are great.
Conclusions/Next steps: Multi-stakeholder consultations in the 20 countries are finalizing five-year plans to scale up programs to reduce rights-related barriers to HIV services, with intensive evaluation and costing of programs over that period. The programmatic experience of this initiative will provide unprecedented, well-evaluated and soundly costed models for rights-based approaches to HIV services for years to come.

TUAD04 Time for transformation: Listening to trans voices

TUAD0401

Data, stories, advocacy, leadership: The positively trans approach

B. McBride, C. Chung
Transgender Law Center, Positively Trans, Oakland, United States

Background: In 2014, Transgender Law Center launched Positively Trans, the first program to focus specifically on increasing advocacy and empowerment by and for transgender people living with HIV, especially transgender women of color living with HIV. Through a series of dynamic and innovative approaches, Positively Trans works to increase the capacity of transgender people living with HIV to advocate for their care, their lives, and the livelihoods of their communities.

Description: Positively Trans works with four key points in mind: data, stories, advocacy, and leadership. For data, Positively Trans completed a national needs assessment of transgender people living with HIV in 2015, which resulted in three reports, focusing primarily on social determinants of health. Positively Trans has facilitated a series of Digital Storytelling Workshops, in which transgender people living with HIV learn the story-telling and technical skills to create their own digital story. Data and stories are brought together in innovative ways to create new strategies by transgender people living with HIV to fight for self-determination in health care and in policy. Positively Trans also works with a National Advisory Board of transgender people living with HIV, mostly transgender women of color living with HIV, who are each leaders in advocacy in their local communities, to build their leadership skills and capacities and provide technical assistance.

Lessons learned: An intersectional approach that focuses on building leaders from within specific communities, combined with evidence- and story-based advocacy, is effective in organizing transgender people living with HIV organizing for their own health, well-being, and self-determination. Members of the National Advisory Board have started their own organizations for transgender people living with HIV and have been able to connect transgender people to the services they need and fight for better policies on a local, state, and national level.

Conclusions/Next steps: The conversation in the United States on HIV has been shifted by Positively Trans to include transgender people at a national level, including Positively Trans's collaboration on federal skill building projects. Next steps include exploring if Positively Trans's approaches can be replicated in other countries and regions internationally and how they would need to change based on local needs.

TUAD0402

Addressing the needs of people with situational gender and ´sexual orientation´ in Tajikistan by HIV services

A. Sarang
SKOSH, Almere, Netherlands

Background: The Western European/North American (WE/NA) understanding of gender and sexuality reflected in the relevant LGBTQ/MSM vocabulary has become a dominant model shaping the global response to HIV. We often neglect other understandings of gender and sexuality that differ from this dominant model. Consequently, HIV programs do not adequately address the needs of individuals outside of the LGBTQ/MSM paradigm. Anthropological research explores the understanding of gender and sexuality in Tajikistan among people with situational gender and ´sexual orientation´.

Methods: The study employed ethnography and historical analysis. The later was done through literature review of concepts of gender and sexuality in the Persian/Tajik tradition affected by the Russian colonization and Sovietization. The ethnographic fieldwork (2016) employed participant observations, 17 interviews and a focus group. The transcripts were coded in MaxQDA11 and analyzed thematically. The decolonial optics were applied as the theoretical framework.

Results: Literature reveals rich homo-erotic tradition in the Persian/Tajik culture and understanding of gender and sexuality based on a "gender/sexuality conflation model" (when gender is defined by the position in sex, rather than the biological sex). Unlike in the WE/NA "gay model", an individual is not required to adhere to a solid inflexible gender and "sexual orientation" identity. People with variable gender find it difficult to decide which identity slot offered by the western vocabulary they should fit in. They are not "MSM" or „gay" as they often identify as women while having sex. They also don´t identify as "transgender women," and in the conservative Tajik society, they prefer to stick to male social roles without manifesting their female selves. The identity problem messes up with sentinel surveillance/indicators, also based on the WE/NA vocabulary that people don't understand.

Conclusions: The results problematize usage of 'universal identity language' in designing the HIV interventions. Eg., in some contexts, the WHO recommendation to separate services for trans* people from MSM is problematic as there is no clear divide. The new requirements/indicators may lead to aggravation of stigma and homo/transphobia. These problems should be given a better thought and be better reflected in international guidelines stressing the importance of local concepts and identity language.

TUAD0403

Breaking the wall: Transgender people and Islamic religious leaders

E. Kor
Public Health and Welfare Organization, EXCO, Kuala Lumpur, Malaysia

Background: Malaysia is a predominantly Muslim majority country, where Islam has an influential role in society, policies and law. Transgender people in Malaysia are often stigmatised and discriminated against; in the past this has been exacerbated by words and actions of some Islamic religious leaders. This creates distrust and tension between the transgender community and religious leaders, both of which are stakeholders in HIV prevention. For many transgender people in Malaysia, faith acts as an important coping mechanism and being excluded from their religion adds a further layer of isolation, which need not be the case.

The purpose of this project is to minimise the schism between Islamic religious leaders and Muslim transgender people in Kuala Lumpur, engage in dialogue to rehumanise transgender people.

Description: This was a grassroots unfunded project undertaken by PKKUM, a local NGO based in Kuala Lumpur, Malaysia. The initial engagement was with top level Islamic religious leaders via a written petition submitted to the Mufti, consisting of over 100 signatories from the transgender community. A pilot set of workshops were undertaken with these religious leaders and members of the transgender community, female sex workers, PLHIV and MSM comprising of more than 100 participants. This provided a safe space where all parties could share experiences, discuss areas of concern and engage in meaningful dialogue.

Lessons learned: There was a genuine willingness of all groups to engage with one another. A pivotal moment was when the Mufti personally apologised for the manner in which transgender people were treated in the past, a key step in bridge-building. There was an identification of the disparity in language terminology used and assurance that transgender people would be welcomed n the mosque.

One outcome of the project was that the Mufti subsequently gave a Friday sermon (khutbahs) to congregants, urging worshipers not to judge or stigmatise the transgender community.

Conclusions/Next steps: The role of Islamic religious leaders towards the transgender community has been seen as unhelpful, however this can be transformed to a positive influence, as advocates to counteract stigma and discrimination.

TUAD0404

Progressive Botswana court affirms that legal recognition of gender identity is at core of human dignity - transgender persons are fully entitled to constitutional protection

T.K. Esterhuizen
Southern Africa Litigation Centre (SALC), LGBTI and Sex Workers Rights Programme, Johannesburg, South Africa

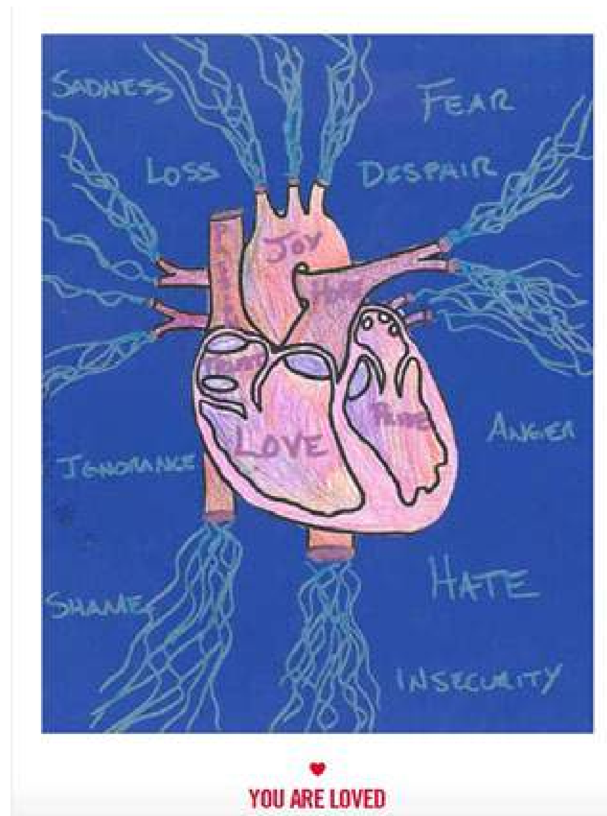
Background: For many transgender persons throughout Africa, obtaining an identity document that matches their expressed gender is virtually impossible. Without an identity document that reflects their gender, they are exposed to not only stigma and discrimination but ongoing distress when they are required to explain intimate details of their life to strangers to merely access routine services such as health care and treatment. However, the Botswana High Court recently took a significant step towards protecting the dignity of transgender people when it ordered the Registrar to change the gender marker on the identity document of a transgender man from female to male. The case also highlights advocacy and litigation strategies that LGBT activists and their lawyers can use to assert their basic rights, even within the most criminalised environments.
Description: The case was brought before the courts after sustained advocacy and legal strategy by brave LGBT activists, who publically sought the recognition of their constitutional and human rights. When meaningful engagement with the government of Botswana failed, a transgender man took his plight to the judiciary and has successfully sought to uphold the fundamental rights of LGBT persons throughout the country.
Lessons learned: The Court acknowledged that recognition of a person's gender identity constitutes the core of one's sense of being and is an integral (part) of a person's identity. Legal recognition of the gender identity is therefore part of the fundamental right to dignity and freedom to express oneself in a manner he or she feels comfortable with. The High Court emphasised that the State (and society) has a duty to respect and uphold the individual right to human dignity despite opposing and different views it might hold with regards to the applicant's gender identity.
Conclusions/Next steps: This legal recognition is an important step towards the realisation of the fundamental rights of transgender persons. However, much more work needs to be done to ensure the respect and recognition of the fundamental rights of transgender people in Botswana, including providing access to adequate gender-affirming treatment and care and the implementation of non-discriminatory healthcare, HIV policies, and employment and education policies.

TUAD0405

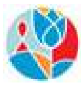
Developing and pilot testing TRANScending love, a multi-methods arts based workshop with African, Caribbean and Black transgender women

C.H. Logie[1], Y. Persad[2], T.B. Ferguson[3], S. Ryan[3], D.M. Yehdego[3], A. Guta[4]
[1]*University of Toronto, Toronto, Canada,* [2]*519 Community Centre, Toronto, Canada,* [3]*Black Coalition for AIDS Prevention, Toronto, Canada,* [4]*University of Windsor, Windsor, Canada*

Background: Transgender women's HIV vulnerabilities are shaped by contexts of social, economic and healthcare exclusion. In Canada, African, Caribbean and Black (ACB) women are also overrepresented in HIV infections; vulnerabilities are similarly shaped by social and structural inequities. There are a scarcity of HIV interventions developed by and for ACB transgender women in Canada who are at the nexus of ACB and transgender women's HIV disparities. We aimed to develop HIV intervention strategies with ACB transgender women in Toronto, Canada.
Description: This community-based study with an ACB AIDS service organization and ACB transgender women community leaders involved a focus group with ACB transgender women (n=8) to explore HIV prevention/care priorities. Findings were presented to a second focus group with ACB transgender community leaders (n=4) to brainstorm next steps. Focus group findings informed the development of the TRANScending Love (T-Love) arts-based workshop that included: 1) hand-held mirrors with glass markers to write messages of self-love, 2) anatomical drawings of hearts to write/draw emotional blocks and coping strategies, and 3) blank 'you are loved' affirmation cards to write messages to other ACB transgender women. We conducted 3 T-Love workshops with 18 ACB transgender women, workshops were followed by a focus group to examine art products and processes. Focus groups were digitally recorded and transcribed verbatim, and analyzed using thematic analyses.
Lessons learned: The first focus group highlighted ACB transgender women´s priorities were not HIV: participants called for researchers to address transgender women´s lack of self-love produced by social and structural exclusion, and to move away from the focus on transgender women´s sexual practices and bodies. The 2nd focus group articulated the need for strengths and arts-based approaches to build self-love and acceptance. Workshop participants described T-Love as empowering in documenting journeys to self-acceptance, and also in building connections and solidarity with other ACB transgender women.
Conclusions/Next steps: Findings highlight the potential for arts-based approaches to foster dialogue and reflection on individual and collective strengths among transgender women. We produced a 'deck' of T-Love cards and disseminated these online and in community forums. Findings can inform in-depth, sustained arts-based engagement to build self-love and community with ACB transgender women.



[Figure 1. TRANScending Love Arts-Based Research with African, Caribbean and Black Trans Women]



TUAE01 Taking testing to the next level

TUAE0101

The impact of performance-based financing on the delivery of HIV testing, prevention of mother to child transmission and antiretroviral delivery in the Cameroon health system

D. de Walque[1], P.J. Robyn[2], H. Saidou[2,3], G. Sorgho[2], M. Steenland[4]
[1]*The World Bank, Development Research Group, Washington, United States,* [2]*The World Bank, Health Nutrition and Population, Washington, United States,* [3]*University of Paris Dauphine, Economics, Paris, France,* [4]*Harvard University, Department of Global Health and Population, School of Public Health, Cambridge, United States*

Background: At scale provision of key services to persons living with HIV is challenging in low resources settings. Performance-based financing (PBF) is a complex health systems intervention aimed at improving coverage and quality of care. An impact evaluation was conducted in Cameroon seeking to isolate the role of specific components of the PBF approach on the delivery of three services at facility-level: HIV testing, prevention of mother to child transmission and antiretroviral delivery.
Methods: The evaluation used a cluster random design at the health facility level to separate the different components of the PBF approach. Facilities were randomly allocated in four evaluation groups to measure the effects of each component. Facilities in group T1 implemented the full PBF package: payments linked to results (quantity and quality of services) including bonus for health workers, management autonomy, enhanced supervision and monitoring. Facilities assigned to group C1 received a fixed per capita budgetary supplement that matches the per capita budgetary allocation for T1 facilities, but was not linked to performance. C2 facilities received no additional resources but the same supervision and monitoring as T1 and C1 facilities. C3 facilities were the 'business as usual' facilities and did not receive any additional resources or inputs. Facility register data documenting facility provision of HIV-related services was collected during a baseline and endline surveys and analyzed.
Results: We found large and statistically significant effects of both PBF and additional financing on HIV testing. An average of 61 more patients ($p< 0.01$) were tested for HIV in PBF facilities than control facilities, and 51 more patients (($p< 0.01$)) were tested monthly in the additional financing arm compared to the control. There was very little change in HIV testing in the additional supervision group, and the effect of PBF was greater than the effect of additional supervision ($p< 0.01$). However, we found no impacts on PMTCT and ART provision.
Conclusions: PBF increased the delivery of HIV testing. A similar improvement was however measured in the additional financing group, suggesting that the complex PBF mechanism might not necessarily add value, even though the comparison between both interventions is delicate.

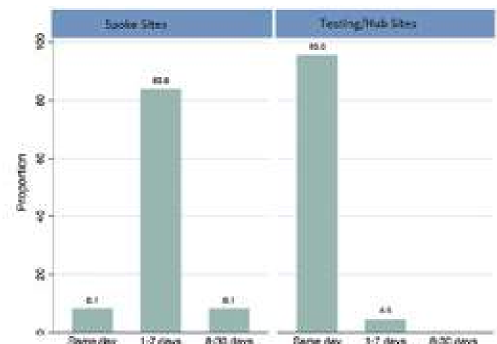
Diagnosing and treating more infants, faster: Findings from the first multi-country evaluation of routine point-of-care early infant diagnosis in eight sub-Saharan countries

F. Bianchi[1], R. Machekano[2], J.-F. Lemaire[3], E. Sacks[2], R. Bailey[3], V. Nzima[4], P. Fassinou[5], A. Mataka[6], C. Odhiambo[7], A. Chadambuka[8], G. Nyoni[9], M.C. Sabonete[10], G.F. Ndayisaba[11], J. Cohn[3]
[1]*Elizabeth Glaser Pediatric AIDS Foundation, Strategic Information and Evaluation, Washington, United States,* [2]*Elizabeth Glaser Pediatric AIDS Foundation, Research, Washington, United States,* [3]*Elizabeth Glaser Pediatric AIDS Foundation, Geneva, Switzerland,* [4]*Elizabeth Glaser Pediatric AIDS Foundation, Yaounde, Cameroon,* [5]*Elizabeth Glaser Pediatric AIDS Foundation, Abidjan, Cote D'Ivoire,* [6]*Elizabeth Glaser Pediatric AIDS Foundation, Maseru, Lesotho,* [7]*Elizabeth Glaser Pediatric AIDS Foundation, Nairobi, Kenya,* [8]*Elizabeth Glaser Pediatric AIDS Foundation, Harare, Zimbabwe,* [9]*Elizabeth Glaser Pediatric AIDS Foundation, Mbabane, Swaziland,* [10]*Elizabeth Glaser Pediatric AIDS Foundation, Maputo, Mozambique,* [11]*Elizabeth Glaser Pediatric AIDS Foundation, Kigali, Rwanda*

Background: Point-of-care early infant diagnosis (POC-EID) may improve the care of HIV-exposed infants compared to conventional testing. POC-EID is being implemented in eight sub-Saharan African countries at POC ("testing") and near-POC ("spoke") sites. A program evaluation was undertaken to assess the impact of POC- or near POC-EID implemented as part of routine care, compared with conventional testing.
Methods: Using a pre-post intervention design, key EID outcomes were compared in each country. Pre-intervention conventional EID data were collected retrospectively from registers across a purposively sampled sub-set of sites. Post-intervention data for specimens processed between December 2016 and December 2017 were collected prospectively using a POC-EID testing form. Median turnaround times (TATs) were compared using Wilcoxon rank-sum test, and proportions with Pearson chi-square test. Kaplan-Meier Estimator was used for the proportion of caregivers who received results within 30 days of sample collection. Prospective data were analyzed by entry point and compared between testing/hub and spoke sites. The cost per test result returned was calculated using Global Fund's total cost of ownership estimates for POC and conventional EID.
Results: POC-EID resulted in a significantly higher percentage of results returned to caregiver and percentage of infants started on treatment sooner, as compared to conventional EID (Table 1). There were no significant differences in percent results returned between testing and spoke sites (Figure 1).

	Conventional EID	POC-EID	p-value
% Results received by caregiver within 30 days	21.18%	99.13%	p<0.001
Median TAT from blood sample collection to result returned to caregiver	55 days (IQR: 31-76)	0 days (IQR: 0-1)	p<0.001
% HIV-infected infants started on treatment	67.33%	90.6%	p<0.001
Median TAT from result returned to caregiver to ART initiation for HIV-infected infants	0 days (IQR: 0-4.5)	0 days (IQR: 0-1)	NS
Median TAT from blood sample collection to ART initiation for HIV-infected infants	49.5 days (IQR: 32-68)	0 days (IQR: 0-2)	p<0.001

[Table 1: Comparing conventional and POC EID on primary service delivery outcomes]



[Figure 1: Distribution of POC in testing/hub and spoke sites by median turnaround time from sample collection to results received by caregivers]

Valid, non-confirmatory tests from different entry points revealed 3.2%, 19.6%, 15.5%, and 2.5% HIV-positivity rates from prevention of mother-to-child transmission entry points, pediatric inpatient, outpatient, and vaccination clinics, respectively. The cost per test result returned (regardless of TAT) was $20-38 for POC and $21-33 for conventional.

Conclusions: Routine use of POC-EID in sub-Saharan Africa is feasible and significantly improves key patient outcomes. Spoke sites can expand access to POC-EID, with minimal differences in patient-level outcomes. POC-EID is particularly important for high-yield entry points such as pediatric wards, where patients may be less likely to receive results from conventional testing with long TATs. Given similar costs per test result returned to caregiver for conventional testing, POC-EID represents an efficient and effective way to identify HIV-infected infants and initiate antiretroviral treatment.

TUAE0103

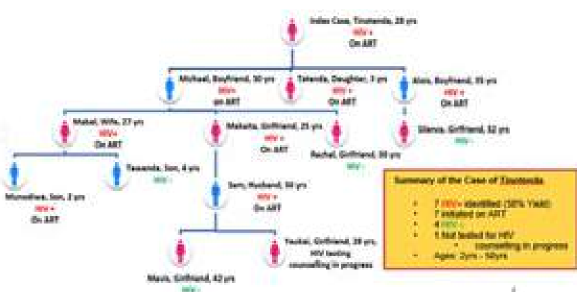
Improving technical efficiency: Reaching first 90 through community index HIV sexual network testing in Zimbabwe. The case of FHI 360 Zimbabwe

A. Muchedzi[1], N. Mahachi[1], T. Moga[1], T. Tafuma[1], P. Mawora[1], D. Harbick[2], T. Nyagura[3], K. Reichert[3]
[1]FHI 360, Technical, Harare, Zimbabwe, [2]FHI 360, Harare, Zimbabwe, [3]USAID, Harare, Zimbabwe

Background: Zimbabwe has made huge progress towards the UNAIDS first 90 target; 74.2% of people living with HIV know their status: with less men-69.7% compared to women-77.1% knowing their status. Reaching the remaining 16% and men is challenging and requires innovative approaches with technical efficiencies. FHI360 is responding with community HIV-index-testing; an approach which involves tracking down sexual contacts of HIV+ index-cases identified at health facilities.

Description: Since October 2016, FHI360 through a strengthened community health system comprising: a team of trained nurses and community cadres working in collaboration with health facilities identifies HIV+ index-cases. The community cadre obtains consent from the index-cases, makes appointments and prepares the household for a visit by the nurse. The nurse provides HIV-testing and other health services to children and primary sexual contacts of the index-case at the household. With consent from the index-case the nurse tracks and tests other sexual partners and the sexual network as illustrated in Figure 1.

Lessons learned: Between October 2016 and September 2017, 14,818 HIV+ index-cases were identified from 330 health facilities and followed to 12,865 households for community index-testing. In the community, 22,147 people were HIV tested, 8,367 (38%) were HIV+, and 5,771 (69%) were linked to care and treatment. FHI360's community index-testing has an average HIV yield rate 10 times more than the health facility yield rate (4%). The case in Figure 1 is one of the many sexual network testing conducted where several PLHIV are identified. In this case 7 PLHIV were identified from one index-case. FHI360 has reached 11,754 men with HIV testing services of which 6,127 (72%) were between 25-49 years



[Figure 1. FHI360 Sexual Network Testing as a part of Community Index Testing in Zimbabwe: The case of Tinotenda]

Conclusions/Next steps: FHI360 achieves and sustains a high yield among individuals tested for HIV using the community HIV index-testing model. This model is reaching people living with HIV who would not ordinarily access HIV testing services (HTS) from the conventional health facility HTS modalities. By going into the community, FHI360 is identifying a critical group of people who are living with HIV and facilitating their treatment initiation. FHI360 is leveraging its community platform to reach a high proportion of men of reproductive age with HIV services.

Cost-of-testing-per-new-HIV-diagnosis as a metric for monitoring cost-effectiveness of testing programmes in low income settings in Southern Africa: Health economic modelling analysis

Background: As prevalence of undiagnosed HIV declines, it is unclear whether testing programmes will continue be cost-effective. The cost-of-testing-per-new-HIV-diagnosis is a potentially useful metric for monitoring country programmes.

Methods: We simulated 1000 setting-scenarios for adult HIV epidemics and ART programmes typical of southern Africa using an individual-based model, and projected 50 years from 2018, during which a minimum package of "core" testing in pregnant women, for diagnosis of symptoms, in sex workers, and in men coming forward for circumcision was assumed to be conducted. For each setting scenario we compared this policy of core testing only with a policy of also having an additional programme of testing (in men only, women only, or both genders). For each setting scenario we randomly selected from various possible rates of testing and degrees to which those with HIV are more likely to test than those without, and considered a range of a unit costs.

Our aim was to asses the relationship between the cost-of-testing-per-new-HIV-diagnosis and the cost-per-DALY averted (the incremental cost-effectiveness ratio; ICER) of the additional testing programme. Cost-effectiveness of the programme was defined by an ICER below US$500. Discount rate 3%/annum.

Cost-of-testing-per-new-HIV-diagnosis (2018-2023)*	Percent of setting-scenarios in which testing programme is cost effective	Median ICER over setting-scenarios
< $50	94%	$189
$50 - $100	95%	$215
$100 - $200	91%	$243
$200 - $300	89%	$288
$300 - $400	78%	$372
$400 - $500	58%	$463
$500 - $600	44%	$542
$600 - $700	29%	$623
$700 - $1000	21$	$704
> $1000 - $1500	2$	$1914
*not discounted; using $500 / DALY cost effectiveness threshold / results for other thresholds will be presented. 1000 setting scenarios.		

[Relationship between cost-per-new-HIV-diagnosis and incremental cost effectiveness ratio for testing programmes in men in low income settings in southern Africa]

Results: There was a strong relationship between the cost-of-testing-per-new-HIV-diagnosis and the ICER (illustrated for testing programmes in men in Table). In general, the ICER was below US$500 per DALY averted so long as the cost-of-testing-per-new-HIV-diagnosis was below US$315. Results were similar when we restricted to setting-scenarios with specific epidemic and programmatic features, such as prevalence of undiagnosed HIV, HIV incidence and the proportion of HIV diagnosed people with viral suppression. When the testing programme was restricted to testing in women beyond the core testing this was not cost effective. However, for over 50% of setting scenarios testing programmes in men were cost- effective when the cost-of-testing-per-new-HIV-diagnosis was < US$585 (and 80% when the cost-of-testing-per-new-HIV-diagnosis was < US$312), regardless of unit cost of testing.

Conclusions: The cost-of-testing-per-new-HIV-diagnosis can be used to monitor the cost-effectiveness of testing programmes. Programmes aimed at men in low income settings in southern Africa are likely to be cost-effective if they cost below US$585 per new diagnosis.

Facility-based HIV self-testing for outpatients dramatically increases HIV testing in Malawi: A cluster randomized trial

K. Dovel[1,2], M. Nyirenda[2], F. Shaba[2], O.A. Offorjebe[3,4], K. Balakaksi[2], B.E. Nichols[5,6], K. Phiri[2], A. Schooley[1,2], R.M. Hoffman[1], EQUIP Innovations for Health

[1]University of California, Division of Infectious Diseases, Los Angeles, United States, [2]Partners in Hope, Lilongwe, Malawi, [3]David Geffen School of Medicine at UCLA, Los Angeles, United States, [4]Charles R. Drew University of Medicine and Science, Los Angeles, United States, [5]Boston University School of Public Health, Department of Global Health, Boston, United States, [6]University of Witwatersrand, Health Economics and Epidemiology Research Office, Department of Internal Medicine, Johannesburg, South Africa

Background: HIV self-testing (HIVST) increases testing coverage in community settings in sub-Saharan Africa, but scalability is a challenge due to resource constraints. Outpatient departments provide an ideal space to integrate HIVST into low-resource health systems due to high client volume and long wait-times. We evaluated an HIVST intervention in outpatient waiting-spaces of hospitals and health centres in Malawi.

Methods: A cluster randomized trial was conducted at 15 health facilities in Central/Southern Malawi between September2017-January2018. Facilities were randomized 1:1:1:

(1) routine provider initiated testing and counseling (PITC);
(2) Optimized PITC (additional provider trainings and job-aids); and
(3) HIVST (including Oraquick HIV self-test® demonstration, distribution, and kit use in outpatient waiting-spaces, private spaces for interpretation, and optional post-test counseling).

The primary outcome was HIV-testing among outpatients. Exit surveys were conducted with a random sample of outpatients.

Results: 5,675 outpatients completed an exit survey. There were no differences by arm (Table). 52% of outpatients in the HIVST arm tested for HIV compared to 14% in Optimized PITC (AOR:6.6 p< 0.001) and 12% in PITC (AOR:7.6 p< 0.001). For HIVST, 60% of outpatients in need of testing (defined as tested> 12months ago and never tested HIV-positive) were tested compared to 18% in Optimized PITC and 16% in PITC. There was no significant difference in the proportion of clients tested who reported previously testing HIV-positive (≤ 1% for all arms). Positivity rates did not differ by arm, however, HIVST was associated with a higher absolute number of new positives identified compared to Optimized PITC (AOR:2.9, p=0.01) and PITC (AOR:4.1, p=0.002). Participants who were tested by HIVST were more likely to want to test again using the same method and more likely to recommend testing to others compared to those tested by Optimized PITC or PITC. No adverse events were reported in the HIVST arm.

	Arm 1: PITC	Arm 2: Optimized PITC	Arm 3: HIVST	Adjusted Odds Ratio* (95% CI)

[Table. Participant characteristics and outcomes across three arms of a HIVST study targeting outpatient clients (n=5,675)]

Conclusions: Facility-based HIVST in outpatient waiting-spaces dramatically increased HIV testing and identification of HIV-infected persons among outpatients in Malawi, with minimal risk for loss of confidentiality or adverse events. Analyses for linkage to care are underway. Evaluations of routine program implementation are needed to determine best strategies to take facility-based HIVST to scale.

Background: Some HIV-1 infected individuals durably control viremia after interruption of early ART (post-treatment controllers, PTC). The mechanisms associated with this phenomenon are unclear. Prevalence of HLA-B*35, associated with rapid progression without therapy, is high among PTC in the VISCONTI study. In contrast, HLA-B*27/57 alleles, associated with HIV-control, are not overrepresented in PTC. We investigated the association between HLA-B*35 and HIV remission.
Methods: CD4+ T-cell counts, plasma viral loads, PBMC-associated HIV-DNA levels were analysed in 245 HLA-typed HIV-infected individuals from the ANRS PRIMO cohort, on ART for at least 12 months since primary infection. HLA and KIR genotyping and NK cell analyses were done in PTC (n=10) from the ANRS VISCONTI study. Results were compared to HIV-infected (viremic, on cART, HIV-controllers) and non-infected individuals.
Results: In the PRIMO cohort, despite similar time since infection, HLA-B*35 individuals (B35, n=64) had lower CD4+ T-cell counts (median 398 cells/mm3, p=0.04) and higher HIV-DNA level (median 3.53 $\log_{10}$ HIV-DNA copies/million PBMC, p=0.046) than HLA-B*27/57 (B27/57, n=21, 543 cells/mm3 and 2.88 $\log_{10}$ HIV-DNA copies) individuals or those carrying other HLAs (others, n=160, 481 cells/mm3 and 3.44 $\log_{10}$ HIV-DNA copies) at the time of treatment initiation. After a similar period on ART (~5 years) the only difference was B27/57 having lower HIV-DNA levels (median < 1.7 $\log_{10}$ vs 2.5 and 2.3 for B35 and others, p=0.01). Among those interrupting the treatment, B35 were more likely to maintain viral control than B27/57 or others (p=0.01). B35 who controlled HIV carried more frequently KIR ligands Bw4 or C2/C2 (f=0.8, p=0.04) than B35 not controllers (f=0.39). In the VISCONTI study, PTC also carried often the Bw4 epitope (f=0.85 vs 0.44 in non-infected controls, p=0.02) and had high prevalence of the KIR B haplotype (f=0.86 vs 0.4). Phenotypical differences and increased anti-HIV activity of NK cells were observed in PTC compared to other HIV-infected individuals (p=0.01).
Conclusions: Our results suggest that HLA-B*35 might favour post-treatment control, despite unfavourable primary HIV-infection, in some early treated individuals. This might be associated with the presence of KIR Bw4 and C2 ligands in the MHC of PTC, enrichment of KIR B genotype and optimal licensing of NK cells.

HCV treatment with direct-acting antivirals (DAAs) in HIV/HCV coinfected subjects affects the dynamics of the HIV-1 reservoir

Y. Ghiglione[1], M.L. Polo[1], A. Solomon[2], G. Poblete[3], M.J. Rolón[3], P. Patterson[4], H. Pérez[3], H. Salomón[1], F. Quiroga[1], G. Turk[1], S.R. Lewin[2,5], N. Laufer[1]
[1]INBIRS Institute (UBA-CONICET), Buenos Aires, Argentina, [2]The University of Melbourne, Peter Doherty Institute, Melbourne, Australia, [3]Hospital Fernández, Infectious Diseases Unit, Buenos Aires, Argentina, [4]Huésped Foundation, Buenos Aires, Argentina, [5]Alfred Health and Monash University, Department of Infectious Diseases, Melbourne, Australia

Background: The effect of direct acting antiviral (DAA) agents for hepatitis C virus (HCV) on the HIV reservoir in co-infected individuals is not completely understood. We hypothesized that cure of HCV would reduce persistent interferon (IFN) signaling and would have downstream effects on the frequency of infected cells and their basal transcriptional activity.
Methods: Nineteen HIV/HCV coinfected individuals on suppressive ART were treated for HCV with sofosbuvir/daclatasvir±ribavirine (12-24 weeks). Blood samples were obtained at enrollment, immediately before HCV treatment (baseline sample, BSL) and at end-of-treatment (EOT) for HCV. HIV-monoinfected individuals on at least one year of ART were included as controls. Cell-associated HIV DNA (total, integrated, 2LTR) and unspliced (US) and multiply spliced (MS) RNA were quantified by real-time PCR. Data was analyzed using non-parametric statistics. CD4 and CD8 cell frequency was determined by flow cytometry.
Results: In the HIV/HCV coinfected group, 79% were male (mean age=49±5.9 years old). The mean times of HIV and HCV diagnosis were 16.2±4.8 years and 13.5±7.3years, respectively. Median CD4+ T-cell count at enrollment was 291 cells/µL (IQR 231-776). All were under cART with undetectable HIV VL. Among the control group, 82% were male, with median CD4+ T-cell count=612 cells/µL (IQR476-863). US HIV RNA was significantly higher in CD4+ T-cells collected at EOT compared to BSL (p=0.01). HIV/HCV individuals had higher US HIV RNA at BSL (p=0.09) and EOT samples (p=0.005), compared to HIV-only individuals, There were no statistically significant differences in HIV MS RNA, 2LTRs or total and integrated HIV DNA between EOT and BL or between HIV/HCV and HIV-only individuals. At EOT compared to BSL, HIV/HCV subjects had significantly higher CD4/CD8 ratios (0.42 (IQR 0.29-0.71) versus 0.50 (IQR 0.31-0.76), p=0.02). This was a result of an increase in $CD4^+$ T-cells but minimal change in $CD8^+$ T-cell counts.
Conclusions: HCV/HIV individuals showed higher levels of HIV unspliced-RNA than HIV monoinfected individuals and this difference was even greater after HCV clearance with DAAs. Thus, HCV clearance, or related downstream effects impact HIV persistence on ART. These changes are consistent with reduced basal transcription in latently infected cells post-HCV clearance which could be secondary to reduction in chronic IFN signaling.

TUPDA0103

IL-10 contributes to, and is a biomarker for, viral persistence in ART-treated, SIV-infected rhesus macaques

J. Harper[1], S. Ribeiro[2], M. Pino[1], L. Micci[1], M. Aid[2], C. Deleage[3], E. Rimmer[4], G. Ayanoglu[4], D. Gorman[4], J. Estes[5], R. Sekaly[2], M. Paiardini[1,6]
[1]Emory University, Atlanta, United States, [2]CASE Western Reserve University, Cleveland, United States, [3]Frederick National Laboratory for Cancer Research, Frederick, United States, [4]Merck Biologics Discovery, San Francisco, United States, [5]Vaccine and Gene Therapy Institute, OHSU, Portland, United States, [6]Yerkes Nationale Primate Research Center, Atlanta, United States

Background: One of the main barrier to designing therapeutic strategies aimed at targeting HIV persistence is our incomplete knowledge of the mechanisms regulating the establishment and maintenance of the HIV reservoir, as well as the lack of biomarkers able to predict its size. Interleukin (IL)-10 is a critical component of the anti-inflammatory responses required to dampen the pro-inflammatory responses acti-

vated by the immune system after an encounter with a pathogen. IL-10 signaling reduces antigen presentation and increases T cell anergy, and IL-10 deficiency in mice prevented the persistence of pathogens normally inducing chronic infections. We hypothesized that IL-10 can lead to a status of immunosenescence and favor HIV persistence.
Methods: Fifteen RMs were infected with SIVmac$_{239}$ and started on cART at day 58 post-infection. cART was maintained for 7 months. Blood, lymph node (LN), and rectal biopsy (RB) were collected longitudinally for flow cytometric and DNAscope analyses. SIV-DNA content was quantified in CD4 T cell subsets, including Tfh. RNAseq analyses were performed on PBMCs.
Results: IL-10 *in vitro* stimulation significantly upregulated pathways involved in HIV persistence, including the expression of pSTAT3, PD-1 and CTLA-4, and histone deacetylases. In vivo, (i) IL-10 levels (plasma and LN) and IL-10 stimulated genes increase upon SIV infection and do not fully normalize with ART (p< 0.01); (ii) before ART, IL-10 and IL-10 stimulated genes levels significantly correlated with multiple markers of disease progression as well as the frequency of CD4$^+$ T-cells harboring SIV-DNA in blood, LN (including Tfh cells), and gut (p< 0.01); (iii) IL-10 levels and IL-10 stimulated genes at pre-ART predict the frequency of LN CD4$^+$ Tfh cells (p=0.0002) and SIV-DNA content in blood CD4 T cells (p=0.0218) and in RB (p=0.0383) after seven months of ART. Finally, among LN follicular SIV-DNA$^+$ cells, those IL-10$^+$ were more stable between the pre- and on-ART time points than their IL-10 negative counterpart, resulting in 85% of SIV-DNA$^+$ cells being IL-10$^+$ on-ART (p=0.0095).
Conclusions: Altogether, our data highlight IL-10 signaling as a mechanism of and a biomarker for viral persistence in ART-treated, SIV-infected rhesus macaques. Modulation of IL-10 represents a novel therapeutic avenue towards an HIV cure.

Background: B cells follicles are considered a site of ongoing viral replication during treated HIV infection due to the exclusion of cytotoxic CD8 T-cells. Recent work has demonstrated that follicular cytotoxic (CXCR5+CD8+) T-cells have the ability to migrate to B cell follicles and are important for HIV control. We investigate the frequency and phenotype of CXCR5+CD8 T-cells in gut-associated lymphoid tissue (GALT) during treated primary HIV infection (PHI) and examine the association with HIV reservoir.
Methods: Gut biopsy samples from terminal ileum (TI) and rectum were collected from HIV+ virally suppressed individuals enrolled in HEATHER, an observational study of treated PHI. Comparisons were made with biopsies from healthy controls (HC). Expression of CD3, CD4, CD8, CXCR5, PD-1, HLA-DR, CD38, Perforin, Granzyme B and Bcl-6 were assessed on gut and peripheral blood mononuclear cells (PBMC) cells by flow cytometry. Total HIV DNA was quantified by qPCR.
Results: GALT samples were analyzed from 21 HIV+ and 8 HC individuals. Longitudinal (baseline & 1-year) biopsies on ART were available for 10 individuals. CXCR5+CD8+ T-cells are found at significantly higher frequency in GALT compared to peripheral blood (mean 9.5% [95%CI 7.5-11.4%] vs. 2.1% [1.2-2.9%] respectively, p< 0.001. The frequency of CD8+CXCR5+ T-cells was similar in HIV+ and HC GALT tissue (TI p=0.76; rectum p=0.06). In the HIV+ group, no change in CXCR5+CD8+ T-cells in GALT was noted between baseline and & 1-year; higher frequency of CXCR5+CD8+ T-cells was observed in rectal tissue compared to TI (p=0.006). An inverse correlation between the frequency of CXCR5+CD8 T-cells and HIV-1 DNA was observed in TI (r=-0.6, p=0.01) but not in the rectum (r=-0.03, p=0.9). CXCR5+CD8+ T-cell percentage correlated with CD4/CD8 ratio (TI r=0.8, p< 0.0001; Rectum r=0.5, p=0.03) & T-follicular helper cell frequency (TI: r=0.5, p=0.03; rectum: r=0.5, p=0.02). Higher expression of Bcl-6, Perforin (p< 0.001), Granzyme B (p< 0.0001), HLA-DR (p=0.0003) and PD-1 (p=0.001) was observed on CXCR5+CD8+ compared to CXCR5-CD8 T-cells in HIV+ GALT.
Conclusions: Follicular CD8+ T-cells in HIV+ GALT persist on ART, exhibit greater cytotoxic potential than CXCR5-CD8 T-cells and may have a role in limiting HIV reservoir in terminal ileum during treated PHI.

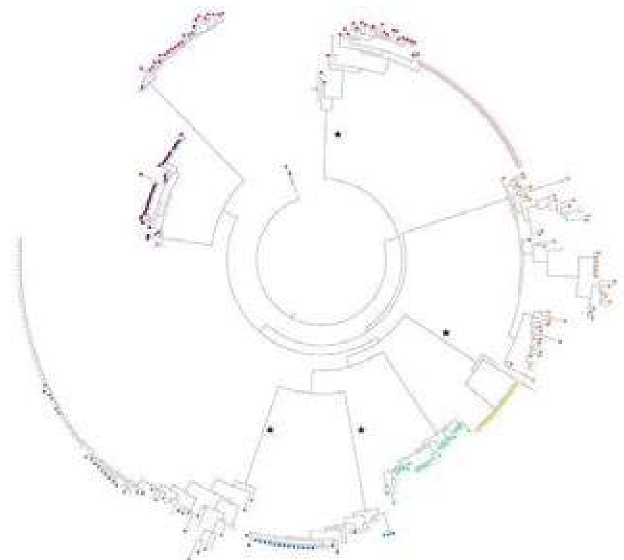
HIV-1 reservoir diversity and genetic compartmentalization in blood and testis

R. Ponte[1,2], R.L. Miller[3], N.N. Kinloch[3], F.H. Omondi[3], F.P. Dupuy[1,2], R. Fromentin[4], P. Brassard[5], V. Mehraj[1,2], N. Chomont[4], A. Poon[6], Z.L. Brumme[3,7], J.-P. Routy[1,2], The ORCHID study group
[1]The Research Institute of the McGill University Health Centre, Montreal, Canada, [2]Chronic Viral Illness Service, Montreal, Canada, [3]Faculty of Health Sciences, Simon Fraser University, Burnaby, Canada, [4]CR-CHUM and Université de Montréal, Montréal, Canada, [5]The Metropolitan Centre for Plastic Surgery, Montreal, Canada, [6]Western University, Department of Pathology and Laboratory Medicine, London, Canada, [7]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

Background: HIV latency is the main barrier to cure, but our knowledge of the genetic landscape of latent HIV genomes, particularly in immune-privileged sites, remains incomplete. Knowing that the testes constitute such a site, we characterize latent HIV diversity in testes and blood in HIV-infected individuals with suppressed viremia on cART.
Methods: PBMC and right/left testicular tissue samples were collected from 8 adults undergoing sex reassignment surgery who had maintained viremia suppression on cART for >6 months. HIV proviral Nef sequences were obtained via single-genome amplification. Phylogenies were reconstructed by maximum-likelihood (RAxML; GTR substitution model). PBMC HIV DNA levels were measured by qPCR; HIV adaptation to host HLA (determined via sequence-based typing) was inferred bioinformatically. Genetic compartmentalization was assessed using Wright's measure of population subdivision (F_{ST}) and Slatkin-Maddison (SM) tests.



[Figure 1. Maximum likelihood phylogeny of all intact PBMC and testis sequences collected, coloured by participant. Filled circles indicate PBMC sequences, open diamonds indicate sequences from the left testis and open squares indicate sequences from the right. Black triangles represent HXB2 and NL4-3 reference sequences. Participant HIV datasets that displayed significant genetic compartmentalization by both FST and SM tests are denoted with asterisks.]

Results: 377 Nef sequences were isolated from PBMC (n=235) and testes (n=142); of these 212/235 (90.2%) and 133/142 (93.7%) were intact/non-hypermutated (median 24 [IQR 21-33] PBMC and 8 [IQR 4-37] testis sequences/participant). Within-host proviral diversity varied markedly (median within-host patristic distance 2.06e^{-2} [IQR 8.30e^{-3}-5.43e^{-2}] substitutions/site), and total HIV DNA correlated with proviral diversity in

PBMC (Spearman rho=0.77, p=0.1). In some participants a single HIV variant dominated, while others harbored predominantly unique sequences. Proviral diversity in PBMC generally exceeded that in testis, but not significantly so (median within-host patristic distance $1.56e^{-2}$ vs. $1.26e^{-2}$ respectively, p=0.4); inferred HIV immune escape burden was also consistent between sites. Both F_{ST} and SM tests identified 4 of 8 participants as having significant HIV genetic compartmentalization between blood and testis (F_{ST} scores=0.89, 0.67, 0.29 and 0.22; all p< 0.05; SM all p< 0.05).
Conclusions: Latent HIV diversity varies widely between individuals; larger reservoirs tend to be more diverse. Detection of identical HIV sequences in blood and testis is consistent with migration of clonally-expanded descendants of latently HIV-infected cells throughout the body, including into immune-privileged sites. Detection of significant genetic compartmentalization between blood and testis in 50% of participants underscores the complexity of the proviral HIV landscape on cART, yet suggests that, at least in some individuals, blood proviral diversity may not be unrepresentative of overall reservoir diversity.

[1]Massachusetts General Hospital, Center for Global Health, Boston, United States, [2]Duke University School of Medicine, Durham, United States, [3]University of North Carolina, Chapel Hill, United States, [4]Mbarara University of Science and Technology, Mbarara, Uganda, [5]Massachusetts General Hospital, Chester M. Pierce, MD Division of Global Psychiatry, Boston, United States, [6]Harvard Medical School, Boston, United States, [7]Epicentre, Mbarara, Uganda, [8]University of Vermont, Department of Pathology & Laboratory Medicine, Burlington, United States, [9]University of Scan Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States, [10]Massachusetts General Hospital, Department of Medicine, Boston, United States, [11]Oregon Health & Science University, Portland, United States, [12]University of California, Department of Medicine, San Francisco, United States, [13]Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States

Background: Decreases in kynurenine/tryptophan (KT) ratio have been associated with decreases in depressive symptoms after initiation of antiretroviral therapy (ART); however, the relationship between depression and other markers of immune activation in persons with HIV (PWH) is less clear.
Methods: We analyzed data from 393 adult PWH in rural Uganda who were enrolled at ART initiation and observed every 3-4 months from 2005-2015. Our exposures of interest were change in levels of soluble CD14 (sCD14), KT ratio, soluble CD163 (sCD163), D-dimer, and interleukin-6 (IL-6) from before to six months after ART initiation. Our outcome of interest was probable depression, defined by a mean score >1.75 on the Hopkins Symptom Checklist depression subscale. We fit modified Poisson regression models and generalized estimating equations (GEE) Poisson regression models with cluster-correlated robust standard errors to respectively examine the relationship between: 1) pre-ART inflammatory marker levels and depression, and 2) 6-month change in marker levels and depression at follow-up visits within two years of ART initiation. Models were adjusted for pre-ART depression, year of ART initiation, and tuberculosis co-infection; and time-varying demographic characteristics, body mass index, smoking, alcohol use, CD4+ count, ART duration, viral suppression (≤400 copies/mL) and self-reported physical health.
Results: There were no statistically significant associations between levels of inflammatory markers and depression in the pre-ART period. However, in multivariable-adjusted GEE regression models, larger decreases in sCD14 and KT ratio from pre-ART to 6-months post-ART were associated with decreased risk of depression (Table, Figure). These associations remained qualitatively similar when additionally adjusted for 6-month change in the level of the other marker and when restricted to follow-up visits where the participant was virally suppressed. We estimated no statistically significant associations between sCD163, D-dimer, or IL-6 and risk of depression.
Conclusions: Greater decreases in sCD14 and KT ratio after ART initiation were independently associated with decreased risk of depression. This may suggest independent sCD14 and KT-mediated pathways leading to depression in PWH and may be targets of future intervention.

Variables associated with neuropsychiatric symptoms in PLWH receiving dolutegravir based therapy in phase III clinical trials

J. van Wyk[1], J. Oyee[2], S. Barthel[2], J. Koteff[3], B. Wynne[3], L. Curtis[2], V. Vannappagari[3], N. Payvandi[1], V. Carr[1], T. Vincent[1], M. Aboud[1]
[1]ViiV Healthcare, Brentford, United Kingdom, [2]GlaxoSmithKline, Stockley Park, United Kingdom, [3]ViiV Healthcare, Research Triangle Park, United States

Background: Analysis of phIII clinical trials for DTG concluded that selected neuropsychiatric symptoms (NPs) occurred at similar frequencies compared with controls. Some observational cohort data suggest that NPs result in higher rates of discontinuation among DTG users. Potential factors associated with discontinuations due to NPs reported in some cohorts include ABC co-administration, older age and female gender. We performed a meta-analysis to assess variables associated with NPs, and explored whether insomnia was associated with subsequent NPs.
Methods: Studies included: SPRING-2, SINGLE, FLAMINGO, ARIA, SAILING. NPs included: Insomnia, anxiety, depression, suicidality, nightmares/abnormal dreams, headache. Exposure adjusted incidence of NPs was calculated from frequencies of reported adverse events (AEs); 95%CIs are based on exact binomial 2-sided CIs. Poisson mixed effects meta-regression models were used to conduct two analyses of prespecified variables in a backward selection on the incidence rate of AEs in patients treated with A) DTG (N=1,672) versus nonDTG (n =1,681) and

B) DTG+ABC (n=943) vs DTG+nonABC (n=729). Significance level was 10%. Insomnia as a precursor to other NPs was analyzed descriptively.

Results: Identified variables associated with NPs are shown in the figure. Overall, adjusted estimates [SE] for NPs rates per 1,000 person years were 5.26 [0.068] with DTG versus 5.21 [0.07] with nonDTG (aRR 1.05 [95%CI 0.9, 1.21], p=0.55]), and 5.4 [0.079] with DTG+ABC versus 5.3 [0.085] with DTG+nonABC (aRR 1.1 [95%CI 0.89, 1.37, p=0.37]). Descriptive analyses of first insomnia events and subsequent non-insomnia events are in the table. First insomnia events with subsequent non-insomnia NPs occurred infrequently (2.2%), with higher rates of first occurrence of non-insomnia NPs (23%).

Conclusions: In this meta-analysis including 3,353 participants, the rate of NPs was similar between DTG and non-DTG treated patients. Variables associated with increased NPs in the DTG vs nonDTG analysis were past psychiatric history, non-EU residence and, in contrast with previous findings, younger age. Within the DTG vs DTG+ABC analysis, past psychiatric history and country of residence showed significant association. Concomitant ABC use was not a variable associated with NPs. There was no indication that insomnia was associated with subsequent CNS

Antiretroviral therapy (ART) interruption is associated with reduced cortical structures compared to uninterrupted ART at age 5 years in HIV-infected children on early ART

E.C. Nwosu[1], M.J. Holmes[1], M.F. Cotton[2], E. Dobbels[2], F. Little[3], B. Laughton[2], A. van der Kouwe[4,5], E.M. Meintjes[1], F.C. Robertson[1]
[1]University of Cape Town, MRC/UCT Medical Imaging Research Unit, Division of Biomedical Engineering, Department of Human Biology, Faculty of Health Sciences, Cape Town, South Africa, [2]Stellenbosch University, Family Clinical Research Unit, Department of Paediatrics & Child Health, Tygerberg Children's Hospital and Faculty of Health Sciences, Cape Town, South Africa, [3]University of Cape Town, Department of Statistical Sciences, Faculty of Sciences, Cape Town, South Africa, [4]Massachusett General Hospital, A.A. Martinos Centre for Biomedical Imaging, Department of Radiology, Charlestown, United States, [5]Harvard Medical School, Department of Radiology, Boston, United States

Background: ART interruption (ATI) has been studied in HIV-infected (HIV+) children and adolescents and may occur due to poor adherence, stock-outs and ART intolerance. Although ATI in early treated children may not affect immune health, neurocognition and quality of health in the short term, its effect on brain development is not clear. Here, we investigated effect of ATI on brain morphometry - cortical thickness (CT) and local gyrification indices (LGIs) - in healthy 5 year-old children who initiated ART before 18 months of age.

Methods: MRI scans were acquired from participants in the Children with HIV early antiretroviral therapy (CHER) trial follow-on study according to protocols approved by the ethics committees of the Universities of Cape Town and Stellenbosch. FreeSurfer software v6.0 (http://freesurfer.net/) was used for automated reconstruction and segmentation. Whole-brain CT and LGIs - a measure of cortical folding - were compared between HIV+ children and uninfected controls (HIV-), and between children with ATI who restarted when CD4% < 25% or CDC severe Stage B and children on continuous ART using a linear regression model controlling for sex, age at scan and age at ART initiation.

Results: Forty-six HIV+ children (24 ART-interrupted - interruption age (median ± IQR = 49.14 ± 36.18 weeks), ART initiation - median ± IQR = 9.14 ± 2.93 weeks, 22 ART-uninterrupted, ART initiation - median ± IQR = 11.86 ± 22.14 weeks) and 18 age-matched uninfected controls (9 boys) (age: mean ± std. = 5.58 ± 0.31 years) were included. HIV+ children showed thicker cortex than controls in bilateral frontal and post central regions and lower gyrification in bilateral anterior cingulate, superior parietal and left superior frontal regions. ATI had thinner cortex than continuous therapy in a left lateral occipital (cluster size: 812.30 mm^2) region. ATI showed lower gyrification than continuous therapy in bilateral superior parietal (cluster size: left - 2970.70 mm^2, right - 865.97 mm^2) regions (figure 1).

Conclusions: ART interruption at a young age may affect the development of cortical structures, leading to parietal gyrification decrease and occipital cortical thinning at age 5 years. The neuropsychological implications of these effects in HIV+ children requires further investigation.

Ongoing white matter alterations in HIV infected and HIV exposed children: A DTI study at 9 years

F. Mberi[1], M. Jankiewicz[1,2], F. Little[3], M. Cotton[4], A. van der Kouwe[1,5,6], B. Laughton[4], E. Meintjes[1,2], M. Holmes[1]
[1]*University of Cape Town, Department of Human Biology, Faculty of Health Sciences, Cape Town, South Africa,* [2]*University of Cape Town, Cape Universities Body Imaging Centre at UCT, Faculty of Health Sciences, Cape Town, South Africa,* [3]*University of Cape Town, Department of Statistical Sciences, Cape Town, South Africa,* [4]*University of Stellenbosch, Family Clinical Research Unit, Department of Paediatrics & Child Health, Tygerberg Children's Hospital and Faculty of Health Sciences, Cape Town, South Africa,* [5]*Massachusetts General Hospital, A.A. Martinos Centre for Biomedical Imaging, Department of Radiology, Charlestown, United States,* [6]*Harvard University, Department of Radiology, Boston, United States*

Background: An increasing number of perinatally HIV-infected (HIV+) infants are growing up on ART. Examination of diffusion tensor imaging (DTI) measures over time can identify the impact of HIV exposure, infection and/or treatment on white matter (WM) maturation. DTI studies report WM regions with reduced fractional anisotropy (FA) and increased mean diffusivity (MD) in HIV+ children on ART, which point to demyelination and/or axonal damage.

In the Children with HIV Early Antiretroviral therapy (CHER) substudy, we reported persistent WM abnormalities in the *inferior/superior longitudinal fasciculus* (ILF/SLF), *inferior fronto-occipital fasciculus* (IFOF), *forceps minor* and *corticospinal tract (CST)* at ages 5 and 7, despite early ART. Here, we further investigate voxelwise group differences of MD and FA in this cohort at age 9.

Methods: Participants are 51 HIV+ and 36 HIV- children (42 Females; mean age±sd: 9.4±0.4; 11 Cape Coloured/76 Xhosa) scanned in Cape Town, South Africa on a 3T Siemens Skyra MRI scanner (Erlangen, Germany).

Structural T1-weighted images and two DWI sets with opposite phase encodings were acquired. Data were processed using TORTOISE (version 3.1.0) and AFNI. Voxelwise group comparison of FA and MD were performed in FSL using a general linear model (GLM) with gender, age and ethnicity as confounders. Axial diffusivity (AD), and radial diffusivity (RD) were extracted for each subject in surviving clusters (threshold p_{th}=0.005 and =0.05) and compared between groups using a student's t-test.

Results: HIV+ children demonstrated lower FA in bilateral CST, right IFOF and *corpus callosum* (CC) (Fig 1 and Table 1), and higher MD bilaterally in CST and ILF, left IFOF and right *anterior thalamic radiation* (ATR). Differences were largely attributable to higher RD.

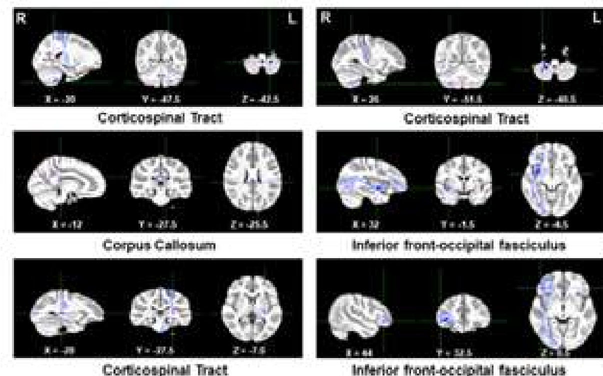

Figure 1: **Clusters showing regions where FA is lower in HIV+ children compared to controls. Corresponding cluster sizes can be found in Table 1. Clusters are shown overlaid on masks of the corresponding WM tracts (JHU White-Matter Tractography Atlas). Peak cluster MNI coordinates are at the base of each image.**

Inferior fronto-occipital fasciculus (R)	248	0.356 (0.115)	0.269 (0.110)	1.003 (0.104)	0.970 (0.086)	0.109	0.579 (0.091)	0.648 (0.100)	0.001
Units of AD, and RD are 10−3 mm2 s−1.									

[Clusters showing significant differences in FA between HIV- and HIV+ children]

Conclusions: Our results indicate that despite early ART, persistent WM alterations in the IFOF, ILF and CST are present from age 5 to 9. Furthermore, although we did not observe CC abnormalities at 5 or 7 years, microstructural abnormalities in CC at 9 years suggest early ART may not prevent ongoing damage.

TUPDB0105

Incidence of stroke in HIV-positive patients: A population-based study in Taiwan

H.-L. Lin[1,2], P.-C. Chen[3]
[1]*China Medical University, PHD Program for Aging Program, Taichung, Taiwan, Province of China,* [2]*Linshin Hospital, Rehabilitation, Taichung, Taiwan, Province of China,* [3]*China Medical University, Public Health, Taichung, Taiwan, Province of China*

Background: Few studies evaluated whether people infected with human immunodeficiencyvirus (HIV) are at an increased risk of stroke in Asian population. This study investigated incidence of stroke in people with HIV infection in comparison with general population in Taiwan.

Methods: Using the claims data of a universal health insurance program, we identified5,961 HIV/AIDS patients without previous stroke from 1998 to 2005 and followed them up until 2011. Standardized incidence ratios (SIRs) were calculated to compare the incidence of overall, ischemic and hemorrhage stroke in HIV/AIDS patients with that in the general population by age, sex and duration of follow-up.
Results: HIV/AIDS patients had higher risk of developing stroke overall (SIR 1.94, 95% confidence interval (CI) 1.58-2.35), ischemic stroke (SIR 2.28, 95% CI 1.74-2.95) and hemorrhage stroke (SIR 2.09, 95% CI 1.40-3.00). The risk remained consistently and significantly higher among all age and sex groups. In all patients and each of age and sex stratifications, the SIR was the highest within one year after diagnosis of HIV/AIDS (SIR [95% CI] for all patients, all stroke, 46.62 [7.63-73.68]; ischemic stroke, 34.47 [13.86-71.02]; hemorrhage stroke, 81.92 [30.06-178.30]).The risk diminished over time, and no increased risk was observed after 8 years of follow-up.
Conclusions: HIV is associated with the highest risk of developing overall, ischemic and hemorrhagic stroke within 1 year after diagnosis among any age groups. This finding may highlight the importance of screening and correcting risk factors for stroke immediately and aggressively after patients diagnosed with HIV and AIDS.

Longitudinal neurocognitive performance in HIV infected individuals in rural Uganda

K. Robertson[1], A. Vecchio[2], D. Saylor[3], G. Nakigozi[4], N. Nakasujja[5], R. Gray[6], M. J. Wawer[6], N. Sacktor[7], Rakai Health Sciences Program
[1]*University of North Carolina, Neurology, Durham, NC, United States,* [2]*Viata-Salute San Raffaele University, Infectious Diseases, Milan, Italy,* [3]*Johns Hopkins, Neurology, Baltimore, United States,* [4]*Rakai Health Sciences Program, Kalisizo, Uganda,* [5]*Makerere University, Kampala, Uganda,* [6]*Johns Hopkins School of Public Health, Baltimore, United States,* [7]*Johns Hopkins University, Neurology, Baltimore, United States*

Background: Neurocognitive impairment in HIV+ individuals remains prevalent despite effective antiretroviral therapy (ART). There is limited data on longitudinal neurocognitive performance in HIV+ individuals in rural Sub-Saharan Africa. By implementing neurocognitive exams for both HIV+ and HIV - individuals, we can establish normative data and monitor neurocognitive function in HIV + persons in an ongoing study in rural Rakai District, Uganda.
Methods: Participants were enrolled in the Rakai Community Cohort Study (400 HIV-, 400 HIV + ART naïve). Personnel were trained to administer standardized neurological and neuropsychological assessments, and participants were stratified by demographic features (age, education, and gender). The HIV+ participants initiated on ART had a follow-up exam to assess neurological function over time.
Results: At baseline there was a significant difference in neurocognitive performance between HIV - (total z score M -.01, SD .50) and HIV + (M -0.26, SD .72, p< .0001). The 333 HIV + participants who returned for a follow-up exam after two years had a mean age of 37.4 years (SD 8.6), education of 5.5 years (SD 3.3), and 49% were women. There was a significant improvement in the total neurocognitive performance of the HIV + participants initiated on ART within the two year follow-up period (F (1,332) = 9.88, p < 0.005; mean time1 = -.26; time 2 = - .16). There was Improved performance in the neurocognitive domains of Fine motor Learning, and Memory (p< 0.0001), while there was no change in Executive functioning, Gross motor, or Speed of processing. The performance in the domains of Fluency and Attention decreased (p< . 008). Overall neurocognitive test deficits (< 1 SD) improved over time (F (1, 332) = 26.86, p < .0001); time1 = 3. 03, time2= 2.39).
Conclusions: Over the course of 2 years on ART, HIV+ participants in this rural, resource limited cohort showed an overall improvement in neurological performance. While there were substantial improvements in learning, memory, and fine motor abilities, there was not the expected improvement in executive functioning, gross motor, speed, fluency, and attention. Overall, neurocognitive test deficits significantly improved over time and warrant further follow-up.

TUPDB0107

Integrase inhibitors and neuropsychiatric adverse events in a large prospective cohort

L. Cuzin[1,2], P. Pugliese[3], C. Katlama[4], I. Ravaux[5], F. Bani-Sadr[6], T. Ferry[7], D. Rey[8], J. Lourenco[9], S. Bregigeon[5], C. Allavena[10], J. Reynes[11], Dat'AIDS Study Group
[1]*CHU de Martinique, Infectious Diseases, Schoelcher, Martinique,* [2]*INSERM UMR 1027, Toulouse, France,* [3]*Nice University Hospital, Nice, France,* [4]*Pitié Salpetrière University Hospital, Paris, France,* [5]*Marseille University Hospitals, Marseille, France,* [6]*Reims Universtiy Hospital, Reims, France,* [7]*Lyon University Hospital, Lyon, France,* [8]*Strasbourg University Hospital, Strasbourg, France,* [9]*Cochin University Hospital, Paris, France,* [10]*Nantes University Hospital, Nantes, France,* [11]*Montpellier University Hospital, Montpellier, France*

Background: In 2016 an unexpectedly high frequency of dolutegravir (DTG) discontinuation for neuropsychiatric reasons was reported, these effects might be more frequent when DTG was used with abacavir (ABC), in women, or in ageing people. Our objective was to search in our large prospectively collected cohort the patients who were treated with an integrase inhibitor (INSTI) and to analyze the frequency and causes of discontinuation.
Methods: The Dat'AIDS cohort is prospectively collected in 18 HIV reference centers in France. Data for all patients starting an INSTI containing regimen between 01/01/2006 and 31/12/2016 were extracted. All causes - chosen by the physician in a limited list of items - of an INSTI containing regimen discontinuation were analyzed, and patients' characteristics related with discontinuation due to neuropsychiatric side effects were searched for.
Results: INSTI were prescribed to 21 315 patients: 6 274 treated with DLT, 3 421 with elvitegravir boosted by cobicistat (EVG/c), and 11 620 with raltegravir (RAL), see Table 1. Discontinuation was observed in 12.5%, 20.2% and 50.9% of the DTG, EVG/c, and RAL treated patients, respectively (p< 0.001). The main reason for DTG and EVG/c discontinuation was intolerance (respectively 7.1% and 9.4% of the patients, p< 0.001). For RAL, treatment simplification (18.7%) was the leading reason. Discontinuation for neuropsychiatric reasons was described in respectively 2.7%, 1.3% and 1.7% of the DTG, EVG/c and RAL treated patients (p< 0.001). In multivariate analysis, discontinuation for a neuropsychiatric reason was related to DTG - versus EVG/C (HR=2.27; 95%CI 1.63-3.17; p< 0.0001) and versus RAL (HR=2.46; 95%CI 2.00-3.40; p< 0.0001), while neither gender (HR for women=1.19; 95%CI 0.97-1.46; p=0.09) nor age (p=0.12) were related. The association with abacavir was not retained in the final model, due to a confusion factor, most of the patients treated by DTG receiving ABC whereas none of the patients treated by EVG/c and few of those treated by RAL did.
Conclusions: Although discontinuation for side effects was less frequent with DTG than with EVG/c, neuropsychiatric side effects were more frequent with DTG, but still remained rare (2.7%). No patient's characteristic could be related with these side effects in this very large population.

		DLT N = 6 274	EVG/c N = 3 421	RAL N = 11 620

TUPDC01 Mortality trends in the ART era

TUPDC0101

Mortality differences after ART initiation in HIV-positive women from Europe, the Americas and sub-Saharan Africa 2000-2014

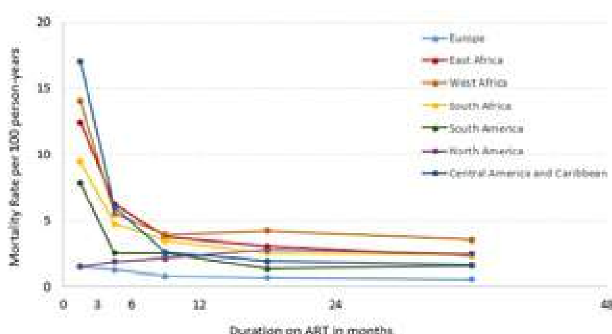
I. Jarrin, Global Mortality Disparities in Women Working Group for IeDEA, EuroSIDA, CASCADE and COHERE in EuroCoord
Instituto de Salud Carlos III, Centro Nacional Epidemiologia, Madrid, Spain

Background: Women account for nearly half of all persons living with HIV/AIDS globally. We aimed to describe geographic disparities in overall mortality after antiretroviral therapy (ART) initiation among HIV-positive women worldwide.

Methods: We pooled data from HIV-positive women over 18 years of age enrolled from 2000 through 2014 and initiating ART within the following cohort collaborations: CASCADE, COHERE, EuroSIDA and 6 regions of IeDEA. Data-contributing regions were categorized as Europe (Eur), East Africa (EAf), West Africa (WAf), South Africa (SAf), South America (SAm), North America (NAm) and Central America and the Caribbean (CAmCRB). Only in NAm were patients required to have a second visit within 12 months of enrollment. Linkages with mortality registries were reported in SAf, NAm and some sites in Eur, and sample tracing of losses to follow-up was conducted in EAf. Inflation factors using mortality ascertainment data from EAf were used to correct mortality under-reporting in WAf. Mortality rates were calculated by region at intervals 0-3, 3-6, 6-12, 12-24 and 24-48 months on ART, and mortality rate ratios estimated at each interval compared to Eur using a piecewise exponential parametric survival model fit through Poisson regression adjusted for age, CD4 T-cell count and period of ART initiation.

	Duration on ART (months)				
	0 - 3	3 - 6	6 - 12	12 - 24	24 - 48
East Africa	7.25 (5.87 - 8.97)	4.24 (3.30 - 5.46)	4.24 (3.35 - 5.37)	3.89 (3.21 - 4.72)	3.63 (3.04 - 4.33)
West Africa	8.95 (7.34 - 10.91)	4.05 (3.21 - 5.11)	4.38 (3.54 - 5.43)	5.37 (4.54 - 6.35)	5.61 (4.84 - 6.51)
South Africa	5.42 (4.43 - 6.64)	3.15 (2.50 - 3.97)	3.77 (3.05 - 4.67)	3.05 (2.56 - 3.63)	3.47 (2.97 - 4.06)
South America	4.47 (2.97 - 6.72)	1.67 (0.84 - 3.32)	2.70 (1.62 - 4.52)	1.69 (1.02 - 2.78)	2.42 (1.65 - 3.55)
North America	0.88 (0.53 - 1.44)	1.25 (0.78 - 2.02)	2.30 (1.61 - 3.27)	3.40 (2.64 - 4.37)	3.72 (2.97 - 4.65)
Central America and Caribbean	9.92 (7.79 - 12.63)	4.12 (2.95 - 5.74)	2.93 (2.07 - 4.15)	2.43 (1.82 - 3.26)	2.50 (1.92 - 3.26)

[Adjusted mortality rate ratios (95% CI) compared to Europe by duration on ART]



[Mortality rates per 100 person-years by time since ART initiation]

Results: A total of 190,175 women (16% Eur, 47% EAf, 13% WAf, 19% SAf, 1% SAm, 3% NAm and 2% CAmCRB) were included. Median age at ART initiation ranged from 33 years in SAf to 40 years in NAm. The proportion of injecting drug users was highest in NAm (18%) and Eur (7%). Only 16% of the women in NAm were of white ethnicity, while 63% and 17% were Black and Hispanic, respectively. Ethnicity data were available for 45% of European women, 26% of whom were Black, largely migrants. Median CD4 count at ART initiation was close to 250 cells/mm³ in Eur and NAm, 141 cells/mm³ in SAf and 170-190 cells/mm³ in other regions. Crude mortality rates and adjusted mortality rate ratios are presented in the figure and table, respectively.

Conclusions: Global variations in mortality in HIV-positive women starting ART show distinct geographical patterns for one-year and four-year mortality that may inform context-specific interventions.

TUPDC0102

High mortality among women living with HIV enrolled in Canada's largest community-based cohort study

A. Kaida[1], R. Gormley[1,2], K. Webster[1], A. Carter[1,2], V. Nicholson[1,3], L. Wang[2], P. Sereda[2], R. Hogg[1,2], A. de Pokomandy[4,5], M. Loutfy[6,7], on behalf of the CHIWOS Research Team
[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]Canadian Aboriginal AIDS Network (CAAN), Vancouver, Canada, [4]Chronic Viral Illness Service, McGill University Health Centre, Montreal, Canada, [5]McGill University, Department of Family Medicine, Montreal, Canada, [6]Women's College Research Institute, Women's College Hospital, Toronto, Canada, [7]University of Toronto, Department of Medicine, Toronto, Canada

Background: Despite HIV treatment advances, there remains considerable inequity in mortality risk among women with HIV in Canada. We measured all-cause and predictors of mortality among women enrolled in the Canadian HIV Women's Sexual and Reproductive Health Cohort study (CHIWOS).

Methods: CHIWOS is Canada's largest community-based study enrolling women with HIV (trans inclusive; ≥16y) across British Columbia, Ontario, and Quebec. Participants complete a peer-administered baseline survey (2013-2015), with 18-month (Wave-2: 2015-2017), and 36-month (Wave-3: 2017-ongoing) follow-up. Among 1,422 women enrolled and followed until December 1st, 2017, we determined incidence and cause of death via comprehensive study notification and follow-up procedures (in British Columbia death was also confirmed via linkage to Vital Statistics). We calculated age-standardized mortality ratios using 2011 Canadian reference populations. Multivariable proportional sub-distribution hazards model (with loss-to-follow-up as a competing risk) identified predictors of mortality.

Results: Median age was 42.5 (IQR:35-50); 4.4% identified as trans, and 22.4% Indigenous, 29.4% African/Caribbean/Black, and 41.1% white. Most women were engaged in HIV medical care (97.4%) and on ART (82.6%). 54 women died (crude mortality rate=11.8 per 1,000 woman-years; 95% CI:9.0-15.3). The age-standardized mortality rate was 4.54 times higher (95%CI: 3.33-5.76) than the general female Canadian population. Primary cause of death was unknown for most women (67%), followed by co-morbidities including cancer and cardiovascular disease (15%), drug/alcohol use (11%), and HIV-related opportunistic infections (6%). Baseline factors significantly ($p< 0.05$) associated with mortality included older age, personal annual income< $20,000, illicit drug use, hazardous alcohol use, tobacco use, sex work, incarceration, depression, violence, and poorer physical health-related-quality-of-life. Independent predictors of age-adjusted mortality included hazardous alcohol use (aHR 4.62, 95% CI=1.66-12.8), current tobacco use (aHR 3.93, 95% CI=1.45-10.7), and depression (aHR 1.95, 95% CI=0.97-3.92). HIV treatment factors (i.e., ART use, VL, CD4) were not predictive of mortality.

Conclusions: We found an alarmingly high mortality rate among a community-based cohort of women with HIV in Canada, a majority of whom were engaged in HIV care. Preventing premature mortality among women with HIV urgently requires women-centred HIV community outreach services that address social disparities and mental health needs, and integrate harm reduction services inclusive of tobacco and hazardous alcohol use.

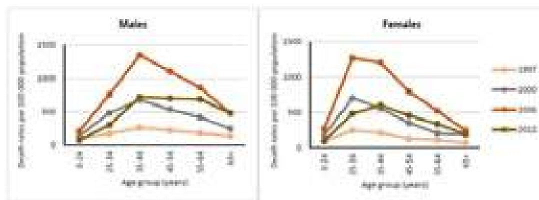
TUPDC0103

Tracking trends in HIV/AIDS mortality pre-and-post ART: South Africa 1997-2012

V. Pillay-van Wyk[1], D. Bradshaw[1], W. Msemburi[1], R. Dorrington[2], R. Laubscher[3], P. Groenewald[1]
[1]South African Medical Research Council, Burden of Disease Research Unit, Cape Town, South Africa, [2]University of Cape Town, Centre for Actuarial Research, Cape Town, South Africa, [3]South African Medical Research Council, Biostatistics Unit, Cape Town, South Africa

Background: South Africa is one of the many countries most affected by the HIV/AIDS epidemic in the world and has one of the most extensive anti-retroviral (ART) rollouts in sub Saharan Africa. This programme was rolled out in 2005. This paper reports the trends in HIV/AIDS mortality pre-and-post ART rollout in South Africa.
Methods: Vital registration cause of death data from Statistics South Africa were adjusted for under-reporting of deaths using demographic methods. Miss-attributed HIV/AIDS deaths were identified by regressing excess mortality on a lagged indicator HIV antenatal clinic prevalence. Background trends in the source-cause (causes to which HIV/AIDS deaths were misclassified) mortality rates were estimated from the trend in cause-specific mortality experienced among 75-84 year olds. Death rates were calculated using mid-year population estimates and the WHO world standard age-weights.
Results: In 1997, 60 336 (14.5%) of deaths were attributed to HIV/AIDS; this number peaked in 2006 at 283 564 (68.1%) and decreased to 153 661 (29.1%) by 2012. Between the ages of 25-34 years females had higher death rates compare to males. This pattern was reversed in those 45 years and older. The male rates for 65+ years continued to increase until 2010 with little age difference in mortality levels over the age of 45 years by 2012 (Fig).



[Fig 1. HIV/AIDS death rates by sex and age group for 1997, 2000, 2006 & 2012]

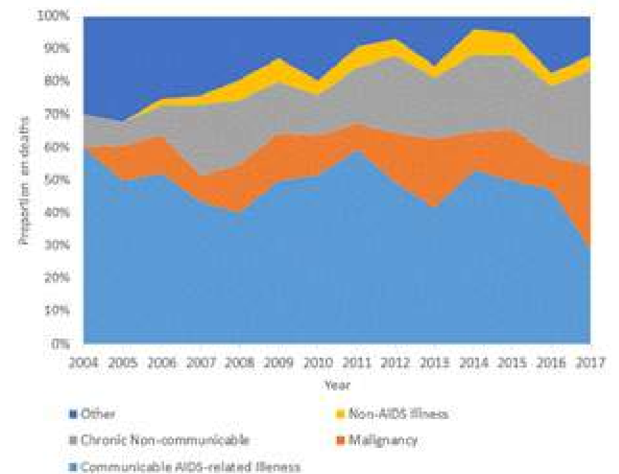
Female death rates peaked in 2005 while males in 2006. Females and males had similar death rates in the earlier period, however males had higher rates than females. While death rates for Black Africans were similar to the national profile, coloureds, whites and Indians had higher rates among males for the entire study period.
Conclusions: HIV/AIDS is the leading cause of death in South Africa even though the number of HIV/AIDS deaths have almost halved since the ART roll out. Our study highlights high male HIV/AIDS mortality rates in the 45+ year olds by 2012. Treatment and prevention programmes should strategize how to target this risk group.

TUPDC0104

Mortality trends among HIV infected patients at Newlands Clinic in Harare, Zimbabwe

T. Shamu[1], C. Chimbetete[1], S. Bote[1], T. Mudzviti[2], R. Luethy[2]
[1]Newlands Clinic, Research, Harare, Zimbabwe, [2]Newlands Clinic, Harare, Zimbabwe

Background: With increasing access to antiretroviral therapy (ART), there is a likely shift in mortality causes among people living with HIV (PLHIV). There are sparse data on mortality patterns among PLHIV in Zimbabwe.
Methods: A retrospective cohort study was conducted at Newlands Clinic in which routinely collected data for patients enrolled and followed up between February 2004 and December 2017 were abstracted from the clinic's database. Patient follow up was commenced from the day of the first clinic visit until exit by death, transfer out, loss to follow up or voluntary cessation of ART. A team of doctors grouped causes of death as communicable AIDS related illness (ARI), malignancies, chronic non-communicable diseases (NCD), non-AIDS related illness or other. Multinomial logistic regression was used to compare change in mortality cause with year of death as the independent variable.
Results: A cohort of 7,845 (62.7% female, n=4,918) patients was followed up for 40,996 person-years (PY). Median enrolment age was 33 years (IQR 19 - 42). Among 896 patients who died, cause of death was unknown for 130 (14.5%). Male patients had a 28% higher risk of dying than female patients (HR 1.28, CI 1.12 - 1.46, p< 0.01). Overall, the most common cause of death was tuberculosis (n = 113, 12.6%), followed by Cryptococcal meningitis (n = 73, 8.1%). The majority of patients died within the first year of enrolment (n = 531, 59.3%), 239 (52.1 %) of these of ARI and 82 (17.9%) of NCDs. While ARI remained the most common cause of death throughout the period, NCDs and malignancies increased in relative proportion (Figure1) (p< 0.01, p=0.04 respectively). There was a significant decline in crude mortality rate from 361/100 PY in 2004 to 35/100 PY in 2017 (IRR 0.10, CI 0.05 - 0.20, p< 0.01).



[Distribution of cause of death over time]

Conclusions: There was a significant decline in mortality rates and change in mortality causes in this cohort. Deaths due to NCDs and malignancies increased over time. ART facilities need to incorporate management of NCDs including cancer in the comprehensive care of PLHIV to reduce mortality.

TUPDC0105

Trends in mortality among HIV-infected subjects: Differences by HCV coinfection status

B. Alejos, Collaboration of Observational HIV Epidemiological Research in Europe (COHERE) in EuroCoord
Instituto de Salud Carlos III, Centro Nacional de Epidemiología, Madrid, Spain

Background: Coinfection by HCV is one of the most common comorbidities in HIV-infected patients. There are currently limited data on trends in cause-specific mortality in subjects co-infected by HCV and HIV compared to subjects only infected by HIV.
Methods: We studied trends from 2000-14 in overall and cause-specific mortality, stratified by HCV status, among HIV-positive adults within the Collaboration of Observational HIV Epidemiological Research Europe (COHERE). Eligible participants were treatment naïve at start of ART and had at least one anti-HCV antibody test result at baseline, defined as the date of cohort recruitment for patients with known HCV status at recruitment, or if unknown, the date of first HCV test after recruitment. Follow-up was divided into calendar periods 2000-2007 and 2008-2014. Cause-specific mortality, based on a simplified algorithm adapted from the CoDe coding system, was categorized as: AIDS-related (AR), Liver-related (LR), Non-AIDS malignancies (NADM), Non-AIDS infections (NADI), cardiovascular, and psychiatric). Adjusted Mortality Rate Ratios (aRR) with 2000-2007 as reference were stratified by HCV status using

multivariable Poisson regression. We used chained equations multiple imputation of missing data including Cause of Death.

Results: 64,209 patients of whom 2,774 died (mortality rate (MR) 8.2/1,000py) were included: 72% males, 48% MSM, 13% HCV-positive, median age 36 years (IQR 29-44), median baseline CD4 383 cells/μL (IQR 207-570). The table shows cause-specific MR per period and the aRR comparing 2008-14 with 2000-07 by HCV status. MR were substantially higher in HCV-coinfected patients for all causes of death and in both periods. All-cause, AR and NADI mortality declined from 2000-07 to 2008-14 for both mono and co-infected individuals. Cardiovascular mortality increased almost two-fold among HCV-positives whereas it remained practically constant among HCV-negatives (interaction p=0.022); LR decreased in both populations although the relative decrease was larger among HCV-negatives (interaction p=0.108).

Conclusions: HCV-coinfection is associated with increased all-cause and cause-specific mortality among HIV-positive patients. Significant relative reductions in all-cause mortality -as well as AR, LR and NADI- over time were observed for both mono and coinfected patients. We anticipate that the introduction of new anti-HCV regimens will significantly impact mortality patterns among co-infected subjects.

TUPDC0106

Mortality and cause of death among HIV patients in London in 2016

S. Croxford[1], R. Miller[2], F. Post[3], J. Figueroa[4], I. Harrison[4], R. Harding[3], V. Delpech[1], S. Lucas[5], S. Dhoot[6], A. Sullivan[6], London Mortality Study Group

[1]Public Health England, London, United Kingdom, [2]University College London, London, United Kingdom, [3]King's College Hospital NHS Foundation Trust, London, United Kingdom, [4]NHS England, London, United Kingdom, [5]Guys & St. Thomas NHS Foundation Trust, London, United Kingdom, [6]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom

Background: Since 2013, the London Mortality Study Group has conducted annual reviews of deaths among people with HIV to reduce avoidable mortality and improve the quality of patient care.

Methods: All London trusts commissioned by NHS England to provide HIV care reported 2016 data on patients who died. Data were submitted using a modified Causes of Death in HIV (CoDe) reporting form. Cause of death was categorised by a pathologist and two clinicians.

Results: There were 206 deaths reported across 20 trusts; 77% of these were among men and the median age at death was 56 years. At the time of death, 81% (134/165) of people were on ART, 61% (113/185) had a CD4< 350 cells/mm³ and 24% (47/192) a VL ≥200 copies/ml. Cause was established for 80% (164) of deaths. Non-AIDS malignancies were the most common cause of death followed by AIDS-defining illnesses. Where reported (n=181), risk factors in the year before death included: smoking (37%), excessive alcohol consumption (19%), non-injecting drug use (IDU) (20%), IDU (7%) and opioid substitution therapy (6%). Co-morbidities were common (n=200): 39% had a history of depression, 33% chronic hypertension, 27% dyslipidemia, 18% HBV/HCV co-infection and 14% diabetes. Almost half of deaths were reported as sudden (44%; 79/177) and 36% (64/178) as unexpected; 60% (63/104) of expected deaths were in hospital. Two thirds of expected deaths (48/72) had a prior end-of-life care discussion, though this information was only available for 57%.

Conclusions: In 2016, 77% of deaths were due to non-AIDS conditions and the majority of patients were on ART and virally suppressed. However, a number of preventable deaths were identified. Underlying risk factors, such as smoking and substance misuse were common. Findings also show improvements are necessary in end-of-life care planning and in collaborative decision making with patients and other specialties, such as oncology and cardiology.

TUPDD01 #UsToo: Violence against key populations

TUPDD0101

Self-reported violence, perpetrators, and post-violence care received by key populations in the Integrated MARPs HIV Prevention Program in Cross River State, Nigeria 2016-2017

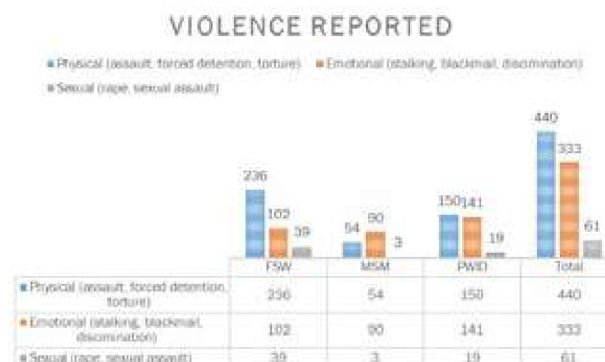
T. Jaiyebo[1], R. Abang[2], A. Yusuf[1], G. Emmanuel[1], A. Osilade[2], O. Olabosinde[1], C. Trout[3], B. Ochonye[1], P. Umoh[1], A. Kalaiwo[4]

[1]Heartland Alliance International, Programs, Abuja, Nigeria, [2]Heartland Alliance International, Programs, Calabar, Nigeria, [3]Heartland Alliance International, Programs, Los Angeles, United States, [4]United States Agency for International Development, Abuja, Nigeria

Background: Men who have sex with men (MSM), female sex workers (FSW) and people who inject drugs (PWID), referred to as key populations (KPs), are highly affected by HIV with Cross Rivers state having one of the highest prevalence rates in Nigeria. Violence against KPs can contribute to poor uptake of HIV services. This research explored the occurrence and types of violence experienced, the perpetrators and post-violence care received.

Methods: Between October 2016 and October 2017, the Integrated MARPs HIV Prevention Program (IMHIPP) in Cross Rivers provided comprehensive HIV services including violence services to 20,687 KPs. This was provided in one-stop-shops, where KPs report violence and receive post-violence care from trained counsellors and clinicians. Qualitative methods were used to collate program data, through interviews, questionnaires and focus group discussions to determine the types of violence, perpetrators and post-violence care required.

Violence was defined as use of force/power that resulted in actual/threatened sexual, physical or emotional harm. Perpetrators were categorized into state actors e.g. police and healthcare workers and non-state actors e.g. family and sexual partners. Post-violence care was classified into: mental health, legal services and medical care which included PEP, STI and HIV testing and treatment.



[Graph 1: types of violence reported]

Perpetrators	Total #	Total %	FSW #	FSW %	MSM #	MSM %	PWID #	PWID %
Perpetrators Non state actors	395	62.7%	269	78.2%	64	54.2%	62	37.1%
State actors	232	37.8%	75	21.8%	53	44.9%	104	62.2%
Both	2	0.3%	0	0%	1	0.8%	1	0.6%
Total #	629		344		118		167	

[Table 1: Table showing the types of perpetrators]

Results: In total, 629 KPs reported violence (FSW: 344, MSM: 118, PWID: 167) with higher numbers of physical (440-FSW: 236; MSM: 54; PWID: 150) and emotional (333- FSW: 102; MSM: 90; PWID: 141) than sexual violence (61-FSW: 39; MSM: 3; PWID: 19). More non-state actors than state actors perpetrated violence (395/62.7 : 232/37.8%). This trend was consistent for FSWs (269/78.2% : 75/21.8%) and MSM (64/54.2% : 53/44.9%), but differed for PWIDs (62/37.1 : 104/ 62.2%).
Most KPs reporting violence received a combination of post-violence care services: medical-(223 - FSW: 52, MSM: 9, PWID: 162), Legal- (316- FSW: 113, MSM: 69, PWID: 134) and mental health - (546 - FSW-336, MSM-43, PWID-167).
Conclusions: Physical, emotional and sexual violence against KPs are common in Cross Rivers state, Nigeria. Screening, documentation and care for victims of violence, such as legal education/safety and security counselling and security stakeholders' engagement are essential to promote an enabling environment for KPs to access HIV services.

TUPDD0102
Partner violence: A significant part of a syndemic among Black men who have sex with men

E. Wu, N. El-Bassel, L. Gilbert
Columbia University School of Social Work, Social Intervention Group, New York, United States

Background: HIV, substance misuse, and partner violence (PV) have long been characterized as a syndemic—interacting and reinforcing epidemics—among key populations such as drug-involved women and female sex workers. There is a nascent recognition of PV as part of the syndemic among MSM, but there is very limited research specifically focused on the key population of Black men who have sex with men (MSM).
Methods: A sample of adult Black MSM (*N*=1,043) completed a screening assessment for a randomized clinical trial of couple-based HIV intervention for Black MSM in New York City. Respondents provided self-reported data on experiencing and perpetrating PV (CTS2 supplemented with gay- and HIV-specific forms of PV), and the following outcome variables: self-reported HIV status, number of male sexual partners, condomless anal intercourse (CAI), and substance misuse. We tested hypotheses that PV would be significantly associated with more adverse levels of each outcome variable.
Results: Table 1 presents prevalence for PV among the sample by type, experiencing vs perpetration, and lifetime vs. past 30 days ("current"); 38.3% and 23.2% experienced lifetime and current PV respectively, and 39.2% and 23.5% reported lifetime and currently perpetrating PV respectively. Hypotheses were validated for currently experiencing PV and perpetrating PV as follows: not knowing one's HIV status (*AOR*=5.1, *95%CI*=2.1-11.7 and *AOR*=3.2, *95%CI*=1.4-7.3 respectively); greater number of male sexual partners (*b*=3.6, *95%CI*=2.6-4.6 and *b*=3.1, *95%CI*=2.1-4.1 respectively); greater number of CAI (*b*=6.4, *95%CI*=2.9-9.8 and *b*=3.7, *95%CI*=0.3-7.2 respectively); binge drinking (*AOR*=2.1, *95%CI*=1.6-2.9 and *AOR*=2.1, *95%CI*=1.5-2.8 respectively); and illicit substance use (*AOR*=2.5, *95%CI*=1.6-4.1 and *AOR*=3.4, *95%CI*=2.1-5.6 respectively). While physical and sexual PV associations were stronger for HIV status, gay-related PV associations were larger for sexual risk behaviors.
Conclusions: The high rates of PV and its multiple associations with HIV risks and substance misuse found in this study underscore the urgent need to address PV as a central factor in the syndemic that underlies Black MSM being and remaining a key, HIV-affected population. Behavioral aspects of combination prevention need to address PV—paying particular attention to gay-specific forms of PV—in order to reduce the HIV and health disparities experienced by Black MSM.

	Experienced PV		Perpetrated PV	
Form of PV	Lifetime n (%)	Current n (%)	Lifetime n (%)	Current n (%)
Psychological (severe)	278 (26.7%)	191 (16.4%)	297 (28.5%)	187 (17.9%)
Physical	229 (22.0%)	106 (10.2%)	229 (22.0%)	104 (10.0%)
Sexual	102 (9.8%)	62 (5.9%)	84 (8.1%)	55 (5.3%)
Injurious	140 (13.4%)	50 (4.8%)	134 (12.8%)	52 (5.0%)
Gay-related	93 (8.9%)	53 (5.1%)	82 (7.9%)	14 (4.5%)
HIV-related	53 (5.1%)	19 (1.8%)	40 (3.8%)	17 (1.6%)

[Table1: Prevalence of partner violence (PV) among a sample of 1,043 black MSM in New York City]

TUPDD0103
Prevalence and predictors of violence against female sex workers in Zambia

K. Malama[1], B. Spire[1], A. Gosset[1], M. Nishimwe[1], P.-J. Coulaud[1], L. Sagaon-Teyssler[1], R. Parker[2], A. Tichacek[2], M. Inambao[3], W. Kilembe[4], S. Allen[2]
[1]Aix-Marseille University, Marseille, France, [2]Rwanda Zambia HIV Research Group, Atlanta, United States, [3]Zambia-Emory HIV Research Project, Ndola, Zambia, [4]Zambia-Emory HIV Research Project, Lusaka, Zambia

Background: Violence is a known risk factor for HIV. In Zambia, where the prevalence of HIV is high (13%) and that of gender-based violence (GBV) even higher (43%), female sex workers (FSW) are particularly susceptible to both outcomes due to their contact with multiple male clients. However, limited data is available on the precise risk factors for violence against Zambian FSW, which would support the implementation of interventions to mitigate against them. We investigated the prevalence and correlates of violence against FSW from their male clients.
Methods: The Zambia-Emory HIV Research Project (ZEHRP) recruited 555 HIV-negative FSW aged 18-45 into a cohort study. FSW were recruited from known hotspots in Ndola and Lusaka between September 2012 and March 2015. At baseline, FSW were asked to provide information on demographics, lifetime sexual history and any previous exposure to violence from their male clients. Forward stepwise logistic regression was used to model the relationship between the outcome (violence from clients, y/n) and potential predictors. The final multivariate model controlled for age, education, age at first sexual encounter, number of years as a sex worker and lifetime number of sexual partners.
Results: From a total of 498 responses, the prevalence of violence against FSW by their male clients was 37% (n=185). In the fitted model, the highest likelihood of FSW facing violence is noted when sex takes place at the client's home (AOR: 2.47, 95%CI: 1.62-3.77, $p<0.001$). The odds of encountering violence are doubled for FSW whose first ever sexual encounter was physically forced in relation to those who engaged willingly (AOR: 2.09, 95%CI: 1.18-3.60, $p<0.05$). FSW who consume alcohol have an almost two-fold increase in odds of experiencing violence from clients compared to their counterparts (AOR: 1.94, 95%CI: 1.13-3.32, $p<0.05$).
Conclusions: HIV prevention interventions for FSW should broaden their scope to address risk factors such as alcohol consumption, location of sex and history of sexual abuse. This would better inform healthcare workers on how to meet FSW needs. Risk reduction education for both FSW and their clients is required to redress gender norms that heighten the risk of violence and HIV.

TUPDD0104

"We´re going to leave you for last because of how you are": Transgender women's experiences of gender-based violence in healthcare, education, and legal settings in Latin America and the Caribbean

M. Lanham[1], K. Ridgeway[1], R. Dayton[1], B.M. Castillo[2], C. Brennan[1], D.A. Davis[1], D. Emmanuel[3], B. Rodriguez[4], G.J. Morales[1], C. Parker[1], J. Cooke[5], K. Santi[5], E. Evens[1]
[1]FHI 360, Durham, United States, [2]ASPIDH Arcoiris, San Salvador, El Salvador, [3]Community Education Empowerment & Development, Bridgetown, Barbados, [4]Family Planning Association of Trinidad and Tobago, Port of Spain, Trinidad and Tobago, [5]United Nations Development Programme, Panama City, Panama

Background: Transgender women experience gender-based violence (GBV) from an early age and face barriers to accessing services, resulting in poor health outcomes including the highest HIV prevalence of any key population. To inform HIV policies and services, trans women worked with LINKAGES (led by FHI 360, supported by USAID and PEPFAR), UNDP, and University of the West Indies to document GBV and transphobia in healthcare, education, and legal settings.
Methods: Trans women, trained as data collectors, conducted 74 structured interviews in El Salvador, Trinidad and Tobago, Barbados, and Haiti in 2016. We conducted qualitative applied thematic analysis to understand the nature and consequences of GBV and transphobia and descriptive quantitative analysis to identify the proportion who experienced GBV in each setting.
Results: A high proportion experienced GBV in education (85.1%), healthcare (82.9%), police/judicial system (80.0%), and other state institutions (66.1%). Emotional abuse was the most common in all settings; participants also experienced economic, physical, and sexual violence, and other human rights violations. Emotional abuse included gossiping, insults, and refusal to use their chosen name. At school, participants were physically threatened and assaulted, harassed in bathrooms, and denied education. In healthcare, participants were given lower priority and received substandard care. Healthcare workers and police blamed participants' health and legal problems on them "because of the way I am" and denied them services. From police, participants also experienced physical and sexual assault, theft, extortion for sex or money, and arbitrary arrest and detention. Participants had difficulty obtaining and using identification cards and passports, sometimes being forced to alter their appearance or being denied an identification card. All violence was clearly linked to gender identity and expression.
Conclusions: These findings demonstrate a need for policies protecting trans women's rights and interventions addressing GBV against trans women. Given that GBV increases HIV risk, decreases HIV treatment adherence, and prevents trans women from accessing health services, HIV service providers need training to provide nondiscriminatory services and screen for and address GBV among trans clients. Integrated interventions addressing both HIV and GBV could help reduce KPs' burden of HIV, increase service utilization, and respect, promote and fulfill their human rights.

TUPDD0105

Women who use drugs in Estonia: Human rights violations as deterrents from HIV treatment

M. Plotko[1], A. Kontautaite[1], D. Matyushina[1], M. Golichenko[2], M. Kalvet[3], E. Antonova[3]
[1]Eurasian Harm Reduction Association, Vilnius, Lithuania, [2]Canadian HIV/AIDS Legal Network, Toronto, Canada, [3]Estonian Association of People who Use Psychotropic Substances 'LUNEST', Johvi, Estonia

Background: HIV prevalence in Estonia is one of the highest in Europe (41.9 cases per million), it is primarily spread among people who inject drugs (PWID), and women represent 40% of new HIV cases as of 2013. Despite the WHO treatment guidelines, HIV treatment, especially among PWID, starts on late stages. In August 2017 a qualitative study was organized in Estonia, in order to explore the social factors that impact lives and health of women with HIV and women who use drugs.
Methods: Research methodology, developed by EHRA and CHALN, was based on in-depth interviews carried out by international and local experts. During the field trip to Estonia in August of 2017 38 interviews were conducted, 20 of them were then transcribed and 37 analyzed through thematic content analysis. To ensure personal data protection and participants safety, their names were coded and there is no reference to their real names in the report. All of the respondents were female, aged 26 - 46 years old, mean age 35 years.
Results: The women interviewed reported that they did not want to get tested or start ART because of the stigma associated with HIV and cases of people's HIV status being disclosed at their workplace or at the workplaces of relatives and partners The disclosure of drug dependence and/or HIV status was the main reason for women's unemployment. In 25 cases drug use alone became grounds for the limitation/deprivation of child custody. Low level of protection from violence and the exclusion of drug user women from shelter programs has been discovered. Women also reported regular police abuse, street drug testing and arbitrary arrest. These systematic human rights violations deter women from health services, including HIV and drug treatment, and create mistrust to social protection services and the police.
Conclusions: Drug laws and drug enforcement practices, combined with stigma related to drugs and HIV, are the main drivers of systematic and serious violations of the human rights of women who use drugs which undermine Estonia's efforts in HIV prevention, care and treatment.

TUPDD0106

Causes and predictors of mortality among people who inject drugs in Tijuana: 2011-2017

B.S. West[1], D. Abramovitz[1], P. Gonzalez-Zuniga[1], G. Rangel[2], D. Werb[1], J. Cepeda[1], L. Beletsky[1], S.A. Strathdee[1]
[1]University of California San Diego, Division of Infectious Diseases and Global Public Health, La Jolla, United States, [2]Mexico/US Border Health Commission, Tijuana, Mexico

Background: People who inject drugs (PWID) experience multiple risk factors for mortality; yet, we know little about causes and predictors of death among PWID in Tijuana, Mexico, an area with high levels of drug injecting and dynamic changes in policy/law enforcement responses to substance use. This study examines rates, causes, and predictors of mortality among PWID.
Methods: Data come from a community-based cohort of PWID aged ≥18 who injected drugs in the past month. Mortality was confirmed by death certificate over 78 months during 2011-2017. Predictors of mortality were identified using Poisson regression with empirical variance estimation, controlling for sex.
Results: Among 863 participants, there were 133 deaths (57 confirmed, 76 unconfirmed), with an incidence rate (IR) of 1.82 deaths per 100 person-years (95% Confidence Interval (CI)=1.35, 2.29) for confirmed deaths and 3.94 for unconfirmed deaths (CI=3.27, 4.60). Confirmed deaths resulted from homicide/trauma (26%), overdose (26%), septic shock (18%), HIV-related causes (9%), organ failure from chronic substance use (9%), and Hepatitis C (7%). In multivariate analysis of confirmed deaths, being stopped/arrested by police for drug selling/trafficking was a highly significant predictor of mortality (Rate Ratio (RR)=6.05, CI=2.22, 16.45); 5.3% of deceased PWID were stopped vs. 0.5% of survivors. Baseline HIV seropositivity (7% among deceased vs. 2.7% among survivors) was associated with 4X higher risk of mortality (RR=4.09, CI=1.36, 12.29); mortality IR was 2.7X higher among HIV+ PWID. PWID living in Tijuana for longer durations were at increased risk for mortality (RR=1.03 per year, CI=1.01, 1.05), while stopping injection for a period of ≥6 months was protective (RR=0.38, CI=0.17, 0.85); 14% of PWID who died stopped injecting vs. 19.6% among survivors.
Conclusions: In addition to overdose and HIV prevention efforts, attention needs to be paid to structural conditions that potentiate mortality risk. Cessation of injection, even for short periods, was associated with lower risk of mortality, indicating a need for improved access to medication-assisted treatment to reduce injecting. Our results also highlight the potential role for police in reducing PWID mortality and the need to transform police encounters from a source of harm to a source of harm reduction.

TUPDD02 Active engagement or missing in action: Community voices in HIV research

TUPDD0201

Process as product: Implementing participatory, rights-based research with female sex workers, men who have sex with men, and transgender women

E. Evens[1], L. Sinette[2], K. Santi[3], J. Cooke[3], M. Lanham[4], G. Morales[4], C. Parker[5], S. Inniss-Grant[6], S. Hunte[7], M. Mendizabal[8], R. Dayton[4]
[1]FHI 360, Health Service Reseearch, Chapel Hill, United States, [2]Friends for Life, Port of Spain, Trinidad and Tobago, [3]UNDP, HIV, Health and Development, Panama City, Panama, [4]FHI 360, Research Utilization, Durham, United States, [5]FHI 360, Behavioral, Epidemiological and Clincal Research, Durham, United States, [6]Independent Consultant, Bridgetown, Barbados, [7]University of the West Indies, Institute for Gender and Development Studies, St. Augustine, Trinidad and Tobago, [8]Asociación Diké de Personas Transgénero y LGBTI+, San Salvador, El Salvador

Background: Addressing the HIV-related needs of key populations (KPs) — men who have sex with men (MSM), female sex workers (FSW), and transgender women — requires new approaches to research. Traditional approaches triggered concerns about human rights violations, data ownership, and unacceptable study questions and methodologies. Meaningful engagement of KPs in research design and implementation addresses these issues and produces high-quality, applicable findings, but what does meaningful engagement look like and how is it fostered?
Methods: The USAID and PEPFAR-supported LINKAGES project, together with UNDP and The University of the West Indies, collaborated with global, national, and local KP-led organizations to conduct participatory, rights-based research on KPs' experiences of violence and its connections with HIV risk in four Latin American and Caribbean countries. KP organizations provided input on study populations, interview topics, recruitment, participant safety, study instruments, analysis, and use of results. All data collectors were KP members.
The study used principles of rights-based research to promote the human rights of stigmatized communities, including respect, gender equity, strengthening alliances between organizations and government, and ensuring the well-being of participants.
Results: We identified strategies to design research that meets the needs of study communities and yields results likely to be used in policies and programs:
1. Collaboration with KPs to define and reach study populations, with MSM providing input on sample sizes to ensure they reflected MSM's educational and occupational diversity and all peers having access to populations difficult to recruit in stigmatized environments;
2. Supporting capacity-building, including training in research ethics and interviewing to ensure a strong voice in the process and allow KP organizations to advocate using the findings, and;
3. Inclusive decision-making through advisory groups to provide feedback on study design/implementation, with each KP group determining the types of violence most important to their community — FSWs focused on workplace violence — resulting in more appropriate results being used to advocate for each groups' priorities.
Conclusions: Meaningful engagement of KPs is an essential requirement of ethical and participatory research and produces better study outcomes more likely to inform policy and practice. Our experiences highlight specific effective methods of meaningful engagement.

TUPDD0202

Adolescent and young people's participation and representation in clinical trials: Lessons from a community-wide HIV testing and treatment study, the HPTN 071 (PopART) study

M. Simwinga[1], J. Mwate[1], T. Ng'ombe[1], S. Belemu[1], N. Makola[2], C. Mubekapi-Musadaidzwa[2], G. Hoddinott[2], R. White[3], K. Shanaube[1], V. Bond[1,4], B. Virginia[1]
[1]Zambart, Lusaka, Zambia, [2]Desmond Tutu TB Centre, Cape Town, South Africa, [3]FHI 360, North Carolina, United States, [4]LSHTM, London, United Kingdom

Background: Community Engagement (CE) is imperative to research for both instrumental and ethical reasons. However, adolescents' and young people's (AYP) participation in research conducted in Africa is infrequent. It is poorly understood how to meaningfully involve AYP in research, promoting critical dialogue between researchers and AYP. HPTN 071 (PopART) is a community based trial in 21 study communities in Zambia and South Africa. The trial includes a nested ancillary study (2016-2017) to evaluate AYP's (15-24 years) uptake of HIV-related services.
Description: Formative research was conducted to identify AYP-specific community stakeholders and AYP possible interventions in consultation with AYP representatives and the existing adult Community Advisory Boards (CABs). Consultations resulted in the creation of 12 AYP-only CABs (aCABs) in Zambia and one AYP-only CAB in South Africa. These CABs met monthly. We report on data collected through group discussions (n=8) and in-depth interviews (n=63) conducted among aCAB members in Zambia in 2017 exploring their perceptions of the aCAB's role in the study. We also reflect on our experiences of establishing and maintaining AYP participation and representation processes from the onset to preliminary results dissemination.
Lessons learned: AYPs were enthusiastic to serve as representatives. However, their participation was constrained by high mobility and the requirement for parental/guardian permission to attend meetings. They requested for formation of AYP-only CABs and not just the inclusion of AYP representatives in adult CABs. Some AYP intervention strategies were both suggested and implemented by them. AYP CABs sought to protect the privacy and confidentiality of AYP research participants and respect their autonomy. For example, they recommended waiver of parental consent for 15-17-year-olds in a survey and rejected the offer of incentives to research participants. AYP leadership, involvement in decision making and determination of specific study activities represented a significant achievement especially in the context of research in Africa where AYP voices are rarely considered.
Conclusions/Next steps: AYP in Africa are capable of participating meaningfully in research that directly impacts their lives. While challenges to participation in research exist, researchers should be encouraged to invest in meaningful partnerships with AYPs. CABs with only AYP representatives are one such strategy.

TUPDD0203

Diverging perspectives on the role of a community advisory board at a biomedical HIV prevention research centre in South Africa

A.M. Lesch, A. De Wet, L. Swartz, A. Kagee, Z. Kafaar, N. Hassan
Stellenbosch University, Psychology, Stellenbosch, South Africa

Background: Community engagement is prescribed as crucial to the successful conduct of biomedical HIV prevention trials. The inclusion of a community advisory board (CAB) in research is one of the most common ways of engaging communities in clinical research. CABs constitute a formal stakeholder advisory mechanism: advising researchers, representing the local community and ensuring that the research is sensitive to the local community context.
While researchers and CABs have a common goal, power imbalances and a range of other challenges may hamper the relationship between these stakeholder groups. In our research to evaluate the community engagement programme at a biomedical HIV prevention research centre in the Western Cape, South Africa, we documented the perspectives

and experiences of multiple stakeholders on the role of the CAB and the relationship between the CAB and research centre staff in the study setting.

Methods: We used purposive sampling to generate a sample of 20 participants from multiple stakeholder groups involved in the research in the study setting. We collected our data using semi-structured interviews. Interviews were audio recorded with the permission of participants and transcribed. We analysed our data using the thematic analysis approach outlined by Braun and Clarke (2006).

Results: The relationship between the CAB and research centre staff was reportedly characterized by feelings of frustration, mistrust and tensions due to the power imbalance between the CAB and the researchers. Research centre staff and CAB members held diverging perspectives on the role of the CAB in the research. While research centre staff viewed the role of the CAB as representing the local community and advising the research team on the operational and ethical aspects of the research, CAB members saw themselves as intermediaries, linking the community to the research centre and facilitating dialogue and engagement between these two entities.

Conclusions: The diverging perspectives held by research centre staff and the CAB hampers the development of trust, mutually beneficial partnerships and ongoing dialogue between the researchers, the CAB and the local community. Building mutually beneficial partnerships and establishing mechanisms for transparent, ongoing dialogue between researchers and the local community is crucial to meaningful community engagement.

TUPDD0204

Stakeholder engagement for HIV clinical trials: A systematic review of the evidence

S. Day[1], M. Blumberg[1], T. Vu[1], Y. Zhao[2], S. Rennie[3], J. Tucker[2,4]
[1]*University of North Carolina, Institute for Global Health and Infectious Diseases, Chapel Hill, United States,* [2]*SESH Global, UNC Project-China, Guangzhou, China,* [3]*University of North Carolina, Social Medicine, Chapel Hill, United States,* [4]*University of North Carolina, School of Medicine, Chapel Hill, United States*

Background: Stakeholder engagement is an essential component of HIV clinical trials. We define stakeholder engagement as input on the design or conduct of HIV clinical trials by individuals or groups with an interest in these trials. Despite its value, stakeholder engagement is often poorly defined and not rigorously evaluated. The objective of our systematic review is to examine the characteristics of stakeholder engagement for HIV clinical trials.

Methods: Four databases (PubMed, Ovid, CINAHL, Web of Science) were searched for English language studies describing stakeholder engagement for HIV clinical trials, with additional studies identified using other methods (e.g. handsearching). Two reviewers independently assessed studies for inclusion, resolving discrepancies via third reviewer. Data were extracted on the location of engagement, engagement methods, stakeholder types, and purpose of stakeholder engagement. Based on UNAIDS Good Participatory Practice (GPP) guidelines, we examined how frequently stakeholder engagement was conducted to inform the following stages: research question development, protocol development, recruitment, enrolment, follow-up, trial results, and dissemination.

Results: Of 452 citations identified, 108 studies were included in the analysis (93 via database search, 15 via other methods). Forty-eight studies (44.4%) described stakeholder engagement in high-income countries, 30 (27.8%) in middle-income countries, and 9 (8.3%) in low-income countries (mixed location/indiscernible: 21 studies; 19.4%). Fifteen distinct methods for stakeholder engagement were identified, including individual (e.g. interviews) and group (e.g. community advisory boards) strategies. Thirty-five types of stakeholders were engaged, with approximately half of studies (59; 54.6%) engaging HIV-affected community stakeholders (e.g. people living with HIV, at-risk for HIV, or related populations of interest). We observed greater frequency of stakeholder engagement to inform recruitment (48 studies; 44.4%) and protocol development (46 studies; 42.6%) (Figure 1). Fewer studies described stakeholder engagement to inform post-trial processes related to trial results (3; 2.8%) and dissemination (11; 10.2%).

Conclusions: We found that stakeholder engagement was more robust in the early stages of clinical trials, with less engagement to inform the later stages. This suggests the current level of stakeholder engagement in later stage HIV clinical trials may be insufficient according to UNAIDS GPP guidelines. Further stakeholder engagement across all clinical trial stages is needed.

[Figure 1. Number of studies conducting stakeholder engagement to inform each of the 7 stages of HIV clinical trial research.]

TUPDD0205

Toward standardized metrics for the conduct of community engagement in HIV biomedical prevention research studies

G. Broder[1], S. Wallace[1], N. Luthuli[2], K. Baepanye[2]
[1]*Fred Hutchinson Cancer Research Center, HIV Vaccine Trials Network, Seattle, United States,* [2]*Fred Hutchinson Cancer Research Center, HIV Vaccine Trials Network, Johannesburg, South Africa*

Background: While Good Participatory Practice standards are in place and there is support for community engagement in clinical HIV prevention research, to date there are no standardized metrics that define its practice and evaluation. The Community Engagement Unit (CEU) of the HIV Vaccine Trials Network sought to create a baseline by which recruitment practices for the two monoclonal antibody AMP Studies could be described, monitored, and assessed.

Description: CEU staff developed recruitment strategy descriptors for each study. These were vetted with the studies' Community Working Groups and edited. Common definitions and time points were established to allow comparisons across sites. Potential participants presenting at the sites were asked, "How did you hear about the AMP Study?" Sites submit their data to the CEU quarterly. CEU staff tabulate it, monitor trends, determine areas where sites need support, and where there are successes to be shared and replicated. Data are presented for January 1 - November 30, 2017.

Lessons learned: All 29 global sites utilize multiple recruitment strategies successfully, but the strategies used vary by region. The most effective recruitment strategy across global sites was referrals (2.4:1 screening to enrollment ratio). The least effective was Print Materials/Ads in Peru/Switzerland/US (5.8:1, 17 sites) and the internet in Africa (6:1, 12 sites). While sites generated a similar number of screening appointments using face to face outreach (719 in Peru/Switzerland/US, 717 in Africa), they represent strikingly different percentages of the total number of persons screened during this period (26% in Peru/Switzerland/US, 50% in Africa), and strikingly different percentages of total enrollment (29% in Peru/Switzerland/US, 56% in Africa). The internet represents the greatest difference between regions, 43% of total enrollments in Peru/Switzerland/US and 0.8% in Africa.

HVTN 704/HPTN 085 TOTALS for 17 HVTN Sites (4 Peru, 1 Switzerland, 12 USA): January 1 - November 30, 2017			
Recruitment Strategy	Initiated the Consent Process (n, percent)	Enrolled	Screening to Enrollment Ratio
Run/Street/Pride Festival/Other face to face outreach conducted by recruiters	719	248	2.9:1
Internet (Craigslist, Social Media, Hook-up websites, www.ampstudy.org, etc.)	[illegible]	[illegible]	[illegible]
Print advertising and materials (flyers, posters, palm cards, newspaper ad, etc.)	[illegible]	[illegible]	5.8:1

[Summary of HVTN Screening to Enrollment Recruitment Data for the AMP Studies]

Tuesday 24 July

Wednesday 25 July

Thursday 26 July

Friday 27 July

Late Breaker Abstracts

Publication Only Abstracts

Author Index

Conclusions/Next steps: Standardized metrics enable meaningful comparisons, and support development of evaluation metrics. It is imperative that all global trial sites are supported with resources enabling use of a range of recruitment strategies, and each site must target the strategies to their local environment. Outreach staff must maximize the use of all available resources and outreach strategies for successful research recruitment, and utilize data to target their efforts to improve their screening to enrollment ratio.

TUPDD0206

GIPA in action: PLHIV leadership and guidance in the development of a new PLHIV quality of life scale for the community and policy sector

G. Brown[1], A. Cogle[2], C. Cooper[3], S. O'Connor[4], B. Allan[5,6], S. Malhotra[7], G. Mikolajczak[8], J. Power[8], A. Lyons[8], F. Drummond[9]
[1]La Trobe University, Australian Research Centre in Sex, Health and Society, Melbourne, Australia, [2]National Association of People Living with HIV, Sydney, Australia, [3]Positive Life, Sydney, Australia, [4]Queensland Positive People, Brisbane, Australia, [5]Australian Society for HIV, Viral Hepatitis and Sexual Health Medicine, Sydney, Australia, [6]International Council of AIDS Service Organizations, Toronto, Canada, [7]Living Positive Victoria, Melbourne, Australia, [8]Australian Research Centre in Sex, Health and Society; La Trobe University, Melbourne, Australia, [9]ViiV Healthcare Australia, Melbourne, Australia

Background: The greater involvement of people with HIV/AIDS (GIPA) has been a foundation of effective responses to HIV. However, in research application of GIPA principles is often limited to consultation rather than full collaboration. The development of the PozQoL quality of life (QoL) scale demonstrates the benefits of full collaboration to achieve high quality research outcomes.

HIV organisations in Australia have prioritised improving the QoL of people living with HIV (PLHIV) in their programs as a strategy to reduce the negative personal impact of HIV and improve treatment uptake and maintenance goals. In order to measure the impact of these efforts, a partnership of PLHIV peer organisations, researchers, and industry was established to pool resources and develop a QoL scale for PLHIV. The scale needed to be short, empirically validated and easy to incorporate into the day-to-day practice of health and community services. This partnership was committed to GIPA being at the centre of the process.

Description: The PozQoL partnership involved active direction from PLHIV peer leadership in the:

· conceptualisation of the research approach,
· prioritisation of the QoL domains to be included in the scale,
· development and review of scale items,
· engagement and mobilisation of the PLHIV community to support the validation survey, and
· analysis and decisions concerning the refinement of the final scale.

Lessons learned: Benefits of the high involvement of PLHIV peer leadership includes:

· a deeper understanding of the complex experiences of PLHIV related to QoL,
· ensuring a balance of statistical rigour, conceptual accuracy, and practical use of the PozQoL scale,
· strengthened relationship across research, community and industry,
· opportunity to demonstrate credibility and authenticity within PLHIV community.

Conclusions/Next steps: Taking participation with PLHIV peer-led organisations beyond consultation to active partnership enabled the study to ensure the research rigour was complemented by practical and conceptual considerations, and high community engagement. This contributed to achieving not only statistical validity but also high ecological validity for the real-world experience of PLHIV. This process has also built scale's credibility across the sector: PozQoL scale is currently being field-tested by 15 community, support and healthcare programs for PLHIV in Australia

TUPDE01 Geomapping to enhance equitable access

TUPDE0101

Where are the HIV positives in Kenya? Unmasking testing yield in a spatial context

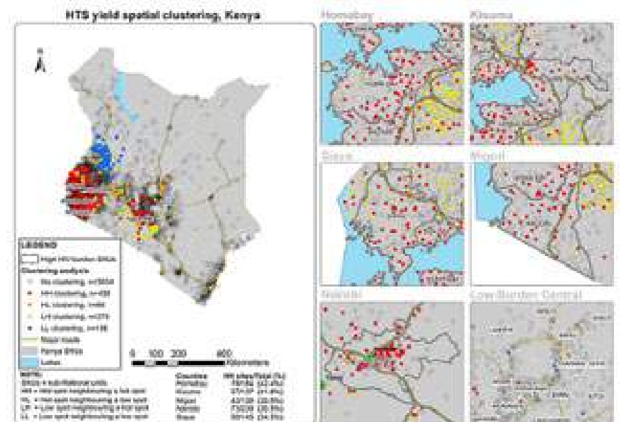
A. Waruru[1,2], J. Wamicwe[3], J. Mwangi[2], L. Ng'ang'a[2], F. Miruka[2], T. N. O. Achia[2], P. Yegon[2], D. Kimanga[2], J. L. Tobias[4], K. M. De Cock[2], T. Tylleskär[1]
[1]University of Bergen, Centre for International Health, Bergen, Norway, [2]Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB (DGHT), Nairobi, Kenya, [3]National AIDS and STI Control Program (NASCOP), Ministry of Health, Nairobi, Kenya, [4]U.S Centers for Disease Control and Prevention (CDC), Division of Global HIV &TB, Atlanta, United States

Background: The UNAIDS 90-90-90 targets provide a framework for assessing coverage of HIV testing services (HTS), linkage to care, and viral load suppression. In Kenya, the bulk of HTS targeting is in 5 high HIV-burden counties: Nairobi, Homabay, Kisumu, Siaya, and Migori, accounting for 45.1% of the estimated people living with HIV PLHIV. Geographic analysis, can help to focus and prioritize to increase diagnosis of PLHIV to reach the "first 90".

Methods: We analyzed routine site-level HTS data in Kenya to assess spatial distribution of HIV-positives (yield) within counties [sub-national units (SNUs)]. We used the global Moran´s Index (Moran's I) in ArcGIS™ ver. 10.51 to assess spatial autocorrelation of yield by site. Inverse Euclidean distances were used to conceptualize spatial relationships; the further the sites were from each other, the lesser the impact of spatial relationship(s). We classified sites as having no-clustering (random distribution), or auto-correlated neighbors as hotspots with hotspots (HH), hotspots with low-spots (HL), low-spots with hotspots (LH), and low-spots with low-spots (LL).

Results: In 2016, out of 4,021 HTS sites, 3,969 (98.7%) had geo-coded data. Global Moran's I was 0.023, expected I was -0.00025, Z-score 33.9 and p< 0.001. Most sites showed no-clustering (3034, 76.4%); others were grouped as: HH (438, 11.0%), HL (66, 1.7%), LH (275, 6.9%), and LL (156, 3.9%). Of the HH sites, 301 (68.7%) were in high HIV-burden SNUs distributed as follows: Homabay with 78/184 (42.4%), Kisumu 57/137 (41.6%), Siaya 50/145 (34.5%), Migori 43/139 (30.9%), and Nairobi 73/239 (30.5%). HH sites in high burden counties were near water bodies (Homabay, Kisumu, Siaya and Migori) or a large city (Nairobi) and in low HIV-burden areas near major roads (Figure).

Conclusions: We identified wide-ranging spatial variation of yield clusters. High HIV-burden SNUs contain most high yielding sites but some are also in low-burden SNUs. Access to HTS is needed everywhere in Kenya, yet, targeting is difficult in low prevalence areas. Geospatial analyses help to define hotspots and priority areas for enhanced HTS to spatially refine targeting and achieve the "first 90".



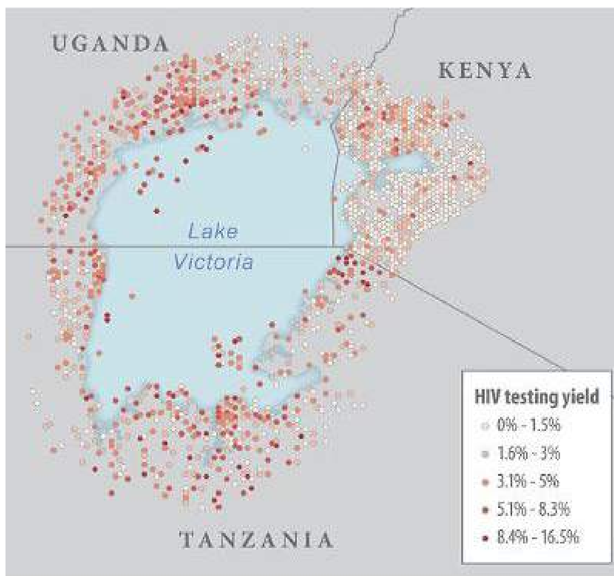
[Spatial distribution of HTS yield in Kenya and in 5 high HIV-burden counties and 1 low burden region, 2016]

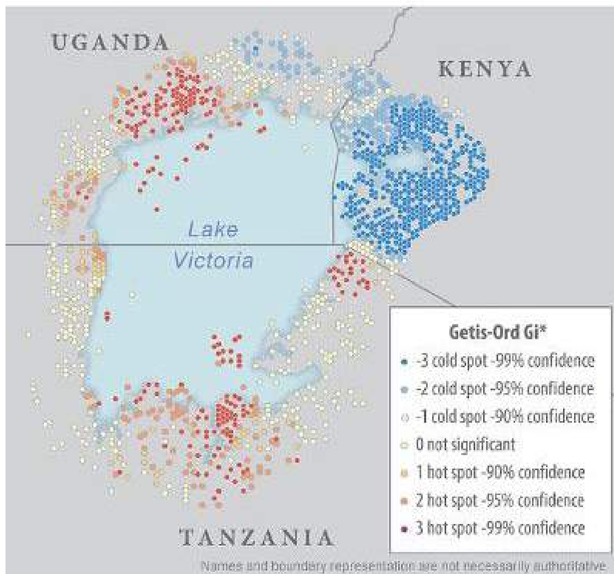
TUPDE0102

Patterns of HIV in the Lake Victoria region, a spatiotemporal analysis

N. Heard[1,2], G. Sarfaty[3], I. Zaidi[4], C. Fellenz[5]
[1]*U.S. Department of State, Office of the U.S. Global AIDS Coordinator and Health Diplomacy, Washington, DC, United States,* [2]*U.S. Department of State, Humanitarian Information Unit, Washington, DC, United States,* [3]*U.S. Agency for International Development, Office of HIV/AIDS, Washington, United States,* [4]*U.S. Department of State, Office of the U.S. Global AIDS Coordinator and Health Diplomacy, Washington, United States,* [5]*U.S. Department of State, Humanitarian Information Unit, Washington, United States*

Background: Fisherfolk are a relatively mobile population subject to a variety of socioeconomic and behavioral risk factors that drive HIV infection in the Lake Victoria Basin. Although country-specific studies have established that populations residing near the lake experience higher HIV prevalence than the general populations of their respective countries, less is known about spatial patterns of HIV in the region as a whole. This study explores routine program data to detect spatial clustering of HIV positivity across Kenya, Tanzania, and Uganda. In addition, the study seeks to characterize the temporal stability of identified clusters of HIV positivity in Lake Victoria Lake Basin.





[Spatial Structure in HIV Testing Yield Within 50 km of Lake Victoria, July-September 2017]

Methods: We evaluated seven reporting quarters of HIV testing data for significant spatial structure. The quarterly data are from 2,256 PEPFAR-supported health facilities within 50 kilometers of the banks of Lake Victoria. We stratified by quarter facility-level data for 15,841,128 tests, of which 384,473 were positive, and aggregated mean HIV positivity to a mesh of tessellated hexagons. The analysis tested for spatial randomness using the Getis-Ord Gi* statistic.

Results: We detected four stable clusters of high HIV testing yield, present in each of the seven quarters, and two unstable clusters, appearing in at least three of the seven quarters. In addition, results indicated one potentially emerging cluster of high yield. A stable cold spot crosses the border of Kenya and Uganda.

Conclusions: Despite labor-related population mobility in the region, HIV testing results show persistent patterns in both space and time. High population mobility complicates linkage to care. However, consistently high testing yield in fixed places suggests that a geographically focused programmatic approach remains a valid and important part of this local response. Future studies should leverage routine program data and consider multiple geographic scales to assess both cross-border and internal disease dynamics.

TUPDE0103

Density mapping of dating app users across time and space in Mumbai, India

B. Eveslage[1], P. Shah[2], C. Parker[1], B. George[3], J.J. Baishya[4]
[1]*FHI 360, Washington, United States,* [2]*FHI 360, LINKAGES, New Delhi, India,* [3]*FHI 360, Country Director, New Delhi, India,* [4]*USAID, New Delhi, India*

Background: Dating apps make it easier and seemingly safer for men who have sex with men (MSM) to find partners. How, then, can HIV programs use available data to better align HIV outreach activities to the specific times and locations of MSM dating app usage while maintaining safety and privacy?

Methods: The USAID and PEPFAR-supported LINKAGES project in India created density maps of location-based dating app users in Mumbai to identify concentrations of users and enhance program coverage. Using ArcGIS software, Mumbai was overlaid with a gridwork of latitude/longitude points each two kilometers apart (374 points), and a second group of points at 1 kilometer distance (410 total). Data collectors used Android phones and an app to set their phone's Global Positioning System (GPS) location for each of the plotted coordinates, then opened Grindr to count the number of nearby online users. The number of online users within one kilometer of each 2-kilometer separated point was collected three times daily, over five days of one week in October 2017. The process was repeated in December 2017 for online users within 500 meters of each 1-kilometer separated point over 7 days. Excel's 3D maps plug-in generated short videos animating the changing density of Grindr users across the week and area of Mumbai. These activities never collected individual location data, and data are not granular enough to target people in physical settings.

[Figure 1: Density mapping in Mumbai compared - 1km radius sampling (left) versus more precise 500m radius sampling (right) showing clear high-density]

Results: An average of 3,810 online Grindr users were counted across metropolitan Mumbai. The highest number of online users was counted on midday Saturday and Sunday. On weekdays, counts increased later in the day. The second mapping revealed high-density locations of dating app use including several time-bound areas and 6 consistent areas with 23 or more online users within 500 meters of each coordinate (Figure 1).
Conclusions: This activity successfully identified physical clusters of online MSM at specific times of dating app usage, and estimated total online users in Mumbai. The LINKAGES program in India used these results to guide outreach to MSM on Grindr at high density locations through peer- and advertisement-based approaches that will be combined with location-specific referrals for services.

TUPDE0104

Optimizing access for the last mile: Geospatial cost model for point of care viral load instrument placement in Zambia

S.J. Girdwood[1], B.E. Nichols[1,2], C. Moyo[3], T. Crompton[4], D. Chimhamhiwa[4], S. Rosen[1,2], on behalf of EQUIP
[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Boston University, Global Health, Boston, United States, [3]EQUIP Zambia, Lusaka, Zambia, [4]Right to Care, GIS Mapping Department, Johannesburg, South Africa

Background: Viral load monitoring programs have been scaled up rapidly throughout Africa, but little attention has been paid to how to optimize viral load access to the most remote healthcare facilities (the "last mile"). For the hardest-to-reach facilities in Zambia, we compared the cost of placing point of care (POC) viral load test instruments at or near facilities to the cost of an expanded sample transportation network (STN) to deliver samples to centralized laboratories.
Methods: Using data from the Zambian viral load program, we developed a geospatial optimization model that first optimized a STN for centralized labs for 90% of estimated viral load volumes, at a cost per test of $23.86. Exploratory cluster analysis was then conducted to identify ideal facilities for POC instrument placement amongst the remaining 10% of volumes. Optimal placement maximized both viral load coverage and instrument utilization. We evaluated the full cost (test and transport) per test under three scenarios:
1) POC placement at all facilities identified for POC;
2) an optimized combination of true on-site POC placement and "near POC" placement at facilities acting as POC hubs; and
3) integration into the centralized STN to allow use of centralized labs.
Results: Exploratory cluster analysis yielded optimal POC placement that covered 3.5% of total viral load volumes. Scenario 2 resulted in a cost per test of $37.97, 21% less than the cost per test of true-POC available at all of the same facilities (Scenario 1, $47.95). This is due to increased POC instrument utilization when an instrument can act as near-POC (median 23% instrument utilization), compared to only true-POC (11%). Scenario 3 was the most costly at $53.2 per test, due to high transport costs under the centralized model ($31.40 per test compared to $4.80 per test in scenario 2).

	Scenario 1 (POC at all facilities)	Scenario 2 (optimized combination of POC and near-POC)	Scenario 3 (expanded sample transport network)
Median total cost per test (IQR)	$47.95 (46.83-50.54)	$37.97 (36.6-40.28)	$53.16 (48.59-58.59)
Test (IQR)	$47.95 (46.83-50.54)	$33.13 (31.99-35.00)	$21.76 (20.33-23.58)
Sample transport (IQR)	$0	$4.80 (4.61-5.28)	$31.40 (28.26-35.01)
Projected annual number of tests conducted (% of total viral load volume)	59,892 (3.5%)		
Total cost of scenario (IQR)	$2.87m ($2.80m-$3.03m)	$2.27m ($2.19m-$2.41m)	$3.19m ($2.91m-$3.51m)
Savings from using optimized POC and near-POC	$597,465	-	$912,419

[Cost per viral load test by scenario for hardest-to-reach patients]

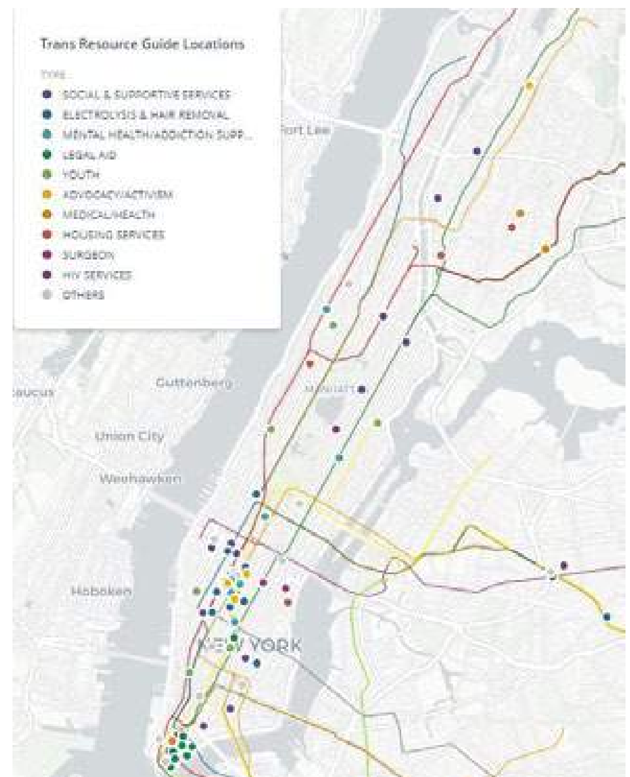
Conclusions: Point of care viral load testing may reduce the costs of providing testing services to the hardest-to-reach populations, despite the cost of equipment and low patient volumes. An optimal combination of true- and near-POC instruments can reduce the cost per test by 21-29% by reducing transport costs and increasing instrument utilization under the POC scenario.

TUPDE0105

Transgender resource map

M. Domingo[1,2]
[1]Callen-Lorde Community Health Center, Population Health, New York, United States, [2]Carto, Brooklyn, United States

Background: Transgender people face daily harassment and discrimination, which impacts their ability to access and receive services like healthcare. In addition to this, Transgender people face additional challenges when receiving services due to lack of competence and prejudice from service providers, especially medical care. It is no surprise this group faces the largest burden in new HIV infections in the United States. Very little has been done to ensure Transgender people are connected to quality and competent social and health services. Callen-Lorde Community Health Center, a leader in Transgender care in the United States, describes its approach to addressing this inequities using an innovative technology approach.
Description: Utilizing GIS (geographic information systems) software, Callen-Lorde's Population Health team mapped the geographic location and distribution of its Transgender patients in New York City's 5 boroughs by census tract. Simultaneously, all transgender specific resources and linkages kept by the clinic for referrals where mapped by address (Figure 1). The map allows individuals to search for specific services available in a given location. Services included things like Behavioral health resources, transgender surgery information, legal assistance and others.



[Figure 1]

Lessons learned: Transgender specific resources were available and abundant in New York, however they were mainly concentrated in the downtown central area of Manhattan, while most patients inhabited the farther regions of the city. Interactive maps and GIS technology allows our supportive staff to link patients to services and come up with outreach strategies to avoid discrimination and harassment. These maps

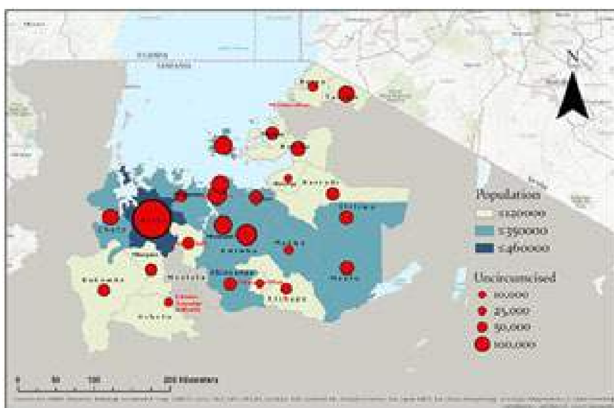
provide an opportunity to invite business into high-needs areas, helping to bridge inequities. Through this program, we are able to understand how to allocate resources in a strategic and targeted approach.
Conclusions/Next steps: GIS technology can be successfully utilized to bridge determinants of health in transgender communities. Innovative approaches are needed to help ensure transgender communities have the tools to connect to service that will support and treat them with dignity.

TUPDE0106

Use of geographic information system mapping for scaling-up voluntary medical male circumcision services in Tanzania

K. Nyalali[1], P. Sekule[1], P. Mwakipesile[1], M. Swai[1], J. Brasileiro[2], C. Brokenshire-Scott[2], L. Mphuru[1], K. Kazaura[3], D. Simbeye[3]
[1]IntraHealth International, Dar es Salaam, Tanzania, United Republic of, [2]IntraHealth International, Chapel Hill, United States, [3]Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of

Background: Scaling-up voluntary medical male circumcision (VMMC) becomes trickier as coverage increases and the number of eligible men decreases. IntraHealth International, with CDC funding, used geographic information system (GIS) mapping with information from community experts to identify geographical areas in Tanzania with large numbers of uncircumcised men for targeted service delivery.
Description: We collected 2016 ward-level male population projection data in the four IntraHealth-supported regions and shape files with geo-referenced points (e.g., ward boundaries, road networks, forests/vegetation, water bodies) from the National Bureau of Statistics. The geo-coordinates of health facilities were extracted from the national health facility registry and DATIM GIS interface and used to geo-reference facility locations. We subtracted 2011-2016 service delivery data on circumcised men from the PROMIS database to establish estimations of uncircumcised men in the respective wards of the four regions. Geo-coded data and shape files were overlaid into GIS software (ArcGIS Pro Esri 2017) and analyzed to create maps of facility locations, coverage and areas with high concentration of uncircumcised men where demand creation and VMMC scale-up were prioritized.
Lessons learned:
· Maps showed over 61% of uncircumcised men were located in 40% of the wards within the four regions.
· Community experts provided additional socio-economic factors needed for consideration in planning VMMC outreach campaigns such as accessibility, availability of water/electricity for sterilization of instruments, and availability of lodging for service providers.
· The number of men circumcised annually increased three-fold from 67,414 in 2016 to 225,093 in 2017; over 92% were aged 10-29 (PEPFAR priority age group), which was three times higher than previous years.
· The project achieved these results with a $7.1 million budget, an average of US$31.12 per client, significantly lower than the national estimate and previous years at US$50 and US$39.36, respectively.



[Distribution of uncircumcised men in IntraHealth-supported regions in Tanzania]

Conclusions/Next steps: Coupled with qualitative socio-economic information from community experts, interactive GIS mapping ensures efficiency in planning and monitoring for high-impact large-scale interventions at a minimum cost. Project designs should consider using interactive GIS maps to make strategic decisions for targeted high-impact interventions.

TUPDX01 PrEP in the real world: What are we learning?

TUPDX0101

The responsibility of PrEP: A qualitative exploration of men who have sex with men's use of informal PrEP in London

S. Paparini[1], W. Nutland[2,3], V.-K. Nguyen[1]
[1]Graduate Institute of International and Development Studies, Anthropology and Sociology of Development, Geneva, Switzerland, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]PrEPster, London, United Kingdom

Background: Concerns have been raised that HIV pre-exposure prophylaxis (PrEP) will lead to 'risk compensation' (that MSM will use condoms less frequently, and increase their sexual risk because of PrEP). In England it has been argued that the drop in HIV incidence can be partially credited to PrEP-related activism and the initiative taken by MSM as early adopters of informal, online-purchased, generic PrEP. This suggests the contrary; namely, that PrEP provides an opportunity for men who have sex with men (MSM) to take individual responsibility for their own sexual health. However little research has examined the issue of "responsibility" in PrEP users.
Methods: An ethnography of PrEP in the United Kingdom has been carried out since 2016, using interviews, focus groups, and participant observation with policymakers, researchers, clinicians and PrEP users. As part of this, a formative qualitative project was conducted in partnership with PrEP activists to inform an intervention to support informal PrEP users. Focus groups were held with 20 MSM, based in London, who obtain PrEP informally, to explore their accounts and experiences of sourcing and using generic PrEP. This presentation reports findings from the focus groups in the context of the broader ethnography.
Results: In participants' accounts responsibility was not a single idea but an overarching theme for framing different concerns: control over their own health, relationships with other MSM and the gay community, and citizenship. The responsibility they felt towards themselves created uncertainties about their sexual risk without PrEP and on PrEP. Their responsibility towards their communities was put into practice through information-sharing and peer support of other potential PrEP-users. The few clinics that supported their informal PrEP use were seen as taking on the State's responsibility for their health as citizens.
Conclusions: The policy conditions in England, and the lack of access to PrEP have given rise to a widespread practice of informal PrEP sourcing and use. This is a self-directed form of prevention, yet has extended the notion of responsibility for PrEP beyond individual PrEP users to a collective responsibility of PrEP shared by MSM communities, and by PrEP providers to adequately support early adopters and informal users.

TUPDX0102

Attitudes regarding HIV, PrEP and condom use jointly predict risk compensation among men who have sex with men - findings from the VicPrEP implementation project, Melbourne

J. de Wit[1,2], D. Murphy[2,3], L. Lal[4,5,6], J. Audsley[5,7], C.K. Fairley[8,9], M. Stoove[4,10], N. Roth[11], R. Moore[12], B.K. Tee[13], N. Puratmaja[6], R.M. Grant[14,15,16], E. Wright[4,5,6]

[1]Utrecht University, Department of Interdisciplinary Social Science, Utrecht, Netherlands, [2]UNSW Sydney, Centre for Social Research in Health, Sydney, Australia, [3]University of Sydney, Department of Gender and Cultural Studies, Sydney, Australia, [4]The Burnet Institute, Melbourne, Australia, [5]The Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia, [6]Monash University, Department of Infectious Diseases, Melbourne, Australia, [7]University of Melbourne, The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [8]Melbourne Sexual Health Centre, Melbourne, Australia, [9]Monash University, Central Clinical School, Melbourne, Australia, [10]Monash University, School of Population Health and Preventive Medicine, Melbourne, Australia, [11]Prahran Market Clinic, Melbourne, Australia, [12]Northside Clinic, Melbourne, Australia, [13]The Centre Clinic, Melbourne, Australia, [14]Gladstone Institutes, San Francisco, United States, [15]University of California-San Francisco, School of Medicine, San Francisco, United States, [16]San Francisco AIDS Foundation, San Francisco, United States

Background: Potential risk compensation related to PrEP remains a major concern, and may exacerbate high rates of sexually transmissible infections. Recent reports from implementation projects provide initial evidence of reduced condom use amongst among men who have sex with men (MSM) using PrEP in community settings. To increase understanding and inform responses to risk compensation we assessed sociodemographic and attitudinal covariates of trends in condom use with casual partners among VicPrEP participants.

Methods: Initiated in 2014, VicPrEP was the first Australian PrEP demonstration project, undertaken through one sexual health clinic and three general practice clinics in Melbourne. A total of 115 participants were enrolled in one year and were offered PrEP for up to 30 months. Participants received baseline and 3-monthly self-report questionnaires during the first year of participation. Five-point rating scales were used to assess condom use (1 = never, 5 = always) and attitudes regarding HIV, PrEP and condoms (1 = low, 5 = high). Prospective data were analyzed using Generalized Estimating Equations.

Results: Frequency of condom use for anal sex with casual partners decreased significantly over one year follow-up (Baseline Median = 3.0, IQR = 2.0-4.0; 12 month Median = 2.0, IQR = 1.0-3.0; Wald Chi2 (df=4) = 21.03, p = 0.000), notably in the first 3 months of using PrEP. Multivariable analysis found that MSM who found HIV a more serious condition and found it more important to remain HIV-negative were more likely to continue condom use, as were MSM more concerned about adverse effects of PrEP. MSM who considered PrEP critical for personal HIV prevention and MSM who experienced more adverse impacts of condom use on sex were less likely to use condoms.

Conclusions: In this community implementation project, condom use with casual partners among MSM decreased markedly upon commencing PrEP. This underscores the importance of stressing PrEP's role as additional HIV prevention tool and that continued condom use contributes to preventing other sexually transmissible infections . Changes in condom use reflect the joint influence of men's attitudes regarding HIIV, PrEP and condoms, offering points of entry for community-based initiatives to raise awareness and examine risk compensation.

TUPDX0103

The new MTV generation: Using methamphetamine, Truvada and Viagra to enhance sex and stay safe

M.A. Hammoud[1], S. Vaccher[1], A. Bourne[2], B. Haire[1], T. Lea[3], F. Jin[1], L. Maher[1], G. Prestage[1]

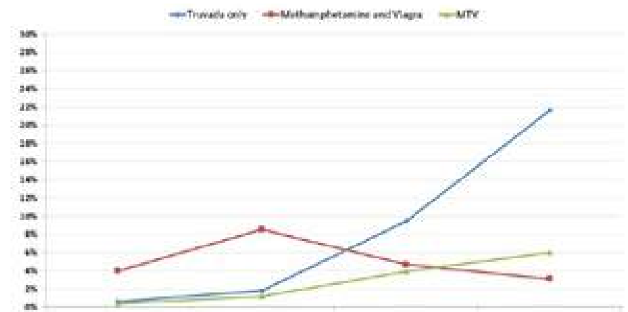
[1]The Kirby Institute, UNSW Australia, Medicine, Sydney, Australia, [2]Australian Research Centre in Sex, Health & Society, La Trobe University, Melbourne, Australia, [3]Centre for Social Research in Health, UNSW, Sydney, Australia

Background: Gay and bisexual men (GBM) often use illicit drugs to enhance sexual pleasure, commonly referred to as 'chemsex'. In particular, the use of methamphetamine and Viagra™ (or other erectile dysfunction medications) both together and separately are strongly predictive of incident HIV infection. Truvada™, as pre-exposure prophylaxis (PrEP), virtually eliminates HIV risk during condomless anal intercourse (CLAI). When HIV-negative GBM in intensive sex partying networks add PrEP to their party drug regimen, they actively reduce the possibility of HIV transmission during chemsex. We describe the prevalence and context of concurrent use of methamphetamine (M), Truvada™ (or its generic formulations, T), and Viagra™ (or other erectile dysfunction medication) (V; collectively, MTV).

Methods: The *Following Lives Undergoing Change* (FLUX) study is an online prospective observational study of licit and illicit drug use among Australian GBM. Between January and July 2017, 1831 HIV-negative and untested/unknown status GBM provided details about their use of MTV. Binary logistic multiple regression analyses were used to estimate adjusted odds ratios (aOR) and associated 95% confidence intervals (95%CI).

Results: During 2017, concurrent MTV use was reported by 6.0% of participants; 3.1% used methamphetamine and Viagra™ or other erectile dysfunction medication ('MV only') and 11.2% used Truvada™ as PrEP ('T only'). MTV prevalence in the cohort over time is shown in Figure 1. In multivariate analysis, compared to use of 'MV only', MTV was independently associated with CLAI with casual partners (aOR=6.78;95%CI=1.42-32.34) and 'fuckbuddies' (aOR=3.47;95%CI=1.41-8.56) in the previous six months. Compared to use of 'T only', MTV was independently associated with being older (aOR=3.95;95%CI=1.55-10.03) and engaging in group sex (aOR=3.31;95%CI=1.82-6.00). Greater social engagement with other gay men (aOR=1.44;95%CI=1.18-1.76) and having more sexual partners (aOR=2.30;95%CI=1.10-4.82) were independently associated with use of MTV compared to use of 'MV only' or 'T only'.

Conclusions: The addition of PrEP mitigates the increased HIV risk associated with party drug regimens, and these data demonstrate that this harm reduction strategy is being utilised by GBM. Interventions that promote harm reduction strategies, including the use of PrEP during chemsex could help reduce HIV transmissions within this at-risk population.



[Figure 1. The new MTV Generation: Using Methamphetamine, Truvada and Viagra to enhance sex and stay safe]

TUPDX0104

High incidence of hepatitis C virus (re-)infections among PrEP users in the Netherlands: Implications for prevention, monitoring and treatment

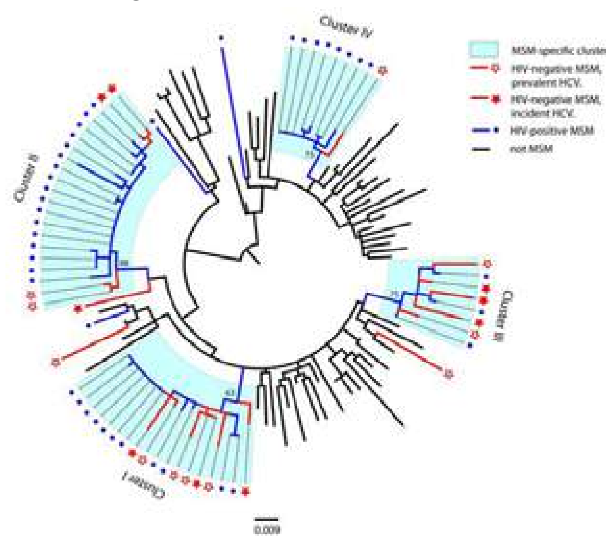
E. Hoornenborg[1], L.N. Coyer[1], R.C.A. Achterbergh[1], M.F. Schim van der Loeff[1], S. Bruisten[1], H.J.C. de Vries[1,2,3], T.J.W. Van de Laar[4], M. Prins[1,2], on behalf of the Amsterdam PrEP Project Team in the HIV Transmission Elimination AMsterdam Initiative (H-TEAM)
[1]*Public Health Service of Amsterdam, Amsterdam, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands,* [3]*RIVM, Bilthoven, Netherlands,* [4]*Sanquin Research, Amsterdam, Netherlands*

Background: Hepatitis C virus (HCV) prevalence was 4.8% among HIV-negative men who have sex with men (MSM) starting pre-exposure prophylaxis (PrEP) in the Netherlands. We studied the HCV incidence rate (IR), characteristics of newly infected individuals, HCV genotype distribution and phylogenetic clustering among MSM and transgender persons (TGP) who use PrEP in the Netherlands.

Methods: HIV-negative MSM (n=374) and TGP (n=2) participating in the Amsterdam PrEP project at the Public Health Service of Amsterdam were tested biannually for HCV antibodies, and subsequently for HCV RNA if antibodies were present. We analyzed data from study start (August 2015) through December 2017. We calculated the HCV IR, overall and separately for primary infection and re-infection, and described baseline characteristics of participants with incident HCV infection. HCV genotyping was performed by sequencing part of the HCV NS5B gene (420 bp). Phylogenetic trees were constructed to compare HCV strains from HIV-negative participants, HIV-positive MSM with acute or chronic HCV in Amsterdam and Dutch risk groups other than MSM.

Results: The median follow-up was 1.76 person years (py) (IQR 1.57-1.98). We diagnosed 12 incident HCV infections, all in MSM: 6 primary infections and 6 re-infections. The overall HCV IR was 1.9/100 py (95%CI 1.1-3.4). The IR of primary infection was 1.0/100 py (95%CI 0.5-2.2) and of re-infection 25.5/100 py (95%CI 11.5-56.8).

Incident HCV infections were of genotype 1a (n=9), 4d (n=1), 2b (n=1) and 3a (n=1). Phylogenetic analysis revealed that 8/9 HCV-1a infections were part of 4 large MSM-specific HCV-1a clusters containing MSM with and without HIV (Figure)



[Hepatitis C virus (HCV) phylogenetic tree for subtype 1a, comparing HCV sequences from HIV negative MSM with HIV positive MSM and unrelated persons.]

Median age of those with incident infection was 35 years (IQR 26-41), most were white (83%), chose for daily PrEP (92%) and reported chemsex (75%) before initiating PrEP (see table).

Conclusions: In the Netherlands, incidence of initial and re-HCV infection among HIV-negative MSM on PrEP was high and comparable to that observed in HIV-positive MSM. The high degree of phylogenetic clustering between HCV strains acquired by MSM with and without HIV suggests a shared transmission network. Regular HCV testing to provide prompt treatment as well interventions to lower HCV-related behavior should be offered to MSM on PrEP.

Age in years, median (IQR)	35 (26-41)
White ethnicity, no. (%)	10 (83%)
Living in Amsterdam, no. (%)	5 (42%)
Chose daily PrEP regimen, no. (%)	11 (92%)
Reported chemsex*, no. (%)	9 (75%)
Total number of anal sex partners in preceding 3 months, median (IQR)	19 (14-34)
Number of receptive condomless anal sex acts with unknown partners in preceding 3 months, median (IQR)	8 (3-22)
Chemsex is defined as use of gamma-hydroxybutyric-acid, mephedrone or crystal-methamphetamine around sex

TUPDX0105

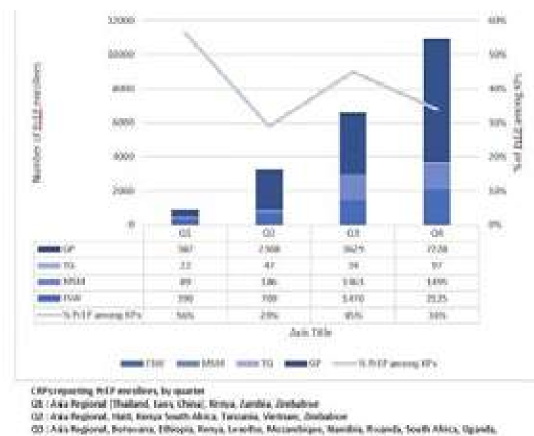
Expansion of HIV pre-exposure prophylaxis (PrEP) among key populations in PEPFAR's global program data, fiscal year 2016-2017

G. Djomand[1], T. Bingham[1], I. Benech[1], T. Wheeler[2], A. Sanicki[3], S. Mital[1]
[1]*Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB, Atlanta, United States,* [2]*United States Agency for International Development, Office of HIV/AIDS, Bureau for Global Health, Washington, DC, United States,* [3]*Office of the US Global AIDS Coordinator, Washington, DC, United States*

Background: Key populations (KP), such as men who have sex with men (MSM), female sex workers (FSW) and transgender persons (TG), experience a disproportionate risk of HIV infection compared to the general population (GP). Pre-exposure prophylaxis (PrEP) represents the preventive use of antiretroviral agents to reduce new HIV infections among HIV-negative individuals with significant risk behavior. PEPFAR, the largest bilateral funder of HIV programs globally, issued guidance to implement PrEP programming to reduce HIV incidence among KP, developed KP-specific monitoring indicators and began collecting KP disaggregated data in 2016-2017.

Methods: Program data on the number of people newly enrolled on oral PrEP are reported on a quarterly basis (Q1-Q4) as site-level totals by all partners receiving PEPFAR support. For each quarter, we summed the number across PEPFAR's 36 country or regional programs (CRP) that reported PrEP results among GP and KPs. We also calculated the proportion of all PrEP results contributed by KP and compared percentage change in PrEP enrollment for GP versus all KP groups between Q1 and Q4.

Results: Of the five CRPs that enrolled patients on PrEP in Q1, only three reported enrolling KPs. This increased to 8 of 13 CRPs in Q3 but decreased to 6 of 9 CRPs in Q4. In Q1, 501 KPs newly initiated PrEP (56% of all results) and in Q4, 3,717 KPs newly initiated PrEP (34% of all results) (Figure 1).



[Number and percentage of PrEP enrolees among key population and general population clients supported by PEPFAR, October 2016-September 2017]

All PrEP enrollment increased 1,133% from Q1 to Q4; 1,768% among GP and 642% among KPs. Among the KP groups, enrollment increased 445% among FSW, 1,580% among MSM, and 341% among TG between Q1 and Q4.

Conclusions: Over the four reporting periods in 2016-2017, PrEP enrollment increased substantially among both KP and GP, albeit with more attenuated success in scaling this effective HIV prevention intervention among key populations compared to the general population. To address slower growth in enrollment among all KPs, particularly for FSW and TG compared to GP, specific efforts are needed to streamline PrEP scale-up through advocacy with host country governments to address restrictive national policies and potential gender inequalities.

Altered TDF/FTC pharmacology in a transgender female cohort: Implications for PrEP

M.L. Cottrell[1], H.M. Prince[2], K. Maffuid[1], A. Poliseno[1], N. White[2], C. Sykes[1], J.A. Nelson[3], A. Peery[2], E. Dellon[2], L. Hightow-Weidman[2], J.L. Adams[4], C. Gay[2], A.D. Kashuba[1]
[1]UNC Eshelman School of Pharmacy, Chapel Hill, United States, [2]University of North Carolina School of Medicine, Chapel Hill, United States, [3]UNC Center for AIDS Research, HIV/STD Laboratory Core, Chapel Hill, United States, [4]University of the Sciences, Philadelphia, United States

Background: Transgender women (TGW) on feminizing hormone therapy (FHT) maintain estradiol (E2) concentrations 2-9 and 6-25 fold higher than cisgender women in the mid-follicular phase and cisgender men, respectively. E2 increases activity of 5´-nucleotidase enzymes, which can decrease the active metabolite tenofovir diphosphate (TFVdp) or increase its competing nucleotide (dATP), depending on cellular location. To assess intracellular pharmacology at HIV transmission sites, we measured TFVdp, emtricitabine triphosphate (FTCtp), and their competing nucleotides (dATP and dCTP, respectively) in rectal tissue (RT) of TGW vs postmenopausal cisgender women (CGW; a low E2 control group).

Methods: HIV-infected women on a Truvada® containing regimen with HIV< 50copies/ml and CrCl>60ml/min enrolled (N=4 TGW; N=4 CGW) between 01/2017 and 01/2018. Serum and RT biopsies were collected at a single visit. FHT included oral or injectable E2, medroxyprogesterone, and spironolactone. Serum E2 was measured with validated immunoassay (lower limits of quantification; LLOQ=20pg/ml). RT was homogenized and TFVdp/FTCtp and dATP/dCTP were measured by LC-MS/MS (LLOQ=0.1 and 0.05ng/ml, respectively). Values below limits of quantification (BLQ) were imputed at sample specific LLOQ (depending on biopsy size; 4/28 measures). All measures were BLQ for 1 TGW, and excluded from statistical analyses (Student's t-test and Pearson correlation using SASv9.4). Median (range) summary data are reported.

Results: Age, BMI and CrCl were 42(34, 46) vs 57(55, 59)years; 30(24, 42) vs 36(27, 38)kg/m²; and 114(100, 192) vs 108(61, 138)ml/min for TGW vs CGW, respectively. E2 concentrations in TGW [252(73, 490)pg/ml] were consistent with peak E2 in a typical periovulatory phase. TFVdp:dATP was 7-fold lower in TGW vs CGW (p=0.006; Table 1). One TGW exhibited TFVdp:dATP below an EC90 target ratio of 0.29. FTCtp:dCTP did not differ between groups and was above an EC90 target ratio of 0.07 in all participants. A significant inverse association was observed for $\log_{10}$E2 and TFVdp:dATP (r= -0.77; p=0.04).

Conclusions: This is the first description of TFVdp/FTCtp rectal concentrations in TGW on FHT. TFVdp relative to dATP was significantly lower in TGW and decreased with increasing E2. A cisgender male comparator will also be studied to confirm these findings. These data confirm in vitro findings and suggest that feminizing E2 may impact PrEP efficacy.

Analyte	CGW (N=4)	TGW (N=3)
TFVdp (fmol/g)	185158 (76265, 223542)	53674 (23240, 1170302)
FTCtp (fmol/g)	17247 (5959, 23181)	138293 (16303, 289495)
dATP (fmol/g)	7532 (5331, 11301)	547827 (6166, 656011)
dCTP (fmol/g)	6099 (2890, 8058)	80097 (5768, 251048)
TFVdp:dATP	20 (14, 30)	2.7 (0.08, 3.8)
FTCtp:dCTP	2.8 (2.0, 2.9)	2.3 (1.2, 2.9)

Background: It has been postulated that the direction of HIV transmission between two individuals can be determined by phylogenetic analysis of HIV sequences. This approach may be problematic, since HIV sequences from newly-infected individuals are often more similar to index sequences from samples collected years before transmission, compared to those from samples collected at the time of transmission. We evaluated the accuracy of phylogenetic methods for determining the direction of HIV transmission by analyzing next-generation sequencing (NGS) data from index-partner pairs enrolled in the HIV Prevention Trials Network [HPTN] 052 trial. HIV-infected index and HIV-uninfected partner participants were enrolled as serodiscordant couples; samples were analyzed from couples with index-to-partner HIV transmission that was confirmed by genetic linkage studies.
Methods: NGS for HIV gp41 (HXB2 coordinates: 7691-8374) was performed using plasma samples from 39 index-partner pairs (78 samples collected within 3 months of partner seroconversion). Maximum likelihood trees were generated using the entire data set using FastTree v.2. Topological patterns of HIV from each index-partner pair were analyzed.
Results: The analysis included 9,368 consensus sequences and 521,145 total sequence reads for the 78 samples analyzed. In 10% (4/39) of couples, the phylogeny was inconsistent with the known direction of transmission. In 26% (10/39) of couples, the phylogeny results could not discern directionality. In 64% (25/39) of couples, the results correctly indicated index-to-partner transmission; in two of these 25 cases, only one index sequence was closest to the most recent common ancestor.
Conclusions: Phylogenetic analysis of NGS data obtained from samples collected within 3 months of transmission correctly determined the direction of transmission in 64% of the cases analyzed. In 36% of the cases, the phylogenetic topology did not support the known direction of infection, and in one-third of these cases the observed topology was opposite to the known direction of transmission. This demonstrates that phylogenetic topology alone may not be sufficient to accurately determine the direction of HIV transmission.

TUPEA002

FAVITES: A framework for the simulation of compatible viral transmission networks, phylogenetic trees and sequences

N. Moshiri[1], M. Ragonnet-Cronin[2], J. Wertheim[2], S. Mirarab[3]
[1]University of California, San Diego, Bioinformatics and Systems Biology Graduate Program, BONITA, United States, [2]University of California, San Diego, Department of Medicine, La Jolla, United States, [3]University of California, San Diego, Department of Electrical and Computer Engineering, La Jolla, United States

Background: Reconstructing HIV transmission networks can greatly enhance epidemic intervention, but transmission network reconstruction methods have various limitations, and their accuracies are poorly understood, largely because it is difficult to obtain „truth" sets on which to test them and properly measure their performance.
Methods: We introduce a novel statistical framework of viral epidemic simulation, FAVITES, which is intended to simulate realistic viral contact networks, transmission networks, phylogenetic trees, and sequence data. The simulation process has been broken down into a series of abstract modules, and each implementation of a given module corresponds to a statistical model for that step of the simulation process. This gives users the flexibility to choose appropriate models and model parameters at ease.
We then perform a series of simulation experiments in which we model HIV transmission based on the at-risk population of San Diego, and we study various properties of the resulting transmission networks as well as analyze the performance of transmission cluster inference methods.
Results: We first show that the simulated phylogenetic trees have similar branch length distributions as trees inferred from a San Diego HIV-1 *pol* multiple sequence alignment as well as one from the Los Alamos National Laboratory, which supports the notion that model and parameter choices for transmission network and phylogenetic tree simulation were realistic and that the tool can indeed simulate realistic data. However, when compared against a profile Hidden Markov Model constructed from the San Diego alignment, the simulated sequences were unrealistic, implying that the model of sequence evolution used (GTR+Gamma) was inappropriate for modeling HIV *pol* evolution. We also show that existing transmission clustering tools tend to yield highly homogeneous clusters, but the clusters are typically incomplete and accuracy is sensitive to the transmission parameters.
Conclusions: We have created a framework that allows for the simulation of transmission networks, phylogenetic trees, and sequence data, and the framework is flexible to the user's virus and population of interest via choice of statistical model and model parameters. Further, we have demonstrated the need for more sophisticated models of HIV sequence evolution, which can easily be plugged into our framework once developed.

TUPEA003

Universal target capture of HIV sequences from NGS libraries

J. Yamaguchi[1], A. Olivo[1], O. Laeyendecker[2], K. Forberg[1], N. Ndembi[3], D. Mbanya[4], L. Kaptue[5], T. Quinn[2], G. Cloherty[1], M. Rodgers[1], M. Berg[1]
[1]Abbott Laboratories, Infectious Disease Research, Abbott Park, United States, [2]NIAID, NIH, Baltimore, United States, [3]Institute of Human Virology, Abuja, Nigeria, [4]Central Hospital de Yaoundé 1, Yaoundé, Cameroon, [5]Université des Montagnes, Bangangté, Cameroon

Background: Global surveillance of viral sequence diversity is needed to keep pace with the constant evolution of HIV. Recent next generation sequencing (NGS) methods have realized the goal of sequencing circulating virus directly from patient specimens. Yet, a simple, universal approach that maximizes sensitivity and sequencing capacity remains elusive. Here we present a novel HIV enrichment strategy to yield near complete genomes from low viral load specimens.
Methods: A non-redundant biotin-labeled probe set (HIV-xGen; n=652) was synthesized to tile all HIV-1 (groups M, N, O, and P) and HIV-2 (A and B) strains. Illumina Nextera barcoded libraries of either gene-specific (HIV-SMART) or randomly primed (Superscript) cDNA derived from in-

fected plasma were hybridized to probes in a single pool and unbound sequences were washed away. Captured viral cDNA was amplified by Illumina adaptor primers, sequenced on a MiSeq, and NGS reads were demultiplexed for alignment with CLC Genomics Workbench 9.0 software.

Results: HIV-xGen probes selectively captured and amplified reads spanning the entirety of the HIV phylogenetic tree. HIV sequences clearly present in unenriched libraries of specimens but previously not observed due to high host background levels, insufficient sequencing depth or the extent of multiplexing, were now enriched by >1000 fold. Thus, xGen selection not only substantially increased the depth of existing sequence, but also extended overall genome coverage by an average of 40%. We characterized 49 new, diverse HIV strains from clinical specimens and demonstrate a viral load cutoff of approximately log 3.5 copies/ml for full length coverage. Genome coverage was < 20% for 5/10 samples with viral loads < log 3.5 copies/ml and >90% for 34/39 samples with higher viral loads.

Conclusions: Characterization of >20 complete genomes at a time is now possible from a single probe hybridization and MiSeq run. With the versatility to capture all HIV strains and the sensitivity to detect low titer specimens, HIV-xGen will serve as an important tool for monitoring HIV sequence diversity.

Near full-length sequence analysis reveals no evidence of HIV-1 replication during therapy

S.-K. Lee[1], A. Rogers[1], Y. Xu[1], J. Warren[1], N. Goonetilleke[1], S. Zhou[1], S. Kosakovsky Pond[2], M. Bednar[1], B. Hauser[1], C. Gay[1], J. Kuruc[1], N. Archin[1], J. Eron[1], D. Margolis[1], R. Swanstrom[1]
[1]University of North Carolina, Chapel Hill, United States, [2]Temple University, Philadelphia, United States

Background: HIV-1 persistence in reservoirs has been the major obstacle for eradication. It is still unclear how HIV-1 maintains its latent reservoirs. Current conflicting data suggest that HIV-1 reservoirs are sustained by long-term survival and/or proliferation of cells infected before the initiation of ART, or by ongoing low-level replication of virus in sanctuary sites where drug concentrations are suboptimal. In this study we investigated the possibility of ongoing viral evolution during suppressive therapy by comparing near full-length viral genomic sequences from plasma at the time of therapy initiation early after infection and from the latent reservoir after years of therapy.

Methods: 5 participants in the UNC Acute Infection Cohort who initiated therapy early after infection and who had been infected with a single variant were selected. The participants spent an average of 61 months on therapy before undergoing leukopheresis for viral outgrowth assays (VOA). 5'- and 3'- half genomes were generated from the pretherapy viremic samples by single genome amplification (SGA), and from the VOA wells by bulk PCR. Phylogenetic trees were inferred from pre-therapy and VOA sequences and interpreted for evidence of divergence.

Results: A total of 78 SGA half-genome sequences from the 5 pretherapy plasma samples and 73 half-genome sequences from VOA wells were used to examine changes in the viral population. Sequences representing virus outgrowth from the reservoir were identical or highly genetically similar to the pre-therapy plasma samples for each participant (see figure), indicating no discernible evolutionary divergence from the pre-therapy sequence as surveyed across the entire genome after an average of 5 years of therapy (average mean pairwise distance 0.08%; range, 0.03%-0.2%, with no phylogenetic clades comprising VOA sequences) (see figure).

No resistance mutations to the drugs used in the regimens were detected. CTL specificity was mapped for one participant and no putative escape mutations were found in the outgrowth virus.

Conclusions: The results do not support the hypothesis of ongoing viral evolution in any of the 5 subjects on suppressive therapy for an average of 5 years. These data are consistent with the reservoir originating from cells infected before the initiation of ART.

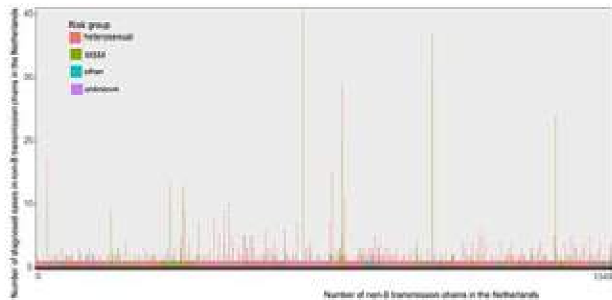
TUPEA005

Many introductions but little transmission of HIV-1 non-B subtypes amongst heterosexuals in the Netherlands

D. Bezemer[1], M. Hall[2], A. van Sighem[1], P. Reiss[1,3], C. Fraser[2], O. Ratmann[4]
[1]HIV Monitoring Foundation, Research, Amsterdam, Netherlands, [2]University of Oxford, Oxford Big Data Institute, Oxford, United Kingdom, [3]Academic Medical Center and Amsterdam Institute for Global Health and Development, Department of Global Health, Amsterdam, Netherlands, [4]Imperial College London, Department of Mathematics, London, United Kingdom

Background: An increasing proportion of newly diagnosed patients is infected with HIV-1 non-B subtypes, but little is known about the number, size, origin and composition of the transmission chains of these patients.

Methods: Viral phylogenetic analysis was used to identify and characterize distinct non-B transmission chains that circulate in the Netherlands. The first available *polymerase* sequence ≥750 nucleotides available per patient in the ATHENA cohort was selected; all available sequences from the Los Alamos National Lab HIV database were used to determine the phylogenetic context of non-B lineages in the Netherlands; and subtype-specific, viral phylogenies were determined with FastTree. Each viral lineage was associated to geographic regions with maximum parsimony based on the location of sequenced individuals, or on self-reported location of HIV acquisition. Dutch subtrees were extracted, and interpreted as distinct transmission chains in the Netherlands.
Results: By June 1st 2015, 9106/23,861 (38%) patients had a sequence available, and 2176 (24%) patients had a non-B subtype strain, of which 2030 in this study. Analysis by sample region had 1349 chains identified in the Netherlands (95%CI:1352-1399), where the majority 92% (1245) consisted of only 1-2 individuals (95%CI: 92-93). The figure illustrates the size of all identified non-B transmission chains in the Netherlands with patients colored by risk group. Ten transmission chains had ≥10 individuals (95%CI: 7-12). Six of these spread predominantly amongst men having sex with men (MSM), included 40% (130/328) of all MSM in the study, 78% of Dutch origin, and 95% reported to be infected in the Netherlands. One cluster of 13 was mixed MSM and heterosexuals. Three large chains included predominantly heterosexuals, and included only 2% (33/1403) of all heterosexuals in this study, 79% of foreign origin, and 56% reported to be infected abroad. Overall 82% of heterosexual in this study reported to be born abroad and 71% to be infected abroad. Only the 6 large national transmission chains amongst MSM were identified when the analysis was performed by region infection.
Conclusions: Viral phylogenetic analysis suggests that HIV-1 non-B infections amongst heterosexuals are predominantly introductions from abroad, whilst a few non-B subtypes formed sub-epidemics amongst MSM in the Netherlands.



[Non-B transmission chains in the Netherlands by size and risk group]

TUPEA006

HIV low level viremia can be caused by production of defective virus

A.J. Stam[1,2], M. Nijhuis[1], S. Loth[1], R. van Crevel[3], J. Rahamat-Langendoen[4], M.A.A. Claassen[5], H.S.M. Ammerlaan[6], J.E. Arends[2], M.E.E. van Kasteren[7], S.F.L. Lelyveld[8], W.F.W. Bierman[9], A.M.J. Wensing[1], LOWERIT Study Team
[1]UMC Utrecht, Medical Microbiology, Virology, Utrecht, Netherlands, [2]UMC Utrecht, Internal Medicine and Infectious Diseases, Utrecht, Netherlands, [3]Radboud University Medical Center, Internal Medicine, Nijmegen, Netherlands, [4]Radboud University Medical Center, Medical Microbiology, Nijmegen, Netherlands, [5]Rijnstate Hospital, Internal Medicine, Arnhem, Netherlands, [6]Catharina Hospital, Internal Medicine, Eindhoven, Netherlands, [7]Sint Elisabeth Hospital, Internal Medicine, Tilburg, Netherlands, [8]Spaarne Gasthuis, Internal Medicine, Haarlem, Netherlands, [9]University Medical Center Groningen, Internal Medicine, University of Groningen, Groningen, Netherlands

Background: A minority of HIV-infected patients demonstrate persistent low level viremia (LLV) despite the use of cART. It is still unclear if LLV is the consequence of viral production by activated HIV-infected cells, ongoing viral replication in sanctuary sites with suboptimal drug penetration, or both. It is important to distinguish between production and replication because ongoing viral replication and evolution may result in treatment failure.
Methods: The Dutch multicenter observational LLV cohort study (LOWERIT) intensively evaluated 31 patients with persistent LLV despite effective therapy and adherence counseling. LLV is defined as multiple viral loads (VL) between 50-1000cp/mL, at least one VL < 200cp/mL after at least 48 weeks of cART. At entry of the cohort all patients were switched to a boosted darunavir containing regimen for a duration of 48 weeks. Four subjects with persistent LLV at baseline, week 4 and week 8 or 12 were further investigated. VL was performed by standard diagnostics assays. RNA was isolated according to a LLV protocol using higher plasma inputs varying from 1.0 to 6.0 mL depending on VL, ultracentrifugation, followed by a RT-PCR of *pol* and Sanger sequencing of reverse transcriptase and protease genes.
Results: Four patients with a median age of 49 (range 45-51) years and median viral loads of 210cp/mL (baseline), 379cp/mL (week 4) and 201cp/mL (week 8/12) had their virus genotyped. There were no evident signs of HIV evolution and as such no selection of drug resistance was observed. Remarkably, in two patients with VL around 200cp/mL the viral population consisted of defective viruses. In one patient a protease active-site mutation was observed and in the other patient multiple stop codons in reverse transcriptase were detected.
Conclusions: Unexplained LLV despite active adherence counseling, effective therapy and frequent follow-up can be a consequence of production of defective HIV. The use of Sanger sequencing according to a low level viremia protocol can be a valuable tool to immediately distinguish between production and replication. Although residual viral replication could not be ruled out in the majority of patients, none of them showed clear signs of evolution nor selection of drug resistance.

Viral fitness and resistance

TUPEA007

Pol replicative capacity impacts disease progression in HIV-1 subtype C infection: Implications for vaccine design

D. Ojwach[1], T. Ndung'u[1,2,3], J. Mann[1]
[1]University of KwaZulu-Natal, HIV Pathogenesis Programme, Doris Duke Medical Research Institute, Durban, South Africa, [2]African Health Research Institute, Durban, South Africa, [3]Ragon Institute of MGH, MIT and Harvard, Massachusetts General Hospital and Harvard Medical School, Boston, United States

Background: CD8+ T cell mediated escape mutations can reduce viral replication and alter HIV-1 disease progression. We investigated the impact of immune-driven sequence variation in Pol, a highly conserved and immunogenic protein essential for viral replication, on viral replication capacity (RC) and disease progression in a large population of individuals infected with HIV-1 subtype C, the most prevalent subtype world-wide.
Methods: 487 patient-derived RT-integrase NL4-3 recombinant viruses were generated by electroporation of a green fluorescent reporter cell line (GXR cells) with plasma-derived *RT-integrase* PCR products and pNL43Δ*RT-integrase.* The replication capacities (RC) of recombinant viruses were determined by calculating the slope of increase in percentage infected cells, as measured by flow cytometry, from days 3-6 following infection.
Results: RT-integrase driven RC correlated significantly with viral load (r=0.28; p<0.0001) and CD4+T cell count (r=-0.27; p<0.0001) for the chronically infected patients and with subsequent viral load set point (r=0.28; p=0.02) and CD4+ T cell decline for the recently infected patients (p=0.013). Interestingly, 108 sequences had 51 additional base pairs compared to HXB2 and displayed significantly lower RC (p=0.0047). An analysis of the relationship between RT-integrase RC and host expression of HLA alleles, showed that HLA-A*3009 (n=5, p=0.048, q=0.07) and HLA-A*3303 (n=10, p=0.07, q=0.12) in the chronic infection cohort and HLA-A*26 (n=6, p=0.08), HLA-B*81(n=5, p=0.05) and HLA-B*07(n=6, p=0.02) in the recent infection cohort, were associated with decreased RC. In the recent infection cohort, increasing numbers of integrase HLA-associated polymorphisms present irrespective of host alleles significantly correlated

with lower RC (*r*=-0.25, *p*=0.024) and the association was stronger when limited to those in A list epitopes (*r*=-0.43, *p*<0.0001).Similar findings were observed with viral load set point suggesting that most HLA-associated polymorphisms that naturally arise in integrase lower RC. In the codon by codon analysis, the most pronounced decreases in RC were at Pol codons 396, 412, 427, 452,916 and 923.
Conclusions: The data suggest that RT-integrase-driven RC is clinically relevant. We identified immune-driven mutations in Pol that may significantly attenuate HIV. These data may inform which Pol epitopes are the most vulnerable for an attenuation-based vaccine.

TUPEA008

Evidence of high-level Raltegravir (RAL) resistance in patients from South Africa failing second-line antiretroviral therapy (ART)

A.E.A. Obasa[1,2], M. Classen[3], R. Cloete[4], K. Singh[2,5], U. Neogi[2], G. Jacobs[6]
[1]Stellenbosch University, Medical Virology, Cape Town, South Africa, [2]Division of Clinical Microbiology, Karolinska Institute, University of Stockholm, Department of Laboratory Medicine, Stockholm, Sweden, [3]National Health Laboratory Service (NHLS) Tygerberg, Department of Pathology, Cape Town, South Africa, [4]University of the Western Cape, South African Medical Research Council Bioinformatics Unit, South African National Bioinformatics Institute, Cape Town, South Africa, [5]University of Missouri, Department of Molecular Microbiology and Immunology and Christopher Bond Life Sciences Center, Missouri, United States, [6]Stellenbosch University, Pathology, Cape Town, South Africa

Background: South Africa has the largest HIV combination antiretroviral therapy (cART) roll-out program worldwide, currently accessible to approximately 3.4 million people. Resistance-associated mutation (RAMs) against antiretroviral inhibitors is a major challenge to the success of cART. HIV-Integrase (IN) has proven to be a viable target for highly specific HIV-1 therapy. There are currently three FDA-approved IN inhibitors (INIs): Raltegravir (RAL), Elvitegravir (EVG) and Dolutegravir (DTG).
Methods: Our diagnostic section at the Division of Medical Virology, Stellenbosch University and National Health Laboratory Services (NHLS), routinely screens for HIV-1 drug RAMs through the characterization of viral strains through analyses of the viral protease (PR) and reverse transcriptase (RT) gene. During this screens, the HIV-1 IN gene was used to analyse RAMs. Plasma samples were obtained from patients failing 2nd line cART and are currently receiving IN inhibitors (INIs). Samples were analysed by nested PCR and population-based conventional Sanger sequencing on the IN gene. RAMs were confirmed using Stanford HIV Drug Resistance Database.
Results: We analysed 13 patients currently receiving RAL as part of their cART regimen. Analyses revealed RAMs were present in 38% (n=5/13) patients. The most common major mutation was Y143R. Of the five patients with RAMs, four had a T97A accessory mutation in combination with major mutation Y143R confers high level of resistance to RAL, and are likely to be associated with low levels of EVG resistance. However, these mutations do not confer resistance to second-generation DTG, which was observed in 30.79% of samples (n=4/13). Genotypic analyses also revealed the absence of major and accessory RAMs at the rate of 53.8% (n= 7/13) and do not confer resistance to INIs.
Conclusions: In the absence of a cure for HIV, long-term cART outcomes need to be monitored effectively for maximum efficiency. RAMs lead to therapy escape mutants, which can ultimately cause cART failure. In the South African context, INIs are potentially a viable option for salvage therapy. Of importance, no major resistance to second-generation DTG were detected. However, there is still a need for the surveillance of the RAMs and ensure that patients receive the best possible treatment and care.

Entry (attachment, receptors and co-receptors, penetration and tropism)

TUPEA009

HIV-1 utilizes cellular galectin-3 to facilitate virological synapse mediated viral transmission and infection among CD4+ T cells

R.-Y. Yuan[1], C.-S. Yeh[1], W.-H. Wang[2], Y.-M.A. Chen[3], H.-Y. Chen[4], F.-T. Liu[4], S.-F. Wang[1,5]
[1]Kaohsiung Medical University, Department of Medical Laboratory Science and Biotechnology, Kaohsiung, Taiwan, Province of China, [2]Kaohsiung Medical University Hospital, Division of Infection Disease, Department of Internal Medicine, Kaohsiung, Taiwan, Province of China, [3]Kaohsiung Medical University, Center for Infectious Disease and Cancer Research, Kaohsiung, Taiwan, Province of China, [4]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, Province of China, [5]Kaohsiung Medical University Hospital, Kaohsiung Medical University, Department of Medical Research, Kaohsiung, Taiwan, Province of China

Background: Galectin-3 (Gal-3) is a -galactoside-binding lectin with multiple functions. Limited information is available regarding the role of Gal-3 in HIV-1 infection. We previously reported that Gal-3 promotes HIV-1 budding and Gal-3 was localized in immunological synapse (IS) as well as membrane lipid rafts. Several components for IS formation were known to be involved in VS formation, such as lipid raft and LFA-1. Accordingly, we hypothesized that cellular Gal-3 may play a role in VS mediated HIV-1 transmission and infection.
Methods: Gal-3 control and knockdown primary human CD 4+ T cells were generated using RNAi. Immunofluorescence staining and immunoblotting were used for evaluating VSs formation and their associated components colocalization with Gal-3. Membrane flotation and laurdan staining were performed to evaluate Gal-3 regulatory effects on polarization of membrane lipid rafts, LFA-1 and HIV viral proteins. Cell-to-Cell transmission and confocal live image observation were conducted to validate VSs formation and HIV cell-cell transmission efficacy correlated with Gal-3 expression. Mass spectrometry was performed to search the potential Gal-3 regulatory components relevant to VSs formation.
Results: Immunofluorescence staining and immunoblotting indicate that HIV-1 infection up-regulated Gal-3 expression and Gal-3 was colocalized with Gag, Env, Alix, CD4, LFA-1 at the lipid rafts(GM1) of cell-cell contact regions of primary CD4+ T cells. Gal-3 knockdown significantly reduced the colocalization of these proteins and VSs formation(~20% reduction) (p< 0.05). Membrane flotation data indicates that Gal-3 expression promoted colocalization and engagement of Gag, Env, LFA-1, Alix and flotinin-1(lipid raft marker) in lower sucrose density fractions. Laurdan staining results indicate significant higher lipid raft polarization toward intercellular contact regions in Gal-3 expressing CD4+ T cells(p< 0.001). Live image observation showed that Gal-3 associated with Gag from HIV-1 infected donor cells to the uninfected target cells via VSs. Cell-to-Cell transmission data indicates that Gal-3 knockdown in primary CD4+ T cells significantly reduced VS mediated HIV-1 transmission(p< 0.01). Mass spectrometry analyses indicate that cholesterol, sphingomyelin and phosphatidylcholine significantly ameliorated in Gal-3 knockdown CD4+ T cells compared with control groups(p< 0.01).
Conclusions: This study indicates that HIV-1 infection up-regulates Gal-3 to be utilized for facilitating VSs formation as well as HIV-1 cell-cell contact transmitted infection.

Viral replicative cycle (reverse transcription, integration, viral assembly and maturation)

TUPEA010

Analysis of the HIV-1 diversity in the remote areas of the Cape Winelands, Overberg and West Coast districts of the Western Cape Province of South Africa

S.G. Mikasi[1], B.G. Jacobs[2], S. Engelbrecht[2]
[1]Stellenbosch University, Pathilogy, Cape Town, South Africa,
[2]Stellenbosch University, Pathology, Cape Town, South Africa

Background: South Africa, with 7.1 million people infected, has the largest HIV-1 population worldwide, whilst approximately 3.4 million people are currently receiving combination antiretroviral therapy (cART). Although HIV-1 subtype C predominates in the region, we have seen an increased detection of non-C and unique recombinant form viral strains within the Western Cape Province. The emergence of HIV-1 drug resistant strains in South Africa is inevitable as cART coverage continues to increase.
Methods: In this study we analyzed the Protease (PR), Reverse Transcriptase (RT) and Intergrase (IN) regions of HIV-1 for diversity and resistance-associated mutations (RAMs) with a laboratory based PCR and Sanger Sequencing protocol. Two hundred HIV-1 viral load (VL) samples, from the Cape Winelands, West Coast and Overberg districts of the Western Cape Province were received from the National Health Laboratory Services (NHLS), with a VL of 2000 copies/ml and above. Sequence-specific subtype analyses were executed with the REGA HIV subtyping tool 3.0. Sequences were screened for RAMs using the Stanford University HIV Drug Resistance Database (HIVdb) 8.1.
Results: We successfully PCR amplified 170 (82.9%) PR, 166 (80.9%) RT and 143(81.3%) IN fragments. We could successfully sequence 173 (84.4%) of the samples included. HIV-1 subtype C was predominant (n = 144; 93.7%), with 5.3% of other subtypes detected. This includes A1 (n = 2; 1.3%), B (n = 4; 2.6%), D (n = 1; 0.7%) and H (n =1; 0.7%). No major RAMs were detected against PR and IN inhibitors. Minor RAMs were detected in 4 PR (3.7%) and 15 IN (16.1%) sequences analysed. RAMs against RT inhibitors were detected in 63 (61.7%) of the sequences analyzed.
Conclusions: As the national cART program continues to expand, HIV-1 diversity, viral load monitoring and drug resistance screening remains critical to the success of cART outcomes and reducing transmission rates. Subtype C is still the driving force of the epidemic in South Africa. Sequence analyses confirm that the majority of patients receiving VL testing have major RAMs against RT inhibitors used in first-line cART. Better surveillance systems for HIV diversity and drug resistance testing are required to ensure optimal success of cART.

TUPEA011

Resolving the intersection of HIV and the actin cytoskeleton

A. Ospina Stella, A. Aggarwal, S. Turville
The Kirby Institute, Sydney, Australia

Background: Direct cell-to-cell transmission of HIV is orders of magnitude more efficient than infection by cell-free virus, and is now recognized as a major mode of viral spread. Since this mechanism is strongly dependent on host cell motility and intercellular interactions, HIV uses multiple strategies to hijack the cellular actin cytoskeleton. Manipulation of actin dynamics leads to cell-type specific changes in leukocyte shape and behaviour that, together, promote overall spread of the infection. However, the involved mechanisms remain poorly understood at the molecular level.
Methods: Our study follows a systematic approach to evaluate the contribution of host actin regulatory proteins in the context of cell-cell HIV spread and cytoskeletal manipulation. To this end, we combined the power of CRISPR/Cas9 gene edition with high-resolution fluorescence microscopy, live cell imaging and self-developed viral transfer assays, to interrogate the loss-of-function phenotype of over 50 cytoskeletal regulators in infected myeloid cells (U937).
Results: Our results confirmed striking and versatile manipulation of the cytoskeleton by HIV, in particular via Rac1 and Cdc42 activated pathways. We also show the involvement of direct actin regulators in HIV-driven shifting of cellular actin pools into diverse membrane protrusion structures associated with cell motility and cell-cell contacts (e.g. Formins = filopodia, Arp2/3 = veils, Wave2 = pseudopodia). Furthermore, we partially characterize the mechanisms by which certain regulators enhance or decrease cell-cell viral transfer (e.g. Dia2, Rac1, cofilin, among others).
Conclusions: Our findings contribute to resolving the complex interactions between HIV and our cytoskeleton. The systematic nature of our study, combined with the use of cell types that are biologically relevant for HIV and of methods that allow total target-protein depletion, represent novel contributions to this field. A better understanding of these processes increases our ability to identify host proteins, rather than viral components, that can be targeted in the fight against HIV.
This not only reduces the probability of drug resistance, but also allows to capitalize resources from other areas of medical research (e.g. aberrant Rac1 activation is shared by all; HIV infection, cardiovascular/neurodegenerative disease and cancer).

Transcriptional and gene expression regulation (including regulatory genes)

TUPEA012

Analysis of Vpu-mediated CD4 and tetherin downregulation across major HIV-1 group M subtypes

G. Umviligihozo[1], K. Cobarrubias[1], S. Chandrarathna[1], N. Reddy[2], H. Byakwaga[3], C. Muzoora[3], B. Bwana[3], G. Lee[4], P.R. Harrigan[5], T. Ndung'u[2], P. Hunt[5], J. Martin[6], D. Bangsberg[7], Z.L. Brumme[1], M. Brockman[1]
[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [2]University of Kwazulu Natal, Durban, South Africa, [3]Mbarara University of Science and Technology, Mbarara, Uganda, [4]BC centre for Excellence in HIV/AIDS, Vancouver, Canada, [5]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [6]University of California, San Francisco, United States, [7]Oregon Health Sciences University, Portland, United States

Background: Downregulation of CD4 and tetherin by the HIV-1 Vpu protein allows virus-infected cells to evade host immunity and promotes viral egress; however, little is known about the functional diversity of Vpu among HIV-1 subtypes.
Methods: Plasma samples were collected from chronic ART-naive HIV-infected individuals from Uganda and Canada. HIV-1 RNA was extracted and Vpu sequences amplified by nested RT-PCR. Amplicons were cloned into an expression vector that features separate promotors driving Vpu and GFP. Vpu clones were functionally assessed by flow cytometry for their abilities to downregulate CD4 and tetherin following transfection into an immortalized CD4+ CEM T-cell line. Each Vpu activity was normalized to that of negative (empty vector, set to 0) and positive (Vpu NL4-3 strain, set to 1.0) controls, such that values below 1.0 indicate reduced function. Vpu sequence polymorphisms associated with functional variation were identified using codon analysis based on Mann-Whitney statistics.
Results: A genetically diverse panel of 238 Vpu sequences was cloned and phylogenetically authenticated. Clones represented four major group M subtypes (A [n=48], B [89], C [18] and D [72]) as well as 1 H and 10 CRFs. The in vitro function of 212 Vpu clones was assessed. Normalized downregulation activity (median [IQR]) was 1.04 [0.95-1.17] for CD4 and 0.92 [0.86-0.96] for tetherin. Significant differences were observed between Vpu clones from different subtypes for downregulation of CD4 ($p=0.005$, Kruskal-Wallis) but not tetherin ($p=0.2$). Overall, subtype B clones displayed better in vitro CD4 downregulation function compared to clones from the other subtypes. Multiple Vpu amino acids were associated with variation in CD4 and tetherin downregulation function ($p<0.05$), which differed between subtypes.

Conclusions: Our results highlight the extent to which global HIV-1 sequence diversity may impact critical Vpu functions. Analysis of natural polymorphisms associated with Vpu function may identify novel motifs associated with natural variation in protein activity that contribute to differences in the disease outcome.

TUPEA013

HIV-1 p55^{Gag} interaction with Dicer induces a dysregulation of specific micro RNAs and other small non-coding RNAs

S.P. Alpuche-Lazcano[1], A. Daher[2], E. Rance[1,2], A.J. Mouland[1,2], A. Gatignol[1,2]
[1]McGill University, Experimental Medicine, Montreal, Canada, [2]Lady Davis Institute, Montreal, Canada

Background: Human immunodeficiency virus type 1 (HIV-1) p55^{Gag} polyprotein is the minimal component required for the virus assembly. During the HIV-1 replication cycle, p55^{Gag} interacts with different cellular RNAs and proteins, possibly disrupting several cellular pathways. RNA interference (RNAi) is a post-transcriptional gene silencing process in mammalian cells that controls cell differentiation, development, and immunity. The RNA Induced Silencing Complex (RISC) is composed of Dicer, TRBP, and Ago2 proteins that mediate the formation of micro RNAs (miRNAs), which target mRNAs. The RNAi pathway is functional during HIV-1 replication, but its activity can be modified. Our hypothesis is that subtle modifications may lead to the modifications of miRNAs processing or activity, and consequently of mRNA levels. Our objectives are to:
1) identify interactions between HIV-1 proteins and components of the RNAi pathway and
2) characterize how these interactions induce modifications in the quantity and quality of miRNAs and other non-coding RNAs.
Methods: We used indirect immunofluorescence, Proximity Ligation Assay (PLA) and co-immunoprecipitation (co-IP) to characterize protein-protein interactions. We determined the cleavage capacity of Dicer using a catalytic assay with miRLet7-c and mir29a. We identified miRNAs and other small RNAs bound to Dicer by using RNA immunoprecipitation and sequencing (RIP-seq) followed by bioinformatics analysis.
Results: We identified that HIV-1 p55^{Gag} co-localizes with Dicer by immunofluorescence on a confocal microscope. By co-immunoprecipitation, we show that the two proteins interact in an RNA-independent fashion. By PLA, we determine that p55^{Gag} -Dicer interaction occurs mainly in the cytoplasm and we quantify the interaction (P< 0.001). Our results show that Dicer catalytic activity is not impaired by p55^{Gag} for the amount or size of miRNAs Let7-c and miR29a. Sequencing analysis shows a dysregulation of the production of specific miRNAs and other small ncRNAs when p55^{Gag} interacts with Dicer.
Conclusions: We have demonstrated by different methods that HIV-1 p55^{Gag} interacts with Dicer. RIP sequencing analysis shows that p55^{Gag} interaction with Dicer changes the binding of several miRNAs and ncRNAs to Dicer, indicating a dysregulation of the incorporation of these miRNAs in the RISC. Our data contribute to the understanding of how HIV-1 can alter cellular gene expression.

Innate immunity

TUPEA014

DDX3 senses abortive HIV-1 RNA transcripts and enhances immunity against HIV-1

M. Stunnenberg, S. Gringhuis, T. Geijtenbeek
Academic Medical Center, Experimental Immunology, Amsterdam, Netherlands

Background: Antiviral immune responses are paramount in limiting HIV-1 replication. However, antiviral immune responses are actively inhibited since the virus blocks viral sensing by RNA sensors. Recently, it was discovered that novel RNA helicase DDX3 senses HIV-1. Interestingly, upon HIV-1 infection the virus integrates in the host genome and during transcription initiation of the virus, abortive HIV-1 RNA transcripts are formed. Abortive HIV-1 RNAs are transported out of the nucleus and are sensed by DDX3, which subsequently results in the induction of antiviral IFN and interferon-stimulated genes (ISGs). Whether abortive RNAs can also induce other innate and adaptive immune responses remains unknown. Studying the effect of DDX3 targeting in immune cells can provide new insights for vaccine design strategies.
Methods: We investigated innate and adaptive immune responses of human monocyte-derived dendritic cells (DCs) upon stimulation with various abortive RNA ligands of DDX3. We studied whether triggering of DDX3 with synthetic abortive HIV-1 RNA constructs induces antiviral IFN and ISGs, DC maturation and limit viral replication capacity. This was examined by qPCR and flow cytometry techniques.
Results: Here we show that triggering DDX3 by synthetic HIV-1 abortive RNA induces antiviral innate and adaptive immunity in human DCs. Upon stimulation with abortive HIV-1 RNA, DCs show IFN-dependent maturation by increased CD86 expression levels. In addition, stimulation of DCs with abortive RNA leads to the activation of adaptive immune responses by inducing various cytokines. Strikingly, stimulation with abortive HIV-1 RNA strongly inhibits replication capacity of HIV-1 infected DCs. These findings show that triggering of the HIV-1 sensor DDX3 with abortive viral transcripts induces antiviral innate and adaptive immunity.
Conclusions: We identified HIV-1 sensor DDX3 as key player in the induction of antiviral immunity by (i) activation of IFN and ISG responses, (ii) induction of DC maturation, (iii) induction of adaptive cytokines and iv) decreasing viral replication capacity. Triggering of DDX3 could direct T helper skewing towards a type I immune response. Therefore, triggering this HIV-1 sensor is important to activate both innate and adaptive immunity against HIV-1 and targeting of DDX3 is important for vaccine design.

TUPEA015

Antiretroviral therapy effect on lymphocyte numbers and phenotypes in HIV infected children

J.T. Orikiiriza[1,2,3], B. Kikaire[3], R. Nabatanzi[4], J. Nakawesi[5], D. Turitwenka[2], A. Kambugu[2], M. Lamorde[2], F. Mubiru[2], J. Normark[6], J. Achan[7], V. Musiime[8], F. Lithander[9], A. Mullen[10], M. Hennessy[11], D.G. Doherty[3]
[1]Rwanda Military Hospital, Pediatrics, Kigali, Rwanda, [2]Infectious Diseases Institute Makerere College of Health Sciences, Research, Kampala, Uganda, [3]Trinity College Dublin, Immunology, Dublin, Ireland, [4]Makerere University, Molecular Immunology, Kampala, Uganda, [5]Mildmay Uganda, Pediatrics and Child Health, Kampala, Uganda, [6]Umeå University, Clinical Microbiology, Umeå, Sweden, [7]Medical Research Council Unit, Research, Banjul, Gambia, [8]Makerere University College of Health Sciences, Pediatrics and Child Health, Kampala, Uganda, [9]University Hospitals Bristol NHS Foundation Trust and University of Bristol, NIHR Bristol Biomedical Research Centre (Nutrition Theme), Bristol, United Kingdom, [10]School of Medicine, King's College London, Diabetes and Nutritional Sciences Division, London, United Kingdom, [11]Trinity College Dublin, Pharmacology and Therapeutics, School of Medicine, Dublin, Ireland

Background: Antiretroviral therapy (ART) leads to restoration of $CD4^+$ T cells however, the effect on other T cell subsets has not been studied in HIV infected children. Our objective was to investigate the effect of ART on circulating lymphocyte numbers and phenotypes in HIV infected Ugandan children.
Methods: Peripheral blood mononuclear cells were prepared from 34 ART-naïve and 40 ART-experienced malnourished children and from 27 ART-naïve and 43 ART-experienced well-nourished children (WNC) with HIV infection. Malnutrition was defined as weight-for-height z score below 2 standard deviations of that expected for age or mid-upper arm circumference < 12.5 cm with no edema. ART-experienced children had received ART for ≥ 6 months. Cells were stained with monoclonal antibodies specific for CD3, CD4, CD8, CD19, CD56 and the V24J18, V1, V2, and V3 T cell receptors. Frequencies and absolute counts of $CD4^+$, $CD8^+$, $CD4^-CD8^-$ (double negative, DN) and $CD4^+CD8^+$ (double positive, DP) T cells, B cells, natural killer (NK) cells, invariant natural killer T (iNKT) cells and the V1, V2 and V3 subsets of T cells were assessed using multicolor flow cytometry and data analysis by Prism version 7.
Results: $CD4^+$ T cell frequencies and numbers were significantly higher in both malnourished (P≤0.0001 and 0.0002, respectively) and WNC (P=0.0003 and 0.05) who received ART compared to ART-naïve children.

While absolute numbers of NK cells were lower in the ART-experienced malnourished children compared to ART-naïve malnourished children (P=0.03) and absolute numbers of B cells were lower in ART-experienced WNC compared to ART-naïve WNC (P=0.02). Interestingly, the frequencies and absolute numbers of DN T cells were significantly reduced in both malnourished (P=0.06 and 0.03) and WNC (P=0.0002 and 0.0001) on ART compared to their ART-naïve counterparts. The frequencies and numbers of V1 T cells were lower in ART-experienced malnourished (P=0.02 and 0.02) children compared to ART-naïve malnourished children. CD8+ T cells, DP T cells, iNKT cells, V2 and V3 T cells were found at similar frequencies and numbers in ART-naïve and ART-experienced patients from both cohorts.

Conclusions: ART efficiently promotes recovery of CD4+ T cell repertoire in malnourished and WNC but inversely affects innate T cell populations.

TUPEA016

Neutrophil dynamics during the highly pathogenic SIVsab infection of pigtailed macaques

E. Brocca Cofano[1,2], H. Tianyu[1,2], R. Sivanandham[1,2], B.B. Policicchio[1,3], P. Sette[1,2], T. Dunsmore[1], G.S. Haret-Richter[1,2], A. Landay[4], C. Apetrei[1,5,6], I. Pandrea[1,2,6]

[1]University of Pittsburgh, Center for Vaccine Research, Pittsburgh, United States, [2]University of Pittsburgh, Pathology, Pittsburgh, United States, [3]University of Pittsburgh, Department of Microbiology and Molecular Genetics, Pittsburgh, United States, [4]Rush University Medical Center, Chicago, United States, [5]University of Pittsburgh, Microbiology and Molecular Genetics, Pittsburgh, United States, [6]University of Pittsburgh, Microbiology and Infectious Diseases, Pittsburgh, United States

Background: Neutrophils are key contributors to the innate immunity. They are rapidly mobilized at the site of infection and fight pathogens through phagocytosis, killing of the infected cells or activation of adaptive immune cells. The interaction between platelet and neutrophils is critical for the neutrophil chemotaxis and function at the inflammation sites. During HIV infection, neutrophil counts and function are impaired, which may lead to the increased incidence of opportunistic infection. We investigated the dynamics, proliferation, apoptosis and function of neutrophils in a highly pathogenic SIV infection and the impact of antiretroviral treatment (ART) on these parameters.

Methods: Seventeen pigtail macaques were included. All animal were infected intravenously with 300TCID50 of SIV. After 42 days, all animals received a triple coformulated antiretroviral therapy (ART) containing tenofovir, emtricitabine and dolutegravir (PMPA+FTC+DTG). Neutrophil absolute counts, apoptosis and proliferation were assessed by flow cytometry. T assess phagocytosis and respiratory burst activity, functional assays were performed, measuring PARs and TF expression on neutrophils after LPS and thrombin stimulation. Cytokines secreted by neutrophils post-PMA stimulation were measured by Luminex.

Results: SIV infection induced a significant loss of circulating neutrophils. After ART, neutrophil counts were partially recovered, but did not reach the preinfection levels. High postinfection levels of apoptosis of neutrophils, which persisted post-ART, may be the factor behind neutrophil loss. Significant increases of neutrophil proliferation (Ki-67) occurred early in SIV infection. During late infection, proliferation decreased below the baseline, suggesting a loss of neutrophil replicative capacity. SIV infection significantly decreased phagocytosis and respiratory bust of neutrophils and ART does not provide any short- or long-term benefit. PAR-1 and TF expression on neutrophils increased after LPS stimulation. A clear decrease of neutrophil capacity to secrete cytokines was observed. ART only partially improved neutrophil function.

Conclusions: Significant decrease of neutrophil counts and function occur in SIV infection, and are not restored by ART. Phagocytosis and respiratory burst alterations, together with LPS-dependent increases of PARs and TF may contribute to the tissue damage and coagulation abnormalities observed during SIV infection.

TUPEA017

SAMHD1 has a central role in restricting HIV-1 in macrophages and is responsive to interferons, viral sensing and tyrosine kinase inhibition

M.A. Szaniawski[1], A.M. Spivak[1], T. Hanley[1], A. Bosque[2], J. Alcami[3], M.T. Coiras[3], V. Planelles[4]

[1]University of Utah, Salt Lake City, United States, [2]George Washington University, Washington, United States, [3]Instituto de Salud Carlos III, Madrid, Spain, [4]University of Utah, Pathology, Salt Lake City, United States

Background: Macrophages are susceptible to HIV-1 infection despite abundant expression of a variety of anti-viral host proteins, perhaps most importantly the restriction factor sterile alpha motif domain and histidine/aspartic-acid domain-containing protein 1 (SAMHD1). SAMHD1 is subject to regulation by multiple cyclin-dependent kinases, which inactivate the enzyme by phosphorylation at a specific threonine residue (T592). We investigated the role of SAMHD1 and its phosphodependent regulation in the context of HIV-1 infection in primary human monocyte-derived macrophages, the ability of various interferons (IFN) and FDA-approved tyrosine kinase inhibitors to modulate this process.

Methods: CD14+ monocytes were isolated from whole blood of healthy donors and differentiated for seven days in medium containing 10% pooled human serum. Mature, adherent macrophages were incubated with various interferons or pharmacologic agents, then analyzed for SAMHD1 protein and T592 phosphorylation or infected with HIV-1. To determine the role of SAMHD1-mediated, IFN-induced HIV-1 restriction, cells were treated with exogenous deoxynucleosides or virus-like particles containing the SIV protein, Vpx.

Results: We show that stimulation by types I, II, and III interferons converge upon activation of SAMHD1 via dephosphorylation at Threonine-592 and do not exert their effect through changes in SAMHD1 protein levels. The IFN-induced anti-viral state was phenocopied by incubation with Dasatinib, a tyrosine kinase inhibitor, which resulted in dephosphorylation of SAMHD1 and profound protection from infection. While IFN-induced dephosphorylation of SAMHD1 correlated with transcriptional downregulation of the cyclin dependent kinase-1, dephosphorylation in response to Dasatinib was effected through a different mechanism.

Conclusions: This study shows that SAMHD1 activation, and not protein induction, is the major effector function induced by types I, II, and III IFN signaling in macrophages, and presents a pharmacologically actionable target through which HIV-1 infection can be subverted. We also show that CDK1 is the main kinase acting on SAMHD1 in primary macrophages. Additionally, regulation of SAMHD1 can be achieved through specific FDA-approved tyrosine kinase inhibitors that very potently restrict infection.

TUPEA018

Evidence for elevated inflammation in young gay and bisexual men

E. Morgan[1], H. Taylor[1], D. Ryan[1], R. D'Aquila[2], B. Mustanski[1]

[1]Northwestern University, Medical Social Sciences, Chicago, United States, [2]Northwestern University, Medicine, Chicago, United States

Background: Young men who have sex with men (YMSM), compared to their heterosexual counterparts, have been found to experience elevated levels of systemic inflammation. Prolonged exposure to increased inflammation has been associated with multiple comorbidities such as cardiovascular disease, diabetes, and cancers. Developing a better understanding of how inflammation varies among YMSM, particularly in the context of HIV infection, is a critical first step towards reducing systemic inflammation and averting its associated comorbidities.

Methods: Data were collected as part of the RADAR cohort of YMSM (aged 16-29) in Chicago from 2015-2017. HIV-positive participants were matched 1:1 with an HIV-negative participant based on demographic factors. C-reactive protein was assayed for all HIV-positive and matched HIV-negative participants. Cytokine panels (GM-CSF, IL-15, VEGF, MIP-1A, MIP-1B, IFN-G, IL-10, IL-12P70, IL-1B, IL-6, TNF-A) were completed for all HIV-positive participants and a subset of the HIV-negative partici-

pants. Pearson's correlation coefficients and adjusted linear regressions were utilized to assess the relationship between sexual risk behaviors and all biomarkers for inflammation.
Results: Among 1,031 RADAR participants, 148 (14.4%) were identified as HIV-positive. No difference in CRP was observed between those infected and uninfected with HIV. HIV status was negatively associated with IL-15 (p< 0.001) and positively associated with VEGF (p< 0.001), IL-12p70 (p< 0.01), IL-1B (p< 0.001), and TNF-A (p< 0.001). CRP was significantly associated with BMI (p< 0.01), however, it was not associated with drug or alcohol use, rectal gonorrhea or chlamydia, viral load, nor anti-retroviral therapy use. Psychosocial factors (e.g. depression, perceived stigma, etc) were minimally associated with VEGF, IFN-G, and IL-12p170, but not with CRP. In adjusted linear regression models, any receptive anal sex and any condomless receptive anal sex were both found to be significantly associated with IL-6 but not CRP.
Conclusions: In this analysis, we observed few significant associations with biomarkers of inflammation among YMSM. These findings suggest that factors responsible for elevated systemic inflammation among this population may be more complicated than previously thought. Further research needs to be conducted in this population to understand this phenomenon and to mitigate associated comorbidities.

Humoral immunity (including broadly neutralizing antibodies)

TUPEA019

Neutralizing antibody response in HIV-1 CRF02_AG infected subjects

A.J. Nanfack[1,2], G. Ambada[1], C. Courtney[2], A. Ndjolo[1], R. Duerr[2]
[1]Chantal Biya International Reference Center (CIRCB), Immunology and Microbiology, Yaounde, Cameroon, [2]New York University School of Medicine, Pathology, New York, United States

Background: One of the greatest challenges in the HIV-1 vaccine field remains the design of immunogens able to elicit antibodies that can neutralize diverse HIV-1 strains. Neutralizing antibodies are a critical component of the protective immunity required for developing an effective HIV-1 vaccine. In addition, it is necessary to design vaccine antigens which induce a potent and broadly neutralizing antibody response against various HIV-1 strains. So far, neutralizing Ab studies have mainly covered subtypes B and C. Here we evaluate neutralizing Ab response in HIV-1 CRF02_AG which is the most prevalent subtype in Cameroon.
Methods: Samples longitudinally collected (spanning on 7 years, 2001 - 2008) from 5 patients infected with HIV-1 CRF02-AG (ART naive) were used for this study. We assessed their breath and potency for heterologous neutralization. We performed TZM-bl neutralization assay using 2 primary viruses (both HIV-1 CRF02_AG), one tier1B (Bal26) and five tier2 (T250, Q23.17, Tro.11, Zm249 and X2131) viruses. Neutralization curves were shown as nonlinear regression fits calculated in GraphPad Prism. IC50 values were determined in the fitted curves for the reciprocal plasma dilutions at 50% neutralization.
Results: Neutralization responses remained weak for all the longitudinal plasma samples with IC50 values not exceeding 39 (plasma dilution) for primary viruses. One patient out of five exhibited a good neutralizing response for all the time points and to almost all the pseudovirus tested; particularly for Bal26 (222≥IC50≥588), Q23.17 (118≥IC50≥222) and X2131(93≥IC50≥322). The neutralizing responses for other patients were very contrasting depending to the pseudovirus tested; moderate response was observed for two patients for X2131 (IC50≥200) while others had IC50 ≤75. T250 was the most difficult pseudovirus to neutralize with the highest IC50 at 145 while Bal 26 was the easiest to neutralize with IC50>500. None of the patient was able to neutralize MLV-env pseudotyped HIV-1, thus confirming that none of the patients were receiving ART at the time of plasma isolation.
Conclusions: We have provided the initial insight into neutralizing breath and potency of HIV-1 CRF02_AG, therefore delivering valuable information into factors that might be mandatory for successful vaccine aiming at eliciting broad neutralizing antibodies against HIV.

TUPEA020

Broadly neutralizing antibodies and their specificities in chronic HIV-1 subtype C infection

K. Robertson[1], B. Ndlovu[1], L. Morris[2], P. Moore[2], T. Ndung'u[1]
[1]University of KwaZulu Natal, HIV Pathogenesis Programme, Durban, South Africa, [2]National Institute for Communicable Diseases, AIDS Virus Research Unit, Johannesburg, South Africa

Background: There is a global need for an effective HIV-1 vaccine and this may be achieved by eliciting broadly neutralizing antibodies (bNAbs). The development of bNabs occurs in only 10-30% of HIV-1 infected individuals. However the mechanism that leads to the development of bNAbs is unknown. The purpose of the study was to identify individuals that developed broadly neutralizing antibodies, determine their specificities on the viral envelope, and characterize the longitudinal kinetics of these bNAbs.
Methods: Twenty antiretroviral naïve individuals with chronic HIV-1 subtype C infection were screened for bNAbs at 3 years post enrolment. A standard panel of 18 HIV-1 pseudoviruses (6 subtype A, 6B and 6C) was used to screen the participants using the TZM-bl luciferase reporter gene assay. To characterize the kinetics of bNAbs over time, the individuals that developed bNAbs were followed up longitudinally for approximately 7 years post enrolment. Plasma viral loads and CD4+T cell counts were measured using Roche Amplicor assay or the Roche Ultrasensitive assay, and Trucount technology respectively. Specificity of the antibodies was determined using site-directed mutagenesis on known bNAb target epitopes.
Results: Forty seven percent of individuals developed bNAbs that neutralized all 18 pseudoviruses. In contrast, 89.5% neutralized at least half of the pseudoviruses. Participant SK008 and SK163 antibodies neutralized with high potency and breadth across heterologous viruses. The antibody longitudinal neutralization profiles illustrated peaks in neutralization, which corresponded to a drop in viral load in participant SK-008. The two participants did not map to the tested epitopes.
Conclusions: A higher than expected percentage of study participants developed bNAbs. Participant SK008 had the highest neutralization capability and should be sequenced longitudinally, along with autologous virus, to assess virus/host co-evolution. Neutralization profiles suggest a switch in antibody specificity and viral escape. Antibodies may be targeting novel epitopes or targeting alternative locations on known epitopes. Data from this study may have relevance to the development of an efficacious HIV-1 vaccine.

TUPEA021

Broadly neutralizing plasma antibodies obtained from an Indian donor with specificity to linear epitopes in V1 and V4 region of viral Env preferentially neutralize HIV-1 clade C

S. Deshpande[1], R. Kumar[1], S. Samal[1], S. Patil[1], T. Shrivastava[1], K.G. Murugavel[2], A.K. Srikrishnan[2], J. Bhattacharya[1,3]
[1]Translational Health Science and Technology Institute (THSTI), HIV Vaccine Translational Research Laboratory (HVTR), Faridabad, India, [2]YRG Care, Chennai, India, [3]International AIDS Vaccine Initiative, New York, United States

Background: Broadly neutralizing antibodies (bnAbs) developed in few individuals infected with HIV-1 are providing viral clues towards design and development of prophylactic and therapeutic vaccines. HIV-1 subtype C which accounts for majority of global infection majorly circulating strain in India.
In an IAVI Protocol G study, we examined the basis of neutralization breadth of plasma antibodies obtained from an anti-retroviral naïve Indian donor chronically infected with HIV-1 subtype C.
Methods: Neutralization breadth of the plasma antibodies was examined using a panel of 50 envelope (Env)-pseudotyped viruses in a TZM-bl assay. Antibody specificities was assessed by using chimeric Envs prepared between sensitive and resistant HIV-1 clade C Envs, depletion by monomeric and trimeric soluble Env proteins and competitive peptide inhibition assay by ELISA and TZM-bl neutralization assay.

Results: The plasma sample with viral RNA load of 50,668 copies/ml was found to neutralize >70% of the panel virus with median ID_{50} of 255.61. Interestingly, the neutralization breadth was found to be associated with HIV-1 clade C. Virus neutralization using chimeric Envs prepared between a sensitive (16055-2.3) Env and a resistant (PG80v1.eJ19) Env, indicate that plasma antibodies have major specificity to V1 and V4 region. Comparable data were obtained using autologous Envs. Significant loss of neutralization breadth of the plasma antibodies was found to be associated with depletion with monomeric gp120. Furthermore, competitive inhibition by different peptide sequences indicated that the neutralization breadth of the plasma antibodies was associated with linear epitopes in V1 and V4 region not reported earlier.

Conclusions: Our study identified discontinuous targets on gp120 associated with enhanced neutralization susceptibility of viruses to plasma of this particular individual. Such information will facilitate rational optimal designing of antigen bait towards successful isolation of bnAbs from this individual and also informed novel vulnerabilities associated with immune evasion in the course of natural infection.

TUPEA022

Generation of immunogens based on virus-like particles carrying HIV-1 envelopes from patients with broadly neutralizing responses within the first 6 months of infection

C. Beltrán-Pavez[1,2], N. González[1], A. Fabra García[3,4], A. Merino Mansilla[1], A. Olvera[5], J.M. Miró[6], C. Brander[5], J. Alcamí[1], E. Yuste[1], V. Sánchez-Merino[4]

[1]Institute of Health Carlos III, ISCIII, National Microbiology Centre, Madrid, Spain, [2]University of Barcelona, Faculty of Pharmacy and Food Science, Barcelona, Spain, [3]Radboud University, Medical Microbiology, Nijmegen, Netherlands, [4]IDIBAPS, Hospital Clinic of Barcelona, Barcelona, Spain, [5]IrsiCaixa. Hospital Germans Trias i Pujol., Badalona, Spain, [6]Hospital Clinic of Barcelona, Barcelona, Spain

Background: It is generally assumed that the induction of broadly neutralizing antibody (bNAbs) requires long periods of antigen exposure, an observation that complicates vaccine design. We have previously reported the identification of patients who displayed broadly neutralizing responses within the first 6 months of HIV infection. We hypothesize that viral envelopes from these patients would be ideal immunogens for bNAb induction. Since additional evidence indicates that native envelope conformation, a lipidic environment and good T-cell responses are required for an efficient induction of bNAbs, we generated HIV-1-Gag virus-like particles (HIV-1-Gag-VLPs) optimized as T-cell immunogens, and carrying HIV-1 envelopes from patients with bNAbs detectable during early stages of infection.

Methods: Plasmas were mapped for recognition of CD4bs, glycans and MPER, by ELISA and neutralization assays. HIV-1 envelopes were amplified and sequenced from plasma viral RNA. Major viral populations were analyzed by Neighbor-Joining, N-GlycoSite and Variable-Region-Characteristics tools. Envelope infectivity was characterized in TZM-bl cells. HIV-1-Gag-VLPs, generated with HIV-1-Gag optimized as a T-cell immunogen, carrying selected envelopes were produced in 293F cells and characterized by electromicroscopy, Western Blot and ELISA.

Results: HIV-1 envelopes from two patients were selected as immunogens: 887 and 936 (96 and 159 d.p.i, respectively), due to the capacity of their sera to neutralize across 4 subtypes (A, B, C and AE), a minor NXS/NXT ratio in N-glysosites and the absence of N332-glycosite. Epitope mapping of plasma from these patients showed recognition of N160 glycosite. Next, we generated expression vectors for these envelopes in which A501C, T605, and L535M mutations were added to stabilize trimers. Pseudotyped viruses generated with these envelopes were infectious, confirming trimer functionality. HIV-Gag-VLP characterization showed a spheric shape and 130 nm in diameter. In addition, VLPs efficiently incorporated both envelopes, and trimers were detected. Finally, antigenic characterization showed that VLPs expressed a significant amount of envelope that is recognized by trimer-specific antibodies (PGT151 and PGT145).

Conclusions: We generated HIV-1-Gag VLPs optimized as T-cell immunogens that incorporate, in a native conformation, HIV-1 envelopes from two patients who show broadly neutralizing responses in early infection. These vaccine prototypes are promising immunogens to reproduce the induction of bNAb in recent infection by vaccination.

TUPEA023

Identification of VRC01-like neutralizing antibody response in HIV-1 subtype C infected individuals from Southern India

P. Nandagopal[1], J. Bhattacharya[2], A.K. Srikrishnan[1], G. Rajat[3], C.R. Swathirajan[1], S. Saravanan[1], R. Vignesh[1], S.S. Solomon[1,4], S. Nikhil[3], M. Joyeeta[3], C. Shweta[3], K.G. Murugavel[1]

[1]YRG Center for AIDS Research and Education, Chennai, India, [2]Translational Health Science & Technology Institute (THSTI), HIV Vaccine Translational Research Laboratory, Faridabad, India, [3]International AIDS Vaccine Initiative (IAVI), New Delhi, India, [4]Johns Hopkins University School of Medicine, Baltimore, United States

Background: Identification of VRC01and other VRC01-like antibodies has been a breakthrough in the field of broadly neutralizing antibodies (bNAbs) owing their strong neutralization profile and enhanced efficacy. These CD4bs-binding antibodies are elicited only in a few individuals and have mostly been isolated from HIV-1 subtype B infected individuals. There are very few reports on the prevalence of VRC01-like antibodies in HIV-1 infected individuals in India.

Methods: In this study, plasma samples from 70 ART-Naïve HIV-1infected individuals at different stages of disease progression were tested against a heterologous panel of viruses (n=11) from subtypes A, B, C, G, AC, BC & AE. Samples with >50% neutralization breadth were then tested against an extended panel (n=19) of subtype C and A viruses to evaluate for broadly cross-reactive neutralization (BCN) response. The plasma samples exhibiting cross-reactive neutralization response were assessed for binding specificity to CD4bs through their affinity for the well-characterized resurfaced stabilized gp120 core (RSC3) protein probe and its cognate CD4bs mutants.

Results: Out of 70 samples screened, 28 (40%) showed neutralization activity, among them 8 (11%) had broad and potent neutralization response and 20 (29%) showed cross-reactive neutralization response. 11 (55%) of these cross-reactive plasma samples exhibited strong binding affinity to RSC3 core protein, of which 7 plasma samples showed reduced (> 3 fold) affinity towards RSCΔ371I/P363N probe (negative control) indicating presence CD4bs-specific neutralization response. In addition, two of these plasma samples from chronically infected individuals (slow progressors-LT-VNP28 & LT-VC 11) showed stronger (>3 fold) affinity towards RSC03/G367R mutant probe, suggesting presence of VRC01-like antibodies (Table.1).

Conclusions: To the best of our knowledge, this is the first report indicating the presence of VRC01-like CD4bs-binding antibodies in the plasma of HIV-1subtype C infected individuals from Southern India, and can pave the way for isolation and characterization of potent bNAbs from India to aid in design and development of vaccines and other therapeutic interventions.

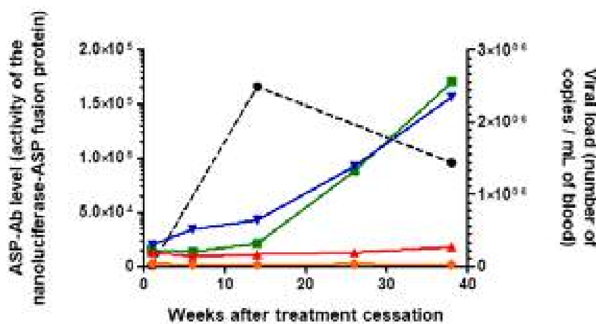
TUPEA024

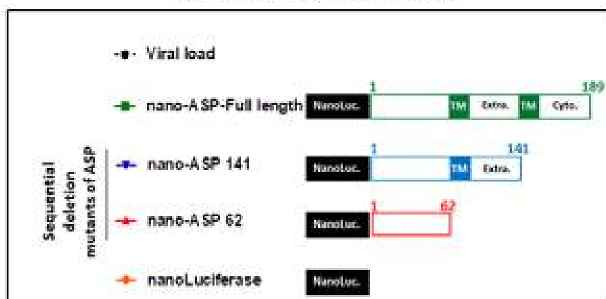
Characterization of the humoral response directed against the Antisense Protein of HIV-1 in patients

J. Savoret[1], P. Van de Perre[2], J.-M. Mesnard[1], A. Gross[1]
[1]*Infectious Disease Research Institute of Montpellier (IRIM), Montpellier, France,* [2]*National Institute of Health and Medical Research (INSERM), Montpellier, France*

Background: Recently we have shown that the gene encoding for the AntiSense Protein (ASP) of HIV-1 is uniquely conserved in the group M of HIV-1, which is responsible for the human pandemic. Although these results suggest a role for ASP in the HIV-1 virulence or transmission, the exact function of ASP in these events remains unknown. To better understand the impact of ASP expression in HIV-1 infection, we assessed the humoral response directed against ASP (referred as ASP-Ab) in HIV-1 infected patients using a nanoluciferase-ASP fusion protein immunoprecipitation system. We then wondered whether this response correlated with delayed progression to AIDS by comparing its dynamic trend over time to that of viral load.

Methods: Plasma samples from 40 HIV-1 infected patients from Burkina Faso (n=20) or South Africa (n=20) were used. The patients were women ineligible for HAART according to local recommendations and were initially recruited for a clinical trial investigating a new peri-exposure prophylaxis to prevent HIV-1 transmission by breastfeeding (PROMISE-PEP trial). In this context, patients were treated for several weeks during pregnancy and treatment was stopped after delivery. Samples were collected at different times after delivery to assess viral load. Taking advantage of this longitudinal follow-up, levels of ASP-Ab were assessed in the collected samples. Using constructs expressing sequential deletion mutants of ASP, the domains of ASP inducing a humoral response in patients were characterized.





[Dynamics of the viral load and of the humoral response directed against several domains of ASP in an untreated HIV-1 infected patient]

Results: High ASP-Ab levels were found in 20% of patients from Burkina Faso and in 10% of South African patients. Deletion of the cytoplasmic N-terminal domain of ASP did not impair the detection of ASP by patients' antibodies, contrary to deletions of predictive transmembrane and extracellular domains of ASP. Interestingly, one patient displayed antibodies recognizing all the deleted-forms of ASP and also showed very low viral load. Otherwise, two patients presented a progressive rise of the ASP-Ab levels after treatment cessation, which was followed by a decline in viral load.

Conclusions: All together, these results showed that the ASP-specific humoral response
(i) preferentially targets a major epitope of ASP;
(ii) varies over time following treatment cessation and
(iii) might be followed by a decline in viral load.

Cellular immunity

TUPEA025

The lower spare respiratory and glycolytic capacity of peripheral blood mononuclear cells from MSM is not associated with CMV infection

Z. Kruize, I. Maurer, K.A. van Dort, N.A. Kootstra
Academic Medical Center, Experimental Immunology, Amsterdam, Netherlands

Background: Previously we observed a higher proportion of senescent T cells in treated HIV-positive individuals and matched HIV-negative controls as compared to blood bank donors (BBD). The high levels of T cell senescence was strongly associated with CMV infection. Mitochondrial function and glycolysis play important roles in proliferation, terminal differentiation and effector functions of immune cells. Here we analyzed the effect of T cell senescence and CMV infection on the cellular energy metabolism.

Methods: PBMCs were obtained from men having sex with men (MSM) (n=40) and BBD (n=26). The immune phenotype (T cell differentiation CD45RA/CCR7/CD27; senescence CD27/CD28/CD57) was determined by flow cytometry.
The cell energy metabolism of PBMCs was analyzed using the Seahorse XFe96 Analyzer: Oxygen consumption rate (OCR) was measured to determine mitochondrial respiration and the extracellular acidification rate (ECAR) was analyzed to determine glycolysis.

Results: Immune phenotyping revealed a significant increase in CD4 and CD8 effector memory T cells ($CD45RA^-CD27^-CCR7^-$) and CD8 effector T cells ($CD45RA^+CD27^-CCR7^-$) in MSM as compared to BBD. Furthermore, a significant increase in CD4 and CD8 T cell senescence ($CD27^-CD28^-$; $CD57^+$; $CD57^+$ of $CD28^-$) was observed.
Analysis of the cell energy metabolism revealed that mitochondrial respiration was comparable between BBD and MSM, however lower spare respiratory capacity was observed in MSM (OCR; BBD 56.71 ± 24.76 vs MSM 36.65 ± 19.45, p=0.0004). The glycolytic capacity was significantly decreased in MSM (ECAR; BBD 7.55 ± 3.09 vs MSM 4.64 ± 1.54, p=$4.5x10^{-6}$).
Multivariate analysis showed that CMV infection was associated with increased proportions of CD8 effector memory, CD8 effector and senescent T cells, but not with lower spare respiratory and glycolytic capacity in MSM.

Conclusions: We observed that MSM had higher proportions of effector memory and senescent CD4 and CD8 T cells as compared to BBD, which could largely be attributed to high prevalence of CMV infection in MSM. Furthermore, we observed a significant decrease in spare respiratory and glycolytic capacity of PBMCs from MSM, which is indicative for a decreased proliferative ability of these cells. The lower spare respiratory and glycolytic capacity was not associated with CMV infection.

TUPEA026

TGF1 enhances R5 tropic HIV infection in activated and resting memory CD4 T cells through upregulating CCR5 expression

K.S. Lam, K.-W. Cheung, Z. Chen
University of Hong Kong, AIDS Institute, Hong Kong, Hong Kong

Background: TGF1 is upregulated in both acute and chronic HIV-1 patients. The level of TGF is associated with AIDS disease progression. However, whether TGF1 contributes to HIV pathogenesis remains largely unknown. Here, we found that TGF1 upregulates one of the major HIV coreceptors, CCR5 in memory CD4 T cells. Therefore, we hypothesize that TGF1 may facilitate R5 tropic HIV-1 infection in memory CD4 T cells through inducing CCR5 expression.
Methods: Memory CD4 T cells were isolated from peripheral blood mononuclear cells. Activated CD4 T cells were prepared by culturing in IL-2 and IL-15 for 4 days. Resting CD4 T cells were enriched by the depletion of CD25, CD69, and HLA-DR positive cells. TGF1 treatment was done for 3 days. Phenotype changes of the cells were analyzed by flow cytometry. The HIV susceptibility of the was studied by using pseudovirus and live-replicating virus. For viral outgrowth assay (VOA), infected resting CD4 T cells were stimulated by anti-CD3/anti-CD28/IL-2/IL-15 followed by co-culturing with MOLT4-CCR5 cell line for 7 days. The viral load was detected by TaqMan qPCR.
Results: Our result shows that TGF1 enhanced the percentage and MFI of CCR5 expression in both activated or resting memory CD4 T cells. This increase was inhibited by the TGF1 type I receptor antagonist - SB431542, indicating that the increase in CCR5 expression is TGF1 dependent. To evaluate the effect of TGF1 on CD4 T cells during HIV-1 infection, TGF1 stimulated CD4 T cells were infected with pseudotyped virus with R5 tropic HIV-1 envelope. We found that HIV-1 infection was significantly increased in TGF1 stimulated activated memory CD4 T cells. In contrast, TGF1 has no effect when the cells were infected with VSV enveloped pseudovirus. These results suggest that TGF1 promotes HIV infection through upregulating CCR5 expression. Due to the low HIV transcription efficiency in resting CD4 T cells, we assessed its susceptibility towards infection by HIV-1_{JR-FL} followed by VOA. Consistently, TGF1 also facilitated HIV infection in resting CD4 T cells.
Conclusions: Our results provide a new insight that TGF1 facilitates R5 tropic HIV-1 infection in activated or resting memory CD4 T cells through upregulating CCR5.

TUPEA027

Changes in circulating gamma delta T cell subset numbers in immunological and virological responders and non-responders among HIV-infected children on antiretroviral therapy

J.T. Orikiiriza[1,2,3], B. Kikaire[3], R. Nabatanzi[4], J. Nakawesi[5], D. Turitwenka[2], A. Kambugu[2], M. Lamorde[2], F. Mubiru[2], J. Normark[6], J. Achan[7], G. Ndeezi[8], V. Musiime[8], F. Lithander[8], A. Mullen[8], M. Hennessy[9], D.G. Doherty[3]
[1]*Rwanda Military Hospital, Pediatrics, Kigali, Rwanda,* [2]*Infectious Diseases Institute Makerere College of Health Sciences, Research, Kampala, Uganda,* [3]*Trinity College Dublin, Immunology, Dublin, Ireland,* [4]*Makerere University, Molecular Immunology, Kampala, Uganda,* [5]*Mildmay Uganda, Pediatrics and Child Health, Kampala, Uganda,* [6]*Umeå University, Clinical Microbiology, Umeå, Sweden,* [7]*Medical Research Council Unit, Research, Banjul, Gambia,* [8]*Makerere University College of Health Sciences, Pediatrics and Child Health, Kampala, Uganda,* [9]*Trinity College Dublin, Pharmacology and Therapeutics, School of Medicine, Dublin, Ireland*

Background: Circulating gamma/delta () T cell numbers are altered in patients with HIV infection, with expansions of V1 T cells and depletions of V2 T cells. T cells play important roles in innate immunity against pathogens and can carry out many functions that are normally mediated by CD4+ T cells, such as cytotoxicity and cytokine secretion. We examined circulating T cell subset frequencies and numbers in HIV-infected children on antiretroviral therapy (ART) in Uganda who achieve immunological response (restoration of CD4+ T cell numbers) and those who do not, and in patients who achieve a virological response (viral load reduction) and those who do not.
Methods: Peripheral blood mononuclear cells were isolated from 42 ART-experienced patients with HIV infection, of whom 4 were immunological non-responders with CD4+ T cell counts < 200/µl of blood, 4 were immunological intermediate responders (200-500 CD4+ T cells/µl) and 34 were immunological adequate responders (>500 CD4+ T cells/µl). Of the 42 patients, 30 had detectable viral loads (≥20 copies/ml) and 12 patients did not. Cells were stained with monoclonal antibodies specific for CD3, V1, V2, and V3 T cell receptor chains. Frequencies and absolute counts of V1, V2 and V3 subsets of T cells were assessed using multicolor flow cytometry.
Results: The frequencies of V1 T cells were significantly lower in the patients who achieved an immunological response compared to the immunological non-responders (P<0.02). These cells were also found at lower frequencies in the virological responders compared to the non-responders (P<0.02). In contrast, V2 T cells remained depleted in the immunological non-responder groups compared to the responders (P<0.05). The frequencies and numbers of V3 T cells were similar in all patient groups except in the intermediate responders.
Conclusions: V1 T cells are expanded in patients with HIV infection and their numbers decrease in patients with good immunological and virological responses to ART. In contrast, V2 T cells are depleted in HIV infection and they remain decreased in patient with a virological non-response, suggesting that they may become infected and killed by HIV.

TUPEA028

Antiviral activity correlates with the phenotype and polyfunctionality of stimulated CD8+ T-cells from HIV+ subjects who initiated cART at different time points after acute infection

J. Salido[1], M.J. Ruiz[1], C. Trifone[1], M.I. Figueroa[2,3], M.P. Caruso[1], M.M. Gherardi[1], O. Sued[3], H. Salomón[1], N. Laufer[1,2], Y. Ghiglione[1], G. Turk[1]
[1]*Universidad de Buenos Aires, Consejo Nacional de Investigaciones Científicas y Técnicas. Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Facultad de Medicina, Ciudad Autónoma de Buenos Aires, Argentina,* [2]*Hospital General de Agudos 'Dr. JA Fernández', Ciudad Autónoma de Buenos Aires, Argentina,* [3]*Fundación Huésped, Ciudad Autónoma de Buenos Aires, Argentina*

Background: HIV functional cure will largely depend on the capacity (natural or artificially modulated) of CD8+ T-cells (CD8TCs) to eliminate remaining infected cells, despite effective cART.
Aim: to evaluate the antiviral capacity of expanded HIV-specific CD8TCs, from HIV+ subjects with different timing of cART initiation after the acute phase of infection.
Methods: PBMCs from 25 HIV+ subjects on cART for 1 year were obtained. Twelve initiated treatment during chronic infection (Delayed Treatment, DT) and 13 within four months post-infection (Early Treatment, ET). PBMCs were stimulated with peptides pools spanning Nef and Gag proteins during 14 days. CD8TC phenotype (CD45RO, CCR7, CD95 and PD1 expression) and function (CD107a/b, IFN, IL-2, MIP-1 and TNF) were analyzed by flow cytometry post-expansion. Direct and indirect antiviral activity of expanded CD8TCs against autologous CD4TCs was evaluated by VITAL Assay (VA) and Viral Inhibition Assay (VIA), respectively. Non-parametric statistics were applied.
Results: HIV-specific CD8TCs showed a homogenous distribution of mono-, bi-, tri-, tetra- and pentafunctional cells in DT, while ET showed a higher proportion of monofunctional cells. A preservation of bulk and HIV-specific memory stem-cell ($CD8TC_{SCM}$) and central memory ($CD8TC_{CM}$) subsets was observed on ET. Contrary, DT showed a fully-differentiated profile (p< 0.005). Despite these, expanded CD8TCs from both groups equally mediated antiviral activity, evaluated either by VIA or VA. Nef-specific CD8TCs showed a higher magnitude of VIA and VA compared to p24-specific cells. VIA inversely correlated with both bulk (p=0.0438) and HIV-specific (p=0.0323) $CD8TC_{SCM}$ and with monofunctional cells (p=0.0235). Instead, VA magnitude directly correlated with the proportion of bulk terminal effectors CD8TCs (p=0.0402), inversely with bulk $CD8TC_{SCM}$ (p=0.0137) as well as directly with %CD107+ (p=0.0257), IFN+ (p=0.0373), TNF+ (p=0.0155) and tri- (p=0.025) and tetrafunctional (p=0.0278) CD8TCs able to degranulate and express IFN simultaneously.

Conclusions: Different cART initiation timing affected CD8TCs phenotype and polyfunctionality. However, it did not afffect direct and indirect antiviral activities. VIA magnitude correlated with CD8TC memory/effector differentiation profile, while VA was also associated with polyfunctionality, particularly with degranulation capacity. Overall, Nef emerged as an interesting candidate for therapeutic formulations aimed to modulate HIV-specific CD8TCs response since Nef-specific cells showed the best performance in our model.

TUPEA029

Comprehensive analysis of TCR cross-recognition against Gag TL9

G. Anmole[1], R.L. Miller[1], F. Ogunshola[2], B.D. Walker[3], T. Ndung'u[2,4], Z.M. Ndhlovu[2,3,4], M.A. Brockman[1,5,6]
[1]*Simon Fraser University, Molecular Biology and Biochemistry, Burnaby, Canada,* [2]*University of KwaZulu Natal, Doris Duke Medical Research Institute, Durban, South Africa,* [3]*Ragon Institute of MGH, MIT and Harvard, Cambridge, United States,* [4]*Africa Health Research Institute, Durban, South Africa,* [5]*Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada,* [6]*British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada*

Background: T cell receptors (TCR) play a crucial role in HIV-1 disease outcome as they recognize and facilitate the elimination of virus-infected cells. The ability of TCR to recognize HIV-1 escape variants also contributes significantly to long-term control. The TCR repertoire is highly diverse and sequence characteristics associated with enhanced cross-recognition of HIV-1 escape variants are poorly understood. To examine this, we characterized the sequence and function of TL9-specific TCR clones isolated from B*81:01 and B*42:01 individuals.
Methods: TCR repertoires from B*81:01 and B*42:01 individuals were examined using single cell sequencing. TCR alpha/beta clones from 3 B*81:01 and 3 B*42:01 individuals were transfected into Jurkat "effector" cells along with an NFAT-driven luciferase reporter and a CD8 expression plasmid. "Effector" cells were co-cultured with target cells expressing B*81:01 or B*42:01 pulsed with all possible single amino acid TL9 variants (N=180). TCR reactivity was quantified by luminescence. TCR recognition profiles were examined using hierarchical clustering and principle component analysis (PCA).
Results: Collectively, the TCR clones responded to 111 (of 171, 65%) TL9 peptide variants. Individual B*81:01 clones responded to 76, 62, and 103 variant peptides; while B*42:01 clones responded to 57, 55, and 63 variant peptides. Limited TCR reactivity against variants at positions 2, 5 and 6 suggested that they served as crucial sites for HLA binding or TCR contact. Hierarchical clustering analysis of TCR function indicated that one public B*42:01 clone grouped with the three B*81:01 clones. Similar results were found using PCA, where the public B*42:01 clone was placed in closer proximity to the B*81:01 clones. These four TCR clones also displayed better recognition of naturally occurring TL9 escape variants, indicating that they may play an important role in limiting disease progression.
Conclusions: This *in vitro* system provides a novel tool to characterize the function of TCR. Clustering TCR clones according to their peptide recognition profiles may aid in the identification of sequence features associated with enhanced antiviral activity, which would support the development of vaccines or therapeutics designed to prevent or eliminate HIV-1 infection.

TUPEA030

Selective immune cell depletion of mycobacterium tuberculosis (Mtb) in whole-blood bactericidal assay (WBA)

G.B. Cross[1,2], B.C. Yeo[2], M.C. Tan[2], R. Verma[2], Q. Lu[3], N.I. Paton[1,2]
[1]*National University Hospital, Singapore, Singapore,* [2]*National University of Singapore, Singapore, Singapore,* [3]*Singapore Clinical Research Institute, Singapore, Singapore*

Background: Whole-blood bactericidal assay (WBA) is an established *ex vivo* model which is used to test anti-mycobacterial efficacy of new drugs. Killing in this model includes a contribution from human immune cells although the exact nature of that contribution is not known. We investigated the effects of individual cell types on the growth of Mtb in WBA using immuno-magnetic a depletion approach.
Methods: Blood drawn from 8 healthy volunteers was depleted, in separate experiments, of macrophages, neutrophils, natural killer (NK), CD4T, CD8T, B and dendritic (DC) cells using specific monoclonal antibodies through a commercialised column-free magnetic platform (STEMCELL EasySep®). Extent of depletion was measured by cell cytometry and flurochrome-conjugated antibodies. Depleted blood was inoculated with Mtb, with and without rifampicin, and incubated for 72 hours. Quantity of viable Mtb was determined converting BACTEC® MGIT® time to positivity (TTP) values to estimate CFU change, using a standard curve of TTP vs. inoculum size.
Results: Most cell lines were successfully depleted (>75%). CD15 and CD123 cells were not successfully depleted (25.8% and 35.1% respectively); results from these are not reported. The difference in Mtb growth from non-cell-depleted blood (log10 CFU), with and without rifampicin present is shown in Table 1.

	NO RIFAMPICIN		WITH RIFAMPICIN	
Cell type depleted	Growth difference	95% CI, p value	Growth difference	95% CI, p value
Neutrophils (CD66b)	+0.62	0.45, 0.80, p<0.0001	-0.30	-0.59, -0.02, p=0.041
DC (CD11c)	+0.47	0.27, 0.68, p=0.001	-0.10	-0.19, -0.02, p=0.021
macrophages (CD14)	+0.23	0.10, 0.35, p=0.003	-0.20	-0.35, -0.04, p=0.018
NK (CD56)	+0.15	0.07, 0.23, p=0.002	-0.08	-0.23, 0.07, p=0.253
CD4T	+0.22	-0.01, 0.44, p=0.058	+0.03	-0.08, 0.13, p=0.544
CD8T	+0.09	-0.05, 0.23, p=0.145	0.00	-0.12, 0.13, p=0.981
CD19B	+0.13	-0.08, 0.35, p=0.173	+0.04	-0.08, 0.16, p=0.4352

[Table 1: Difference in Mtb growth (log10 CFU) vs non-cell-depleted blood]

In the absence of rifampicin, depletion of neutrophils, DCs, macrophages and NK cells increased Mtb colony count in WBA, with neutrophil depletion having the greatest impact. In the presence of rifampicin, depletion of neutrophils, DCs and macrophages enhanced bactericidal activity of the drug compared to intact whole blood.
Conclusions: In WBA, we found that innate immune cells, but not adaptive immune cells, control Mtb growth (depletion increases Mtb colony count). The paradoxical enhanced killing of Mtb seen with depletion of some innate immune cells (neutrophils, DCs and macrophages) when blood was incubated with rifampicin, may reflect intracellular sequestration of TB in these phagocytic cell populations and consequently partial protection from direct drug killing. Our results show that innate immune cells may play an important but complex role in WBA, which is important to understand when using the assay for TB drug screening purposes.

TUPEA031

An increased of T cell immunity in HIV-infected patients: A post-hoc analysis of the IPROTECT1 therapeutic vaccine Phase II study

P. Debre[1], B. Combadière[2], V. Vieillard[2], Iprotect1 Study Group
[1]*APHP, Paris, France,* [2]*CIMI-Paris, Paris, France*

Background: 3S is a highly conserved motif of HIV-gp41 protein that induced expression of NKp44L, a ligand of an activating NK receptor, on CD4+ T cells. High level of anti-3S antibodies (Abs) is associated with lower HIV-1 disease progression. Preclinical studies in infected macaques demonstrated that anti-3S Abs are associated with CD4+ T cell protection. VAC-3S is a therapeutic vaccine composed of 3S motifs-coupled with CRM197 carrier in aluminum salt adjuvant. Previous Phase 1 study demonstrated the safety of VAC-3S.

Methods: IPROTECT1 was a randomized, double-blind, placebo-controlled Phase 2 Study. Eighty-six patients with HIV RNA < 50 cp/mL on ART, with CD4 between 200 and 500 c/mm³ were randomized to receive 16 µg (n=24), 32 µg (n=25), 64 µg (n=23) VAC-3S or placebo (n=14). The primary endpoint was the proportion of vaccine responders one month after the third injection (W12). A post-hoc analysis, categorized patients in 3 groups according to anti-3S Ab response: non-responders (< 4-fold increase), low-responders (between 4 and 10-fold increase), and high-responders (≥10 fold-increase).
Results: Results: VAC-3S was well tolerated with no SAEs and no systemic AEs leading to premature discontinuation. The rate of immunization versus placebo was 45.8% (p=0.0026), 62.5% (p=0.0002) and 47.8% (p=0.0020) in the 16, 32 and 64 µg groups, respectively. In post-hoc analysis, 20 patients were HR, 16 LR and 50 NR. CD4 nadir, age, HIV duration did not impact anti-3S response. At week 48, a significant increase in CD4 count (+ 60 CD4/mm³; p=0.0029) was observed in patients with anti-3S Ab >100 AU. In high-responders was specifically determined significant increased of CD4/CD8 ratio and CD4 cell count (p=0.0029), and very significant decreased of PD1 on CD4+ T cells. (p=0.0005). Furthermore, anti-3S production was correlated positively with soluble dipeptidyl-peptidase 4 (DPP4) activity (p=0.0088, r=0.33), and negatively with expression of NKp44L activity in CD4+ T cells (p< 0.0001; r=-0.76).
Conclusions: VAC-3S was safe and induced a significant anti-3S Ab response. Very significant modulation of major markers associated with HIV protection was observed in patients with higher rate of anti-3S Ab.

Mucosal immunity

TUPEA032

Mucosal IL-7 response in the gut during HIV/SIV acute infection

C. Moraes-Cabe[1], M. Rancez[1], B. de Muylder[1], S. Morgado[1], M. Mas[1], R. Cheynier[1], A. Couedel-Courteille[1,2]
[1]Institut Cochin - INSERM U1016 - CNRS UMR8104 - Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [2]Université Paris Diderot, Paris, France

Background: The very early events of the mucosal immune response to HIV/SIV infection still remain poorly understood. Our previous results demonstrate that IL-7 is expressed in the gut as part of the cytokine storm that occurs during initial virus dissemination, coincidently with viral spread and associated with an increased production of chemokines, leading to immune cell homing. The aim of this work was to identify mucosal cells responsible for this early IL-7 production as well as those responding to IL-7 by chemokine production in the gut.
Methods: We thus analysed separately different cell types, known to be present in the gut mucosa to find out how much they can up-regulate their IL-7 production upon inflammatory conditions or how much they are able to secrete chemokines upon IL-7 stimulation. We used epithelial and endothelial cells isolated from gut mucosa of healthy macaques, as well as human endothelial cells differentiated from circulating endothelial cell precursors. These cells were cultured with the supernatant of SIV-infected or non-infected activated PBL or stimulated by pro-inflammatory cytokines with or without IL-7. IL-7 production was measured by RT-qPCR and ELISA in the supernatant of cultured cells. CD127 expression was analysed by RT-qPCR and FACS analysis. Chemokine production was measured by RT-qPCR and MSD.
Results: We demonstrated that supernatants of infected activated PBLs boosted IL-7 production by epithelial cells, contrarily to the supernatants of non-infected PBLs. These cells also up-regulated their IL-7 production when stimulated by Interferons (IFNs). Endothelial cells showed an increased expression of CD127 when stimulated by TNF or IFNs, with higher expression when co-stimulated by IL-7, suggesting an increased responsiveness of cells to the IL-7 present in the gut environment during the SIV infection driven inflammatory status. In addition, IL-7 combined to inflammatory cytokines induced higher expression of chemokines by endothelial cells, such as IP-10, IL-8 and RANTES, which are important chemo-attractive molecules for immune cells.
Conclusions: This work demonstrates that IL-7 production by intestinal epithelial cells is up regulated by inflammatory signals and identifies endothelial cells as one of the chemokine-expressing cell types under IL-7 stimulation.

TUPEA033

Genital inflammation and cervical T-cell activation associated with sexually transmitted infections in adolescent girls and young women at high risk of HIV infection

S. Dabee[1], S.L. Barnabas[1,2], H.B. Jaspan[1,3], S.Z. Jaumdally[1], H. Gamieldien[1], K. Lennard[1], L. Masson[1], D.A. Lewis[4,5,6], C. Gray[1,7], J. Dietrich[8], G. Gray[8,9], N.N. Mkhize[6], A.-L. Williamson[1,7], T.J. Hope[10], F. Chiodi[11], R. Shattock[12], L.-G. Bekker[1,2], J.-A.S. Passmore[1,7]
[1]Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Cape Town, South Africa, [2]Desmond Tutu HIV Foundation, Cape Town, South Africa, [3]Seattle Children's, Seattle, United States, [4]Western Sydney Sexual Health Centre, Parramatta, Australia, [5]University of Sydney, Centre for Infectious Diseases and Microbiology & Marie Bashir Institute for Infectious Diseases and Biosecurity, Sydney, Australia, [6]National Institute for Communicable Diseases, Johannesburg, South Africa, [7]National Health Laboratory Service, Cape Town, South Africa, [8]Perinatal HIV Research Unit, Health Sciences, University of Witwatersrand, Johannesburg, South Africa, [9]South African Medical Research Council, Cape Town, South Africa, [10]Feinberg School of Medicine, Northwestern University, Department of Cell and Molecular Biology, Chicago, United States, [11]Karolinska Institutet, Stockholm, Sweden, [12]Imperial College London, Department of Infectious Diseases, London, United Kingdom

Background: Sexually transmitted infections (STIs) increase the risk of HIV transmission and acquisition, but the underlying mechanisms are not fully known. Adolescent girls and young women (AGYW) are a key population disproportionately susceptible to HIV and other STIs. We hypothesised that STIs increase genital inflammatory cytokine concentrations and activated T-cells in AGYW.
Methods: In a cohort of 298 AGYW (16-22 years) from Cape Town and Soweto, South Africa, *Chlamydia trachomatis* (generic and L-serovar specific assays), *Neisseria gonorrhoeae*, *Trichomonas vaginalis*, *Mycoplasma genitalium*, Herpes simplex virus (HSV)-2, *Haemophilus ducreyi* and *Treponema pallidum* were measured from vulvovaginal swabs using multiplex PCR, and HSV-2 serology was performed. Bacterial vaginosis (BV) was diagnosed using Nugent scoring. Concentrations of 44 cytokines were measured from genital secretions by Luminex. Cervical T-cell activation and proliferation markers (CCR5, CD38, HLADR, and Ki67) were measured from fresh cytobrushes using flow cytometry.
Results: Overall, 115/298 (38.6%) of these AGYW from South Africa had ≥1 STI (10% having multiple STIs) and all were asymptomatic. *T. vaginalis* and *C. trachomatis* were the most inflammatory infections, both significantly associated with 10/44 cytokines being elevated compared to AGYW with no STIs or BV. *T. vaginalis*-induced cytokine elevation had a significantly larger effect size than with *C. trachomatis*. *T. vaginalis* was also associated with the largest increase in CD4+CCR5+ and activated CD4+CD38+HLADR+ T-cell frequencies compared to other infections. *C. trachomatis* was more inflammatory in Cape Town-based AGYW while *T. vaginalis* was more inflammatory in Soweto. Interestingly, having detectable genital HSV-2 DNA was not associated with genital inflammation, although being HSV-2 seropositive was associated with the upregulation of 16/44 cytokines after adjusting for co-infections.
Conclusions: STIs are associated with increased HIV risk. Our findings suggest that a strong genital cytokine response, and an influx of activated HIV target cells to the genital mucosa, may be important mechanisms for elevated HIV risk. Devising new strategies to manage STI prevalence or moderate inflammatory responses to STIs could decrease the incidence of new HIV infections in AGYW.

TUPEA034

Differential genital inflammation associated with *Chlamydia trachomatis* sequence types in adolescent girls and young women at high risk of HIV infection

S. Barnabas[1,2,3], B. Versteeg[4], S. Dabee[2], D. Lewis[5,6,7], E. Muller[7], H. Jaspan[2,8], S. Jaumdally[2], H. Gamieldien[2], L. Masson[2], N. Mkhize[7], J. Dietrich[9], G. Gray[9,10], L.-G. Bekker[2,3], H. de Vries[4], S. Bruisten[4], J.-A. Passmore[2,11]
[1]Family Clinical Research Unit, Stellenbosch University, Cape Town, South Africa, [2]Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Cape Town, South Africa, [3]Desmond Tutu HIV Foundation, Cape Town, South Africa, [4]GGD Public Health Service, Amsterdam, Netherlands, [5]Western Sydney Sexual Health Centre, Sydney, Australia, [6]Centre for Infectious Diseases and Microbiology & Marie Bashir Institute for Infectious Diseases and Biosecurity, Westmead Clinical School, University of Sydney, Sydney, Australia, [7]National Institute for Communicable Diseases, National Health Laboratory Service, Johannesburg, South Africa, [8]Seattle Children's, Seattle, United States, [9]Perinatal HIV Research Unit, Faculty of Health Sciences, University of Witwatersrand, Johannesburg, South Africa, [10]South African Medical Research Council, Cape Town, South Africa, [11]National Health Laboratory Service, Cape Town, South Africa

Background: *Chlamydia trachomatis* is highly prevalent in young people, with significant genetic diversity that may influence pathogenesis. *C. trachomatis* increases HIV risk in adolescent girls and young women (AGYW), and causes reproductive complications. We hypothesized that different *C. trachomatis* strains could increase genital inflammation, which could may influence HIV acquisition risk.
Methods: We enrolled 298 AGYW (16-22 years) from Cape Town (CPT) and Soweto, Johannesburg (JHB) South Africa (WISH cohort) who were tested for: *C. trachomatis* (including L-serovars), *Neisseria gonorrhoeae*, *Trichomonas vaginalis*, *Mycoplasma genitalium*, Herpes simplex virus (HSV)-2, *Haemophilus ducreyi* and *Treponema pallidum* using multiplex PCR. Forty-four cytokines were measured in genital secretions by Luminex. The sequence types of *C. trachomatis* were determined using multilocus sequence typing based on five non-housekeeping and the *ompA* genes.(CPT n=52; JHB n=23).
Results: *C. trachomatis* was the most prevalent bacterial infection, found in of AGYW 41.6% in Cape Town and 17.4% in Soweto. It was associated with significantly elevated concentrations of 10/44 cytokines compared to their STI/BV-negative counterparts, including IL-1, IL-6, TNF-, IP-10, MIG, G-CSF, HGF, SCF, IFN-γ and IL-4. *C. trachomatis* was more inflammatory in Soweto (n=26) than in Cape Town (n=62). MLST was performed successfully on 75/88 cases, and 34 different sequence types (ST) (including 7 genovars) were detected. Of these, 15 were novel types. The three most common ones were ST12d (n=12), ST530b (n=11) and ST3 (n=9). There were no significant differences (p=0.187) in distribution by geographical site, as seen in a minimum spanning tree. Differential inflammation levels were seen, with ST12d being most inflammatory (IL-3, MCP-3, IFN-2 and -NGF upregulated). Cytokines were down regulated for ST319 (PDGF-BB, IL-7, HGF, IL-18, GM-CSF, MIP-1, IL-1, TRAIL and SDF-1), ST551 (IL-10, Eotaxin, IL-12(p70), IL-13, FGF basic, IL-9 and IFN-γ) and ST188d (SCGF-, MCP-3, IL-16, IL-2R, IFN-2, -NGF, and CTACK) while ST530b was neutral for inflammatory markers compared to uninfected women.
Conclusions: *C. trachomatis* was highly prevalent in this at-risk population and was associated with a robust inflammatory profile, although inflammation was sequence type-dependent. Understanding the mechanism through which *C. trachomatis* may increase inflammation and possibly HIV acquisition could be important in reducing HIV risk.

HIV testing and retesting (e.g. point of care diagnostics)

TUPEB035

Laboratory development of a modified ELISA assay for HIV-1 incidence estimation

L. Bai[1], R. Xin[1], C. Huang[1], N. Xiang[2], W. Chen[2], X.-G. Zhang[3], Professional Institution for HIV Lab Diagnosis and Intervention in Beijing
[1]Beijing Center for Disease Control and Prevention, AIDS and STI, Beijing, China, [2]Beijing Huada GBI Biotechnologies Ltd., Beijing, China, [3]Chinese Center for Disease Control and Prevention, National Institute for Viral Disease Control and Prevention, Beijing, China

Background: BED HIV-1 Capture EIA (BED-CEIA) was developed by US CDC to detect potential recent HIV-1 infections. Despite limitations of high cost and complicated operation procedures, it has been widely used in multiple cross-sectional analyses worldwide for HIV-1 incidence estimation, it was the only approved diagnostic kit for research use worldwide. In our study, we established a modified version of BED-CEIA named BED HIV-1 Capture Chemiluminescence Enzyme Immunoassay(BED-CCLEIA).
Methods: Biotinylated HIV-1 gp41 Peptides of subtype B ,E and D were synthesized separately and biotinylated by Beijing Scilight Biotechnology. HIV-1seroconversion panels were from BBI Diagnostics(Panel Z) and China national standards materials(PRB926, PRB958), with total 4 specimen.
Reproducibility and stability study of BED-CCLEIA were conducted. Reliability analysis was made with clinical specimen and HIV-1 Seroconversion Panels mentioned above.
Results: Our BED-CCLEIA exhibited a good concordance with BED-CEIA in experiment with controls from BED-CEIA (r^2 =0.95). Its intra-run CV was less than 10%, and inter-run CV was less than 15%, stability study(within 6 days at 37C) found no loss of the standardized values.
Controls and Calibrators were made and displayed a close RLU values with those from BED-CEIA, 95% confidence intervals had no significant difference with BED- CEIA.
A total of 246 HIV-1 serum samples and 4 recent HIV-1 infection samples were tested by BED-CCLEIA. the sensitivity and specificity was 96.2% and 80.1% respectively compared with BED-CEIA, the accordance rate was 87.4%. The results of consistent analysis indicated that the two methods achieve better coherence with a Kappa value of 0.75. Likewise, both the two identified the 4 specimens as recent infections.
Conclusions: Our modified assay displayed similar performance characteristics to the BED-CEIA in laboratory experiments. Further studies should be done to define the cut off value and window period which are applicable for hiv incidence analysis in china.

Implementation lessons of integrating early infant diagnosis of HIV at point of care using Xpert® HIV-1 Qual in four public hospitals in Myanmar

W.L. Yee[1], H. Htay[1], Y. Mohamed[2,3], H.H. Tin[4], W. Thein[4], L.L. Kyaw[4], W.W. Yee[4], M.M. Aye[4], S. Badman[5], A. Vallely[5], X.-S. Chen[6], S. Crowe[2], M. Stoové[2], D. Anderson[2], P. Agius[2], C. Ryan[2], A. Kelly-Hanku[5], S. Luchters[2,3,7]
[1]Burnet Institute, Yangon, Myanmar, [2]Burnet Institute, Melbourne, Australia, [3]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia, [4]National Health Laboratory, Yangon, Myanmar, [5]Kirby Institute, University of New South Wales, Sydney, Australia, [6]National Center for STD Control, Nanjing, China, [7]International Centre for Reproductive Health (ICRH), Department of Obsterics and Gynaecology, Ghent University, Ghent, Belgium

Background: Low coverage and delays in result communication of early infant diagnosis (EID) of HIV with centralized laboratory-based testing using dried blood spots has led to delays in treatment initiation. Point-of-care (POC) EID testing could improve timely treatment initiation, but differences in health systems could impact feasibility. We assessed the challenges and enablers to implementing the POC Xpert® HIV-1 qualitative assay in Myanmar.

Description: As part of a 14-month two-country randomized controlled stepped-wedge trial in Myanmar and Papua New Guinea, we integrated the Xpert® HIV-1 Qual test in routine services at four public hospitals in Myanmar, using public-sector healthcare workers. The time of transition to intervention POC testing was randomized across hospitals and introduced in a stepwise manner. During implementation, challenges and enabling factors encountered by hospital and research staff were observed, discussed, documented and synthesized by the research team.
Lessons learned: Limitations in clinic space, inconsistent power supply and inability to securely position the device at POC challenged implementation of POC EID testing. High staff workload led to ambiguities in task-sharing and a weak sense of ownership of the testing process. Communication gaps between health workers occasionally affected testing success and results communication. Successful strategies included implementing dedicated times for providing PMTCT services and improved communication protocols among health staff, and between health staff and patients. Implementation improved with on-site medico-social workers for results communication, and higher qualified laboratory technologists for conducting tests. The ease of use and short duration of the test was appreciated by the staff, but required accessibility to technical assistance from the reference laboratory to overcome technical challenges. The short shelf-life of the test and long delays in procurement hindered the implementation.
Conclusions/Next steps: Implementation of the Xpert® HIV-1 Qual for EID into public hospitals in Myanmar was feasible, but challenging given the suboptimal supply chain, convoluted communication pathways and logistical constraints. Dedicated PMTCT clinic times and clarity around roles and responsibilities facilitated introduction of this POC test. Improved coordination between hospital staff, test suppliers and technical support staff will ensure that the potential benefits of the POC EID testing are effectively harnessed.

TUPEB037

Volume and yield of pediatric HIV testing by modality in 21 PEPFAR-supported African programs

G. Siberry[1], J. Roffenbender[2]
[1]*US Department of State, Office of the Global AIDS Coordinator, Rockville, United States,* [2]*US Department of State, Office of the Global AIDS Coordinator (PEPFAR), Washington, United States*

Background: Case-finding for children living with HIV (CLHIV) remains suboptimal, contributing to persistently lower antiretroviral treatment (ART) coverage for children (< 15 years old).
Methods: Volumes and positivity rates of HIV testing for children in PEPFAR-supported programs in Africa during 2017 (fiscal year) were analyzed overall and by four modalities: inpatient wards, index testing, outpatient departments (OPD) and tuberculosis (TB) clinic. Early infant virologic diagnostic testing was excluded. Total testing exceeds the sum of the four selected modalities because we did not break out test results reported under modalities that were difficult to characterize for children (e.g, voluntary testing and counseling) or that were not primarily case-finding channels (eg, pre-circumcision testing). Results from Ghana were excluded because they were incomplete.
Results: HIV testing volume (volume), contribution to overall testing volume (% of Volume), positivity rates (POS rate), and contribution to country program positive results varied widely across the 21 country programs [Table]. In most countries, OPD testing contributed the greatest testing volume testing (51.5%) and cases identified (48.3%); however, on average, the OPD positivity rate (1.6%) was lower than the positivity rate overall (1.9%) and for all other modalities: inpatient, 2.0%; index, 4.8%; TB, 5.0%. While TB positivity rates were high in many countries, it accounted for < 2% of testing volumes (except 5% for South Sudan) and contributed < 6% of case-finding. Inpatient POS rate was < 5% for all countries except Botswana (6.3%). While index testing POS rates varied greatly, they were as high or higher than the overall POS rate for all but 3 countries (South Africa, Swaziland, Zambia) and accounted for >10% of new cases in 12 countries including >20% of all new cases in six countries.
Conclusions: Tracking pediatric testing results overall and by modality can help countries adjust testing programs to optimize identification and treatment of CLHIV. Inpatient testing remains an important but declining source of case identification. Index testing has variable yield that may reflect whether testing is limited to biologic children of parents with HIV; scaling this approach with fidelity is a key strategy for finding children in all settings.

TUPEB038

Adapting HIV testing algorithms and clinical advice for people with persistently indeterminate test results - a novel national referral clinical service

C. Brown[1,2], S. Fidler[3,4], M. Khan[3], S. Kaye[3], D. Muir[4], P. Patel[1], A. Menezes[1], T. Mbisa[1], J. Tosswill[1], G. Taylor[3,4]
[1]*Public Health England, National Infection Service, London, United Kingdom,* [2]*Royal Free London NHS Foundation Trust, London, United Kingdom,* [3]*Imperial College London, London, United Kingdom,* [4]*Imperial College Healthcare NHS Trust, London, United Kingdom*

Background: HIV diagnosis relies on detecting HIV-specific antibody, viral antigens, genome, or whole virions. Certain rare individuals with persistently indeterminate test results have to live with uncertainty as to their true HIV status, and their best clinical management remains unknown. This may become increasingly an issue with the widespread availability of PrEP, PEP and early ART initiation, potentially delaying or altering the development of HIV-specific antibodies. We describe a new national referral clinical service, established to explore novel diagnostic algorithms and offer counselling and management of individuals with persistently indeterminate HIV test results.
Description: Eligible individuals were referred to our clinic by their medical provider via the Virus Reference Department of Public Health England, with the following results: multiple "reactive" or indeterminate HIV antibody tests on different platforms with indeterminate Western Blot profiles, in the absence of confirmed HIV RNA, DNA or p24 antigen tests. Additional blood was drawn for repeat multiple HIV antibody EIAs including in-house typing assays, HIV Western blot, HIV RNA (including ultralow copy HIV RNA to 1 copy /ml) HIV DNA (total and sorted CD4+ T-cells) including multiple primer sets, p24 antigen; infection screen including EBV, CMV, VZV, HTLV, HBV, HCV, STS; auto-antibodies; immune activation markers; HLA-DR and CD25 expression on CD4 and CD8 cells and CD4, CD8 counts and CD4:8 ratio.
Lessons learned: The first six individuals attended the service between October 2017 and January 2018: five were diagnosed with HIV infection, with one awaiting further investigation. Western blots sometimes yielded greater clarity, no co-infections were found, and CD4 counts and T-cell activation markers were normal. Ultra-sensitive RNA viral load and DNA testing on freshly-processed samples were useful adjuvants to traditional tests (see table).

Patient	HIV-1 EIA (Murex) S/CO	HIV Western blot	HIV RNA Ultra-sensitive	HIV DNA	CD4 count (300-1400)	CD4:8 ratio	CD4 DR% (4.6-10.9)	CD8 DR% (5.7-38.2)
1	7.5	p17, p24, gp41, gp160	1	+ve	807	2.0	5	13
2	15.3	p17, p24, gp41, gp120, gp160	0	-ve	785	2.5	8	23
3	16.5	p17, p24, p51, p66, gp41, gp120, gp160	9	+ve	811	2.0	7	16
4	6.4	p17, p25, p55, p31, p51, p66, gp41, gp120, gp160	0	-ve	1359	1.5	8	26
5	11.3	p24, gp160	17	-ve	1498	2.9	6	18
6	8.1	p24, gp120, gp160	0	-ve	839	2.1	5	17

[Testing details]

Conclusions/Next steps: This preliminary report of a novel HIV testing strategy has shown that with freshly processed samples, increased blood volumes and new technology, it has been possible to reach a definitive HIV diagnosis. As no data exist to inform the clinical management of cases identified as HIV+ in this setting, prolonged follow-up is required with support and counselling for people who have had to live with uncertainty for many years. Increased patient numbers will be presented.

TUPEB039

Making a big impact on expanding HIV inpatient testing with a small EHR modification

T. Nguyen[1], M. Hart[2], M. Tran[2], J. Rocha[2], A. Grigoriu, M.D.[2], W. Bracco[2], S. Walsh, M.D.[2], K. Lushbough, MD[3], M. Ghias[3], Y. Elamir, MD[3], W. Grist, MD[3], K. Bogdansky,MD[3], C. Faludi[3], L. Alerte[3]
[1]Jersey City Medical Center - RWJBarnabas Health, Center for Comprehensive Care, Jersey City, United States, [2]Jersey City Medical Center, Center for Comprehensive Care, Jersey City, United States, [3]Jersey City Medical Center, Jersey City, United States

Background: The CDC estimates over 1.2 million Americans are living with HIV and, of those, approximately 14% are unaware of their HIV-positive status. Since 2014, most hospitals adopted some form of Electronic Health Records (EHR) and the Centers for Medicare & Medicaid Services extended Medicare coverage for annual HIV screenings. Despite these developments, there has been limited progress in expanding HIV testing in inpatient settings. The present study was conducted at Jersey City Medical Center (JCMC) in an effort to expand HIV testing by implementing EHR modification in the form of testing prompts.
Methods: This retrospective study reviewed data since May 20, 2015 at JCMC, a teaching hospital that passed all lab work orders through an EHR system. The number of daily orders for HIV screenings was recorded for 371 consecutive days before EHR modification (n=371) to establish baseline data.
EHR modification occurred on the 372nd day of the study (May 25, 2016). This modification featured testing prompts displaying CDC guidelines for screening patients over the age of 18 for HIV whenever a physician ordered lab work for admitted patients. Orders for HIV screenings on this transitional date were excluded from analysis.
After EHR modification was completed, the number of daily orders for HIV screenings was recorded for an additional 371 consecutive days (n=371) for comparison until May 31, 2017. Testing data was available for all 743 consecutive days. Data was reviewed using unpaired t-test analysis.
Results: Since the beginning of this study - before testing prompts were implemented - JCMC inpatient units ordered an average of 8.58 (SD=3.36) HIV screenings per day. The average number of daily orders for HIV screenings increased twofold after EHR modification (M=17.25, SD=4.50), $t(740) = 29.72$, $p < .00001$. JCMC identified 134 HIV-positive and linked over 93% of these patients to care.
Conclusions: Conventional HIV screening methods in the inpatient setting might not be sufficient at detecting most HIV-positive cases. By implementing testing prompts in its EHR system to encourage increased testing for HIV, Jersey City Medical Center was able to increase the number of individuals aware of their HIV status and link them to care as needed.

CD4 measurement (e.g. point of care diagnostics)

TUPEB040

Performance evaluation of a point-of-care (POC) CD4 test device (Visitect® CD4) for use in resource-limited settings

V. Vidhyavathi[1], K. Kanthamani[1], P. Nandagopal[1], H. Syed Iqbal[1], J. Forbes[2], S. Sunil Suhas[3], E. Valente[2], S. Crowe[4], C. McMurran[2], D. Anderson[4], P. Balakrishnan[1]
[1]YRG Centre for AIDS Research and Education, Voluntary Health Services, Chennai, India, Infectious Diseases Laboratory, Chennai, India, [2]Omega Diagnostics, Scotland, United Kingdom, [3]Johns Hopkins University School of Medicine, Infectious Diseases Laboratory, Baltimore, United States, [4]Burnet Institute and Monash University, Melbourne, Australia

Background: CD4+ T lymphocyte counts remain the most common surrogate marker indicating immune status and disease progression in HIV-infected individuals. Although WHO guidelines recommend antiretroviral therapy (ART) irrespective of CD4 levels, establishing the CD4count is still important for prioritization of ART and monitoring in many settings. Laboratory-based CD4 measurement with the initial investment in flow cytometric technology, infrastructure requirements and expensive reagents makes it unaffordable for many resource-limited countries like India. Point- of- care (POC) CD4 testing would reduce costs and increase the likelihood of retention in care.
Methods: We evaluated the performance of the Visitect®CD4 lateral flow POC device using both finger-prick and venous blood samples from patients (n=200) attending the HIV clinic at YRG CARE Chennai, from May to September 2017.Visitect®CD4 test compares the patient blood test line intensity to that of a reference line of 350 cells/µL (Figure 1). The results of finger-prick and venous blood samples from each patient were assessed visually and compared with CD4 counts in the same venous blood sample measured by NAVIOS flow cytometer (Beckman Coulter, CA, USA).Visitect CD4 results were available within one hour.
Results: In our study, 123 were males and 77 were females and their median age was 40 years(IQR 36-48).Of 200 patients,144 had a CD4 count of < 350cells /µL and 56 had a CD4 count of >350cells /µL by flow cytometry. The sensitivity and specificity of the Visitect® CD4 test was calculated by comparing the POC test with flow cytometric results. Concordance between flow cytometric CD4 and Visitect CD4 was higher using venous blood versus finger prick samples (97 vs. 84%) (Table 1).
Conclusions:

	Flowcytometry			
Visitect®CD4 Test (Visual reading)	Venous blood		Fingerprick blood	
	<350 cells/µL	>350 cells/µL	<350 cells/µL	>350 cells/µL
<350 cells/µL	140	18	121	16
>350 cells/µL	04	38	23	40
Sensitivity %	97%		84%	
Specificity %	68%		74%	
Positive predictive value	89%		88%	
Negative predictive value	91%		64%	
Efficiency	89%		81%	

[Table 1. Performance characteristics of Visitect®CD4 Test]

The rapid POC Visitect CD4 test device provided acceptable results and is potentially a cost-effective alternative method to flow cytometric CD4 testing for the clinical management of HIV infection in resource-limited settings, further strengthening patient care in remote areas.

[Visitect®CD4 test device]

Viral load measurement (e.g. point of care diagnostics)

TUPEB041

Achieving the 3rd 90: Monitoring of viral load testing in Jhpiego- MCSP facilities in Haiti: A program intervention

S. Martelly[1], S.T. Omero[2], S. Stender[3], R.K. Bestien[2], R. Masse[4], K. Francois[5]
[1]Jhpiego, HIV/TB ID, Haiti, Haiti, [2]Jhpiego, Haiti, Haiti, [3]Jhpiego, Baltimore, United States, [4]USAID, Haiti, Haiti, [5]PNLS, Haiti, Haiti

Background: To achieve the 3rd 90, Haiti introduced viral load testing in July 2016, as the primary laboratory testing method to monitor HIV viremia in ART clients. Data indicated that 93,294 patients were on ART. Of those, 61,092 (65%) benefited from viral load testing, available in 99% of ART facilities. The low testing rate was due to lack of training and education offered to providers and clients. Jhpiego-Maternal Child Survival Program (MCSP) provided technical assistance to health facilities throughout Haiti, focusing on building the capacity of front line providers to offer routine viral load testing, and to act promptly if a patient's viral load is detectable. The testing has empowered providers to seek better longitudinal care for their clients.
Description: From October 2016 to September 2017,Jhpiego-MCSP project scaled up routine viral load testing in 42 facilities by training providers. A viral load reporting tool was developed to facilitate registration of clients, and to track clients testing eligibility. The tool involved adults and children on ART for 6 months, pregnant women on ART for 4 months, clients undetectable for 1 year, and with clinical failure. Also, assistance was provided with the transport of laboratory specimens, as well as return of test results to the clinician. Jhpiego-MSCP educated clients during supports group meetings to improve knowledge of viral load testing. Finally, the project collected and analyzed data in Excel, to monitor client's clinical status.
Lessons learned: From October 2016 to December 2017, 12,027 clients received ART (31% men; 69% women; of those, 7,897(66%) had a viral load test and received their results. A total of 5,029 (64%) achieved viral suppression (< 1000 copies/ml). All results were received within a 15-day time frame, through email accounts, set up by the National laboratory (LNSP). 2,868 clients with detectable viral (>1000 copies/ml), were monitored closely to reinforce adherence to ART.
Conclusions/Next steps: The utilization of the viral load tool as a clinical management tool, contributes to ensure proper care of people living with HIV. However, viral suppression rates are low, indicating clearly that more supportive counseling and innovative strategies are required for epidemic control of HIV in Haiti by 2020.

TUPEB042

Field evaluation of the Biocentric® platform for HIV viral load testing utilizing plasma samples in Swaziland: A diagnostic accuracy study

G. Maphalala[1], P.A.D. Uribe[2], Q. Mpala[2], P. Nxumalo[2], S. Kalombola[2], A. Bekele[2], T. Chawinga[2], M. Maphalala[2], R. Nesbitt[2], N. Ntshalintshali[3], R. de la Tour[4], E. Fajardo[5], J. Goiri[4], N. Phugwayo[1], S. Dlamini[1], A. Jani[2], I. Ciglenecki[4], B. Kerschberger[2]
[1]Ministry of Health (National Reference Laboratory), Mbabane, Swaziland, [2]Medecins Sans Frontieres (OCG), Mbabane, Swaziland, [3]Clinton Health Access Initiative (CHAI), Mbabane, Swaziland, [4]Medecins Sans Frontieres (OCG), Geneva, Switzerland, [5]Medecins Sans Frontieres (Access Campaign), Geneva, Switzerland

Background: Viral load (VL) testing is recommended by the World Health Organization (WHO) to monitor the effectiveness of antiretroviral therapy (ART), and it is being scaled-up in resource-limited settings. However, not all VL platforms commercially available have been thoroughly evaluated. We assessed the diagnostic performance of the Biocentric assay for VL quantification under routine field conditions in Swaziland.
Methods: From 10/2016 to 03/2017, paired plasma samples were collected prospectively from pre-ART and ART patients at Nhlangano and Lobamba health centres. Samples were tested blindly on the national reference method (Roche) and compared to the Biocentric assay at two labs (Nhlangano: Lab-1, Mbabane: Lab-2). Laboratory staff in Lab-1 were experienced with the Biocentric method and staff in the newly established Lab-2 were newly trained. We calculated precision (correlation, Bland-Altman) and accuracy (sensitivity, specificity) using the WHO-recommended VL threshold of 3.0 log_{10} (=1,000) copies/ml. In addition, the positive (PPV) and negative predictive (NPV) values were calculated assuming that 20% of VLs are detectable in patients on ART.
Results: In total 370 patients participated, of whom 364 (98.4%) paired samples were successfully analysed. Seventy (19.2%) samples had a VL>3.0 log_{10} on the reference standard. The correlation between both methods was high (r=0.93, p< 0.01) and the Bland-Altman analysis showed a minimal mean difference (-0.02 log_{10}; 95% limits of agreement: -1.15 to 1.11). Overall sensitivity and specificity were 88.6% (78.7-94.9) and 98.3% (96.1-99.4). Sensitivity was higher in Lab-1 (100% [71.5-100]) compared to Lab-2 (86.4% [75.0-94.0]) and specificity was similar (Lab-1: 97.9% [94.6-99.4]; Lab-2: 99.1% [94.9-100.0]). For both labs combined, the PPV was 92.9% (84.5-96.9) and the NPV was 97.2% (94.7-98.5). The PPV was similar between Lab-1 (92.1% [81.6-96.9]) and Lab-2 (95.9% [76.6-99.4]), and the NPV was higher in Lab-1 (100%) compared to Lab-2 (96.7% [93.9-98.2]).
Conclusions: The diagnostic performance of the Biocentric assay was comparable with the reference Roche assay. Inter-laboratory differences indicate, however, that attention should be paid to provision of sufficient trainings and quality control processes during the scale-up of VL testing.

TUPEB043

Increased access to HIV viral load testing among ART patients in Côte d'Ivoire (2015 to 2017)

C. Adje-Toure[1,2], A. Ekra[3], A. Micheline[1], L. Ya Kouadio[1], J.B. Amani[1], J. Hedje[1]
[1]Center for Disease Control, DGHT, Abidjan, Cote D'Ivoire, [2]Center for Disease Control, Abidjan, Cote D'Ivoire, [3]Center for Disease Control, DGHPT, Abidjan, Cote D'Ivoire

Background: Côte d'Ivoire use of HIV Viral load (VL) for the monitoring of patients receiving antiretroviral therapy (ART) began in 1998 as a pilot program under the UNAIDS/Ministry of Health Drug Access Initiative (DAI). From 2002 to 2014, VL testing was available to less than 10% of patients for immunologic and/or clinical failure monitoring, and was accessible only in Abidjan the capital. Following WHO 2015 guidelines and the need to increase access to VL testing, CDC used the lab in the box approach to scale-up and decentralize access to VL testing.
Methods: We analyzed 2015-2017 VL test results from aggregate patient data obtained from the laboratory information system of 15 VL laboratories. Testing coverage and viral load suppression rate by age group, gender and region were assessed. VL was measured using plasma on the Roche Ampliprep Cobas Taqman 48&96; patients had access to VL testing every 6 months during the first year and yearly thereafter.
Results: A total of 221,990 patients received ART nationally between October 2015 and August 2017, with a 12-month retention rate of 85%. Access to at least one VL test per year increased from 14% to 61% for a total of 134,877 patients during the study period, including 41.5% from districts outside of Abidjan. The number of laboratories increased from 6 to 15 in the same period. Among patients with access, 74% were female and 5.6% children (0-14 years). Seventy seven percent of tested patients achieved VL < 1000 copies/mL [95% CI: 55-82]; the VL suppression rate was similar for female and male, 78% and 77% respectively. While children and adolescents (15-19 years) had the lowest rate at 56% and 55% respectively, young adults' (20-24 years) rate was 67%, and patients ≥25 years, 79%.
Conclusions: The experience of Côte d'Ivoire provides evidence that routine VL can be achieved using appropriate scale-up strategies such as lab in the box, minimized reagent stock out, and a strong sample transportation system. The low rate of VL suppression in children and adolescents is a challenge that needs to be addressed in order to minimize appearance of HIV drug resistance strains.

TUPEB044

Are all people on antiretroviral treatment having their HIV viral load monitored? Gaps analysis in Latin America and the Caribbean

A. Leal, G. Ravasi, M. Alonso
Pan American Health Organization, Washington, United States

Background: By December 2016, Latin America and Caribbean (LAC) countries reached 56% antiretroviral treatment (ART) coverage among estimated people living with HIV in the region. Since 2013, WHO recommends viral load (VL) testing as preferred monitoring tool during ART, but gaps in VL access and coverage persist.

Description: We analyzed data officially reported in 2017 by 31 LAC country to UNAIDS /WHO/UNICEF through the Global AIDS Monitoring reporting system and AIDS Medicine and Diagnostic Service (AMDS) survey (situation at December 2016) to assess existing gaps in VL policies, capacity and coverage.

Lessons learned: All reporting countries have routine VL monitoring policies; 10% (3/31) reported partial implementation (Belize, Bolivia and Haiti). Most countries (80%; 25/31) have VL lab capacity; only Organization of Eastern Caribbean States (OECS) countries outsource VL testing to an external lab (Barbados). Most countries (61%; 19/31) recommend biannual VL monitoring, 32% (10/31) annual and 2 countries more frequent monitoring (Costa Rica, Bahamas). Comparing annual estimated VL volumes (based on people on ART and VL testing frequency in national policies; Data reported by 22 countries) 59% (13/22) countries performed ≤75% of the estimated volume (regional median 59%), while four (El Salvador, Grenada, Mexico, Peru) exceeded their estimated amount. VL coverage (proportion on ART with at least one VL test/year; data reported by 24/31 countries) showed a regional median of 82.4% (Range: 17.7-100); 42% countries (10/24) reporting VL coverage ≤75%; 3 countries with < 50% (Cuba, Ecuador, Haiti). VL coverage was 83.8% in Latin America (10 countries) and 74.5% in the Caribbean (14); 84.7% in men; 87.6% in women; 80% in children < 15; 84.6% in persons ≥15.

Conclusions/Next steps: Despite the adoption of routine VL monitoring policies and availability of lab services, VL coverage in people on ART falls short in many LAC countries. Programmatic causes should be further investigated and addressed to ensure optimal laboratory monitoring during treatment. In addition some inefficiencies were detected (too frequent VL monitoring; number of tests exceeding estimated volume) which should also be corrected.

Measuring ART adherence (drug levels, dried blood spots, hair sampling)

TUPEB045

A method to analyze tenofovir alafenamide (TAF) in hair for adherence monitoring

H. Okochi, A. Louie, K. Kuncze, C. Koss, L. Benet, N. Phung, M. Gandhi, UCSF Hair Analytical Laboratory (HAL)
University of California, San Francisco, United States

Background: As tenofovir (TFV) alafenamide (TAF)/emtricitabine (FTC) is increasingly used for HIV treatment and is under study for pre-exposure prophylaxis, methods to measure exposure and adherence to TAF are needed. Antiretroviral concentrations in hair samples reflect cumulative exposure and predict HIV treatment and prevention outcomes. TAF is metabolized to TFV in the plasma and then taken up into hair over time. We describe a method to analyze exposure to TAF/FTC in hair.

Methods: Hair samples were collected from patients on TAF/FTC-based therapy with HIV-1 RNA< 40 copies/ml for ≥6 months and >95% adherence (reported by patient and provider). TFV and FTC were extracted from hair (~5 mg) using 50% methanol containing trifluoroacetic acid and hydrazine dihydrochloride at 37°C overnight in a shaking water bath. The solution was evaporated and then injected into liquid chromatography/tandem mass spectrometry (Shimadzu LC-10S pump coupled to a Waters Quattro Ultima triple quadrupole mass spectrometer) using a reverse phase column (Synergi Polar-RP, 4 μm, 4.6x150mm). The linear dynamic standard curve range for TFV was 0.002-0.4 ng/mg hair and FTC was 0.02-4 ng/mg hair.

Results: The Figure shows sample chromatograms of hair TFV and FTC concentrations in 3 patients on TAF/FTC-based treatment. Hair from each individual were run in replicate 10 times with an average TFV concentration of 0.0293 nanograms/milligram (ng/mg) (standard deviation (SD) 0.0018, coefficient of variation (%CV) 6.14) in patient A; 0.0490 ng/mg (SD 0.0024, %CV 4.90) in patient B; 0.0533 ng/mg (SD 0.0021; %CV 3.94) in patient C. FTC concentrations also shown (Figure).

Conclusions: We describe a method to assess adherence and exposure to TAF/FTC in hair samples. Cumulative TFV concentrations among adherent patients on TAF using hair were similar to those in adherent patients on tenofovir-disoproxil-fumarate (TDF) in previous studies, despite levels of TFV or its metabolites in plasma and dried blood spots (DBS) being lower on TAF than TDF. Hair is collected non-invasively and stored and shipped without a cold chain or biohazard, offering additional advantages over plasma and DBS metrics. As TAF use expands for treatment and is anticipated for HIV prevention, an objective metric to monitor TAF adherence via hair levels will be useful.

TUPEB046

A method to quantify dolutegravir, poised to become first-line therapy worldwide, in small hair samples as a metric of adherence and exposure

H. Okochi[1], N. Phung[1], K. Kuncze[1], S. Lockman[2], C. Koss[1], L. Benet[1], A. Louie[1], M. Gandhi[1], UCSF Hair Analytical Laboratory (HAL)
[1]*University of California, San Francisco, United States,* [2]*Harvard University, Boston, United States*

Background: Dolutegravir (DTG) has broad indications for HIV treatment, is an option for first-line therapy in global guidelines, and is being studied for prevention-of-mother-to-child-transmission (PMTCT). A long-acting investigational integrase inhibitor, cabotegravir, with similar chemical structural moieties to DTG, will have roles in both pre-exposure prophylaxis and treatment. Hair levels of antiretrovirals have proven useful as biomarkers of adherence and long-term exposure. We report, for the first time, the development of an assay to measure DTG concentrations in hair using liquid chromatography-tandem mass spectrometry (LC-MS/MS).

Methods: Hair samples were collected from HIV-infected patients on DTG-based regimens with long-standing virologic suppression (HIV-1-RNA < 40 copies/ml) and provider-and self-reported high adherence for analytical development and optimization. Sample preparation consisted of the incubation of hair (2 mg) in acidified methanol containing $^{13}C,^{2}H_{5}$-DTG (internal standard). The sample was evaporated to dryness and reconstituted. DTG was then extracted via liquid-liquid extraction using methyl *tert*-butyl ether and ethyl acetate. The organic layer was evaporated to dryness, reconstituted, and analyzed by the LC-MS/

MS system (Shimadzu Fluminent UFLC coupled to AB-Sciex API 5000 triple quadrupole mass spectrometer) via multiple reaction monitoring electrospray in positive ionization mode. The standard curve was linear over the range of 0.01-10 ng/mg. Quantitation of DTG was determined by plotting peak area ratios of DTG to $^{13}C,^{2}H_{5}$-DTG versus the nominal concentration of DTG.

Results: We quantified DTG concentrations in hair from six patients on DTG-based regimens (1.15, 1.93, 1.98, 4.42, 4.48 and 6.48 ng/mg). The analytical method exhibited high sensitivity (0.01 ng/mg) and a wide linear dynamic range (0.01-10 ng/mg) using 20-30 strands of hair. Precision (defined by the coefficient of variation) and accuracy (defined by relative error) were both < 15%.

Conclusions: We describe the development of a sensitive, specific, accurate and precise method to determine long-term adherence and exposure to DTG using small hair samples (20-30 strands). A similar method can be applied to analyze cabotegravir for exposure at the end of the dosing interval. Given that DTG is poised for first-line therapy worldwide and the recent launch of a large-scale study of DTG for PMTCT, the development of objective adherence assays to this ARV is important.

Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]Institute of Human Virology-Nigeria, Abuja, Nigeria, [4]Henry M. Jackson Foundation for the Advancement of Military Medicine, Abuja, Nigeria, [5]Population Council Nigeria, Abuja, Nigeria, [6]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [7]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: As access to antiretroviral therapy (ART) increases, so does the potential for evolution and transmission of drug resistance. Surveillance for HIV drug resistance (HIVDR) informs the selection of empiric ART regimens and indications for genotypic testing. We evaluated HIVDR among ART-experienced and ART-naïve men who have sex with men (MSM) in Lagos and Abuja, Nigeria.

Methods: Adult MSM were recruited into the TRUST/RV368 cohort using respondent-driven sampling. Genotypic testing for HIVDR was performed upon enrollment of HIV-positive participants with HIV RNA ≥1000 copies/mL and at the time of seroconversion in participants with incident HIV. Major mutations conferring resistance to nucleoside reverse transcriptase inhibitors (NRTIs), non-nucleoside reverse transcriptase inhibitors (NNRTIs) and protease inhibitors (PIs) were identified using the IAS-USA 2017 Update of the Drug Resistance Mutations in HIV. Prior ART exposure was assessed by self-report and review of medical records. Samples from ART-naïve participants were evaluated for World Health Organization surveillance drug resistance mutations (SDRMs).

Results: From 3 April 2013 to 23 February 2016, 299 participants underwent HIVDR testing. Participants had median age 24 (interquartile range [IQR] 21-27) years, median CD4 350 (IQR 244-475), and mean HIV RNA 4.7 (standard deviation 0.73) log_{10}copies/mL. Among the 144 ART-naïve participants, 78 (54.2%) were < 25 years old and 31 (21.5%) had CD4 >500 cells/mm³. SDRMs were observed among two of 66 (3.0%) ART-naïve participants in Lagos and nine of 78 (12.0%) in Abuja. Of the 155 ART-experienced participants, 151 (97.4%) were prescribed ART at the time of HIVDR testing. Among ART-experienced participants, high-level resistance to NNRTIs was detected in 22 (14.2%) and NRTI resistance in 13 (8.4%). The most common mutations were K103N and M184V (Table). No major PI resistance mutations were detected.

	Lagos	Abuja	Total
ART-Naïve Participants	(n=66)	(n=78)	(n=144)

Abbreviations: ART, antiretroviral therapy; SDRM, World Health Organization surveillance drug resistance mutation; NRTI, nucleoside reverse transcriptase inhibitor; NNRTI, non-nucleoside reverse transcriptase inhibitor; PI, protease inhibitor

[Table. Antiretroviral Drug Resistance among Nigerian Men who have Sex with Men]

Conclusions: HIVDR among ART-experienced Nigerian MSM demonstrated a pattern consistent with failure of first-line therapy with NNRTI and NRTI components. Evidence of transmitted drug resistance was uncommon in Lagos but moderately common in Abuja, although underreporting of ART use may have led to misclassification of some participants as ART-naïve. These data support current empiric guidelines for PI-based second-line therapy and reinforce the importance of ART adherence programs with continued surveillance for HIVDR.

TUPEB048

HIV Integrase inhibitors resistance in treatment naïve HIV-1 infected populations in Taiwan: Impact of next generation sequencing

H.-C. Tsai, I.-T. Chen, P.-Y. Chou, S.S.-J. Lee, Y.-S. Chen

Kaohsiung Veterans General Hospital, Infectious Diseases, Kaohsiung, Taiwan, Province of China

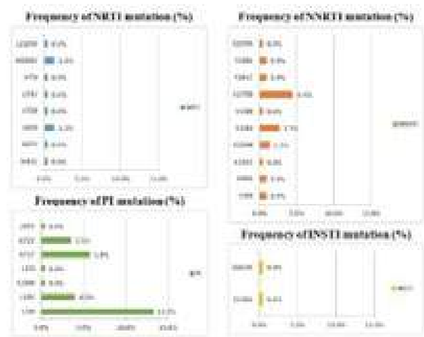
Background: Although HIV Integrase Strand Transfer Inhibitor (INSTI) resistance is low in HIV-1 infected treatment naïve population. As the use of INSTIs becomes more widespread, continued surveillance of primary INSTI resistance may be warranted. The aim of this study was to monitor the prevalence of INSTI resistance in Taiwan by using population sequencing and Illumina MiSeq sequencing.

Methods: A prospective study was conducted in antiretroviral therapy-naïve HIV-1-infected individuals at VGHKS from January 2013 to Dec 2017 in Taiwan. Drug resistance mutations were determined by ViroSeq™

system. In house PCR was used for genotyping INSTI resistance. Illumina MiSeq sequencing were used for measurement of INSTI resistances (≥1%) and compared the results with those from population sequencing. The drug resistance associated mutations were defined by the the 2017 IAS-USA HIV drug resistance associated mutations list and the integrase substitutions with a Stanford HIVdb score ≥ 10 to at least one INSTI.

Results: Among the total of 224 HIV-1 infected treatment naïve patients had tested for resistance in 2013 to 2017, of whom 97% were infected by MSM and 3% were infected by heterosexual. Subtype B HIV-1strains were found in 96% of the individuals and subtype CRF01_AE in 4%. The prevalence rate for NRTI, NNRTI, PI and INSTI resistance was 4%, 5.8%, 0.4% and 0.9%, respectively. The most common INSTI resistance associated mutation was G163K (0.4%) and E138A (0.4%). Among the 38 patients had simutaneously Illumina MiSeq sequencing and population sequencing, none had INSTI resistance associated mutation but the Illumina MiSeq sequencing detected 3 more INSTI resistance associated mutations (G163R 3.25%, S153Y 1.36% and Y143H 2.06%).

Conclusions: Our findings showed a low rate of HIV drug resistance to INSTIs (0.9%) in treatment naïve patients. Illumina MiSeq sequencing detected more INSTI resistance associated mutations at a low frequency. The clinical implications need further study.



[Prevalence of NRTI/NNRTI/PI/INSTI drug resistance associated mutations]

TUPEB049

Patterns of antiretroviral drug resistance in a rural HIV-1 infected cohort: Amajuba District, South Africa

J. Flores-Gonzalez
Madadeni Regional Hospital, Internal Medicine, Newcastle, South Africa

Background: One of the largest threats to the WHO 90/90/90 targets in HIV infection is the development of antiretroviral drug resistance. This is particularly of importance in rural underserved areas compared to urban settings. We explored the frequency and types of Drug Resistance associated Mutations (DRM) in an HIV infected population in rural Northern Kwazulu-Natal, South Africa.

Methods: Cross sectional,descriptive study of an adult cohort (> 15 years) attending the Advanced Care HIV Clinic at Madadeni Hospital who underwent genotype HIV resistance testing by DNA sequencing perfprmed at the Albert Luthuli Durban) and Charlotte Maxeke (Johannesburg) Hospitals Referral Laboratories. Stanford HIV Database algorithm was applied.

Results: 47 specimens from 50 patients were available: 5 treatment naïve patients, 14 first Line ART Failure (TDF + FTC/3TC + EFV/NVP) and 28 second Line ART Failure (ZDV + FTC/3TC + LPVr/ATVr) were analized. Female o Male ratio was 1,82. Mean age =27,9 (Range= 15-58). Wild type virus was confirmed in all treatment naïve patients.All first Line treatment failure cases showed high level resistance to EFV/NVP; 50 % were fully susceptible to ETV/RIL. ZDV associated DRM were absent in 13/14 cases (92,8 %); ABC and TDF resistance was present in 12/14 (85,7 %) and 9/14 (64,2 %), respectively. Among 28 successfully amplified specimens from second line ATR failure patients, PI associated DRM were detected in 19/28 (67,8 %). Among these, most common major PI mutations were M 46 I (71,4 %), V 82 A (57,1 %) and I 54 V (47,6 %). Concerning DRV resistance, 13/28 (46,4 %) demonstrated full susceptibility, 3/28 (10,7 %) intermediate level resistance and 12/28 (42,8 %) low level resistance.

Conclusions: Currently recommended First and Second Line ART regimens in the South African context remain valid, however,the accumulated resistance strains to DRV is concerning and demonstrates need for early detection of virological failure and optimization of adherence counselling and support, particularly in rural areas. First Line INSTI-based regimen will likely be needed in the way forward to achieving the 90/90/90 strategy success.

TUPEB050

HIV drug resistance analysis by Next Generation Sequencing among HIV infected pregnant women from Buenos Aires, Argentina

J.A. Sfalcin[1], A.G. Gomez[1], D. Cecchini[2], I. Zapiola[3], S. Fernandez Giuliano[3], L. Mammana[3], A. Seravalle[1], F.F. Fay[1], M.B. Bouzas[3]
[1]Centro de Diagnostico Medico de Alta Complejidad (CIBIC), Rosario, Argentina, [2]Hospital Cosme Argerich, Buenos Aires, Argentina, [3]Hospital de Infecciosas F. J. Muñiz, Buenos Aires, Argentina

Background: HIV-1 genotypic resistance testing is recommended in pregnant women to identify mutations associated with drug resistance, improving the selection of antiretroviral therapy (ART). Next Generation Sequencing (NGS) genotyping is able to detect minority variants (MVs) which cannot be detected by standard sequencing (SS) techniques as TRUGENE (Siemens). MVs have been shown to increase the risk of virological failure but its clinical use is still controversial. We aimed to evaluate the performance of NGS in a retrospective study from a cohort of HIV-infected pregnant women.

Methods: Baseline plasma samples collected during 2008-2014 corresponding to 40 naïve patients from a cohort of HIV-infected pregnant women were included in the present study. The median virus load was 4.2 log copies/mL and the median CD4 cell count was 390 cells/mm3. All samples previously genotyped by TRUGENE HIV-1 Genotyping Kit were sequenced using a PHAC protocol on a Miseq sequencer (Illumina). Bioinformatics analysis was performed using the HyDRA software for different thresholds of sensibility (NGS 1% and NGS 20%) and resistance mutations were identified according to WHO guidelines (TDRMs) and Stanford University major mutation lists (DRMs).

Results: 100% of sensitivity and specificity was observed between TRUGENE and NGS at 20% threshold. In addition, at NGS 1% MVs were detected, increasing the number of patients from 20 to 35% for TDRMS and from 25 to 42.5% for DRMs. The highest number of MVs was observed in the protease gene (table 1), representing less than 5% of the viral population for each patient. Thirty one patients received ART; of them 96.7% received boosted protease inhibitor (PI)-based therapy, with an adequate virological response in 86.6%.

Drug and mutation type	Trugene (n, %)	NGS 1% (n, %)	Percentage change in mutation prevalence with NGS (1%)
All TDRM	8 (20)	14 (35)	+75%
All DRM	10 (25)	17 (42.5)	+70%
IP TDRM	1 (2.5)	6 (15)	+500%
IP DRM	1 (2.5)	6 (15)	+500%
NRTI TDRM	2 (5)	4 (10)	+100%
NRTI DRM	2 (5)	3 (10)	+50%
NNRTI TDRM	6 (15)	7 (17.5)	+17%
NNRTI DRM	8 (20)	11 (27.5)	+37.5%

[Table 1. Number of patients with drug associated mutations for NGS (1%) and Trugene]

Conclusions: NGS increased the detection of resistance mutations, mostly in the protease gene. Such mutations had a low frequency (< 5%) within the viral population for each patient and were not associated with virologic failure. Considering its high genetic barrier, detection of additional mutations by NGS may not predict an impact in the efficacy of boosted PIs-based ART on this population. Despite this, NGS technology may improve drug resistance surveillance.

TUPEB051

Validation of a cost effective and sensitive HIV-1C integrase genotyping assay

K. Seatla[1,2], W. Choga[1], M. Mogwele[1,3], T. Diphoko[1,4], T. Mogashoa[1,5], L. Mupfumi[1,5], I. Kasvosve[4], S. Moyo[1,6], S. Gaseitsiwe[1,6]
[1]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [2]Faculty of Health Sciences, University of Botswana, Gaborone, Botswana, [3]University of Botswana, Department of Biological Sciences, Gaborone, Botswana, [4]University of Botswana, Department of Medical Laboratory Sciences, Gaborone, Botswana, [5]University of Botswana, Faculty of Health Sciences, Gaborone, Botswana, [6]Harvard T.H. Chan School of Public Health, Department of Immunology & Infectious Diseases, Boston, United States

Background: Increasing access to highly potent antiretroviral (ARV) drugs necessitates the need for more sensitive monitoring of HIV drug resistance in Low and Middle Income Countries (LMIC). Botswana was one the first countries to introduce dolutegravir (DTG) based combination antiretroviral therapy (cART) as first line regimen. We optimised and evaluated an in-house integrase drug resistance assay (IH-Int) evaluated and compared to a commercially assay in Botswana with a background of HIV-1C infection.
Methods: We used 61 specimens from treatment naïve participants enrolled in a previous completed study. Specimens were tested using either ViroSeq™ Integrase Genotyping kit (VS) following manufacture's recommendation and an IH-Int. Drug resistance mutations were analysed using the Stanford HIV drug resistance database. We compared the concordance in mutations calls and amino acid sequence similarity between the two assays. The pairwise nucleotide and amino-acid identity were analysed using Mega 7.0.26.
Results: Among 61 specimens tested with IH-Int, 56 (92%) successfully amplified and for the 52 tested by VS, 42 (81%) successfully amplified. The lowest viral load detected by VS was 431 copies/ml and IH-Int 528 copies/ml. A total of 23 paired sequences showed a concordance of 96% in terms of major and minor INSTI mutations. One mutation, E92Q, was detected by VS and not detected by the IH-Int. The mean amino acid and nucleotide similarity were 99.73% (SD = 0.67) and 99.63% (SD = 0.98%). All participants were infected with HIV-1C. The cost per test of IH-Int was 40-70USD and for VS 200-300 USD.
Conclusions: The IH-Int assay had a high amplification success rate and high concordance with the commercial assay. It is significantly more affordable than the commercial assay. Our assay has the needed specifications for routine monitoring of participants on Dolutegravir based regimens in Botswana.

TUPEB052

Next generation sequencing of pooled samples provides comparable data to sanger sequencing for the detection of HIV protease inhibitor mutations

M. Yousif[1,2], S. Carmona[3,4], J. Ledwaba[1], K. Steegen[3,4], L. Morris[1,2], G. Hunt[1,2]
[1]National Institute for Communicable Diseases, Centre for HIV and STI, Johannesburg, South Africa, [2]University of the Witwatersrand, Virology, Johannesburg, South Africa, [3]University of the Witwatersrand, Molecular Medicine and Haematology, Johannesburg, South Africa, [4]National Health Laboratory Service, Johannesburg, South Africa

Background: South African national guidelines recommend HIV drug resistance (HIVDR) testing for all HIV-infected patients failing a protease inhibitor (PI) based regimen. Currently, Sanger sequencing is used for HIVDR testing, however the implementation of next generation sequencing (NGS) could improve sensitivity, reduce cost and increase specimen throughput. The aims of this study were to compare Sanger and Illumina NGS methods for their ability to detect PI drug resistance mutations among patients failing a PI regimen.
Methods: A total of 162 specimens with PI mutations detected by Sanger sequencing were selected for this study. A 1.7kb fragment spanning protease and reverse transcriptase genes was amplified using an in-house PCR assay. Library preparation was performed using a Nextera XT kit. Paired-end libraries were indexed and pooled in a single MiSeq run (96 specimens) and sequenced using MiSeq Reagent kit V3. FastQ files were analysed using DeepChek®. A consensus sequence was generated for each specimen to compare with Sanger sequences.
Results: The validation process of the NGS and Sanger sequences was done successfully using phylogenetic analysis and pairwise analysis. At the nucleotide level pairwise distance was >99%, while at the amino acid level it was >98%. Using a 15% cut-off for generating a consensus sequence, 155/162 (95.7%) of specimens showed similar HIVdb resistance mutation scores between Sanger and NGS, while 7 specimens (4.3%) showed discordance between the two techniques. When using 5-15% consensus cut-off, an additional 13 specimens (8%) showed discordance.
Conclusions: Detection of DRMs using MiSeq and Sanger sequencing showed high concordance (95.7%). The difference in the HIVdb resistance mutation scores was due to discrepancies in mutations detected. The discrepancies had minor impact on clinical interpretation as all scores were >15 for LPV/r and ATZ/r, which is the cut-off for switching patients to 3rd line therapy. The use of NGS for HIVDR testing is therefore reliable and allows for large specimen numbers to be tested in a more efficient workflow.

Background: The objective of the LOWER study is to analyse the clinical and virological characteristics of HIV-1 infected patients (pts) with multi-drug resistance (MDR) to antiretroviral therapy (ART).
Methods: From April to November 2017, this nation-wide study has enrolled pts with extended resistance in 13 large HIV centres in Germany. For inclusion, signed informed consent and documented evidence of major resistance-associated mutations (RAMs) to ≥3 ART classes of NRTIs, NNRTIs, PIs or INSTIs were mandated. In this sub-analysis, a first description of the cohort is provided.
Results: Of 243 pts (218 males, 25 females) with documented extended resistance, 208 (85.6%) had RAMs affecting NRTIs, NNRTIs and PIs, while 12 (4.9%) had RAMs affecting NRTIs, INSTIs and NNRTIs or PIs (triple class resistance, TCR). The remaining 23 (9.5%) pts had RAMs affecting all four classes (quadruple class resistance, QCR). Patient characteristics are depicted in Table 1. Median age was 55.1 years and median time since first HIV diagnosis was 24.6 years. Many pts had advanced HIV disease and extensive exposure to ART. In the vast majority, ART had been initiated prior to 2000 and had included exposure to mono- or dual therapy with nucleoside analogues. Only 7 patients had initiated ART after 2007, among them one patient with QCR. Of all patients with TCR and QCR, 89.5 % and 65.2 %, respectively, had a current HIV-RNA level below 50 copies/ml; only 7 patients had exhausted current treatment options. Of all patients, less than 5% showed a profound immune deficiency of less than 200 CD4-cells/µl.
Conclusions: In this large cohort of pts with extended resistance representing 25-30 % of all HIV-1 infected pts with MDR in clinical care in Germany, the vast majority had acquired MDR with insufficient ART regimens prior to 2000. Incident MDR is a rare event in Germany and the rate of pts with exhausted options remains low. Our results emphasize the caveats in the design of clinical trials testing new treatment options in patients in need for further options.

	Total	TCR	QCR
n (male gender, %)	243 (89.7 %)	220 (90.9 %)	23 (78.3 %)
Median age, years (range)	55.1 (21.4-80.1)	55.1 (21.4-80.1)	55.1 (28.8-66.3)
Non-R5 tropic virus	51.1 %	49.4 %	60.0 %
Median CD4 cells/µl (range)	566 (10-2293)	584 (107-2293)	336 (10-1077)
CD4 < 200 cells/µl	4.9 %	1.8 %	34.8 %
Prior AIDS-defining illness	53.7 %	53.0 %	60.9 %
Current HIV-RNA < 50 copies/ml	87.2 %	89.5 %	65.2 %
Initiation of ART prior 2000	82.1 %	81.5 %	89.5 %
Initiation of ART 2000-2007	14.7 %	15.6 %	5.3 %
Initiation of ART after 2007	3.1 %	2.9 %	5.3 %
Exposure to mono/dual NRTI regimens	76.2 %	75.5 %	84.2 %

Satisfaction with anal cancer screening among men who have sex with men who are at risk for and living with HIV in Abuja, Nigeria

W. Dauda[1], C.H. Nnaji[1], N. Ndembi[1], J.M. Palefsky[2], U.C. Ononaku[1], C. Katu[1], A. Mitchell[3], T.A. Crowell[4,5], S.D. Baral[6], M.E. Charurat[3], K.J. Cullen[7], R.G. Nowak[3,7]

[1]Institute of Human Virology Nigeria, Research, Abuja, Nigeria, [2]University of California, Department of Medicine, San Francisco, United States, [3]Institute of Human Virology, University of Maryland, School of Medicine, Baltimore, United States, [4]U.S.Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [5]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [7]University of Maryland, Marlene and Stewart Greenebaum Cancer Center, Baltimore, United States

Background: Men who have sex with men (MSM) living with HIV are at increased risk for anal cancer despite effective antiretroviral therapy. Our objective was to evaluate satisfaction with anal cancer screening using high-resolution-anoscopy(HRA) among MSM at risk for and living with HIV.

Methods: Between March and August 2017, 190 MSM were screened for anal cancer at an HIV clinic in Abuja, Nigeria. Participants completed a 22-item questionnaire that evaluated level of satisfaction, distress, and whether symptoms of anal cancer would motivate future screening. Questions were on a 5-point likert scale and then categorized into three ordinal groups. Analyses characterized differences in satisfaction or knowledge of HRA by HIV status using Chi-square tests.

Results: Participants had a median age of 24 years(interquartile range: 22-28) and 63%(119/190) were living with HIV. There was no difference by HIV infection status in satisfaction (96-100%) on 10 of the 19 items related to convenience, staff interpersonal skills, physical surroundings, perceived technical competence, and general satisfaction (p>0.05). 89% were very anxious about having the procedure and 98% agreed to strongly recommend screening to their friends. HIV-uninfected as compared to MSM living with HIV reported more pain during the procedure (19.7% vs 8.5%, p=0.05), found it as uncomfortable as expected (17.1% vs. 6.7%, p=0.07) and agreed it caused great discomfort (19.7% vs. 9.2%, p=0.10), suggesting a trend towards more pain. HIV-uninfected participants also reported waiting longer (9.9% vs. 3.4%, p=0.10). Irrespective of HIV status, only 26-27% agreed to seek additional screening if they had rectal or abdominal pain, any bleeding, or constipation and/or unusually shaped stools.

Conclusions: Overall satisfaction was relatively high for HRA, indicating that implementation of anal cancer screening as part of services provided in a HIV clinic would be feasible with high acceptability. However, common symptoms of anal cancer were not understood as reasons to seek future screening. Anal cancers as a contributor to HIV-related morbidity and mortality have been understudied likely resulting in the limited awareness of common symptoms observed here. Moving forward necessitates increased dialogue of the illness, the utility of screening, and strategies to integrate into existing health systems.

TUPEB055

Effect of CD4 count on the performance of GeneXpert test for tuberculosis (TB) in people living with HIV (PLHIV) in Swaziland: A cross sectional diagnostic study

M. Pasipamire[1], N. Mahlalela[2], D. Khumalo[3], G. Maphalala[3], N. Lukhele[1], P. Mndzebele[1], S. Haumba[2]

[1]Ministry of Health, Swaziland National AIDS Programme, Mbabane, Swaziland, [2]University Research Co. LLC, Mbabane, Swaziland, [3]Swaziland National Reference Laboratory, Mbabane, Swaziland

Background: Swaziland has made progress in controlling the dual TB and HIV epidemic through the implementation of TB/HIV collaborative activities. Through the collaboration, 90% of PLHIV are routinely screened for TB. However, case detection remain a challenge despite increasing median CD4 count (CD4) among those initiating ART. We therefore conducted a study to evaluate diagnostic performance of Xpert-MTB/RIF (GeneXpert) by CD4 against sputum culture.

Methods: A cross sectional study was conducted from April to September 2015 at 4 health facilities. Participants attending ART clinics who screened positive for TB using the 4 symptom-based screening tool were enrolled for TB diagnostic evaluation. Two sputum samples were collected for GeneXpert and TB culture using MGIT. Blood was collected for CD4 testing using FACS Calibur. All samples were tested at National Reference Laboratory. Sensitivity and specificity analyses were done to evaluate GeneXpert. Logistic regression was done to determine factors associated with a true-positive GeneXpert (GeneXpert MTB-detected+ culture-positive). All analyses were done in STATA 12. Proportions, adjusted odds ratios (aOR) with 95% confidence intervals (95%CI) and p-values (p) were reported.

Results: There were 390/417 (94%) participants with sputum collected, 367 (94%) and 365 (94%) had valid culture and GeneXpert results respectively. Thirty (8%) had TB culture-positive results. Of the 30, 15 (50%) had MTB-detected by GeneXpert. The sensitivity of GeneXpert was 78% at CD4< 100 but decreased to 67% and 27% at CD4 of 100-< 200 and CD4≥200 cells/mm³ respectively. The specificity was consistently 100% at all CD4 levels. Positive predictive value was 100% for CD4< 200.

In multivariable analysis, GeneXpert was more likely to be truly-positive among those with CD4< 100 compared to those with CD4 ≥200 (aOR=16.47 (95%CI=1.69-36.34), p< 0.001). Those who were underweight (BMI< 18.5) were more likely to have a true positive GeneXpert compared to those with normal BMI of 18.5-25 (aOR=5.67 (1.50-21.45), p-value=0.011. Sex was not a significant factor (see Table).

Variable	Univariate			Multivariate		
	OR	95% CI	p-value	aOR	95% CI	p-value
CD4 count (cells/mm³)						
>200	1	Ref		1	Ref	
100-200	7.08	1.70 - 29.45	0.000	7.83	4.01 - 67.63	0.009
<100	11.80	3.85 - 49.53	0.007	16.47	1.69 - 36.34	0.000
Body mass index (kg/m²)						
18-25	1	Ref		1	Ref	
<18.5	4.18	1.23 - 14.24	0.022	5.67	1.50 - 21.45	0.011

[Table_Factors associated with true positive GeneXpert (MTB-detected culture positive) results measured against culture]

Conclusions: In Swaziland, CD4 count was an independent factor associated with true-positive GeneXpert test. Therefore as the HIV epidemic is controlled, efforts to improve and increase the pace of new TB diagnostic technologies should be prioritised to maximise TB case detection.

TUPEB056

Anal, oral and genital distribution of HPV in PrEP-users MSM: Results at baseline of the ANRS IPERGAY HPV sub-study

L. Cotte[1], D. Veyer[2], I. Charreau[3], J.F. Flejou[4], H. Péré[5], E. Cua[6], J. Chas[7], I. Heard[8], C. Delaugerre[9], C. Capitant[3], J.M. Molina[10], IPERAGY ANRS
[1]Hopital Croix Rousse, Lyon, France, [2]Hopital Europeen Georges Pompidou, Virology, Paris, France, [3]SC10, Kremlin Bicetre, France, [4]Hopital Saint Antoine, Paris, France, [5]Hopital HEGP, Paris, France, [6]Hopital Universitaire de Nice, Nice, France, [7]Hopital Tenon, Paris, France, [8]Hopital Pitie Salpétrière, Paris, France, [9]Hopital Saint Louis - Université Paris Diderot, Virology, Paris, France, [10]Hopital Saint Louis, Paris, France

Background: HPV infection has been well studied in HIV-infected men having sex with men (MSM), but is less known in HIV-negative subjects. We report preliminary results of a study that aimed to describe the molecular epidemiology of HPV in 3 different anatomic sites to better understand the natural history of HPV.

Methods: HIV-negative MSM enrolled in the ANRS IPERGAY trial were included in the HPV sub-study. Anal, oral and genital swabs were collected at baseline and every 6 months during a 2-year-follow-up for HPV genotyping. Anal cytology was obtained at baseline and after 18/24 months. HPV genotyping was performed using AnyplexTM II HPV28 (Seegene®) that detects 19 high-risk (HR) and 9 low-risk (LR) HPV genotypes.

Results: 164 participants were enrolled, median age:34 (IQR: 27-42) years. The baseline prevalence of anal, oral and genital HPV infection was 92%, 12% and 37%, respectively. The prevalence of anal, oral and genital HR/LR HPV was 83%/68%, 11%/3% and 25%/12%, respectively. Multiple infections were observed in 77%, 3% and 17% of anal, oral and genital sites, with a median of 4 genotypes at the anal site. Anal cytology was normal at baseline in 32%, ASCUS in 23%, ASCH in 1%, LSIL in 40%, HSIL in 4% of cases. Participants with normal cytology were infected with a median of 2.5 HPV genotypes (IQR:1-4) vs. 4 (IQR:2-6) (p=0.006) in participants with abnormal cytology. Abnormal cytology results were associated with HR16 (p=0.046), HR66 (p=0.049), LR11 (p=0.012) and LR61 (p=0.01). HPV included in the nonavalent vaccine (HR 16, 18, 31, 33, 45, 52 and 58; LR 6 and 11) represented 38%, 43% and 36% of anal, oral and genital HR and 26%, 33% and 21% of anal, oral and genital LR, respectively.

Conclusions: High-risk HIV-negative MSM enrolled in the ANRS IPERGAY PrEP trial were heavily infected with HR and LR HPV at baseline; 2/3 of them presented with abnormal anal cytology. The number of detected HPV genotypes was associated with abnormal cytology, as well as HPV 16, 66, 11 and 61. Part of these infections could have been prevented by the nonavalent HPV vaccine.

TUPEB057

Diagnostic value of 18 FDG PET/CT in undiagnosed opportunistic infections among symptomatic HIV/AIDS patients

U.E. Mathew[1], N. Nischal[1], M. Tripati[2], C. Das[3], M. Soneja[1]
[1]All India Institute of Medical Sciences (AIIMS), Department of Internal Medicine, New Delhi, India, [2]All India Institute of Medical Sciences (AIIMS), Department of Nuclear Medcine, New Delhi, India, [3]All India Institute of Medical Sciences (AIIMS), Radiology, New Delhi, India

Background: Positron emission tomography (PET) with [F-18]-fluorodeoxy-glucose (FDG) is a sensitive tool for the localisation of pathology. However, the interpretation of FDG PET scans in HIV patients is challenging. We undertook this study to evaluate the diagnostic utility of 18 FDG-PET/CT scan in the diagnosis of opportunistic infections and correlate the SUVmax with specific opportunistic infections.

Methods: A total of 25 symptomatic HIV patients were enrolled in our prospective observational study. Patients were subjected to sequential investigative investigations according to our institute's protocol for evaluation of PUO patients and those who remain undiagnosed underwent FDG PET scans and were then included in this study.

Results: The study population were predominantly males (64% ;16/25) with mean age of 36.5 ± 15.5 years (range 21 - 52 years).The median CD4 count was 226 cells / mm^3 and majority of participants (72%) were on combined anti-retroviral therapy (cART). Predominant mode of transmission was through heterosexual contact (80%). Majority of our patients (92%) presented with fever of duration more than 3 weeks. All standard serological tests were inconclusive in our study population.

FDG PET CT was contributory to diagnosis in 24/25 patients and was able to detect opportunistic infection/neoplasm in 18 patients with disease. The most common finding was lymphadenopathy (96%) but metabolically active lymph nodes were present only in 18 patients (72%). Of the 3 patients with neurological symptoms, 2 of them had low FDG uptake corresponding to a diagnosis of PML while one patient had no FDG uptake and presumed to have drug induced encephalopathy secondary to Efavirenz. Sensitivity of PET-CT in diagnosing opportunistic infections/neoplasms was 100% with specificity of 71%, diagnostic accuracy of 92%, PPV of 94% and NPV of 100%. In comparison, CECT was contributory to diagnosis in 9 patients only. Moreover, three patients with imaging features suggestive of TB in CECT were suspicious for malignancy by FDG PET CT and confirmed to be malignant subsequently.

Conclusions: 18 FDG-PET CT is a useful diagnostic tool helpful to differentiate infections and malignancy in HIV infected patients and localise the best possible site for biopsy.

TUPEB058

Cervical cancer screening and prevalence and treatment of cervical abnormality in women living with HIV: Results from the Malawi population-based HIV impact assessment (MPHIA) 2015-16

S. Jonnalagadda[1], D. Payne[2], A. Voetsch[1], S. Forhan[1], E. Radin[3], C. West[2], A. Maida[2], L. Sithole[4], M. Odo[5], H. Patel[1], J. Cuervo-Rojas[3], C. Wang[3], H. Longwe[6], E. Kim[2], MPHIA Study Team
[1]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States, [2]Centers for Disease Control and Prevention, Lilongwe, Malawi, [3]ICAP at Columbia University, New York, United States, [4]National AIDS Commission, Government of Malawi, Lilongwe, Malawi, [5]Ministry of Health, Government of Malawi, Lilongwe, Malawi, [6]ICAP at Columbia University, Pretoria, South Africa

Background: Cervical cancer (CC) screening and treatment of cervical pre-cancer is effective in CC prevention. UNAIDS recommends that all women living with HIV should be offered CC screening and treatment, if needed. Early antiretroviral treatment (ART) and HIV viral suppression (VS) might reduce risk of progression to invasive CC in HIV-positive women. We used the 2015-16 Malawi Population-based HIV Impact Assessment (MPHIA) data to describe CC screening in HIV-positive women in Malawi, a high HIV burden country with highest CC incidence, globally.

Methods: MPHIA is a nationally representative household survey. Consenting females aged 15-64 years were interviewed and tested for HIV using the national rapid test algorithm; positives were confirmed using Geenius™ HIV 1/2 Confirmatory Assay (Bio-Rad). ART use was defined as self-reported or presence of detectable ART in blood. Self-reported CC screening data were analyzed by HIV test result and ART status using weighted percentages and 95% confidence intervals (CI) that account for complex survey design.

Results: Among 1,507 HIV-positive women, 295 (16.0%; 95% CI: 13.4% - 18.6%) reported CC screening, compared to 758 of 8,375 (7.4%; 95% CI: 6.3% - 7.7%) HIV-negative women.

Among 1,110/1507 HIV-positive women on ART, 83.0% (95% CI: 80.0% - 86.0%) reported not being screened for CC. Percentage of HIV-positive women on ART who were not screened for CC was greatest in those aged 15-24 years (94.9%) and in women in rural areas (68.4%) (Table 1).

Among women screened for CC, 18/295 (5.3%; 95% CI: 2.3%-8.3%) HIV-positive and 23/758 (3.7%; 95% CI: 2.2%-5.2%) HIV-negative women reported an abnormal result. Of the 41 women with abnormal results, 17 (47.5%; 95% CI: 28.8%-66.3%) reported receiving same day pre-cancer treatment; 11 (30.0%; 95% CI: 12.5% - 47.3%) reported receiving different day treatment and 13 (22.6; 95% CI: 11.0%-34.1%) reported not receiving treatment. No differences were observed in pre-cancer treatment by HIV status.

Conclusions: CC screening in Malawi was low in general and in HIV-positive women, even among those on ART, indicating a missed opportunity. In the HIV test and treat era, strengthening integration of CC screening with HIV services could play a vital role in CC prevention.

Variable	Unweighted number of HIV positive women screened	Weighted percent of HIV positive women screened	95% CI	Unweighted Number of HIV positive women not screened	Weighted percent of HIV positive women not screened	95% CI	Unweighted denominator of HIV positive women
All HIV+ women on ART	237	17.0	14.0 - 20.0	873	83.0	80.0 - 86.0	1,110

TUPEB059

Xpert MTB/RIF for rapid diagnosis of extra-pulmonary tuberculosis in high HIV and tuberculosis burden settings

M. Tadesse[1], M. Bezabih[2], G. Abebe[1], D. Yilma[3], L. Rigouts[4]
[1]Jimma University, Mycobacteriology Research Center, Jimma, Ethiopia, [2]Jimma University, Pathology, Jimma, Ethiopia, [3]Jimma University, Internal Medicine, Jimma, Ethiopia, [4]Institute of Tropical Medicine, Biomedical Sciences, Antwerp, Belgium

Background: Ethiopia is known to have high prevalence of HIV and tuberculosis. The proportion of extra-pulmonary tuberculosis (EPTB) cases increased to 58% in HIV-infected patients. However, the diagnosis of EPTB remains challenging and EPTB cause excess mortality in people living with HIV.
The currently available tools are either low in sensitivity or require longer time to confirm EPTB. We determined the clinical utility of the Xpert MTB/RIF for the diagnosis EPTB in Ethiopia.
Methods: This study was carried out at a public tertiary care hospital in Ethiopia from August 2016 to June 2017. A total of 232 (68 HIV-positive and 164 HIV-negative) patients with clinically presumed of EPTB were included. Site-specific extra-pulmonary samples (98 lymph node aspirates, 63 pleural fluids, 38 cerebrospinal fluid and 33 peritoneal fluids) were collected and examined for TB by culture and Xpert MTB/RIF. The diagnostic accuracy of Xpert MTB/RIF was calculated compared to culture and stratified by HIV status and specimen types.
Results: Overall, 98 (42.2%) specimens were positive for *M. tuberculosis* by culture and 103 (44.4%) by Xpert MTB/RIF**.** There was higher proportion of EPTB cases among HIV-infected patients (48.5% versus 39.6%) than HIV-uninfected patients. The sensitivity of Xpert MTB/RIF for EPTB was 88% among HIV-infected patients and 92% among HIV-uninfected patients, with no statistically significant difference between the two groups. However, the Xpert MTB/RIF sensitivity was quite different among the specimen types. Xpert MTB/RIF has highest sensitivity for lymph node TB (91%), modest for TB meningitis (81%) and lowest for pleural (47%) or abdominal TB (43%). A negative Xpert MTB/RIF test on fluid specimens does not exclude the diagnosis of pleural or abdominal TB and patients with a high clinical probability of EPTB should be started on anti-TB treatment. The Xpert MTB/RIF specificity was high (92%) and not significantly affected by HIV-status or specimen types.
Conclusions: Xpert MTB/RIF is likely to be of greatest utility when diagnosing patients suspected of lymph node TB or TB meningitis, even in HIV-infected patients. Xpert MTB/RIF offered a rapid diagnosis and particularly important in life-threatening forms of EPTB, such as TB meningitis.

TUPEB060

Diagnostic accuracy of Xpert MTB/Rif in detecting pulmonary tuberculosis among people living with HIV at the research institue for tropical medicine

A. Gianan[1], N. Macalalad[2], M. Lucero[2]
[1]Research Institute for Tropical Medicine, Las Pinas, Philippines, [2]Research Institute for Tropical Medicine, Muntinlupa, Philippines

Background: Tuberculosis is a leading killer among people living with human immunodeficiency virus (HIV). HIV-infected individuals with latent TB are approximately 20-30 times more likely to develop TB disease than those who are HIV uninfected, at a rate of 8-10% per year. In the Philippines, there are 1,379,390 cases diagnosed with tuberculosis, 98.9% of this is Pulmonary TB while extra pulmonary TB is the remaining 1.1%.(6) At the Research Institute for Tropical Medicine (RITM), there have been about 5,000 cases of HIV since 1980's.
This study determined the diagnostic validity of Xpert MTB/Rif in identifying the presence of Pulmonary Tuberculosis among HIV patients at the Research Institute for Tropical Medicine.
Methods: This is a prospective cross sectional analytical study among HIV patients aged 19 and above who are infected with HIV and enrolled in RITM seen from January 2015 - March 2016. Patients with signs and symptoms of PTB were enrolled and submitted sputum for AFB smear, Xpert MTB/Rif and TB culture. This was processed following RITM protocol for pulmonary samples for Xpert MTB/Rif based on WHO guidelines.
All samples were processed for AFB smear and TB culture as part of the usual procedure for diagnosing PTB. Epi info was used for data entry program using single data entry system. Statistical analysis included the determination of sensitivity, specificity, positive predictive value, and negative predictive value of the Xpert MTB/Rif and AFB sputum smear using MTB culture as the gold standard. Categorical values were reported as frequencies and percentage while numerical values were reported as mean and standard deviation.
Results: A total of 272 patients were enrolled in the study. Xpert MTB/Rif has a sensitivity of 60.78% and specificity of 97.8%, high positive predictive value (88.57) and high negative predictive value (89.90). The turn around time for Xpert MTB/Rif and AFB smear is 4 and 6 days respectively. A prevalence (21.89%) of culture-proven pulmonary TB was diagnosed in this patient population.
Conclusions: Use of Xpert MTB/RIF as a screening tool might effectively reduce the risk of MDR-TB in HIV care and treatment settings and improve the prognosis of affected patients.

TUPEB061

Evaluation of a prototype cobas®MTB assay for use on the cobas® 6800/8800 Systems for the detection of *Mycobacterium tuberculosis* in a high burden HIV patient population

L. Scott[1], A. David[1], J. Furrer[2], F. Schneider[2], L. Govender[1], S. Kumar[2], F. Bastos[2], S. Lange[2], P. Loetscher[2], N. Martinson[3,4], E.M. Marlowe[5], W. Stevens[1,6]
[1]University of the Witwatersrand, Department of Molecular Medicine and Haematology, School of Pathology, Faculty of Health Science, Johannesburg, South Africa, [2]Roche Molecular Diagnostics, Development, Rotkreuz, Switzerland, [3]Perinatal HIV Research Unit Chris Hani Baragwanath Hospital, Johannesburg, South Africa, [4]Johns Hopkins University Center for Tuberculosis Research, Baltimore, United States, [5]Roche Molecular Diagnostics, Medical & Scientific Affairs, Pleasanton, United States, [6]National Priority Program of the National Health Laboratory Service, Johannesburg, South Africa

Background: *Mycobacterium tuberculosis* (MTB) is the leading cause of infectious disease death worldwide, especially in persons living with HIV/AIDS (PLWH). Per WHO guidelines, all PLWH should be tested for MTB. The study objective was to initiate preliminary evaluation of a prototype cobas® MTB assay for use on the cobas® 6800/8800 Systems to detect MTB from sputum and sediment specimens in a high burden HIV population.

Methods: A prospective accuracy evaluation was conducted to determine the sensitivity and specificity of the prototype cobas® MTB assay (cobas). Specimens tested included matched raw sputum and sediment among adults with presumptive TB in Johannesburg, South Africa. The performance of the prototype cobas was compared to the standard of care Cepheid Xpert® MTB/RIF and the commercially available Abbott RealTime MTB assays.

Results: A total of 294 patients were enrolled (59.9% HIV+) in the evaluation. Among smear +/culture + patients cobas identified 73/73 (100%) patients with TB from sediment and 72/73 (98.6%) from raw sputum, compared to 100% & 97.3% Xpert and 97.3% & 98.6% Abbott. Among the smear -/culture + patients, cobas identified 17/22 (77.3%) from sediment and 18/22 (81.8%) from raw sputum, compared to 77.3% & 72.7% for both Xpert and Abbott. Specificity was 95.5% & 97% for sediment and raw sputum, compared to 98.5 & 97.5 Xpert and 95.0% & 96%% Abbott respectively. Among the HIV cohort (n=176), in smear +/culture + patients cobas identified 52/52 (100%) patients with TB from sediment as well as raw sputum, compared to 100% & 98.1% Xpert and 98.1% & 100% Abbott. In smear -/culture + patients, cobas identified 13/17 (76.5%) from sediment and 14/17 (82.4%) from raw sputum, compared to 76.5% & 70.6% for both Xpert & Abbott. Specificity in HIV + patients was 94.4% and 95.3% in sediment and raw sputum, compared to 98.1% & 97.2% Xpert and 93.5% & 96.3% Abbott.

Conclusions: The prototype **cobas**® MTB for use on the **cobas**® 6800/8800 Systems demonstrated comparable performance to existing technologies, for both raw sputum and sediment specimens. This investigational MTB assay offers an automated, high-throughput, polyvalent platform for laboratories serving high burden HIV populations.

TUPEB062

Stopping HIV in its tracks - expanding testing for HIV and a common comorbid infection can halt the epidemic

C. Lushbough[1], L. Alerte[2], K. Bogdansky[3], Y. Elamir[3], C. Faludi[3], M. Ghias[3], W. Grist[3], K. Gyekye[2], M. Hart[2], T. Nguyen[2], J. Rocha[2], M. Tran[2], A. Grigoriu[1]
[1]*RWJ Barnabas Health - Jersey City Medical Center, Internal Medicine, Jersey City, United States,* [2]*RWJ Barnabas Health, Jersey City, United States,* [3]*RWJ Barnabas Health - Jersey City Medical Center, Jersey City, United States*

Background: It is estimated that 37,000 individuals are diagnosed with HIV while 160,000 are diagnosed with Hepatitis C Virus (HCV), often concurrently, in the state of New Jersey alone. Both viruses are well-known and widespread challenges to personal, societal, and governmental resources and, ultimately, human life. Current guidelines from the USPSTF recommend offering HIV screening every 1 - 5 years in accordance with risk and a 1-time screening for HCV infection to adults born between 1945 and 1965 (baby boomers). Early detection allows for early treatment, cure, and slowing of the spread of disease. We posited that expanding routine testing outside these recommendations would aid in early identification, management, containment, and, ideally, cure of these often-dreaded and still-fatal diseases.

Description: Jersey City Medical Center (JCMC) implemented EHR screening prompts to encourage providers routinely to screen all admitted patients equal to or greater than 18 years of age for HIV and HCV. JCMC's IT and Laboratory departments collected data continuously from January 1, 2016 to September 30, 2017.

Lessons learned: Testing volume increased 20% compared to baseline before intervention, resulting in the screening of 9,915 patients for HIV and 7,867 patients (3,335 baby boomers and 4,532 non-baby boomers) for HCV. Routine testing of eligible patients at our hospital revealed the profound impact of early identification: 1.80% of patients tested were positive for HIV while 3.85% were positive for HCV. Devastatingly, of those who tested positive for HCV, 40.3% did not meet screening guidelines. Finally, 46% of all positive patients were able to be connected with ongoing outpatient care.

Conclusions/Next steps: Given the nature of our high risk patient population - on all sides of current guidelines - and results thus far, we feel it is imperative to maximize the routine screening for HIV and HCV. We plan to maximize testing of inpatients by linking testing orders to admission order and are reviewing the plausibility of offering rapid testing to high risk populations such as those who frequent methadone clinics and needle exchange programs.

Biomarkers for the prediction of morbidity and mortality

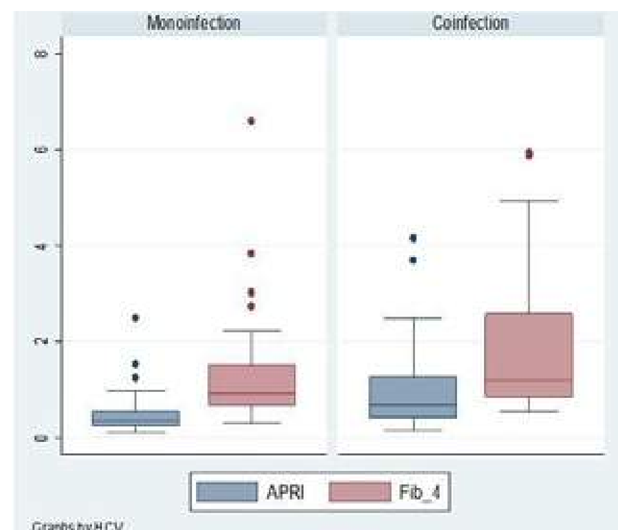
Predictive value of hepatitis C seropositivity or liver fibrosis scores to detect low CD4+ T-cells counts following treatment for HIV in Egyptians: A cross-sectional study

A. Cordie[1], W. Kamal[2], M. Elsayid[3], A. Elsharkawy[1], S. Abdel Alem[1], Z. Abdellatif[1], M. Al Askalany[4], S. Meshaal[5], A. Kandeel[2], A. d'Arminio Monforte[6], G. Esmat[1]
[1]*Cairo University Hospitals, Endemic Hepatogastroenterology and Infectious Diseases, Cairo, Egypt,* [2]*Ministry of Health and Population, Preventive Sector, Cairo, Egypt,* [3]*Ministry of Health and Population, Cairo, Egypt,* [4]*Ministry of Health and Population, Imbaba Fever Hospital, Cairo, Egypt,* [5]*Cairo University Hospitals, Clinical Pathology Department, Cairo, Egypt,* [6]*University of Milan, Clinic of Infectious Diseases, Health Sciences, Milan, Italy*

Background: Hepatitis C viral co-infection and subsequent hepatic fibrosis development are thought to be associated with poor restoration of CD4+ T-cells. Less costly indicators of low CD4+ T-cell counts are needed in resource-limited settings. Our study aimed to assess whether or not an association exists between HCV seropositivity, calculated AST to platelet ratio index (APRI) or fibrosis-4 (FIB-4) score and low CD4+ T-cell counts < 200 cell/mm3 despite HIV viral load (VL) suppression.

Methods: This represents a cross-sectional study that comprised 94 patients living with HIV attending Imbaba Fever Hospital, Cairo, Egypt between June 2016 and May 2017. All patients received emtricitabine/tenofovir plus efavirenz for at least 6 months and had a suppressed VL. Out of them, 38 patients tested positive for HCV antibodies. Demographic data, recent CD4+ T-cell counts, platelet counts and serum ALT and AST levels were collected. Patients with reactive hepatitis B surface antigen, body mass index > 30kg/m² or reported regular alcohol intake were excluded. APRI and FIB4 scores were calculated. Independent predictors for CD4+ T-cell counts < 200 cell/mm³ after at least 6 months of VL suppression were identified by multivariable logistic regression.



[Figure.1: Median APRI and FIB4 scores in HIV monoinfected or HCV coinfected patients]

Results: HIV/HCV co-infected patients were more frequently males (92.1% vs. 71.4%, p=0.01) and smokers (73.7% vs. 46.4%, p=0.009). They had significantly lower mean CD4+ T-cell counts (299.33 ±150.72 vs. 412.53

±158.72 cells/mm3, P< 0.001), but higher median APRI and FIB4 scores (Figure 1). Both groups were comparable regarding age, BMI and ART duration. Higher APRI score was an independent predictor of CD4+ T-cell counts < 200 cell/mm3 despite VL suppression (30 patients) (OR, 2.83; 95% CI, 1.21-6.63, p=0.02). APRI score of >0.5 is associated with nearly 7 folds higher odds of having CD4 count < 200 (OR, 7.16; 95% CI, 1.43-35.96, p=0.01).
Both HCV seropositivity (OR, 2.32; 95% CI, 0.64-8.39, p=0.2) and higher FIB4 (OR, 1.38; 95% CI, 0.95-1.99, p=0.09) were not predictors.
Conclusions: HCV can affect negatively CD4+ T-cell counts among PLHIV. APRI score, but not FIB4 can be used as a simple independent predictor of low CD4+ T-cell counts in PLHIV and undetectable VL. These predictors deserve further validation.

TUPEB064

Evaluation of plasma glutathione levels in HIV-infected children in Benin City, Nigeria: A cross-sectional study

E. Ogonor, W.E. Sadoh, P.O. Abiodun
University of Benin Teaching Hospital, Child Health, Benin, Nigeria

Background: Glutathione is the most potent anti-oxidant in the human body and a principal tool for effective immune function in the normal population. Impaired glutathione metabolism as a result chronic oxidative stress during HIV infection has been shown to play a significant role in the disease pathogenesis and progression. While several studies have suggested HIV infection leads to glutathione deficiency, the evidence is inconclusive. Furthermore, there is dearth of literature on glutathione levels in HIV infected children in sub-Saharan Africa which has a high disease burden. Thus, the objectives of this study were to compare plasma glutathione levels between HIV infected and uninfected children and to determine if plasma glutathione has any relationship with WHO clinical and immunologic staging of HIV disease.
Methods: A cross-sectional study was conducted among 258 HIV infected children and their age and sex-matched controls in the two major hospitals (University of Benin Teaching Hospital and Central Hospital) that provide pediatric HIV care in Benin City between December 2015 and April 2016. Information was obtained using questionnaire. Almost all the HIV infected children (96.5%) were on antiretroviral therapy. Samples were collected in the morning and plasma glutathione levels were determined in both groups using the spectrophotometric method involving the Dithio-bis -2-nitrobenzoic acid/Glutathione reductase enzyme (DTNB/GR) technique. Data was statistically analyzed using paired t-test and spearman rank correlation.
Results: The mean (± SD) plasma glutathione level of the HIV infected children was 8.82 ± 2.39 µmol/l, and it was significantly lower than the mean (± SD) plasma glutathione level of the HIV uninfected, 13.11 ± 3.20 µmol/l (t = -17.35, p < 0.0001). Furthermore, there was no significant correlation between plasma glutathione and both WHO immunologic staging (r= 0.011, *p*= 0.869) and clinical staging of HIV (r=0.053, *p*=0.379).
Conclusions: The study supports the assertion that HIV/AIDS plays a pivotal role is causing glutathione depletion in infected children. Although it can be inferred that glutathione has no relationship with severity of HIV disease, further studies are needed to ascertain the benefit of glutathione supplementation in HIV infected children.

Characteristics	HIV positive Children n = 258 (%)	HIV negative Children n = 258 (%	χ2	p-value

Longitudinal change in leukocyte telomere length and mitochondrial DNA in people living with HIV

R. Minami, S. Takahama, M. Komatsu, M. Yamamoto
National Hospital Organization, Kyushu Medical Center, Internal Medicine, Fukuoka, Japan

Background: Premature aging is an important issue in people living with HIV (PLHIV). Telomere length (TL) shortening and alterations in the biogenesis of mitochondrial DNA (mtDNA) are recognized as markers of cellular aging. Our previous cross-sectional study showed significant leukocyte TL shortening and decreased leukocyte mtDNA in PLHIV compared with healthy controls. In this study, we measured longitudinal changes in leukocyte TL and mtDNA in PLHIV receiving combination antiretroviral therapy (cART), and examined the clinical parameters affecting these changes.
Methods: We recruited PLHIV who visited our hospital from February 2012 to March 2017, and 141 HIV-uninfected controls. All PLHIV had received cART for > 6 months and had undetectable viral loads. Relative TL and mtDNA in leukocytes were estimated by quantitative real-time PCR. Linear regression analysis was used to determine the factors associated with longitudinal changes in TL and mtDNA. We assessed several variables associated with HIV infection (CD4, HIV-RNA before cART), cART (duration, regimen), and other clinical factors. We also measured TCR rearrangement excision circles (TREC) in peripheral blood to assess thymic output. Variables found to be important in univariate analysis were multivariate model candidates.
Results: Longitudinal assessment was possible in 278 cases. The median measurement interval was 45.5 months. At baseline and the second measurement, TL and mtDNA decreased significantly in PLHIV compared with the controls. The change in TL and mtDNA varied between PLHIV. During the follow up, TL recovered in younger PLHIV, while it shortened more in older PLHIV. Young age (< 50), renal function, TREC, and mtDNA were significantly positively related to the change in TL, and multivariate analysis showed that age, TREC, and mtDNA were independent factors. An NRTI sparing regimen, TREC, and TL were significantly positively related to the change in mtDNA, and each was an independent factor in multivariate analysis.
Conclusions: In our longitudinal study, TL and mtDNA recovery was positively correlated with TREC, which decreases with age and the progression of immunodeficiency in PLHIV. Our findings indicated that early ART with decreased toxicity can help improve outcomes among PLHIV.

TUPEB066

Plasma biomarkers of systemic inflammation and immune activation in advanced HIV infection in sub-Saharan Africa before and during antiretroviral therapy

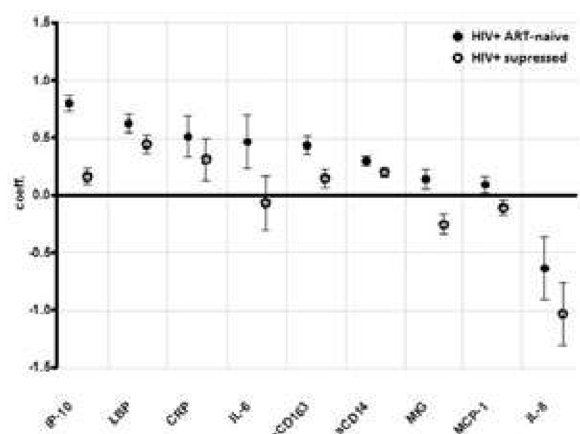
S. Kroeze[1], F. Wit[2], T. Rossouw[3], C. Kityo[4], M. Siwale[5], S. Akanmu[6], K. Mandaliya[7], P. Ondoa[1], P. Reiss[1,2], T. Rinke de Wit[1], N. Kootstra[8], R. Hamers[1]
[1]Academic Medical Center, Global Health, Netherlands, Netherlands, [2]Stichting HIV Monitoring, Amsterdam, Netherlands, [3]University of Pretoria, Immunology, Pretoria, South Africa, [4]Joint Clinical Research Centre, Kampala, Uganda, [5]Lusaka Trust Hospital, Lusaka, Zambia, [6]Lagos University Teaching Hospital, Lagos, Nigeria, [7]Coast Province General Hospital, Mombasa, Kenya, [8]Academic Medical Center, Experimental Immunology, Netherlands, Netherlands

Background: Elevated plasma biomarkers of HIV-induced systemic inflammation and immune activation (IIA) are characteristic of untreated HIV infection, and residual IIA during sustained viral suppression on antiretroviral therapy (ART) has been associated with (non)AIDS events and mortality. However, data in African populations with advanced HIV are limited. We assessed to what extent ART reduces IIA, and what factors are associated with residual IIA during suppressive ART in a multi-country cohort.
Methods: We included HIV-1-positive adults from 5 African countries enrolled in the PASER-M cohort, who had plasma HIV-RNA< 50 cps/ml after 12 months of ART (M12) on non-nucleoside reverse-transcriptase

inhibitor-based first-line ART, and HIV-negative blood bank donors (BBD) from 3 African countries. We measured 9 plasma biomarkers of monocyte activation (sCD14, sCD163), inflammation (CRP, IP-10/CXCL10, IL-6, IL-8/CXCL-8, MCP1/CCL2, MIG/CXCL9), and microbial translocation (LBP). Differences between log_{10}-transformed biomarker levels pre-ART and M12 were assessed using multivariable linear regression adjusting for age, sex and country. Associations of independent variables with IIA pre-ART and at M12 were assessed using multivariable linear regression.
Results: We included 428 HIV-positive participants and 90 HIV-negative BBD (Table). Compared to BBD, untreated HIV-positive participants had higher biomarker levels (all, except for IL-8/CXCL-8). In untreated HIV-positive participants, biomarker levels were positively associated with plasma HIV-RNA (IP-10, MCP1, sCD14, LBP, CRP) and negatively associated with CD4 (IL-8/CXCL-8, IP-10, MCP1, sCD14, CRP). In treated HIV-positive participants (M12), all biomarkers had decreased significantly compared to pre-ART values, with IP-10 showing the greatest decrease (Figure). Compared to BBD, treated HIV-positive participants (M12) had higher levels of sCD14, sCD163, IP-10/CXCL-10 and LBP, lower levels of IL8/CXCL-8, MCP1/CCL2 and MIG/CXCL9, and similar levels of IL-6. Biomarker levels at M12 were positively associated with pre-ART levels of the same biomarker; additionally, sCD14 and IP-10 at M12 were positively associated with pre-ART HIV-RNA. IIA was not associated with body mass index, pulmonary tuberculosis, chronic hepatitis B or HIV-1 subtype.
Conclusions: Suppressive ART partially mitigated IIA. Residual IIA was associated with high biomarker levels and HIV-RNA before ART start. These findings support policies for early ART initiation in African populations.

		HIV-positive (n=428)	HIV-negative (n=90)
Sex	Female	248 (58.0%)	22 (24.4%)
Age (median, IQR)		36 (32-42)	36 (30-44)
CD4 (median, IQR)		136 (75-203)	-
Country	Kenya	104 (24%)	-
	Nigeria	61 (14%)	29 (32%)
	South Africa	68 (16%)	30 (33%)
	Uganda	128 (30%)	31 (34%)
	Zambia	67 (16%)	-

[Patient characteristics]



The figure shows results of the multivariable linear regression analysis, adjusted for sex, age and country. The ratio of regression coefficients is plotted for each biomarker. Numerator: HIV-positive participants, either pre-ART (filled dots) or with viral suppression after 12 months of ART (M12) (open dots). Denominator: HIV-negative blood bank donors.

Background: Distal Sensory Peripheral Neuropathy (DSPN) is a common complication of HIV that may be a direct consequence of HIV infection, drug toxicity, or co-infections. The prevalence of DSPN in resource-limited settings (RLS) has not been studied comprehensively. Here we provide estimates of DSPN prevalence and severity in seven RLS countries for HIV+ ART-naive individuals compared to similar normative comparison participants without HIV.
Methods: Participants from AIDS Clinical Trials Group (ACTG) 5199 (International Neurological Study (INS, n=860 HIV+)) and ACTG 5271, the International Neurocognitive Normative Study (INNS, n=2400 HIV-) underwent the ACTG Neurological Examination to quantify presence, severity, and duration of neuropathy symptoms and signs (tingling, numbness, sensory loss; temperature, vibration, reflexes). HIV- normative data were used as comparisons to general population prevalence in these RLS settings. Associations between ART regimen and other covariates with neuropathy were estimated from generalized estimating equations.
Results: At baseline, 21.3% of HIV+ participants were diagnosed with DSPN, compared to 8.5% of HIV negative in the same settings (^{2}(df =1) = 96.49, p< .00001). DSPN decreased after beginning ART: 20.3% week 48, 17.5% week 96, 15.3% week 144, 10.3% week 192 Most of the DSPN was of equivocal or subclinical severity (>95%). Older individuals had higher odds of neuropathy (OR=1.49 (95% CI 1.25, 1.77) for each 10-year increment (p< 0.001). Women were more likely to have DSPN than men (Males OR=0.70 (95% CI 0.49, 0.99, p=0.046)). The prevalence of DSPN over time did not differ by randomized ART regimen, CD4 or RNA.
Conclusions: There was substantial prevalence of DSPN in HIV+ prior to ART initiation when compared to normative HIV- in RLS. DSPN in milder forms is often not detected in clinical practice. DSPN prevalence decreased with ART over time. Identification of strategies to reverse including early ART initiation or to ameliorate residual DSPN symptoms may improve functioning in individuals in RLS allowing more 'feet of the ground'.

Subjective and objective improvement on cognition after discontinuing efavirenz in asymptomatic HIV patients

C.S. Hakkers[1], J.E. Arends[1], G.E. van den Berk[2], M.H.M. Ensing[1], I. Hooijenga[2], M. Vink[1], M.J.E. van Zandvoort[1], A.I.M. Hoepelman[1]
[1]UMC Utrecht, Utrecht, Netherlands, [2]OLVG Hospital, Amsterdam, Netherlands

Background: Combination Anti-Retroviral Treatment (cART) toxicity has an effect on cognition in HIV, with Efavirenz as the most notable example. Little is known about the long-term effect of Efavirenz use in patients who don't report overt cognitive complaints. The aim of this study was to assess the effect of switching Efavirenz (EFV) to Rilpivirine (RPV) in cognitive asymptomatic patients. We hypothesize an improvement in neurocognitive functioning when discontinuing Efavirenz.

Methods: 54 virologically suppressed, cognitive asymptomatic male HIV-infected patients on TDF/FTC/EFV (Atripla) were included and randomized (2:1) to switch to TDF/FTC/RPV (Eviplera) (switch group) or continue on Atripla (control group) for 12 weeks. At baseline and week 12, all patients underwent a standardized extensive neuropsychological assessment (NPA), and filled in questionnaires on quality of life, participation in society and mood. Effects of the switch were analyzed per group using a linear mixed Model. Moreover, Normative Comparison (NC) was used to assess improvement at individual level as compared to the control group.

Results: 14 control and 34 switch subjects completed the study. There were no differences at baseline for age, years of education or composite NPA Z-score. Group-analysis demonstrated a significantly better improvement for the switch group on the domains attention (p=0.041) and speed of information processing (p=0.014). NC- analyses showed that 5 (15%) out of the 34 patients who switched improved on NPA-score as compared to the control group. No improvement was found in quality of life, participation or mood as measured by questionnaires. Interestingly, subjective improvement in everyday life after switch (discontinuing Efavirenz) made 74% of the switch group chose for a regime without Efavirenz after study completion.

Conclusions: Switching from Atripla to Eviplera resulted in objective cognitive improvement on group level in cognitive asymptomatic patients. There is a discrepancy in objective and subjective cognitive complaints in this asymptomatic group which makes it challenging to identify patients that would benefit from discontinuing Efavirenz at beforehand.

TUPEB069

Different association pattern of each cognitive impairment with age and time of infection in HIV-infected patients

K. Komatsu[1], E. Kinai[1], M. Sakamoto[2], T. Taniguchi[3], A. Nakao[4], T. Sakata[5], A. Iizuka[5], T. Koyama[6], T. Ogata[7], A. Inui[8], S. Oka[1], for the HIV-Associated Neurocognitive Disorders in Japanese (J-HAND) Study Group
[1]National Center for Global Health and Medicine, AIDS Clinical Center, Tokyo, Japan, [2]Center for Comprehensive Community Medicine, Saga University, Saga, Japan, [3]Chiba University Hospital, Division of Infectious Diseases, Chiba, Japan, [4]Ehime University, Department of Hematology, Toon, Japan, [5]National Hospital Organization Fukuyama Medical Center, Fukuyama, Japan, [6]Kagoshima University Hospital, Kagoshima, Japan, [7]Kumamoto University Hospital, Kumamoto, Japan, [8]Juntendo University Faculty of Medicine, Department of General Medicine, Tokyo, Japan

Background: Despite a number of epidemiologic reports of HIV-associated neurocognitive disorders (HAND), detailed clinical characteristics, especially when and who can have worsening in each different cognitive function, and what function can be improved by antiretroviral therapy (ART), are still unknown.

Methods: In a Japanese nationwide multicenter study of 17 facilities with 1,399 HIV-infected patients
(J-HAND study), 728 participants completed 14 neuropsychological (NP) tests; Verbal Fluency (VF; category and letter), Digit Span (DS; forward and backward), Trail Making Test (TMT) A-B, Rey-Osterrieth Complex Figure Test (ROCFT; copy, immediate and delayed recall), Story Memory Test (SMT; immediate and delayed recall), Digit Symbol Subset (DSS), Grooved Pegboard (GP; dominant and non-dominant).

Results: In visuospatial and motor function, the prevalence of lower score (declined one or more standard deviation) significantly increased along age and time since diagnosis (p< 0.001 and < 0.001 in all three ROCFT and p=0.017 and 0.024 in GP (dominant), respectively) despite well-suppression of viral-load. Meanwhile, in VF letter, it decreased along age and time since diagnosis (p=0.001 and 0.005, respectively). Also in multivariate analysis, older age was associated with lower score in all three ROCFT and GP dominant [odds ratio (OR) [95% confidence interval (CI)] 1.801 (1.217-2.664), 2.402 (1.366-3.055), 2.691 (1.720-4.211), and 2.302 (1.145-4.628), respectively], and longer time since diagnosis was associated with lower score in ROCFT (delayed recall) (OR 1.224, 95%CI 1.045-1.434). In VF letter, older age and longer time since diagnosis were associated with better score [OR (95%CI) 0.449 (0.234-0.861) and 0.831 (0.692-0.997)]. In DSS and TMT-A, longer time since diagnosis were associated with better score [OR (95%CI): 0.808 (0.670-0.973) and 0.795 (0.665-0.949), respectively]. ART was significantly associated with better score in all NP tests.

Conclusions: Older patients in the late stage of HIV infection have higher risk of visuospatial and motor impairment despite ART. Meanwhile, younger patients in early stage of infection are more likely to have verbal impairment, which can be resolved by ART. Based on these findings, concise evaluation and appropriate supports can be established in accordance to individual background.

TUPEB070

Brain metabolic markers in HIV-infected individuals with or without antiretroviral therapy by magnetic resonance spectroscopy

J. Tanuma[1], T. Iida[1], M. Morooka[2], N. Arai[3], K. Kubota[2,4], S. Oka[1], Y. Ishizaka[5], M. Shimura[5]
[1]National Center for Global Health and Medicine, AIDS Clinical Center, Tokyo, Japan, [2]National Center for Global Health and Medicine, Department of Radiology, Tokyo, Japan, [3]National Center for Global Health and Medicine, Department of Neurology, Tokyo, Japan, [4]Southern TOHOKU General Hospital, Department of Radiology, Fukushima, Japan, [5]National Center for Global Health and Medicine, Department of Intractable Diseases, Tokyo, Japan

Background: HIV-associated neurocognitive disorder (HAND) has been a persistent concern even in the setting of suppressive antiretroviral therapy (ART). However, pathophysiology of HAND has not been well

understood. We aim to investigate brain metabolic markers in HIV-infected individuals with or without ART compared to those in non-HIV infected individuals with magnetic resonance spectroscopy (MRS).
Methods: From April 2013 through March 2015, 59 adult HIV-infected individuals including 37 with ART and 22 without ART and 24 age-matched healthy volunteers underwent MR imaging and single voxel ^{1}H-MR spectroscopy at 3.0 tesla to obtain ratios of N-acetylaspartate (NAA), choline (Cho), myo-inositol (MI) and lactate (Lac) to creatine (Cr) in left frontal white matter (FWM), parietal white matter (PWM), and hippocampus. The effect of ART central nervous penetration (CPE) score on those ratios was also studied. All participants were evaluated for cognitive function with a standard neurologic examination and a 70-minute battery of neuropsychological tests based on the Frascati criteria. Kruskal-Wallis test was used to compare brain metabolic markers between the groups.
Results: No significant difference was observed in ratios of NAA/Cr, Cho/Cr, MI/Cr between the groups in FWM, PWM and hippocampus. In contrast, Lac/Cr ratio in FWM was significantly higher in HIV-infected individuals not receiving ART than in HIV-infected individuals receiving ART and HIV-uninfected individuals (mean +/- SD, 0.35 +/- 0.25 in HIV-negative, 0.49 +/-0.28 in HIV-positive with ART, 0.65 +/- 0.55 in HIV-positive without ART, p=0.047). Among HIV-infected individuals, 10 in 37 with ART and 3 in 22 without ART were diagnosed as asymptomatic neurocognitive impairment (ANI), which did not correlate with any brain metabolite ratios. For those on ART, CPE scores were not associated with any brain metabolite ratios.
Conclusions: Lac/Cr ratio was the highest in the group of HIV-infected individuals without ART, whereas other metabolites were similar across the groups regardless of ANI diagnosis or CPE score.

TUPEB071

The effect of alcohol consumption on specific neuropsychological testing domains in patients enrolled in the Neurocognitive Assessment in the Metabolic and Aging COhort study (NAMACO)

K. Darling[1], N. Benghalem[1], I. Locatelli[1], I. Nadin[1], P. Brugger[2], K. Gutbrod[3], S. Frueh[4], R. Pignatti[5], U. Kunze[6], T. Lecompte[7], C. Hauser[3], B. Hasse[2], P. Tarr[8], M. Stoeckle[6], C. Di Benedetto[5], P. Schmid[4], R. Du Pasquier[1], M. Cavassini[1]
[1]Lausanne University Hospital, Lausanne, Switzerland, [2]Zurich University Hospital, Zurich, Switzerland, [3]Berne University Hospital, Berne, Switzerland, [4]St-Gallen University Hospital, St-Gallen, Switzerland, [5]Lugano University Hospital, Lugano, Switzerland, [6]Basel University Hospital, Basel, Switzerland, [7]Geneva University Hospital, Geneva, Switzerland, [8]Bruderholz Hospital, Bruderholz, Switzerland

Background: HIV-associated neurocognitive disorders (HANDs) are diagnosed based on neuropsychological (NP) testing and functional assessment. The effect of active or previous alcohol consumption on HANDs development is unknown. The aim of this study was to examine the effect of alcohol consumption on NP function among well-treated HIV-positive persons.
Methods: We analysed 981 patients aged >45 years old enrolled in the NAMACO (Neurocognitive Assessment in the Metabolic and Aging COhort) study. NAMACO is an ongoing, prospective, longitudinal, multicentre and multilingual study within the Swiss HIV Cohort Study (SHCS). NP testing was performed in five domains: motor skills, speed of information processing, attention/working memory, executive functions and verbal learning memory. Dichotomous and continuous outcomes for NP impairment were defined for each domain then analysed per domain and after summarising domains. Alcohol consumption was scored using a validated Alcohol Use Disorders Identification Test (AUDIT-C): consumption quantity and frequency, and occurrence/absence of binge drinking. Logistic and linear regression models were applied to estimate alcohol effect on, respectively, dichotomous and continuous NP impairment outcomes. All models were adjusted for socio-demographic data.
Results: Most included patients (mean age 54.5 years, 80% men, 92% Caucasian) had undetectable viral loads (96% with < 50 copies/ml; median nadir CD4 180). Binge drinking (4.2% of patients) significantly negatively impacted motor skills (OR 2.3, P=0.01), speed of information (OR 2.1, P=0.02) and overall NP function (OR 1.88, P=0.06). A significant U-shaped effect of AUDIT-C score was observed for motor skills and overall function, and a non-significant trend was observed for executive functions and speed of information (Figure 1). Continuous outcome models demonstrated a significant effect of increasing AUDIT-C score and binge drinking on executive and overall functions.
Conclusions: This is the first study to examine the effect of alcohol consumption on specific NP domains as well as on NP performance overall, using a validated score. We observe that the NP domains of motor skills and executive function are impaired with increased consumption while other domains are preserved. In assessing with HANDs, it may be possible to assess the contribution of alcohol by restricting NP analysis to domains we observe to be impaired.

TUPEB072

Higher prevalence of neurocognitive impairment among aging HIV-infected women despite lower comorbidities than men

A. Hiransuthikul[1], J. Samajarn[2], P. Vongsayan[2], N. Kijpaisalratana[2], W. Akarathanawat[2], A. Chutinet[2], S. Keadpudsa[1], T. Apornpong[1], S. Sakulrak[1], P. Chan[3], S. Gatechompol[1], W.M. Han[1], A. Sangarlangkarn[1], K. Ruxrungtham[1,4], A. Avihingsanon[1], HIV-NAT 006/HIV-NAT 207 Study Team
[1]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Chulalongkorn Stroke Center, King Chulalongkorn Memorial Hospital, Division of Neurology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]SEARCH, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [4]Faculty of Medicine, Chulalongkorn University, Department of Medicine, Bangkok, Thailand

Background: Neurocognitive impairment (NCI) is a major reason for poor quality of life and poor adherence among HIV-infected individuals. We assessed the prevalence and risk factors of NCI among aging HIV population. The association of subclinical atherosclerosis by common carotid intima-media thickness (cIMT) and NCI was also determined.
Methods: This was a cross sectional study of HIV-infected Thai individuals age ≥50 years who were followed in a prospective long term cohort at HIV-NAT, Thailand. Demographics, comorbidities, and cardiovascular risk factors were assessed. Cognitive performance was evaluated by the Thai version of the Montreal Cognitive Assessment (MoCA) with a cut-off of < 25/30 for diagnosis of NCI. Abnormal cIMT was defined as cIMT ≥0.9 mm or presence of carotid plaque.
Results: Among 357 participants (median [IQR] age of 54.4 [52.2-60.4] years, 37.5% female) enrolled, median CD4 was 614 (477-797) cells/µL, 97.2% had HIV RNA < 40 copies/mL, and the most common ART were TDF (84%) and efavirenz (58.3%). A total of 216 (60.5%) had NCI, and women had higher NCI prevalence than men (70.9% vs 54.3%, p=0.002). Women performed significantly worse than men in visuospatial/executive, naming, attention, language, abstraction, and orientation domains (p< 0.05). More women had education lower than bachelor degree (82.1% vs 61.0%, p< 0.001) and income < 300$/month (52.2% vs 31.8%, p< 0.001); whereas more men had HBV infection (25.1% vs 14.9%, p=0.02), HCV infection (13.1 vs 6%, p=0.03), class C CDC classification (20% vs 9.2%, p=0.007), diabetes mellitus (21.1% vs 9.7%, p=0.005), hypertension (51.1% vs 29.1%, p< 0.001), abnormal cIMT (6.4% vs 1.6%, p=0.042), and lower median CD4 cell counts (599 vs 675 cells/µL, p=0.01).
In multivariable regression analysis, women (adjusted odd ratio [aOR] 1.9; 95%CI 1.1-3.6, p=0.019), age ≥60 years (aOR 1.9; 95%CI 1.1-3.4, p=0.03), and education lower than bachelor degree (aOR 2.2; 95%CI 1.3-3.6, p=0.002) were associated with NCI. cIMT and HIV related factors were not associated with NCI.
Conclusions: In our aging HIV-infected cohort, women was independently associated with NCI despite lower NCI risk. More research is needed to understand the differences in the pathology, risk factors, and patient outcomes of NCI between HIV-infected men and women.

Depression and other psychiatric manifestations

TUPEB073

Association between changes in hazardous drinking and subsequent antiretroviral medication adherence, HIV viral control, and condomless sex

D. Satre[1,2], W. Leyden[2], C. Hare[3], S. Catz[4], M. Horberg[5], E. Williams[6], M. Silverberg[2]
[1]University of California, Psychiatry, San Francisco, United States, [2]Kaiser Permanente, Division of Research, Oakland, United States, [3]Kaiser Permanente, San Francisco, United States, [4]University of California, Davis, United States, [5]Kaiser Permanente Mid-Atlantic States, Rockville, United States, [6]University of Washington, Seattle, United States

Background: Previous studies of people with HIV (PWH) have found that hazardous drinking is common, and associated with condomless sex, worse antiretroviral (ART) adherence, and worse viral control. Here, we examined the association between changes in hazardous drinking and these outcomes in a sample of PWH.
Methods: Participants included 614 PWH from an HIV clinic in San Francisco, randomized to three alcohol interventions. The sample was 16% Hispanic, 10% Black, 63% White, 7% other; 97% male; with mean age of 49 years. Data included follow-up interviews at 6, 12 and 24 months, with self-reported alcohol measures (any days drinking over 4/5 drinks for women/men respectively, in the prior 30 days), any condomless sex with a negative/unknown status partner, ART adherence >95%; and HIV viral suppression (HIV RNA < 75/mL). The primary exposure was change in alcohol use compared with baseline, categorized as an increase (any, and ≥3 days), decrease (any, and ≥3 days) or no change (reference). Odds ratios were obtained using GEE methods that accounted for repeated observations, adjusting for demographics.
Results: At 24 months, 40% reported a decrease in hazardous drinking frequency (20% ≥3 days), 9% reported an increase (4% ≥3 days), and 51% reported no change. In adjusted models, any increase in hazardous drinking was associated with lower rates of ART adherence >95% (OR = 0.67, 95% CI = 0.45, 0.99, p = 0.046), and greater odds of condomless sex (OR = 1.41, 95% CI = 1.0, 2.0, p = 0.053). Those who reported a greater decrease in drinking (reduced by ≥3 days), had better HIV viral suppression in bivariate analysis (p < 0.03), which was not significant in the adjusted analysis (OR = 0.65, 95% CI = 0.39, 1.11, p = 0.112).
Conclusions: In this sample of PWH enrolled in a primary-care based alcohol intervention study, an increase in hazardous drinking was associated with worse ART adherence and higher prevalence of sexual HIV transmission risk behavior. Increased hazardous drinking should be an indicator to providers that PWH are at risk for other problems such as worse HIV treatment adherence and condomless sex.

TUPEB074

Prevalence of depression and suicidal ideation among people living with hiv/aids in a tertiary health facility in Ibadan, Nigeria

S.O. Ngene[1,2], F.A. Adenuga[3], B. Olusola Margaret[4], E. Godwin Joseph[5]
[1]One Love Foundation Support Group for PLWHA, Ibadan, Nigeria, [2]College of Medicine, University of Ibadan, Department of Epidemiology and Medical Statistics, Ibadan, Nigeria, [3]University of Ibadan, Department of Obstetrics and Gynaecology, Ibadan, Nigeria, [4]College of Medicine, University of Ibadan, Institute of Infectious Disease, Ibadan, Nigeria, [5]College of Medicine, University of Ibadan, Department of Chemical Pathology, Ibadan, Nigeria

Background: Depression and suicidal ideation is a common public health problem among people living HIV/AIDS, triggering profound detrimental impacts on quality of life, treatment adherence, disease progression, and mortality. There is dearth of information about these psychiatric co-morbidities particularly in the developing country context. This study thus investigated the prevalence of depression and suicidal ideation among people living with HIV/AIDS (PLWHA) in Ibadan, Nigeria.
Methods: A cross sectional study was conducted among 141 respondents that were selected using a systematic sampling technique. Data on socio-demographic characteristics, depression and reported attempt to commit suicide were collected using a pretested interviewer-administered questionnaire. The prevalence of depression was assessed using a 10-item Edinburgh depression scale. Descriptive statistics was used to describe the general characteristics of the sample while predictors of depression were determined using the Chi-Square test and binary logistic regression. All analyses were performed at a statistical significance level of 0.05.
Results: The mean age of the respondents was 35.0 years (standard deviation = 11.0). One half of the respondents were female. About 63.8% of the respondents were currently married. About 68.8% of the respondents were had at least two living children. Most respondents were depressed, about 6.4 % had ever attempted committing suicide. Gender (AOR = 3.72, 95% CI, 1.67 - 8.29), Ages 25-34 years (AOR = 4.50, 95% CI, 1.48 - 13.69), 35-44 years (AOR = 6.04, 95% CI, 2.01 - 18.14) and ≥ 45 years (AOR = 3.68, 95% CI, 1.05 - 12.93) independently predicted depression.
Conclusions: The finding of this study indicated that depression and suicidal ideation were common among PLWHA. These results identify potential targets to mitigate risk through establishment of psychological counselling services and promoting greater adaptation to living with HIV/AIDS.

TUPEB075

Results of anxiety and depression screening as part of routine HIV care

M.J. Kleene, E. van Gorsel, J. Lijmer, D. Ait Moha, K. Brinkman, I. Schouten, N. van der Meche, G. van den Berk
OLVG, Internal Medicine, Amsterdam, Netherlands

Background: Anxiety and depression are prevalent comorbidities in HIV. In the Netherlands, suicide is an important cause of death among HIV patients. To enhance the quality of HIV care, we started screening routinely for depression and / or anxiety as part of a regular HIV quality of life questionnaire. Here we report the preliminary results.
Methods: Anxiety and depression were measured using the 14 items of the Hospital Anxiety and Depression Scale (HADS) with a cut-off score of 15 to identify people with a potential disorder. Participants were asked to complete the HADS by rating how they have felt on the basis of symptoms that had occurred in the week before their consultation.
Results: From November 2016 until December 2017, 1091 individuals participated. 1032 (94.6 %) were male, median age was 50.9 yrs;(range 20-81). HADS score was > 15 in 298 /1091 of cases (27.3 %) ,12-15 in 128 /1091 (11. 7%) and < 12 in 665 /1091 (60.9%) patients.
Psychiatric evaluation was performed in 52 /298 patients (17.7%), resulting in a psychiatric diagnosis (figure 1) in 48 /52 (90.6%) patients. Already 49 /298 (patients (16.4%) reported that they received psychosocial care and 110 /298 (patients (36.9%)) considered that a referral not necessary after discussion and with 83 / 298 patients (27.9%) the score was not discussed during the outpatient visits.
Conclusions: Regular assessment of mental health leads to earlier recognition of psychiatric disorders such as depression and an anxiety disorder which has proven to effectively prevent further deterioration . In 27.3% of cases, an elevated HADS score was observed, leading to a new psychiatric diagnosis in 48 patients, 4 patients did not receive a psychiatric diagnosis. In this case, it led to referral of 53 patients who otherwise wouldn't have been in psychiatric care. In most other cases it initiated a conversation about the patients mental health and overall health related quality of life.

TUPEB076

Higher prevalence of depression among aging HIV-positive compared to HIV-negative individuals

A. Hiransuthikul[1], S. Sakulrak[1], T. Apornpong[1], A. Avihingsanon[1], J. Jamthong[1], W.M. Han[1], S. Gatechompol[1], S. Kerr[1,2], A. Sangarlangkarn[1], K. Ruxrungtham[1,3], HIV-NAT 207 Study Team
[1]*HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand,* [2]*Kirby Institute, University of New South Wales, Sydney, Australia,* [3]*Chulalongkorn University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand*

Background: Depression is associated with HIV infection in many ways: a risk for HIV acquisition, a comorbidity of HIV infection, progression to AIDS, and one of the major causes contributing to poor quality of life among HIV-positive individuals. We sought to assess the prevalence and risk factors of depression among aging people living with HIV.
Methods: This was a cross sectional study of aging (≥50 years) HIV-positive and HIV-negative Thai individuals enrolled at HIV-NAT, Thailand. Depression was evaluated by a 15-item depression screening test developed and validated by the Department of Mental Health, Ministry of Public Health of Thailand. A cut-off of >6/15 indicates clinical depression. Multivariable logistic regression was used to determine factors associated with depression.
Results: Among 358 HIV-positive and 103 HIV-negative participants enrolled, with median (IQR) age of 54.8 (52.1-59.1) years and 37.5% were female, 105 (22.8%) had depression. Median (IQR) duration since ART initiation was 16.1 (12.5-19.1) years, 97.2% had HIV RNA < 50 copies/mL, and 58.4% had lipodystrophy, in the HIV-positive participants. Compared to HIV-negative participants, HIV-positive participants more frequently had income lower than 5000 THB (160 USD) per month (22.9% vs 12.6%, p=0.02), were unemployed (18.4% vs 8.7%, p=0.02), had hypertension (42.7% vs 26.2%, p=0.002), and had depression (25.4% vs 13.6%, p=.0.01).
More HIV-positive than HIV-negative participants had feelings of disappointment and self-blame (19.8% vs 6.8%, p=0.002), loss of self-confidence (21.2% vs 5.8%, p< 0.001), loss of interest (19.3% vs 6.8%, p=0.003), slower thinking (52.2% vs 40.8%, p=0.04), loss of appetite (15.9% vs 7.8%, p=0.04), and trouble falling asleep (37.7% vs 24.3%, p=0.01).
In multivariable models, HIV-positive status (adjusted odd ratio [aOR] 1.99; 95%CI 1.07-3.7, p=0.03) and income less than 5000 THB ($160) per month (aOR 1.89; 95%CI 1.14-3.13, p=0.01) were associated with depression. Among HIV-positive individuals, history of exposure to stavudine was associated with depression (aOR 1.88; 95%CI 1.02-3.45, p=0.04). Lipodystrophy was not associated with depression in HIV-positive individuals (p=0.5).
Conclusions: Depression is not uncommon among aging HIV-positive Thai individuals. HIV-positive status, low income and a history of stavudine use were independently associated with depression.

TUPEB077

Association between access to public distribution system, food security and depression among female sex workers in India

S.K. Patel[1], B. Mahapatra[1], M. Battala[1], Y. Atmavilas[2]
[1]*Population Council, HIV and AIDS Program, New Delhi, India,* [2]*Bill and Melinda Gates Foundation, New Delhi, India*

Background: Food security is one of the important contributing factors among female sex workers (FSWs) to engage in risky sexual behaviors and mental health problems in developing countries. However, studies exploring the relationship between food security and mental health among FSWs in India are limited despite having potential program and policy implications. This study examines the prevalence of depression, and its association with FSW's access to public distribution system (PDS) and their food security in India.
Methods: The study draws data from a large cross-sectional survey conducted in Nov-Dec 2017 among 3589 FSWs across five states of India. Besides collecting information on the FSWs' background characteristics, other information were also collected such as food security, access to PDS in the past 12 months, and depression was assessed using CESD-R10 scale. Descriptive statistics, frequency, bivariate and multivariate logistic regressions were used for analysis.
Results: More than half of the FSWs (52%) were found to have depression in the past 12 months. FSWs from Tamil Nadu state experienced higher depression (66%) compared to other states. At the same time, approximately two-fifths of FSWs reported not having food security (44%) and not accessing PDS (41%). FSWs who did have not have access to PDS (56% vs. 49%, AOR: 1.2, 95% CI: 1.1-1.4) and reported of food insecurity (68% vs. 39%, AOR: 3.2, 95% CI: 2.7-3.6) were more likely to be depressed than others. FSWs who belonged to the below poverty line category were more than two times higher likely to be depressed than their counter parts.
Conclusions: The study highlighted that depression is significantly associated with not having access to PDS and food insecurity among FSWs. The current HIV prevention activities in India require an integrated program approach to focus on addressing the mental health and social protection issues. To support this, the PDS should be strengthen among the FSWs as it has been one of the most important instrument of ensuring food security in India. To support this, interventions and research-based evidence will be highly needed to ensure that mental health issues are properly addressed among high-risk groups.

TUPEB078

Prevalence and treatment of insomnia in persons with HIV well engaged in medical care

S. Oster, P. Barbosa, S. Prieto, P. Bloom, D. Fierer, J. Weiss
Icahn School of Medicine at Mount Sinai, Medicine, New York, United States

Background: Studies have shown a higher prevalence for rates of insomnia in persons with HIV infection than in the general population. High rates of comorbid psychiatric diagnosis in persons with HIV infection contribute to insomnia symptomatology. Effectively treating insomnia is important for increasing quality of life within this patient population.
Methods: This is an analysis of baseline data from a larger study of the effects of Mindfulness-based Stress Reduction on chronic inflammation in HIV-infected adults 45 years and older with virologic suppression. The participants were categorized as either positive for insomnia (I-POS) or negative for insomnia (I-NEG) at baseline by review of chart diagnosis of insomnia and/or medication prescribed for insomnia. I-NEG and I-POS subjects were compared at baseline on self-report measures of depression (Beck Depression Inventory-II; BDI), anxiety (PROMIS), and fatigue (PROMIS).
Results: 84 subjects were recruited from HIV practices at Mount Sinai Health System. The subjects had a mean age of 58.2 years (SD=6.7) and were predominantly male (56%), and members of ethnic minority groups (57.1% black, non-Hispanic; 33.3% Hispanic). They had a mean CD4+ count of 620.7 cells/mm^3 (SD=333.0) and 71.4% had a comorbid psychiatric diagnosis. Forty-three of the 84 patients (51.2%) had insomnia (I-POS). The I-POS and I-NEG groups did not differ significantly on baseline characteristics other than comorbid psychiatric diagnosis being higher in I-POS subjects (81.4%) than in I-NEG subjects (61.1%) [p=0.038]. Being on an antiretroviral regimen containing efavirenz (n=7) was not related to a diagnosis of insomnia. There were no significant differences in baseline depression, fatigue, or anxiety scores between the I-POS group (means = 15.6, 22.3, 19.9 respectively) and the I-NEG group (means = 14.9, 20.1, 18.1). Less than half (46.5%) of the I-POS participants were prescribed medication specifically to treat insomnia.
Conclusions: Older adults with HIV infection who are engaged in medical treatment and adherent to antiviral therapy with virologic suppression still report a high prevalence of insomnia. Comorbid psychiatric diagnosis is related to the prevalence of insomnia. Further research into additional treatment for insomnia, particularly non-pharmacologic (e.g., mindfulness based interventions and cognitive behavioral therapy for insomnia [CBT-I]) is warranted in persons aging with HIV infection.

TUPEB079

Comparison of depression and anxiety between HIV-positive and HIV-negative people

F. Lampe[1], A. Miners[2], N. Kreif[3], A. Miltz[1], A. Phillips[1], J. Sewell[1], L. Sherr[1], J. Anderson[4], R. Gilson[1], R. O'Connell[5], A. Clarke[6], M. Johnson[7], E. Wilkins[8], S. Collins[9], J. Elford[10], A. Speakman[1], A. Rodger[1], for the ASTRA and AURAH Study Groups
[1]University College London, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]University of York, York, United Kingdom, [4]Homerton University Hospital NHS Foundation Trust, London, United Kingdom, [5]Barts Health NHS Trust, London, United Kingdom, [6]Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom, [7]Royal Free London NHS Foundation Trust, London, United Kingdom, [8]Pennine Acute Hospitals NHS Trust, Manchester, United Kingdom, [9]HIV i-Base, London, United Kingdom, [10]City University London, London, United Kingdom

Background: People with HIV experience a high burden of mental health problems, but the extent to which this is due to HIV specifically is unclear. We compared the prevalence of depression and anxiety between people with HIV and a matched 'at risk' HIV-negative group.
Methods: HIV-negative individuals in the AURAH study, recruited from UK GUM clinics (2013-14) were matched (with replacement) to HIV-positive individuals in the ASTRA study, recruited from UK HIV-outpatients (2011-12). Individuals aged 30-69 years were included. Matching variables were: gender/sexual orientation; age; ethnicity; education level. Depressive symptoms [PHQ-9 score≥10/27], anxiety symptoms [GAD-7 score≥10/21], and depression overall [subject report of current medical or other therapy for depression, and/or major or other depressive disorder on PHQ-9], were compared between HIV-positive and HIV-negative groups, using logistic generalised estimating equations, adjusted for matching variables, accounting for repeated observations. The HIV-positive group was assessed overall, and split by: (i) ART/VL status; (ii) time since HIV diagnosis.
Results: 2699 HIV-positive and 759 unique HIV-negative individuals (2699 matches with replacement) were included; mean age 45 years; 73% MSM; 16% women; 17% Black African ethnicity; 44% university education. Prevalences for HIV-positive versus HIV-negative were: 26.5% vs 11.5% for depressive symptoms [adjusted odds ratio, aOR(95%CI): 3.2(2.4,4.3)]; 21.2% vs 10.9% for anxiety symptoms [2.7(2.0,3.6)]; 34.5% vs 16.3% for depression overall [2.6(2.0,3.3)]. For each measure, odd ratios for HIV-positive versus HIV-negative were elevated across all ART/VL categories, and increased steadily with longer time since HIV diagnosis. For example, for depression overall, compared to HIV-negative, aOR were 2.5(1.9,3.2) for on ART with VL≤50c/mL, 3.6(2.6,5.1) for on ART with VL>50c/mL and 2.6(1.9,3.6) for not on ART, and 1.6(1.1,1.2), 2.2(1.6,3.0), 2.4(1.8,3.2), 2.9(2.2,3.9), 3.3(2.4,4.4) and 4.1(2.9,5.8) for time since HIV diagnosis < 2, 2-5, 5-10, 10-15, 15-20 and ≥20 years respectively.
Conclusions: These results give further evidence that living with HIV has a considerable adverse impact on mental health. The effect was evident among those recently diagnosed, but longer time since diagnosis appears to be a crucial additional factor, which may reflect poorer HIV prognosis in earlier years and/or psychological, socio-economic or biological effects of ageing with HIV.

Malignancies (AIDS and non-AIDS)

TUPEB080

Burden and characteristics of cancer in an HIV cohort at Newlands Clinic, Zimbabwe: A cross sectional descriptive study

S. Bote[1], T. Shamu[2], C. Chimbetete[1,3], M. Wellington[3]
[1]Newlands Clinic, HIV Care, Harare, Zimbabwe, [2]Newlands Clinic, Lab Services, Harare, Zimbabwe, [3]Newlands Clinic, Medical, Harare, Zimbabwe

Background: HIV- infected persons have increased risk of AIDS-defining (ADC) and non-AIDS defining cancer (NADC). However, the burden of cancer has not been documented in Zimbabwe. Thus, we described the burden, characteristics and outcomes of cancer in an HIV cohort in Zimbabwe.
Methods: Data from all cancer cases diagnosed (histologically) and recorded at Newlands Clinic between February 2004 to 30 October 2017 were abstracted. CD4 counts, viral loads, WHO stage, antiretroviral therapy regimen (ART) and outcomes were analysed using SPSS and presented as frequencies, percentages, medians and interquartile ranges (IQR).
Results: A total of 8589 patients were seen during the study period and 185 cancers were recorded. These were presented (illustrated in table 1) according to the following year bands (year of diagnosis): up to 2004 (pre-ART era), 2005-2010 (early ART era) and 2011-2017 (post-ART era).
In pre-ART era (up to 2004), 11 cases were diagnosed, median age was 34 (IQR19-39) years; 6/11 were females and 10/11 were in WHO 4. The median CD4 count was 158 (IQR 23-317) cells/mm^3 and 10/11 were ART naïve. ADCs; Kaposi's sarcoma (KS) was diagnosed in 72.7% (n=8), and Non-Hodgkin's lymphoma (NHL) in 18.2% (n=2). There was 1/11 NADC.
Between 2005 and 2010, 40 cases were diagnosed, 60.0% (n=24) females and median age 37 (IQR 32-44) years. 50% were ART naïve and 92.5% (n=37) were in WHO 3 or 4. There were 80% (n=32) ADCs and 20% (n=8) NADCs.
Post-ART era (2011-2017); 134 cases were recorded; median age 41 (IQR 35-49) years and 66.4% (n=89) females. The median CD4 count was 223 (IQR 116-456) cells/mm^3 and 63.2% (n=84) were WHO 3 or 4. The majority were on ART (79.1%, n=106). ADCs comprised 68.7% while NADCs were 31.3% (n=41).
At the time of analysis, 38.4% (n=71) had died and 93.4% (n=67) of these were directly related to cancer.
Conclusions: KS prevalence decreased in the post ART era while other ADCs (NHL and cervical cancer) and NADCs increased over time. Cancer related mortality was high. Active surveillance of cancer with early detection and treatment is recommended at all stages of HIV infection.

Cancer Type	Pre ART era (Up to 31 December 2004)	Early ART era (1 January 2005 - 31 December 2010)	Post ART era with increased cancer screening(1 January 2011-31 October 2017
Total Cancer Cases	11	40	134
AIDS-Defining Cancer (n,%)	10 (90.)	32 (80.0)	92 (68.6)
Kaposi´s Sarcoma	8 (72.7)	25 (62.5)	11 (11.9)

TUPEB081

The impact of HIV on hepatocellular cancer survival in Nigeria

E. Okeke[1], M. Davwar Pantong[1], B. Mullen[2], M. Duguru[1], O. Agbaji[1], A. Sagay[1], R. Murphy[2], C. Hawkins[2]
[1]Jos University Teaching Hospital, Jos, Nigeria, [2]Northwestern University, Feinberg School of Medicine, Chicago, United States

Background: Hepatocellular carcinoma (HCC) is an increasing cause of mortality in HIV-infected patients. Despite the high prevalence of both HIV and HCC in Nigeria, the impact of HIV on HCC presentation and survival in this region is unknown. The aims of this study were to compare host and tumor characteristics between HCC patients with and without HIV and examine the impact of HIV on survival.

Methods: This prospective observational study was conducted at the Jos University Teaching Hospital, Jos, Nigeria. Adults (>18yrs) with a known HIV serostatus and diagnosis of HCC using AASLD criteria were enrolled between Sept-2015 and Sept-2017 and followed until Dec-2017. Demographic features, tumor characteristics, and survival were compared between HCC patients with and without HIV using Fisher's exact or chi-square tests. Survival curves were generated using Kaplan-Meier plots and compared using the log rank test.

Results: 101 patients (10 HIV-infected and 91 HIV-uninfected) were enrolled [male 72%; median age 48 (IQR 35-60)]. 60% HIV-infected patients were receiving ART; 90% had CD4 counts ≥ 200/mm³ at the time of HCC diagnosis and 25% had HIV RNA levels < 50 copies/mL. 70% HIV-infected and 56% HIV-uninfected were infected with chronic HBV (HBsAg+). Most patients (98%) had ≥1 symptom of HCC at presentation. Alcohol use was reported in one-third of patients and median quantities consumed did not differ between HIV-infected and -uninfected patients. The duration of symptoms prior to HCC diagnosis was significantly shorter in HIV-infected vs. HIV-uninfected patients [93 (IQR 54-132) vs. 155 (93-248] days; p=0.02]. By the end of follow-up 10/10 (100%) HIV-infected and 97/101 (96%) HIV-uninfected patients had died. The probability of survival at three months was 22% and 48% in HIV-infected and -uninfected patients, respectively (p=0.02). Median time to death was significantly shorter in HIV -infected vs. -uninfected patients [23 (IQR 12-88) vs. 80 (IQR 26-177) days; p=0.04].

Conclusions: Extremely high rates of early mortality were observed in this relatively young cohort of Nigerian patients with HCC. HIV infection was associated with a faster disease course and significantly shorter survival. More aggressive HCC surveillance may be warranted in HIV-infected patients particularly if they are co-infected with chronic HBV.

TUPEB082

Characteristics of HIV positive Rwandan women testing positive for human papillomavirus (HPV) and visual inspection after acetic acid (VIA): Implications for cervical cancer prevention in resource limited settings

G. Murenzi[1], J.D. Sinayobye[1], T. Rurangwa[2], H.-Y. Kim[3], K. Anastos[4], P.E. Castle[5], A. Adedimeji[5]
[1]Rwanda Military Hospital, Research and Clinical Education Division, Kigali, Rwanda, [2]Rwanda Military Hospital, Obstetrics and Gynecology, Kigali, Rwanda, [3]Data Solutions, New York, United States, [4]Albert Einstein College of Medicine, Medicine, Epidemiology and Population Health, Bronx, United States, [5]Albert Einstein College of Medicine, Epidemiology and Population Health, Bronx, United States

Background: With expanded access to ARTs, HIV+ women in LMICs are living longer, but may have increased risk of invasive cervical cancer (ICC), the 2nd most common cause of cancer morbidity in LMIC women. While HPV vaccine is most effective in preventing ICC, generations of women already exposed to HPV will not benefit from vaccination. Thus, secondary prevention remains a necessary strategy to reduce incidence of ICC. Limited resources for prevention however require identifying optimal methods for screening, including understanding characteristics of women who are most at risk for ICC. This study describes the characteristics of women most at risk for HPV and VIA positivity after screening for ICC and cervical precancer.

Methods: We recruited 2478 HIV+ Rwandan women aged 30-54 years receiving care from selected health facilities located in Kigali. We evaluated screening tests (high risk HPV testing and VIA) traditional triage tests (HPV16/18/45 detection, VIA), and potential new biomarkers for triage (E6/E7, CINtec Plus [p16 and Ki-67 Dual Stain] of screen-positive women. All screen positive women undergo ascertainment to obtain unbiased estimates of sensitivity specificity, and positive and negative predictive value. We conducted preliminary descriptive statistics to highlight associations between socio-demographic characteristics that predict HPV and VIA positivity.

Results: Overall, 2478 women were enrolled of which 653 (26.4%) tested positive for HPV [HPV+] and 482 (19.5%) for VIA [VIA+]. Mean age was 39.5 for HPV[+] and 40.9 for VIA[+]. Majority of women were married, lived in Kigali and of low socioeconomic status. Age, marital status, age of sexual debut, age when had first child and use of oral contraceptives were significantly associated (p=< 0.0001; 95% CI) with HPV[+]. Significant association was found between being married, low socioeconomic status, contraceptive use and pre-menopausal status and VIA[+].

Conclusions: Understanding predisposing factors as well as characteristics of women most at risk for HPV and VIA could help inform the design of programs aimed at preventing ICC through early screening and detection using optimal strategies that maximize the use of scarce resources in LMICs.

Early detection of anal cancer in men who have sex with men (MSM) living with HIV by incorporating digital anorectal examinations (DARE) into routine HIV care: A prospective cohort study

J.J. Ong[1,2], S. Walker[2], A. Grulich[3], J. Hoy[2,4], T. Read[2,5], C. Bradshaw[2,5], S. Garland[6], R. Hillman[7], D. Templeton[3], J. Hocking[8], B. Eu[9], B. Tee[10], E. Chow[2,5], C. Fairley[2,5]
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Monash University, Melbourne, Australia, [3]Kirby Institute, University of New South Wales, Sydney, Australia, [4]The Alfred Hospital, Melbourne, Australia, [5]Melbourne Sexual Health Centre, Melbourne, Australia, [6]University of Melbourne, Department of Obstetrics and Gynaecology, Melbourne, Australia, [7]University of Sydney, Westmead Clinical School, Sydney, Australia, [8]University of Melbourne, Melbourne, Australia, [9]Prahran Market Clinic, Prahran, Australia, [10]Victorian AIDS Council, Melbourne, Australia

Background: MSM living with HIV have the highest risk for anal cancer. The majority of anal cancers are detected in late stages where morbidity and mortality are high. We provide 'real-world' data on the feasibility of incorporating regular DARE into routine HIV care for MSM living with HIV. We monitored the referral rate to colorectal specialists, which may be a driver of cost.

Methods: In 2014, we recruited 327 MSM living with HIV, aged 35 and above, from Melbourne, Australia. Men were recruited from one major sexual health centre(n=187), two high HIV caseload general practices (n=118) and one tertiary hospital (n=22). Men were followed for two years and DARE was recommended at baseline, year 1 and year 2. Data were collected regarding patient and physician experience, and health service use. An ordered logit model was used to assess the relationship between sociodemographic factors and the number of DAREs received (1, 2 or 3). Potential confounding factors such as the site of recruitment, income level and HIV duration were adjusted for.

Results: Men had a mean age of 51 (SD±9) years, were Australian born (69%), current smokers (32%), and had a mean CD4 of 630 (SD±265) cells per mm³, with no significant differences between clinical sites. Overall, 232(71%) men received all three DAREs, 71(22%) received two DAREs, and 24(7%) only had one DARE. The referral rate to a colorectal surgeon was 3.8 referrals per 100 DAREs: lowest in the sexual health clinic (1.7/100 DARE), followed by GP clinics (5.6/100 DARE) and the tertiary hospital (13.2/100 DARE, P=0.01). One stage 1 anal cancer and eight anal intraepithelial lesions were detected. Receiving a greater number of DAREs was associated with: age >50 years(adjusted odds ratio(AOR)=1.98, 95%CI:1.10-3.55), ex-smoker(AOR=2.32, 95%CI:1.17-4.56), and current smoker (AOR=2.00, 95%CI:1.00-3.98).

[Figure 1 DARE diagnoses at baseline, year 1 and year 2 visits for men who have sex with men living with HIV, Australia.]

Conclusions: Integrating an early cancer detection program into routine HIV clinical care is feasible, particularly in settings where anal cytology and high-resolution anoscopy services are unavailable. Though referral rates to colorectal surgeons remained low over the two years, there was heterogeneity depending on site of recruitment. An education program to up-skill HIV physicians in early anal cancer detection could reduce the number of referrals.

Cardio-vascular disease

Undiagnosed heart disease in a cohort of Malawian HIV-infected adults on antiretroviral therapy

R. Hoffman[1], T. Canan[2], F. Chibwana[3], D. Kahn[1], J. Grotts[4], L. Longwe[3], Z. Boas[2], K. Gama[3], A. Moses[3], J. Currier[1], J. Currier[2], EQUIP Innovation for Health

[1]David Geffen School of Medicine at the University of California, Department of Medicine, Los Angeles, United States, [2]David Geffen School of Medicine at the University of California, Department of Cardiology, Los Angeles, United States, [3]Partners in Hope Medical Center, Lilongwe, Malawi, [4]University of California, Department of Biostatistics, Los Angeles, United States

Background: Antiretroviral therapy (ART) extends lifespan to near normal and has been associated with high rates of non-communicable diseases, particularly hypertension and heart disease. Limited data exist around rates of heart disease in stable patients on ART in sub-Saharan Africa.

Methods: Between June 2016 to October 2017, we performed blood pressure measurements, electrocardiograms (ECG), and echocardiograms on HIV-infected adults (≥18 years) who were on ART ≥12 months, and were attending routine clinic visits, to evaluate rates of hypertension and undiagnosed heart disease. Surveys were performed to collect sociodemographic and lifestyle information. Uni- and multivariate logistic regression was used to evaluate predictors of echocardiographically-confirmed heart disease.

Results: A total of 202 individuals were evaluated, median age 45 years, (IQR 39,52), 52% female, median duration on ART 6.8 years (IQR 4.6,8.8), 27% on medication for hypertension, and 7% of those with a viral load in the last year (5/67) with virologic failure (>1,000 copies/ml). Twenty-four percent of participants did not carry a diagnosis of hypertension but had an elevated systolic (≥140 mmHg) and/or diastolic (≥90mmHg) blood pressure at the clinic visit (measurement confirmed by a second clinician at the time of the visit). Only 2% of individuals were characterized as having a sedentary lifestyle. Two percent of the cohort reported smoking, and 17% reported alcohol intake (average of 4 drinks per week). One-quarter of individuals (n=50) had one or more abnormalities on echocardiogram. The most common findings were mild mitral, aortic, or tricuspid valve regurgitation (17%), left ventricular hypertrophy defined as septum or wall >1.2cm (10%), reduced left ventricular systolic function defined by ejection fraction < 50% (5%), and small pericardial effusion (5%). Predictors of an abnormal echocardiogram included older age, longer duration on ART, elevated blood pressure, abnormal ECG, and virologic failure (Table).

In multivariate analysis, older age (aOR:1.04, p=0.02), abnormal ECG (aOR:3.6, p=0.001), and virologic failure (aOR:27.7, p=0.003) remained significant.

Conclusions: Hypertension and undiagnosed heart disease were common in this cohort of HIV-infected individuals on ART in Malawi. ECG may be a simple screening tool to identify high-risk patients. Long-term follow-up is needed to determine whether mild abnormalities progress to clinically significant disease.

Variable	Unadjusted OR (95% CI)	P - value
Age (median 45, IQR 39-52)	1.05 (1.01-1.08)	0.005

*Echocardiograms were performed by local clinicians or radiology technicians and over-read by cardiologists. Limited echocardiograms were considered abnormal based on evaluation of ventricular size and function, atrial size, valvular morphology and function, presence of pericardial fluid, and inferior vena cava size and collapse.
**Electrocardiograms were read initially by local clinicians and over-read by cardiologists. Abnormal electrocardiogram was defined by abnormalities in any of the following: rate, rhythm, axis, intervals, morphology and/or ischemic changes.
†Viral load only included if a value was measured within 12 months of the clinic visit during which echocardiogram was performed (n=67)

[Associations between patient characteristics and abnormal echocardiogram in HIV-infected adults on ART in Malawi, n = 202]*

TUPEB085

Morbidity among HIV-positive people: A population-based study in 43,545 UK patients

P. McGettigan[1], M. Daskalopoulou[2], S. Denaxas[2], N. Matin[3]

[1]Queen Mary University of London, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Barts Health NHS Trust, HIV Medicine, London, United Kingdom

Background: Age-associated comorbidities are more prevalent amongst HIV-positive populations compared with general population groups but this has not been examined in the UK. We used linked electronic health records (EHRs) in England to compare prevalence of and risk factors for nine cardiovascular, respiratory, and renal co-morbidities, and multi-morbidity amongst HIV-diagnosed cases and non-HIV-diagnosed controls.

Methods: We constructed a nested case-control study using anonymised linked primary care and hospital EHR data and CALIBER tools.1 Amongst adult patients registered with one of 707 general practices in England between 01/1997 and 07/2016, we identified HIV-diagnosed cases by developing an EHR phenotyping algorithm using HIV diagnoses during the study period, and matched to non-HIV-diagnosed controls by five-year age groups and sex (1:4 ratio). Previously-validated case definitions identified patients with asthma, chronic obstructive pulmonary disease (COPD), type II diabetes, heart failure, hypertension, myocardial infarction, peripheral arterial disease, renal disease, and stroke.2 Multi-morbidity was examined as the presence of at least two co-morbidities. Conditional logistic regression was used to derive odds ratios (ORs) for the association of HIV diagnosis with prevalence of each co-morbidity.

Results: Among 43,545 individuals (38% female, mean age at matching 39 years), there were significant differences (p< 0.001) in morbidity risk factors between HIV-diagnosed cases (n=8,709) and controls (n=34,836) in terms of ethnicity (black African 28% vs 2% respectively), current smoking (28% vs 23%) and heavy alcohol use (10% vs 6%). (Table

1) HIV-diagnosed cases had significantly higher odds of prevalent diagnoses for hypertension, asthma, type II diabetes, renal disease, stroke, myocardial infarction, and of multi-morbidity compared with age and sex-matched controls. (Table) Heart failure, COPD, peripheral arterial disease, or unstable angina did not appear more prevalent amongst HIV-diagnosed cases.

Conclusions: This large UK-based study of HIV-associated morbidity in almost nine thousand HIV-diagnosed cases is the first to include general population controls and is unique in demonstrating a substantially higher burden of co-morbidity and of multi-morbidity amongst HIV-positive cases versus the controls.

Effects of Nef exosomes on bystander uninfected cells

M. Bukrinsky[1], B. Brichacek[1], D. Sviridov[2]
[1]George Washington University School of Medicine and Health Sciences, Microbiology, Immunology and Tropical Medicine, Washington, United States, [2]Baker Heart and Diabetes Research Institute, Melbourne, Australia

Background: Recent studies demonstrated that Nef is incorporated into extracellular vesicles (exosomes) produced by HIV-infected cells and that exosomal Nef has pathogenic activity against uninfected bystander cells. However, mechanisms of this activity have not been determined, limiting the search for therapeutic agents. The purpose of this study was to determine whether the effects of exosomal Nef mimic the effects of endogenously produced Nef.

Methods: Exosomes were purified by differential centrifugation from supernatants of Nef-transfected HEK293T cells. Exosomal RNA was assayed by RNAseq, and exosomal proteins - by mass spectrometry. Monocyte-derived macrophages (MDM) were differentiated for 6 days in the presence of M-CSF and treated with Nef exosomes for 48 h. ABCA1 expression was assayed by Western blot, cholesterol efflux - by release of radiolabeled cholesterol, and lipid rafts - using fluorescently labeled cholera toxin B subunit. HIV infection was analyzed by fusion assay, and cytokine release - by ELISA.

Results: Analysis of exosomes from Nef-transfected cells demonstrated the presence of Nef protein and mRNA and increased abundance (relative to exosomes from mock-transfected cells) of miRNAs regulating cholesterol metabolism, in particular hsa-miR-27a-3p. Exosomal Nef downregulated ABCA1, inhibited cholesterol efflux, and increased abundance of lipid rafts in MDM. MDM treated with Nef exosomes exhibited pro-inflammatory features producing increased amounts of IL-6 and TNF in response to LPS stimulation.

Conclusions: Nef exosomes released from HIV-infected cells suppress cholesterol efflux in macrophages and likely in other cells. This increases lipid raft abundance and promotes pro-inflammatory responses. Given that Nef is produced from infected cells even when virus production is fully blocked by anti-retroviral treatment, these findings may explain persistent inflammation observed in successfully treated HIV patients with undetectable HIV load.

TUPEB087

Is the risk of myocardial infarction in PLHIV associated with atazanavir or darunavir exposure?

D. Costagliola[1], V. Potard[1], S. Lang[2], N. de Castro[3], L. Cotte[4], X. Duval[5], C. Duvivier[6], S. Grabar[1,7], M. Mary-Krause[1], M. Partisani[8], S. Ronot-Bregigeon[9], A. Simon[10], P. Tattevin[11], L. Weiss[12], D. Zucman[13], C. Katlama[1,10], F. Raffi[14], F. Boccara[2], for the French Hospital Database on HIV (FHDH-ANRS CO4)
[1]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France, [2]AP-HP, Hôpital Saint-Antoine, Paris, France, [3]AP-HP, Hôpital Saint-Louis, Paris, France, [4]Hospices Civils de Lyon, Hôpital de la Croix-Rousse, Lyon, France, [5]AP-HP, Hôpital Bichat Claude Bernard, Paris, France, [6]AP-HP, Centre d'Infectiologie Necker-Pasteur, Paris, France, [7]AP-HP, Groupe Hospitalier Cochin Broca Hôtel-Dieu, Paris, France, [8]Hôpitaux Universitaires de Strasbourg, Strasbourg, France, [9]AP-HM, Hôpital Sainte Marguerite, Marseille, France, [10]AP-HP, Hôpital Pitié-Salpêtrière, Paris, France, [11]Hôpital Universitaire Pontchaillou, Rennes, France, [12]AP-HP, Hôpital Européen Georges Pompidou, Paris, France, [13]AP-HP, Hôpital Foch, Suresnes, France, [14]CHU de Nantes, Nantes, France

Background: The DAD study has reported an increased risk of cardiovascular diseases in PLHIV exposed to darunavir (DRV) but not to atazanavir (ATV). Our objective was to evaluate associations between exposure to ATV or DRV and the risk of myocardial infarction (MI) in a nested case-control study within FHDH-ANRS-CO4.

Methods: Cases were patients who had a first validated MI between 2006 and 2012, using the European Society of Cardiology definition. Up to 5 controls were selected at random with replacement among patients with no history of MI, followed at the time of MI diagnosis (index date) in the same clinical center, matched with the case for age (+/- 3 years) and sex. Conditional logistic regression models were used to adjust for potential confounders not considered to be on the causal pathway between ARV and MI (sub-Saharan origin, family history of premature coronary artery disease, hypertension, smoking, current cocaine or IV drug use, body mass index, viral load (VL), CD4 nadir and CD4/CD8 ratio) and for cumulative exposure to each antiretroviral drug (ARV).

Odds-ratio per 5 years	Atazanavir	Darunavir
Univariable analysis	1.32 (0.84-2.08)	1.14 (0.36-3.59)
Multivariable analysis adjusted for exposure to other ARVs	1.39 (0.84-2.29)	0.61 (0.16-2.36)
Multivariable analysis adjusted for exposure to other ARVs and potential confounders	1.54 (0.87-2.73)	0.51 (0.11-2.32)
Multivariable analysis adjusted for exposure to lopinavir, indinavir and abacavir	1.27 (0.80-2.03)	0.86 (0.27-2.75)
Multivariable analysis adjusted for exposure to lopinavir, indinavir and abacavir and potential confounders	1.29 (0.76-2.20)	0.79 (0.21-2.98)

[Risk of myocardial infarction according to exposure to ARV]

Results: A total of 408 validated MI cases and 1250 controls were included. At enrollment in FHDH, 81% of participants were ARV naïve. Cases were mainly male (88%) with a median age of 49 years. All traditional cardiovascular risk factors were more frequent in cases than in controls. At the index date, 69% of cases and 76% of controls had a VL< 50 copies/mL (p=0.0070), the CD4 nadir was lower (161 vs 185/mm³, p=0.0387) and the CD8 count higher (914 vs 837/mm³, p< 0.0001) in cases compared to controls, while no difference was observed for the current CD4 count

(498 vs 495/mm3, p=.3664). A total of 109 cases (27%) and 288 controls (23%) had been exposed to ATV and 41 (10%) cases and 107 (9%) controls to DRV. There was no significant association between exposure to ATV or DRV and the risk of MI (Table). Results were robust in sensitivity analyses.
Conclusions: In FHDH, exposures to ATV or to DRV were not significantly associated with the risk of myocardial infarction, adjusting for complete ARV history contrary to the analysis in DAD.

TUPEB088

Association between CD4 cell count and blood pressure and its variation with Body Mass Index categories in HIV-infected patients

C. Akem Dimala[1,2,3], B. Momo Kadia[4], B.-L. Kemah[3,5], M. Tindong[3,6], S.P. Choukem[3,7,8]
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Southend University Hospital, Essex, United Kingdom, [3]Health and Human Development (2HD) Research Network, Douala`, Cameroon, [4]Foumbot District Hospital, Foumbot, Cameroon, [5]Ashford and St Peter's Hospitals NHS, Department of Vascular Surgery, Surrey, United Kingdom, [6]Universite Libres Bruxelle, Department of Public Health, Brussels, Belgium, [7]Douala General Hospital, Department of Internal Medicine, Douala, Cameroon, [8]Faculty of Health Sciences, University of Buea, Department of Internal Medicine and Paediatrics, Buea, Cameroon

Background: There are increasing reports of an association between low CD4 cell count in HIV infected patients and hypertension through mechanisms of persistent immune activation and chronic inflammation. Although a raised body mass index (BMI) is a known risk factor for hypertension, its effect on the CD4 count-blood pressure association has still not been fully elucidated. The aim of this study was to establish whether an independent relationship exists between CD4 count and hypertension and if this relationship is modified or confounded by BMI.
Methods: A secondary data analysis of a cross-sectional study carried out at a referral hospital of the South West region of Cameroon was conducted. This study enrolled two hundred HIV/AIDS patients to whom a standardized questionnaire was administered and a physical examination done. Standard WHO definitions of hypertension and BMI categories were used. A linear regression model and the Chi-square test were used to test for associations between continuous and categorical variables respectively, and a logistic regression model was used to assess for the association between CD4 cell count and hypertension while controlling for confounders.
Results: No linear association was observed between the log CD4 cell count and both systolic (p = 0.200, r = 0.12) and diastolic blood pressures (p = 0.123, r = 0.14) respectively. Patients with CD4 cell count ≥350 cells/µl were three times more likely to have hypertension (OR: 3.07, 95% CI: 1.32 - 7.16, p = 0.006). After adjusting for BMI, patients with CD4 cell count ≥350 cells/µl were two and a half times more likely to have hypertension (AOR: 2.50, 95% CI: 1.05 - 5.93, p = 0.032) and there was no effect modification from BMI (test of homogeneity, p = 0.721). There was no independent relationship between CD4 count and hypertension after controlling for age, sex, family history of hypertension, BMI-defined overweight, HAART use and duration of HIV infection (AOR: 1.66, 95% CI: 0.48 - 5.71, p = 0.419).
Conclusions: This study did not identify any independent relationship between CD4 count and hypertension. Large prospective studies are therefore recommended to better explore this relationship between HIV-infection and CD4 cell count.

TUPEB089

Endothelial colony forming cell function is reduced and negatively associated with activated monocytes in HIV

S. Gupta[1], Z. Liu[2], E. Sims[3], M. Repass[3], L. Haneline[4], M. Yoder[4]
[1]Indiana University School of Medicine, Medicine/Infectious Diseases, Indianapolis, United States, [2]Indiana University School of Medicine, Biostatistics, Indianapolis, United States, [3]Indiana University School of Medicine, Medicine, Indianapolis, United States, [4]Indiana University School of Medicine, Pediatrics, Indianapolis, United States

Background: HIV infection is associated with a higher risk of cardiovascular disease, perhaps due to inflammation from higher levels of activated intermediate CD14+16+ monocytes. We previously found that the numbers of true endothelial progenitor cells, or endothelial colony forming cells (ECFC), were negatively associated with the numbers CD14+16+ monocytes in HIV-infected patients. We sought to extend these findings by assessing the effects of HIV and CD14+16+ monocytes on actual ECFC function to generate new blood vessels.
Methods: We prospectively obtained blood samples from 15 HIV-healthy volunteers, 8 HIV+/ART-naïve patients, and 15 HIV+/ART+ patients who were virologically-suppressed while receiving a standard TDF(or TAF)/FTC/INSTI regimen (Table). Using ANOVA, we compared the effects of plasma from these three groups on ECFC proliferative capacity function parameters (network area, cell area, network length, network branch points) using IncuCyte assays. We also performed Pearson correlations to identify associations between these ECFC functional parameters with CD14+16-, CD14+16+, and CD14dim16+ monocyte subsets from these same groups.
Results: ECFC proliferative capacity parameters were significantly worse in HIV+/ART- patients compared to HIV- controls and HIV+/ART+ patients (Table), even when adjusted for demographics, CD4, HIV-1 RNA, and classic CVD risk factors (smoking, BMI, lipids). Network length and branch points were also worse in HIV+/ART+ compared to HIV- controls. In the HIV+ patients, each ECFC proliferative capacity parameter was negatively correlated with proportions of CD14+16+ monocytes (-0.66< r< -0.58; all p< 0.05), with similar correlations in the individual HIV+/ART- and HIV+/ART+ groups; no correlations were found with the other monocyte subsets. No significant correlations between ECFC functional parameters and monocyte subsets were found in the HIV- group.

Characteristic	HIV- (n=15)	HIV+/ART- (n=8)	HIV+/ART+ (n=15)	P-value

CD4 cell count (SD)/µL	------	525.75 (220.27)	584.47 (323.73)	0.65
Network area (SD), mm/mm2	0.1118 (0.0372)	0.07612 (0.0312)	0.1067 (0.0467)	0.019
Cell area (SD), mm2/mm2	0.1947 (0.0340)	0.1443 (0.0226)	0.1869 (0.0515)	0.0008
Network length (SD), mm/mm2	2.6284 (0.4851)	1.7340 (0.4359)	2.3829 (0.5634)	<0.0001
Network branch points (SD), 1/mm2	7.2713 (2.2585)	3.2967 (1.5425)	5.7103 (2.8635)	<0.0001

[Table: Participant Characteristics and ECFC Proliferative Capacity Parameters]

Conclusions: The ability of ECFC to generate new blood networks were significantly impaired by plasma from untreated HIV and ART-treated HIV when compared to HIV-negative, healthy volunteers. These functional parameters were adversely associated specifically with activated, intermediate monocytes. These data extend our previous findings by demonstrating that HIV-related inflammation may impair vascular regenerative potential and thus may be a novel mechanism by which HIV, even when treated with modern ART, is associated with a higher risk of cardiovascular disease.

TUPEB090

Clinical characteristics and mortality outcomes of people Living with HIV (PLHIV) with Atrial Fibrillation in British Columbia, Canada

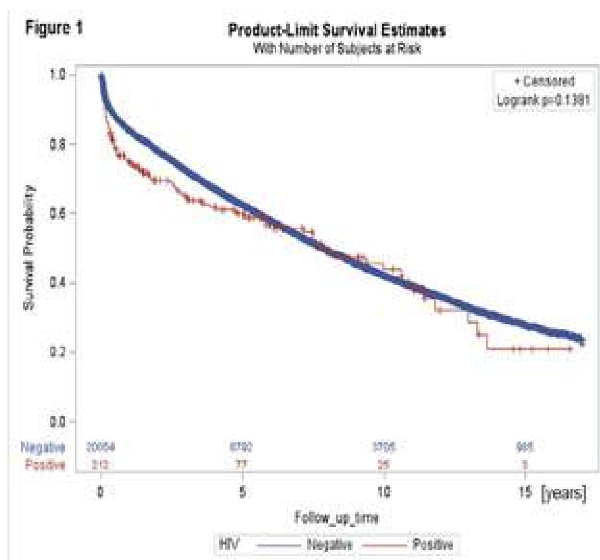
P. Vizcarra[1,2], K. Salters[2], O. Eyawo[2,3], M. Ye[2], M. Lu[2], M. Bennett[4,5], J.S. Gonzalez Montaner[2,6], R.S. Hogg[2,3], S. Guillemi[2]
[1]HIGA 'Gral San Martin', Infectious Disease, La Plata, Argentina, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [4]Vancouver Coastal Health, Vancouver, Canada, [5]University of British Columbia, Department of Medicine, Division of Cardiology, Vancouver, Canada, [6]University of British Columbia, Faculty of Medicine, Vancouver, Canada

Background: Previous research from our group demonstrated that PLHIV were diagnosed with Atrial Fibrillation (AF) a median of 10 years earlier than HIV-negative individuals (HIV-neg). This current analysis compares comorbidities, treatment-uptake and outcomes of PLHIV vs. HIV-neg individuals with AF diagnosis.

Methods: We used data from the Comparative Outcomes and Service Utilization Trends (COAST) study, a population-based cohort of PLHIV and a 10% general population sample aged ≥19 years, that utilizes clinical and administrative health data from the BC Centre for Excellence in HIV/AIDS and Population Data BC. International Classification of Diseases 9/10 codes were used to identify AF diagnosis, comorbidities, stroke and mortality outcomes, from 1996 to 2013. Bivariable analyses, comparing comorbidities, treatment-uptake and age-adjusted incidence rate estimates are presented.

	PLHIV (n=212)	HIV-negative individuals (n= 20,064)	p-values
Substance use disorder (with alcohol), N (%)	102 (48)	2,058 (10)	<0.001
Chronic kidney disease, N (%)	54 (25)	3,529 (18)	0.003
Hypertension, N (%)	123 (58)	14,925 (74)	<0.001
Ischemic heart disease, N (%)	95 (45)	12,058 (60)	<0.001
Heart failure, N (%)	95 (45)	10,218 (51)	0.076
Diabetes mellitus, N (%)	55 (26)	6,172 (31)	0.130
Chronic obstructive pulmonary disease, N (%)	56 (26)	4,961 (25)	0.570
Hyperthyroidism, N (%)	6 (3)	692 (3)	0.623
Anticoagulants utilization, N (%); [Warfarin]; [Direct oral anticoagulants]	96 (45); [90 (42)]; [12 (6)]	11,252 (56); [10,501 (52)]; [1,720 (9)]	0.002; [0.004]; [0.172]

[Table 1. Prevalence of AF-related conditions and anticoagulation uptake]



[Kaplan-Meier survival curve for atrial fibrillation in PLHIV and HIV-negative individuals]

Results: A total of 20,276 individuals diagnosed with AF were identified (PLHIV: 212, HIV-neg: 20,064). Age-adjusted incidence rate of AF was 4.8 per 1000 Person-Years (‰PY) in PLHIV and 4.0‰PY in HIV-neg, rate ratio (RR): 1.2 (95%CI: 0.9-1.4). Compared to HIV-neg population, PLHIV had higher prevalence of substance and alcohol use (48% vs. 10%, p< 0.001) and chronic kidney disease (25% vs. 18%, p=0.003) while HIV-neg had more hypertension (74% vs. 58%, p< 0.001) and ischemic heart disease (60% vs. 45%, p< 0.001). PLHIV with AF received less oral anticoagulation (45% vs. 56%, p=0.002), warfarin being the main agent (42% vs. 52%, p=0.004) (Table 1).

The age-adjusted rate for stroke was significantly higher in PLHIV [48.5 per 100 Person-Years (%PY); 95%CI: 44.2-52.8] vs. 12.9%PY (95%CI: 12.5-13.4) in HIV-neg, RR: 3.7 (95%CI: 3.4-4).

The age-adjusted rate for all-cause mortality was 9.5%PY (95%CI: 7.3-11.7) in PLHIV vs. 3.5%PY (95%CI: 3.3-3.6) in HIV-neg (RR: 2.7; 95%CI: 2.1-3.4). The highest RR was observed among men aged 19-49 years (RR: 6.9; 95%CI: 3.5-13.6). Figure 1 shows survival estimates for both populations.

Conclusions: PLHIV had less traditional underlying conditions for AF and oral anticoagulants utilization compared to HIV-neg. Incidence of stroke and mortality rates were higher in PLHIV. The latter was particularly higher among younger men living with HIV. This finding illustrates the need to consider AF diagnosis and treatment at an earlier age in PLHIV.

TUPEB091

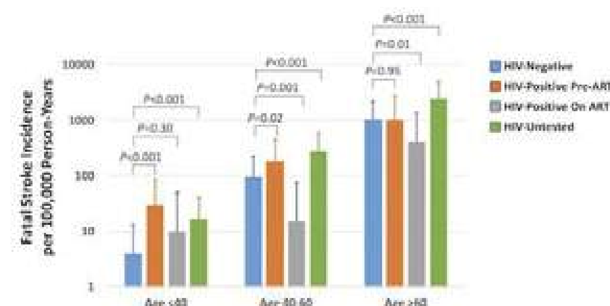
HIV infection, antiretroviral therapy and stroke mortality in South Africa: A population-based cohort study

M. Siedner[1], K. Herbst[2], J. Manne-Goehler[3], A. Abdallah[4], A. Vandormael[5], D. Pillay[6], F. Tanser[6], T. Barnighausen[6]
[1]Harvard Medical School, Boston, United States, [2]Africa Health Research Institute, Mtubatuba, South Africa, [3]Harvard School of Public Health, Boston, United States, [4]Mbarara University of Science and Technology, Mbarara, Uganda, [5]University of KwaZulu-Natal, Durban, South Africa, [6]Africa Health Research Institute, Durban, South Africa

Background: HIV infection, particularly with advanced and untreated disease, is associated with increased risk of stroke in resource-rich settings. However, less is known about the contributions of HIV infection, or its treatment, on stroke in sub-Saharan Africa, where nearly 70% of the world's population living with HIV reside.

Methods: We conducted a population cohort study in which residents over 15 years of age in the rural uMkhanyakude District of Northern KwaZulu-Natal were observed from 2004-2016. Individuals were offered HIV testing annually and deaths were investigated with verbal autopsy. Our primary outcome of interest was fatal stroke, as determined by the immediate or underlying cause of death at verbal autopsy (GBD code 108 or VA code 04.02). Our primary explanatory variable of interest was a time-varying indicator of HIV-status, defined as HIV-negative, HIV-positive, or HIV-unknown; and, separately, using a fourth category that divided HIV-positive individuals into those prior to and after antiretroviral therapy (ART) initiation, which was determined by clinical records. We estimated fatal stroke incidence rates and fit Cox proportional hazards models, adjusted for age and sex, with robust standard errors.

Results: A total of 99,101 individuals contributed 549,606 person-years of observation. We documented 1,084 fatal strokes, for an overall crude incidence of 197 strokes per 100,000 person-years (95% CI: 185-209). Whereas younger individuals with HIV not on ART had a significantly higher crude incidence of stroke than uninfected individuals, there was no difference between these groups in those over 60 years, as the rate of stroke in the general population increased (Figure).



[Fatal stroke incidence by HIV serostatus and age in rural South Africa]

	Adjusted Hazard Ratio	95%CI	P-value
Female	1.09	0.96 - 1.24	0.20
Age <40	Reference		
Age 40-60	15.01	10.95 - 20.58	<0.001
Age >60	136.46	102.66 - 181.39	<0.001
HIV negative	Reference		
HIV positive pre-ART	1.79	1.30 - 2.46	<0.001
HIV positive on ART	0.57	0.30 - 1.09	0.09
HIV positive (all)	1.31	0.97 - 1.77	0.08

[Cox proportional hazards model of predictors of fatal stroke]

In contrast, people over 40 with HIV who had initiated ART had a significantly lower incidence of fatal stroke than HIV-uninfected individuals. In hazard models adjusted for age and sex, the increased risk of stroke due to HIV infection appears entirely accounted for by HIV-positive participants not yet on ART.

Conclusions: Fatal stroke is common in rural South Africa. Although untreated HIV infection increases the incidence of fatal stroke in younger individuals, those on ART appears to have a decreased rate of stroke compared to the general population, particularly in older age groups.

TUPEB092

Within subject variability of HDL-cholesterol in HIV-infected patients

B. Roca[1], A. Mendoza[1], M. Roca[2], L. Castillo[1], C. González[1], L. Pastor[1]
[1]Hospital General Universitario de Castellón, Castellón de la Plana, Spain, [2]Hospital Provincial de Castellón, Castellón de la Plana, Spain

Background: Within-subject variability of cardiovascular risk factors may influence the development of cardiovascular disease. We aimed to improve knowledge on HDL-cholesterol variability and its clinical significance in HIV-infected patients, a population at high risk of cardiovascular disease.

Methods: This was:

1) A cross-sectional study to quantify variability of HDL-cholesterol between two consecutive visits and to determine factors associated with such variability, and

2) A retrospective-prospective cohort study to assess the possible relationship between HDL-cholesterol variability and the occurrence of cardiovascular events. Both studies were carried out in the same group of patients.

Results: A total of 307 patients were included, mean ± standard deviation of their age was 45.1 ± 8.5 years, and 225 of them (73.3 %) were male. The absolute difference (after squaring and root squaring) of serum HDL-cholesterol level between the first and the second visit was 12.1 ± 9.2 mg/dL. In 65 patients (21.2 %) the absolute value of the difference between both serum HDL-cholesterol level results was 20 mg/dL or higher. In a multivariable analysis, the number of cigarettes smoked per day showed a significant, negative, correlation with the absolute difference in serum HDL-cholesterol level between the two visits. Overall, during the retrospective and the prospective cohort parts of the study, a total of 26 patients (8.5 %) suffered a cardiovascular event; variability of HDL-cholesterol was similar in those patients than in those who did not suffer a cardiovascular event (P = 0.71).

Conclusions: Within-subject variability of HDL-cholesterol was substantial among our HIV-infected patients. Smoking was inversely correlated with such variability.

TUPEB093

Increased type I INF response among HIV infected men with cardiovascular disease

P. Vassalini[1], L. Celani[1], E.N. Cavallari[1], M. Statzu[2], G. Corano Scheri[1], G. Antonelli[2], V. Vullo[1], C. Scagnolari[2], G. d'Ettorre[1]
[1]Sapienza University of Rome, Public Health and Infectious Diseases, Rome, Italy, [2]Sapienza University of Rome, Pasteur Institute-Cenci Bolognetti Foundation, Department of Molecular Medicine, Laboratory of Virology, Rome, Italy

Background: Continuous production of type I IFN is a prominent feature of chronic HIV infection and might contribute to immune activation leading to immune dysfunction and premature bone, brain and atherosclerotic vascular disease. In this case control study, we examined the hypothesis that alterations in blood IFN production might contribute to the presence of coronary atherosclerosis in patients with HIV.

Methods: One hundred and six long term virologically suppressed HIV men with (n= 34) or without (n=72) coronary heart disease (CHD), recruited from the Dpt. of Public Health and Infectious Diseases of the "Sapienza" University of Rome (Italy), were included in this study. A control group of gender and age matched healthy individuals (n= 22) was also examined. IFN-alpha/beta and ISG56 mRNAs levels were evaluated in blood samples using TaqMan assays. Differences between groups were examined using the Mann-Whitney test. Pearson correlation coefficient was used to determine correlations. A p-value less than 0.05 was considered statistically significant. All analyses were performed with SPSS v.17.0 for Windows.

Results: There were no significant differences, between the two groups in age, CD4 T cell count, or antiretroviral therapy duration. Increased amount of IFN-alpha, IFN-beta and ISG56 mRNAs was recorded in HIV men with CHD compared to those without CHD and healthy controls (CHD + vs CHD -,; p< 0.001; CHD + vs Healthy subjects, p< 0.001 for all genes analyzed). In contrast, similar levels of IFN-alpha/beta and ISG56 were recorded between HIV patients without CHD and healthy subjects. High levels of IFN-beta and ISG56 gene expression in HIV infected patients showed significant correlations with the Framingham Risk score (IFN-beta p=0.04 r=0.237; ISG56 p=0.022 r=0.347). No such differences were recorded for IFN alpha levels (p>0.05). In addition, no relationships were recorded between IFN-alpha/beta and ISG56 levels and the presence of significant stenoses (i.e grade II-IV).

Conclusions: We provide evidence that the measurement of type I IFN response might help to identify HIV individuals at risk for cardiovascular disease progression.

TUPEB094

Early detection of cardiac dysfunction in asymptomatic adult HIV-infected patients

H.S. Toh[1], C.-T. Liao[2], W.-T. Chang[2], H.-J. Tang[3], Z.-C. Chen[2], H.-C. Ku[3]
[1]Chimei Medical Center, Department of Intensive Care Medicine, Tainan, Taiwan, Province of China, [2]Chimei Medical Center, Department of Cardiology, Tainan, Taiwan, Province of China, [3]Chimei Medical Center, Department of Infectious Diseases, Tainan, Taiwan, Province of China

Background: HIV infection is associated with cardiac dysfunction due to multifactorial causes. However, early cardiac dysfunction is usually asymptomatic and cardiovascular disease (CVD) is always detected late. 2D speckle-tracking echocardiography (2DSTE) has been used to detect early cardiac deformation in various CVD. This study aims to explore the early cardiac deformation and dysfunction by 2DSTE in asymptomatic HIV-infected patients in Taiwan.

Methods: HIV-infected patients were recruited prospectively from a medical center in southern Taiwan from 1 June 2017 to 31 October 2017. Medical records, history of HIV infection, risk factors for CVD were reviewed. Patients with symptoms or history of heart failure were excluded. 2DSTE was performed to calculate left ventricular (LV) and right ventricular (RV) global longitudinal strain (GLS). A cut-off value of -15% and -18% was used to define impaired LV and RV GLS respectively.

Results: A total of 100 patients were recruited during the period. Their mean age was 37.4 years and 94 of them are male. 44% had history of AIDS and 8 of them have a CD4 count < 200 cells/mm3 at the time of

enrolment. The mean CD4 count was 515.6 cells/mm3 and 87% of them had a viral load < 200 copies/mm3. The median duration of HIV diagnosed and antiretroviral treatment are 3 years (IQR 2-5.5) and 36 months (IQR 14-37) respectively. In echocardiography, only one patient has impaired LV ejection fraction (< 50%) and 8 patients have impaired RV systolic function (TAPSE < 16mm). However, 9 patients have pulmonary hypertension. The mean LV GLS was -18.9 ± 2.6% and RV GLS was -20.0 ± 6.7%. 91% and 68% of the patients have abnormal LV GLS and RV GLS, respectively.

Conclusions: This is the first study applying 2DSTE in Asian HIV-infected population. We found that impaired cardiac deformation is highly prevalent, despite a preserved LV and RV systolic function derived by the traditional echocardiography. Besides, a relatively high proportion of pulmonary hypertension is also noted. Further study is needed to investigate the clinical impact of these early changes and the effect of antiretroviral therapy.

Echocardiographic data	N = 100
LV ejection fraction (LVEF %), mean ± SD	66.0 ± 5.3
LV systolic dysfunction (LVEF < 50%), n(%)	1 (1)
LV diastolic dysfunction (E/A < 0.8), n (%)	7 (7)
LV GLS (%), mean ± SD	-18.9 ± 2.6
Impaired LV GLS (LVGLS < -15%), n (%)	91 (91)
RV systolic dysfunction (S' <11.5 or TAPSE <16), n (%)	8 (8)
RV GLS (%), mean ± SD	-20.0 ± 6.7
Impaired RV GLS (RVGLS < -18%), n (%)	68 (68)

TUPEB095

Effect of statin on coronary calcium distribution, mass and volume scores and associations with immune activation among HIV+ persons on antiretroviral therapy

C.T. Longenecker[1,2], S. Margevicius[1], J. Lipinski[1], M.D. Schluchter[1], D.L. Wilson[1], G.A. McComsey[1,2]
[1]*Case Western Reserve University School of Medicine, Cleveland, United States,* [2]*University Hospitals Cleveland Medical Center, Cleveland, United States*

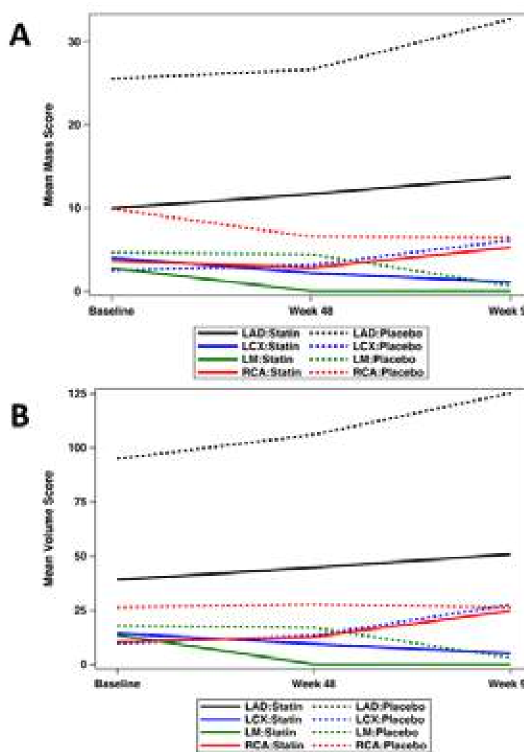
Background: Although inflammation has been associated with whole heart coronary artery calcium (CAC) among HIV+ persons on antiretroviral therapy (ART), prior studies have not evaluated the distribution of calcium or separated mass vs. volume components of the calcium score which have been differentially associated with clinical events in the general population. Statins may also have a greater effect on mass compared to volume of calcified coronary plaque.

Methods: The SATURN-HIV trial randomized 147 HIV+ subjects on ART to rosuvastatin 10mg daily vs. placebo. We re-analyzed coronary calcium scans from 0, 48, and 96 weeks to determine mass and volume scores in addition to per vessel and whole heart Agatston score. We also calculated number of vessels with any CAC and the diffusivity index [1-(CAC in most affected vessel/total CAC). Mixed effects models, ordinal logistic regression, and generalized estimating equations were used to examine the statin effect and associations with biomarkers of inflammation and immune activation across the 3 time points.

Results: Median age at study entry was 46 years; 78% were male and 68% African American. Median CD4+ was 613 and half were on protease-inhibitors. Fifty-four subjects had CAC >0 at baseline, of whom 24 (16% of subjects overall) had >1 vessel affected with a mean (SD) diffusivity index of 0.24 (0.17) in statin vs. 0.18 (0.15) in placebo. Randomization to statin therapy was not associated with change in mass score (p=0.65, Figure), volume score (p=0.76, Figure), number of involved vessels (p=0.51), or diffusivity index (p=0.13).

After adjustment for age and systolic blood pressure, there was an association of soluble CD14 with total Agatston score (p=0.05) and borderline association with number of involved vessels (p=0.09) across all 3 time points. There were no consistent longitudinal associations of inflammation markers with diffusivity index or mass/volume score.

Conclusions: Among HIV+ persons on ART, rosuvastatin 10mg daily did not have a significant effect on volume, mass, or regional distribution of coronary calcium over 96 weeks. We extend previous cross-sectional observations to show that soluble CD14 is associated with whole heart CAC over time and independently of age and systolic blood pressure.



[Figure. Effect of rosuvastatin 10mg daily on (A) coronary calcium mass score and (B) volume score. LAD, left anterior descending; LCX, left circumflex; LM, left main; RCA, right coronary artery]

TUPEB096

Age moderates the association between HIV infection and carotid intima media thickness: Evidence for elevated risk in younger HIV-infected individuals

Y. Ding[1,2], H. Lin[3], C. Ning[1], X. Qiao[1], X. Chen[1], D. Zhao[1], K. Wang[1], L. Li[1], Z. Jin[1], X. Chen[3], M. Gao[1,2], N. He[1,2]
[1]*Fudan University School of Public Health, Epidemiology, Shanghai, China,* [2]*The Key Laboratory of Public Health Safety of Ministry of Education, Fudan University, Shanghai, China,* [3]*Taizhou City Center for Disease Control and Prevention, Taizhou, China*

Background: Individuals with human immunodeficiency virus (HIV) infection are at increased risk of cardiovascular disease (CVD) in spite of combination antiretroviral therapy (cART). Atherosclerosis is a well-known predictor of CVD in the general population. HIV infection has been associated with subclinical atherosclerosis but data are not consistent and limited by relatively small sample. We evaluated possible effect modification (interaction) of age on the association of HIV infection and carotid atherosclerosis.

Methods: This study was conducted in 2017 in Taizhou prefecture, Zhejiang province in Southeastern China. 1391 HIV-infected adults and 2782 age-, and gender- frequency-matched HIV-uninfected individuals were recruited and administered with a face-to-face questionnaire interview and physical examinations. Carotid intima-media thickness (cIMT) was measured by ultrasonography.

Results: 1311 (94.2%) of 1391 HIV-infected patients were on cART with median duration of 2.3 years (interquartile range 0.6-4.4). HIV-infected individuals had significantly higher values of cIMT than HIV-uninfected individuals (0.74±0.38 vs 0.69±0.39; *P*< 0.001). This association remains sig-

nificant after adjustment for age, sex, education, smoking, body mass index, waist circumference above cut-off, dyslipidemia, and hypertension (*P*< 0.001). A significant but negative interaction between age and HIV infection on cIMT was observed (*P*=0.008). Age-stratified analysis showed that the difference in cIMT between HIV-infected and uninfected individuals was significant in the young (17-29 years) (0.56±0.16 vs 0.47±0.13 mm; *P*< 0.001) and middle-aged (30-49 years) (0.66±0.24 vs 0.61±0.20 mm; *P*< 0.001) adults but not in the older adults (≥50 years) (0.93±0.52 vs 0.90±0.43 mm; *P*=0.207). Such age-specific differences remained significant (B=0.10, SE=0.01, *P*< 0.001; B=0.06, SE=0.01, *P*< 0.001, respectively) in the young and older age groups after adjustment for above-mentioned variables with multiple linear regression. For HIV-infected individuals, cIMT was independently associated with age (B=0.01 per 10 years, SE=0.007, *P*< 0.001), waist circumference above cut-off (B=0.05, SE=0.02, *P*=0.021) and on cART (B=-0.10, SE=0.04, *P*=0.013).

Conclusions: The more evident effect of HIV infection on subclinical atherosclerosis is more evident among young and middle-aged HIV-infected individuals, partly due to lesser important role of traditional risk factors and more important role of HIV infection on atherosclerosis among younger HIV-infected patients.

TUPEB097

Prevalence of early cardiac dysfunction and covariates in children living with HIV in Western Kenya

A. McCrary[1], W. Nyandiko[2], A. Keter[3], M. Nyambura[3], N. Thielman[4], G. Bloomfield[4], P. Barker[5]

[1]Duke University, Pediatric Cardiology, Durham, United States, [2]Moi University, Child Health, Eldoret, Kenya, [3]Moi University, Biostatistics, Eldoret, Kenya, [4]Duke University, Medicine and Global Health, Durham, United States, [5]Duke University, Pediatrics, Durham, United States

Background: HIV-associated cardiac dysfunction has severe consequences, and traditional measures of echocardiography underestimate disease. Novel echocardiographic measures may detect early disease in time for possible intervention. The aims of this study are to define the prevalence of early cardiac dysfunction in children living with HIV and the relationships between cardiac function and same-day HIV viral load levels.

Methods: Using a cross-sectional study design, we performed echocardiograms and obtained plasma HIV RNA levels on children who were perinatally infected with HIV engaged in care at Moi Teaching and Referral Hospital in Eldoret, Kenya. Early cardiac dysfunction was defined as left ventricular global longitudinal strain (LVGLS) z-score < -2 or myocardial performance index (MPI) ≥ 0.5. The relationship between measures of cardiac function and HIV RNA levels and the assessment of other clinical covariates (age, sex, duration prior to and on antiretrovirals, and AZT exposure) with measures of cardiac function were modeled using linear regression.

Results: 303 children (mean age 9.8±3.2 years, range 1-16 years) with perinatally acquired HIV were enrolled. The mean BMI-for-age z-s core was -1.0±1.1. The median duration on antiretrovirals was 5.4 years (IQR 3.1, 7.7). 117 children (38.6%) had been exposed to AZT (median duration of exposure 2.6 years, IQR 0.0, 5.4). 101 of 298 (33.9%) had HIV RNA measurements ≥ 40 copies/ml. 9 of 303 (3%) children had LVGLS-for-BSA z-scores ≤ -2 meeting the criteria for early cardiac dysfunction, and 69 of 293 (23.5%) children had an MPI ≥ 0.5. In multivariate analysis, neither LVGLS z-score nor MPI were associated with HIV RNA levels ≥ 40 copies/ml or any clinical variables in the model [0.11 (95%CI -0.28, 0.5) and 0.0 (95%CI -0.02, 0.02), respectively].

Conclusions: Nearly one quarter of these HIV-infected children demonstrated echocardiographic evidence of cardiac dysfunction, based primarily on abnormal MPI measurements. This finding was not correlated with same-day HIV RNA levels or other clinically relevant variables. Further investigation into the clinical significance of this finding is urgently needed as abnormal MPI measurements have been shown to be predictive of heart failure in at risk populations.

Switching from an abacavir (ABC)/lamivudine (3TC)-based regimen to a single-tablet regimen of elvitegravir/cobicistat/emtricitabine/tenofovir alafenamide (E/C/F/TAF): Cardiovascular disease risk profile analysis from a randomized controlled study in virologically-suppressed adults

F. Raffi[1], A. Antinori[2], M. Ramgopal[3], J.M. Molina[4], H.J. Stellbrink[5], G. Rizzardini[6], J. Olalla[7], A. Gori[8], C. Miralles[9], P. Kumar[10], M. Das[11], E.T. Chan[11], W. Garner[11], D. Piontkowsky[11], S.K. Chuck[11], R. Haubrich[11]

[1]CHU de Nantes, Nantes, France, [2]Istituto Nazionale Malattie Infettive Lazzaro Spallanzani IRCCS, Rome, Italy, [3]Midway Immunology and Research Center, Fort Pierce, United States, [4]Hôpital Saint Louis, Paris, France, [5]ICH Study Center, Hamburg, Germany, [6]ASST Fatebenefratelli Sacco - Ospedale Luigi Sacco, Milan, Italy, [7]Hospital Costa del Sol, Marbella, Spain, [8]ASST di Monza - Azienda Ospedaliera San Gerardo, Monza, Italy, [9]CHU de Vigo - Hospital Alvaro Cunqueiro, Vigo, Spain, [10]Georgetown University Medical Center, Georgetown, United States, [11]Gilead Sciences, Foster City, United States

Background: In addition to HIV infection, lopinavir, darunavir, and abacavir (ABC) have been associated with increased cardiovascular disease (CVD). Switching from an ABC/3TC-based regimen (ABR) to E/C/F/TAF maintained high virologic suppression and was well tolerated through 24 weeks. Given the increased CVD risk associated with ABC, the effect of the switching from ABR to E/C/F/TAF on CVD risk was evaluated.

Methods: Adults with HIV-1 RNA < 50 copies/mL were randomized 2:1 to switch to E/C/F/TAF or continue their current ABR in an open-label, international study. Two equations were used to calculate participants' CVD risk at baseline and week 24: 1) American College of Cardiology/American Heart Association (ACC/AHA) 2013 Pooled Cohort Risk equation estimated the 10-year risk for a first atherosclerotic cardiovascular event (ASCVD); 2) D:A:D Study 2015 equation estimated the 5-year risk and accounted for current ABC use and cumulative exposure to other NRTIs and PIs.

Results: Baseline CVD risks were balanced between arms for both equations used (table). At week 24, ASCVD analysis showed small median increases in CVD risk that were not different between E/C/F/TAF and ABR arms (+0.1% vs +0.2%; p=0.46); D:A:D analysis showed a decreased median CVD risk in E/C/F/TAF vs. an increased median CVD risk in ABR arm (-0.8% vs +0.2%, p < 0.001).

Conclusions: Compared to the ASCVD analysis, using a validated equation specific for people living with HIV (PLH) that accounted for the CVD risk associated with ABC (D:A:D equation) demonstrated switching from ABR to E/C/F/TAF decreased CVD risk statistically significantly. For PLH with CVD risk factors, switching from ABC/3TC-based regimens to E/C/F/TAF may be clinically beneficial.

	E/C/F/TAF (N=183)		ABC/3TC + 3rd Agent (ABR) (N=91)		
CVD Risk Score	N	Median (Q1, Q3)	N	Median (Q1, Q3)	P-value
ASCVD Equation (%): Estimates 10 Year CVD risk, sex- and race-specific					
Baseline	175	4.4 (2.0, 10.5)	88	4.8 (1.5, 7.2)	0.38
Change at Week 24	159	0.1 (-0.5, 1.0)	85	0.2 (-0.3, 1.1)	0.46
D:A:D: Equation (Full) (%): Estimates 5 Year CVD Risk					
Baseline	161	3.3 (1.7, 6.8)	79	3.4 (1.7, 6.6)	0.67
Change at Week 24	147	-0.8 (-1.9, -0.2)	77	0.2 (-0.3, 0.7)	<0.001

P-values for the between treatment group comparisons are based on the 2-sided Wilcoxon rank sum test. The ACC/AHA Pooled Cohort Equation risk estimates are valid for ages 40-79 years, for total cholesterol 130-320 mg/dL, for HDL 20-100 mg/dL, and for SBP 90-200 mmHg. The D:A:D risk estimates are valid for ages 18-75 years, for total cholesterol 2.3-9.9 mmol/L, for HDL 0.41-2.6 mmol/L, for SBP 90-180 mmHg, and for CD4 20-1350 cells/uL. The out of range values for each were imputed as follows: if the values were less than the lower bound of the valid range, the lower bound value was used for calculation; if the values were more than the upper bound of the valid range, the upper bound value was used for calculation.

TUPEB099

Menopause, cardiovascular risk factors, and cerebrovascular function in the women's interagency HIV study

F. Chow[1], Y. Ma[2], R. Scherzer[2], P. Tien[2]
[1]University of California, San Francisco, Neurology, San Francisco, United States, [2]University of California, San Francisco, Medicine, San Francisco, United States

Background: Rates of cerebrovascular disease are higher in women living with HIV (WLWH) than in demographics-matched HIV-uninfected (HIV-) women. Although cardiovascular (CV) risk profiles differ between women and men, most studies investigating stroke risk factors in HIV have not been stratified by sex or have been in men-only cohorts. We evaluated the association of HIV, traditional vascular risk factors, peri/postmenopause (defined by undetectable anti-Mullerian hormone), and immune activation with cerebral vasoreactivity, a measure of cerebrovascular function that correlates with stroke risk, in the Women's Interagency HIV Study (WIHS).
Methods: We recruited women from the San Francisco WIHS site who were ≥40 years of age with at least one CV risk factor. WLWH were on stable antiretrovirals for at least 24 weeks with undetectable HIV RNA and CD4 count ≥400 cells/mm^3. Cerebral vasoreactivity was assessed using the transcranial Doppler breath holding challenge. We used linear regression models to identify risk factors associated with cerebral vasoreactivity.
Results: We included 31 WLWH and 16 HIV- women of a similar mean age (56 vs. 53 years, p=0.31). WLWH were 29% white, 39% black, and 19% Hispanic, while HIV- women were 13% white, 69% black, and 6% Hispanic (p=0.22). Median duration of HIV infection was 14 years. Of traditional vascular risk factors, WLWH had smaller median waist circumference (103 vs. 116 cm, p=0.008) and lower median body mass index (30 vs. 36 kg/m^2, p=0.059) compared with HIV- women. HIV was associated with lower (worse) cerebral vasoreactivity, although this was not statistically significant (-0.13, p=0.37). In age and race-adjusted linear regression models, peri/postmenopause (-0.71, p=0.013), hepatitis C (-0.44, p=0.044), history of CV disease (-0.50, p=0.038), current smoking (-0.29, p=0.11), and higher sCD163 (-0.19 per doubling, p=0.072) were associated with lower cerebral vasoreactivity, although the latter two did not reach statistical significance.
Conclusions: We did not find a statistically significant association between HIV and cerebrovascular function in this small cohort of virally suppressed WLWH. These data provide preliminary evidence that menopause, in addition to several modifiable vascular risk factors, may significantly impact cerebrovascular risk in women with well-controlled HIV.

TUPEB100

CVD risk progression upon initiation of ART in an African cohort

A. Vos[1,2,3], M. Moorhouse[2], S. Lalla-Edwards[2], K. Klipstein-Grobusch[1,4], D. Grobbee[1], R. Barth[3], F. Venter[2]
[1]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands, [2]Wits Reproductive Health and HIV Institute, Witwatersrand University, Johannesburg, South Africa, [3]Department of Internal Medicine, University Medical Center Utrecht, Utrecht, Netherlands, [4]School of Public Health, Witwatersrand University, Johannesburg, South Africa

Background: The risk of cardiovascular disease (CVD) is increased in HIV infection. Initiation of antiretroviral therapy (ART) modifies the risk. This study aims to gain insight into CVD risk and progression of CVD risk in a well characterized cohort of HIV-infected individuals initiating ART in a clinical trial.
Methods: We used the data from one of three sites of a clinical randomized controlled trial (clinical.trial.gov NCT02670772) comparing low-dose stavudine to tenofovir in South Africa, from 2012 to 2016. Both drugs were administered with efavirenz and lamivudine for 96 weeks in antiretroviral-naïve HIV-infected adults. Only participants with a follow-up of more than 6 months were included. CVD risk was calculated at baseline and at end of follow-up using the 10-year Framingham risk score (FRS. The difference in CVD risk progression per year was tested using a Mann-Whitney U Test.
Results: 497 participants (82.8% of the total cohort) were available for this analysis. Median follow-up time was 95.2 weeks. Mean age at baseline was 34.9 (SD 7.8) years, and 56.7% were female. 74 patients (14.9%) were smokers, 47 participants (9.5%) were on anti-hypertensive drugs and 1% were known diabetics. Mean CD4 cell count was 200cells/mm^3 at baseline. CVD risk was low in general; 96.2% had a FRS < 10% both at baseline and at end of follow-up. There was a small gain in weight (1.5kg) and glucose overall but no impact on blood pressure over 96 weeks. Median FRS in the whole group was 1.85% at baseline and 1.94% at end of follow-up (p < 0.001). Median progression of FRS per year was 0.118% for the stavudine group and 0.016% for the tenofovir group (p < 0.001).
Conclusions: CVD risk according to the FRS is low in a young urban ART-naïve HIV-infected population. Stavudine use is associated with a sharper increase in 10-year CVD risk than TDF use, but is now rarely used anywhere in the world. CVD risk over a longer period, as well as the development of locally appropriate correlates with clinical end points, needs evaluation in future studies. More research is indicated on the effect of previous d4T exposure on current CVD risk.

TUPEB101

Prevalence and risk factors associated with carotid plaque and intima-medial thickness in virologically suppressed HIV-infected Asians

A. Avihingsanon[1,2], S. Siwamogsatham[2], A. Chutinet[2], O. Putcharoen[2], T. Aponpong[1], A. Hiransuthikul,[1], S. Gatechompol[1], W. Min Han[1], S. J. Kerr[1,3], K. Ruxrungtham[1,2], HIV-NAT 207/HIV-NAT006 Study Team
[1]HIV-NAT, Thai Red Cross AIDS Centre, Bangkok, Thailand, [2]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]Kirby Institute, University of New South Wales, Sydney, Thailand

Background: The magnitude and risk factors of subclinical atherosclerosis in an Asian HIV-infected population is limited. Carotid intima-media thickness (cIMT) test has been one of the predictors for the risk of cardiovascular disease (CVDs) and mortality. We evaluated the prevalence and risk factors related to carotid atherosclerosis among well suppressed HIV-infected adults receiving long-term ART from Thailand.
Methods: A cross-sectional study of HIV-infected adults aged >50 years and free from CVDs was conducted in Thailand. Ultrasonography of the carotid was performed and read by cIMT experienced neurologists who were blinded from the patient care. Subclinical atherosclerosis was defined by carotid plaque or cIMT of the common carotid artery >0.9 mm. Multiple logistic regression was used to predict the prevalence of subclinical atherosclerosis and the relationship between other covariates.
Results: Totally 316 HIV-infected adults (median age 54.4 years, 61% men, 15.8% diabetes, 40.2% hypertension) were included. The median duration of ART was 16.3 years and 32% were currently on boosted PI. The mean overall cIMT of the common carotid arteries were 0.63 (IQR 0.55-0.72) mm. Men had higher cIMT (0.64 (IQR 0.56-0.76) vs 0.60 (IQR 0.53-0.70), p=0.03. Overall, 3.8% had ciMT >0.9 mm and 27.6% had carotid plaque. From the multivariate logistic regression analysis, age [odds ratio (OR) 1.06; 95% confidence interval (CI) 1.003-1.12; p=0.04] and CD4 nadir < 200 cells/mm^3 [OR 1.8; 95%CI 1.02-3.18, p=0.04] were significantly associated with subclinical atherosclerosis. ART regimen and hs-CRP were not associated with subclinical atherosclerosis.
Conclusions: In this well suppressed HIV-infected Asian cohort, one-third of them had subclinical atherosclerosis. Advanced age and low nadir CD4 cell count was significantly associated with subclinical atherosclerosis. This findings support early ART initiation.

TUPEB102

Predictor of cardiovascular events and mortality in a Spanish cohort of HIV-infected patients

H. Albendín Iglesias[1], C.S. Caro Martinez[2], A. Perez Salvador[1], C.E. Galera Peñaranda[1], E. Bernal Morell[3]
[1]HCUVA, Internal Medicine, Murcia, Spain, [2]Hospital Vega Baja, Cardiology, Alicante, Spain, [3]Hospital General Reina Sofia, Infectious Diseases, Murcia, Spain

Background: HIV infection is characterized by a state of profound and continuous immune-activation. It is likely that the variables associated with the control of the infection are predictors of cardiovascular events. The objective of our study was to evaluate the predictors of major adverse cardiac events (MACE).
Methods: Retrospective analysis of 671 medical records of HIV-infected patients who were attended in the Internal Medicine consultation of the Virgen de la Arrixaca Hospital (Murcia) for the period January 2000 to December 2013. Events MACE that occurred until September 2017 were collected. The median follow-up was 16.7 years. A univariate and multivariate Cox analysis was performed to evaluate the factors associated with MACE.
Results: Fifty five MACE occurred during the follow-up period. The MACE predictors were age (per year, Hazard ratio (HR) =1.07, 95% Confidence interval (CI), 1.04-1.09, p < 0.001), male sex (HR = 2.26, 95% CI, 1.26-4.04, p = 0.006), arterial hypertension (HR =1.41, 95% CI, 1.06-1.85, p = 0.016), diabetes mellitus (HR = 1.49, 95% CI,1.05-1.85, p =0.026), chronic kidney disease (HR = 2.39, 95% CI, 1.01-5.62, p = 0.047), AIDS (HR = 1.59, 95% CI, 1.21-2.1, p = 0.001) and the CD4 / CD8 ratio less than 0.4 (HR = 2.49, 95% CI, 1.43-4.32, p = 0.001), HIV viral load higher than 200 copies/ml (HR = 4.45, 95% CI, 2.47-8.01, p < 0.001). In the multivariable Cox regression analysis, the independent predictors of MACE were age (per year, HR =1.07, 95% CI, 1.04-1.10, p < 0.001), sex male (HR = 2.16, 95% CI, 1.06-4.41, p = 0.034), smoking (HR = 1.42, 95% CI, 1.01-2.00; = 0.047) and the HIV viral load higher than 200 copies/ml (HR = 5.94, 95% CI 3.13-11.26, p < 0.001). The C statistic model was 0.78 (95% CI, 0.71-0.84, p < 0.001).
Conclusions: Traditional risk factors (smoking habits, sex male and age) were associated with MACE events as general population. On the other hand, HIV viral load > 200 copies was a powerful predictor of MACE event in HIV infected patients. So it is highlights the importance of antiretroviral treatment and virological control to prevent cardiovascular events.

TUPEB103

Changes in cardiovascular risk calculation and in fasting lipids in virologically suppressed patients randomized to switch to tenofovir alafenamide versus continuing abacavir

A. Winston[1], D.A. Wohl[2], H.-J. Stellbrink[3], L. Lopez-Cortes[4], P. Mallon[5], P.E. Sax[6], I. Brar[7], Y.-P. Liu[8], L. Zhong[8], S.E. Collins[8], H. Martin[8], D. Sengupta[8], E. Quirk[8], M. Das[8]
[1]Imperial College, Section of Infectious Diseases, Department of Medicine, London, United Kingdom, [2]University of North Carolina, Department of Medicine, Division of Infectious Diseases, Chapel Hill, United States, [3]ICH Study Center, Hamburg, Germany, [4]Hospital Universitario Virgen del Rocio/CSIC/Universidad de Sevilla, Instituto de Biomedicina de Sevilla, Sevilla, Spain, [5]University College Dublin, School of Medicine, Dublin, Ireland, [6]Brigham and Women's Hospital and Harvard Medical School, Division of Infectious Diseases, Boston, United States, [7]Henry Ford Hospital, Detroit, United States, [8]Gilead Sciences Inc., Foster City, United States

Background: Both tenofovir alafenamide (TAF) and abacavir (ABC) are considered lipid-neutral antiretroviral drugs, however comparisons between these agents have not thus far been described. We examined the effect of switching from ABC-containing to TAF-containing regimens on fasting lipids and cardiovascular (CV) risk.
Methods: We analyzed 1119 virologically suppressed participants in two randomized controlled trials of switching from ABC to TAF. Study 1717 assessed switching from ABC/ lamivudine (3TC) + 3rd agent to emtricitabine (FTC)/TAF + remaining on the same 3rd agent (n=556), and Study 1844 from ABC/dolutegravir/3TC to bictegravir/FTC/TAF (n=563). We assessed fasting lipids, 10-year CV risk using the AHA/ACC Pooled Cohort Equations and 5-year CV risk using the D:A:D algorithm (full model). Individuals were classified using clinical cutoffs for risk scores: <7.5%, 7.5% to < 10%, and ≥ 10%. We assessed the change in risk categories from baseline using rank analysis of covariance, and compared median changes from baseline with Wilcoxon rank sum test.

	TAF-containing regimen	ABC-containing regimen	
	Week 48 median (Q1, Q3)	Week 48 median (Q1, Q3)	p value
Total Cholesterol (mg/dL)			
Baseline	188 (165, 219)	194 (168, 220)	0.22
Change at Week 48	0 (-17, 19)	2 (-15, 20)	0.23
Direct LDL Cholesterol (mg/dL)			
Baseline	117 (97, 130)	121 (101, 143)	0.06
Change at Week 48	1.5 (-13.0, 19.0)	3.0 (-12.0, 16.0)	0.88
Non-HDL Cholesterol (mg/dL)			
Baseline	133 (112, 161)	138 (116, 164)	0.13
Change at Week 48	1.0 (-16.0, 17.0)	2.0 (-15.0, 17.0)	0.90
HDL Cholesterol (mg/dL)			
Baseline	52 (42, 63)	50 (42, 62)	0.17
Change at Week 48	-1 (-6, 4)	1 (-4, 7)	<0.001
Total Cholesterol : HDL ratio			
Baseline	3.6 (2.9, 4.4)	3.8 (3.0, 4.7)	0.07
Change at Week 48	0.0 (-0.4, 0.4)	0.0 (-0.5, 0.4)	0.16
Triglycerides (mg/dL)			
Baseline	118 (81, 160)	119 (86, 171)	0.36
Change at Week 48	-4.0 (-29.0, 29.0)	1.5 (-30, 30)	0.27
ACC/AHA 10-year risk score			
Baseline	4.3 (2.0, 8.9)	4.1 (1.8, 9.2)	0.57
Change at Week 48	0.0 (-0.7, 0.9)	0.0 (-0.7, 0.6)	0.16
D:A:D CVD 5-year risk score			
Baseline	3.6 (1.7, 7.3)	3.3 (1.5, 6.8)	0.23
Change at Week 48	-0.6 (-1.6, -0.2)	0.2 (-0.1, 0.7)	<0.001

The ACC/AHA Pooled Cohort Equations risk estimates are valid for ages 40-79 years, for total cholesterol 130-320 mg/dL, for HDL 20-100 mg/dL, for SBP 90-200 mmHg. The D:A:D risk estimates are valid for ages 18-75 years, for total cholesterol 2.3-9.8 mmol/L (89-383 mg/dL), for HDL 0.41-2.6 mmol/L (16-100 mg/dL), for SBP 90-180 mmHg, and for CD4 20-1350 /uL. The out of range values for each were imputed as follows: if the values were less than the lower bound of the valid range, the lower bound value was used for calculation; if the values were more than the upper bound of the valid range, the upper bound value was used for calculation.

[Table]

Results: 562 adults switched to TAF and 557 continued ABC. Baseline characteristics were balanced: median age 49 years (range 20 to 79), 85% men, 22% black, median CD4 count 683 cells/μL (interquartile range 510, 893), 33% hypertension and 10% diabetes. At Week 48, no differences were seen in TC, LDL, non-HDL, triglycerides or TC:HDL ratio. Participants who switched to TAF had a small decline in HDL compared to ABC. There were no differences in 10-year CV risk categories or median risk change at Week 48 by AHA/ACC equations (p=0.80 and p=0.16). Using the D:A:D algorithm, TAF was associated with a small decline in CV risk compared to ABC at Week 48 (p< 0.001) attributable to the removal of the coefficient for current ABC use. Virologic suppression and safety were similar between groups.
Conclusions: Switching from ABC to TAF did not result in clinically significant changes in lipids or in the calculated AHA/ACC ASCVD or D:A:D CV risk scores. These findings suggest that TAF and ABC have similar effects on lipids and CV risk calculations that do not include ABC as a CV risk factor.

TUPEB104

Cardiovascular disease risk assessments and fasting lipid changes in virologically suppressed patients randomized to switch to tenofovir alafenamide versus continuing tenofovir disoproxil fumarate

C. Orkin[1], F. Castelli[2], Y. Yazdanpanah[3], J. Rockstroh[4], C. Brinson[5], G. Diperri[6], Y.-P. Liu[7], L. Zhong[7], S.E. Collins[7], H. Martin[7], D. Sengupta[7], M. Das[7]
[1]Royal London Hospital, Grahame Hayton Unit, London, United Kingdom, [2]University of Brescia and Spedali Civili General Hospital, University Department of Infectious and Tropical Diseases, Brescia, Italy, [3]Hôpital Bichat Claude Bernard, Paris, France, [4]University Hospital Bonn, Bonn, Germany, [5]Central Texas Clinical Research, Austin, United States, [6]University of Torino, Unit of Infectious Diseases, Department of Medical Sciences, Torino, Italy, [7]Gilead Sciences Inc., Foster City, United States

Background: The 91% higher plasma levels of tenofovir (TFV) from tenofovir disoproxil fumarate (TDF) versus tenofovir alafenamide (TAF) are associated with lower fasting levels of protective (HDL) and harmful (LDL) cholesterol through an unclear mechanism. No difference in atherosclerotic cardiovascular disease (ASCVD) risk scores are seen in treatment-naïve patients. The impact on cardiovascular risk of switching from a regimen containing TDF to one containing TAF is unknown.

Methods: We pooled data from 2587 virologically suppressed participants on 3 randomized, active controlled trials that assessed switching to TAF versus continuing TDF. We measured fasting lipids and calculated 10-year ASCVD risk using the AHA/ACC Pooled Cohort Equations. We classified individuals by clinical risk categories: < 7.5%, 7.5% to < 10%, and ≥ 10% using the rank analysis of covariance method to compare the change from baseline in risk categories and Wilcoxon rank sum test to compare median values at Week 48.
Results: 1537 adults switched to TAF and 1050 continued TDF. Baseline characteristics included: 87% men, 21% Black, median CD count 654 cells/μL (IQR 500, 830), 25% hypertension and 5% diabetes, were balanced between groups. Median age was 44 years (IQR 35, 50) versus 45 years (IQR 36, 51) for TAF versus TDF respectively (p=0.021). At Week 48, there was a small difference in median change from baseline ASCVD scores, no difference in median risk score between TAF and TDF groups (see table) and no change from baseline in categorical ASCVD risk score classifications (p= 0.06). After switching to TAF, modest increases were observed in all fasting lipids and a small difference in TC:HDL ratio between groups.
Conclusions: Switching from TDF to TAF did not result in any significant change in ASCVD risk scores at Week 48 compared to continuing TDF and did not alter clinical classifications of ASCVD risk despite modest increases in both protective (HDL) and harmful (LDL) cholesterol. We used the AHA/ACC equation to compare calculated risk scores in TDF versus TAF takers within a relatively young, healthy, and mostly male cohort with low baseline cardiovascular risk. Long term cohort data is needed to characterize clinical cardiovascular event rates.

	TAF-containing regimen	TDF-containing regimen	
	Median (Q1, Q3)	Median (Q1, Q3)	p value
ACC/AHA 10-year risk score			
Baseline	2.7 (1.1, 5.6)	3.0 (1.3, 5.8)	0.092
Week 48	2.9 (1.3, 6.0)	2.9 (1.3, 5.7)	0.97
Change from baseline at Week 48	0.1 (-0.3, 0.7)	0.0 (-0.5, 0.5)	<0.001
Total Cholesterol (mg/dL)			
Change from baseline	17 (-2, 37)	3 (-12, 18)	<0.001
Direct LDL Cholesterol (mg/dL)			
Change from baseline	9 (-7, 26)	1 (-13, 13)	<0.001
Non-HDL Cholesterol (mg/dL)			
Change from baseline	15 (-3, 33)	3 (-12, 16)	<0.001
HDL Cholesterol (mg/dL)			
Change from baseline	2 (-3, 8)	0 (-4, 6)	<0.001
TC:HDL ratio			
Change from baseline	0.1 (-0.3, 0.6)	0.0 (-0.4, 0.4)	<0.001
Triglycerides (mg/dL)			
Change from baseline	8 (-22, 44)	0 (-29, 28)	<0.001

The ACC/AHA ASCVD risk estimates are valid for ages 40-79 years, for total cholesterol 130-320 mg/dL, for HDL 20-100 mg/dL, for SBP 90-200 mmHg; the out of range values were imputed as follows: if the values were less than the lower bound of the valid range, the lower bound value was used for calculation; if the values were more than the upper bound of the valid range, the upper bound value was used for calculation.

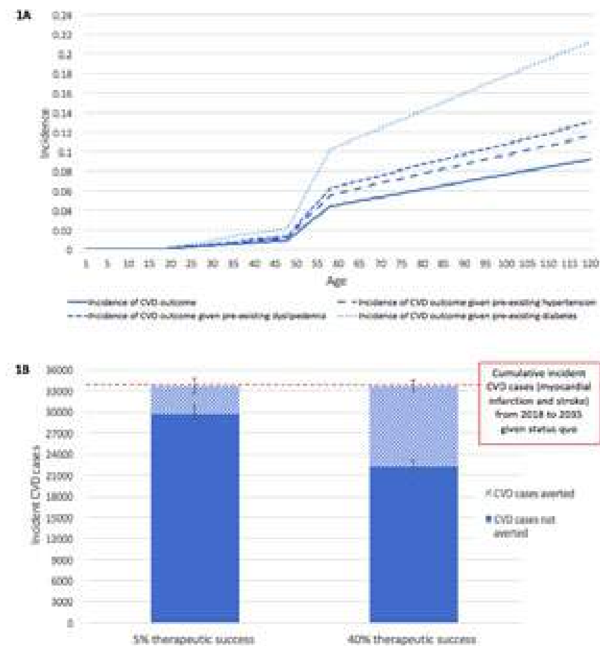
TUPEB105

The potential impact of integrating services for the secondary prevention of cardiovascular outcomes into HIV care in Kenya: A mathematical modelling study

R. Cassidy, P. Perez-Guzman, T. Hallett, M. Smit
Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom

Background: Cardiovascular disease (CVD) is estimated to contribute more than 13% of deaths in Kenya. National guidelines now recommend integration of secondary preventative services for CVD risk factors into care for people living with HIV (PLHIV). However, coverage remains very low. Our aim is to quantify the impact of comprehensive provision of antihypertensive and lipid lowering medication as per national guidelines on CVD incidence amongst PLHIV in care.
Methods: We developed an individual-based multi-disease model for Kenya, simulating HIV infection, progression and treatment, and incidence of major non-communicable diseases (NCDs). The model was parameterized using national and regional surveillance and epidemiological data and accounts for the impact of pre-existing NCDs (diabetes, hypertension and dyslipidaemia) on risk of CVD outcome (myocardial infarction (MI) and stroke) (Figure 1A). We evaluated the impact of integrating a screen-and-treat intervention for hypertension and dyslipidaemia into HIV care on CVD outcomes, using recommended screening intervals (every three years) and treatment guidelines, from 2018 to 2035. Therapeutic Success (TS) was assumed to range from 5-40% and to decease CVD risk to that of age-matched controls without hypertension or dyslipidaemia.
Results: Our model predicts a baseline of 33,700 (32,619-34,781) cases of CVD outcomes between 2018 and 2035 amongst PLHIV in care, MI incidence of 102.7 (98.8-106.6) and stroke incidence of 104.7 (100.4-108.9) per 100,000 person-years. Prevalence of related NCDs is predicted to increase over the same period (hypertension: 40.2% to 54.9%, dyslipidaemia: 26.4% to 39.3% and diabetes: 1.8% to 4.0%). A screen-and-treat intervention could avert 12%-34% of MI cases and 11%-33% of stroke cases among PLHIV between 2018 and 2035 (Figure 1B), depending on assumed probability of TS. This equates to 1 case averted for every 87-261 screening tests administered, depending on TS assumed. MI incidence could decrease to between 94.0 (89.5-98.6) and 68.5 (64.1-72.9) and stroke incidence to between 93.1 (89.7-96.5) and 68.8 (64.1-73.5) per 100,000 person-years.
Conclusions: Screening and treatment of high blood pressure and cholesterol in PLHIV in care could avert a large burden of CVD outcomes in this population, with the impact strongly modulated by the probability of achieving treatment success.



[Fig 1A Incidence of CVD by age given pre-existing NCD. 1B Cumulative incident number of CVD cases between 2018-2035 at baseline and with intervention.]

TUPEB106

Improvement in the prediction of cardiovascular events by adding HIV-viral load to a cardiovascular risk scale

H. Albendín Iglesias[1], C.S. Caro Martinez[2], A. Perez Salvador[1], C.E. Galera Peñaranda[1], E. Bernal Morell[3]
[1]HCUVA, Internal Medicine, Murcia, Spain, [2]Hospital Vega Baja, Cardiology, Alicante, Spain, [3]Hospital General Reina Sofia, Infectious Diseases, Murcia, Spain

Background: The immunovirological variables in HIV infected patients can be predictors of cardiovascular events. The aim of our study was to analyze the discriminative improvement of the COMVIH-COR scale by adding variables such as HIV viral load.

Methods: Retrospective analysis of 671 medical records of HIV-infected patients who were attended in the Internal Medicine consultation of the Virgen de la Arrixaca Hospital (Murcia) for the period January 2000 to December 2013. Major adverse cardiac events (MACE) that occurred until September 2017 were collected. The median follow-up was 16.7 years. The COMVIH-COR scale was calculated at the event or at the end of the follow-up. The improvement in the reclassification of the COMVIH-COR scale after the addition of the viral load variable greater than 200 copies/ml was performed.
Results: The COMVIH-COR risk scale was calculated in 507 patients. The area under the curve COMVIH-COR risk scale model was 0.72 (95% confidence interval (CI), 0.68-0.76) compared to 0.76 (95% CI, 0.72-0.79) of the model in which CV greater than 200 copies/ml was added to the COMVIH-COR scale (p = 0.201). The Integrated Discrimination Improvement (IDI) showed that the viral load improved the classification of the COMVIH-COR risk scale for the prediction of MACE events. (Relative IDI, 3.8%, p = 0.014). Similarly, the NRI (Net Reclassification Index) showed an improvement in the reclassification of the risk when it was added to the COMVIH-COR (p = 0.021) The distribution of the MACE event rate (per 1000 patient / year) according to the viral load and the risk level showed higher rates in those patients with HIV viral load higher than 200 copies/ml in all levels: low (2.8 versus 1.6), moderate (11.9 versus 5.1), at high risk or very high (13.2 versus 7.4).
Conclusions: The COMVIH-COR risk scale developed for HIV-infected patients had a modest predictive capacity for major adverse cardiac events. The addition of a virological marker (HIV viral load > 200 copies/ml) to the COMVIH-COR scale significantly improved its predictive capacity, which suggests that in clinical practice we should take into account the control of HIV replication as a factor of cardiovascular risk.

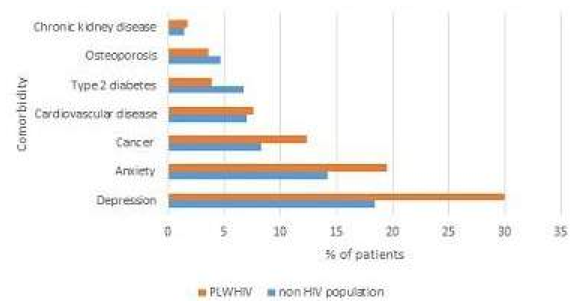
Chronic disease prevalence and management in Australian adults with HIV: Use of a national longitudinal general practice dataset to identify and address gaps in patient care

C. Weston[1], K. Lembke[1], J. Yoo[1], N. Raffoul[1], D. Gracey[2], J. Reeve[1]
[1]*NPS MedicineWise, Sydney, Australia,* [2]*Royal Prince Alfred Hospital, Sydney, Australia*

Background: The evolution of HIV into a chronic disease presents new challenges for the management of a range of HIV-associated non-AIDS comorbidities.
Cardiovascular (CV) disease and its prevention are important considerations in the management of people living with HIV (PLWHIV). Limited literature exists on how CV and renal diseases are managed in PLWHIV in Australia. We aimed to characterise PLWHIV being cared for their general practitioners, and investigate how well their CV and renal risk factors were being managed in line with current guidelines.
Methods: An Australian primary care dataset was used to characterise the prevalence of selected co-morbidities in PLWHIV. A cardiovascular and renal focus were selected after interviews with HIV specialists and general practitioners. The ethics approved real-world dataset used contains longitudinal, de-identified, whole-of-practice data from general practices and holds individual patient data for more than 3.5 million Australians. The management of risk factors for cardiovascular and renal disease was then compared to best practice guidelines.
Results: In September 2017, 4,492 patients 18 years or older were identified in the dataset as PLWHIV, representing 17.7% of the estimated 25,313 PLWHIV in Australia. Males accounted for 95.3% of the cohort and 66.5% were 45-74 years old.
Depression, anxiety, cardiovascular disease and cancer were the commonest co-morbidities recorded and were all more common than in the non-HIV population (Chart 1). Local guidelines recommend annual monitoring of cardiovascular and renal risk factors. Sixty three percent of PLWHIV had a blood pressure recorded in the dataset in the last year, 60% an eGFR, and 25% an LDL-cholesterol.
Of those with measurements available, 74% had a systolic blood pressure below 140mm Hg, 17% had a LDL cholesterol below 2 mmol/L (target management goals) and 30% had an eGFR in the normal range (>90mL/min/1.73m²).



[Chart 1: Prevalence of comorbidities in PLWHIV compared to the non HIV population]

Conclusions: This study quantified the significant level of co-morbidities in Australians living with HIV and identified specific areas for improvement in the management of cardiovascular and renal risk factors. The study was used as the basis of a reflective quality improvement activity delivered to 16 general practices, with the aim of improving the quality of clinical care in Australians living with HIV.

Bone disease

TUPEB108

Prevalence and predictors of bone mineral density among perinatally HIV-infected adolescents on antiretroviral therapy (ART) in the Cape Town Adolescent Antiretroviral Cohort (CTAAC)

S. Mahtab[1], C. Scott[2], T. Machemedze[1], N.A. Asafu-Agyei[1], L. Frigati[1], L. Myer[3,4], H. Zar[1]
[1]*University of Cape Town, Department of Pediatrics & Child Health, Red Cross War Memorial Children's Hospital, and SA MRC Unit on Child & Adolescent Health, Cape Town, South Africa,* [2]*University of Cape Town, Department of Pediatric Rheumatology, Red Cross War Memorial Children's Hospital, Cape Town, South Africa,* [3]*University of Cape Town, Division of Epidemiology & Biostatistics, Cape Town, South Africa,* [4]*University of Cape Town, Centre for Infectious Diseases Epidemiology & Research, Cape Town, South Africa*

Background: Access to ART has reduced morbidity and mortality in perinatally HIV-infected adolescents (PHIVA), but long-term complications including low bone mineral density (BMD) remains a concern. In high income countries, low BMD has been reported in 10-54% of HIV-infected adolescents. We studied the prevalence and predictors of low BMD among South African PHIVA on ART.
Methods: We evaluated the calcaneus stiffness index (SI) in a cross-sectional analysis using Quantitative Ultrasonography (QUS), a reliable and non-invasive method to screen BMD. Adolescents 11-17 years old were included. SI was considered low if z-score < -2 SD using age and sex matched HIV-uninfected controls (HIV-) as a reference. Multiple logistic regression was used to examine the adjusted association between low SI and both HIV-related and traditional risk factors in PHIVA.
Results: Overall 407 PHIVA (median age: 14 years; 50% female; median age at ART initiation: 4.2 years) and 92 HIV- (median age: 14 years; 54% female) were included. Median duration on ART was 9.8 years (IQR 6.8-11.5) with 38% initiating ART at ≤2 years of age. PHIV+ had low mean SI and BMI z-score compared to HIV- (99 vs 105, p=< 0.001) and (-0.19 vs 0.43, p=< 0.001) respectively.
At Tanner Stage I, the mean SI between PHIVA and HIV- were similar (93 vs 94, p=0.832). During puberty, mean SI increased with Tanner stage in both PHIVA and HIV- but there was more significant increase among HIV- controls; Tanner stage II-III (96 vs 101, p=0.009) and Tanner stage IV-V (104 vs 112, p=0.001).
Among PHIVA on ART, 52 (13%) had low SI. After adjusting for age, gender and Tanner stage, exposure to Lopinavir/Ritonavir (LPV/r) (OR=2.31, p=0.012) and viral load >50 copies/ml (OR=2.06, p=0.023) were associated with increased risk of low SI. However, exposure to Efavirenz (EFV) (OR=0.41, p=0.009) was associated with decreased risk of low SI.

Conclusions: In South African PHIVA, SI appears significantly different from HIV- controls especially in late puberty. LPV/r exposure and high viral load are risk factors for low SI and exposure to EFV seems to be associated with better SI. Longitudinal study of BMD is needed to evaluate long term effects.

Variable	OR* (95% CI)	p-value
Viral load(copies/ml) <50, ≥50	Ref, 2.06 (1.11-3.83)	0.023
CD4 count (cells/ul) ≤499, ≥500	Ref, 0.53 (0.27-1.05)	0.067
WHO HIV staging Stage I-II, Stage III-IV	Ref, 1.84 (0.67-5.04)	0.234

Increased beta-2 microglobulinuria predicts low BMD in young HIV+ patients on TDF

T. Taniguchi[1], M. Tsukiji[2], T. Sakurai[1], H. Igari[1]
[1]*Chiba University Hospital, Department of Infectious Diseases, Chiba, Japan,* [2]*Chiba Unversity Hospital, Department of Pharmacy, Chiba, Japan*

Background: HIV+ patients treated with Tenofovir Disoproxil Fumarate (TDF) are known to have risk for developing low bone mineral density (BMD) and hence are in high risk for fracture. However, current recommendation is to screen bone density with dual-energy x-ray absorptiometry (DXA) in men aged ≥50 and postmenopausal women. We evaluated the prevalence and risks for low BMD in our HIV+ patients, and then sub-analyzed patients aged < 50 and on TDF.

Methods: A single-centered cross-sectional study was performed among HIV+ patients, analyzing BMD by DXA. We assessed factors associated with low BMD (osteopenia or osteoporosis, defined by T-scores of -1.0 to >-2.5, and ≤ -2.5, respectively) in either lumbar spine or hip by chi-square or Fisher's exact test for univariate and binary logistic regression for multivariate analyses.

Results: Of 215 HIV+ patients with DXA performed (median age 46 [interquartile range (IQR) 39-57], 87% male, median CD4+ cell count [CD4] 516 cells/mm[sup]3[/sup] [IQR 333-684] and 71% (n=153) on TDF), 61% (n=127) had low BMD in either lumbar spine or hip. When adjusted by age, sex, CD4 count and smoking habit, patients on TDF (adjusted odds ratio (aOR): 2.1[95% confidence interval (CI); 0.97-4.7]), increased beta-2 microglobulinuria (> 320mcg/L) (aOR: 2.5 [95%CI; 1.2-5.3] and Body Mass Index (BMI) < 25 (aOR: 2.4[95%CI; 1.2-5.0] were risk factors for low BMD. Patients aged < 50 and on TDF (n=105) had high rate of low BMD (64%, n=67) , and after adjustment with age, sex, smoking habit, BMI and CD4 count, significant risk factor for low BMD in this population was increased beta-2 microglobulinuria (aOR: 3.5[95%CI; 1.1-11.1]).

Conclusions: Low BMD is common in young HIV+ patients on TDF. High risk patients warrants screening for low BMD with DXA. Young HIV+ patients on TDF with increased beta-2 microglobulinuria have 3.5-fold higher risk for developing low BMD. To determine high risk patients for low BMD, a spot urine beta-2 microglobulin test may be helpful.

TUPEB110

Vitamin D does not modulate Immune-mediated bone loss during ART initiation

E.T. Overton[1], E. Chan[2], T. Brown[3], J. Kinslow[4], A. Landay[4], K. Melbourne[5], H. Ribaudo[2], M. Yin[6], ACTG 5280 Study Team
[1]*University of Alabama, Birmingham, United States,* [2]*Harvard Chan School of Public Health, Boston, United States,* [3]*Johns Hopkins University School of Medicine, Baltimore, United States,* [4]*Rush Medical College, Chicago, United States,* [5]*Gilead Sciences, Foster City, United States,* [6]*Columbia University, Medicine, New York, United States*

Background: Bone loss with ART initiation may be related to changes in immune function, including expression of receptor activator of nuclear factor kappa-B ligand (RANKL) which leads to osteoclast activation. Vitamin D (VitD) and calcium(Ca) supplementation (vitamin D3 4000 IU calcium carbonate 1000 mg daily) attenuates ART-associated bone loss, but it is unclear whether this effect is mediated through immunomodulation.

Methods: In this secondary analysis of A5280, a 48-week, randomized, double-blind, placebo-controlled study of VitD/Ca supplementation in HIV+ persons initiating efavirenz/emtricitabine/tenofovir, we measured lymphocyte phenotypes and RANKL expression by median fluorescence intensity (MFI) on cells at baseline and 48 weeks. Changes were evaluated within and between treatment groups by Wilcoxon signed rank and Wilcoxon rank sum tests, respectively. Spearman correlations were estimated to evaluate the relationship between cellular phenotypes and bone mineral denity (BMD).

Results: Of 165 eligible participants enrolled, 138 had samples for cellular phenotypes at baseline and week 48 (64 in VitD/Ca and 74 in placebo). Markers of CD4, CD8, and B cell activation (CD38+HLA-DR+) declined from baseline to 48 weeks (all p < 0.001, table), but did not differ between arms. There was no decline in either %T cells (CD4 and CD8) expressing RANKL or expression of RANKL by MFI. B cell expression of RANKL by MFI declined in both arms with a greater decline in the placebo arm. CD4 and CD8 activation markers were not correlated with BMD at baseline (|r|≤ 0.15 and p>0.09 for all), but greater declines in CD4 activation correlated with greater declines in hip and spine BMD in both arms (0.25 ≤ r ≤0.37, all p < 0.05). A greater decline in CD8 activation was correlated with greater declines in both hip and spine BMD in the placebo arm only (hip r=0.31, p=0.009; spine r=0.25, p=0.035). Other correlations between changes in markers and BMD were modest and not apparent on scatterplots.

	VitD/Ca Arm			Placebo Arm		
	Baseline Median (Q1, Q3)	Change Median (Q1, Q3)	p-value (within arm)	Baseline Median (Q1, Q3)	Change Median (Q1, Q3)	p-value (within arm)
%(CD4+) CD38+HLA-DR+	6.8 (3.8, 12.8)	-3.0 (-5.8, -0.9)	<0.001	8.3 (4.6, 11.1)	-3.6 (-7.0, -1.1)	<0.001
% (CD8+) CD38+ HLA-DR+	18.0 (12.3, 33.0)	-13.9 (-23.2 -9.1)	<0.001	22.8 (12.5, 32.2)	-17.2 (-25.8, -7.7)	<0.001
% (CD19+) CD38+ HLA-DR+	94.0 (88.0, 97.4)	-2.0 (-5.1, -0.3)	<0.001	92.5 (86.2, 95.9)	-3.1 (-6.7, -0.1)	<0.001
% (CD4+) RANKL+	77.3 (62.1, 87.1)	1.1 (-3.1, 8.1)	0.20	74.0 (49.4, 91.6)	0.7 (-3.7, 6.5)	0.44
% (CD8+) RANKL+	81.1 (68.3, 90.5)	-0.9 (-5.4, 5.5)	0.84	82.9 (63.6, 91.2)	-0.2 (-5.8, 5.8)	0.70
CD4+ RANKL MFI	1223 (1126, 1415)	3 (-81, 119)	0.70	1215 (1081, 1485)	10 (-86, 101)	0.83
CD8+ RANKL MFI	1226 (1112, 1453)	-18 (-108, 135)	0.90	1268 (1118, 1477)	-15 (-113, 91)	0.32
CD19+ RANKL MFI	8230 (7014, 9684)	-694 (-1646, 445)	0.002	8189 (6892, 9327)	-1187 (-2488, -250)	<0.001

[Table: Changes in Selected Lymphocyte Phenotype Markers and RANKL Expression from Baseline to Week 48 by Treatment Arm]

Conclusions: Reductions in markers of T and B cell activation are characteristic of ART initiation. Reductions in lymphocyte activation modestly correlate with bone loss. However, VitD/Ca supplementation does not appear to mitigate bone loss through modulation of immune activation or expression of RANKL.

TUPEB111

Bone mineral density and prevalence of osteoporosis in HIV-infected patients in comparison with a reference Spanish population: The importance of local normative ranges

C. Sobrino[1], J. Gallego[2], M.J. Vivancos[2], F. Lopez[1], M.J. Perez-Elías[2], J. Loarce[1], M. Vazquez[1], J.L. Casado[2]
[1]Ramon y Cajal Hospital, Rheumatology, Madrid, Spain, [2]Ramon y Cajal Hospital, Infectious Diseases, Madrid, Spain

Background: HIV-infected patients have less bone mineral density (BMD) than non-HIV population. According to current guidelines, the normal BMD reference range is that derived from the US NHANES III (National Health and Nutrition Examination Survey). However, local variations of BMD could change the interpretation of bone loss and the prevalence of osteoporosis (OP) in this population.
Methods: This was a cross-sectional study in a homogenous cohort of HIV-infected patients (RyC cohort, EC 009/17). Data of femoral neck and spine BMD were obtained by DXA (Dual-Energy X-ray Absorptiometry) from 949 patients (241 women, 25%) and compared with the results of a nationally representative Spanish cohort (14 centers) including 2442 subjects (1305 women, 53%) aged 20-80 years.
Results: Overall, mean age was 45.4 yrs (women, 46.5 yrs). The Spanish reference cohort showed a reduced BMD (-7%, 3-12%) in comparison with NHANES, especially in middle aged women. HIV-infected patients had a lower BMD than Spanish cohort in both spine and femoral neck localizations for the different age strata (p< 0.001), not significant in femoral neck for males aged 30-39 (n=152 patients, 0.848 vs 0.869 gr/cm2; p =0.07). Using NHANES data, the prevalence of OP was 26% in women in the Spanish cohort and 41% in our HIV population.
By contrast, if the Spanish data are used as normative range, the prevalence of OP decreased in HIV females, significant between 40-60 years (from 26.5 to 23.5% in spine, p< 0.01).
Although OP in spine was less frequent in males by using Spanish data (p< 0.01, OP decrease from 17.8 to 6.5%), there was more OP in femoral neck in males older than 40 yrs (from 13.5 to 21% in 60-69; p< 0.01).
Conclusions: Our data demonstrate that HIV-infected patients had a significantly reduced BMD in comparison with both US and Spanish reference data for all the age strata.
However, the prevalence of osteoporosis could change if local representative cohorts are used as normative data, with almost 30% of patients being reclassified.

TUPEB112

Abnormal bone histomorphometry in men with HIV infection before and after ART initiation

J. Ramalho[1], C. Steller[1], J. Galvão[2], M. Eira[3], R. Pereira[1], M. Yin[4], T. Nickolas[4], L.M. Reis[1], V. Jorgetti[1], R.M. Moyses[1]
[1]University of São Paulo, São Paulo, Brazil, [2]Universidade 9 de Julho, São Paulo, Brazil, [3]Instituto de Infectologia Emilio Ribas, São Paulo, Brazil, [4]Columbia University, New York, United States

Background: Reduction in bone mineral density (BMD) is a known metabolic complication of HIV infection and antiretrovial therapy (ART). We aimed to investigate changes in bone-related proteins and bone histomorphometry in ART-naïve HIV men initiating treatment with tenofovir disoproxil fumarate (TDF), lamivudine (3TC) and efavirenz (EFV).
Methods: In 16 ART-naïve men with HIV infection, we evaluated bone structure, turnover and mineralization by iliac crest bone biopsy with histomorphometry before and 12 months after ART initiation. Receptor activator of nuclear factor kappa- ligand (RANKL) and fibroblast growth factor (FGF-23) levels in serum and bone were determined using MILLIPLEX@ multiplex assays. Main exclusion criteria were eGFR < 60ml/min/1,73m², metabolic bone disease, cirrhosis, diabetes, and medications affecting bone metabolism. BMD was assessed by DXA.
Results: Mean age was 29..8 years, mean BMI was 24.4±2.4, [MY1] with median viral load of 28,685 (5,628-68,540) copies/mL and mean CD4 of 478±189 cells. At baseline, three patients (19%) had Z score ≤ -2 at any site. Before treatment, 25% had low bone trabecular volume and 19% had decreased cortical thickness. Cortical porosity was normal in all of them. Decreased bone formation rate was seen in 88% and abnormal mineralization lag time in 63%. Increased osteoclastic and eroded surface were seen in 44 and 31%, respectively. We observed reduction in BMD at L1-L4 (-2.1%, p 0,048), FN (-2,8%, p 0.001) and TH (-3%, p 0.04) after 12 months. Histomorphetric study revealed reduction in osteoblastic surface (1.3 [0.5 - 2.3] vs 3.5 [1.8 - 6.4]%, p 0.02) and increase in cortical porosity (3.7 ± 1.7% vs 6.3 ± 3.5%, p 0.049) and thickness (663.5 ± 163.1 vs 886.9 ± 349.4 mm, p 0.04). Reduction in serum RANKL (15.2 [10.0 - 21.9] vs 10.9 [7.5 - 16.8] pg/ml, p 0.049) and FGF-23 (18.1 [13.4 - 25.4] vs 14.11 [8.9 - 21.7], p 0.04) levels were also detected.
Conclusions: Abnormalities in bone volume, turnover and mineralization are common among HIV-infected persons even before ART exposure. Bone loss with TDF, 3TC and EFV was accompanied by changes in cortical parameters and in osteoblastic surface, along with reduction in serum RANKL and FGF-23.

Renal disease

TUPEB113

Renal safety of TAF vs. TDF or ABC in a pooled analysis of 27 Phase 2/3 clinical trials

S.K. Gupta[1], F.A. Post[2], J.R. Arribas[3], A. Pozniak[4], D. Podzamczer[5], A. Clarke[6], T. Mudrikova[7], E. Negredo[8], S. Guo[9], L. Zhong[9], H. Martin[9], E. Quirk[9], D. Sengupta[9], M. Das[9]
[1]Indiana University, School of Medicine, Department of Infectious Diseases, Indianapolis, United States, [2]Kings College London, London, United States, [3]Hospital Universitario La Paz, Madrid, Spain, [4]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom, [5]Hospital Universitari de Bellvitge, Barcelona, Spain, [6]Royal Sussex County Hospital, Brighton, United Kingdom, [7]University Medical Center Utrecht, Department of Internal Medicine, Utrecht, Netherlands, [8]Germans Trias i Pujol University Hospital- Universitat Autònoma de Barcelona, Barcelona, Spain, [9]Gilead Sciences Inc., Foster City, United States

Background: Compared to tenofovir disoproxil fumarate (TDF), tenofovir alafenamide (TAF) has improved renal safety in individual randomized trials. We present pooled analyses of renal safety of TAF vs. TDF or TAF vs. abacavir (ABC) in treatment-naïve and switch studies including over 7500 children and adults.
Methods: We pooled data from 27 studies (7 in treatment-naïve participants, 19 in virologically suppressed, 1 in both treatment-naïve and virologically suppressed adults). Most studies were randomized and double-blinded; pediatric studies were single-arm, open-label. All participants who initiated or switched to TAF-based regimens (elvitegravir/cobicistat/emtricitabine [FTC]/TAF, rilpivirine/FTC/TAF, FTC/TAF, bictegravir/FTC/TAF) were compared with those who initiated or continued regimens containing either TDF or ABC. Rates of participants discontinuing drug due to renal adverse events (AEs) or proximal renal tubulopathy (PRT, determined using common MedDRA terms) from each group were analyzed. We compared urine albumin/creatinine (Cr; UACR), beta-2-microglobulin (B2m):Cr, and retinol binding protein (RBP:Cr) from 11 randomized studies.
Results: 7662 participants were enrolled across studies (n=7595 TAF, n=2668 TDF, n=916 ABC). Baseline median age was 42 years, 19% women, 27% Black. Pooled data included exposure of 12,575 person-years (py) to TAF, 5947 to TDF, and 1029 to ABC. Three vs. 16 (p< 0.001) participants discontinued TAF- vs. TDF-based regimens due to a renal AE. None vs. 10 cases of PRT occurred with TAF vs. TDF (p< 0.001). Participants initiating TAF- vs. TDF- or ABC-based regimens had greater decreases or smaller increases at Week 48 in renal biomarkers (p< 0.05; Table). Participants

switching from TDF to TAF had decreases in tubular proteins at Weeks 48 and 96 (p< 0.001; Table). No differences in proteinuria were noted after switching to TAF- vs. continuing ABC-based regimens.

Conclusions: HIV-1-infected individuals who initiated or switched to TAF had significantly fewer renal AEs, including 0 PRT cases, compared to those on TDF. These pooled data from 27 studies, with over 12,500 py of follow-up in children and adults on TAF, strongly suggest a comparative renal safety advantage for TAF compared to TDF. Finally, initiating TAF vs. ABC was associated with biomarker improvements, and overall results demonstrated that TAF has a renal AE profile that is similar to ABC.

Estimates of glomerular filtration rate in HIV infected individuals using creatinine and cystatin c based measurements

A. Spence[1], R. Teran[2], R. Harold[3], N. Nigam[4], A. Paredes[1], P. Kumar[1], J. Timpone[1], J. Umans[5,6], S. Kassaye[1]
[1]Georgetown University Medical Center, Division of Infectious Diseases and Travel Medicine, Washington, United States, [2]Columbia University, Department of Epidemiology, New York, United States, [3]George Washington University, Division of Infectious Diseases, Washington, United States, [4]University of Chicago, Section of Gastroenterology, Hepatology, and Nutrition, Chicago, United States, [5]Medstar Health Research Institute, Hyattsville, United States, [6]Georgetown-Howard Universities Center for Clinical and Translational Science, Washington, United States

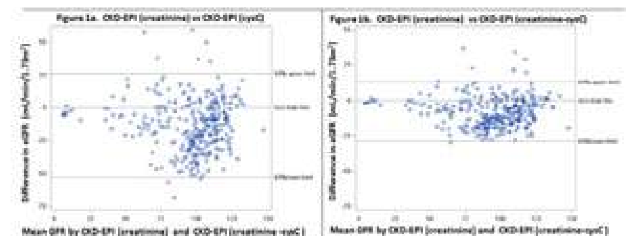
Background: Development of chronic kidney disease (CKD) in individuals with HIV is multifactorial, affected by virus, viral co-infection, and/or antiretroviral (ARV) use. Assessing kidney dysfunction by accurate estimations of glomerular filtration rate (GFR) is important for HIV therapeutic decisions. We compared GFR estimates (eGFR) using creatinine and cystatin c (cysC) based equations.

Methods: Participants were enrolled in a cross-sectional study. Demographics and creatinine (IDMS-creatinine standardized) were abstracted from the medical record. CysC was measured in a certified laboratory using an immunoassay standardized to the ERM®-DA471/IFCC reference. GFRs were calculated using Chronic Kidney Disease Epidemiology Collaboration creatinine (CKD-EPIc), CKD-EPIc-cysC (creatinine + cysC), and CKD-EPIcysC (cysC) equations (creatinine + cysC). Participants with at least two creatinine-based estimates of GFR < 60 were considered to have CKD. Agreement was assessed by the Bland-Altman method.

Results: Among 306 HIV-infected participants, the median age was 49(range: 21-83), 216(71%) were male, and 182(60%) African-American. The baseline median CD4+ was 640mm3 (IQR 454-808), 94% had an HIV RNA < 200c/mL, and only 7(2%) were not on ARVs. 44(15%) had HIV/HCV co-infection, and 20(7%) had HIV/HBV co-infection. CysC measurements were performed on 301(98%), and 36(11%) had CKD.

Plots of differences between eGFR by creatinine only versus cysC-containing (figure 1a) or creatinine only versus cysC with creatinine (figure 1b) demonstrated varying limits of agreement. The 95% limits of agreement were wider, -68.5 and 59.3 mL/min/1.73m2 (CKD-EPIc and CKD-EPIcysC) vs -29.6 and 36.9 (CKD-EPIc and CKD-EPIc-cysC). Percent agreement between estimates was 65.4% (CKD-EPIc and CKD-EPIcysC) vs 73% (CKD-EPIc and CKD-EPIc-cysC). There were differences in classification across stage I and II categories of kidney function, with use of cysC leading to more participants classified in stage I (CKD-EPIcysC 76% and CKD-EPIc-cysC 73%) compared to 54% in stage I using the CKD-EPIc estimate (table 1).

Conclusions: Both CKD-EPIc-cysC and CKD-EPIcysC GFR estimates demonstrated varying agreement with CKD-EPIc in this predominantly African-American cohort, with 20-23% of individuals with stage I disease by cysC differentially categorized as stage II using creatinine-only based estimates. Further studies are needed that provide a longitudinal assessment of factors, including race, that mediate differences between cysC-based versus creatinine-based estimates of GFR in HIV-positive individuals.



[Figure 1 (Bland Altman Plot): Figure 1a plots agreement between a creatinine based estimate of GFR and a cysC based estimate. Figure 1b plots agreement between a creatinine based estimate of GFR and a creatinine-cysC-based estimate.]

STAGE	CKD-EPI Creatinine No.(%)	CKD-EPI Cystatin C No.(%)	CKD-EPI Creatinine-Cystatin C No.(%)
I	163 (54%)	229 (76%)	219 (73%)
II	102 (34%)	47 (16%)	56 (19%)
IIIa	19 (6%)	9 (3%)	12 (4%)
IIIb	9 (3%)	8 (3%)	6 (2%)
IV	0 (0%)	1 (0%)	1 (0%)
V	8 (3%)	7 (2%)	7 (2%)
Stage I = GFR >90 mL/min per 1.73m^2; Stage II - GFR 60 to 89 mL/min per 1.73m^2; Stage IIIa - GFR 45 to 59 mL/min per 1.73m^2; Stage IIIb - GFR 30 to 44 mL/min per 1.73m^2; Stage IV - GFR 15 to 29 mL/min per 1.73m^2; Stage V - GFR <15 mL/min per 1.73m^2 or treatment by dialysis

TUPEB115

The prevalence of impaired renal function in well-treated people living with HIV is low but remains higher than in uninfected controls

N. Petersen[1], A. Dehlbæk Knudsen[1], A. Mocroft[2], D. Kirkegaard-Klitbo[1], E. Arici[1], J. Lundgren[3], T. Benfield[4], P. Oturai[5], B. Nordestgaard[6,7], B. Feldt-Rasmussen[8], S. Dam Nielsen[1], L. Ryom[3]
[1]Rigshospitalet, Viro-Immunology Research Unit, Department of Infectious Diseases, Copenhagen, Denmark, [2]Institute for Global Health, UCL, Centre for Clinical Research, Epidemiology, Modelling and Evaluation (CREME), London, United Kingdom, [3]CHIP, Center of Excellence for Health, Immunity and Infections, Department of Infectious Diseases, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [4]Hvidovre Hospital, Department of Infectious Diseases, Copenhagen, Denmark, [5]Rigshospitalet, Department of Clinical Physiology, Nuclear Medicine and PET, University of Copenhagen, Copenhagen, Denmark, [6]Herlev and Gentofte Hospital, The Copenhagen General Population Study, Department of Clinical Biochemistry, Copenhagen, Denmark, [7]University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, Denmark, [8]Rigshospitalet, Department of Nephrology, Copenhagen, Denmark

Background: The prevalence of renal diseases appears to be higher among people living with HIV (PLWH) compared to HIV-negative persons, although previous studies focused in populations at increased risk of renal disease, such as those with uncontrolled HIV infection, of African descent or with hepatitis C (HCV) coinfection. We therefore aimed to determine if HIV is an independent predictor of impaired renal function in HIV-populations without these risks compared to that in matched uninfected controls.
Methods: Caucasian PLWH, virologically suppressed on combination antiretroviral treatment, without IDU, or HCV co-infection were recruited from the Copenhagen comorbidity in HIV infection (COCOMO) study. Sex and age matched uninfected controls were recruited from the Copenhagen General Population Study. We defined impaired renal function as estimated glomerular filtration rate (eGFR) ≤60 mL/min/1.73m² in a single measurement and assessed associated factors using logistic regression adjusting for age, sex, BMI, cumulative smoking, diabetes, hypertension, and educational level.
Results: Among 598 PLWH and 2,598 controls, the prevalence of impaired renal function was 4% (95%CI: 2%-5%) and 2% (95%CI: 1%-2%), respectively. After adjustment, HIV status was independently associated with impaired renal function, odds ratio (OR): 3.4 (95%CI: 1.8-6.3). Aside from HIV, older age (OR per decade older: 5.3 [95%CI 3.9-7.2]), male sex (OR: 4.3 [95%CI 2.2-8.3]), and diabetes (OR: 2.9 [95%CI 1.2-6.7]) were independently associated with impaired renal function. Among PLWH, mode of transmission, current CD4 T cell count, CD4 T cell nadir, time with HIV and previous AIDS-defining diagnosis were not associated with impaired renal function. The association between HIV and impaired renal function increased as persons aged (p=0.02, test for interaction).
Conclusions:

	PLWH (N=598)	Uninfected controls (N=2,598)	PLWH with impaired renal function (N=21)
Age, median (IQR)	51 (44-60)	51 (44-60)	72 (67-75)
Sex (male), n (%)	530 (89)	2313 (89)	15 (72)
Diabetes, n (%)	27 (5)	10 (4)	4 (19)
Hypertension, n (%)	266 (46)	1458 (56)	18 (86)
BMI (kg/m2), median (IQR)	24 (22-27)	26 (24-29)	23 (20-27)
Pack-years, median (IQR]	19 (8-33)	15 (6-26)	19 (15-40)
Serum creatinine, mg/dl, median (IQR)	83 (76-92)	82 (75-89)	111 (94-129)
eGFR, ml/min/1.73m2 (CKD-EPI), median (IQR)	89 (78-100)	91 (82-100)	56 (48-58)
eGFR ≤60 ml/min/1.73 m2, n (%)	21 (4)	43 (2)	21 (100)

[Characteristics]

The prevalence of impaired renal function was low among well-treated PLWH with few other risk factors for impaired renal function. However, the prevalence of impaired renal function, even in this low-risk group, remained higher than in uninfected controls. HIV was an independent risk factor and the impact of HIV seemed to be accentuated among older individuals. Impaired renal function, albeit relatively rare in well-treated PLWH, therefore still remains a concern requiring ongoing attention and monitoring.

Metabolic, lipid and endocrine complications, including obesity and lipodystrophy

TUPEB116

Triglycerides/glucose index is a simple and clinically useful surrogate for insulin resistance among non-diabetic HIV-infected Aging in Asia

T. Apornpong[1], N. Sookkasame[1], S. Sakulrak[1], A. Hiransuthikul[1], W.M. Han[1], S. Gatechompol[1], S. Kerr[1], L. Wattanachanya[2], K. Ruxrungtham[1,3], A. Avihingsanon[1], HIV-NAT 207 Study Team
[1]HIV-NAT, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Division of Endocrinology and Metabolism, Department of Medicine, and Hormonal and Metabolic Disorders Research Unit, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]Chulalongkorn University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand

Background: Insulin resistance (IR) is associated with a cluster of abnormalities that increase cardiovascular diseases (CVDs). Direct measurement of insulin resistance are clinically impractical. Several indices including 1) metabolic syndrome (Mets), 2) plasma triglyceride/high-density lipoprotein cholesterol ratio (TG/HDL-C index) and 3) Plasma triglyceride x glucose (TyG) index have been proposed to identify individuals who are insulin resistant. We aimed to evaluate the abilities of TyG index and TG/HDL-C to predict IR among Asian HIV-infected aging (≥50 years old) patients without diabetes, who received ART for a median of 16 years.
Methods: We enrolled 285 virologically suppressed HIV-infected Thais without overt diabetes mellitus/CVD to this analysis. Homeostatic model assessment (HOMA-IR) was used to establish insulin resistance using a cut off of >2. The TyG index was calculated as ln[triglycerides (mg dl^{-1}) × fasting glucose (mg dl^{-1})/2]. Pearson's correlation coefficients were used to assess the linear relationship between TyG index, HOMA-IR and ASCVD, and ROC analysis was used to assess threshold cutoffs.
Results: 58.25% were males with median age 54 yrs, BMI of 23 kg/m2. In the IR group, hypertension, body mass index (BMI), waist hip ratio, body fat, visceral fat rating, fasting insulin, fasting plasma glucose, triglyceride levels, TG/HDL-C index, TyG index and Mets were significantly higher than in the non-IR group.
The median TyG index was significantly different between the IR group (N=84) and non-IR group (N=201), at 9.1 (IQR8.7-9.4) and 8.7 (IQR 8.3-9.1), respectively (P< 0.001).
The median TG/HDL-C index was significantly higher among the IR group than non-IR group [4.3 (IQR 2.8-6.3) vs 2.8 (IQR 1.8-4.5); P< 0.001]. The TyG index and TG/HDL-C were well correlated with HOMA-IR (r=0.39; P< 0.001 and r=0.31; P< 0.001, respectively).
The TyG index showed a strong positive association with ASCVD (r=0.35; P< 0.001). The cut-off of the TyG index for diagnosis of insulin resistance was 9.0 with sensitivity 0.61 and specificity 0.72. HOMA-IR score increased by 57% for every 1 unit increase in TyG.
Conclusions: Compared with HOMA-IR, the TyG index is a simple, and clinically useful surrogate marker of insulin resistance among Aging HIV-infected patients.

TUPEB117

Obesity and inflammation in HIV+ mono-infected individuals on antiretroviral therapy (ART) in the Miami Adult Studies in HIV (MASH) cohort

J. Hernandez, M. Mudgal, A. Campa, S. Martinez, L. Seminario, J. Jasmin, A. Johnson, C. Teeman, Q. Liu, M.K. Baum
Florida International University, Miami, United States

Background: Obesity is becoming increasingly prevalent in People Living with HIV (PLWH). In the U.S., 22% and 18% of PLWH are overweight and obese. These prevalence rates are comparable to the national average, and are higher among minorities. Obesity is independently associated with systemic inflammation in PLWH. In HIV-infected individuals on ART, levels of inflammation tend to decrease.

However, HIV infection is associated with chronic low-level inflammation even after years of ART use. The purpose of this study is to determine the association between obesity and inflammation in HIV+ mono-infected and HIV/HBV/HCV un-infected individuals.
Methods: Participants were selected from the ongoing Miami Adult Studies in HIV (MASH) cohort. The HIV mono-infected participants were on stable ART. Obesity (BMI ≥30kg/m²) was obtained from the anthropometric assessment. Blood samples were collected to assess inflammation and lipid panel. Inflammation was assessed with high sensitivity C-reactive protein (hsCRP) levels > 3 mg/L; a commercial laboratory determined the lipid panel. Descriptive statistics, Wilcoxon test, and regression analyses were used to analyze the data.
Results: There were 384 participants; mean age was 53.6±8.3 SD years, 56% were male and 63% Black non-Hispanics; 65% (n=251) were HIV mono-infected and the rest were not infected. Obesity was significantly associated with higher hsCRP levels among HIV mono-infected compared to un-infected individuals (P< 0.001). Multiple regression showed that in the HIV mono-infected group, obesity was also strongly related to hypertriglyceridemia (P< 0.001), lower HDL cholesterol levels (P=0.002), and hyperglycemia (P< 0.001). Compared to uninfected, the HIV mono-infected group had higher triglycerides levels [median 112.5 (IQR=81-171) vs. 97 (IQR=69-151), (P=0.004)] and lower HDL levels [median 54 (IQR=44-68) vs. 56 (IQR=47-71), (P=0.038)]. Obese HIV mono-infected individuals were 2.64 times more likely to have high levels of inflammation (OR=2.64, 95% CI:1.516-4.590, P < 0.001) than those of normal weight (BMI < 25kg/m²) after controlling for age, gender and smoking status.
Conclusions: Obese HIV mono-infected participants on stable ART had high levels of inflammation, dyslipidemia and hyperglycemia. These risk factors contribute to chronic low-grade inflammation, creating an inflammatory environment that promotes disease progression and increase in non-AIDS co-morbidities including metabolic syndrome, cardiovascular diseases, and diabetes.

TUPEB118

No evidence of increased risk of thyroid dysfunction in well-treated people living with HIV

M. Harsløf[1], A. Dehlbæk Knudsen[1], T. Benfield[2], J. Lundgren[1], B. G. Nordestgaard[3,4], U. Feldt-Rasmussen[5], S. Dam Nielsen[1]
[1]Rigshospitalet, University of Copenhagen, Viro-immunology Research Unit, Department of Infectious Diseases, Copenhagen, Denmark, [2]Hvidovre Hospital, University of Copenhagen, Department of Infectious Diseases, Copenhagen, Denmark, [3]Herlev Hospital, University of Copenhagen, The Copenhagen General Population Study, Department of Clinical Biochemistry, Herlev and Gentofte Hospital, Herlev, Denmark, [4]University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, Denmark, [5]Rigshospitalet, University of Copenhagen, Department of Medical Endocrinology, Copenhagen, Denmark

Background: Autoimmune thyroid diseases have been reported following immune reconstitution and older observational studies without uninfected controls have suggested an increased prevalence of thyroid dysfunction in people living with HIV (PLWH).
Our primary aims were to investigate the prevalence and associated risk factors of thyroid dysfunction in well treated PLWH and matched uninfected controls and to examine whether HIV is independently associated with thyroid dysfunction in the modern combination antiretroviral therapy (cART) era.
Methods: 826 PLWH from the Copenhagen co-morbidity in HIV infection (COCOMO) Study were frequency matched on age and sex with 2,503 uninfected controls recruited from the Copenhagen General Population Study. Thyroid stimulating hormone (TSH), free thyroxine, total thyroxine and total triiodothyronine were measured, and medical treatment for hypo- or hyperthyroidism was recorded. We used multinomial logistic regression adjusting for age, sex, ancestry, smoking, alcohol, diabetes, high-sensitivity C-reactive protein and estimated glomerular filtration rate to examine the association between HIV and thyroid dysfunction and multivariate linear regression to study the association between HIV and serum TSH concentrations. Further multinomial regression in PLWH was used to examine the association between HIV-related risk factors (CD4 T cell count, CD4 T cell nadir, and duration of HIV) and hypothyroidism and hyperthyroidism.
Results: The PLWH were generally well-treated with 95% having undetectable viral replication. Among PLWH and controls 31 (3.8%) and 114 (4.6%) had hypothyroidism, and 7 (0.8%) and 21 (0.8%) had hyperthyroidism, respectively. In adjusted analyses, we found no significant associations between HIV and hypothyroidism OR 0.8 [0.6, 1.3] p = 0.40 or between HIV and hyperthyroidism OR 1.1 [0.5, 2.5] p=0.91. Serum TSH concentration was comparable for HIV infected and uninfected individuals (p=0.6). HIV-related risk factors were not associated with hypothyroidism or hyperthyroidism.
Conclusions: The prevalence of hyperthyroidism and hypothyroidism was similar in well treated PLWH and uninfected controls. HIV status was not associated with thyroid dysfunction or with serum TSH concentration. CD4 T cell counts, CD4 T cell nadir and duration of HIV were not associated with hypothyroidism or with hyperthyroidism. Thus, in well-treated PLWH there was no evidence of increased risk of thyroid dysfunction.

Thyroid function	PLWH n=826	Uninfected controls, n=2,503	p
Medical treatment for hypothyroidism, n (%)	5 (0.6)	38 (1.5)	0.07
Medical treatment for hyperthyroidism, n (%)	3 (0.4)	7 (0.3)	0.99
Biochemical thyroid function, n (%)			0.86
Euthyroid	787 (96.3)	2,366 (96.3)	
Overt hypothyroidism	8 (1.0)	16 (0.7)	
Subclinical hypothyroidism	18 (2.2)	61 (2.5)	
Overt hyperthyroidism	1 (0.1)	3 (0.1)	
Subclinical hyperthyroidism	3 (0.4)	11 (0.4)	

[Table 1: Medical treatment for thyroid dysfunction and results from thyroid function assays in nontreated PLWH and uninfected controls]

TUPEB119

Higher prevalence of insulin resistance among non diabetes HIV-infected ageing Asian received long term ART compared to HIV uninfected control

T. Apornpong[1], N. Sookkasame[1], S. Sakulrak[1], A. Hiransuthikul[1], W.M. Han[1], S. Gatechompol[1], L. Wattanachanya[2], J. Jamthong[1], S.J. Kerr[1,3], A. Sangarlangkarn[1], K. Ruxrungtham[1,4], A. Avihingsanon[1], HIV-NAT 207 Study Team
[1]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Division of Endocrinology and Metabolism, Department of Medicine, and Hormonal and Metabolic Disorders Research Unit, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]Kirby Institute, University of New South Wales, Sydney, Australia, [4]Chulalongkorn University, Research and Innovation, Bangkok, Thailand

Background: Insulin resistance (IR), a risk factor for type 2 diabetes mellitus (T2DM) and cardiovascular disease, is increasingly seen in HIV-infected patients. Asians typically have higher visceral fat compared to non-Asians at the same body mass index (BMI). We determined the prevalence and predictors of IR, in an ageing population of HIV positive who received long term ART and age/sex matched HIV-negative controls.
Methods: A cross sectional study was conducted in Bangkok among 297 HIV infected and 86 HIV negative controls aged ≥50 years without overt T2DM. Homeostatic model assessment (HOMA-IR) was used to establish IR, using a cut off of >2. Visceral fat rating was measured using body impedance assessment, and liver fibrosis was performed by Fibroscan. Multiple logistic regression was performed to find associations between IR and potential risk factors.
Results: Participants were male (60%) with median (IQR) age 54.4 (51.9-58.3) years. Most were non-smokers and reported no alcohol consumption. HIV positive had been taking ART for a median of 16.1 (11.9-19.1) years and 97% had HIV RNA< 50 c/mL. Baseline characteristics amongst study groups were similar, but compared to HIV-negative participants, HIV-positive participants had lower BMI (median 22.8 vs 24.6kg/m²), percent body fat (23%VS 25.4%), and visceral fat rating in the high range (26% VS 44%), but higher prevalence of hypertension (HT) (37% VS 20%) and Hepatitis C (10% VS 2%). IR was prevalent in 29% of HIV-positive compared to 16% in HIV-negative participants. In an adjusted model (Table 1), IR was associated with HIV status (adjusted odds ratio [aOR] 5.22

(95%CI 1.91 - 14.24); P=001), HT (aOR 2.8 (95%CI 1.48-5.28); P=0.002) , hs-CRP >3mg/L (aOR 2.35 (95%CI 1.15 - 4.79); P=0.02), high visceral fat scores (aOR 3.87 (95%CI 1.81 - 8.29); P=0.001 and higher liver fibrosis scores (aOR 1.08 (95%CI 1.002 - 1.17); P=0.045). Association of ART regimen and IR was not observed.

Conclusions: Despite having lower BMI and body fat, aging HIV-infected patients had a significantly higher prevalence of IR compared to HIV negative controls. Apart from HIV infection, IR in our cohort was associated with HT, high hs-CRP, visceral fat rating and liver fibrosis.

		Univariate			Multivariate	
Risk factors	OR	95%CI	p	aOR	95%CI	p

At risk alcohol consumption increases risk for metabolic comorbidities in persons living with HIV (PLWH)

P. Molina[1], L. Simon[2], D. Welsh[2], T. Ferguson[2], M. Brashear[2], S. Primeaux[2], D. Mercante[2]
[1]*Louisiana State University Health Sciences Center, Physiology and Alcohol Research Center, New Orleans, United States,* [2]*LSUHSC, New Orleans, United States*

Background: Reduced HIV mortality in the post-ART era and increased survival of PLWH is associated with an increased risk of metabolic comorbidities. Similarly, at risk alcohol consumption is associated with increased risk for comorbidities, and its prevalence is higher in PLWH. Our preclinical studies show that chronic binge alcohol administered simian immunodeficiency virus (SIV)-infected ART male rhesus macaques develop metabolic dyshomeostasis despite the absence of fasting dysglycemia. We hypothesized that at risk alcohol use increases the prevalence of metabolic dyshomeostasis in PLWH.

Methods: PLWH (N=365; 69% male; 84% African American; mean age 48.2 ±10 yrs), in care were enrolled in our ongoing longitudinal translational study. Measures of insulin resistance (IR; by homeostasis model assessment (HOMA), lipid profile, Bennet index, and insulin sensitivity index (McAuley index) corrected for fat free mass (Mffm), alcohol use (self-report and phosphatidylethanolamine (Peth)), and body composition were obtained. Multivariable linear and logistic regression analyses were performed to assess associations between metabolic parameters and alcohol consumption.

Results: 40.3% of subjects met at risk drinking criteria (AUDIT ≥8) and 48.5% met IR criteria (HOMA-IR >1.9). Visceral adiposity index (VAI) calculated as (waist:hip circumference/ lean mass:total mass) was higher in women than in men (median 0.60 in women vs. 0.29 in men). IR (HOMA-IR, and Bennet index) was associated with alcohol use (Time Line Follow Back and PEth), after adjusting for gender, age, waist circumference (p-value< 0.05). Frequency of elevated HOMA-IR was 60.7% in PEth positive PLWH in contrast to only 39.2% in PEth negative PLWH. IR (Mffm) index was associated with increasing AUDIT and PEth (p-value = 0.01). In women, menopausal status was an effect modifier of the association of alcohol use and IR.

Conclusions: These findings indicate a positive association of alcohol use and IR in PLWH. Our current studies will further elucidate the potential mechanisms, and whether lifestyle interventions such as exercise can ameliorate the disease burden in these individuals.

TUPEB121

Weight gain after ARV initiation correlates with increased inflammatory biomarkers and protease inhibitor usage

E. Laidlaw[1], A. Gouel-Cheron[1], S. Kuriakose[2], A. Pau[1], A. Rupert[2], M. Nason[1], V. Sheikh[1], J. Mican[1], M. Manion[1], I. Sereti[1]
[1]*NIAID/NIH, Bethesda, United States,* [2]*Leidos Biomedical Research, Inc., Frederick, United States*

Background: People with HIV (PWHIV), despite viral suppression on ART, are at greater risk for metabolic diseases, possibly compounded by obesity. Greater weight increases have been associated with lower CD4 counts and higher viral loads (VL) at pre-ART, and with specific ARV class. Higher levels of IL-6 and CRP have been associated with obesity in PWHIV. We hypothesized greater weight gain after ART initiation is associated with immune dysregulation and inflammation.

Methods: ART-naïve participants with CD4 < 100 cells/μL were enrolled in a prospective study, initiated on ART, and followed for 160 weeks (wk). Participants who were lost to follow-up, had VL >500 c/mL at wk160, or became pregnant were excluded from this analysis.

Participants' BMI were calculated at wk 0, 48, 160 and were categorized as underweight/normal (BMI< 25), overweight (BMI 25-30), and obese (BMI >30). Percent weight change from 0-48 weeks and from 0-160 weeks were grouped into changes < 0%, 0-10%, 10-30%, and >30%. Non-parametric testing (Kruskal-Wallis, Spearman Rank), Fisher Test, and linear regression were used for all analyses.

Results: 143 participants were included, baseline characteristics are listed in Table 1. Median percent weight change was +14% (IQR 7.7%; 24%) at wk48 and +18% (7%; 28%) at wk160. At wk0, 46 (32%) participants were overweight or obese, which increased to 102 (71%) at wk160. There was no statistical difference between BMI at wk160 and baseline OI (p=0.24) or CD4 (p=0.601). Regression analysis was performed on five biomarkers at wk160 and weight change. Only CRP (p=0.009) and sCD14 (p=0.007) had a significant correlation. Since the largest weight gain occurred in the first year, further analysis at wk48 was done. In a multivariate linear regression, adjusting for baseline OI, CD4, age, and gender, ART regimen was significantly associated with weight change at wk48: negatively with NNRTI (p=0.012), positively with PI (p=0.001), but not with InSTI (p=0.38).

Conclusions: Significant weight gains are observed in HIV participants starting ART at low CD4 counts that can lead to obesity with higher levels of persistent inflammation. Differences in regimen may be related to selection bias and should be addressed in trials with randomized treatments.

	Patients (n=143)
Gender, n (%)	Male: 103 (72%); Female 40 (28%)
Age pre-ART (years), median (IQR)	39 (31; 46)
Race, n (%)	Black 78 (55%); White 48 (33%); Indian/Alaskan Native 1 (1%); Multiple Races 11 (8%); Unknown 5 (3%)
Ethnicity, n (%)	Hispanic/Latino 55 (39%); Not Hispanic/Latino 86 (61%)
BMI, mean (IQR)	Pre-ART 23.4 (20.5; 25.8)
Cholesterol (mg/dL), median (IQR)	Total 147 (123; 175); Triglycerides 144 (100; 198); HDL 35 (26; 46); LDL 84 (62; 104)
CD4 (cells/μL), median (IQR)	Pre-ART 22 (9; 50)
Viral Load pre-ART (log 10 copies/ml), mean (IQR)	5.12 (4.69; 5.5)
ARV Class Initiated at week 0	PI 41 (28.7%); NNRTI 91 (63.6%); InSTI 21 (14.7%)

TUPEB122

Obesity, overweight and NCDs in HIV+ patients in urban DREAM centres in Mozambique: A review of routine clinical data

F. Ciccacci[1], A.M. Doro Altan[2], A. Passanduca[3], E. Mutemba[3], N. Majid[3], S. Orlando[1], S. Mancinelli[1], P. Scarcella[1], L. Palombi[1], M.C. Marazzi[4]
[1]University of Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy, [2]Community of S. Egidio, DREAM Program, Rome, Italy, [3]Community of S. Egidio, DREAM Program, Maputo, Mozambique, [4]LUMSA University, Rome, Italy

Background: Economic growth in African countries is driving to new health challenges for health systems. Despite nutritional interventions to reduce impact of wasting, especially in HIV programs, few epidemiological data about overweight, obesity and NCDs are available. Mozambique is one of the most HIV affected countries in the world (83.000 new HIV infections in 2016), and is now experiencing the raise of new health concerns linked to increase of life expectancy of general population and HIV+ patients.

Methods: A retrospective analysis of routine clinical and laboratory data from HIV+ patients collected in 3 urban health centers (Maputo, Machava and Beira) run by DREAM program in Mozambique was carried out. All HIV+ patients aged>18 years, attending the centers in the period 1-Jan-2017 to 23-Jan-2018 were considered. Nutritional status was evaluated through BMI: < 18.5 wasting, 18.5-24.9 normal weight, 25-29.9 overweight, >30 obesity.

Results: Files from 12,946 patients (69.4% women) in ART were analyzed. Median age, BMI, HB and CD4 were respectively: 40 years (34-48 - n.12,946) 23.5kg/m2 (20.8-27.4 - n.12,946), 12.2mg/dL (11.1-13.3 - n.13,431) 497cell/mm3 (342-665 - n.13,389), 82.9% of patients (7,513/9,965) with a VL measurement in the period were < 400copies/mL.

Nutritional status was as follows: 997(7.7%) were malnourished, 6,953(53.7%) normal weight, 3,133(24.2%) over-weight, 1,863(14.4%) obese. In a logistic regression model, obese and overweight patients were more likely women (OR=2.2 CI:2.05-2.49), had CD4 count>200cell/mm3 (OR=1.9 CI:1.61-2.24), had better housing conditions (OR=1.6 CI:1,30-2.16) and a secondary school degree (OR=1.2 CI:1.15-1.43).

In a multivariate analysis, patients with BMI>24.9 had increased risk of being affected with hypertension (OR=2.8 CI:1.78-4.47), diabetes (OR=6.6 CI:1.37-32.52) and eGFR< 90ml/min (OR=1.4 CI:1.20-1.76).

Conclusions: Obesity and overweigh are common among PLWH on treatment in Mozambique, and requires special interventions. New epidemiology challenges are arising with the improvements of socio-economic conditions of African patients and health programs should pay special attention to overweight, obesity and related NCDs.

TUPEB123

Incidence and risk factors for type 2 diabetes mellitus in HIV-positive adults in TAHOD

Background: Comorbidities including diabetes mellitus (DM) among HIV-infected adults are of increasing clinical concern in the combination antiretroviral therapy era (cART). Studies have shown that hepatitis C (HCV) co-infection is linked to the development of type 2 DM in HIV-infected adults. We aimed to determine incidence and risk factors associated with DM in HIV-positive adults in Asian settings.

Methods: HIV-positive patients from the TREAT Asia HIV Observational Database (TAHOD) without DM prior to ART initiation were included in the analysis. DM was defined as having a fasting blood glucose ≥126 mg/dL, HbA1C ≥6.5%, a 2-hour plasma glucose ≥200 mg/dL, or a random plasma glucose ≥200 mg/dL. HCV co-infection was defined by a positive anti-HCV antibody test. Cox regression models, stratified by site, were used to identify risk factors associated with DM.

Results: Of 1927 patients included, 127 patients were diagnosed with DM after ART initiation. Median follow-up time from ART initiation was 5.9 years (IQR: 2.8-8.9 years). The crude incidence rate of DM was 1.08 per 100 person-years (100PYS), 95% confidence interval [CI] (0.9-1.3). The incidence of DM was 1.18 per 100PYS among patients with positive anti-HCV, and 1.05 per 100PYS in HCV negative patients. Positive anti-HCV was not associated with DM in the univariate analysis (p=0.22). In multivariate analysis, age 41-50 years (hazard ratio [HR]: 2.90, 95% CI: 1.46-5.76, p=0.002) and age >50 years (HR: 5.0, 95% CI: 2.34-10.75, p< 0.01) compared to age ≤30 years, body mass index (BMI) >30 kg/m^2 (HR: 3.98, 95% CI: 1.37-11.58, p=0.011) and high blood pressure (HR:1.83 95% CI: 1.00-3.36, p=0.050) were significantly associated with the development of DM. The hazard was reduced for female sex (HR: 0.51, 95% CI: 0.29-0.9, p=0.021).

Conclusions: Type 2 DM in this Asian cohort of HIV-infected adults is common and associated with hypertension, BMI and age but not HCV co-infection; early detection and proper management of DM are essential.

TUPEB124

Immune activation and insulin resistance: Evaluating the association between microbial translocation and insulin resistance in HIV-infected adults in Uganda; a cross-sectional analysis

M. Reid[1], I. Golovaty[1], Y. Ma[1], S. Okello[2], R. Sentongo[2], M. Feng[3], A. Tsai[4], B. Kakuhikire[2], R. Tracy[5], P. Hunt[6], M. Siedner[2], P. Tien[1]
[1]UCSF, Department of Medicine, San Francisco, United States, [2]Mbarara University of Science & Technology, Department of Medicine, Mbarara, Uganda, [3]Massachusetts General Hospital, Department of Medicine, Boston, United States, [4]Massachusetts General Hospital, Department of Psychiatry, Boston, United States, [5]University of Vermont, Department of Pathology and Laboratory Medicine, Burlington, United States, [6]UCSF, Department of Experimental Medicine, San Francisco, United States

Background: Microbial translocation and resulting immune activation are hypothesized to contribute to insulin resistance (IR) among people with HIV. Yet, whether microbial translocation and/or monocyte activation are drivers of IR in HIV+ adults in East Africa, where genetics, environmental exposures, and HIV disease treatment differ substantially from North American and European countries, is unknown.

Methods: Using multivariable regression analysis, we evaluated associations of HIV infection and homeostasis model assessment of insulin resistance (HOMA-IR) in 297 adults (70 HIV+ women, 79 HIV+ men, 73 HIV- women, 76 HIV- men) from the UGANDAC cohort. We aimed to determine whether intestinal fatty acid binding protein (I-FABP), monocyte activation markers soluble (s)CD14 and sCD163, and the pro-inflammatory cytokine interleukin 6 (IL-6) mediated this association. We excluded individuals with a diagnosis of diabetes.

Results: HIV+ and HIV- participants were of similar mean age (51 years) and body mass index (BMI) (23kg/m^2). Mean (standard deviation [SD]) HOMA-IR was significantly greater in HIV+ participants (2.5 [SD=3.8] vs. 1.8 [SD=2.4]) p=0.043). Markers of immune activation and I-FABP were generally higher among HIV+ compared to HIV- participants. In multivariable regression analyses, HIV infection was associated with 37% greater HOMA-IR than those without HIV infection (Table);greater BMI and female sex were also associated with greater HOMA-IR in adjusted models. Addition of sCD14 to models strengthened the association of HIV-serostatus and female sex with HOMA-IR. Neither addition of sCD163 nor I-FABP affected these associations. In models restricted to HIV+ only, neither CD4 nadir nor pre-treatment viral load were associated with greater HOMA-IR, but BMI (7%, 95% CI: 2%, 13%) and female gender (73%, 95% CI: 18%, 154%) were.

Conclusions: HIV infection is associated with greater IR in Uganda. This association was not mediated by decreased gut integrity. Interestingly, the association of IR with HIV infection and female gender were strengthened after adjustment for sCD14 but not sCD163, and the association of BMI was not altered by either immune marker, suggesting the possibility of distinct immune pathways to IR in Uganda. Further study is needed to understand the relationship of HIV, obesity, and sex hormones on IR in this setting.

TUPEB125

Immunosuppression and HIV viremia associated with increased atherogenic cholesterol concentrations in older people with HIV

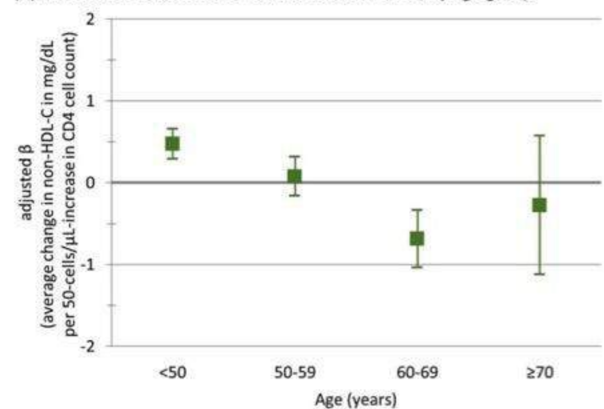
M. Levy, A. Greenberg, M. Magnus, N. Younes, A. Castel, DC Cohort Executive Committee
Milken Institute School of Public Health at the George Washington University, Department of Epidemiology and Biostatistics, Washington, United States

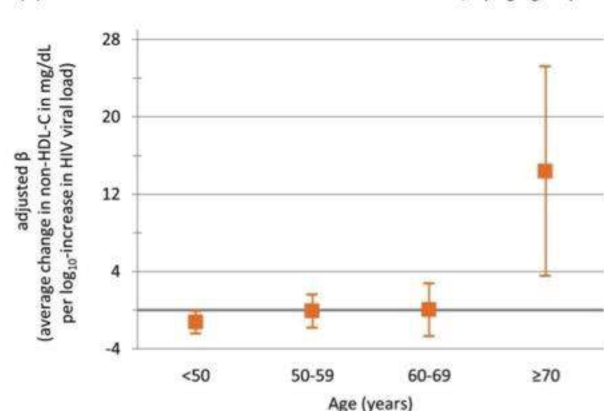
Background: Immunosuppression and HIV viremia have been associated with unfavorable lipid profiles. Prior research has also shown that older HIV-infected persons may have a greater prevalence of metabolic and cardiovascular disease than is expected due to the independent effects of HIV and age alone. To explore reasons for this disproportionate burden, we investigated whether associations of CD4 count and HIV viral load (VL) with non-high-density lipoprotein cholesterol (non-HDL-C) and HDL-C differed by age.

Methods: Longitudinal clinical and laboratory data were collected between 2011-2016 for HIV-infected outpatients enrolled in the DC Cohort study, a multicenter prospective observational study in Washington, DC. Using data for 3,912 patients aged ≥21 years with ≥1 cholesterol result and contemporaneous CD4/VL results, we conducted multivariable linear regression with generalized estimating equations to model non-HDL-C and HDL-C concentrations. Pairwise interaction terms among CD4 count, HIV VL, and age were included and followed by stratified analyses.

Results: Among 3,912 patients (median age 50; 78% male; 76% Black), 8% had CD4 count ≤199 cells/μL and 18% had HIV VL ≥200 copies/mL. Associations between CD4 count/VL and non-HDL-C concentrations differed by age. Higher CD4 count was associated with higher non-HDL-C among patients aged ≤49 (=+0.47 mg/dL per 50-cells/μL-increase in CD4 count [95% CI: 0.29, 0.65]), but was associated with lower non-HDL-C among patients aged 60-69 (=-0.69 mg/dL [95% CI: -1.04, -0.34]) (CD4-age interaction, p< 0.001) (Figure). Higher log10 VL was associated with lower non-HDL-C among patients aged ≤49 (=-1.26 mg/dL per log10-increase in VL [95% CI: -2.44, -0.09]), but was associated with higher non-HDL-C among patients aged ≥70 (=+14.37 mg/dL [95% CI: 3.54, 25.20]) (VL-age interaction, p< 0.001). Although no age differences were detected for HDL-C, higher log10 VL was more strongly associated with lower HDL-C concentration when CD4 count was ≤199 cells/μL (=-2.66 mg/dL per log10-increase in VL [95% CI: -3.52, -1.80]) versus 200-500 (=-2.15 [95% CI: -2.79, -1.52]) or >500 cells/μL (=-1.51 [95% CI: -2.17, -0.85]) (CD4-VL interaction, p=0.001).

Conclusions: We detected an age-modified relationship between immunosuppression and viremia and atherogenic cholesterol patterns. These findings may contribute to our understanding of the high risk of dyslipidemia observed among persons aging with HIV.





*Adjusted for CD4 count, log_{10} HIV viral load, sex, race/ethnicity, HIV transmission group, history of smoking, history of injection drug use, depression, anxiety/stress disorder, hypertension, diabetes, body mass index category, hepatitis C infection, chronic kidney disease, serum albumin, length of time since HIV diagnosis, current antiretroviral regimen class, and current use of a lipid-lowering agent.

F/TAF, E/C/F/TAF and R/F/TAF do NOT contribute to insulin resistance: The TAF-IR study

C.D. Spinner[1], S. Schulz[1], U. Bauer[1], J. Schneider[1], J. Bobardt[1], R.M. Schmid[1], A. Zink[2], A. Balogh[3], H. Bidner[4], E. Wolf[3], R. Iakoubov[1]
[1]University Hospital Klinikum rechts der Isar, Department of Medicine II, Munich, Germany, [2]University Hospital Klinikum rechts der Isar, Department of Dermatology and Allergology, Munich, Germany, [3]Muc Research, Munich, Germany, [4]University Hospital Klinikum rechts der Isar, Münchner Studienzentrum, Munich, Germany

Background: The change in insulin-sensitivity (IS) and evolution of diabetes-mellitus in HIV-patients, both contributing to cardiovascular morbidity and mortality, has been associated with specific antiretroviral drugs or classes. Only limited data exists on metabolic effects of regimens including newer drugs such as fixed dose combinations (FDC) based on tenofovir alafenamide (TAF), particularly concerning IS.
Methods: In this prospective, open-label, randomized study we investigated the effects on IS of tenofovir alafenamide/emtricitabine (F/TAF) alone and in FDC with elvitegravir/cobicistat (E/C/F/TAF) or rilpivirine (R/F/TAF). Healthy, male volunteers were randomly assigned to one of the three study arms (10 per study arm). IS was measured using golden standard method of hyperinsulinemic euglycemic clamp (HEGC) technique before and 14 days after initiation of study medication. Before both measurements, a constant insulin infusion (2 mIU/(kg*min)) was infused over 2 hours, glucose infusion was adjusted as necessary to achieve stable glucose levels (target 90±5 mg/dl). Adherence to study medication was verified by pill counting and plasma TAF level measurements. IS was evaluated using the mean glucose disposal rate normalized to body weight (M_{BW}, [mg glucose/(min*kg)]), as calculated during clamp measurement. Sample size was calculated to detect a relevant decrease in M_{BW} of ≥3. To test for statistical significance of global differences in baseline characteristics between groups and pairwise differences in IS (baseline versus day 14), the Kruskal-Wallis test and the paired Student's t-test were used, respectively.
Results: N=30 subjects underwent randomization; 1 subject in the F/TAF arm withdrew consent and 1 in the R/F/TAF arm had to be excluded due to technical error during HEGC, resulting in 28 subjects in the per-protocol population. No significant differences were detected concerning baseline characteristics.

Parameter (Mean±SD)	F/TAF	E/C/F/TAF	R/F/TAF
Number of Subjects	9	10	9
Age (years)	26.3 (±6.3)	27.0 (±3.2)	24.8 (±3.5)
Weight (kg)	76.7 (±11.4)	73.5 (±6.1)	81.4 (±8.0)
Body height (cm)	181.1 (±12.0)	180.6 (±3.4)	184.8 (±6.9)
BMI (kg/m2)	23.3 (±0.9)	22.5 (±1.8)	23.8 (±1.1)
Fasting blood glucose (mg/dl)	85.1 (±6.4)	84.3 (±5.7)	79.4 (±8.7)

[Table 1: Baseline characteristics of the per-protocol study population]

IS did not differ between groups before treatment. None of the studied antiretroviral combinations resulted in a significant change of IS after 14 days compared to baseline, as measured by M_{BW} (F/TAF: 11.42±3.04 (SD, standard deviation) vs. 11.43±3.23, p=0.49; E/C/FTAF 10.04±2.49 vs. 10.95±4.26, p=0.30; R/F/TAF: 11.03±1.96 vs. 13.01±4.11, p=0.13).
Conclusions: Our study shows for the first time that neither treatment with FDC of F/TAF, nor E/C/F/TAF, nor R/F/TAF affects IS, as measured by HEGC.

Hepatic complications (e.g. NASH)

TUPEB127

A comprehensive assessment of hepatobiliary disorders in HIV-infected patients treated with dolutegravir, elvitegravir, raltegravir or darunavir in the OPERA Database

M. Wohlfeiler[1], K. Mounzer[2], L. Brunet[3], J. Fusco[3], V. Vannappagari[4], L. Curtis[5], N. Payvandi[5], M. Aboud[4], R. Hsu[6,7], P. Lackey[8], G. Fusco[3]
[1]AIDS Healthcare Foundation, Miami, United States, [2]Philadelphia FIGHT, Philadelphia, United States, [3]Epividian, Durham, United States, [4]ViiV Healthcare, Research Triangle Park, United States, [5]GlaxoSmithKline, London, United Kingdom, [6]AIDS Healthcare Foundation, New York, United States, [7]NYU Langone Medical Center, New York, United States, [8]Carolinas Healthcare System, Charlotte, United States

Background: We aimed to conduct a comprehensive assessment of hepatobiliary disorders occurring before and after prescription of regimens based on recommended core agents - dolutegravir (DTG), elvitegravir (EVG), raltegravir (RAL), or darunavir (DRV).
Methods: HIV-positive patients in the OPERA® Observational Database initiating a common core agent between 08/01/2013 and 10/31/2016 were included, with follow-up extending to 10/31/2017. Hepatobiliary disorders consisted of drug-induced liver injury (DILI), moderate liver chemistry elevations (LCE), or severe LCE (See Figure 1 for definitions). The proportion of patients with hepatobiliary disorders was calculated by core agent. History was defined as disorders occurring within 12 months of initiation. Prevalent disorders were those occurring during follow-up. Incident disorders excluded patients with any history of hepatobiliary disorders or advanced liver fibrosis (Fib-4>3.25). To account for multiple comparisons, the Sidak Correction was applied (adjusted alpha level: 0.017).
Results: Out of 21046 patients, 34% initiated DTG, 42% EVG, 7% RAL and 16% DRV. Compared to DTG users, EVG users were younger and were less likely to have comorbidities or use lipid lowering agents (Table 1). They were significantly less likely to have a history or prevalent moderate LCE, or prevalent severe LCE (Figure 1). RAL users were older than DTG users and more likely to have comorbidities or use lipid lowering agents (Table 1). They were significantly less likely to have a history of moderate and/or severe LCE, but more likely to have prevalent or incident moderate LCE during follow-up (Figure 1). DRV users were older than DTG users, less likely to have comorbidities or use lipid lowering agents (Table 1). They were significantly less likely to have a history of moderate LCE, but there was no difference in prevalent or incident elevations (Figure 1). No DILI diagnoses were recorded.
Conclusions: Despite a lower proportion of patients with a history of LCE, RAL users had a significantly higher overall LCE incidence than DTG users. DRV and EVG users similarly had lower proportions of patients with a history of LCE than DTG, but no difference in incidence of moderate or severe LCE. Channeling of comorbid patients away from EVG and towards DTG and RAL was observed.

TUPEB128

Prevalence and risk factors for significant liver fibrosis evaluated by non-invasive markers in HIV-infected Thais

T. Chiraunyanann[1], W. Sretapanya[2], K. Yuenyongchaiwai[3], C. Akekawatchai[4]
[1]*Bureau of AIDS, TB and STIs, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand,* [2]*Nakhon Nayok Hospital, Nokhon Nayok, Thailand,* [3]*Faculty of Allied Health Sciences, Thammasat University, Department of Physical, Pathumthani, Thailand,* [4]*Faculty of Allied Health Sciences, Thammasat University, Department of Medical Technology, Pathumthani, Thailand*

Background: Accumulating studies indicate an increase of liver-related diseases in HIV-infected patients. Our previous study has demonstrated high prevalence of HBV and/or HCV coinfection in HIV-infected Thais mostly receiving relatively long-term suppressive anti-retroviral therapy (ART). This study aimed to examine prevalence and risks for liver fibrosis, a common pathological feature of chronic liver diseases, in the HIV-infected group.

Methods: A single-center cross-sectional study was conducted from October 2011 to June 2013 in 352 HIV-infected patients. Combination ART received by 77.2% (median duration, 25 (IQR: 1-50) months. Prevalence of hepatitis B (HBV), hepatitis C (HCV) virus coinfection and triple infection were 8.2%, 7.2% and 0.3% respectively The patients were examined for significant liver fibrosis, defined as aspartate aminotransferase to platelet ratio index (APRI) > 0.5 and fibrosis-4 (FIB-4) score >1.45. Logistic regression analysis was performed to determine risks for significant fibrosis in this studied group.

Results: A total of 352 (49% male, 51% female) patients were recruited. Median age was 39 (IQR: 33-47) years and median CD4+ cell count was 346 (IQR: 176-519) cells/ml.The rates of significant liver fibrosis assessed by APRI and FIB-4 score were 16.4% and 17.3% respectively. Univariate and multivariate analyses identified HCV coinfection as predictive factors for significant fibrosis by APRI (OR 7.3, 95% CI 2.8-19.6, *P*< 0.001) and FIB-4 score (OR 7.5, 95% CI 2.6-21.2, *P*< 0.001), together with age difference, being male, CD4+ cell count < 350 cells/ml. The analysis also indicated that treatment with a first-line regimen of lamivudine, zidovudine and nevirapine was a protective factor for liver fibrosis assessed by FIB-4 score (OR 0.3, 95% CI 0.1-0.7, *P*< 0.005).

Conclusions: The prevalence of liver fibrosis in this studied group is high. HCV coinfection is a major risk and a current standard ART may be protective for development of liver fibrosis in HIV-infected Thais.

TUPEB129

Microbiota and gut-liver axis in HIV mono-infection: A pilot study of the impact of the gut microbiome on liver disease

C. Yanavich[1], H. Perazzo[2], F. Li[1], B. Grinsztejn[2], G. Aldrovandi[1], V. Veloso[2]
[1]*University of California, Pediatrics, Los Angeles, United States,* [2]*Instituto Nacional de Infectologia Evandro Chagas - Fundação Oswaldo Cruz, Rio de Janeiro, Brazil*

Background: Emerging evidence suggests the gut microbiome plays a role in the pathogenesis of liver steatosis and fibrosis in HIV uninfected persons. Limited data exist on the relationship between liver disease and the gut microbiome in HIV infection. We aimed to characterize the gut microbiome and assess the gut-liver axis relationship in HIV-infected patients.

Methods: Rectal swabs from PROSPEC-HIV-study (NCT02542020) participants in Rio de Janeiro, Brazil were subjected to 16S rRNA gene sequencing. Sequencing data from 82 HIV mono-infected participants were stratified by liver heath status: normal (n=30), steatosis (n=30), or fibrosis (n=22). Liver fibrosis and steatosis were defined by liver stiffness measurement (LSM ≥ 8 Kpa) and Controlled Attenuation Paramenter (CAP ≥ 248 dB/m) using Fibroscan™. Participants with recent antibiotic use were excluded. Statistical analyses performed using ZINB and RF methods.

Results: Of the 82 participants, 66% were female and had median: age of 46.4 years; duration of antiretroviral therapy of 8.3 years, and BMI 27.9 Kg/m²; 16% with Type 2 diabetes were included.

Taxonomic compositions across the normal, steatosis and fibrosis groups were similar, although a significant effect was observed (r^2=0.04, p=0.003). No differences were observed in bacterial diversity, but differences in key species seen for the fibrosis and steatosis groups versus those with normal liver assessments.

After adjusting for age, gender and BMI, participants with fibrosis showed a decreased abundance of *Bacteroides stercoris*, unclassified *Faecalibacterium*, and *Parabacteroides distasonis* as well as increased *Sneathia sanguinegens*. Those with steatosis had decreased *Bacteroides dorei* and unclassified *Bifidobacterium* as well as increased *Prevotella copri, Finegoldia magna, and Ruminococcus bromii.* At the genus level, decreases in *Parabacteroides* and *Bacteroides* were observed in the fibrosis group and decreased *Akkermansia* and increased *Finegoldia* were observed in the steatosis group. Additional analyses of the differences in the predicted functional composition of bacterial communities is planned.

Conclusions: HIV mono-infected persons with liver disease possess distinct microbial profiles. Some of the discriminatory bacteria observed in this cohort are similar to those associated with NASH/NAFLD in HIV-negative populations suggesting common mechanisms. Further studies are needed to define the role of the gut microbiota in the pathogenesis of liver disease in HIV-infected persons.

Cohort Characteristics	Results
Liver health status	Total participants (n=82); Normal (n=30); Steatosis (n=30); Fibrosis (n=22)
Sex	Male 34%; Female 66%
Age	46.4 years (IQR 41-52)
Body Mass Index (BMI) (median)	27.9 Kg/m2 (IQR 25.9-30.8)
Clinical History	Hypertension 26%; Diabetes 16%; Dyslipidemia 24%
Total Duration of Antiretroviral Therapy (ART)	8.3 years (IQR 4-15)
Cumulative ART Backbone	AZT-Backbone 45%; TDF-Backbone 51%; Data not available 4%
Current ART Backbone	AZT-Backbone 70%; TDF-Backbone 24%; Data not available 6%
Nadir CD4 (median)	190.5 cells/mm3 (IQR 86-299)

Predictors of hepatic steatosis and fibrosis in HIV infected and un-Infected adults in the Miami Adult Studies on HIV (MASH) cohort

M.K. Baum[1], K. Sherman[2], J. Chen[3], A. Campa[1], S. Martinez[1], P. Greer[1], R. Laird[1], A. Laird[1], Q. Liu[1], C. Teeman[1], R. Ehman[3]
[1]Florida International University, Miami, United States, [2]University of Cincinnati, Cincinnati, United States, [3]Mayo Clinic, Rochester, United States

Background: Magnetic Resonance elastography (MRE) is a non-invasive, highly accurate method to assess both hepatic fibrosis and liver fat content (steatosis). Studies to date have reported contradictory results regarding the frequency of hepatic steatosis and its association with liver fibrosis in those with HIV. The objective of this study was to examine the relationship between the predictors of liver fat and association with liver fibrosis in HIV infected and un-infected adults in the MASH cohort.
Methods: Cross-sectional analyses from an observational longitudinal MASH cohort in Miami were conducted. BMI was obtained by anthropometric measurements. HIV viral load was obtained from the participants' medical chart. Hepatitis B and C were excluded. MRE was conducted on a 3T Siemens MAGNETOM Prisma MRI and liver fat was calculated from the proton density fat fraction (PDFF) of the liver MRE scans; significant steatosis was defined as fat fraction >5%. Wilcoxon Two-Sample test and regression models were used for analyses.
Results: There were 251 HIV infected (mean age 53.2 years±7.7 SD; 65% Black), and 133 HIV/HBV/HCV un-infected study participants (mean age 54.0 years±8.95 SD; 59% Black). BMI was significantly higher in the un-infected controls (mean 30.93±6.69 SD) compared with HIV infected group (mean 29.27±6.15 SD). However, liver fat was significantly associated with elevated liver stiffness only in the HIV mono-infected group (=0.068, SE=0.02, P< 0.001). BMI was significantly associated with elevated liver fat in both the HIV mono-infected, (OR=1.152 [95%CI:1.046-1.269, P=0.0042]) and the un-infected groups (OR=1.187 (95% CI: 1.073-1.314, P< 0.001)].
Conclusions: MRI-based assessment of liver fat fraction utilizing PDFF determination in a cohort of HIV infected and HIV/HBV/HCV un-infected adults shows that increased liver fat content (steatosis) in both groups was associated with higher levels of BMI as might be expected. However, elevated liver fat was associated with increased liver stiffness in only the HIV infected adults. This suggests that HIV infection and obesity might work synergistically to contribute to development of hepatic fibrosis.

TUPEB131

Elderly patients on antiretroviral therapy with dolutegravir are at increased risk for ALT elevation

P. de Leuw[1], K. Wiedmann[1], N. Filmann[2], I. Krznaric[3], P. Ingiliz[3], A. Haberl[1], G. Kann[1], G. Schüttfort[1], J. Severain[1], T. Wolf[1], C. Stephan[1]
[1]University Hospital Frankfurt, Department of Infectious Diseases, Frankfurt am Main, Germany, [2]Institute of Biostatistics and Mathematical/ Goethe University, Department of Medicine, Frankfurt am Main, Germany, [3]Center for Infectious Diseases Berlin, Berlin, Germany

Background: Liver toxicity is an important adverse event in patients on ART. Even though newer antiretroviral drugs like integrase inhibitors are generally well tolerated, ageing patients might be at higher risk for elevation of liver enzymes most possibly due to comorbidity and/or co-medication.
Methods: Pooled data from the HIV clinical cohorts at Goethe University Frankfurt and the Center for Infectious Diseases Berlin were analyzed retrospectively for liver enzyme elevations in patients, who initiated dolutegravir(DTG), elvitegravir(EVG), or raltegravir(RAL)-containing ART prior to February, 1st(Table 1). Study visits were at baseline, week 4, 12, 36 and 52. Statistics were done with non-parametrical tests (Wilcoxon-matched-pairs-test,Mann-Whitney-test,Friedman-test,Van-Elteren-test). P-values< 0.05 were considered as significant.
Results: We included 486 patients (male 408,female 78) in our analysis; 333 on DTG, 48 on EVG and 105 on RAL. Median Baseline ALT levels were 28 IU/ml(range 8-677) in the DTG group, 26 IU/ml(r:12-134) in the EVG group, and 28 IU/ml(r:8-210) in the RAL group(p>0.1). We observed a highly significant increase in ALT-levels in the DTG-group in patients aged >/= 60 years (Median change 10.5 IU/ml(r:5-228),p>0.001) between baseline and week 4. ALT-levels then declined significantly(p>0.001) consecutively and there was no difference between baseline levels and week 52(Median 31.5(8-120),p>0.1). The elevation was not associated with any liver associated comorbidity or intake of concomitant medication(p>0.1). No significant change in ALT values was observed of patients aged >/= 60 in the RAL- or EVG-group(p>0.1) during all study timepoints up to week 52. In patients aged< 60 years we did not observe any significant change in ALT-levels in the DTG, RAL or EVG arm(p>0.1). Furthermore, there was no significant difference in liver enzymes in HIV/HCV-coinfected compared to HIV-monoinfected patients (p>0.1) in any of the three treatment groups during 52 weeks of therapy.
Conclusions: In our analysis integrase inhibitors did not cause clinically significant elevation of liver enzymes. However in elderly patients aged >/= 60 years dolutegravir caused significantly more ALT-elevations at week 4 compared to elvitegravir or raltegravir. ALT normalized up to week 52 and none of the patients had to stop treatment due to liver toxicity. Clinicians should be aware of this when they start doultegravir in elderly patients.

Mean age (range) – years	51 (22-81)	Liver disease – no. (%)

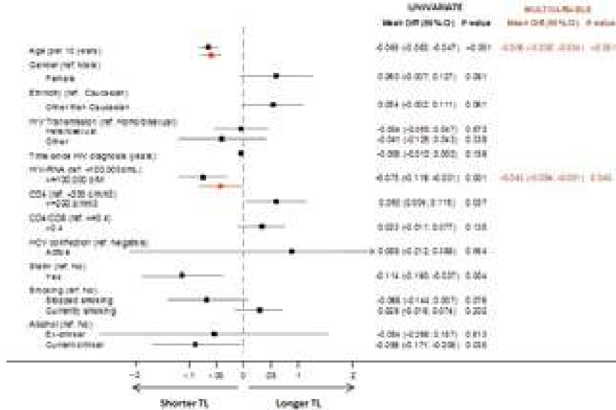
Determinants of telomere length in antiretroviral treatment naïve HIV-positive participants enrolled in NEAT 001/ANRS 143

B. Alejos[1], N. Stella-Ascariz[2], R. Montejano[2], J. Rodriguez-Centeno[2], C. Schwimmer[3], J.I. Bernardino[2], B. Rodes[2], S. Esser[4], C. Goujard[5], R. Sarmento-Castro[6], R. de Miguel[2], A. Esteban[2], C. Wallet[7], F. Raffi[8], J.R. Arribas[2], ANRS 143/NEAT 001 Study Group
[1]Institute of Health Carlos III, Centro Nacional de Epidemiologia, Madrid, Spain, [2]Hospital La Paz Institute for Health Research, Madrid, Spain, [3]INSERM, Bordeaux, France, [4]University Hospital Essen, Essen, Germany, [5]Bicêtre Hospital, Internal Medicine Unit, Le Kremlin-Bicêtre, France, [6]Centro Hospitalar do Porto, Hospital Joaquim Urbano Unit, Porto, Portugal, [7]CHU de Bordeaux, Bordeaux, France, [8]CHU de Nantes, Nantes, France

Background: .There are limited data about determinants of blood telomere length (TL) in antiretroviral treatment (ART) naïve HIV-Positive patients. Our aim is to investigate factors associated with baseline TL in participants enrolled in NEAT001/ANRS143, a randomized, open-label trial comparing ritonavir boosted darunavir (DRV/r) + raltegravir (RAL) or tenofovir disoproxil fumarate /emtricitabine (TDF/FTC) in 805 ART-naive HIV-positive adults.
Methods: For this cross-sectional study we randomly selected 201 participants who had stored samples available. We measured TL at baseline (telomere to single copy gene ratio) with monochrome quantitative multiplex PCR. Samples were tested in triplicate and those with a coefficient of variation > 0.10 were retested. We used multivariable predictive linear regression to calculate mean differences and 95% confidence intervals (CI) for the association between baseline TL and predictive factors.

Results: Baseline characteristics of the 201 participants did not differ from parent trial population: male 89%, mean age 38.7±10.6 years, Caucasian 83.6%, sexual transmission 93%, mean estimated time since HIV diagnosis 2.1±3.1 years, HIV-1 RNA load 4.7±0.6 log10 copies/mL, CD4 nadir/baseline 301±117/324±128 cells/µL and CD4/CD8 ratio 0.4±0.6. Mean blood TL at baseline was 0.738 ± 0.152. In the univariate analysis, shorter TL was associated with older age (per 10 years) (P< 0.001), HIV-1 RNA ≥100,000 copies/ml (P=0.001), CD4 < 200 cells/µL (P=0.037), statins treatment (P=0.004), and current alcohol consumption (P=0.035). There were not significant associations between TL and gender, ethnicity, HIV transmission mechanism, time since HIV diagnosis, CD4/CD8 ratio, HCV coinfection, and tobacco. In the multivariable analysis, older age (P< 0.001) and HIV-RNA ≥100,000 copies/ml (P=0.043) were independently associated with shorter TL (Figure).

Conclusions: This is the first randomized clinical trial evaluating baseline blood TL in ART-naive patients. As expected, older age was associated with shorter blood TL. The only HIV related factor independently associated with shorter blood TL was high HIV RNA level. Despite its reported association with other parameters of immunosenescence, a low CD4/CD8 ratio was not independently associated with shorter blood TL.



[Figure: Univariate and multivariable associations between baseline TL and predictive factors]

NCDs burden and risk factors in a cohort of HIV+ patients >40 years old in Malawi

F. Ciccacci[1], V.T. Tolno[2], A.M. Doro Altan[3], G. Liotta[1], S. Orlando[1], S. Mancinelli[1], L. Palombi[1], M.C. Marazzi[4]

[1]*University of Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy,* [2]*Community of S. Egidio, DREAM Program, Blantyre, Malawi,* [3]*Community of S. Egidio, DREAM Program, Rome, Italy,* [4]*LUMSA University, Rome, Italy*

Background: HIV-infected patients have increased risk of NCDs. HIV+ patients in Africa are experiencing growing comorbidities due to increase in life expectancy and long-time ART. HIV prevalence in Malawi is one of highest in the world (10.8% in women and 6.4% in men), few data are available about NCDs epidemiology in HIV+ adult and elderly patients in Malawi.

Methods: A retrospective analysis of routine clinical and laboratory data from all HIV+ patients aged>40 years in care collected in 14 health centers run by DREAM program in Malawi was carried out. Clinical and laboratory data were performed in the period Jan 2017- Jan 2018.

Results: Files from 7071 patients (62.1% women) in ART were analyzed. Median time of ART was 98,9(64.8-118.0) months; median BMI, HB and CD4 count, were respectively: 21.63kg/m2(19.5-24.5), 13mg/dL(12-14) and 457cell/mm3(328-613). 13.0%(905/7071) patients had BMI< 18.5, elderly patients>65 years were more likely to be malnourished (OR=2.0 CI:1.54-2.59). 9.6%(677/7071) patients were diagnosed with arterial hypertension, in a logistic regression age>65 years (OR=2.5 CI:1.94-3.43) and Nadir CD4< 200 (OR=1.5 CI:1.29-1.86) were independently associated with hypertension. Only 55 patients (0.77%) were diagnosed with diabetes, 1.9% among >65years patients (OR=2.7 CI:1.25-6.22). 12.7% (897/7,071) patients had macrocyclic anemia (diagnosed as RBC< =4,000,000/mm3 and MCV>100fL); in a multivariate analysis only age>65years (OR=2.5 CI:2.00-3.35) and therapy containing AZT (OR=4.2 CI:3.60-4.94) were independently associated with macrocytic anemia. 5% (351/7,071) patients had serum creatinine>1:3mg/dL; in a logistic regression model, age>65 (OR=1.5 CI:1.03-2.43]), time of ART>5years (OR=1.6 CI:1.15-2.44]), CD4 count< 200cell/mm3 (OR=1.7 CI:1.20-2.48]) were independently associated with increased serum creatinine.

Conclusions: The present data show the burden of NCDs in aging HIV+ patients in Malawi, especially when in long-time ART. The expanding of HIV treatment programs will require special attention to such comorbidities in adult and elderly patients.

TUPEB134

Frailty is associated with HIV and female gender in Asians over 50

T.C. Do[1,2], S.J. Kerr[3], A. Avihingsanon[4], S. Suksawek[4], S. Klungklang[4], J.A. Ananworanich[4,5], P. Reiss[6,7], F. Wit[6,7]

[1]*HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT), Medicine, Bangkok, Thailand,* [2]*University of Amsterdam, Medicine, Amsterdam, Netherlands,* [3]*HIV Netherlands Australia Thailand Research Collaboration, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, Bangkok, Thailand,* [4]*HIV Netherlands Australia Thailand Research Collaboration, Thai Red Cross AIDS Research Centre, Bangkok, Thailand,* [5]*U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States,* [6]*Academic Medical Center and Amsterdam Institute for Global Health and Development, Department of Global Health, Amsterdam, Netherlands,* [7]*HIV Monitoring Foundation, Amsterdam, Netherlands*

Background: To assess prevalence and factors associated with the Fried frailty phenotype (1) comparing Asians living with HIV to HIV-negative controls matched by sex, and aged 50 to 80 years.

Methods: Cross-sectional analysis of HIV-positive participants presenting for routine visits in the HIV-NAT006 cohort (clinicaltrials.gov NCT00411983) at the Thai Red Cross AIDS Research Center (TRCARC), in Bangkok's urban area. HIV-negative controls were recruited at TRCARC in the same period through fliers and word of mouth. Frailty phenotype (1) utilizes five domains: walking-speed, grip-strength, unintentional weight-loss, self-reported exhaustion and low physical activity. Scoring poorly in one or two criteria denotes pre-frailty, and in ≥3 denotes frailty (1-3). Logistic regression assessed factors associated with pre-frailty. Covariates with a univariable P< 0.15 were included in multivariable models.

Results: A total of 324 HIV-positive participants, mean (SD) age 56.0 (5.5) years, of whom 37.0 percent women, and 131 HIV-negative controls, mean (SD) age 58.3 (5.8) years, of whom 32.6 percent women, were enrolled, all >50 years.

HIV-positive subjects were on cART for a mean (SD) duration of 15.2 (4.5) years. Comorbidity prevalence in the HIV-positive group was: hypertension 36.7%, hyperlipidemia 34.0%, diabetes 15.1%, renal dysfunction 7.1%, hepatitis B seroprevalence of 13.0%, and hepatitis C seroprevalence of 4.4%, and cardiovascular disease 2.2%. Pre-frailty (62.0% vs. 46.2%) (P≤0.005), and frailty (6.5% vs. 1.5%) were more prevalent in the HIV-positive group as was the case for each of the five domains (Figure). In multivariable analysis, factors independently associated with pre-frailty and frailty were HIV status (OR 2.04, 95%CI 1.24-3.35, P< 0.005) and female gender (OR 3.97, 95% CI 2.36-6.67, P< 0.001) (Table). In the analysis of HIV-positive subjects only, of the sociodemographic, HIV-related, and comorbidity-related covariates, only hypertension (OR 2.40, 95% CI 1.32-4.35, P< 0.004) was significantly associated with frailty.

Conclusions: In these middle-aged Asians HIV-positive status and female gender were associated with frailty. The association with hypertension in those with HIV needs further investigation. Frailty assessment and potential interventions are warranted in view of its association with poor health outcomes including hospitalization, falls and mortality.

Comparison of physical health conditions among older adults living with HIV and age-gender matched non-HIV older adults: Chiang Mai, Northern Thailand

W. Sitthi[1], K. Srithanaviboonchai[1,2], A. Tangmunkongvorakul[1], K. Rerkasem[1,2]
[1]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [2]Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

Background: The number of older adults living with HIV (OALHIV), defined as HIV-infected person who are 50 years old or older, has increasing rapidly worldwide due to successfulness of antiretroviral therapy programs. There has been evidenced that HIV infection may possibly result in early manifestations of clinical syndromes generally associated with advanced age. The aim of this study is to compare the socio-demographic characteristics and physical health statuses of the OALHIVs with age and gender matched non HIV-infected persons.

Methods: The study was conducted in 2016 at 12 government community hospitals located in Chiang Mai province, Northern Thailand. For each hospital, 30 OALHIVs and 30 non-HIV patients (age and gender matched with OALHIVs) who came to general outpatient departments on the days of survey were recruited. After enrollment, participants underwent a face to face interview, medical record review, measurement for blood pressure and height and weight measurement to calculate body mass index (BMI).

Results: Of 728 participants (364 OALHIVs and 364 non-HIV older adults), the OALHIVs were more likely to be single/widowed/divorced (AOR, 4.51; 95% CI, 3.10-6.55), have a household income less than 5,000 baht (143 USD) per month (AOR, 1.55; 95% CI, 1.07-2.24 have a BMI less than 18.5 kg/m2 (AOR, 3.07; 95% CI, 1.79-5.27) and have BMI 18.5-22.9 kg/m2 (AOR, 2.94; 95% CI, 2.00-4.33) rather than equal or higher than 23.0 kg/m2, have chronic kidney disease (CKD) (AOR, 3.91; 95% CI, 1.71-8.98), and have dyslipidemia (AOR, 4.37; 95% CI, 2.84-6.73) than the HIV-negative group. In contrast, OALHIVs were less likely to have cardiovascular disease (AOR, 0.31; 95 CI, 0.14-0.70).

Conclusions: The OALHIVs participants had a higher chance of living alone, having lower income, having lower BMI, and suffering from chronic health conditions including CKD and dyslipidemia than their age and gender matched non-HIV counterparts. Routine screening of major NCDs and provision of integrated NCD/HIV medical care are needed for.

TUPEB136

Beyond the 60s: Changing co-morbidities in people living with HIV aged over 60 attending clinic in 2010 and 2017

M.J. Lee[1], J. Bilinska[1], E. Wallis[1], L. Campbell[1], R. Patel[2], C. Smith[3], C. Williams[1], H. Iveson[4], R. Kulasegaram[1]
[1]Guy's and St Thomas Hospital NHS Foundation Trust, Harrison Wing, Department of HIV, London, United Kingdom, [2]St George's University London, London, United Kingdom, [3]University College London, Institute of Epidemiology and Health Care, London, United Kingdom, [4]Salisbury NHS Foundation Trust, Salisbury, United Kingdom

Background: People living with HIV (PLHIV) are increasingly living longer due to effective antiretroviral (ARV) therapy. We characterised and compared within clinic cohorts across two time points, the prevalence of co-morbidities in PLHIV aged over 60s (PLHIV60s) attending a London HIV clinic.

Methods: The cohorts included all PLHIV60s under regular follow-up in December 2010 and September 2017. Demographics, ARV history, co-morbidities, and investigation results were included.

Results: A greater proportion of the clinic population were aged over 60 in 2017 (300/3299, 9.1%) than in 2010 (126/2700, 4.7%). 85 (67.5%) patients under follow-up in 2010 remained so in 2017, 7 were lost to follow up (5.6%), 13 transferred care (10.3%), and 21 died (16.7%). Causes of death include malignancy (8/14), HIV-related complications (3/14), sepsis (2/14), and motor neurone disease (1/14). Median age, gender, ethnicity, and sexual orientation was similar in both cohorts. Age range was 60-83 in 2010 and 60-90 in 2017.

299/300 (99.7%) were on ARVs in 2017, and 119/126(94%) in 2010. Currently, 285/299 (95.3%) remain virally suppressed (< 200copies/ml). Median baseline CD4 count were similar (189 vs 222cells/μL, p=0.19). Prevalence of co-morbidities are summarised in Table 1.

Co-morbidities	2010 (n=126)		2017 (n=300)		p-value
Ischaemic heart disease	22	17.5%	28	9.3%	**0.0211**
Chronic kidney disease stage 3 or worse (CKD3+)	20	15.9%	91	30.3%	**0.0016**
Osteopaenia/osteoporosis	27	21.4%	110	36.7%	**0.0021**
Hypercholesterolaemia	65	51.6%	171	57.0%	0.3369
Diabetes Melitus (Type 1 or 2)	14	11.1%	42	14.0%	0.5299
Hypertension	-	-	132	44.0%	-
Heart Failure (Left ventricular ejection fraction <55%)	-	-	12	4.0%	-
Malignancy	-	-	50	16.7%	-
>3 of above co-morbidities	28	22.2%	92	30.7%	0.077

[Table 1]

In 2017, mean duration of TDF exposure in patients with or without CKD3+ was 65 vs 80 months (p=0.035). TDF exposure was associated with CKD3+ (OR=1.0046 per month longer, 95%CI 1.0003 - 1.0090, p=0.034), and a trend remained after adjusting for age, ethnicity, diabetes and hypertension (p=0.089).

169/300 (58.9%) had a body mass index ≥25. Of those with liver transient elastography results, 20/49(40.8%) had evidence of fatty liver (CAP>280). 29% (50/272) were on ≥ 5 concomitant drugs. 155/272 (57.0%) had at least 1 drug-drug interactions (DDI). Older age was associated with increasing concomitant drugs (r=0.13, p=0.03) and DDIs (r=0.15, p=0.01).

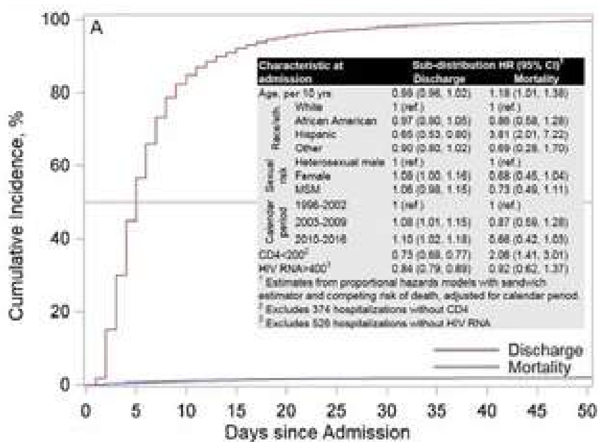
Conclusions: The proportion of PLHIV60s in our cohort has doubled over 7 years. Fatty liver disease, renal dysfunction, and osteopenia/osteoporosis are increasingly diagnosed in PLHIV60s, likely reflecting improved monitoring in line with updated national guidelines. Multiple co-morbidities, polypharmacy and DDIs were common in PLHIV60s. Reviewing ARVs regularly is essential to optimise co-morbidities and quality of life of PLHIV as life expectancies continue to improve.

TUPEB137

Hospitalization outcomes of HIV-infected patients in a Southeastern US Clinical Cohort, 1996-2016

T. Davy-Mendez, S. Napravnik, O. Zakharova, D.A. Wohl, C.E. Farel, J.J. Eron
University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Background: Hospitalizations outcomes among HIV-infected patients are not well known. This study examined length-of-stay, mortality, and readmission among hospitalized patients in care and factors associated with worse hospitalization outcomes.
Methods: We included hospitalizations at University of North Carolina (UNC) 1996-2016 among patients enrolled in the UNC Center for AIDS Research HIV Clinical Cohort. We excluded hospitalizations taking place after loss-to-follow-up (18 months without clinical visit), but patients reentering care contributed additional hospitalizations. We examined time from admission to discharge, accounting for the competing risk of inpatient death, and estimated sub-distribution hazard ratios (sHR) comparing patient characteristics, adjusting for calendar time. For index hospitalizations (without a hospital discharge in the prior 30 days), we used log-binomial models to estimate risk ratios (RR) of a composite outcome of death or readmission within 30 days, adjusting for calendar period. Sandwich estimators and GEE, respectively, were used to account for repeat hospitalizations per patient.
Results: We included 7,302 hospitalizations among 1,953 patients, who were 31% female, 35% MSM, 63% African-American, and contributed a median of 2 (IQR 1, 4) hospitalizations and 8 years (IQR 4, 13) of follow-up.



[Figure. Time from hospital admission to discharge accounting for competing risk of death]

Median time to discharge was 5 days (IQR 3, 8), with 1.8% inpatient mortality (Figure). CD4< 200 at admission, HIV RNA>400 at admission, and Hispanic ethnicity were associated with longer hospital stays, while being hospitalized in more recent years was associated with shorter hospitalization (Figure). CD4< 200, Hispanic ethnicity, and older age were associated with increased rates of inpatient mortality, but there were no changes over time (Figure). Of 5,598 index hospitalizations, 18.8% (95% CI 17.6, 20.1) resulted in readmission within 30 days. No death occurred before readmission. Readmission risk was higher for patients of African-American race (RR 1.18; 95% CI 1.01, 1.38), with CD4< 200 (1.49; 1.30, 1.71) and HIV RNA>400 (1.19; 1.04, 1.35). There were no statistically significant changes in readmission risk over the study period.
Conclusions: In this HIV-infected patient population, hospital length-of-stay has decreased in the past 20 years, however, high readmission risks have remained similar. Uncontrolled HIV, including low CD4 and detectable HIV RNA, and minority race/ethnicity were associated with worse hospitalization outcomes.

TUPEB138

Vestibular function among Multicenter AIDS Cohort Study (MACS) and Women Interagency HIV Study (WIHS) participants

M. Plankey[1], M. Pichert[1], G. Springer[2], H. Cohen[3]
[1]*Georgetown University, Washington, United States,* [2]*John Hopkins University, Baltimore, United States,* [3]*Bayler College of Medicine, Houston, United States*

Background: We investigated vestibular function loss (VFL) among well-characterized middle-aged HIV+ and HIV- men and women in the Multicenter AIDS Study (MACS) and Women's Interagency HIV Study (WIHS) using standardized diagnostic VF testing.
Methods: 138 men of the Baltimore-DC site of the MACS (median age 54; 80 (59%) HIV+) and 102 women of the DC site of the WIHS (median age 49; 84 (82%) HIV+) underwent vestibular evoked myogenic potential (VEMP) and electronystagmography (ENG) including bi-thermic caloric (BCT) stimulation testing. A positive peripheral VF outcome was defined as an abnormal or absent BCT response; a central VF outcome was either an abnormal saccade peak velocity, saccade accuracy, or saccade latency (SAC) from the VEMP/ENG testing. Any VFL was defined as +BCT or +SAC or both. Adjusted for sex, age, viral suppression (< 20 copies/ml), ever using monotherapy, ever HAART, proportional odds regression models were run with combined data and HIV+ data only.
Results: 19% (14% HIV+) of men and 40% (32% HIV+) of women had 1 or greater BCT or SAC abnormality. After adjusting a 10-year increase in age, being male, being HIV+ was borderline statistically significantly associated with any VFL (2.30; 95% CI 0.9, 5.87, p=0.0803). For analysis limited to HIV+ participants, albeit not statistically significant, yet in the expected direction, current HAART and viral suppression (0.54, 95% CI 0.24, 1.21 p=0.132) demonstrated a decreased odds of VFL (0.83, 95% CI 0.23, 3.01 p=0.780) and increased odds with monotherapy (1.08; 95% CI (0.47, 2.53 p=0.780).
Conclusions: In this small sample of HIV+ and HIV- middle-aged men and women, we found that HIV disease *may* increase odds of peripheral and central vestibular dysfunction. As we expected, HAART use concomitant with lower HIV RNA viral load were found to be protective for VFL; given its neurotoxic side effects, monotherapy use increased the odds. Larger longitudinal studies are necessary to elucidate whether HIV has a direct deleterious effects on the vestibular system and if so, whether vestibular function worsens among adults beyond middle age where balance disorders and concomitant falls are more likely to occur.

[Characteristics of sample]

Immune reconstitution disorders / immune reconstitution inflammatory syndrome (IRIS)

TUPEB139

Treatment of immune reconstitution inflammatory syndrome with TNF-alpha inhibitors in HIV-infected patients

A.C.E. Laparra[1], N. Lerolle[2], M. Gerin[3], A. Cheret[2], N. De Castro[4], S. Gallien[5], V. Martinez[6], F. Lanternier[7], A. Bourgarit[3], C. Goujard[2]
[1]Assistance Publique des Hôpitaux de Paris, 94, Clamart, France, [2]CHU Kremlin-Bicêtre, Kremlin-Bicêtre, France, [3]Hôpital Jean Verdier, Bondy, France, [4]CHU Saint Louis, Paris, France, [5]CHU Henri-Mondor, Créteil, France, [6]CHU Pitié Salpétrière, Paris, France, [7]CHU Necker, Paris, France

Background: Immune reconstitution inflammatory syndrome (IRIS) is an exaggerated immune response against various pathogens, highly prevalent in HIV-infected patients after initiation of antiretroviral therapy. IRIS treatment relies mostly on steroids with unclear benefit in most severe cases, for which TNF-alpha inhibitors could be an alternative in steroid-resistant cases.
Methods: We retrospectively collected data from six HIV-infected patients treated with TNF-alpha inhibitors for steroid-resistant IRIS in French university hospitals between March 2013 and August 2017. Medical charts were reviewed to evaluate efficacy and safety of TNF-alpha inhibitors (TNF-I) in this setting.
Results: Median age was 38 years [36,3-44], 50% were women. One patient had cryptoccocal meningitis and 5 had microbiologically proven tuberculosis (TB) or cryptoccocosis with two cases of TB meningitis. Median CD4 count at TB or cryptoccocosis diagnosis was 76 cells/mm^3 [43-130] and median plasma HIV RNA was 5.82 log [5.05 - 6.00]. At IRIS onset, median CD4 count increase was 100 cells/mm^3 [53 - 411] and HIV RNA was 2.65 log [2,1-3,15]. Corticosteroids initial dose was 1 mg/kg/day, except for one TB patient who received high-dose methylprednisolone. TNF-alpha inhibitors were started after a median of 3.0 months [0.75-12] after IRIS diagnosis, after a median of 3 months [1,6-6,2] of corticosteroids, with a median duration of 4.5 months [2.0-11.2]. Three cases were treated with infliximab, three with with adalimumab. Five patients experienced a clinical and radiological improvement within 2 months [1-4] after initiation of TNF-I. Normalization of CRP levels occurred within a delay of 5.5 months [4.0-7.0]. All patients interrupted corticosteroids after a median of 3.0 months [0-7.7]. All neurological IRIS cases needed CSF drainage and suffered from residual neurological damages. One failure occurred after two infusions of infliximab with lymph node enlargement. No serious side effects were noticed under TNF-I during a follow-up period of 12 months [8-16]. No IRIS recurrence was seen after TNF-I cessation.
Conclusions: TNF-alpha inhibitors therapy resulted in significant improvement in severe steroid-resistant IRIS in HIV-infected patients, especially in those experiencing neurological IRIS. Although difficult to implement, further studies are needed to evaluate the potential benefits and risks of this therapy in HIV-infected patients.

Other non-communicable diseases

TUPEB140

Sleep and Circadian disruption interact with HIV, contributing to inflammation and immune activation

K. Weber[1], H. Burgess[2], J. Burke-Miller[3], L. McClellan[4], E. Daubert[4], C. Bond[4], R. Morack[4], M. Cohen[5], A. French[6]
[1]CORE Center, Chicago WIHS, Chicago, United States, [2]Rush University, Behavioral Science and Internal Medicine, Chicago, United States, [3]Hektoen Institute of Medicine, Chicago, United States, [4]Hektoen Institute of Medicine, Chicago WIHS, Chicago, United States, [5]Rush University, Medicine, Chicago, United States, [6]CORE Center/ Stroger Hospital of Cook County, Division of Infectious Diseases, Chicago, United States

Background: Sleep disturbance is highly prevalent in HIV+ individuals, depressed women, and aging populations. Poor sleep is associated with systemic inflammation and greater risk for cardiometabolic and cognitive disorders. HIV also degrades tryptophan, a precursor of melatonin that regulates the sleep/wake cycle. We sought to quantify sleep and circadian disruption and their association with markers of inflammation/ immune activation in midlife HIV+ and HIV-women.
Methods: We assessed sleep subjectively with the Pittsburgh Sleep Quality Index (PSQI), objectively using 7 days of wrist actigraphy, and collected first morning urine to assess overnight secretion of melatonin metabolite and creatinine in 92 (63 HIV+/29 HIV-) WIHS women. We measured usCRP, IL-6, sCD14 and sCD163 in plasma with commercial ELISA. We evaluated correlations between PSQI, actigraphy-derived sleep metrics (wake after sleep onset-WASO, wake bouts, total sleep, efficiency, fragmentation), circadian disruption (creatinine adjusted urinary melatonin-CAUM), and inflammatory/activation markers.
Results: Key characteristics, including mean PSQI score, did not differ significantly ($p < 0.05$) by HIV status (Table 1); 92% of HIV+ women were on HAART; 84% were aviremic; mean (sd) CD4 count =741 (369). Sleep duration < 6 hours was observed in 32% of women. PSQI score positively correlated with WASO and sleep fragmentation (r=.31, p=.004; r=.28, p=.008 respectively) and negatively with sleep efficiency (r=-.35, p=.001). Poor sleep quality was significantly correlated with lower urinary melatonin metabolite regardless of HIV status (partial r=-.22, p=.039). In HIV+ women, PSQI total score, PSQI>5 correlated with higher sCD163 (r=.30, p=.020; r=.37, p=.003; respectively) but not in HIV- women (r=-.14, p=.481; r=-.09, p=.648 respectively). In HIV+ women, PSQI score correlated with higher sCD163 even after adjusting for viral load and CAUM (partial r=.32, p=.013). In HIV+ women, CAUM and IL-6 were negatively correlated (r=-.33, p=.011) including among HIV+ aviremic women (r=-.37, p=.008). There was no relationship between CAUM and biomarkers in HIV- women.
Conclusions: Sleep and circadian disruption are highly prevalent in midlife HIV+ and HIV- women and, in HIV, are associated with higher levels of IL-6 and sCD163. Further study is warranted to determine the how sleep and circadian disruption contribute to persistent inflammation/ immune activation and associated morbidity in the context of HIV.

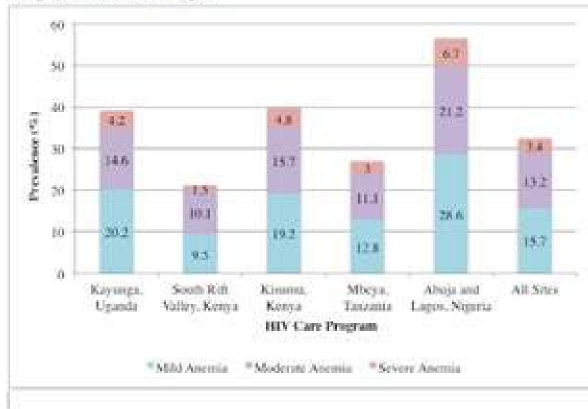
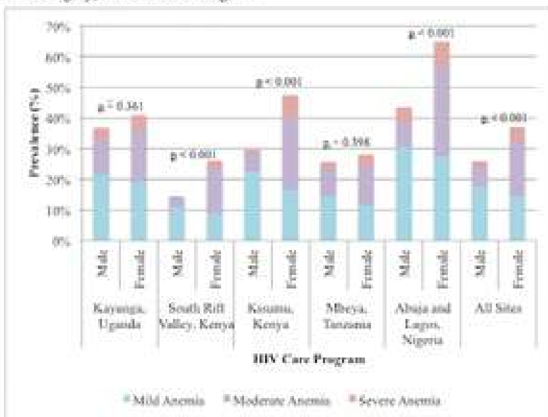
Prevalence of and factors associated with anemia among HIV-infected adults in a multi-site African cohort

A.P. Parikh[1,2], D.M. Reed[1,2], T.A. Crowell[1,2], A.L. Esber[1,2], L. Maganga[3], Y. Adamu[4], F. Kiweewa[5], J. Maswai[1,6,7], J. Owuoth[1,7,8], J.A. Ake[1], C.S. Polyak[1,2], RV329 AFRICOS Study Team
[1]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]Mbeya Medical Research Centre, Mbeya, Tanzania, United Republic of, [4]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Abuja, Nigeria, [5]Makerere University-Walter Reed Project, Kampala, Uganda, [6]Henry M. Jackson Foundation Medical Research International, Kericho, Kenya, [7]Kenya Medical Research Institute, Nairobi, Kenya, [8]Henry M. Jackson Foundation Medical Research International, Kisumu, Kenya

Background: Anemia is a known predictor of morbidity and mortality in HIV-infected adults, but remains poorly characterized across different countries in sub-Saharan Africa. We describe the prevalence of and factors associated with anemia among HIV-infected adults in Uganda, Kenya, Tanzania, and Nigeria.

Methods: AFRICOS is a prospective observational cohort study enrolling participants in five PEPFAR-supported HIV care programs. Sociobehavioral questionnaires and clinical assessments, including hemoglobin (Hb) measurements, were collected at enrollment. Mild anemia was defined as Hb 11-12.9 g/dL for men and 11-11.9 g/dL for women, moderate: Hb 8-10.9 g/dL, and severe as Hb < 8 g/dL. We used logistic regression to estimate adjusted odds ratios (AORs) and 95% confidence intervals (CIs) for factors associated with moderate-to-severe anemia (Hb < 11g/dL) among HIV-infected men and non-pregnant women at enrollment, controlling for age, body mass index, and renal insufficiency.





[Prevalence of Anemia among HIV-infected Adults at Enrollment]

Results: As of September 2017, 2678 HIV-infected participants were enrolled, of whom 2645 had Hb measurements and met our inclusion criteria. The prevalence of any, mild, moderate, and severe anemia varied by program, and was greatest in Nigeria (Figure 1). Moderate-to-severe anemia was observed in 439 participants, including 348 (79.3%) women. Regression analysis found that compared to Uganda, moderate-to-severe anemia was more common in Kisumu (AOR: 2.11, 95% CI: 1.44-3.09) and Nigeria (AOR: 1.99, 95% CI: 1.16-3.41), while women had greater odds of moderate-to-severe anemia than men (4.50, 4.34-6.06). HIV-related factors, including HIV viremia >50 copies/mL compared to < 50 copies/mL (1.59, 1.17-2.18), WHO stage IV compared to stage I (2.11, 1.20-3.69), and enrollment CD4 < 200 cells/mm³ (4.63, 3.28-6.52) compared to enrollment CD4 500+ cells mm³, were all significantly associated with higher odds of moderate-to-severe anemia. Conversely, being on ART (0.58, 0.42-0.81) or Cotrimoxazole (0.64, 0.43-0.95) was associated with decreased odds.

Conclusions: Anemia in this cohort of HIV-infected African adults is common, underscoring the need for HIV care models to address early screening and management of anemia. Factors associated with moderate-to-severe anemia are consistent with prior studies conducted in adult HIV-infected populations. Longitudinal research is necessary to explore the etiologies of HIV-associated anemia in an African context.

TUPEB142

Obstructive sleep apnea among HIV-infected persons in the highly active antiretroviral therapy era: A nation-wide longitudinal cohort study in Taiwan, 2000 - 2010

Y.-C. Chen[1], C.-Y. Lin[2], C.-C. Chen[3], H.-Y. Liu[4], N.-Y. Ko[5]
[1]National Cheng Kung University, Department of Nursing, College of Medicine, Tainan, Taiwan, Province of China, [2]National Cheng Kung University Hospital, Otolaryngology, Tainan, Taiwan, Province of China, [3]National Cheng Kung University, Nursing, Tainan, Taiwan, Province of China, [4]National Cheng Kung University Hospital, Tainan, Taiwan, Province of China, [5]National Cheng Kung University, Tainan, Taiwan, Province of China

Background: Obstructive sleep apnea (OSA) is a common disease in HIV patients and as an independent risk factor for all-cause mortality. Some gaps in knowledge on the effects of early detection and continuing highly active antiretroviral therapy (HAART) that are not mentioned. This study compared the incidences of OSA between patients with HIV and those without, as well as aimed to evaluate the risk factors of OSA and to determine the effect of HAART on the incidences of OSA among HIV-infected persons.

Methods: A population-based cohort design was conducted using the National Health Insurance Research Database (NHIRD) contained 13,962 HIV-positive and 738,482 HIV-negative individuals from the general populations. Incidences of OSA were defined as the new diagnosis appearing after HIV diagnosis (ICD-9: 78051, 78053, 78057 or 32723). The age- and sex-standardized incidence ratio (SIR) was calculated to estimate the relative risk of OSA. Cox proportional hazards models were applied to evaluate the risk factors of OSA, and further to access the HAART effect on incidences of OSA among HIV-infected persons.

Results: Over 11 years of follow-up, the HIV-infected persons had a 1.4-fold OSA risk compared to that of the general population (SIR: 1.4, 95% CI, 1.15-1.68). The risk factors for OSA in HIV-infected persons were higher monthly salary (adjusted hazard ratio [aHR], 2.23; 95% CI, 1.29-3.85 for ≥ 42,000 NTD per month), obesity (aHR, 4.12, 95% CI, 1.38-12.29), fatigue (aHR, 1.72, 95% CI, 1.03-2.09), hyperlipidemia (aHR 2.45, 95% CI, 1.36-4.41), and chronic obstructive pulmonary disease (aHR, 2.52, 95% CI, 1.43-4.47). HAART is a protection factor for OSA (aHR, 0.12; 95% CI, 0.07-0.19) in HIV-infected persons, particularly in those with greater than or equal to six months of HAART.

Conclusions: HIV-infected persons have an elevated risk for OSA compared to the general population. Early detection and continuing HAART over a six-month period may reduce the risk of OSA.

TUPEB143

Computed tomography quantification of emphysema in people living with HIV and uninfected controls

A. Ronit[1], T. Kristensen[2], V. Hoseth[1], D. Abou-Kassem[1], T. Kühl[3], T. Benfield[1], J. Gerstoft[1], S. Afzal[4], B.G. Nordestgaard[4,5], J.D. Lundgren[6], J. Vestbo[7], K.F. Kofoed[2,3], S.D. Nielsen[1]
[1]University Hospital Rigshospitalet, Department of Infectious Diseases, Copenhagen E, Denmark, [2]University Hospital Rigshospitalet, Department of Radiology, Copenhagen E, Denmark, [3]University Hospital Rigshospitalet, Department of Cardiology, Copenhagen E, Denmark, [4]Herlev and Gentofte Hospital, The Copenhagen General Population Study, Department of Clinical Biochemistry, Herlev, Denmark, [5]University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, Denmark, [6]University Hospital Rigshospitalet, CHIP, Department of Infectious Diseases, Copenhagen E, Denmark, [7]University of Manchester, Division of Infection, Immunity and Respiratory Medicine, Manchester, United Kingdom

Background: People living with HIV (PLWH) may be susceptible to the development of emphysema. We assessed emphysema by computed tomography (CT) using quantitative and visual approaches in PLWH and uninfected controls.
Methods: Spirometry and chest CTs were obtained in PLWH from the Copenhagen comorbidity in HIV infection (COCOMO) Study and in uninfected controls from the Copenhagen General Population Study (CGPS) who were aged above 40 years. Emphysema was primarily quantified using low attenuation area below -950 Hounsfield units (%LAA-950), and secondarily by the 15th percentile density index (PD15) and by semi-quantitative visual scales. Breathlessness was defined by the modified medical research council scale with ≥2 signifying more breathlessness. Sputum was defined by duration of 3 months per year.vMultivariable logistic regression analyses adjusted for age, sex, ethnicity and cumulative smoking were computed to determine adjusted odds ratio (aOR) for emphysema.
Results: Of 742 PLWH, 21.2% and 4.7% had emphysema according to the %LAA-950 threshold with cut-offs at 5% and 10%, respectively. Of 470 uninfected controls, these numbers were 24.3% (p= 0.23) and 4.0% (p= 0.68). HIV was not independently associated with emphysema defined by each of the two %LAA-950 thresholds (aOR 0.96 [95%CI: 0.71-1.29]; aOR 1.25 [0.68-2.36]), by visually assessed emphysema (aOR 1.53 [95%CI: 0.85-2.83]) or by lung density determined by PD15. We found no interaction between HIV and age or HIV and cumulative smoking for the two %LAA-950 thresholds (all p-interactions>0.1). Emphysema (%LAA-950>10%) seemed to be more prevalent in PLWH with airflow limitation (FEV_1/FVC< lower limit of normal) compared to uninfected individuals with airflow limitation (17/77 vs 4/49, p= 0.07). Breathlessness (8/35 vs 1/19, p< 0.0001) and sputum production (12/35 vs 0/19, p< 0.0001) were more common in PLWH with emphysema than in uninfected controls with emphysema.
Conclusions: HIV was not independently associated with emphysema and HIV did not augment the effect of age or cigarette smoking. However, the clinical impact of emphysema was greater in PLWH, and emphysema seemed to be more prevalent in PLWH with airflow limitation than uninfected controls with airflow limitation.

	OR (95%CI) for LAA950 >5%	P-value	aOR (95%CI for LAA950 >5%	P-value	OR (95%CI) for LAA950 >10%	P-value	aOR (95%CI) for LAA950 >10%	P-value

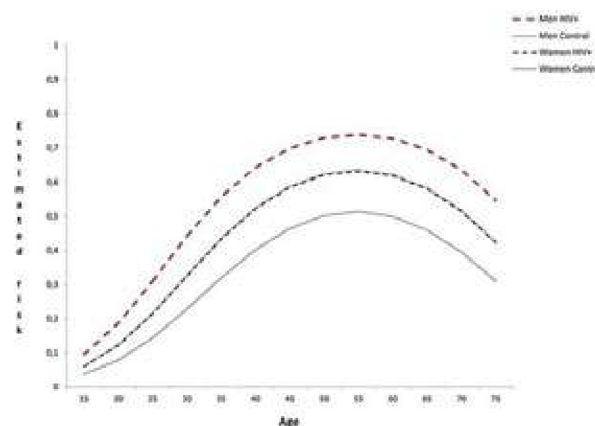
Severe periodontitis is more common in HIV-infected patients

H. Groenewegen[1], W.F.W. Bierman[2], K. Delli[1], P.U. Dijkstra[1,3], W. Nesse[1,4], A. Vissink[1], F.K.L. Spijkervet[1]
[1]University of Groningen and University Medical Center Groningen, Oral and Maxillofacial Surgery, Groningen, Netherlands, [2]University of Groningen and University Medical Center Groningen, Internal Medicine, Division of Infectious Diseases, Groningen, Netherlands, [3]University of Groningen and University Medical Center Groningen, Rehabilitation, Center of Rehabilitation, Groningen, Netherlands, [4]Wilhelmina Hospital, Oral and Maxillofacial Surgery, Assen, Netherlands

Background: Periodontitis and HIV both are associated with age related diseases because of their chronic inflammation and immune activation. Due to variation of research methodology , i.e., diverse definitions of periodontitis, differences in social and economic status and oral care awareness of included patients, the prevalence of periodontitis in HIV-infected patients is unclear. The aim of this study was to assess the prevalence of severe periodontitis in a representative population of HIV-infected patients and compare it with prevalence in controls. Additionally, presence of age-related diseases, HIV infection characteristics, oral health care characteristics and smoking status were explored as risk factors of severe periodontitis in HIV-infected patients.
Methods: In this cross-sectional controlled study, 258 outpatients with HIV infection were recruited. Periodontal status was assessed by applying the Dutch Periodontal Screening Index (DPSI). DPSI score 4, corresponding with periodontal pocket depth ≥6mm, indicates severe periodontitis. In addition, patients filled in a health and oral care assessment questionnaire. HIV characteristics (viral load, CD4+ T-cell count, CD4+/CD8+, type of cART, and CD4+ nadir) were collected from the medical charts. For comparing the periodontal status of HIV-infected patients with unaffected subjects, 539 controls were included from the same geographic area.
Results: Severe periodontitis was more prevalent in HIV-infected patients than in controls (65,5% versus 35,8%, p=0,002). HIV infection, age and gender were significant risk factors for severe periodontitis. In particular, older male HIV-infected patients ran a higher risk of having severe periodontitis (figure). Strikingly, 44,3% of HIV-infected patients did not disclose the HIV infection to their dentists as well as that independently of their DPSI score, all patients rated the importance of their dental health as very high. Clinical, HIV infection characteristics and type of cART did not predict severe periodontitis.
Conclusions: Prevalence of severe periodontitis is almost twice as high in patients with HIV infection compared to controls. Moreover, age and gender were risk factors for severe periodontitis in HIV-infected patients, while HIV characteristics were not predictors for severity of periodontitis.



[Estimated risk for severe periodontitis in HIV-infected patients and controls based on logistic regression analysis.]

Prevalence of diarrhea in HIV clinical trials in the recent post-combined antiretroviral therapy (cART) era: Analysis of data from 39 clinical trials from 2008-2017 in over 20,000 patients

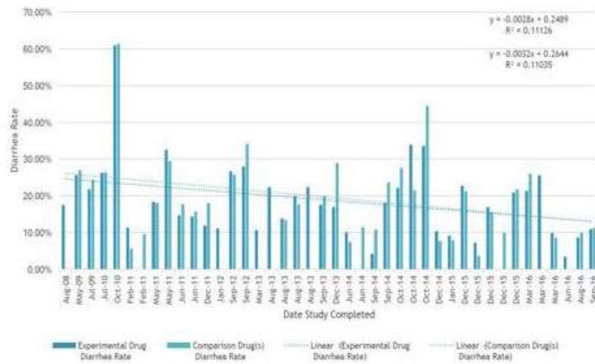
D.M. Asmuth[1], G. Blick[2], P.G. Clay[3], K. MacFarlane[4], P. Chaturvedi[4]
[1]University of California Davis Medical Center, Sacramento, CA, United States, [2]Health Care Advocates International, LLC, Stratford, CT, United States, [3]University of North Texas System College of Pharmacy, Fort Worth, TX, United States, [4]Napo Pharmaceuticals, San Francisco, CA, United States

Background: Despite the perception that gastrointestinal manifestations of HIV infection have declined over time, patients often complain of multiple loose stools per day with significant urgency, bloating, and unwanted disruptions in their quality of life when directly queried. In order to examine whether the rate of HIV-associated diarrhea has changed over time, we interrogated the publicly available NIH database of clinicaltrials.gov that reported the adverse event frequency of diarrhea from 2008-2016.

Methods: Pivotal efficacy intervention trials conducted in the US (including multinational trials) with greater than 100 participants were selected for analysis. Both comparative and switch studies that reported diarrhea as an adverse event were included.

Results: 39 trials met the inclusion criteria with 20,354 trial subjects receiving cART. 12,004 subjects received experimental therapy and 8,350 received the comparator regimen. The weighted average of the prevalence of diarrhea was 17.58% and 18.62% for those receiving experimental versus comparator regimens, respectively. The median prevalence of reported diarrhea was similar at 17.54% and 18.04%, respectively. The linear regression of diarrhea rates by date of completion of the study reveals beta coefficients of -0.0028 and -0.0032 for the experimental drugs versus the comparator regimens, respectively (see graph). These small beta coefficient values, which represent the slope of the line of rates of diarrhea over time, supports the hypothesis that the prevalence of diarrhea in pivotal clinical trials has remained nearly constant over time. The slope of the line does not change if trials with the protease inhibitors best known for increasing GI symptoms are excluded.

Conclusions: The prevalence of diarrhea in ART clinical trials has not declined significantly in the last 10 years. Diarrhea remains a significant comorbidity in HIV-positive patients, even those virally suppressed in clinical trials, with a prevalence of diarrhea of around 18%. These findings emphasize the need for more targeted epidemiologic and interventional studies to characterize the residual morbidity of gastrointestinal disease in people living with HIV as we seek to improve their quality of life and reduce this disruption in their activities of daily living.



[Diarrhea Rates by Date Study Completed]

The relationship between co-morbidities, physical activity and exercise level in persons living with HIV

E. Sefcik[1], J. Perazzo[2], I. Corless[3], K. Kirksey[4], M.J. Hamilton[1], L. Davis[5], J.C. Phillips[6], C. Dawon Rose[7], R. Schnall[8], K. Adams Tufts[9], P. Chaiphibalsarisdi[10], R. Musanti[11], M. Kesterson[5], P. Orton[12], A. Kulkarni[5], A. Gilson[5], B. Cazares[1], N. DeAnda[5], A. Webel[13]
[1]Texas A&M University-Corpus Christi, College of Nursing and Health Sciences, Corpus Christi, United States, [2]University of Cincinnati, Cincinnati, United States, [3]MGH Institue of Health Professions, Boston, United States, [4]Harris Health System, Nursing Administration, Houston, United States, [5]Texas A&M University-Corpus Christi, College of Education and Human Development, Corpus Christi, United States, [6]University of Ottawa, Ottawa, Canada, [7]University of California, San Francisco, United States, [8]Columbia University, New York City, United States, [9]Old Dominion University, Norfolk, United States, [10]St. Louis College, Bangkok, Thailand, [11]Rutgers University, Newark, United States, [12]Durban University of Technology, Durban, South Africa, [13]Case Western Reserve University, Frances Payne Bolton School of Nursing, Cleveland, United States

Background: Persons living with HIV (PLHIV) develop chronic diseases, such as cardiovascular disease and cancer, earlier and more often than individuals without HIV. Physical activity can mitigate symptoms commonly experienced by PLHIV living with chronic co-morbidities, but little is known about the relationship between physical and mental co-morbidities and physical activity. We conducted a multi-site observational study to examine the relationships between physical activity, exercise level and co-morbidities.

Methods: Seven-hundred and two PLHIV completed validated, cross-sectional measures of self-reported exercise (7-day physical activity recall and Godin Leisure Time Activity Questionnaire). Co-morbid conditions were abstracted from participant´s medical charts using a standardized form. One fourth of the subjects were recruited during each season of the year from seven geographically diverse sites in the United States and Thailand. Descriptive statistics and Spearman's Rho correlation analyses examined the relationships between co-morbidities and physical activity.

Results: Participants' mean age was 50.5±11.1 years; with 61% male, majority of whom were on ART (92%) with undetectable viral load (79.5%). Seventy-one percent (n=496) were currently diagnosed with at least one of 49 co-morbid conditions. Co-morbidities were categorized as: mental health (n=166, 23.65%); cardiovascular disease (CVD) (n=231, 32.86%); pulmonary disease (n=65, 9.26%); type II diabetes (n=53, 7.55%); end stage renal disease (n=6, 0.8%); hepatic disease (n=62, 8.83%); cancer (n=31, 4.42%); and autoimmune disease (n=16, 2.28%). Total time spent on physical activity and intensity (light, moderate, or vigorous) were reported for the previous week. Mental health ($r = -.017$), CVD ($r = -.197$), pulmonary ($r = -.139$), type II diabetes ($r = -.139$), and cancer ($r = -.118$) co-morbidities were associated ($p < 0.05$) with lower reported physical activity and exercise levels. Linear regression analysis (controlling for age, gender, and body mass index) showed that co-morbidity category remained a significant predictor of exercise in at least one exercise category.

Conclusions: PLHIV with mental health, pulmonary, type II diabetes, and cancer co-morbidities reported less frequent and lower intensity exercise levels. Co-morbidities can have a negative effect on the ability of PLHIV to engage in activities of daily living, particularly physical exercise. Further research needs to investigate approaches to improve the physical activity and exercise level in PLHIV with co-morbidities.

TUPEB147

Heterogeneity in pulmonary function indices by HIV status and cumulative smoking intensity among well-controlled HIV-infected persons compared to HIV-uninfected participants in the AGEHIV cohort

S.O. Verboeket[1,2], F.W. Wit[1,2,3], G.D. Kirk[4], M.B. Drummond[5], R.P. van Steenwijk[6], R.A. van Zoest[1,2], M.F. Schim van der Loeff[7], P. Reiss[1,2,3]

[1]Academic Medical Center, Department of Internal Medicine, Amsterdam Public Health Research Institute, Amsterdam, Netherlands, [2]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, [3]HIV Monitoring Foundation, Amsterdam, Netherlands, [4]Johns Hopkins University, Department of Epidemiology, Bloomberg School of Public Health, Baltimore, United States, [5]University of North Carolina, Division of Pulmonary and Critical Care Medicine, Chapel Hill, United States, [6]Academic Medical Center, Department of Pulmonary Medicine, Amsterdam, Netherlands, [7]Public Health Service of Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands

Background: Pulmonary function impairments are more common among people living with HIV (PLWHIV), as are the risk behaviors causing them. To understand the effects of HIV infection independent of risk behavior, pulmonary function was evaluated in the AGE_hIV cohort study, including lifestyle-comparable HIV-infected and HIV-uninfected participants aged ≥ 45 years in Amsterdam. We investigated the prevalence and determinants of obstructive lung disease (OLD) and to evaluate its determinants.

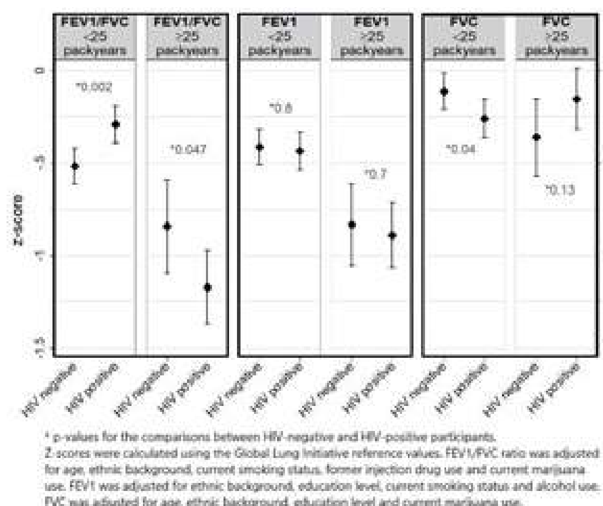
Methods: The prevalence of OLD (Forced Expiratory Volume in 1-second to Forced Vital Capacity ratio or FEV1/FVC < 70%) in 544 HIV-infected and 529 HIV-uninfected participants was determined using spirometry. Logistic regression was used to adjust for confounding variables including biometrics, demographics and risk behaviors. Additional explanatory models were constructed including HIV-related parameters and markers for chronic inflammation. Finally, determinants of z-scores of the individual spirometry indices were evaluated using linear regression.

Results: The prevalence of OLD was similar between HIV-infected and HIV-uninfected participants (23.0% and 23.4%, respectively; p=0.9). Multivariable logistic regression analysis showed a statistically significant interaction between HIV-infection and the number of pack-years (p=0.006): never-smoking HIV-infected participants were less likely to have OLD compared to never-smoking HIV-uninfected participants (9% vs. 21%, OR 0.35).

	Model 1 (a)			Model 2 (a)		
	OR	95%-CI	p-value	OR	95%-CI	p-value
HIV infection	0.88	0.65-1.17	0.4	**0.35**	**0.21-0.58**	**<0.001**
Pack-years per √(pack-years) increase (b)	x	x	x	**1.13**	**1.04-1.23**	**0.006**
Interaction: HIV infection x √(pack-years) (b)	x	x	x	**1.23**	**1.09-1.38**	**0.006**
Years since smoking cessation, per 10 years	x	x	x	1.10	0.88-1.37	0.4
Interaction: years since smoke cessation x √(pack-years) (b)	x	x	x	**0.91**	**0.85-0.98**	**0.009**
Daily marijuana use	x	x	x	2.06	0.92-4.64	0.08
Former injection drug use	x	x	x	1.87	0.84-4.19	0.13
(a) Both models are adjusted for age, height and BMI. (b) Variables were transformed to not violate the linearity assumption of the logistic regression model. Abbreviations/definitions: OR=Odds Ratio, CI=Confidence interval, pack-years=the equivalent of having smoked 1 pack of cigarettes daily during 1 year. The following variables were excluded as they were non-significant or did not influence the effect of HIV on the outcome: ethnicity, sexual orientation, employment status, current smoking status, current alcohol use.						

[Multivariable logistic regression models evaluating factors associated with the probability of OLD.]

However, the effect of pack-years on odds of OLD was stronger in the HIV-infected, so that from >25 pack-years the odds for the HIV infected were (non-significantly) higher. HIV-infection was associated with a lower FVC, but not a lower FEV1 among participants with less than 25 pack-years.



[Mean adjusted Z-scores with 95% confidence intervals of spirometry indices, by smoking history and HIV-status]

Within the latter subgroup, a history of *Pneumocystis jirovecii* pneumonia and/or AIDS, and higher plasma levels of IL-6 were independently associated with a lower FVC in the HIV-infected group.

Conclusions: Both HIV-infected and HIV-uninfected participants had a notably high prevalence of OLD. Our results suggest that among persons with limited lifetime smoking exposure, the higher FEV1/FVC ratio observed among PLWHIV compared to HIV-uninfected persons may represent prior pulmonary tissue damage with resulting lower FVC. This effect appears to be obviated with greater smoking exposure. Future studies should explore the role of chronic inflammation, prior pulmonary infections and other potential HIV-associated pathogenic mechanisms which may drive a restrictive processes in the lungs of PLWHIV.

Patient-reported outcomes among HIV-1-infected adults randomized to B/F/TAF versus DTG/ABC/3TC in two Phase 3 controlled clinical trials over 48 weeks

D. Wohl[1], A. Clarke[2], F. Maggiolo[3], W. Garner[4], M. Laouri[4], H. Martin[4], E. Quirk[4]

[1]University of North Carolina, Department of Medicine, Division of Infectious Diseases, Chapel Hill, United States, [2]Royal Sussex County Hospital, Brighton, United Kingdom, [3]Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, [4]Gilead Sciences Inc., Foster City, United States

Background: As efficacy of triple-drug antiretroviral therapy remains high, patient wellbeing (e.g., patient-reported outcomes) has become an important differentiator among regimens. Bictegravir, a novel, unboosted integrase strand transfer inhibitor, coformulated with emtricitabine and tenofovir alafenamide (B/F/TAF), demonstrated high efficacy and was well tolerated through week (W) 48, with no resistance in two phase 3 studies of treatment-naïve adults. We aimed to characterize change in symptoms of adult patients with HIV-1-infection after initiating or switching to B/F/TAF versus ABC/DTG/3TC.

Methods: Treatment-naïve adults were randomized (1:1) to receive blinded treatment with B/F/TAF or ABC/DTG/3TC (study 1489). Virologically suppressed adults were randomized (1:1) to switch to B/F/TAF or continue ABC/DTG/3TC in blinded fashion (study 1844). Across studies, HIV Symptoms Distress Module (HIV-SI) was administered at baseline (BL), W4, W12, and W48. Responses were dichotomized as bothersome/not. Treatment differences were assessed using logistic regression models adjusted for BL HIV-SI count, age, sex, BL Veterans Aging Cohort Study Index, medical history of serious mental illness, BL Short Form [SF]-36

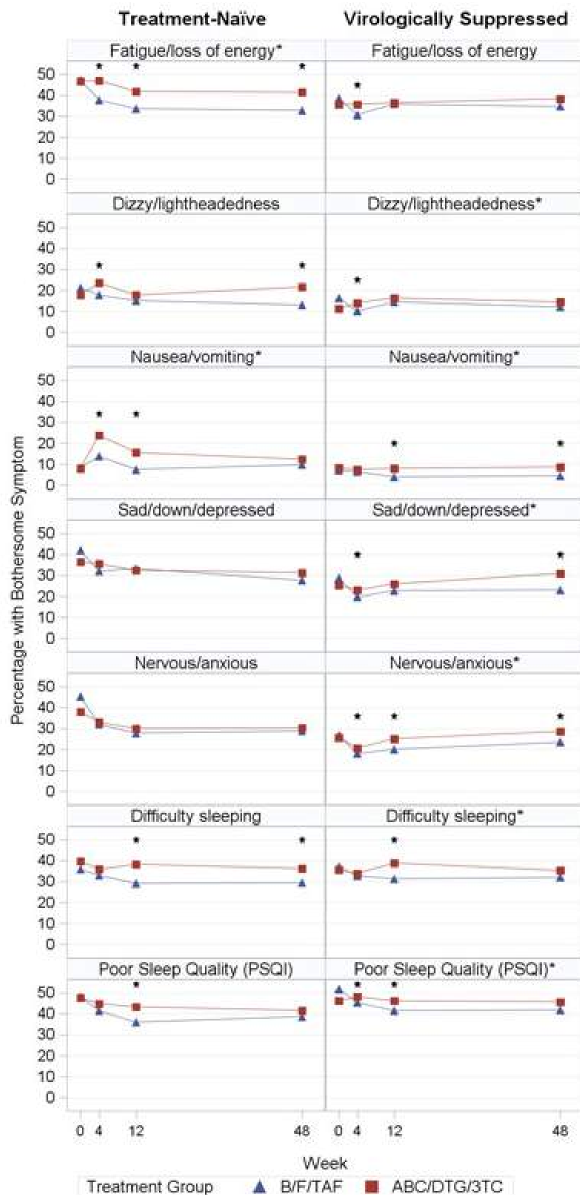
Author Index

Physical Component Summary [PCS], BL SF-36 Mental Component Summary [MCS], and years since HIV diagnosis (study 1844 only). Longitudinal modeling of bothersome symptoms was conducted using generalized, mixed model including treatment, time, time-by-treatment, and additional covariates. Pittsburgh Sleep Quality Index (PSQI) was administered with same frequency as HIV-SI, and total score was dichotomized as good/poor sleep quality. Similar models to HIV-SI were applied using BL sleep quality and BL SF-36 MCS as covariates.

	Treatment-naïve adults (study 1489)				Virologically suppressed adults (study 1844)			
Bothersome Symptom	Week 4	Week 12	Week 48	Longitudinal Model	Week 4	Week 12	Week 48	Longitudinal Model
Fatigue/loss of energy	X	X	X	X	X			
Dizzy/ lightheadedness	X		X		X			X
Nausea/vomiting	X	X		X		X	X	X
Sad/down/ depressed					X		X	X
Nervous/anxious					X	X	X	X
Difficulty sleeping		X	X			X		X
Poor sleep quality (PSQI)		X			X	X		X

X = statistically significant favoring the B/F/TAF group Statistical significance was assessed using p<0.05 Note: Only symptoms where at least two or more timepoints showed significance in either study were included. No symptom favored ABC/DTG/3TC at two or more timepoints for either study

[Comparison of patient-reported outcomes (B/F/TAF vs ABC/DTG/3TC) from adjusted logistic regression analyses and longitudinal analyses]



[Prevalence of bothersome symptoms over time by treatment group]

Results: Bothersome symptoms were reported by fewer participants on B/F/TAF than ABC/DTG/3TC in both studies (figure). For treatment-naïve adults, fatigue/loss of energy, nausea/vomiting, dizzy/lightheadedness, and difficulty sleeping significantly favored B/F/TAF at ≥2 timepoints (table). Fatigue and nausea were significantly less common for B/F/TAF in longitudinal models. For virologically suppressed participants, nausea/vomiting, sad/down/depressed, nervous/anxious, and poor sleep quality (from the PSQI) significantly favored B/F/TAF at ≥2 timepoints and in longitudinal models. No symptom favored ABC/DTG/3TC at ≥2 timepoints in either study.

Conclusions: Results suggest that patient-reported wellbeing may be better with B/F/TAF compared to ABC/DTG/3TC. B/F/TAF was associated with significantly lower prevalence of multiple bothersome symptoms across gastrointestinal disorders, neuropsychiatric events, and sleep. No symptoms favored ABC/DTG/3TC.

TUPEB149

Failure of antiretroviral therapy (ART) in adults in Australia is mainly due to ART toxicity

K.J. Siefried[1], L. Mao[2], S. Riches[1], S. Kerr[1], J. Rule[3,4], J. McAllister[1], J. de Wit[2,5], A. Carr[1], The PAART Study Investigators

[1]St Vincent's Centre for Applied Medical Research, Immunology and Infectious Diseases, Sydney, Australia, [2]University of New South Wales, Centre for Social Research in Health, Sydney, Australia, [3]University of New South Wales, School of Public Health and Community Medicine, Sydney, Australia, [4]National Association of People with HIV Australia, Sydney, Australia, [5]Utrecht University, Utrecht, Netherlands

Background: Lifelong antiretroviral therapy (ART) is recommended for all patients. Reasons for ART failure in virologically-suppressed patients are poorly understood.

Methods: We recruited 522 adults living with HIV on stable ART for ≥3 months with undetectable viral load into a nationwide cohort between September 2014 and November 2015. ART failure was defined by ART switch (for toxicity or interactions), virological failure, progression to AIDS, death, or loss to follow-up. Factors associated with ART failure through Month 12 were determined using Cox proportional hazards regression.

Results: 115 episodes of ART failure occurred in 102 participants (19.5%), primarily for toxicity requiring an ART switch (n=64, 12.3%); mostly nephrotoxicity (n=21, 4.0%), central nervous system symptoms (n=14, 2.7%), side effects (e.g. nausea/vomiting) (n=16, 3.1%), hepatotoxicity (n=8, 1.5%), and metabolic toxicity (n=6, 1.1%). Other reasons for ART failure were: virological failure (n=26, 5.0%); drug interactions (n=13, 2.5%); death (n=3, 0.6%); AIDS (n=2, 0.4%); loss to follow-up (n=2, 0.4%); and difficulty taking ART (n=1, 0.2%). The median time to the first failure event was 187 days (IQR 105-282).

Conclusions: Despite near universal ART availability and government-subsidised healthcare, nearly 20% of our sample experienced ART failure over 12 months, primarily for toxicity. Virological failure was less common.

TUPEB150

Hospitalisations over a year follow-up in a cohort of adults living with HIV with sustained viral suppression in Australia

K.J. Siefried[1], L. Mao[2], J. Rule[3,4], J. de Wit[2,5], A. Carr[1], The PAART study investigators

[1]St Vincent's Centre for Applied Medical Research, Immunology and Infectious Diseases, Sydney, Australia, [2]University of New South Wales, Centre for Social Research in Health, Sydney, Australia, [3]University of New South Wales, School of Public Health and Community Medicine, Sydney, Australia, [4]National Association of People with HIV Australia, Sydney, Australia, [5]Utrecht University, Utrecht, Netherlands

Background: Patients successfully treated with antiretroviral therapy (ART) for HIV develop few AIDS-defining events, are successfully aging and living longer. It has been proposed a "fourth 90" be added to the HIV treatment cascade, comprising quality of life outcomes. The aim of this longitudinal analysis is to understand the reasons and risks for hospi-

talisation as one potential component of the "fourth 90" in an Australian cohort, in part of a wider effort to incorporate the "fourth 90" into the HIV treatment cascade.

Methods: We recruited adults living with HIV on stable ART into a national cohort at 17 sites. A 90-item survey recorded demographics, physical health, life stressors, social supports, HIV disclosure, stigma/discrimination, healthcare access, treatment adherence and side effects, health/treatment perceptions, and financial/employment status. Neurocognitive, clinical and virological data were collected. Hospitalisations over 12 months were recorded. Baseline variables that were bivariately associated with hospitalisation (p< 0.05) in the following year of follow-up were included in a Cox proportional hazards regression model.

Results: Of 522 adults, 94.5% were male, mean age 50.8 years, mean HIV duration 12 years, median ART duration 11.0 years (IQR 1.2-6.8), and median duration HIV RNA < 50 copies/mL 3.3 years (IQR 1.2-6.8). Over 12 months, 94 (18.0%) participants had 143 hospitalisations, 1 hospitalisation resulted in death. Hospitalisations were for various non-AIDS reasons including serious non-AIDS events (SNAEs) (see Table). No participant was hospitalised with AIDS in the first 12 months of follow-up. Twenty-eight baseline variables bivariately associated (p< 0.05) with hospitalisation over the following 12 months, including being on a protease inhibitor. However, the only variable significant in multivariable Cox regression was having started ART to prevent HIV disease progression (adjusted hazards ratio 0.6 [95% confidence interval 0.4-0.9] p=0.029).

Conclusions: In this population of adults with suppressed HIV, hospitalisations were common over 12 months, most commonly for procedures (minor or diagnostic) or SNAEs. Preventable reasons for hospitalisation included accidents, renal issues and infection. Hospitalisations were largely not predictable, the only significant variable being starting ART to prevent HIV disease progression, potentially a surrogate for early HIV disease.

Reason for hospitalisation	Episodes, n (%)
Procedure - minor or diagnostic	25 (17.5)
Serious Non-AIDS Event (SNAE)	14 (9.8)
Accident / assault	13 (9.1)
Renal (stone, calculus, tumour, UTI)	11 (7.7)
Neurological	11 (7.7)
Infection	11 (7.7)
Cardiac (non-SNAE)	8 (5.6)
Other (various)	50 (34.9)
Total	143 (100)

[Table. Reasons for hospitalisation]

TUPEB151

Elevations of serum creatine kinase among HIV-positive individuals receiving dolutegravir-based therapy versus non-integrase inhibitor-based therapy

G.-J. Chen[1], H.-Y. Sun[1], A. Cheng[1], K.-Y. Lin[2], S.-P. Yang[3], W.-C. Liu[1], P.-Y. Wu[3], C.-C. Hong[1], S.-C. Chang[1]

[1]National Taiwan University Hospital and National Taiwan University College of Medicine, Department of Internal Medicine, Taiepi, Taiwan, Province of China, [2]National Taiwan University Hospital Jin-Shan Branch, Department of Medicine, New Taipei City, Taiwan, Province of China, [3]National Taiwan University Hospital, Center of Infection Control, Taipei, Taiwan, Province of China

Background: Integrase strand transfer inhibitor (InSTI) is an increasingly used antiretroviral agent in both initial and salvage therapy across different local and international guidelines. Reports from randomized clinical trials and real-life cohort study have suggested that the first-generation InSTI, raltegravir, might be associated with an increased risk of creatine kinase (CK) elevation and skeletal muscle toxicity. However, real-life data systematically evaluating the risk of CK elevation among HIV-positive patients receiving dolutegravir (DTG)-containing antiretroviral therapy are scarce.

Methods: HIV-positive patients who sought medical attention at the National Taiwan University Hospital between January 2017 and January 2018 were included in this study. Patients were prospectively interviewed to inquire into their practices of weight training and alcohol consumption. Laboratory tests including liver function, renal function, creatine kinase, plasma HIV RNA load and CD4 cell counts were tested every 3-6 months in accordance with the national HIV treatment guidelines. The incidence of elevation of serum CK and rhabdomyolysis (defined as >10-fold of the upper limit of normal) was estimated among patients who received DTG-containing antiretroviral therapy versus patients who received non-InSTI based therapy.

Results: 1335 HIV-positive patients with a median age of 37.9 years and 96.6% being male were included in this study: 339 patients who received DTG-containing antiretroviral therapy provided 651 laboratory results of CK measurements while 996 who received non-InSTI-based antiretroviral therapy contributed 1544 laboratory results of CK measurements. Among patients receiving DTG-containing therapy, the rate of CK elevation was 15.8% (103/651), which was similar to the 13.7% (211/1544) among those receiving non-InSTI based therapy (difference, 2.1%; 95% CI, -1.1-5.6%). The rate of rhabdomyolysis was also similar between both groups (1.1% versus 0.7%; difference, 0.4%; 95% CI, -0.5-1.6%). The risk of CK elevation increased with patient's self-reported intensity of weight training (≤0.5 versus >0.5 hours/day), but was not associated with the use of DTG-containing antiretroviral therapy. All episodes of elevated CK or rhabdomyolysis in either group of patients were self-limited during the study period and no treatment was required.

Conclusions: In this single-center prospective cohort study, DTG-containing antiretroviral therapy was not associated with an increased risk of asymptomatic CK elevation or rhabdomyolysis.

Natural history, morbidity patterns and survival

TUPEC152

Risk factors associated with AIDS-related mortality among people living with HIV: A national observational cohort study between 2005- 2017 in Papua New Guinea

S. Miyano[1,2], P. Boas[3], N. Dala[3], G. Anup[1]

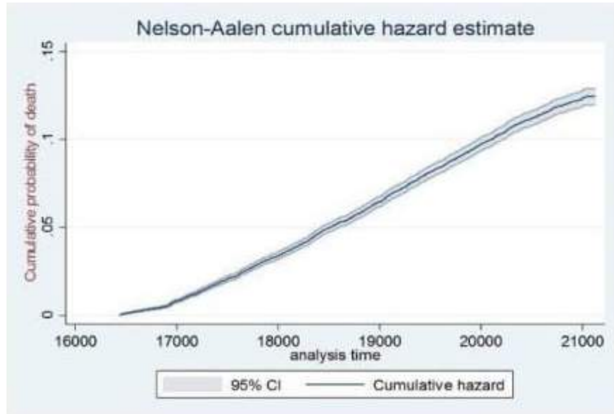
[1]World Health Organization, HIV/STI/Hepatitis Programme, Port Moresby, Papua New Guinea, [2]National Center for Global Health and Medicine, Tokyo, Japan, [3]National Department of Health, HIV/STI Programme, Port Moresby, Papua New Guinea

Background: Papua New Guinea (PNG) shows the highest HIV prevalence among the 22 Pacific Island countries (0.89%), and over 95% of HIV cases in the Pacific are reported from PNG. However, there has been no assessment on mortality among people living with HIV (PLHIV) by using the national database. This study aimed to estimate mortality among PLHIV, and explore risk factors associated with AIDS-related mortality in PNG.

Methods: The National HIV Patient Cohort Database (HPDB) was used to analyse the data of PLHIV from 2005 to 2017 coming to clinics focusing on socio-demographics, registration year, WHO clinical stage, CD4 cell count, TB status, hepatitis B virus (HBV) infection, sexual risk behaviours, and treatment outcomes. Nelson-Aalen Cumulative Hazard Estimates were used to overall estimated probability of death, and risk factors associated with mortality were explored by Cox's proportional hazard model.

Results: Over twelve years, 31,997 PHLIV were followed up for 64,526 patient-years (male 40.2%, female 59.7%, transgender 0.1%). At the first visit, the mean age was 35.5 years, the mean CD4 cell count was 236.2 cells/mm^3, and TB and HBV co-infection was respectively found in 11.6% and 12.9% among those screened. Overall mortality was 4.84 per 100 person-years while it has been drastically decreasing from 160 in 2005 to 0.54 in 2017. PLHIV, who were in lower CD4 cell count (adjusted HR; 1.89, 95% CI 1.62- 2.15, *p*< 0.001), TB co-infection (adjusted HR; 1.4, 95% CI 1.54- 2.12, *p*< 0.001), older age group (adjusted HR; 1.20, 95% CI 1.12- 1.33, *p*< 0.001), and poor WHO clinical stage (adjusted HR; 1.10, 95% CI 1.02- 1.15, *p*< 0.001), showed significantly higher mortality while gender, sexual risk behaviours and HBV co-infection did not show any significance.

Conclusions: This is the first longitudinal cohort analysis reviewing AIDS-related death and its risk factors in PNG. The mortality has been successfully decreased year by year since 2005. However, traditional types of factors associated with AIDS-related mortality are still remaining. From a programmatic point of view, it is crucial to re-emphasize the importance of doing the "basics" such as earlier diagnosis and treatment of HIV infection, and proper management of HIV-associated TB.



[Nelson- Aalen cumulative hazard estimates]

TUPEC153

Exploring declines in mortality after ART initiation: Evidence from seven sub-Saharan African population-based studies between 2005 and 2014

E. Slaymaker[1], K. Risher[2], G. Reniers[2], D. Obor[3], M. Urassa[4], A.J. Herbst[5], V. Hosegood[6], R. Newton[7,8], T. Lutalo[9], A. Crampin[10,11], S. Gregson[12,13], M. Marston[2], K. Tomlin[2], B. Zaba[2]
[1]London School of Hygiene & Tropical Medicine, Population Health, West Byfleet, United Kingdom, [2]London School of Hygiene & Tropical Medicine, Population Health, London, United Kingdom, [3]CDC/KEMRI, Kisumu, Kenya, [4]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [5]Africa Health Research Institute, Durban, South Africa, [6]University of Southampton, Southampton, United Kingdom, [7]University of York, York, Uganda, [8]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, [9]Rakai Health Sciences Project, Entebbe, Uganda, [10]Malawi Epidemiology and Intervention Research Unit, Lilongwe, Malawi, [11]London School of Hygiene & Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom, [12]Imperial College, London, United Kingdom, [13]Biomedical Research and Training Institute, Harare, Zimbabwe

Background: We used community demographic data with information on HIV status, diagnosis and treatment from studies that comprise the Network for Analysing Longitudinal, Population-based HIV/AIDS data on Africa (ALPHA) to estimate mortality among people who had started ART by duration of infection, measures of morbidity and clinic attendance.

Methods: We used data on adults aged 15-59 from Kenya (Kisumu), Malawi (Karonga), South Africa (uMkhanyakude), Tanzania (Kisesa), Uganda (Masaka and Rakai) and Zimbabwe (Manicaland).

We estimated population-based mortality rates by time since ART initiation for people who initiated treatment whilst resident in one of the study areas, based on self-report in surveys or clinic data linked to individual-level demographic surveillance system (DSS) data. Deaths were observed in the DSS. Data on clinic visits, ART prescriptions and refill dates were used to describe timeliness of clinic attendance (on ART and on time for last refill; on ART but late for last refill; not on ART).

We fitted piecewise exponential models for men and women with time since initiation split into < 6 months, 6-11 months, 12-23 months, 24-35 months and >36 months. Time-varying covariates included age, calendar year, clinical stage, timeliness of clinic attendance, and for a subset of observed sero-convertors, duration of infection. Other covariates were sex, CD4 count at initiation and study.

Results: ART initiation was observed for 2,811 men and 7,153 women. 405 men and 519 women died (mean exposure 2.7 person-years).

Between 2005 and 2014, the mortality among people who had initiated ART fell (Table 1). This decline were seen at all times following ART initiation, in all studies and at all ages.

In three studies, we could adjust for CD4 at initiation and (time-varying) timeliness of clinic attendance and clinical stage. For men, the effect of calendar year was stronger after adjustment (HR 0.82 (p=0.001) versus 0.85 (p=0.002)).

Conclusions: Mortality among adults post-ART initiation declined substantially between 2005 and 2014. These declines are not immediately explained by more timely presentation or better attendance for treatment. There was rapid expansion and decentralisation of services in these resource-poor rural settings in this period. Treatment may have improved and contributed to improved survival.

TUPEC154

Time-dependent effect of HCV coinfection in overall and cause-specific mortality in HIV-positive individuals

B. Alejos[1], J. del Amo[1], J. Berenguer[2], M. Riera[3], M. Garcia[4], V. Asensi[5], O. Bisbal[6], R. Muga[7], J. Gonzalez[8], I. Jarrin[1], CoRIS cohort Study Group
[1]Instituto de Salud Carlos III, Centro Nacional de Epidemiología, Madrid, Spain, [2]Hospital Gregorio Marañon, Madrid, Spain, [3]Hospital Son Espases, Palma de Mallorca, Spain, [4]Hospital de Navarra, Pamplona, Spain, [5]Hospital Central de Asturias, Oviedo, Spain, [6]Hospital Doce de Octubre, Madrid, Spain, [7]Hospital Germans Trials i Pujol, Badalona, Spain, [8]Hospital La Paz, Madrid, Spain

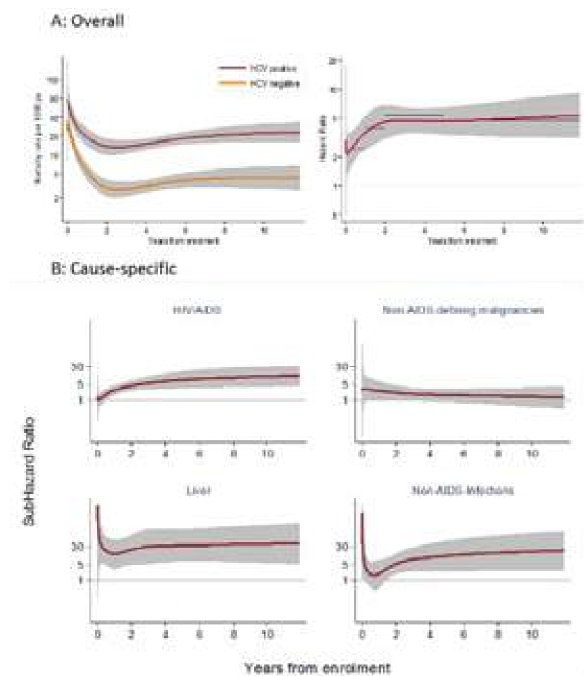
Background: Coinfection by hepatitis C virus (HCV) is one of the most common comorbidities in HIV-positive individuals. We aimed to study time-dependent effects for HCV coinfection in overall and cause-specific mortality in HIV-positive individuals in the cohort of the Spanish Network of HIV Research (CoRIS).

Methods: We fitted extended Flexible Parametrical Models (FPM) to estimate time-dependent (sub) hazard Ratios (sHR) for HCV coinfection in overall and cause-specific mortality. Cox regression including interaction with follow-up time interval was also performed. FPM were similarly applied to estimate time-varying excess mortality compared to Spanish general population. Cause-specific groups were created based on a simplified algorithm adapted from the CoDe coding system: HIV/AIDS, Liver-related, Non-AIDS-malignancies and Non-AIDS-infections. We only considered participants who had at least one HCV test result (anti-HCV antibody or HCV RNA) during follow-up. Participants were followed-up from enrolment to death or loss to follow-up, whatever arose first.

Results: In 10,406 patients there were 357 deaths; 37% were HIV/AIDS, 15% Non-AIDS malignancies, 12% liver-related and 8% Non-AIDS-infections related. Figure A shows overall mortality rates (MR) and hazard ratio (HR) for HCV coinfection using FPM (red line) and categorizing

follow-up time (black line). Overall mortality rates among both mono and coinfected subjects decrease over time only up to 2.5 years after enrolment. The significant effect of HCV coinfection on overall mortality increases up to the second year after enrolment and remains stable during the rest of follow-up. Further, the analysis using FPM better describes the time depend effect of HCV coinfection. For cause-specific mortality time-dependent effects of HCV coinfection were just observed for HIV/AIDS and Non-AIDS-infections (Figure B). Liver mortality was constantly higher during all the follow-up among HCV coinfected subjects and no differences were detected for Non-AIDS-malignancies. Similar patterns were observed when modelling excess mortality (data not shown).

Conclusions: HCV-coinfection is associated with increased all-cause, HIV/AIDS, liver and Non-AIDS infections related mortality among HIV-positive patients. Differential effect of HCV coinfection over time was found for overall, HIV/AIDS and Non-AIDS-infections mortality. FPM offer a clinically interpretable and easy to implement alternative to better describe the time-dependent effect of HCV coinfection.



[Mortality Rates (MR) and effect of HCV coinfection on overall and cause-specific mortality]

TUPEC155

Antiretroviral treatment scheme complexity predicts AIDS mortality in in Mexico: A longitudinal study from 2012 to 2016

G. La Hera Fuentes[1], M. Valenzuela-Lara[2], P. Uribe-Zúñiga[2], C. Magis-Rodríguez[2], J.E. Hernández-Avila[3], A. Quezada-Sanchez[3], E. Morales Carmona[3], L.I. Espín Arellano[3], S. Bautista-Arredondo[3,4]
[1]National Institute of Public Heath in Mexico, Cuernavaca, Bolivia, [2]National Center for the Prevention and Control of HIV and AIDS (CENSIDA), Mexico City, Mexico, [3]National Institute of Public Health, Cuernavaca, Mexico, [4]School of Public Health, UC Berkeley, Berkeley, United States

Background: Worldwide, only 43% of people under antiretroviral treatment (ART) are virally suppressed. Despite multiple efforts to design and evaluate behavioral and technological interventions to increase adherence, results are disappointing: most interventions have relatively small and short effects. Simple and effective alternatives to improve adherence among HIV/AIDS patients are still needed. In this study, we analyze the impact of two dimensions of treatment scheme complexity - dosage and number of pills - on the survival rates of Mexican patients.

Methods: A survival analysis was conducted with data from the Antiretroviral Administration, Logistics and Surveillance System on 40,377 adult patients under treatment from 2012-2016. We examined time-to-failure (death) including time-varying treatment variables, such as CD4 counts and age. Using two Multivariate Cox proportional hazard models we explored the effect of ART scheme complexity and other clinical and socio-demographic characteristics on mortality. We applied Kaplan-Meier techniques for descriptive analysis and log-rank test to compare survival curves.

Results: Mean age of entry was 34 years old, with 81% male. The average follow-up time was 26 months, with 9.6% death cases. The mean failure-time was 7.9 months. Patients under two-pills regimens were 40% more likely to die than those under one pill schemes (HR=1.4); similarly, patients with three or more pills regimens were 30% more likely to die, with a HR of 1.3. The number of prescriptions per day increased mortality risk by 30% (HR=1.3) per additional dosage per day. Both Multivariate Cox analyses showed that males were at higher risk of death (HR=1.1) compared with females, and older patients (30-49 years, HR=1.3; >50, HR=1.8) compared to younger patients (< 30). Primary level clinics showed higher mortality than secondary hospitals (HR=1.4).

Conclusions: Simpler treatment regimens with fewer number of pills and one prescription per day contribute to the survival of the patients. Our study contributes to the literature on interventions to increase adherence and survival of HIV/AIDS patients. In addition to other factors that contribute to loss-to-follow-up, simplification of treatment seems to be a clear, simple alternative to improve their chances to benefit from ART.

CD4/CD8 ratio normalization and its determinants in long-term virologically suppressed HIV-infected Thais

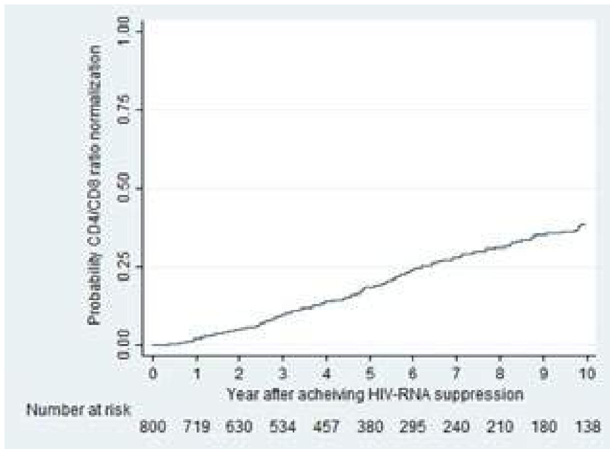
W.M. Han[1], T. Apornpong[1], S.J. Kerr[1,2], S. Gatechompol[1], A. Hiransuthikul[1], T. Do[1], S. Ubolyam[1], A. Avihingsanon[1,3], K. Ruxrungtham[1,4], on behalf of HIV-NAT 006 team
[1]HIV-NAT, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, [2]Kirby Institute, University of New South Wales, Sydney, Australia, [3]Chulalongkorn University, Division of Allergy and Immunology, Bangkok, Thailand, [4]Chualongkorn University, Research and Innovation, Bangkok, Thailand

Background: Immune restoration is often incomplete after ART in HIV patients, both quantitatively and qualitatively. We studied the incidence and probability of CD4/CD8 normalization in an adult Thai HIV cohort and explored factors associated with the normalization.

Methods: We analyzed data from HIV-infected Thai adults between 1996 to 2017 in the HIV-NAT 006 prospective long-term cohort in Bangkok, Thailand. Normalization was defined as CD4/CD8 ratio more than or equal 1 of two consecutive visits, and normalization probability was calculated using the Kaplan-Meier method. Multivariate Cox regression was used to evaluate demographic, disease and treatment characteristics associated with CD4/CD8 ratio normalization.

Results: A total of 1067 ART-naïve patients with baseline CD4/CD8 ratio of < 0.8 and started combination ART, and later had sustained viral suppression (HIV RNA viral load below detection limits according to the method used: ≤500 copies/mL from year 1996 to 1999 and ≤50 copies/mL thereafter) were enrolled. The median baseline CD4 count and HIV-RNA viral load level were 227 (interquartile range [IQR], 128 - 321) cells/mm³ and 4.8 (IQR, 4.4 - 5.2) $\log_{10}$ copies/mL, respectively. Participants were virologically suppressed for a median of 6.1 (IQR: 3 - 10.8) years. The incidence rate of normalization was 4.38 (95% confidence interval [CI]: 3.81-5.04) per 100 person-years, with probabilities of CD4/CD8 normalization at 2, 5 and 10 years after viral suppression of 5.1%, 18.6% and 39.1%, respectively (Figure 1). In multivariate analysis, the factors associated with normalization were female sex (hazard ratio[HR]: 2.13, 95% CI: 1.6 - 2.9, p< 0.001) and baseline CD4 counts >350 cells/mm³ (HR: 3.77, 95% CI: 2.5 - 5.8, p< 0.001). No association of normalization was found with CDC staging, antiretroviral regimen or viral co-infections such as hepatitis B and hepatitis C.

Conclusions: Our findings show that complete immune recovery is uncommon in an Asian setting, with only approximately 20% and 40% of participants achieving CD4/CD8 ratio normalization, after 5 and 10 years of with viral suppression, respectively. Earlier ART initiation may have increased the ratio sooner.



[Figure 1: Kaplan-Meier curve showing probability of CD4/CD8 ratio normalization with a median of 6.15 years of viral suppression]

Epidemiology of HIV in the general population

TUPEC157

Universal test and treat: Loss to follow-up among patients initiated on antiretroviral therapy in South Africa under evidence-based guidelines

K. Hirasen[1], C.J. Hendrickson[1], T. Sineke[1], M.P. Fox[1,2,3], I. Mokhele[1], D. Onoya[1]
[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Boston University School of Public Health, Department of Global Health, Boston, United States, [3]Boston University School of Public Health, Department of Epidemiology, Boston, United States

Background: In an effort to reach national targets, in September 2016 South Africa implemented the World Health Organization's (WHO) recommendation for Universal Test and Treat (UTT), expanding first-line ART to all HIV positive patients irrespective of traditionally used clinical indicators/thresholds such as WHO staging or CD4 cell counts. To evaluate the impact of this policy change we compare loss to follow-up (LTFU) among HIV positive, ART naïve, patients initiating first-line ART pre- and post-UTT roll-out within a large public-sector HIV clinical cohort in Johannesburg, South Africa.

Methods: We conducted an analysis of HIV positive adult patients who initiated standard first-line triple combination ART within the Right to Care (RTC) Clinical Cohort in South Africa. We compare two non-pregnant, tuberculosis-free groups: 1) those who initiated treatment pre-UTT (01/10/2015-28/02/2016); and 2) those who initiated treatment post-UTT (01/10/2016-28/02/2017). Our outcome was LTFU by 6 months post-ART initiation defined as being >3 months late for the last scheduled visit with no subsequent visit. We used Cox proportional hazards models to evaluate the relationship between pre-UTT vs. post-UTT ART initiation and LTFU using adjusted hazard ratios (aHR). Baseline characteristics which resulted in a ≥±10% change in the primary exposure effect were included in the adjusted model.

Results: We included 2662 patients in our analysis (1154 initiated pre-UTT, 1508 post-UTT). Patient characteristics at ART initiation were similar between groups, apart from a higher proportion of post-UTT patients with CD4 cell counts >500 copies/mm^3 (23.1 vs. 0.3% pre-UTT). By 6 months post-ART initiation a higher proportion of patients who initiated under UTT guidelines were LTFU (11.4 vs. 8.0% pre-UTT). This translated into a 72% increase in LTFU (aHR 1.72; 95%CI: 1.28-2.31) (Table). Additionally, younger patients were 60% more likely to be LTFU (18-29 vs. 30-44 years; aHR 1.60; 95%CI: 1.17-2.19).

Conclusions: In this study patients starting ART under UTT guidelines were almost twice as likely to be LTFU by 6 months post-initiation compared with initiates under previous guidelines. While expanded guidelines may result in greater numbers of patients on ART, this policy change may also promote intermittent health seeking behaviour, potentially among patients not yet ready for life-long therapy.

TUPEC158

Assessing the clinical significance of persistent low level viremia on subsequent virologic failure

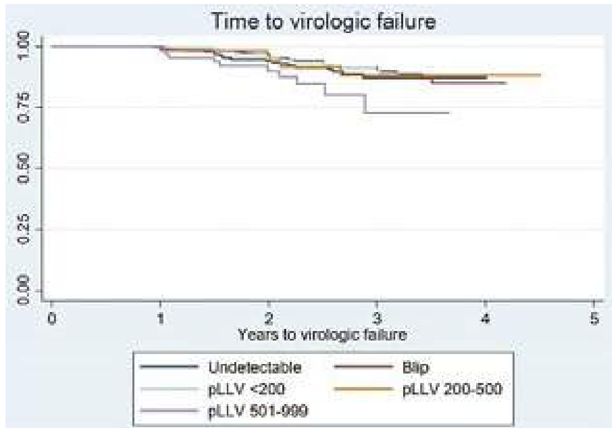
A. Esber[1,2], C. Polyak[1,2], F. Kiweewa[3], J. Maswai[1,4,5], J. Owuoth[1,5,6], L. Maganga[7], Y. Adamu[8], J. Ake[1], T. Crowell[1,2]
[1]U.S. Military HIV Research Program, Silver Spring, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]Makerere University, Walter Reed Project, Kampala, Uganda, [4]Henry M. Jackson Foundation Medical Research International, Kericho, Kenya, [5]Kenya Medical Research Institute, Nairobi, Kenya, [6]Henry M. Jackson Foundation Medical Research International, Kisumu, Kenya, [7]Mbeya Medical Research Centre, Mbeya, Tanzania, United Republic of, [8]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Abuja, Nigeria

Background: WHO guidelines identify HIV RNA less than 1000 copies/ml as the goal of antiretroviral therapy (ART). However, the clinical implications of viremia below this threshold are unclear in the African context. Our objective was to assess associations of persistent low level viremia (pLLV) and transient viral blips with risk of subsequent virologic failure.

Methods: The African Cohort Study enrolls HIV-infected participants in Uganda, Kenya, Tanzania, and Nigeria. Clinical assessments are performed every six months. PLLV was defined as HIV RNA < 1000 copies /mL on ≥ 2 consecutive assessments, a blip as a single detectable HIV RNA < 1000 copies/mL with subsequent return to undetectable, and virologic failure as any HIV RNA ≥1000 copies/mL. Kaplan-Meier estimation was used to evaluate time to failure. We used Cox proportional hazards to estimate hazard ratios (HRs) for five levels of HIV RNA: undetectable, blip < 1000 copies/ml, pLLV < 200 copies/ml, pLLV 200-500 copies/ml, and pLLV 501-999 copies/ml. If participants fell into multiple pLLV categories they were classified into the greater HIV RNA category.

Results: We included 1,687 participants in our analysis with a median follow-up time of 2.02 years (IQR 1.5-2.7 years). There were 533 participants with undetectable HIV RNA, 567 with blips, 455 with pLLV < 200 copies/ml, 63 with pLLV 200-500 copies/ml, and 69 with pLLV 501-999 copies/ml. During follow-up, 108 (6%) participants experienced virologic failure. Participants with HIV RNA 501-999 copies/ml had a statistically

significantly lower survival curve. In the Cox model, the hazard rate of virologic failure for participants with pLLV between 501-999 copies/ml was 2.68 times (95% CI: 1.31, 5.49) the rate of failure of participants with pLLV < 200 copies/ml. There were no significant differences in risk of virologic failure comparing lower levels of pLLV or blips to those with undetectable HIV RNA.
Conclusions: Our findings suggest that participants with persistent HIV RNA 501-999 copies/mL are at significantly increased risk of virologic failure. Further investigation is needed to better characterize factors contributing to the increased risk of failure among participants with pLLV and consideration may need to be given to lowering the HIV RNA target for successful ART.



[Time to Virologic failure]

TUPEC159
HIV positivity by age among VMMC clients in 14 countries and comparison to PHIA results

D.H. Watts[1], C. Cooney[1], J.S. Cavanaugh[1], N. Kothegal[2], H. Patel[2], V. Kiggundu[3], A.G. Thomas[4], N. Parks[3], C. Toledo[2]
[1]U.S. Department of State, Office of the Global AIDS Coordinator, Washington, United States, [2]Centers for Disease Control and Prevention, US DHHS, Division of Global HIV and TB, Atlanta, United States, [3]U.S. Agency for International Development, Office of HIV/AIDS, Washington, United States, [4]U.S. Department of Defense, DoD HIV/AIDS Prevention Program, Defense Health Agency, San Diego, United States

Background: Voluntary medical male circumcision (VMMC) is an important HIV prevention modality, conferring a long-term 60% reduction in HIV acquisition risk for men. VMMC programs include HIV education and offer testing. Starting in 2017, PEPFAR incorporated age-disaggregated reporting of HIV testing results in VMMC programs. These results could potentially provide insight on HIV prevalence in the general male population. We evaluated the results by age across countries to assess testing yield and to compare to published data from Population-based HIV Impact Assessments (PHIA) surveys completed between 2016-2017 where available.
Methods: Data regarding status among those testing at VMMC sites (positive, negative, unknown) and positivity rate by age bands were analyzed globally and within each country. For countries, where age disaggregated data from the PHIA surveys have been published, prevalences were compared by inspection to evaluate comparability.
Results: HIV status among all clients testing at VMMC sites in 2017 was negative in 3,002,941 (91.5%), positive in 24,101 (0.7%), and unknown in 256,159 (7.8%). Age disaggregated data were available for 68% of VMMC clients tested for HIV. Results by age band are shown in the table. The rate of positivity increases with age. PHIA confidence intervals did not include positivity rates in VMMC settings except in those under age 20 in Tanzania and Uganda and under age 15 in Zambia.
Conclusions: Despite low positivity in those below age 15, testing detects an important population of children living with HIV in some countries; age-diaggregated results allow countries to tailor testing strategies by age. All VMMC programs should have a mechanism to link those testing positive to treatment. HIV seroprevalence is lower among VMMC clients than population-based rates, suggesting potential prior testing or other self-selection factors among those seeking VMMC. These selection biases make VMMC testing not indicative of population rates of HIV.

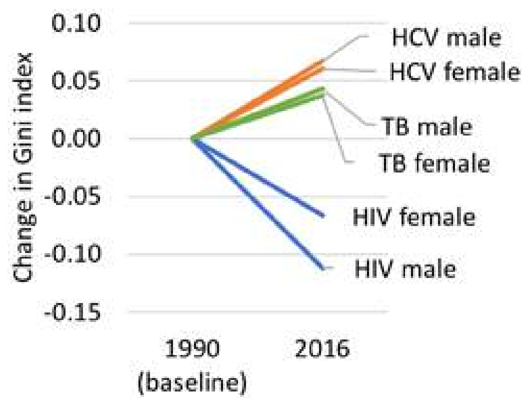
TUPEC160
Inequality in global HIV, TB, and hepatitis C burden from 1990 to 2016

D. Gotham[1], P. von Philipsborn[2], F. Steinbeis[3], J. Sim[4]
[1]Independent, Boston, United States, [2]LMU University of Munich, Pettenkofer School of Public Health, Munich, Germany, [3]Charité - Universitätsmedizin Berlin, Medizinische Klinik mit Schwerpunkt Infektiologie und Pneumologie, Berlin, Germany, [4]Imperial College London, London, United Kingdom

Background: The Gini Index (GI) and Theil Index (TI) are metrics commonly used in economics to measure inequality in the distribution of resources such as income or wealth. A GI of 0 represents perfect equality, and 1 - perfect inequality (100% burden in a single country). The TI can be 'decomposed' to show the proportion of inequality contributed by between-region versus within-region inequality. We applied these measures to the global burden of HIV, tuberculosis (TB), and hepatitis C (HCV).
Methods: Age-standardised country-level prevalence, incidence, and disability-adjusted life years lost (DALYs) rates were extracted from the Global Burden of Disease study. We calculated population-weighted GI and TI values for 1990 and 2016 in Stata/MP (version 14.0). Theil indices were decomposed at the level of 7 world regions (high-income countries; Latin America and the Caribbean (LAC); North Africa and the Middle East (MENA); sub-Saharan Africa; South Asia; Southeast Asia, East Asia and Oceania; Europe, Eastern Europe, and Central Asia (EECA)).
Results: Results are shown in the Table and Figure. Sensitivity analysis using all-age instead of age-standardized data did not substantially affect the findings.

	Gini value in 2016 (change 1990-2016)			% of inequality contributed by between-region differences	
Disease	Prevalence	Incidence	DALYs	1990	2016
HIV	0.78 (-0.09)	0.72 (-0.15)	0.77 (-0.09)	55%	55%
HCV	0.36 (+0.03)	0.37 (0.00)	0.50 (+0.06)	45%	55%
TB	0.27 (+0.03)	0.43 (+0.02)	0.59 (+0.04)	66%	58%

[Table. Changes in Gini index between 1990 and 2016, and changes in proportion of inequality contributed by between-region differences.]



[Changes in Gini index value by disease and sex, 1990-2016.]

Conclusions: Global inter-country inequality in the burden of HIV, HCV, and TB, as measured by the Gini index, is of similar magnitude as global inter-country income inequality (reported as 0.63 by Hellebrandt et al, SSRN Electron J. 2015). Global inequality was substantially higher for HIV than TB or HCV, but decreased since 1990 , while global inequality increased for HCV and TB. The decrease in inequality for HIV began after 2003. The decrease in HIV inequality was substantially greater for men than women. In all years, inequality in TB was greater in terms of disability and life years lost than it is in terms of prevalence. For all three diseases in 1990 and 2016, approximately half of relative inequality was contributed by differences in burden within individual world regions, and half by differences between regions (between-region component increased for HCV, decreased for TB, and did not change for HIV). Among regions, the highest inequality for HIV was seen between countries in LAC, for TB in MENA, and for HCV in EECA.

TUPEC161

High rates of female sterilization could impact HIV prevalence in high burden areas in India - couple-centered intervention strategies may help in consolidation of prevention gains

R. Brahme[1], S. Sonavale[1], R. Joshi[2], S. Venkatesh[3], C. Kadu[1], R. Yadav[1], N. Dulhani[1], A. Lokhande[1], Y. Raj[3], P. Kumar[3], P. Deoraj[4], S. Acharya[5], S. Godbole[1]
[1]National AIDS Research Institute, Pune, India, [2]PHD Student at National AIDS Research Institute, Pune, India, [3]National AIDS Control Organization, N Delhi, India, [4]Maharashtra AIDS Control Society, Mumbai, India, [5]Mumbai District AIDS Control Organization, Mumbai, India

Background: Maharashtra, a high HIV-burden Indian state has shown a steady decline in HIV prevalence among antenatal women since 2003, as evidenced by data from HIV Sentinel Surveillance (HSS) although there is a geographic variation across the state. HSS in India is a systematically conducted cross-sectional surveillance, at fixed sites among specific population subgroups, at regular intervals. We explored time-series data from HSS to understand other district-level factors as potential drivers of the epidemic.
Methods: Data from 5 rounds of HSS (2005-15) among ANC attendees in Maharashtra across 67 consistent sites in 35 districts were analysed. We used univariate and multivariate regression and multi-level modelling with district and state-level characteristics such as demographics, reproductive history and HIV knowledge from National Family Health Survey-3 (NFHS- 3) to predict HIV prevalence.
Results: Across 5 rounds of HSS (2005-15), being 'older' (AOR: 1.07, 95%C.I-1.050, 1.094, p< 0.001), 'Illiterate' (AOR: 1.56, 95%C.I:1.33-1.83, p=0.023), 'spouse in transport-related occupation' (AOR 1.693, 95%C.I.:1.41-2.00, p-< 0.001) and 'urban residence' (AOR: 1.151, 95%C.I.: 1.007-1.314, p=0.038,) increased the likelihood of HIV positivity. District-level properties like 'sex-ratio at birth' (= - 0.003, p=< 0.001), 'percent women sterilized' (=0.032, p=< 0.001), 'percent women accessing ANC-services' (=0.020, p=< 0.001) were significantly associated with HIV. Increase in F/M ratio by 1/ 1000 (AOR: 0.996, 95%CI: 0.994-0.997, p< 0.001) decreased the odds of being HIV-infected by 0.4%. Increase in 'female sterilization rate' (AOR: 1.034, 95%CI: 1.020-1.047, p < 0.001) and 'percent women accessing ANC-services' (AOR: 1.013, 95%CI: 1.002-1.024, p< 0.01) increased odds of HIV infection by 3% and 1% respectively.
Conclusions: Illiteracy and having a spouse in transport-related occupations, continue to remain the risk factors for acquiring HIV infection among women otherwise at low HIV-risk in Maharashtra. We identified several district level factors which are not normally in the framework of HIV-prevention programs, like 'sex ratio' and 'female sterilization' as significantly associated with HIV prevalence. Couples wherein women are sterilized, are less likely to use condoms, as demonstrated in Africa. Focus on 'couple-centered' interventions could help consolidate HIV prevention gains. Additionally convergence between RCH and HIV programs would be important in the Indian context to achieve HIV elimination goals.

TUPEC162

HIV prevalence in Argentina: 5 years of follow-up (2013-2017)

N. Haag[1], M. Pedrola[2,3], M. Laurido[2]
[1]AHF Argentina, HIV Testing and Prevention, Buenos Aires, Argentina, [2]AHF Argentina, Buenos Aires, Argentina, [3]AHF Latin America, Buenos Aires, Argentina

Background: According to the UNAIDS report of 2016, adult HIV prevalence in Argentina is 0.4% and remain stable in last dedade. This information comes from the estimation of HIV cases reported to the Ministry of Health in relation to the total country population. Therefore a study of 5 consecutive years on the HIV prevalence in general population was carried out.
Methods: Between January 2, 2013 and December 30, 2017, HIV antibody determinations through a previously validated rapid test (Alere Determine™ HIV-1/2) were performed in individuals from different provinces of Argentina, which together represent more than 60% of the total country population. Testing was carried out in public places, where people voluntarily approached to be tested. Counselling was given to all individuals and for positive cases established the appropriate referral. The information was collected in an Ad Hoc database, and descriptive statistics, T-test, Chi2, Fisher exact or Mid P tests were used as appropriate.
Results: Determinations were made in 118078 individuals. Age range: 18 months to over 49 years, but 99% were older than 15 years. Gender distribution: women 54.1%, men 45.2%, transgender 0.7%. There were 1035 HIV positive results. Prevalence: 0.88% (95%CI: 0.82-0.93). It was the first HIV test for 58.1%, and prevalence in subjects tested for the first time was higher than in those previously tested (0.93% vs. 0.79%, p= 0.006). Although the prevalence was significantly higher in men than in women (1.19% versus 0.56%, p < 0.001), the highest level was observed in transgender (4.86%, p < 0.001). Regarding annual prevalences, they remained stable between 2013 and 2016 (1.00%, 1.08%, 0.99%, and 0.91%, respectively), and dropped significantly in 2017 (0.67%, p < 0.05).
Conclusions: This was the largest study on HIV prevalence ever made in our country. Prevalence observed in the general population was twice as high as that reported for the adult population of Argentina by UNAIDS from 2013 to 2016, and remained higher although dropped significantly in 2017. This large-scale study shows that it is necessary to update the estimates of the population living with HIV for Argentina.

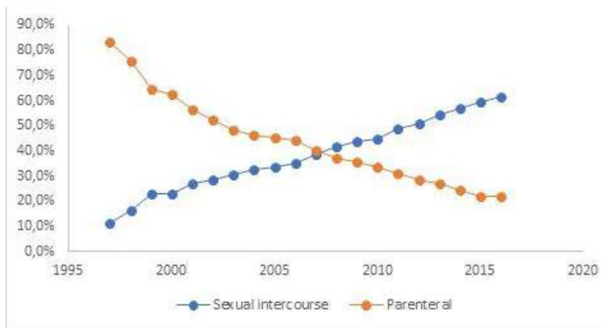
TUPEC163

The main ways of HIV transmission in Ukraine

O. Bidovanets, L. Hetman, O. Andreeva
Public Health Center of the Ministry of Health of Ukraine, Kyiv, Ukraine

Background: The study of HIV transmission gives an insight to the impact of the disease prevalence on the populace. Until recently Ukraine was considered to be the country with the HIV-transmission caused by the parenteral infusion, in particular by injection drug use. We aimed at investigating the peculiarities of the main ways of HIV transmission among the Ukrainian population over the period of 1997-2017 years.

Methods: We analyzed annual reporting forms N Reporting Form No. 2-HIV/AIDS „Report on Persons with Conditions and Diseases Caused by the Human Immunodeficiency Virus (HIV) Virus in 20__ Years" (annual), approved by the Order of the Ministry of Health of Ukraine as of March 5, 2013, No. 180, over the period of 20 years (1997 - 2017).
Results: The analysis of annual reports showed that from 1997 to 2008, the main route of HIV transmission among the Ukrainian population was parenteral (mainly with the injection drug use), and since 2008, the prevalence of HIV among injection drug users has been decreasing with the simultaneous growth of HIV-infection transmitted through sexual intercourse. In particular, there was an increased in the HIV infection incidence among men who had sex with men (MSM). This was found to be 50 cases in 2005, and 277 in 2014. As a rule, representatives of this group concealed their sexual orientation, especially in rural areas. A significant role is played by a group of MSM who are bisexual and may be a kind of „bridge" between MSM and heterosexual relationships. Due to decentralization there is a possibility of cooperation with the population of remote places in the region, which will allow to identify groups of potentially possible HIV-infected people.
Conclusions: Among the population of Ukraine, sexual intercourse is fast becoming the major factor causing the prevalence of HIV infection. It is therefore necessary to develop an algorithm for identifying potentially HIV-infected people, in particular among the rural population and MSM.



[The main methods of HIV transmission in Ukraine]

TUPEC164

National and sub-national HIV/AIDS-related mortality in Iran from 1990 to 2015: A modified approach to estimation

B. Moazen[1,2], NASBOD Collaborators
[1]*Heidelberg University, Public Health, Heidelberg, Germany,*
[2]*Non-Communicable Diseases Research Center, EMRI, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of*

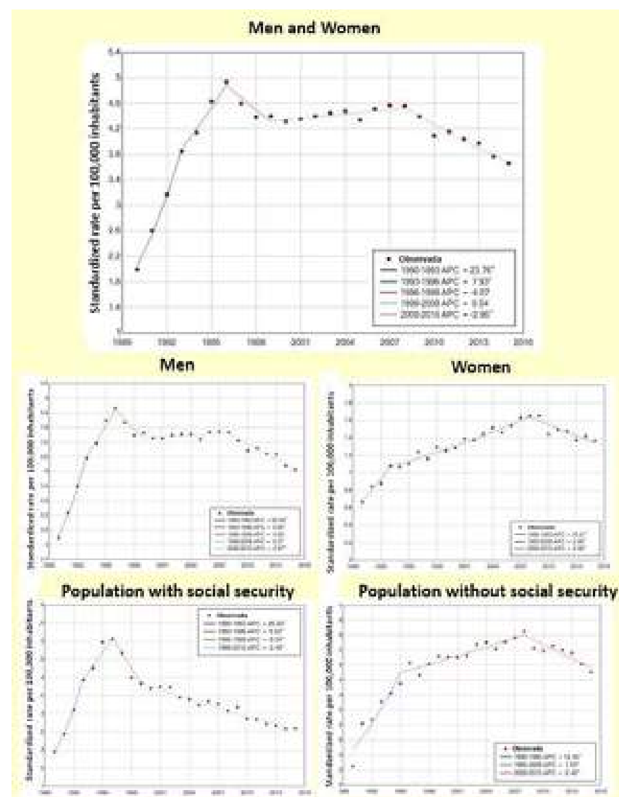
Background: Surveillance of HIV/AIDS mortality is crucial to evaluate a country's response to the disease and progress towards the goals set forth by the global community such as the sustainable development goals (SDGs) and the United Nations Programme on HIV/AIDS (UNAIDS) 90-90-90. This report from National and Sub-National Burden of Diseases, Injuries, and Risk Factors study 2015 (NASBOD 2015) provides estimates of mortality due to HIV/AIDS in Iran from 1990 to 2015.
Methods: Data from the death registration system of Iranian Ministry of Health and Medical Education, and the records of Tehran and Esfahan cemeteries were used as the main sources of data in NASBOD study. Death registration incompleteness and misclassification were addressed using demographical and statistical methods. Trends of mortality due to HIV/AIDS at national and sub-national levels were estimated applying multiple statistical models.
Results: According to our estimation, a total of 474 men (95% uncertainty interval [UI]: 175-1,332) and 256 women (95% UI: 36-1,871) died due to HIV/AIDS in 2015, which accounted for 0.22% and 0.17% of all deaths in men and women in Iran, respectively. After reaching its peak in 1995, overall deaths due to HIV/AIDS in both sexes have steadily declined. Excluding one age group (+65 years), HIV death rates were remarkably higher among men than women in the year 2015. Despite the decreasing rate, the number of deaths due to HIV/AIDS among women nearly tripled over the years studied. At sub-national level, the highest and the lowest annual percent change were found at 10.97% and -1.36% for women, and 4.04% and 3.47% for men, respectively.
Conclusions: The findings of our study (474) were remarkably lower than UNAIDS (4,000) but higher than GBD (339) estimates in 2015. The increasing number of deaths due to HIV/AIDS among Iranian women is a cause for concern, and highlights the need for urgent gender-oriented interventions to address the issue. In order to reach international goals. evidence-based interventions are needed to prevent infection and promote early diagnosis of HIV/AIDS, provide access to treatment, and ensure treatment adherence especially among the most at-risk populations in Iran.

TUPEC165

A twenty-six trend analysis of HIV/AIDS mortality in Mexico between 1990 and 2015

E. Bravo-García[1], H. Ortiz-Pérez[2]
[1]*Censida, Mexico, Mexico,* [2]*UAM Xochimilco, Departamento de Atención a la Salud, Mexico, Mexico*

Background: Mexico assumed as public policy to guarantee free and universal access to HAART in 2003. However, the next years, the AIDS mortality did not decrease as expected. Actually, The aim of the study was to analyze the magnitude, distribution, and trends of HIV/AIDS mortality in Mexico.
Methods: Official vital statistics on mortality from *CONAPO*, and population estimates from *INEGI*, were used to calculate AIDS mortality standardized rates. HIV/AIDS mortality trends were analyzed by *JointPoint regression model.*



[HIV/AIDS Mortality in Mexico, by sex and social security access, from 1990 to 2015]

Results: The evolution of general mortality due to HIV / AIDS shows 5 trends: from 1990 to 1993 it registered its maximum growth with an Annual Percent Change (APC = 23.8); between 1993 and 1996 it continued to grow, although with less intensity (APC = 7.9).Between the years 1999 and 2008, the mortality trend remained unchanged; and as of 2008 mortality has registered a significant downward trend until 2015 (APC = -3.0)

From 2010 to 2015, HIV/AIDS mortality in men was almost five times higher than in women (6.6 vs. 1.4 per 100,000, respectively). Because more than 80% of deaths correspond to men, their trends are similar to general mortality. In women they are different: there were two ascending trends (1990-1993, APC = 16.21 and 1993-2008, APC = 2.88). But between 2008 and 2015 it already has a downward trend (APC = -2.86)
Mortality among people lacking social security was almost double that registered in people with social security (5.0 vs 2.7 per 100,000). In both cases, the last trend is downward in both cases and the rate of reduction is almost the same (APC = 2.5 and 2.4, respectively).
Conclusions: Although the recent trend of HIV/AIDS mortality is downward, it disproportionately affects women, and people who do not have social security. It is necessary to focus actions of prevention and integral attention in both groups. If it is not possible to increase the descending APC among women and people without social security, it will be difficult to continue decreasing the HIV/AIDS mortality in Mexico.

TUPEC166

Alcohol consumption and its associations with other substance use and HIV infection in Rakai, Uganda

J. Wagman[1], D. Nabukalu[2], J. Kagaayi[2], D.S. Kigozi[2], R. Ssekubugu[2], F. Nalugoda[2], G. Kigozi[2]
[1]University of California San Diego, La Jolla, United States, [2]Rakai Health Sciences Program, Kalisizo, Uganda

Background: Associations between alcohol consumption and HIV risk are well established. Little is known, however about this relationship in Uganda. Less is known about other substance use and its co-occurrence with alcohol consumption. This study estimated the prevalence of alcohol and other substance use, and associations between alcohol and HIV infection in Rakai, Uganda.
Methods: We analyzed cross-sectional data from men and women (15-49 years) participating in the Rakai Community Cohort Study (2016-2017), an ongoing HIV surveillance cohort. The main dependent variable was past 12 month alcohol use (yes/no). Independent variables were past 12 month use of other drugs, including marijuana, amphetamines, aero fuels, mayirungi, heroin (yes/no) and HIV status (positive/negative). Logistic regression estimated associations between alcohol use, drug use and HIV infection. Adjusted models controlled for demographics (sex, age, education, occupation, marital status, socioeconomic status), community type (fishing/general community), and past year sexual risk behaviors (number of sex partners, consistent condom use).
Results: Of 18,700 participants, 54% were women, 84% were Christian, 66% had a primary school education or less, 45% consumed alcohol, 3% used other drugs, and 19% were people living with HIV (PLHIV). Alcohol use was less likely in women vs. men (aOR = 0.65, 95% CI: 0.61 - 0.71, p < 0.01), residents in general vs. fishing communities (aOR = 0.86, 95% CI: 0.78 - 0.95, p < 0.02), and non-drug users vs. drug users (aOR=0.38, 95% CI: 0.30 - 0.48, p < 0.01). Alcohol use was more likely in participants with 2+ sex partners (aOR = 3.44, 95% CI: 3.00 - 3.93, p < 0.01) and PLHIV (aOR = 1.12, 95% CI; 1.03 -1.22, p=0.01).
Conclusions: Alcohol use is common in Rakai, particularly in men and in fishing villages. Irrespective of sex and community type, the odds of alcohol use were higher among PLHIV and people with multiple sex partners, implying need to integrate alcohol reduction approaches into HIV prevention and treatment programs. Although other drug use is uncommon, it is linked to higher odds of alcohol use. Further research is warranted to better understand the epidemiology of poly-drug use in Rakai and Uganda.

Epidemiology of HIV in MSM

TUPEC167

Sexual behavior and STI-related correlates of depressive symptoms among a population of MSM in Senegal

M. Holtzman[1], D. Diouf[2], S. Ketende[3], C. Lyons[1], B. Liestman[3], K. Coly[3], C. Ndour[4], S. Mboup[4], K. Diop[4], C. Toure-Kane[4], N. Leye-Diouf[4], A. Cheng[5], S. Baral[3], G. Turpin[3], F. Drame[2]
[1]Johns Hopkins University, Epidemiology, Baltimore, United States, [2]Enda Sante, Dakar, Senegal, [3]Johns Hopkins University, Baltimore, United States, [4]Institut de Recherche en Santé, de Surveillance Epidemiologique et de Formation, Dakar, Senegal, [5]USAID, Washington, United States

Background: Mental health has been recognized as a determinant of HIV and STI risks through increased exposure as well as limited uptake of HIV prevention and treatment services. Mental health has been seen as particularly relevant determinant of HIV and STI-risks among MSM, who face high burdens of social stigma, a risk factor for depression. These analyses examine sexual behavior and STI-related correlates of depressive symptoms among MSM in Senegal.
Methods: This study utilized baseline data from the HIV Prevention 2.0(HP2) study, which enrolled 724 adult MSM in three cities in Senegal including Dakar, Thies, and Mbour using respondent-driven sampling(RDS) with a structured survey instrument and depressive symptoms assessed by the patient health questionnaire-9 (PHQ-9). Severity of depressive symptoms were measured with a PHQ-9 cut off of 10 or greater, used clinically to screen for moderate-to-severe depression. Logistic regression analyses applied RDS weights to account for purposive sampling.
Results: Approximately 58% had PHQ-9 scores of 5 or higher and 25% (181/724) 10 or greater. PHQ-9 of 10 or greater was associated with condom use by partner type. Participants reporting regular partners only in their last 1 - 3 anal sex acts and who used a condom in these encounters had 6.7 times the odds of endorsing a PHQ-9 over 10 compared to participants reporting casual partners only and inconsistent condom use with these partners (p <.05). Consistent condom use with varied partners carried an OR of 3.9 comparing those reporting casual partners only and inconsistent condom use (p <.05). Any STI symptoms in the past 12 months was associated with PHQ-9 scores of 10 and higher (OR= 2.25, p<.05).
Conclusions: Taken together, these results demonstrate that depressive symptoms constitute a serious burden among MSM in Senegal, supporting the need for mental health services. Encouragingly, these data suggest multiple opportunities to address mental health in STI visits or other outreach services. Holistic approaches to health necessitates effective integration of mental health interventions into broader health services and may potentiate the impact of HIV prevention and treatment services if implemented at scale in Senegal.

TUPEC168

Association between HPV persistence and HIV in young men who have sex with men: Interim findings from the P18 cohort study

F. Kapadia[1,2], P. Halkitis[3,4], D. Ompad[1,5], C. Quinlan[6], R. Greene[7]
[1]New York University, College of Global Public Health, Department of Epidemiology, New York, United States, [2]New York University, School of Medicine, Department of Population Health, New York, United States, [3]Rutgers University, Department of Biostatistics, East Brunswick, United States, [4]Rutgers University, Department of Social and Behavioral Health Sciences, East Brunswick, United States, [5]ew York University Rory Meyers College of Nursing, Center for Drug Use and HIV Research, New York, United States, [6]New York University, Center for Health, Identity, Behavior and Prevention Studies, New York, United States, [7]New York University School of Medicine, Bellevue Adult Primary Care Center, New York, United States

Background: HPV persistence, or the detection of similar HPV types two or more times over a given time period, is an important risk factor for HPV disease progression. Prior studies suggest that HPV persistence

was more common among HIV seropositive women than seronegative women. However, few studies have examined this association in younger men who have sex with men (YMSM), who bear a disproportionately higher burden of both HPV and HIV infections.

Methods: Participants (n=209) who completed visits at 6-month intervals as part of the on-going P18 prospective cohort study took part in site- (anal and oral) and type- (high risk, low risk, and vaccine preventable) specific HPV testing via nucleic acid hybridization assay. Associations between HPV incidence, persistence and clearance, overall as well as by type, and HIV serostatus were examined.

Results: In this sample of n=209 YMSM (mean age=23.8 years, 38.8% Hispanic/Latino, 26.3% Black, 16.7% White, 18.2% Asian/Pacific Islander or other race/ethnicity), HPV incidence, persistence and clearance was identified in 22.0%, 40.2% and 9.5% of the sample. The remaining 28.2% of YMSM were HPV negative across visits. HPV persistence was associated with anal sex partners (P< 0.05). Among individuals with persistent HPV infection, 51% of YMSM were identified as high-risk types and 42.7% as vaccine-preventable types. Finally, in multivariable regression models adjusted for age and race/ethnicity, compared to YMSM who remained HPV negative across visits, HIV seroprevalence was associated with persistent HPV infection (aOR=32.1, 95% CI 3.8, 270.5) and persistent infection with high-risk HPV types (aOR=7.03, 95% CI 2.07,23.92).

Conclusions: These findings provide evidence for strong associations between HPV persistence, particularly persistence of high-risk HPV types, and HIV infection in YMSM. In YMSM, the development of HPV associated neoplasia has been shown to begin at earlier ages and HPV persistence may contribute to development of anal cancer. Given, the strong associations between HPV persistence and HIV seropositive status in this sample of young men, efforts to promote syndromic surveillance as well as anogential screening via digital rectal exam and cytology, especially for HIV seropositive men with high-risk HPV are warranted.

HIV transmission clustering among gay men in Nigeria: A genetic distance clustering analysis using a social network model

Y. Li[1], H. Omari[2], N. Ndembi[3], S. Tovanabutra[4,5], T.A. Crowell[4,5], G. Kijak[4,5], R. Nowak[2], C. Gaydos[6], S. Baral[7], E. Volz[8], J. Ake[3], H. Liu[1], S. Adebajo[9], M. Charurat[2]

[1]University of Maryland at College Park, Epidemiology & Biostatistics, College Park, United States, [2]University of Maryland School of Medicine, Institute of Human Virology, Baltimore, United States, [3]Institute of Human Virology Nigeria, Abuja, Nigeria, [4]Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Silver Spring, United States, [5]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [6]Johns Hopkins University School of Medicine, Baltimore, United States, [7]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [8]Imperial College, Infectious Disease Epidemiology, London, United Kingdom, [9]Population Council, Abuja, Nigeria

Background: HIV transmission among men who have sex with men (MSM) in sub-Saharan Africa continues unabated at alarmingly high rates. To inform prevention efforts, we sought to uncover and characterize HIV transmission events among Nigerian MSM using genetic-clustering methods.

Methods: We analyzed RT-pol sequences from 348 HIV-infected individuals enrolled in the TRUST/RV368 study, a cohort of MSM in Abuja and Lagos, Nigeria, recruited using respondent-driven sampling between 2013 and 2015. Pairwise genetic distances were determined between sampled individuals and transmission clusters were defined among individuals whose sequences had a genetic distance of ≤1.5%. A latent space model including paired characteristics was used to analyze factors associated with HIV transmission clusters.

Results: Among 348 sequenced individuals, a total of 140(40.2%) individuals were found to be the members of HIV transmission clusters. With 42 identified transmission clusters, 29 (69.0%) of them were paired. The largest transmission cluster consisted of 16 individuals. Compared two individuals with different characteristics, two individuals were more likely to be in the same transmission cluster if they have the same ART status (OR=5.26; 95% CI: 4.75 - 5.73), sharing the same sexual identity (OR = 1.33; 95%CI: 1.30 - 1.36), and having greater age differences (OR=1.16; 95% CI: 1.01-1.29 per one-year age difference). In an additional analysis, compared to two individuals having different ART status (treated and untreated), untreated and newly diagnosed pairs were more likely to be in the same transmission cluster (OR= 8.99; 95% CI: 5.77-15.02). Individual factors associated with increased clustering including being employed (OR= 1.85, 95% CI: 1.49-2.25 compared to unemployed) and having viral load >1,000 copies/mL (OR = 7.10, 95% CI: 1.21-59.95).

Conclusions: There is a high level of genetically-clustered HIV transmission among MSM in Nigeria. Paired characteristics are important factors to include in transmission cluster analysis. Our social network models further underscore the importance of universal ART for MSM as part of prevention strategies to interdict forward HIV transmission.

Using syndemics theory to investigate HIV sexual risk affecting gay and bisexual Hispanics/Latinos in Philadelphia, PA: Findings from the National HIV Behavioral Surveillance, 2008-2014

O. Martinez[1], K. Brady[2], E.C. Levine[3], K. Page[4], S. Grieb[4], J. Shinefeld[5], M. Cecilia Zea[6], A. Martinez-Donate[7], W. Davis[8]

[1]Temple University, School of Social Work, College of Public Health, Philadelphia, United States, [2]Philadelphia Department of Public Health, Philadelphia, United States, [3]Temple University, Philadelphia, United States, [4]Johns Hopkins University, Baltimore, United States, [5]Philadelphia Department of Health, Philadelphia, United States, [6]George Washington University, Washington, DC, United States, [7]Drexel University, Philadelphia, United States, [8]John Hopkins University, Baltimore, United States

Background: Gay and bisexual Latino men continue to be disproportionately impacted by HIV/AIDS. Identifying factors associated with sexual risk is imperative for developing effective prevention strategies.

Methods: Working with data from the National HIV Behavioral Surveillance, we explored the impact of syndemic factors - heavy drinking, sex work, and homophobic discrimination - on sexual HIV risk behaviors including total male partners and (main and casual) condomless anal intercourse among gay and bisexual Latinos (N=464). Analyses took two forms: a syndemic approach, using the cumulative number of factors as a predictor; and a non-syndemic approach, incorporating factors as unique predictors. Simultaneously, we convened the Mid-Atlantic Latino Center for AIDS Research Consortium to develop recommendations for prevention interventions.

Results: Seventy percent of participants were from Puerto Rico, and a majority self-identified as Black (52%). Eighty-eight percent of participants had at least a high school education. In multivariable syndemic analyses, participants with 2+ factors reported significantly more male partners (b=3.96) and CAI casual partners (b=4.73) than those with none. In non-syndemic models, homophobic discrimination (b=2.44) and sex work (b=3.82) were significantly associated with total male partners. Heavy drinking was associated with casual UAI partners (b=1.71). Group members determined that multi-faceted, tailored interventions encompassing individual and cumulative risk are urgently needed to effectively address HIV in this population.

Conclusions: Multiple psychosocial conditions inform sexual risk among gay and bisexual Latinos, and such conditions may sometimes interact to exacerbate risk. HIV prevention programs, building from community-based approaches, should recognize and address multiple syndemic factors concurrently.

TUPEC171

HIV risk behavior outcomes associated with access to resources embedded in MSM and heterosexual social capital networks among MSM in greater Tokyo

A. Rolander
University of Melbourne, Sociology, Melbourne, Australia

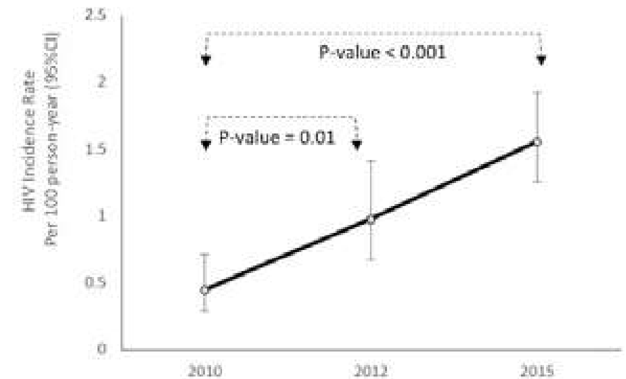
Background: Social capital (SC) is an important determinant of HIV risk in modern society characterized by human connection. Previous studies have suggested that social capital is positively associated with reduced HIV risk, however, few have investigated if associations vary between men-who-have-sex-with-men (MSM) and heterosexual alters (possessors of actual resources embedded in social capital networks) and HIV risk outcomes. Using cross-sectional data from an online MSM survey in Greater Tokyo, we investigated whether social capital is associated with reduced HIV risk behaviors, defined as condom use with regular and non-regular male and female partners, self-efficacy, and HIV-testing, independent of socioeconomic status. A total of 1657 subjects participated in the study.
Methods: To measure social capital, we used eighteen questions assessing the respondents' ability to access both physical and mental-support resources embedded in social networks. Potential confounders included eight demographic and structural antecedent factors. Respondents were grouped into three levels of social capital. High SC respondents were defined as 1.0 standard deviation (SD) above the overall mean, low SC respondents as one SD below the overall mean, and medium SC respondents in-between; thus 20% to 30% of respondents were grouped into the high and low SC categories.
Results: Multivariate models revealed that lifetime HIV testing was significantly associated with high MSM SC [odds ratio (OR), 3.16; 95% CI, 2.09-4.79], university education (OR, 1.44; 95% CI, 1.07-1.92) and age (OR, 1.04 95% CI, 1.02-1.05). Non-regular male partner condom usage was significantly associated with high heterosexual SC (OR, 2.03; 95% CI, 1.15 - 3.59), and residing outside Tokyo (OR, 1.69; 95% CI, 1.01-2.82). Regular male partner condom usage was significantly associated with university education (OR, 1.49; 95% CI, 1.14-1.95), and significantly negatively associated with High MSM SC (OR, 0.62 95% CI, 0.42-0.91). Female partner condom usage was significantly associated with heterosexual SC (OR, 1.09; 95% CI, 1.00-1.17).
Conclusions: In order to close the HIV-risk gap for greater Tokyo MSM, policy interventions should focus more specifically on deprived socio-demographic groups, such as those who have less educational attainment and exposure to sex-education and not blindly promote social capital without considering potential negative outcomes.

TUPEC172

Trend in HIV incidence and prevalence in men who have sex with men in Georgia, 2010 to 2015

A. Noori[1], N. Shengelia[2], I. Chikovani[2], A. Mirzazadeh[3,4]
[1]*McMaster University, Department of Health Research Methods, Evidence, and Impact (HEI), Ontario, Canada,* [2]*Curatio International Foundation, Tbilisi, Georgia,* [3]*Institute of Global Health Sciences, University of California, San Francisco (UCSF), Department of Epidemiology & Biostatistics, San Francisco, United States,* [4]*HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of*

Background: To measure the impact of HIV prevention and care programs, it is crucial looking at both HIV incidence and prevalence estimates and trend over time. We estimated the HIV incidence and prevalence and assessed the trend using data from three cross-sectional surveys of men who have sex with men (MSM) in Georgia.
Methods: Using respondent-driven sampling strategy, eligible MSM (a 18 years or older man with oral or anal sex with another man in past 12 months) were recruited in Tbilisi and Batumi in 2010, 2012 and 2015 into a behavioral survey and HIV testing. To estimate the HIV incidence, we divided the number MSM tested positive for HIV to the time at risk. We calculated the time at risk as years since age at first anal intercourse to the age at last HIV-negative test or the age at first HIV-positive test, accounted for the interval censorship. We assessed the trend in HIV prevalence by Chi2 test for trend. For HIV incidence rate, we used Kaplan Meier method and compared the rates in three survey rounds by log-rank test.
Results: The HIV prevalence significantly increased (p-value for trend < 0.001) form 7.0% in 2010 to 13.0% in 2012 and 20.7% in 2015. Likewise, the HIV incidence rate (Figure 1) significantly increased form 0.45 per 100 person-years in 2010 to 0.98 per 100 person-years in 2012 (p-value for trend =0.01) and 1.56 per 100 person-years in 2015 (p-value for trend < 0.001). In survey 2015, young MSM (4.48 per 100 person-years, p-value< 0.001), single MSM (1.79, p-value 0.003) and less educated MSM (1.90, p-value 0.009) had a higher HIV incidence.
Conclusions: Our findings suggest the continuous transmission of HIV among men who have sex in two major cities in Georgia and the need for scaling up the coverage and accessibility of combination prevention packages including rapid HIV diagnosis and response.



[Figure 1 - Trend in HIV incidence rate per 100 person-years among men who have sex with men in Georgia, 2010 to 2015]

TUPEC173

Migration and risk among gay, bisexual and other men who have sex with men in New York City (NYC)

J.E. Egan[1,2], V. Nandi[3], V. Frye[4], R. Stall[1,2], B.A. Koblin[5]
[1]*University of Pittsburgh, Graduate School of Public Health, Social and Behavioral Health Sciences, Pittsburgh, United States,* [2]*University of Pittsburgh, Center for LGBT Health Research, Pittsburgh, United States,* [3]*New York Blood Center, Data Analytic Services Laboratory, New York, United States,* [4]*The City University of New York, School of Medicine, New York, United States,* [5]*New York Blood Center, New York, United States*

Background: Migration may be an important contextually driven moment of heightened risk for MSM. Introduction into new socio-sexual networks with unfamiliar expectations in a new city may impact a newly migrated man's ability to negotiate risk in the same way he may at home. Using data from the NYCM2M study, this paper aims to understand of geo-temporal HIV risk associated with migration to a gay-centric urban center. We hypothesized that recent migrants would experience a heightened period of HIV risk and substance and that this increased risk would translate into HIV seroconversion.
Methods: M2MNYC is a cross-sectional study designed to identify neighborhood-level characteristics within the urban environment that influence sexual risk behaviors, substance use and mental health among MSM living in NYC. Between 2010 and 2012, using modified venue-based time-space sampling, men were recruited through face-to-face outreach and mobile apps. A total of 1,493 men completed the cross-sectional ACASI survey. Logistic regression and a Cox proportional hazards multivariable regression were used for analysis. The hazard ratio takes into account not if an individual is HIV-positive or negative, but how much time passed before seroconversion after migration. We focused on seroconversion within the first 10 years of migration to NYC.
Results: The sample included 738 recent (within the past 10 years) NYC migrants. In multivariable analyses, compared to those who had lived in NYC for 6-10 years, living in NYC for >1 year was not significantly associated with increased risk, being in NYC from 2-5 years was associated with an increase in general unprotected sex (aOR=1.89, CI=1.22,2.88) and

heavy drinking (aOR=1.92, CI=1.06,3.50). Compared to White men, Black men had a cox proportional hazard of 5.17 (p< 0.001) and Latino men had a hazard ratio of 3.03 (p=0.01) for post-migration HIV seroconversion.
Conclusions: These findings support research suggesting that migration, space, and place likely play a significant role in exposure to risk and increased risk behaviors. Most striking are our findings that suggest that migration to NYC may pose far greater risk of seroconversion for Black and Latino MSM. This paper raises important questions to consider as we enter the next generation of bio-behavioral HIV prevention.

A lesser-known epidemic: HIV and STI prevalence among key populations in Angola

W.M. Miller[1], M.E. Herce[2,3], J.K. Edwards[4], J.M. Cardao[5], M.L. Furtado[6], G. Cristino[7], A.M. Diaz[7], S.S. Weir[1,4]
[1]University of North Carollina at Chapel Hill, Carolina Population Center, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, UNC Institute for Global Health & Infectious Diseases, Department of Medicine, Chapel Hill, United States, [3]UNC Project-Malawi, Lilongwe, Malawi, [4]University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [5]USAID Angola, Luanda, Angola, [6]Instituto Nacional de Luta Contra a SIDA (INLS), Luanda, Angola, [7]LINKAGES Project, Luanda, Angola

Background: A dearth of research exists on the HIV epidemic among key populations in Angola and no prior studies have measured the prevalence of other sexually transmitted infections (STIs). This study aimed to measure the prevalence of HIV and STIs among key populations in Angola.
Methods: The University of North Carolina at Chapel Hill, under the USAID/PEPFAR-supported and FHI 360-led LINKAGES project, conducted a biobehavioral survey in five provinces of Angola between October 2016 and June 2017. Priorities of Local AIDS Control Efforts (PLACE), a venue-based sampling strategy, was used to recruit participants from social venues for a cross-sectional behavioral survey. Based on the behavioral questionnaire, participants were categorized as female sex workers (FSW), men who have sex with men (MSM), or transgender women (TGW). Biomarkers included rapid HIV; syphilis and hepatitis B testing; and collection of urine and anal and vaginal swabs for gonorrhea, chlamydia, and trichomoniasis lab-based testing. Individuals were assigned weights based on the probability of recruitment at a venue.
Results: In total, 1,876 FSW, 1,016 MSM and 89 TGW were recruited. The prevalence of HIV was 8% among FSW, 2% among MSM, and 9% among TGW. The prevalence of other STIs ranged from 3-15% among FSW, 2-14% among MSM and 0-13% among TGW (Table 1). Among MSM, a urethral STI (9% prevalence) and an anal STI (7%) were similarly common but only 12% of MSM with a urethral STI also had an anal STI and 14% of men with an anal STI also had a urethral STI. Among TGW there were no participants with both a urethral and an anal STI.
Conclusions: High prevalence of HIV and other STIs among FSW, MSM, and TGW in Angola is evidence that integrated diagnosis and treatment services are needed for these populations. The HIV prevalence was higher among TGW than MSM. The lower than anticipated percentage of multisite infections with an anal and urethral STI indicates that MSM and TGW practice seemingly exclusive insertive *or* receptive anal sex, which could help orient HIV prevention programs given the higher risk of HIV acquisition through receptive sex.

	HIV (n/N) %	Syphilis (n/N) %	Gonorrhea (n/N) %	Chlamydia (n/N) %	Trichomoniasis (n/N) %	Hepatitis B (n/N) %

TUPEC175

Characterizing resilience and viral load among midlife and older gay, bisexual, and other men who have sex with men

J.E. Egan[1,2], M.R. Friedman[2,3], S.A. Haberlen[4], M. Plankey[5], L.A. Teplin[6], S. Shoptaw[7], D.E. Siconolfi[8], R. Stall[1,2]
[1]University of Pittsburgh, Graduate School of Public Health, Behavioral and Community Health Sciences, Pittsburgh, United States, [2]University of Pittsburgh, Center for LGBT Health Research, Pittsburgh, United States, [3]University of Pittsburgh, Graduate School of Public Health, Infectious Diseases and Microbiology, Pittsburgh, United States, [4]Johns Hopkins University, Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [5]Georgetown University Medical Center, Department of Medicine, Division of Infectious Diseases, Washington, United States, [6]Feinberg School of Medicine, Departments of Psychiatry and Behavioral Sciences and Medicine: Infectious Diseases, Chicago, United States, [7]David Geffen School of Medicine at UCLA, Department of Family Medicine, Los Angeles, United States, [8]Rand Corporation, Pittsburgh, United States

Background: How psychosocial resilience impacts the health of middle-aged and aging men who have sex with men (MOMSM) living with HIV is undiscovered. The aim of this study was to characterize resilience among MOMSM and investigate its association with detectable viral load.
Methods: 1,143 seropositive and seronegative MOMSM in the Multicenter AIDS Cohort Study (MACS) completed the 14-item global resilience scale (RS-14) in 2016-2017 as part of a 4-year study of resilience and healthy aging. Scores from the RS-14 were calculated and categorized into: high (scores 82-89) or moderate/low (scores 14-81) resilience. Multivariable logistic regression was used to estimate the odds of high resilience adjusting for age, race, education, depression symptoms, and HIV status. Among the HIV+ men, a multivariable model estimated the relationship between resilience and detectable viral load.
Results: Characteristics of the sample include: mean age=61.9, SD=8.7; 31.2% racial minority; 20.4% depressed (CESD>=16); 46.6% HIV+ among whom 17.5% had a detectable viral load (≥20 copies/mL, Roche Taqman). Overall 64.1% of participants reported having high, 13.3% moderate, and 22.6% low resilience. Black race (compared to white, aOR=2.34, CI=1.49, 3.65) and older age (aOR=1.02, CI=1.00,1.05) were positively associated with high resilience. Having depression symptoms (aOR=0.17, CI=0.12,0.25), and only high school (aOR=0.55, CI=.33, 0.92) or college aOR=0.70, CI=0.50, 0.98) compared to postgraduate education were less likely to indicate high resilience. There were no statistically significant differences in resilience level by HIV status. Men with high resilience were less likely to have detectable viral load (aOR=0.47, CI=0.25,0.90, see Table). Black men had greater odds of having a detectable viral load compared to white men (aOR=2.88, CI=1.51,5.49).
Conclusions: MOMSM with high resilience had half the odds of having detectable viral load, independent of sociodemographic co-factors and depression symptoms. Given that 1 in 3 men in the sample did not meet the criteria for high resilience, future research will investigate risk and protective factors associated with high resilience, to inform multi-level interventions to strengthen resilience and improve HIV outcomes including viral suppression.

High HIV and other STI prevalence among transgender, gay, bisexual and other men who have sex with men (MSM) in Nairobi, Kenya

J. Kimani[1,2], R. Kabuti[1], E. Irungu[1], P. Muthoga[1], A. Mugambi[1], C. Nyamweya[1], P. Weatherburn[3], E. Fearon[3], A. Bourne[4], A.D. Smith[5], TRANSFORM

[1]Partners for Health and Development, Nairobi, Kenya, [2]University of Manitoba, Department of Medical Microbiology and Infectious Diseases, Winnipeg, Canada, [3]London School of Hygiene and Tropical Medicine, Department of Public Health, London, United Kingdom, [4]La Trobe University, Australian Research Centre in Sex, Health & Society, Melbourne, Australia, [5]University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom

Background: Gay, bisexual and other men who have sex with men are a key target population for HIV prevention and control in Kenya. Whilst male sex workers are the focus of ongoing research in Nairobi, HIV/STI prevalence has not been assessed among the broader MSM population since 2010. This study set out to assess prevalence of HIV and other STIs representative of all MSM in Nairobi.

Methods: Respondent-driven sampling (RDS) was employed to recruit 618 MSM. Eligibility criteria were age 18+, male gender (birth or currently), Nairobi residence and reporting of consensual oral or anal intercourse with a male partner in the last year. Consenting participants undertook a computer-assisted survey including current experience of anogenital STI symptoms (urethral or rectal pain, discharge or ulceration). Participants tested for HIV [Determine®, First Response® & Xpert® HIV-Qual, syphilis [RPR/TPHA], hepatitis B and C [HBsAg and HCV ELISA], urine and rectal chlamydia (CT) and gonorrhoea (GC [Xpert® CTNG]). Associations with prevalent HIV were assessed using multivariate logistic regression. Frequency and association measures were adjusted for RDS sampling using the RDS-II method.

Results: Only three participants declined rectal swabs, one completed HIV testing only, and one declined all investigations. HIV prevalence was 26.4%[22.6-30.6] including 0.5%[0.2-1.5] detected solely by 4th generation testing. Prevalent HIV was independently associated with age, lower education, Kenyan birth, transgender identity and exclusive sex with men in the past 3 months (table). Prevalence of syphilis was 0.8%[0.3-1.9]; hepatitis B 4.4%[3.4-6.9]; hepatitis C 0.5%[0.2-1.5]. 6.4%[4.5-9.0] of participants reported current symptoms consistent with urethritis. Prevalence of urethral GC and CT were 4.4%[2.9-6.7] and 7.3%[5.2-10.3] respectively. 8.6%[6.3-11.6] of participants reported symptoms consistent with proctitis. The prevalence of rectal GC and CT were 13.3%[10.4-16.8] and 8.7%[6.7-11.2] respectively. Overall, only 17.7%[9.2-31.2] with urethral CT/NG and 17.8%[10.7-28.0] rectal CT/NG were symptomatic.

[Associations with prevalent HIV infection: MSM in Nairobi, Kenya (2017)]

Conclusions: HIV prevalence among MSM remains considerably higher than among other men in Nairobi, whilst the prevalence of syphilis and hepatitis C are relatively low. Chlamydia and gonorrhoea infections, particularly rectal, are common and frequently asymptomatic. Increasing the capacity of MSM-friendly and community-based providers to offer CT/NG screening should be prioritised.

TUPEC177

Increasing prevalence rate among MSM in Brazil: Results of a comparison of 2009 and 2016 national survey

Background: The HIV epidemic among men who have sex with men (MSM) appears to be increasing in many countries. Brazil completed a second national Biological Behavioral Surveillance Survey among MSM in 12 cities in 2016, overlapping with 9 cities from the 2009 survey. The objective of this paper is to closely compare the results of HIV prevalence in the cities where the survey was repeated.

Methods: The surveys, using Respondent Driven Sampling (RDS), were conducted in 10 cities in 2009, and 12 cities in 2016, with 9 conducted in the same cities in both surveys. We recruited 3,333 MSM in 2009 and 2,992 in 2016. MSM were considered positive if: 1) they tested positive in the survey; or 2) not testing in the survey, they reported testing positive and were taking ART. RDS-Analyst and Gile's estimator were used for weighting and calculation of HIV prevalence for both surveys. Using the complex analysis functions in STATA™ v14 data were merged by year with each city as a stratum. Poisson regression was used to compare HIV prevalence by year adjusting for age, race, socioeconomic status, and an interaction term between age and year.

Results: HIV prevalence increased from 12.1% (10.0 - 14.5), in 2009, to 18.4% (15.4 - 21.7), in 2016. The prevalence ratio (PR) among MSM ≥25 yrs. in 2009 (19.8%; 15.3 - 24.2) compared to 2016 (19.9%; 16.0 - 23.8) did not change (PR=1.0; 0.7 - 1.3). The PR among MSM < 25, however, increased 140% (PR=2.4; 1.4 - 4.0) jumping from 4.0% (2.6 - 5.4) to 9.4% (5.8 - 13.1). Only age and the interaction term were significant.

Conclusions: HIV prevalence increased substantially among younger MSM. Although the HIV prevalence among older MSM did not change from 2009 to 2016, it is extremely high compared to the general population. We hypothesize that the use of social networking applications to find partners, the medicalization of AIDS prevention, and a sharp political movement to the right, including ending many programs targeted to

sexual minorities, such as comprehensive sex education, were among the reasons for this increase among youth and maintenance among older MSM.

	HIV Prevalence (2016)			HIV Prevalence (2009)			Prevalence Ratio (PR)	
Age	n/N	%	95%CI	n/N	%	95%CI	PR	95%CI
<25 yrs.	138/1799	9.4	5.8 - 13.1	94/1683	4.0	2.6 - 5.4	2.4	1.4 - 4.0
≥25 yrs.	258/1163	19.8	15.3 - 24.2	258/1625	19.9	16.0 - 23.8	1.0	0.7 - 1.3

TUPEC178

Why local terms are important: Different behavior and risk profiles of common local variants of men who have sex with men in Myanmar

S.T. Thein, Y.K. Aung, K. Gustafson
Population Services International/Myanmar, Yangon, Myanmar

Background: Worldwide, men who have sex with men (MSM) are one of the priority populations for HIV prevention and care interventions. In Myanmar, there are several local terms for variants of MSM. The most well-known version comprises three variants, named "Apwint", "Apone", and "Tha-Nge". This assessment explored the behavior and HIV-risk among these three variants.
Methods: This assessment was conducted among MSM in Myitkyina, a township in Northern Myanmar, in December 2016. Respondent-driven sampling, a coupon-based chain referral method, was used to recruit hard-to-reach MSM for HIV risk behavior and service utilization assessment. A total of 176 MSM were interviewed, including 50 Apwint, 42 Apone, and 84 Tha-Nge. RDS Analyst 0.57 was used for the analysis.
Results: The profiles were distinctly different among the three variants of MSM. Apwint dressed like women (88%), and identified themselves as women (94.7%), whereas Tha-Nge dressed like men (100%) and identified themselves as men (98.4%). Apone mostly dressed like men (80%) yet 43% identified themselves as women. Average number of sexual partners within last month varied from 7 (Apwint), 3 (Apone), to 1.5 (Tha-Nge). Usual sexual position was receptive for 98% of Apwint, and 63.9% of Apone, but insertive for 94% of Tha-Nge. Consistent condom use was reported among only 30.2% (Apwint), 38.7% (Apone), and 47.9% (Tha-Nge). Exposure to services was highest among Apwint (93.7%), moderate among Apone (62.4%), and lowest among Tha-Nge (51.1%). Recalls on HIV testing within past 12 months followed same pattern: 91.8% (Apwint), 74.0% (Apone), and 69.7% (Tha-Nge). Reported HIV positive rates were also highest among Apwint (30.7%), followed by Apone (15.6%), and Tha-Nge (10.9%).
Conclusions: This assessment showed distinctly different behavior and risk profiles among the three local variants of MSM in Myanmar. The findings highlighted the importance of local terminology in differentiating the high-risk subgroups among HIV priority populations, and potential need for novel targeting strategies and interventions.

TUPEC179

Innovative strategies through peer segmentation to reach men who have sex with men (MSM) in Ghana

S.E. Owusu
Maritime Life Precious Foundation, Programs, Takoradi, Ghana

Background: Ghana faces challenges in identifying HIV positive persons among Men who have Sex with Men (MSM). There are different segments of MSM who engage in risky sexual behaviors but are often not reached by HIV programs. Reaching different typologies of MSM require using innovative approaches through segmentation to identify high risk and closeted MSM who are HIV positive.
Description: Multiple innovative strategies through MSM segmentation were introduced in 4 districts in May 2017. Peer educators were trained to segment their peers into different networks based on their risk behaviors and link them for targeted testing services. These subgroups include MSM PLHIV and their sexual partners, MSM sex workers, bisexuals, 'high class' MSM (e.g. Lawyers, politicians, etc) and MSM drug users.
Peer Educators and Nurses used peer-driven, innovative and cross-cutting community initiatives such as sexual network testing (SNT), PLHIV partner testing (PPT) and door to door testing approaches to reach different high-risk MSM positives in different networks.
SNT used the sexual network of high risk MSM to link their sex partners within the last six months for HIV Testing Services (HTS).
PPT targeted MSM PLHIV who had been initiated on ART to introduce their recent MSM partners to a targeted HTS outreach session.
Door-to-Door testing: Nurses visited the rooms or any convenient place of hard-to-reach MSM and provided HTS.
Lessons learned: HIV positive yield among MSM increased across the 4 districts after the introduction of innovative strategies through effective segmentation of MSM. Between January and April 2017, 228 MSM were tested; 7 MSM (HIV+ yield of 3.0%) were diagnosed positive across the 4 districts. After the introduction of the interventions of MSM segmentation between May and August 2017, 241 MSM were tested and 38 were diagnosed HIV positive (15.8% yield) across the 4 districts.
Conclusions/Next steps:
• Innovative and targeted approaches to HTS through effective segmentation of MSM is an effective and efficient way of reaching out to closeted MSM and should be extended to other districts in the country.
• We will explore which of the innovative approaches is more efficient at attaining greater HIV+ yield among the subgroups.

TUPEC180

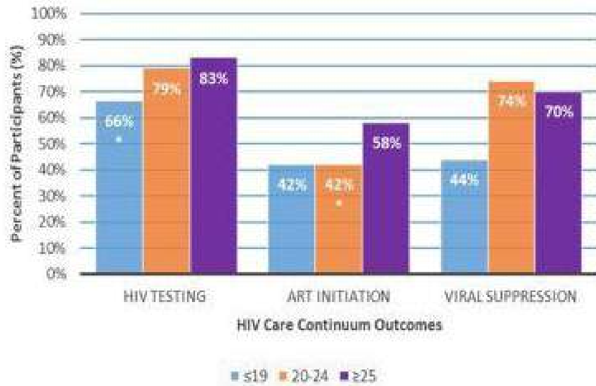
HIV treatment and prevention needs assessment: Comparison between younger and older men who have sex with men in Nigeria

H.O. Ramadhani[1], N. Sam-Agudu[1,2,3], U. Ononaku[3], W. Anom[3], C. Gaydos[4], N. Ndembi[3], S. Baral[5], S. Adebajo[6], T.A. Crowell[7,8], M. Charurat[1]
[1]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [2]University of Maryland School of Medicine, Department of Pediatrics, Baltimore, United States, [3]Institute of Human Virology, Abuja, Nigeria, [4]Johns Hopkins Medical Institute, Baltimore, United States, [5]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [6]Population Council, Abuja, Nigeria, [7]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [8]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States

Background: Men who have sex men (MSM) frequently experience depression, behaviorally related stigma and discrimination but are often unable to access supportive services to manage these challenges. These challenges disproportionally impact young MSM and may influence HIV prevention and treatment needs as well as health-seeking behavior. Here we compare health-seeking behavior, HIV prevention practices and HIV care continuum outcomes among younger and older MSM in Nigeria.
Methods: The TRUST/RV368 cohort employed respondent-driven-sampling (RDS) to recruit MSM into HIV/STI prevention and treatment services in Abuja and Lagos, Nigeria. Participants completed standardized questionnaire that captured information including health-seeking behavior, exposure to HIV prevention education and participation in HIV prevention meetings in the previous 12 months. Participants were tested for HIV and, if positive, offered antiretroviral therapy (ART) with HIV RNA monitoring every 3 (Abuja) or 6 (Lagos) months. Participants were categorized into age groups, (≤19, 20-24, and ≥25) years. Logistic regression models were used for age comparison and exposure to HIV education, HIV prevention meetings and health seeking behavior and chi-square test for HIV care continuum outcomes.
Results: Between March 2013 and December 2017, total of 2090 MSM were recruited and 1227 (58.7%) were younger than 25 years. Overall, decreased odds of exposure to HIV education was associated with younger age, < 19 vs. ≥ 25 years, (Odds ratio, OR =0.5; 95% CI, 0.4 - 0.6) and 20 - 24 vs. ≥ 25 years, (OR =0.7; 95% CI, 0.6 - 0.8). Among the HIV negative, younger MSM < 19 vs. ≥ 25 years, (OR =2.6; 95% CI, 1.5 - 4.5) have higher odds of reporting avoiding seeking health care and decreased odds of participating in HIV prevention meetings (OR =0.6; 95% CI, 0.4 - 1.0).

Furthermore, among participants unaware of HIV status at enrollment, HIV testing and ART initiation was significantly lower for younger MSM compared to older MSM (figure 1)

Conclusions: Our finding underscores that younger MSM lag behind older MSM in many aspects of HIV treatment and prevention. Interventions to improve HIV prevention and treatment specific to young MSM such as treatment support are essential in order to improve health and prevent new infections.



[Figure 1. HIV Care continuum outcomes]

TUPEC181

Quality of life and associated factors among men who have sex with men in a metropolis in Brazil

J. Costa, H. Coelho, M. Silveira, P. Bonolo, M.D.G. Ceccato,
ECOART Study Group
Federal University of Minas Gerais, Belo Horizonte, Brazil

Background: The HIV epidemic in Brazil has been rising mainly within younger men who have sex with men (MSM). The prevalence of HIV in this population is 19.8%, yet studies regarding this risk group are still lacking. We aimed to assess the quality of life (QoL) and its influencing factors within MSM.

Methods: We conducted a baseline evaluation of a cohort of 426 patients from three referral centers in HIV care in Belo Horizonte, Brazil. We obtained sociodemographic, clinical and behavioral data through face-to-face interviews using the WHOQOLHIV-bref instrument to assess QoL. Factors associated with overall HRQoL were evaluated using multilevel linear regression.

Results: The majority of eligible patients (92.6%) participated in the survey. Respondents were 82.6% male with a mean age of 34.5±10.9 years. The main risk/exposure group for HIV infection was MSM (51.7%), followed by heterosexual woman (27.7%). Compared to other risk groups, a higher proportion of MSM was younger (70.1% aged below 33 yo), not married (87.2%) had no children (93.4%), belonged to upper/upper middle class (46,7%), were employed (71.1%) and had 13+ years of education (50.7%). They showed a lower proportion of signs and symptoms of depression (16.1%), co-morbidities (11.8%) and AIDS-defining symptoms (12.8%). The vast majority of them (90.5%) were able to fully comprehend the orientations regarding their pharmacological treatment (p< 0.05 for all comparisons).

This data translates into average values of WHOQoLHIV-bref domains of 16.0±2.8 for physical, 16.0±2.5 for psychological, 16.0±2.4 for independence, 16.0±2.7 for social, 15.0±2.4 for environment and 15.0±3.3 for spirituality. Except for the spirituality domain, MSM showed higher QoL domain scores than those of other risk groups (p< 0.05).

Controlled for the healthcare facility, factors independently associated with lower QoL among MSM were: the presence of signs and symptoms of depression [OR = -2.41 (IC95% -3.30; -0.33)] and anxiety [OR=-2.6 (-2.47; -0.34)] as well as the presence of other co-morbidities [OR=-2.76 (-3.16; -0.53)].

Conclusions: MSM showed high levels of HRQoL. The results highlight the need to enhance strategies in screening for symptoms of anxiety/depression and co-morbidities, as well as the need to provide psychological support to increase HRQoL of MSM living with HIV/AIDS.

TUPEC182

Prevalence of HIV and other sexually transmitted infections and their association with sexual behavior and substance use among 1351 MSM in Lebanon

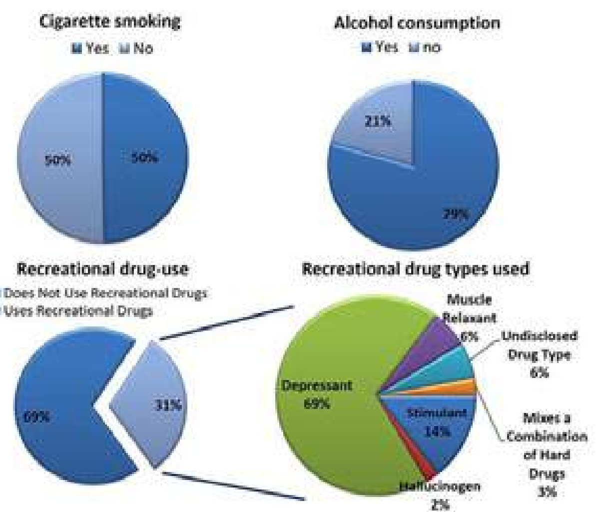
A. Assi[1,2], S. Abu Zaki[2], N. Kinge[2], D. Abou Abbas[2], J. Naous[2], A. Ghanem[1,2], R. Aaraj[2], R. Maher[2], Z. Bakouny[1], G. Azzi[2], R. Tomb[1]
[1]Faculty of Medicine, University of Saint-Joseph, Beirut, Lebanon, [2]Marsa Sexual Health Center, Beirut, Lebanon

Background: Men who sex with men (MSM) in Lebanon are subject to stigma and criminalization (Jimenez 2013) and do not have access to basic sexual health services including PrePrep. Substance-use behaviors among youth in Lebanon are becoming prevalent (Ghandour 2014) and studies in other countries attest to associations between substance-use and sexual risky behaviors among MSM (Zellner 2015). No data exists in Lebanon and the MENA region that evaluates rates of sexually transmitted infections (STIs) along with sexual practices and substance-use among MSM. The aim was to assess rate of HIV and other STIs and common risky practices, including substance-use behaviors, among MSM in Lebanon.

Methods: An anonymous questionnaire was administered by trained sexual health educators to 1351 MSM who presented consecutively to a sexual health clinic in Lebanon between 2015 and 2017. Collected sexual health indicators were: demographics, substance-use, sexual practices and risky exposures. STI status was collected through rapid testing and/or medical consultation. Determinants of condom-use and substance-use behaviors were assessed using regression models.

Results: Rates of STIs were: HIV = 5.4%, Syphilis = 2.7%, HBV = 0.2%, HCV = 0.7%, symptoms indicative of HPV = 44.5% and Gonorrhea / Chlamydia = 20.8%. Only 26% received sexual health education from reliable sources (educational or healthcare systems). Recreational drug use behavior was reported by 31%. Rates of other substances were collected in Figure 1. The majority (81%) reported having multiple partners in the past 3 months and 45% reported inconsistent condom-use with casual partners. Condom-use behavior was associated (p< 0.001) with source of sexual health education (adj.OR: 1.67) and level of education (adj.OR: 2.12). Recreational drug use was associated (p< 0.001) with smoking (adj. OR: 4.25), having multiple partners (adj.OR: 4.14), and being a university student (adj.OR: 2.08).

Conclusions: This study is the first in Lebanon and MENA region to include a large sample of MSM to assess STI status, substance-use behavior and other risky behaviors. The results reflect an urgent need for: 1) accurate sexual health and harm reduction education, including awareness campaigns, that are accessible to everyone and especially key populations; 2) introducing PreP to the MSM community in order to contain the HIV epidemic; 3)relevant governmental policies to advocate for acceptance and protection of sexual diversity.



[Substance use of 1351 MSM in Lebanon: cigarette smoking, alcohol consumption, recreational drug use in addition to the reported types of drugs]

Human immunodeficiency virus (HIV) and the association of male circumcision with HIV, and history of Viral and non-viral sexually transmitted infections in Rwandan men who have sex with men

J.D.A. Sinayobye[1,2], A. Adedimeji[3], V. Patel[4], H.Y. Kim[5], Q. Shi[5], G. Murenzi[1], P. Mugenzi[1], P.E. Castle[3], L. Mutesa[6], B. Kateera[6], J. Palefsky[7], K. Anastos[4]
[1]Rwanda Military Hospital, KIgali, Rwanda, [2]COTREC REGIONAL LTD, Kigali, Rwanda, [3]Albert Einstein College of Medicine, Epidemiology and Population Health, Bronx, United States, [4]Albert Einstein College of Medicine, General Internal Medicine, Bronx, United States, [5]New York Medical College, Valhalla, United States, [6]University of Rwanda, Kigali, Rwanda, [7]University of California, San Francisco, United States

Background: Male circumcision (MC) protects against HIV acquisition and other sexually transmitted infections (STIs) in heterosexual men. However, results from numerous studies of MC on risk for STI in HIV-infected men who have sex with men (MSM) remain inconclusive. There are few studies MSM in Africa and Rwanda. We therefore examined the associations of male circumcision with HIV infection, and self-reported history of viral and non-viral STIs in Rwandan MSM.
Methods: 322 self-identified MSM in Kigali, Rwanda completed a 45-minute questionnaire, including prior history of STI, using audio-computer assisted survey interview (ACASI). Respondents were tested for HIV. Data were analyzed using SAS. Alpha ≤ 0.05 was considered to be statistically significant.
Results: Participants were 90 % aged 18-36 years, 90.7 % were single, 59% had low income (< $25/month) and most were circumcised (72%). HIV prevalence was 13.6% in the study population and 5.8% when we excluded 27 participants deliberately recruited with HIV infection. Fewer HIV-positive MSM were circumcised (43% vs.76%) and were less likely to report viral STIs (29.5% vs. 11.9%) and non-viral STIs (45% vs. 19%) than HIV-uninfected MSM. In multivariate stepwise logistic regression, MC was inversely associated with HIV infection (adjusted OR (aOR) 0.30; 95 % CI [0.15 - 0.65]). Age 25-35 years (aOR 3.5; 95% CI [1.3 - 8.9]) and ≥ 36 years (aOR 22.7; 95% CI [7.3-70.4]) versus age < =24 years were respectively associated with increased likelihood of having HIV infection. MC (aOR 0.25; 95 % CI [0.13-0.48]) was associated with lower risk of viral STDs whereas a previous report of sex with a man at least 10 years older (aOR 2.8; 95%CI [1.42-5.79]) was associated with higher risk of viral STIs. Male circumcision (aOR 0.99; 95%CI [0.5-1.9]), marital status and sex with a man ≥10 years older were not associated with non-viral STIs.
Conclusions: We found a higher HIV prevalence (5.7%) in Rwandan MSM than in general population of men (4.4%) living in Kigali, and that MC was associated with significantly reduced risk of HIV and other viral STIs, but not of non-viral STIs.

TUPEC184

HSV-2 and HSV-1/2 coinfection are associated with HIV among young sexual minority men: Findings from the P18 cohort

D. Ompad[1,2,3], F. Kapadia[1,2,3], R. Greene[3,4,5], P. Halkitis[3,6,7]
[1]New York University College of Global Public Health, Department of Epidemiology, New York, United States, [2]New York University Rory Meyers College of Nursing, Center for Drug Use and HIV Research, New York, United States, [3]New York University College of Global Public Health, Center for Health, Identity, Behavior, and Prevention Studies, New York, United States, [4]New York University School of Medicine, New York, United States, [5]Bellevue Hospital, Adult Primary Care Center, New York, United States, [6]Rutgers University School of Public Health, New Brunswick and Newark, United States, [7]Rutgers University RWJ School of Medicine, New Brunswick, United States

Background: There is a strong and consistent relationship between HIV and herpes simplex virus (HSV)-2. Disparities in HIV may be attributable, in part, to HSV-2. Less understood, however, is the relationship between HSV-1 and HIV, which is of interest given the higher prevalence of HSV-1 vs. HSV-2 as well as virological and pathological similarities between HSV-1 and HSV-2.
Methods: P18 is an ongoing prospective cohort study of young sexual minority men (YSMM) in New York City. At each semi-annual visit, men complete risk assessment surveys and undergo HIV testing. Beginning in October 2015, serologic testing for HSV-1 and HSV-2 was conducted among 484 YSMM.
Results: The mean age of the sample is 23.7 years (range 22-25). Most were male- (92.1%) and gay-identified (83.8%); 33.3% were Hispanic/Latino, 29.8% were black, 26.2% were white, 10.7% were Asian or another race. HIV prevalence was 7.9%. Prevalence of any HSV was 68%; 48.4% had HSV-1 only, 7.9% had HSV-2 only, and 11.8% were co-infected with HSV-1 and HSV-2. Of the 38 HIV+ men, 94.7% were co-infected with at least one HSV-type; 29.0% had HSV-1 only, 21.1% had HSV-2 only, and 44.7% were co-infected with HSV-1 and HSV-2. Blacks were significantly more likely to have HSV-1 and HSV-2 as compared to Whites. Only 5.8% of those testing positive for HSV-1 or -2 reported painful sores on their penis or genitals. Almost 58% had been ever tested for herpes; 57.0% of those with HSV-1 and 63.3% of those with HSV-2 had never been tested. In a multivariate logistic regression model, HSV-2 and HSV1/2 coinfection were associated with increased odds for HIV after controlling from race/ethnicity (HSV-2 AOR=15.6, 95% CI=3.1, 78.2 and HSV-1/2 AOR=26.2, 95% CI=5.7, 120.4) as compared to no HSV.
Conclusions: These cross-sectional data suggest that HSV-2 and HSV-1/2 coinfection are associated with HIV infection; HSV-1/2 coinfection demonstrates a larger AOR than HSV-2 alone. Moreover, there are racial disparities in HSV-1 and HSV-2 prevalence. HSV may lead to HIV especially since it often goes undiagnosed and can be asymptomatic. Prospective studies are needed to determine whether both HSV-1 and HSV-2 increase risk for HIV acquisition.

TUPEC185

Risk factors for HIV infection among young MSM in Chiang Mai, Thailand

Q. Kaewpoowat[1,2], S. Chariyalertsak[1], P. Saokhieo[1], R. Khampan[1], R. Songsupa[1], T. Supindham[1]
[1]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [2]Faculty of Medicine, Chiang Mai University, Department of Medicine, Chiang Mai, Thailand

Background: Young men who have sex with men (YMSM) are one of the high-risk populations for contracting and transmitting HIV. Understanding their sexual practices and risk factors is crucial for planning further prevention program.
Methods: The data was obtained from the clients who sought for HIV testing and consented for this observational study at PIMAN center, a HIV voluntary counseling and testing unit for MSM in Chiang Mai, Thailand. Demographic data, sexual behaviors, substance use, and attitude toward HIV were collected by computer assisted self-interview (CASI). HIV rapid testing was performed on site.
Results: During January 2013 - December 2017, 1368 clients requested HIV testing at PIMAN center. Of those, 864 (63%) were YMSM (age 16-24, median age = 21 years). Majority (75%) were university/college students. Self-reported gender were gay (60%), transgender women (22%), bisexual (13%) and heterosexual (4%). Median sexual debut age was 17 year-old. Median number of partners in past 6 months was 6. The rate of regular condom use and lubricant use was 30% and 51% respectively. Active alcohol consumption (85%) and smoking (27%) were common among participants, but illicit drug use was only found in 6%. Trading money, gifts or valuables with sex were reported in 10% of the population. Forty-six percent sought sexual partners online and 87% of those eventually engaged in sexual activities. Majority (60%) perceived their HIV risk as "no to low-risk". One third (30%) reported knowing friends or relatives living with HIV and 52% answered that they felt comfortable having meals, working and taking care of people living with HIV infection. Eighty clients (9%) were tested positive for HIV. Receptive anal intercourse, current/previous illicit drugs use, seeking sexual partners on the internet, having sex ≥ 3 times/week and self-perception of "moderate to high-risk" for HIV infection are independently associated with HIV positive on multivariate analysis.
Conclusions: HIV prevalence among young MSM remains high. More efforts should be made to improve HIV attitude and preventive practices among this population. Online media has the potential to access the high-risk sub-group.

What is happening to condom use? A longitudinal sexual event-level analysis of anal intercourse by partner HIV status concordance among men who have sex with men in Vancouver, Canada

N.J. Lachowsky[1,2], L. Wang[1], N. Bacani[1], H.L. Armstrong[1,3], G. Olarewaju[1], R. Crosby[4], E.A. Roth[2], R.S. Hogg[1,5], D.M. Moore[1,3], Momentum Health Study
[1]British Columbia Centre for Excellence in HIV/AIDS, Division of Epidemiology & Population Health, Vancouver, Canada, [2]University of Victoria, Victoria, Canada, [3]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [4]University of Kentucky, Lexington, United States, [5]Simon Fraser University, Burnaby, Canada

Background: Condoms are a mainstay of HIV prevention among men who have sex with men (MSM). Promotion of Treatment as Prevention in British Columbia has been followed by the campaign "Undetectable = Untransmissible" (U=U). We evaluated trends in condom-use during anal intercourse among HIV-positive and HIV-negative MSM disaggregated by partner HIV status concordance in Vancouver, Canada.
Methods: Prospective data were collected from 09/2014-02/2017 from sexually-active Vancouver MSM, recruited using respondent-driven sampling (RDS). Participants completed assessments every six months, providing event-level data on their last sexual encounter with their five most recent partners. We used four-level mixed effects models (RDS recruitment chain; participant; visit; event) to evaluate temporal trends (6-month calendar periods) among four outcomes: condomless receptive anal intercourse (RAI), condom-protected RAI, condomless insertive anal intercourse (IAI), and condom-protected IAI. Analyses were conducted overall and stratified by participant self-reported HIV status for different partner HIV status concordances: seroconcordant, serodiscordant, and unknown status. Odds ratio (OR) and 95% confidence intervals (95%CI) are shown.
Results: 481 participants completed 1303 visits reporting on 3786 sexual events (29.7% from self-reported HIV-positive MSM). Of note, HIV-negative MSM reported PrEP use in only 3.0% of events. There were no significant trends in condomless RAI overall (mean=26.3%), by participant HIV status, or by partner concordance (all *P*>0.05). There was an overall decrease in seroconcordant condom-protected RAI (20% to 14.7%; OR=0.87, 95%CI:0.77-0.99) driven by a significant decrease among HIV-negative MSM (24.0% to 18.3%, OR=0.88, 95%CI:0.77-0.99). There were significant increases in condomless IAI with seroconcordant (29.6% to 34.9%, OR=1.10, 95%CI:1.00-1.22) and unknown status partners (9.1% to 20.9%, OR=1.22, 95%CI:1.02-1.45). There was a decrease in seroconcordant condom-protected IAI among HIV-positive participants (3.3% to 0.0%, OR=0.57, 95%CI:0.37-0.88).
Conclusions: No significant trends in condom-use during serodiscordant anal intercourse highlights no risk compensation based upon Treatment as Prevention or U=U principles. Further, levels of condomless RAI were stable. However, condom-protected sex decreased between seroconcordant partners, perhaps indirectly reflecting reduced perceived HIV risk, increased confidence of assumed HIV concordance, or both; this has important implications for STI transmission. Finally, increases in condomless IAI with unknown status partners may reflect shifting expectations of HIV status disclosure and perceived risk.

Changing demographic among Latino MSM diagnosed with HIV in Florida, 2006-2015: Implications for primary and secondary HIV prevention

D.M. Sheehan[1,2], E. Cyrus[2], K.P. Fennie[1], L.M. Maddox[3], E.C. Spencer[3], M.J. Trepka[1]
[1]Florida International University, Department of Epidemiology, Miami, United States, [2]Center for Research on US Latino HIV/AIDS and Drug Abuse, Miami, United States, [3]Florida Department of Health, HIV/AIDS Section, Bureau of Communicable Diseases, Tallahassee, United States

Background: From 2011-2015, HIV diagnoses in the United States (U.S.) decreased among most groups, but increased 14% among Latino men who have sex with men (MSM). To help understand these trends and guide HIV prevention strategies, the study's objective was to compare longitudinally country of birth and age among newly diagnosed Latino MSM in Florida.
Methods: We used records from Latinos who met Centers for Disease Control and Prevention HIV case definition over a 10-year period (2006-2015) and were reported to the Florida Department of Health HIV/AIDS surveillance system. The following birth countries/regions categories were examined: Central America, Cuba, Mexico, Puerto Rico, South America, U.S.-mainland, and other. The following age categories were examined: 0-12, 13-24, 25-49, ≥50. SAS 9.4 was used to compare trends in country of birth and age by year using a two-sided Cochran-Armitage Trend Test.
Results: Of 12,084 new diagnoses among Latinos, 7,654 (63.3%) were among MSM. The proportion of diagnoses attributable to MSM increased from 52.1% in 2006 to 72.8% in 2015 (p-value < .0001). Additionally, compared to the decreasing trend in the proportion of new MSM diagnoses born in U.S.-mainland (31.8% to 27.1%), the proportion born in Cuba (20.1 to 30.2%; p-value < .0001) and South America (13.6% to 16.6%; p-value .0005) increased significantly. The proportion born in Central America decreased at a significantly faster rate than the proportion born in U.S.-mainland (9.5% to 3.7%; p-value < .0001). Further, the increasing proportion of MSM aged 13-24 (12.0% to 23.8%; p-value < .0001) and ≥50 (8.2% to 11.2%; p-value 0.0112) was significantly different than the decreasing trend of MSM aged 25-49 (79.8% to 65.0%).
Conclusions: Over the past 10 years, the Latino MSM population newly diagnosed with HIV has changed significantly with respect to birth country and age. In Florida, the state with the 2nd highest HIV rate in the U.S. excluding District of Columbia, HIV prevention strategies should consider targeting Cuban and South American immigrants and young and older Latinos to address the increasing trend in HIV diagnoses among Latino MSM. Similar analyses may be performed across U.S. states to inform national strategies.

TUPEC188

Prevalence and correlates of group sex participation alongside other risky sexual practices among men who have sex with men in Malawi

L. Kapanda[1], V. Jumbe[2], G. Trapence[3], C. Izugbara[4], A. Muula[1]
[1]University of Malawi - College of Medicine - School of Public Health and Family Medicine, Department of Public Health, Blantyre, Malawi, [2]University of Malawi - College of Medicine - School of Public Health and Family Medicine, Health Systems and Policy, Blantyre, Malawi, [3]Centre for Development of People (CEDEP), Lilongwe, Malawi, [4]Africa Population and Health Research Centre (APHRC), Nairobi, Kenya

Background: HIV prevalence among Malawian adult men is estimated at 6.4% compared to 18.2% among men who have sex with men (MSM). Little is known about prevalence of group sex events (GSEs) participation among Malawian MSM. We assessed GSEs participation alongside other risky sexual practices and characterized these experiences to inform HIV and other STIs prevention among MSM.
Methods: Between May and November 2016, we recruited MSM through Respondent Driven Sampling (RDS) in a cross-sectional study done in Lilongwe. We enquired from MSM about participation in group sex and other sexual practices that increase HIV and other STIs acquisition and transmission.

Results: Of 455 responders, 94 (21% RDS weighted) participated in GSEs in the prior year. Almost half (48%) of GSE attendees had single marital status with a woman, 30% were bisexuals. Almost 23% reported either condomless anal sex (CAS) or non-lubricant use with at least one of their partners (insertive: 37%; receptive: 28% and both 35%). In bivariate analysis, single MSM were less likely to participate in group sex (Odds Ratio (OR) 0.23 CI: 0.11 - 0.48) compared to those married to a female. Participants were 2.4 times likely to participate in GSEs under alcohol influence (OR 2.4 (CI: 1.04 - 5.7). In multivariable regression analysis, MSM aged 30-34 were almost three and half times likely to participate in GSEs (Adjusted Odds Ratio (AOR) 3.4, CI: 1.01 - 12.1) compared to 18 - 24 age group. Men participating in GSEs were almost four times to have felt STI symptoms past 12 months (OR 3.9, CI: 1.5 - 10.3), had low risk HIV perception (OR 0.34 CI: 0.14 - 0.86) compared to non GSE attendees.
Conclusions: We established prevalence of group sex participation alongside other sexual behaviours such as bisexual interactions, CAS, non-lubricant use and GSEs participation under alcohol influence. These sexual practices coupled with low perception towards HIV, pose significant risk for HIV, STIs acquisition and transmission within the group sex setting. Our findings demonstrate the importance of focusing on risky sexual behaviors that occur among MSM partnerships and offer opportunity to develop risk reduction interventions specific to GSEs participation among Malawian MSM.

TUPEC189

HIV prevalence and incidence among men who have sex with men attending community-based HIV testing and counseling clinics in metropolitan Manila, 2012-2017

C. Lagman[1], J.D. Rosadiño[1], R. Ditangco[2], R. Paktaghan[1], L.V. Le[3], Y.R. Lo[3], F. van Griensven[4]
[1]*LoveYourself Foundation, Manila, Philippines,* [2]*Research Institute for Tropical Medicine, Manila, Philippines,* [3]*World Health Organization, Manila, Philippines,* [4]*Thai Red Cross AIDS Research Center and UCSF Department of Epidemiology and Biostatistics, Bangkok, Thailand*

Background: Little is known about HIV prevalence and incidence among men who have sex with men (MSM) in the Philippines. This information is essential to understand the HIV epidemic and to inform and implement targeted behavioral and biomedical interventions in this population.
Methods: LoveYourself Foundation (LYS) operates 2 community-based clinics providing HIV/STI testing, counseling and treatment services for MSM and transgender in metropolitan Manila, the Philippines. Testing is provided free-of charge. Blood specimens are collected by phlebotomy and evaluated for the presence of HIV infection using 3rd Gen EIA rapid testing. Men testing HIV infected are referred instantly for publicly funded antiretroviral treatment available at the clinic. Condoms, lubricants and risk behavior counseling are provided at every visit. Here we report the HIV prevalence among first-time testers and HIV incidence among those returning for retesting (testing HIV uninfected previously) from 2012 to 2017.
Results: LYS clinics experienced a strong increase in new HIV testers, from 1,379 in 2012 to 11,290 in 2017. Overall HIV prevalence during this period was 15.7%, highest in 2012, 23.0%, and lowest in 2017, 13.2% (table). HIV prevalence during the observation period inclined with age: from 8.7% in 15-to-21-year olds, 14.4% in those 22-to-25 years to 18.6% in men 26 years and older. While the number of HIV seroconversions among re-testers increased from one in 2012 to 246 in 2017, HIV incidence density in the retest population remained approximately the same, ~4.0 per 100-person years (PY) (discounting 2012 due to small numbers) (table). HIV incidence density was inversely associated with age: 5.8 in 15-to-21-year olds, 4.8 in those 22-to-25 and 3.8 per 100 PY in those of 26 years and older.
Conclusions: HIV prevalence and incidence are high among MSM attending HIV testing and counseling services in community-based clinics in Metropolitan Manila, the Philippines. HIV incidence was highest among the youngest MSM. Increased behavioral and biomedical interventions, including HIV pre-exposure prophylaxis, in MSM are urgently necessary.

	Newly tested	HIV infected	HIV prevalence	PY of follow-up re-testers	Newly HIV infected	HIV incidence density/100 PY
Year	N	n	% (95% CI)	N	n	n/N (95%CI)

TUPEC190

HIV epidemics in migrants from Latin America & Caribbean in Europe are driven by MSM

J. Del Amo[1], I. Jarrín[1], V. Hernando[1], B. Alejos[1], A. Pharris[2], T. Noori[2]
[1]*Institute of Health Carlos III, National Center for Epiemiology, Madrid, Spain,* [2]*European Centre for Diseases Prevention and Control, Stockholm, Sweden*

Background: We aim to quantify the contribution of migrants from subregions with distinct HIV epidemics within Latin America & the Caribbean (LAC) to HIV reports in the European Union/European Economic Area (EU/EEA), describe trends by transmission category and estimate median CD4 count at diagnosis overtime.
Methods: HIV reports to the European Surveillance System (TESSy) from 30 EU/EEA countries from 2004 till 2015 pooled in December 2016 were analysed. To minimize artificial declines due to reporting delay, 2015 was excluded when appropriate. Cases from LAC were divided into Andean (AA), Caribbean (Cb), Central (CA), South-America (SA) UN sub-regions. Differences in CD4 counts at HIV diagnosis over time for each sub-region were modelled using multivariate median regression analyses adjusting for transmission category, age and sex.
Results: Of 375,743 cases reported in 2004-2015, 19,928 (5%) were from LAC; of which, 31% from unknown LAC sub-region, 27% from Cb, 24% from SA, 9% from AA and 9% from CA. More than half (53%) were in men who have sex with men (MSM) varying from 84% of reported cases originating from SA to 46% of cases originating from Cb. Absolute (+679) and relative (+167%) increases in the number of HIV diagnoses in MSM from LAC were reported from 2004 to 2014. Absolute (-215) and relative (-27%) declines in heterosexually transmitted cases from LAC were reported from 2010 to 2014. Median CD4 counts in 2004 were 275, 370, 376, 303 and 301 cells/mm^3 for CA, AA, SA, Cb and unknown LAC region. Compared to values in 2004, for all sub-regions, median CD4 counts did not show statistically significant increases overtime but were higher in women, MSM and people under 30 years of age (data not shown for age) in multivariable analyses (table).
Conclusions: The current HIV epidemic in migrants from LAC in the EU/EEA is driven by on-going transmission among MSM, (which most likely takes place post-migration) largely from South and Andean-America, who consistently show higher CD4 counts at diagnosis. Heterosexually transmitted cases, largely from Central-America and the Caribbean are decreasing. Increased testing and combination preventive interventions, such as pre-exposure prophylaxis are needed in migrant MSM.

Bisexuality among men who have sex with men and transgender women in sub-Saharan Africa: Findings from the HPTN 75 study

K. Ondeng'e[1], C. Mbeda[1], A. Ogendo[1], V. Akelo[1], X. Guo[2], W. Chege[3], E. Hamilton[4], J. Lucas[4], T. Sandfort[5]
[1]Centre for Global Health Research, Kenya Medical Research Institute, HIV Research Branch, Kisumu, Kenya, [2]Vaccines and Infectious Disease Division, Fred Hutchinson, Seattle, United States, [3]Prevention Sciences Program, Division of AIDS, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, United States, [4]Science Facilitation Dept., FHI 360, Durham, United States, [5]HIV Center for Clinical and Behavioural Studies, New York State Psychiatric Institute and Columbia University, New York, United States

Background: Studies in sub-Saharan Africa (SSA) among men who have sex with men and transgender women (MSM&TW) have primarily focused on the epidemiology of HIV infection. However, little is known about important behavioral variations within this population, despite the critical role it plays in the ongoing general epidemic. We set out to identify personal, interpersonal and contextual characteristics of MSM&TW in SSA, who engage in sex with both men and women versus those who only have sex with men.
Methods: Four sites (Kisumu, Kenya; Blantyre, Malawi; Cape Town and Soweto, South Africa) enrolled a total of 401 adult MSM&TW. Psychosocial and behavioral data were collected using a structured questionnaire. Participants who had sex with both men and women (PSMW) were compared with those who only had sex with men (PSMO). For this analysis, data from the enrollment visit were available for 387 participants. For all reported differences: P<.05.
Results: Overall, 21.7% (84/387) of the MSM&TW reported having had sex with both men and women in the preceding three months. PSMW were more likely to be married (17.9% vs. 4.0 %) have children (46.4% versus 15.5%), identify as bisexual (64.3% versus 30.0%), and less likely to identify as female or transgender (9.6% versus 23.3%). Compared to PSMO, PSMW were on average older (26.0 versus 23.8 years) and more likely to be from Blantyre (43.3%) and less likely from Cape Town and Soweto (7.5% and 7.1%). PSMO had on average more lifetime sexual partners but few sexual partners in the previous three months than PSMW (7.3 versus 5.3 and 1.8 versus 2.3, respectively). Furthermore, PSMW were more likely to prefer to be the insertive partner in anal sex (75.0% versus 33.3%) respectively. Finally, PSMW were less likely to test HIV positive (10.7% versus 19.8%).
Conclusions: Our findings demonstrate that there is a substantial proportion of sub-Saharan African MSM&TW who recently have engaged in sex with both men and women. We also found significant differences in sexual behavior and risk factors that may place these populations at risk for HIV infection. In-depth understanding of their practices presents an opportunity for developing targeted public health interventions.

TUPEC192

Transactional sex among men who have sex with men participating in the CohMSM prospective cohort study in West Africa

C.H. Kounta[1,2], L. Sagaon-Teyssier[1,2], P.-J. Coulaud[1,2], M. Mora[1,2], G. Maradan[1,2], M. Bourrelly[1,2], A.A. Keita[3], S.-A.B. Yoro[4], C. Anoma[4], C. Coulibaly[5], E.T.T. Dah[5,6], S. Agbomadji[7], E. Mensah[7], A. Bernier[8], C. Couderc[9], B.D. Keita[3], B. Spire[1,10], C. Laurent[9], the CohMSM Study Group
[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France, [2]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [3]ARCAD Sida, Bamako, Mali, [4]Espace Confiance, Abidjan, Cote D'Ivoire, [5]Association Africaine Solidarité, Ouagadougou, Burkina Faso, [6]Centre Muraz, Bobo Dioulasso, Burkina Faso, [7]Espoir Vie Togo, Lomé, Togo, [8]Coalition Internationale Sida, Pantin, France, [9]IRD, INSERM, Univ Montpellier, TransVIHMI, Montpellier, France, [10]RS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France

Background: Men who have sex with men (MSM) are at much greater risk of HIV infection, especially in sub-Saharan Africa, where little is known about their involvement in transactional sex (TS). We aimed to characterize MSM reporting TS (MSM-TS) and to identify factors associated with TS in that population in West Africa.
Methods: We used data from the prospective cohort study CohMSM conducted in Burkina Faso, Côte d'Ivoire, Mali and Togo. We focused on MSM recruited between 06/2015 and 06/2017 by a team of trained peer educators. Participants completed scheduled study visits at 6 months and 12 months, which included a medical examination, HIV screening, counselling and a face-to-face interview. At each visit, participants provided information on their sociodemographic and economic characteristics, sexual behaviours, HIV risk-reduction strategies, alcohol and drug use, and on stigmatization. Three stigmatization sub-scores (experienced, perceived, internalized) were constructed according to the algorithm of Ha and al. 2013. A mixed-effects logistic regression was used for data analysis.
Results: Of the 608 participants recruited at baseline, 528 and 447, respectively, had a follow-up visit at 6 and 12 months. During a total of 1583 study visits, 413 TS events were reported, with 36.8% of participants reporting no TS, 12.5% regular TS and 50.7% occasional TS. MSM-TS were younger, 69.7% of MSM-TS had an educational level < high-school diploma and 83.6% were unmarried. The following factors were associated with a greater likelihood of TS: unstable housing (aOR[95%CI]:1.950[1.2-3.3]), searching for male sexual partners on the internet during the previous month (aOR[95%CI]:1.394[1.1-1.8]), group sex with men (aOR[95%CI]:2.523[1.7-3.6]), and reporting - for the previous 6 months - multiple male sexual partners (aOR[95%CI]:2.197[1.6-3.0]), unprotected receptive anal sex (aOR[95%CI]:1.338[1.0-1.8]), alcohol consumption (aOR[95%CI]:1.452[1.1-1.9]), drug use (aOR[95%CI]:2.029[1.4-3.0]), and sexual violence by male partners (aOR[95%CI]:2.120[1.3-3.5]), after adjusting for country of study, younger age, an educational level < high-school diploma, satisfaction with current sex life and experiencing stigmatization.
Conclusions: A large proportion of MSM in the CohMSM study who engaged in TS had high-risk HIV-infection exposure practices and were characterized by socioeconomic difficulties. Existing targeted prevention interventions should be strengthened to improve HIV prevention efforts in this subpopulation.

TUPEC193

Factors associated with discrimination based on sexual orientation among MSM in 12 Brazilian cities

L. Magno[1], I. Dourado[2], F. Alves[1], M.A. Veras[3], L.A. V. da Silva[4], M. Drew Crosland Guimarães[5], A. Fachel Leal[6], D. Knauth[6], A.M. de Brito[7], C. Kendall[8], L. Kerr[9], The Brazilian MSM Group
[1]Bahia State University, Department of Life Sciences, Salvador, Brazil, [2]Federal University of Bahia, Health Collective Institute, Salvador, Brazil, [3]Santa Casa of São Paulo State, School of Medicine, São Paulo, Brazil, [4]Federal University of Bahia, Institute of Humanities, Arts & Sciences Professor Milton Santos, Salvador, Brazil, [5]Federal University of Minas Gerais, Department of Preventive and Social Medicine, Belo Horizonte, Brazil, [6]Federal University of Rio Grande do Sul, Department of Social Medicine, Porto Alegre, Brazil, [7]Fiocruz Foundation, Aggeu Magalhães Institute, Recife, Brazil, [8]Tulane University, Global Community Health and Behavioral Sciences, New Orleans, United States, [9]Federal University of Ceará, Department of Community Health, Fortaleza, Brazil

Background: Discrimination based on sexual orientation (DBSO) may influence vulnerability to HIV through increased exposure to risky sexual behaviors and poor health seeking. We aim to estimate factors associated with high levels of DBSO among men who have sex with men (MSM) in Brazil.

Methods: We conducted a cross-sectional study using respondent driven sampling in 12 Brazilian cities in 2016 among 4,176 MSM. Latent Class Analysis (LCA) was used to characterize DBSO among MSM based on 12 variables in the survey and to link levels of DBSO to risky sex practices. For each city individuals were weighted using RDSAnalyst; combined 12-city data was weighted using each city as a stratum. Logistic regression was used to measure factors associated with high DBSO. Odds ratios (OR) with 95% CI were estimated.

Results: Most MSM were younger than 25 years old (58.3%), single (85.3%), with 12+ years of education (70.4%), and self-identified as black (62.8%). DBSO was classified into three LCA classes: class 1 (n=208) denominated "high DBSO" were MSM reporting high proportions (above 70%) for all of the 12 variables; class 2 (n=1,141) "average DBSO" and class 3 (n=1,562) „low DBSO" was applied to MSM reporting lower proportions for all 12 variables. There was a positive association between sexual violence (OR: 3.16, 95% CI: 1.36-7.34), physical violence (OR: 7.42, 95% CI: 3.07-17.96), family disapproval of sexual orientation (OR: 3.38, 95% CI: 1.11-10.24), suicidal ideation (OR: 4.41, 95% CI: 1.93-10.04), binge drinking (OR: 6.65, 95% CI: 1.35-32.61), and unprotected anal sex with stable partners (OR: 3.54, 95% CI: 1.42-8.82) among those with "high DBSO", as compared to "low DBSO". Reporting a religious affiliation (OR: 0.37; 95% CI: 0.14-0.97) was negatively associated with "high DBSO" as compared to "low DBSO".

Conclusions: Several aspects of Brazilian male gender identity may contribute to the high levels of DBSO reported by MSM in Brazil, including "machismo", misogyny, and patriarchy. These characteristics can increase exposure of MSM to violence, alcohol consumption, suicidal ideas, stigma, and discrimination, all known risk factors for HIV infection. Anti-discrimination and gender diversity policies are urgently needed to address DBSO routinely faced by MSM.

TUPEC194

Recent decreases in unsuppressed viral load among HIV-positive men who have sex with men in Vancouver, Canada from 2012-2017

H.L. Armstrong[1,2], J. Gitelman[3], Z. Cui[1], N. Bacani[1], P. Sereda[1], N.J. Lachowsky[1,4], K.G. Card[1,5], H. Fisher Raymond[6], J. Montaner[1,2], R.S. Hogg[1,5], E.A. Roth[4], M. Hull[1,2], T. Howard[7], D.M. Moore[1,2]
[1]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of British Columbia, Medicine, Vancouver, Canada, [3]McGill University, Montreal, Canada, [4]University of Victoria, Victoria, Canada, [5]Simon Fraser University, Burnaby, Canada, [6]Rutgers University, New Brunswick, United States, [7]Momentum Health Study Community Advisory Board, Vancouver, Canada

Background: The majority of people diagnosed with HIV in Canada are men who have sex with men (MSM). Since 2010, British Columbia has implemented Treatment as Prevention (TasP) as policy. We examined trends in virologic suppression and determinants of significant viremia among a cohort of HIV-positive MSM in Vancouver over a five-year period.

Methods: Using respondent-driven sampling, male-identified participants ≥16 years old living in Metro Vancouver and reporting sex with another man in the past 6 months were recruited into the Momentum Health Study between 02/2012-02/2015. Study visits occurred every 6 months, up to 02/2017, and included a computer-assisted self-interview and clinical CD4 and viral load (VL) testing. We also linked participant data with the BC HIV Drug Treatment Program to obtain drug dispensing and VL data. We conducted a trend analysis of VL suppression using univariable generalized estimating equation (GEE) multi-level modelling (RDS chain: participant: visit) with calendar time as the independent variable. Univariable and multivariable GEE identified factors associated with episodes of VL ≥200 copies/mL.

Results: Of 774 participants, 223 were HIV-positive at baseline and 11 were diagnosed during follow-up; 2 had incomplete data and were excluded from this analysis (n=232). We observed a significant trend towards reduced levels of unsuppressed VL (>200 copies/mL) from 22% of individuals (07/2012-12/2012) to 12% (07/2016-12/2016) (OR:0.87; 95%CI:0.83-0.92 for each 6-month period; *p*< 0.0001 for trend). 175 HIV-positive MSM had ≥1 follow-up visit (total visits=1271; median follow-up=3.5 years). Median age was 47 years (Q1,Q3:39,52); most identified as gay (85.7%) and white (80.6%). Factors associated with episodes of VL ≥200 copies/mL included younger age, substance use (i.e., ecstasy and crystal methamphetamine), seeking sex online, and lower HIV treatment optimism. MSM who reported condomless anal sex with an HIV-negative partner were less likely to have periods of unsuppressed VL (Table 1).

Conclusions: During a period when TasP policy was actively promoted, we observed a significant trend towards reduced community VL among HIV-positive MSM in Vancouver. In order to maximize rates of VL suppression, continued efforts should promote antiretroviral therapy to younger MSM, those who seek sex online, and those who use substances.

	Adjusted Odds Ratio	95% Confidence Interval		p value

TUPEC195

Factors associated with unprotected receptive anal sex among MSM in Brazil: A national RDS study

M.D. Crosland Guimaraes[1], G. Machado Rocha[2], A.M. de Brito[3], I. Dourado[4], M.A. Veras[5], L. Magno[6], C. Kendall[7,8], L. Kerr[8], The Brazilian MSM Group
[1]Federal University of Minas Gerais, Belo Horizonte, Brazil, [2]Federal University of São João Del-Rei, Divinópolis, Brazil, [3]Aggeu Magalhães Institute - FIOCRUZ, Recife, Brazil, [4]Collective Health Institute, Federal University of Bahia, Salvador, Brazil, [5]Santa Casa Faculty of Medical Sciences, São Paulo, Brazil, [6]State University of Bahia, Department of Life Sciences, Salvador, Brazil, [7]Tulane School of Public Health and Tropical Medicine, Center for Global Health Equity, New Orleans, United States, [8]Federal University of Ceará, Department of Community Health, Fortaleza, Brazil

Background: Unprotected receptive anal intercourse (URAI) is the riskiest sexual behavior for HIV infection among men who have sex with men (MSM). The incidence of HIV among younger MSM is increasing in many countries. The aim of this study was to estimate the prevalence and factors associated with URAI among MSM in Brazil, stratified by age.

Methods: Cross-sectional study of 4,175 MSM recruited from 12 Brazilian cities by respondent driven sampling in 2016. Participants were interviewed and the associations of behavioral, sociodemographic, and health service related variables with URAI were assessed by age groups (18-24 or 25+ years old). Odds ratios with 95% confidence intervals were obtained using multiple logistic regression. For each city, individuals were weighted using RDS Analyst®. Combined data was analyzed by SAS® complex survey procedure using each city as a stratum.
Results: There was a higher proportion of MSM 18-24 years old (58.3%) in the sample. Among these younger MSM, there were higher proportions of single (90.3%), white (34.8%), 12+ years of education (75.2%) and higher socioeconomic status (46.0%), as compared to those 25+ years old (78.4%, 28.2%, 63.5%, 34.3%, respectively) (p< 0.01). The prevalence of URAI was also higher among younger MSM (41.9% vs 29.7%) (p< 0.01). Multivariate analysis indicated that perception of risk, sexual identity, self-rated health status, and exchanging sex for money were associated with URAI among younger MSM only. History of sexual violence, sex with younger partners, having six or more partners and unprotected sexual debut were associated with URAI among older MSM only (Table 1). Marital status, having stable partner in the past six month, and reporting sex with men only were associated with URAI in both groups. None of the health service related variables assessed (e.g. access to STI testing, condoms, lubricants or counseling) were associated with URAI.

Variables	Adjusted Odds Ratios (95% Confidence Intervals)	
	18-24 years old (n=2503)	25+ years old (n=1626)
Moderate/High self-perceived risk of HIV infection:	1.75 (1.09-2.82)	
Regular/Poor self-rated health status:	1.86 (1.17-2.96)	
Sel-reported Gay/Homosexual sexual identity:	2.75 (1.63-4.63)	
Exchanged sex for money in the past six month:	1.93 (1.17-3.19)	
Lifetime history of sexual violence:		2.07 (1.14-3.75)
Predominant age of sexual partners (5+ years younger):		2.39(1.30-4.42)
Six or more sexual partners in the past six months:		2.72 (1.36-5.42)
First sexual intercourse was unprotected:		2.04 (1.18-3.52)

[Table 1. Multivariate analysis of URAI among MSM in Brazil (shown variables which differed by age groups).]

Conclusions: MSM remain disproportionately affected by HIV in Brazil. The high proportion of URAI is of public health concern. Despite access to free condoms and lubricants, preventive efforts may not be reaching MSM effectively. Age specific and sensible intervention approaches, including stigma, discrimination, and perception of risk must be considered.

Epidemiology of HIV in infants, children and adolescents

TUPEC196

Virologic outcomes of perinatally infected adolescents in the period of early adolescence in South Africa (10-15 years)

P. Nyakato[1], M. Schomaker[1], N. Sipambo[2], K. Technau[3], G. Fatti[4], H. Rabie[5], F. Tanser[6], B. Eley[7], J. Euvrard[1,8], R. Wood[9], P. Tsondai[1], M.-A. Davies[1]
[1]Centre for Infectious Disease Epidemiology and Research, School of Public Health and Family Medicine, Faculty of Health Sciences, University of Cape Town, Cape Town, South Africa, [2]Harriet Shezi Children's Clinic, Chris Hani Baragwanath Academic Hospital, Johannesburg, South Africa, [3]Rahima Moosa Mother and Child Hospital and Department of Paediatrics & Child Health, University of Witwatersrand, Department of Paediatrics & Child Health, Johannesburg, South Africa, [4]Keth'impilo, Durban, South Africa, [5]Tygerberg Academic Hospital, University of Stellenbosch, Department of Paediatrics and Child Health, Stellenbosch, South Africa, [6]Africa Centre for Health and Population Studies, University of KwaZulu-Natal, Somkhele, Durban, South Africa, [7]Red Cross War Memorial Children's Hospital and Department of Paediatrics and Child Health, University of Cape Town, Department of Paediatrics and Child Health, Cape Town, South Africa, [8]Khayelitsha ART Programme and Médecins Sans Frontières, Khayelitsha, Cape Town, South Africa, [9]Gugulethu HIV Programme and Desmond Tutu HIV Centre, Cape Town, South Africa

Background: HIV infected adolescents are at higher risk of poor treatment outcomes compared to adults or children both due to their developmental stage and because the transition from paediatric to adult/adolescent care can be very challenging with impacts on adherence and retention. We sought to describe the virologic outcomes of adolescents that started antiretroviral therapy (ART) before the age of 10 years.
Methods: We included all adolescents aged 10-15 years who initiated ART before age 10 years (as a proxy for being perinatally infected) from 2004-2015 in 9 IeDEA-SA collaborative cohorts, and had at least 1 viral load (VL) measurement after the age of 10 years. We defined viral non-suppression as any viral load ≥400 copies/ml. Mixed effects logistic regression models were used to explore the association between current age and viral non-suppression adjusting for patient characteristics and time on ART as potential confounders.
Results: The median age at ART start among 4,827 adolescent children (49% female) who started ART before the age of 10 years was 7.2 years (Interquartile range (IQR): 6.0, 8.4). At age 10 years, 25% of these adolescents had VL ≥400 copies/ml. The overall probability of virologic non-suppression by age 15 years was 18% (95% Confidence Interval [CI]: 16%, 21%). The probability of non-suppression increased with increasing age on treatment (adjusted Odds Ratio [aOR]: 1.14 per year increase in age; 95% CI:1.02, 1.29) and was higher in those who started ART in more recent years (compared to reference period of 2004-2007 aOR: 1.90 95% CI 1.32, 2.73; for years 2008-2010 and aOR 6.56 ; 95%CI: 4.05, 10.65 for years 2011-2015).
Conclusions: As perinatally infected children progress into adolescence, the likelihood of poor virologic outcomes increases with age on treatment. It is a concern that children that initiated ART in the later years after 2010 are also at a higher risk of virologic failure.

VL≥400	Crude Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)
Age in years	1.21 (1.16, 1.26)	1.14 (1.02, 1.29)
Duration on art by age 10	1.12 (1.08, 1.17)	1.07 (0.95, 1.21)
Female (ref Male)	0.89 (0.72, 1.09)	0.85 (0.62, 1.16)
Immunnally suppressed at baseline as defined by CDC	9.65 (7.58, 12.27)	10.28 (7.11, 14.86)
Year of Starting ART: 2008-2010 vs 2004-2007	2.20 (1.76, 2.75)	1.90 (1.32, 2.73)
Year of Starting ART: 2011-2015 vs 2004-2007	4.99 (3.81, 6.54)	6.56 (4.05, 10.65)
WHO stage 3/4 vs 1/2	1.01 (.077, 1.33)	1.05 (0.75, 1.48)
"Third" drug in regimen: NVP vs EFV	1.05 (0.34, 3.25)	2.34 (0.50, 10.84)
"Third" drug in regimen: PI vs EFV	0.63 (0.37, 1.08)	0.22 (0.10, 0.46)

[Factors associated with virologic non-suppression among perinatally HIV infected adolescents during early adolescence (10-15 years)]

TUPEC197

High HIV prevalence among adolescent girls and young women participating in a community-based HIV testing services program in Western Kenya

H.-H.M. Truong[1], R. Fatch[1], D. Ogindo[2], M.A. Guzé[3], E. Wandera[2], E. Akama[2], F. Otieno[2], D. Bushman[3], E.A. Bukusi[2], P. Oyaro[4], C.R. Cohen[3]
[1]University of California, Medicine, San Francisco, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]University of California, Obstetrics, Gynecology & Reproductive Sciences, San Francisco, United States, [4]RCTP-FACES NGO, Kisumu, Kenya

Background: Adolescents (15-19 years old) and young people (20-24 years old) are priority populations for HIV prevention efforts globally. Adolescent girls and young women comprise 20% of new infections worldwide and 25% of new infections in sub-Saharan Africa. In Homa Bay County, Kenya, HIV prevalence is 6.7% among youth (15-24 years old), and this age group represents 22% of persons living with HIV. We assessed HIV prevalence among youth participating in a community-based HIV testing services (HTS) program.

Methods: The FACES Hybrid HTS program, which entailed community mapping, household census, multi-disease community health campaigns (CHCs) and home-based HTS, was piloted in Homa Bay County from July through September 2016. Same-day ART initiation was offered to persons newly-diagnosed at the CHCs. Demographic factors associated with HIV status were assessed using multivariable logistic regression. Multiple imputation via chained equations was used to impute missing values. Multivariable models used the imputed dataset and were adjusted for sex, age, education, marital status, sexual history and alcohol use.

Results: A total of 2,705 youth were reached, of whom 1,506 (56%) were female and 1,575 (58%) were adolescents. HIV prevalence was 5.7% overall. Of the 153 HIV-positive youth, 123 (80%) were previously-diagnosed and 30 (20%) were newly-diagnosed. HIV prevalence was 3.4% among adolescent girls, 15.3% among young women, 1.7% among adolescent boys and 1.4% among young men. Prevalence of newly-diagnosed HIV cases was 0.7% among adolescent girls, 2.5% among young women, 0.7% among adolescent boys and 0.5% among young men. HIV-positive status among youth was associated with female sex (aOR=4.38; p< 0.01) and ages 20-24 years (aOR=2.42; p< 0.01). Of the 25 youth who were newly-diagnosed at the CHCs, 56% initiated ART the same day as part of the campaign.

Conclusions: HIV prevalence was high among adolescent girls and young women participating in the Hybrid HTS program. These data highlight the importance of expanding the reach of HIV testing and prevention services for these priority populations. Community-based HTS may be an effective approach for reaching a broader base of adolescents and young people in order to reduce the number of new infections and improve linkage of HIV-positive youth to treatment.

TUPEC198

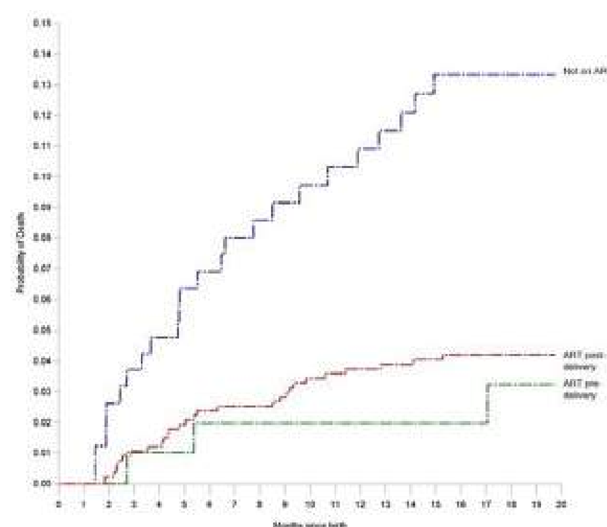
Timing of maternal ART and mortality risk in HIV-exposed uninfected infants: Findings from a prospective cohort of a nationally representative sample of mother-infant pairs from Zimbabwe 2013-2014

M.R. Patel[1], A. Mushavi[2], S. Balachandra[3], G. Shambira[4], J. Nyakura[4], O. Mugurungi[2], B. Tippett Barr[3], P.H. Kilmarx[1,3], T.-H. Dinh[1]
[1]U.S. Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV/TB, Atlanta, United States, [2]Ministry of Health & Child Care of Zimbabwe, AIDS & TB Department, Harare, Zimbabwe, [3]U.S. Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV/TB, Harare, Zimbabwe, [4]University of Zimbabwe, Department of Community Health, Harare, Zimbabwe

Background: It is well-established that maternal antiretroviral therapy (ART) could eliminate mother-to-child HIV transmission (MTCT); however, evidence on mortality among HIV-exposed uninfected infants (HEUI) is limited. We examined mortality among HEUI overall and by maternal ART timing and explored potential causes of death (COD).

Methods: We analyzed data from a prospective cohort of a nationally representative sample of mother-infant pairs in Zimbabwe recruited from (n=151) immunization clinics from February-August 2013, enrolled at 4-12 weeks age, and followed every 3 months until incident HIV-infection, death, or 18 months. We estimated cumulative mortality probability and hazard ratios (HR) with 95% confidence intervals (CI) for HEUI using Kaplan-Meir curves and Cox regression, respectively; unadjusted for complex survey design.

Results: Of 1188 HIV-exposed infants (HEI), 73 (6.1%) contracted HIV. The remaining 1115 HEUI infants had a median enrollment age of 6.6 weeks (interquartile range [IQR]: 6.0-8.9 weeks) and were 48.6% female. Overall, 54 (4.8%) HEUI infants died at a median of 5.5 months (IQR: 3.6-9.8 months). The most common symptoms preceding death were diarrhea (22% [n=12]), difficulty breathing (14.8% [n=8]), not eating (16.7% [n=9]), fever (9.3% [n=5]), and cough (7.4% [n=4]). Most mothers of HEUI were on ART pre-conception (36.4%) or during pregnancy (29.3%); 9.6% post-delivery and 24.7% never. Due to non-significant difference, we combined ART pre-conception and during pregnancy, as ART pre-delivery. Mortality was higher among HEUI with mothers never on ART (8.7%) compared with mothers on ART pre- and post-delivery (2.8% and 3.7%, respectively). Compared to HEUI with mothers never on ART, cumulative mortality at 20-months age was lower among HEUI with mothers on ART pre-delivery (HR=0.31, 95% CI: 0.18-0.56) and with mothers on ART post-delivery (HR=0.23, 95% CI: 0.67-0.76); the difference between HEUI with mothers on ART pre- and post-delivery was non-significant (Figure).



[Figure. Cumulative Mortality of HIV-exposed uninfected infants by maternal ART timing]

Conclusions: The mortality risk was significantly lower among infants born to HIV-infected mothers starting ART pre-delivery, emphasizing the importantance of early maternal ART initiation. Pneumonia- and gastro-intestinal infection-like symptoms were commonly reported as potential COD, suggesting that besides routine early infant diagnosis efforts, targeting early HIV diagnosis and care for HEI with potential opportunistic infections could prevent early mortality in this population.

TUPEC199

Achieving the second 90: Linking adolescents living with HIV to treatment in rural Malawi in the era of Test and Treat

E. Wetzel[1], K. Simon[1,2], T. Beyene[1,2], R. Turetsky[1], A. Kabwinja[1], W. Kammera[1], B. Chavula[1], C. Chikoti[1], H. Chibowa[3], J. Mhango[1], P. Kazembe[1,2], S. Ahmed[1,2], M. Kim[1,2]
[1]Baylor College of Medicine Children's Foundation, Lilongwe, Malawi, [2]Baylor College of Medicine International Pediatric AIDS Initiative, Houston, United States, [3]Ministry of Health, Lilongwe, Malawi

Background: In 2016, Malawi transitioned to "Test and Treat," a policy where all people living with HIV (PLHIV) are treated with lifelong antiretroviral therapy (ART) regardless of clinical or immunological status.

This policy has associated concerns for linkage to ART, with particular concern for adolescents living with HIV (ALHIV, 10-19y). There are unique challenges linking ALHIV to ART due to developmental changes, increased fear of stigma and rejection, or lack of social support. We examined linkage to treatment amongst ALHIV compared to other ages in the era of test and treat in rural Malawi.

Methods: A retrospective analysis of routinely collected Baylor-Tingathe program data of ART naïve patients from the Ministry of Health (MoH) ART referral registers was conducted at 14 health centers in Mangochi District from October to December 2017. Demographic data of treatment naïve patients who were registered in the ART referral register to ease linkage to treatment were assessed. Chi-square test compared the proportion of patients who linked to treatment in the adolescent age group (10-19y) compared to other ages.

Results: Overall, 846 patients (65% female) were included in the analysis, 59 (7%) of whom were ALHIV. After one month of registration in the ART referral register, 709 (84%) were initiated on ART, 104 (12%) had unknown linkage status, 32 (4%) refused ART, and 1 (< 1%) died. Compared to other age groups, ALHIV had the lowest linkage to ART (81%) (Table 1). Linkage was highest among children < 10y at 92% (55/60). ALHIV had poorer linkage compared to all other ages, although not statistically significant (81% vs 84%, p=0.59).

Age at Registration (Years)	Total Registered	Started ART within one month	Percent Linkage to ART
<10	60	55	92%
10-19	59	48	81%
20-24	138	116	84%
25-49	507	422	83%
50+	82	68	83%
Total	846	709	84%

[Table 1. Patients recorded in the ART referral register and those who started ART within one month at 14 sites in Mangochi Oct - Dec 2017]

Conclusions: ALHIV age 10-19y had the lowest linkage to ART compared to other age groups. This suggests that ALHIV may be particularly vulnerable to poor linkage in the era of test and treat. Understanding potential demographic differences in linkage to treatment is imperative in implementing appropriate and targeted strategies to achieve the second 90.

TUPEC200

Survival of children living with AIDS in Brazil - Cohort BIAIDS - Brazil

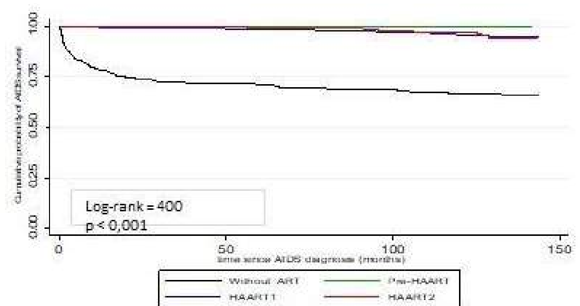
C.S.B. Domingues[1], M.V. Tancredi[1], I.A. Guibu[2], E.A. Waldman[3], F.A. Pires[4], M.A. Gutierrez[4], A.S. Benzaken[5], G.F.M. Pereira[5]
[1]STD/AIDS Reference Center, Sao Paulo State Program of STD/AIDS, Department of Health, Sao Paulo, Brazil, [2]Santa Casa de Sao Paulo School of Medicine, Sao Paulo, Brazil, [3]School of Public Health of University of Sao Paulo, Epidemiology, Sao Paulo, Brazil, [4]Heart Institute, School of Medicine of University of Sao Paulo, Sao Paulo, Brazil, [5]Brazilian Ministry of Health, Department of Surveillance, Prevention and Control of STIs, HIV/AIDS and Viral Hepatitis, Brasilia, Brazil

Background: Brazil was the first middle-income country to offer universal access to AIDS treatment since 1996 and has developed a national plan to eliminate mother-to-child transmission of HIV (MTCT). This study aimed to estimate the survival of children living with AIDS (CLWA) under 13 years of age and to investigate predictors of death with a basic AIDS cause in Brazil among 2003-2007, followed up until 2014.

Methods: Retrospective cohort. Data from the Brazilian Integrated Base of AIDS Cohort (BIAIDS-BRAZIL Cohort) was obtained from a probabilistic record linkage methodology applied to databases of the Ministry of Health: Information System of Notification Diseases (SINAN-AIDS), Control of Laboratory Tests (Siscel)/Logistic Control System of Medicines (Siclom) and Mortality Information System. Kaplan-Meier method, Cox model and estimates of the hazard ratios (HR), with 95% confidence intervals (CI=95%) were used for survival analysis. The main variable was the antiretroviral therapy (ART). To identify factors associated with the outcomes of interest, sociodemographic characteristics, clinical, therapeutic and laboratory evolution were analyzed. The values for each age range were set as altered TCD4+ count: under 1 year < 1,500 cells/mm³; 1-5 years < 1000 cells/mm³ and 6-12 years < 500 cells/mm³.

Results: During the period of 2003-2007, 2,569 CLWA were reported, with 280 deaths, predominance of MTCT in 99% of the cases. All children had detectable viral load, 80% of them >1,000 copies. The probability of surviving 144 months was 65% for those who did not use ART, 100% for those with Pre-HAART (27 children), 95% with HAART1 and 95% with HAART2. They were associated with AIDS death independent of other exposures: non-use of ART (HR=2.4;95%CI1.7-3.6); to have had TCD4+ in the normal diagnosis for age (HR=0.3;95%CI0.2-0.5).

Conclusions: The probability of survival was increased once and a half times, from 65% to 95% in 144 months, due to the introduction of more powerful therapeutic regimens adopted in the country. They were associated with survival time, as an independent prognostic factor: use of HAART and TCD4+ at the time of diagnosis. The success of the Brazilian policy has had a great impact in the reduction of mortality and increasing survival of the CLWA.



Note:
PRE-HAART = Nucleosidic Reverse Transcriptase Inhibitors
HAART1 = Non-Nucleosidic Reverse Transcriptase Inhibitors / Protease Inhibitors
HAART2 = Schemes containing at least one THIRD LINE ART

[Cumulative probability of survival in children with AIDS by treatment regim, Brazil, 2003 - 2007]

Special cases in the diagnosis of HIV-1 perinatally infected children younger than 18-month-old from Argentina

M.D. Golemba[1], D. Mecikovsky[2], M. Ortíz de Zárate[3], G. Silva[4], P.C. Aulicino[1], M. Pineda[1], M. Taicz[2], V. Rossi[3], R. Bologna[2], A.M. Mangano[1]
[1]Laboratorio de Biología Celular y Retrovirus, Hospital de Pediatría 'Juan P. Garrahan' CONICET, CABA, Argentina, [2]Servicio de Epidemiologia e Infectologia, Hospital de Pediatría 'Juan P. Garrahan', CABA, Argentina, [3]Hospital Materno Infantil Ramón Sarda, CABA, Argentina, [4]Laboratorio de Alta Complejidad de Misiones. Parque de la Salud. Ministerio de Salud Publica, Misiones, Argentina

Background: Prompt identification of HIV infection in children is important to allow early initiation of antiretroviral therapy (ART). However, there are some "special cases", with discordant results between their samples, making HIV-1diagnosis difficult and delaying the ART initiation.
The aim of this work was to analyze the „special cases" among the HIV-1 positive children diagnosed in a five-year period in Argentina.

Methods: A total of 39 HIV-1 infected children younger than 18-month-old by vertical transmission (without breastfeeding) were diagnosed at Retrovirus Laboratory (2013-2017) from different public referral centers: Pediatric Garrahan Hospital, Buenos Aires (GH), Sarda Maternity, Buenos Aires (SM) and Misiones Province (MP).
HIV-1 diagnostic was carried out by PCR-DNA and/or viral load-RNA (pVL) with at least two independent positive samples from each patient, as suggested by the National-Guidelines.

Results: Twenty two out of 39 children had a „late" positive diagnosis (>60 days of life), and the majority came from GH and MP. On the contrary, most of the patients (8/10) from the maternity SM were diagnosed at early stages (< 60 days of life).
Among the eight „special cases" identified, four had a first sample before the first month of life with negative result (Group A, Table 1), whereas the other four had pVL < 1000 copies/mL (Group B, Table 1). Surprisingly in

the absence of antepartum or intrapartum ARV prophylaxis, one patient had negative result in the first sample at 22 days-old and the other one had < 1000 copies/mL at 28 days-old.

Patients, Group A	1st Sample (day)	2nd Sample (day)	3th Sample (day)	Mother under ART	Intrapartum ARV prophylaxis	Neonatal ARV prophylaxis
5783	Negative (22)	Positive (120)	Positive (176)	No	No	No
6200	Negative (0)	Positive (35)	Positive (42)	Yes	Yes	Yes
6184	Negative (8)	Negative (36)	Positive (120)	Yes	Yes	Yes
6331	Negative (3)	Negative (35)	Positive (77)	Yes	Yes	Yes
Patients, Group B	**pVL 1st Sample (day)**	**pVL 2nd Sample (day)**	**pVL 3th Sample (day)**	**Mother under ART**	**Intrapartum ARV prophylaxis**	**Neonatal ARV prophylaxis**
5696	<65 copies/ml (2)	ND copies/ml (28)	45708 copies/ml (268)	No	No	No
6115	<229 copies/ml (62)	190 copies/ml (67)	1010 copies/ml (89)	Yes	Yes	Yes
5791	<794 copies/ml (3)	76 copies/ml (12)	4898 copies/ml (17)	No	No	Yes
6466	<240 copies/ml (10)	218776 copies/ml (22)	Positive DNA-PCR (43)	Yes	Yes	Yes

['Special Cases' with first sample with DNA HIV-1 and/or pVL negative (Group A) and with low pVL (<1000 copies/ml) (Group B)]

Conclusions: Despite the great effort to early diagnosis of HIV-1 perinatal infection in Argentina, there is still several cases of late diagnosis, mainly because children are lately referred for testing in referral laboratories. It is important to mention that during early diagnosis some samples can test negative by PCR-DNA and/or pVL or very low copies/mL (below the limit of 5,000 copies/mL suggested by the International-Guidelines). These cases are important diagnostic challenges in the daily routine highlighting the need of interdisciplinary work and close follow up of HIV-1 exposed children.

TUPEC202

Mapping and population size estimates of street children in six cities with extrapolation to national level in Iran

M. Vameghi[1], P. Roshanfekr[1], D. Ali[2], S. Madani[2], M. Noroozi[2], W. McFarland[3], A. Mirzazadeh[3,4]

[1]University of Social Welfare and Rehabilitation Sciences, Social Welfare Management Research Center, Tehran, Iran, Islamic Republic of, [2]University of Social Welfare and Rehabilitation Sciences, Tehran, Iran, Islamic Republic of, [3]Institute for Global Health Sciences, University of California, Department of Epidemiology and Biostatistics, San Francisco, United States, [4]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of

Background: Iran national HIV strategic plan 2015-2020 has included street children as one of the key population at high-risk for HIV. Knowing the population size of street children is critical for advocacy and planning for this vulnerable population. We adapted and applied four different methods, to locate and estimate the population size of street children in six major cities in Iran.

Methods: Our population size estimation methods included direct and indirect count of street children, wisdom of crowds and unique object multiplier in a rapid assessment and response study. From March to May 2017, by interview with (114 city-level, 223 local-level and 933 street children) key informants and field observations, we located 464 public venues accommodated frequently by street children in Tehran, Mashhad, Karaj, Kermanshah, Zahedan and Bandar Abbas. After estimating the count by each method, we calculated the median and interquartile range (IQR) of the four estimates in each city. Using the total number of street children estimated for all six cities, we calculated the rate of street children per 10000 total population and used this rate to estimate the total number of street children in Iran in 2018.

Results: Recruited street children were 13.8 (SD 2.3) years old, 9.8% girl, %53.9 born in Afghanistan or had Afghani nationality, and %11.9 have never attended school. The median (IQR) size estimations ranged from 234 (IQR 181, 404) in Kermanshah to 2090 (IQR 1803, 2965) in Tehran. The median number of street children using all methods combined in all six cities was 5317 (IQR 4123, 7315). This corresponds to the rate of 16.4 (IQR 12.7, 22.5) per 10000 children aged 5-19 years old, or 3.2 (2.5, 4.4) per 10,000 total populations. Applying the median (IQR) rate to the total population of Iran in 2018 (81142994 person), the total number for street children in Iran is estimated at about 26000 (IQR 20286, 35703) children.

Conclusions: The number of street children is considerable in Iran across many cities and venues, majority from immigrant population. Our estimations can be used to advocate and planning for services that improve health and reduce vulnerability of street children in Iran.

TUPEC203

HIV status awareness among mothers and their under-5 children in Malawi: Results from a population HIV survey

N. Conan[1], M. Chihana[1], C.P. Paye[2], A. Chijuwa[3], R. Ortuno[4], E. Goemaere[5], H. Huerga[2], D. Maman[2]

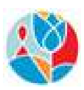
[1]Epicentre, Cape Town, South Africa, [2]Epicentre, Paris, France, [3]Ministry of Health, Nsanje, Malawi, [4]Medecins sans Frontieres, Blantyre, Malawi, [5]Southern Africa Medical Unit, Cape Town, South Africa

Background: Mothers' awareness of their own HIV status is the first step for HIV diagnosis in children. We assessed the HIV status awareness of mothers of HIV-positive under-five children in Nsanje, Malawi.

Methods: A cross-sectional population survey was implemented between September and December 2016. Children below five years whose mothers were HIV-positive or with an unknown HIV status were recruited. A multistage cluster sampling was used to select 2,443 households. Informed consent was requested from parents or legal guardians. Child HIV status was assessed using a rapid HIV antibody test algorithm or Deoxy-ribonucleic Acid (DNA) PCR, depending on the age of the child. A standardised questionnaire was administered to the mother or legal guardian.

Results: Of the 1,568 under-five children listed during the survey, 236 (52.1% girls) were included. The median age was 24.0 months [IQR: 12-36]. Overall 149/236 (63.1%) children had been tested for HIV prior to the survey. Of them, 94/149 (63.1%) had been tested previously at least 2 times and 85/149 (57.0%) were tested in the previous 12 months. However, 20/149 (13.4%) had never received the test result. Out of the 227 children tested during the survey, 17 (1.1%, 95%CI: 0.7- 1.8) were HIV-positive. The mothers of 8/17 (47.1%) were not aware of the HIV status of their child and among them, 4 (50.0%) mothers were not aware of their own HIV status. The median age of the children not aware of their HIV-positivity was 2.5 months [IQR: 1-3.5]. Two of the 8 children unaware of their HIV status had been previously tested for HIV, one at 4 months using DNA PCR and another at 17 months using rapid test.

Conclusions: In Nsanje, despite the low HIV prevalence among under-five children, a high proportion of HIV-positive children was not diagnosed and almost half of the mothers were not aware of their child HIV-positive status. This was partly due to undiagnosed HIV among mothers. High proportion of previously tested children who did not receive their test result is a concern. Programs should strengthen strategies for HIV testing among mothers and children.



TUPEC204

TB-HIV program monitoring in PEPFAR-supported countries: Screening, prevention, and treatment results for children and adults, October 1, 2016 - September 30, 2017

K. O'Connor[1], V. Ryan[2], R. Golin[2], C. Nichols[2], G. Anyalechi[1], H. Kirking[1], M. Patel[1]
[1]Centers for Disease Control, Division of Global HIV and TB, Atlanta, United States, [2]USAID, Office of HIV/AIDS, Washington, United States

Background: Worldwide, an estimated 52,000 children living with HIV died from TB in 2016. Timely and accurate diagnosis and linkage to treatment or prevention for both diseases can reduce pediatric morbidity and mortality, and is an integral part of the President's Emergency Plan for AIDS Relief (PEPFAR). We analyzed TB/HIV clinical service data for children (< 15 years) and adults (≥15 years) reported by PEPFAR-supported country and regional programs from October 1, 2016 - September 30, 2017.

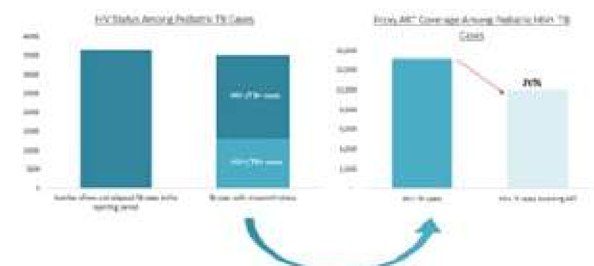
Methods: We analyzed age-disaggregated program data from TB clinics on patients with a documented HIV status and antiretroviral therapy (ART) coverage, and data from ART clinics on patients routinely screened for TB, initiated on and completed TB preventive therapy (TPT). We assessed the completeness of age-disaggregated data and computed descriptive statistics with the complete data. Proxy ART coverage is comparing the number of ART patients to HIV-positive patients.

Results: Thirty-two PEPFAR programs reported on ≥1 TB/HIV clinical indicator. Fifteen programs (47%) reported complete age disaggregates for HIV status and ART status among TB clinic patients. Twelve programs (38%) reported completed age disaggregates for ART patients screened for TB and 11 programs (34%) reported complete age disaggregates for ART patients initiated on and completing TPT.

	Reported on TB/HIV Indicator in FY17	Had complete age disaggregated data on indicators for HIV and ART status of TB patients	Had complete age disaggregated data on ART patients screened for TB	Had complete age disaggregated data for all PEPFAR-supported patients on ART	Had compelete age disaggregated data on TB treatment for ART patients
Botswana	X		X		
Cameroon	X	X	X	X	
Cote d´Ivoire	X	X		X	
Ethiopia	X			X	
Kenya	X	X		X	X
Lesotho	X		X	X	X
Mozambique	X			X	X
South Africa	X	X		X	
Zimbabwe	X	X	X	X	

[Sample Complete Age-Disaggregated Data across TB/HIV data, October 1, 2016 - September 30, 2017]

Out of 35,035 children diagnosed with TB attending TB clinics, 96% had documented HIV status; similar to adults (96%). Of these children, 13,219 (38%) were HIV-positive (CLHIV); 61% were known HIV-positive and 39% were newly diagnosed HIV-positive. Within TB clinics, only 76% of CLHIV were linked to ART; lower than adults (90%). Out of 174,214 children on ART attending HIV clinics, 72% were screened for TB; similar to adults (71%). A total of 42,559 children on ART were initiated on TPT, of whom 25,745 (60%) completed TPT; similar to adults (62%).



[HIV Status among Pediatric TB Cases and Proxy ART Coverage of HIV+ TB Cases, October 1, 2016 - September 30, 2017]

Conclusions: Less than 50% of PEPFAR-supported programs reported complete age-disaggregated data on TB/HIV clinical service data; improved reporting is needed to better understand programmatic challenges and opportunities among children. There is still a critical need for additional HIV testing and ART initiation among eligible TB patients. There is also need for improved TB screening, and TPT completion among ART patients.

TUPEC205

Efficacy of intensive adherence counselling in reversing virologic failure in adolescents on long-term ART in Uganda

J. Sproule[1], J. Byawaka[2], J. Birungi[2], R.S.A. Mazzola[1], M. Nanfuka[2], D. Moore[1,3], M. Etukoit[2]
[1]University of British Columbia, Vancouver, Canada, [2]The AIDS Support Organization, Kampala, Uganda, [3]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

Background: Current WHO guidelines recommend viral load (VL) testing to monitor antiretroviral therapy (ART) efficacy, and intensive adherence counselling (IAC) for those who have elevated VL. Consequently, many patients who have been on long-term ART will be diagnosed with virologic failure after long periods of viremia. We evaluated the effectiveness of IAC in reversing virologic failure among adolescents who have been on long-term ART in Uganda, a population with unique challenges to adherence.

Methods: We conducted an analysis of data collected at 6 sites of The AIDS Support Organization (TASO). We selected patients aged 10-18 who had been on ART for ≥4 years, had not had a previous VL test and had a measured VL ≥1000 copies/mL between January 2014 and June 2016. Data was recorded in the TASO clinical database with adherence measured by pill counts. Patients were informed of their VL and underwent monthly IAC sessions for at least three months, followed by repeat VL testing. We conducted bivariate and multivariate logistic regression analyses to examine factors associated with reversal of virologic failure.

Results: A total of 185 adolescents (52.4% female) with a mean age of 13.7 years (SD = 2.4) met the inclusion criteria. Participants had been on ART for a mean of 4.5 years (SD = 2.70). Thirty-eight percent had VL between 1000 and 10,000 copies/mL and 62% had VLs ≥10,000 copies/mL.

Overall, 41 (22%) of patients had a VL< 1000 copies/mL on repeat testing. Reversal of virologic failure varied by TASO site, from 46.2% Masindi to 5.6% in Entebbe (p=0.004).

Only 26.2% of patients had ≥95% adherence after the third IAC session. Compared to those with ≥95% adherence, adolescents with < 85% adherence were less likely to reverse virologic failure (OR=0.11, 95%CI (0.027-0.414). Notably, there was no difference in reversal of virologic failure associated with the level of viremia.

Conclusions: Only 22.2% of adolescents who had been on ART for ≥4 years were able to reverse virologic failure following IAC. Given that only a minority of patients achieved >95% adherence, programmatic changes may be needed to improve adolescent outcomes.

Epidemiology of HIV in other key vulnerable populations (e.g. PWID, women, TGW, sex-workers, prison populations, older groups)

TUPEC206

Forty percent reduction in HIV prevalence among randomly sampled female sex workers in Mombasa, Kenya following intensive prevention programmes

G. Manguro[1], C. Gichuki[1], F. Ampt[2], M. Temmerman[3], M. Chersich[4], S. Luchters[2], P. Gichangi[1], WHISPER/SHOUT Clinical Trial Group
[1]International Center for Reproductive Health Kenya, Mombasa, Kenya, [2]Burnett Institute, Melbourne, Australia, [3]Aga Khan University Hospital, Nairobi, Kenya, [4]University of Witwatersrand, Johannesburg, Kenya

Background: An estimated 30% of female sex workers (FSW) in Kenya are HIV-infected compared to 7% of general-population women. In a 2012 survey in Mombasa, HIV prevalence among FSWs was 20%. Since then, multiple interventions, centering on peer educators, sex worker clinics and research programmes have targeted FSWs in Mombasa. These have raised HIV awareness and reduced high-risk behaviours, but it is not known if these have translated into declines in HIV transmission.
Methods: We recruited 882 FSWs from 93 sex work venues in Mombasa, Kenya between September 2016 and May 2017. First stage sampling involved random proportionate to size selection of 102 sex work venues (clusters), using a sampling frame of 760 previously enumerated venues. At the second stage, 10 FSWs were consecutively selected from each venue. Eligible women were 16-34 years, not pregnant and active sex workers in the last 6 months. Prevalence estimates were weighted to account for differences in probabilities of recruitment. Multivariate logistic regression models identified correlates of HIV infection.
Results: Mean age of participants was 25.4 years. As many as 41.6% had no education or completed only primary-level. Median duration of sex work was 4 years (inter-quartile range (IQR)=2-6). The majority did not live with a partner (68%), though 57% reported having a boyfriend. Median number of clients within the past seven days was 4 (IQR=3-6). Overall, weighted HIV prevalence was 11.8% (95% confidence interval (95%CI)=9.5-14.7), and varied with age and level of education. Odds of HIV infection was 15.1 fold higher in women aged 30-34 years than those 16-20 (95%CI adjusted odds ratio=5.6-40.3). Conversely, women with tertiary education had 80% lower odds of HIV than those with no or primary education (adjusted odds ratio=0.20, 95%CI=0.59-0.71).
Conclusions: HIV prevalence among FWSs in Mombasa in 2016/2017 was 41% lower than previous estimates. It is plausible that this decline is due to the multiple, peer-led interventions in the area. While reductions are pleasing, HIV infection levels remain unacceptably high. Considering the central role FSWs play in sustaining population-level infections, continued or further strengthening of these programs is required.

TUPEC207

Intimate partner violence is a key predictor of HIV risk among Black heterosexual women in Baltimore, MD, USA

A.N. Cimino[1], G. Yi[1], J. Campbell[1], K.K. Gundersen[2], J.K. Stockman[2]
[1]Johns Hopkins University, School of Nursing, Baltimore, United States, [2]University of California, San Diego, Global Public Health, Division of Infectious Diseases and Global Public Health, San Diego, United States

Background: Black women are the largest group of US heterosexuals newly infected with HIV, and have the highest rates of HIV mortality. Childhood and adulthood violence were separately identified as direct and indirect risk factors for HIV, and Black women disproportionally experience both types of violence. This study examines the relationship between abuse groups (no lifetime abuse, childhood abuse only, adult intimate partner violence [IPV] only, and childhood abuse and adult IPV) and HIV risk among Black women who had a male sex partner in the past year.
Methods: Black women (N=707) were recruited from STD clinics in Baltimore, MD, USA, a city with the highest HIV prevalence among US women. Using an audio computer self-interview technique, participants provided demographic information, past-year sexual risk behaviors, and lifetime abuse history (being punched, slammed against wall, beat-up, controlled, afraid, strangled, threatened/used a weapon, forced/threatened to have sex by partner/ex-partner, and/or experiencing childhood abuse [physical and/or sexual]). HIV risk was a composite of a male partner who: used injection and/or non-injections drugs, has sex with other men, has concurrent female sex partners, was incarcerated, has a STD, or tested positive for HIV. Analyses included descriptives, correlations, and linear regression.
Results: Over half (50.6% n=358) experienced lifetime abuse: 12.6% (n=45) experienced childhood physical and/or sexual abuse only, 35.5% (n=127) experienced adult IPV only, and 52% (n=186) experienced both childhood abuse and adult IPV. Experiencing abuse significantly predicted HIV risk, $F(703)=30.67, p< .01$, with the adult IPV only category being statistically significant, ($B=1.56$, SE $B=.33$; $t=4.68, p< .01$) in reference to the no abuse category. Among women experiencing adult IPV only, there were significant correlations between HIV risk and use of force or threats to have sex (r=.21), threatened with or used a weapon (r=.22), physical violence (r=.22) and strangulation (r=.21); whereas controlling (r=.28), afraid (r=.21), forced sex (r=1.6), weapon use (r=.15) and choking to unconsciousness (r=2.8) were significant for the childhood abuse and adult IPV group.
Conclusions: IPV is a key factor in HIV risk among Black women. Integrated IPV and HIV prevention programs should be widely implemented, especially in regions with high prevalence of these intersecting epidemics.

TUPEC208

The 2014 HIV care cascade and virologic response over time among transgender people in a large multi-site Canadian cohort

A. Rich[1,2], P. Sereda[1], M. Ye[1], J. Zhu[1], A. Scheim[3], C. Cooper[4], S. Walmsley[5], M. Klein[6], S. Sanche[7], D. Kelly[8], S. Rourke[9], N. Machouf[10], R. Hogg[1,11], on behalf of the Canadian Observational Cohort Collaboration
[1]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of British Columbia, Vancouver, Canada, [3]University of California San Diego, San Diego, United States, [4]University of Ottawa, Ottawa, Canada, [5]University Health Network, Toronto, Canada, [6]McGill University, Montreal, Canada, [7]University of Saskatchewan, Saskatoon, Canada, [8]Memorial University of Newfoundland, St. John's, Canada, [9]University of Toronto, Toronto, Canada, [10]Clinique de Médicine Urbaine du Quartier Latin, Montreal, Canada, [11]Simon Fraser University, Burnaby, Canada

Background: Transgender (trans) people are a key HIV priority population. The current study is one of the first to characterize the HIV clinical care cascade and viral response over time for trans people in Canada. This study hypothesized that trans people would be less well engaged at each step of the HIV care cascade than non-trans people and have poorer virologic response over time.
Methods: The Canadian HIV Observational Cohort (CANOC) provided data for this study; participants were HIV diagnosed patients who had initiated antiretroviral treatment (ART) since 2000. Trans people were matched with non-trans comparison groups using a 1 trans person: 1 non-trans man: 1 non-trans woman scheme. Chi-square tests assessed differences in bivariable relationships and penalized likelihood Cox proportional hazards models examined the relationship between gender and time to virologic outcomes, adjusted for HIV-related clinical characteristics.
Results: Of the total trans sample (n=43), 91% were from British Columbia and 9% were from Ontario. 21% were White, 2% Black, 26% Indigenous, and 51% were of other or unknown race/ethnicity. In 2014, trans people (n=19 with full year follow up) were well engaged in care and on ART, though largely unsuppressed. The proportion of trans and non-trans people was similar at each cascade step (Table 1), with no significant differences between the groups. In multivariable models of virologic outcomes over time, there were no significant differences between trans and non-trans groups, though non-trans women had significantly slower time to initial viral suppression than non-trans men (HR 0.24, 95% CI: 0.10, 0.56).

Conclusions: Counter to hypotheses, there were no significant differences between trans and non-trans groups in the cascade nor viral suppression and rebound over time. In this initial study, such low suppression levels for all groups is likely related to skew to early ART initiation era in the matched sample. Improved gender ascertainment in clinical cohorts is needed to facilitate further research with larger sample sizes and better characterize HIV clinical care and virologic outcomes for this priority population.

	Care Cascade Step		
	Retained in care, N (%)	On ART, N (%)	Virologically suppressed, N (%)
Gender			
Non-trans man	17 (89.47)	19 (100.00)	3 (15.79)
Non-trans woman	16 (84.21)	19 (100.00)	3 (15.79)
Trans person	18 (94.74)	19 (100.00)	5 (26.32)

[HIV Clinical Care Cascade by gender, 2014 (n=57)]

TUPEC209

Patterns of HIV risk and viremia among people who inject drugs in a community-based cohort in Baltimore, Maryland

B.L. Genberg[1], D. Celentano[1,2], J. Astemborski[1], G. Kirk[1,2], S. Mehta[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Johns Hopkins University School of Medicine, Infectious Disease, Baltimore, United States

Background: Although HIV incidence among people who inject drugs (PWID) in the US has declined substantially over the past decade, there is potential for increases among a new generation using prescription opioids without experience with safe injection practices or harm reduction. In an urban setting with both a historical heroin epidemic and an emerging group of users, we characterized phenotypes of drug use and the associations with prospective injection-related risk and HIV viremia in a long-standing cohort of PWID in Baltimore, Maryland, USA.

Methods: We included data on recent (prior six months) injection and non-injection use of heroin, crack/cocaine, speedball, marijuana, alcohol and prescription opioids, tranquilizers or sedatives (acquired from non-physician source), among PWID in the ALIVE (AIDS Linked to the IntraVenous Experience) cohort between 2014-2017 to define baseline drug use phenotypes using latent class analysis. Logistic regression analysis with generalized estimating equations was used to prospectively examine associations between phenotypes and HIV risk.

Results: Among 1,381 PWID, 32% were female, 81% African-American, 30% HIV-positive, and the median age was 53 years. Five phenotypes emerged:
1) None/Alcohol-only (43%),
2) Crack/cocaine-predominant (24%),
3) Heroin-predominant (18%),
4) Prescription drug-predominant (7%), and
5) Poly-substance use (8%).
Younger, White, HIV- and HCV-negative PWID were more likely to be in groups 3, 4, and 5, in which higher frequency of injection and use of a greater number of substances was reported (Table 1).

Phenotype	N	Median number (interquartile range) of substances used (past 6 months)	Recent (past 6 months) injection drug use (%)	Needle exchange (past 6 months) (%)	Adjusted odds ratios (95% CI) for sharing
1: None/Alcohol-only	678	0 (0-1)	4	44	--
2: Crack/cocaine	256	2 (2-3)	41	48	1.00
3: Heroin	251	3 (2-4)	100	42	1.08 (0.61-1.90)
4: Prescription drugs	83	5 (4-6)	58	29	2.53 (1.23-5.23)
5: Poly-substance	108	7 (6-8)	100	45	2.48 (1.25-4.91)

[Table 1: Drug use phenotypes in the ALIVE cohort (2014-2017) and adjusted odds ratios and 95% confidence intervals for sharing injection equipment]

Among PWID actively injecting, those in the prescription drug group were less likely than all others to use needle exchange. The prescription drug and poly-substance groups had more than a two-fold increased risk of sharing, compared to the crack/cocaine group, adjusting for age, sex, race and HIV-status (Table 1). Among HIV-positive PWID, the prescription drug group was more likely to have detectable viral load (adjusted odds ratio=2.13, 95% CI: 1.19-3.83) compared to the crack/cocaine group.

Conclusions: In this urban setting, HIV-positive PWID using prescription drugs represented the highest risk of HIV transmission due to detectable viremia and decreased safe injection practices. Increased efforts are required to bolster antiretroviral treatment and adherence in this group. Harm reduction interventions should target PWID using prescription drugs and multiple substances.

TUPEC210

HIV among female sex workers in Amsterdam, a tale of one city and one specialised health centre (P&G292)

A.E. van Dijk[1], T. Heijman[2], M. van Rooijen[2], M. Kroone[2], E. Marra[2], E. Freriks[2], A.A. Hogewoning[2,3], M.F. Schim van der Loeff[2,4]
[1]Public Health Service Amsterdam, Infectious Diseases, Prositution and Health Centre, Amsterdam, Netherlands, [2]Public Health Service Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, [3]Department of Dermatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [4]Amsterdam Infection and Immunity Institute (AI&I), Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background: Worldwide, female sex workers (FSW) are at high risk for HIV and other sexually transmitted infections (STI). In 2000 the Netherlands legalized sex work to increase safer and healthier work conditions. In 2008, a specialized care facility for sex workers (SW), the Prostitution & Health Centre (P&G292), was established in Amsterdam aiming to provide sexual healthcare and social support for sex workers. P&G292 is funded by the city of Amsterdam and located in the city centre. Annually around 3,500 FSW are reached by P&G292, which is estimated to be half of the Amsterdam FSW population. We aimed to assess STI and HIV positivity rates among FSW seeking care at P&G292.

Methods: P&G292 offers free consultations for FSW at the clinic and at their workplace; FSW may also attend the regular STI clinic. FSW are tested for STIs and HIV at each consultation. We assessed HIV prevalence and incidence among FSW in the period 2011-16.

Results: From 2011 through 2016, 3,212 women had 9,457 STI consultations. The majority had a non-Dutch ethnicity (72%). FSW reported a median of 300 sexual partners in the preceding 6 months (IQR 100-500). In 8,603 (91%) of the consultations women reported consistent condom use with all their clients during vaginal sex. The positivity rate for bacterial STIs was 9% (848/9,457). 20/2,426 women (0.8%) reported they had ever injected drugs; seven (0.3%) reported recent drug injecting (last 6 months).
The prevalence of HIV among FSW was 0.5%: eight women (0.3%) self-reported to be HIV infected at their first consultation and seven women (0.2%) were newly diagnosed with HIV at their first consultation. 2/1621 women (0.1%) were diagnosed with HIV during a subsequent consultation. Fifteen women (0.5%) declined to be tested for HIV.

Conclusions: Among FSW in Amsterdam, condom use with clients was very high, bacterial STI positivity rate was relatively low and injecting drugs uncommon. Dutch prostitution laws differ from those in many other countries. The legal nature of prostitution contributes to easy access of FSW to health and social services. These factors help explain the low HIV prevalence of 0.5% among FSW.

TUPEC211

HIV among male sex workers in Amsterdam, a tale of one city and one specialised health centre (P&G292)

A. van Dijk[1], T. Heijman[1], M. van Rooijen[1], S. van der Kolk[1], E. Marra[1], E. Freriks[1], M. Kroone[1], A. Hogewoning[1,2], M.F. Schim van der Loeff[1,3]
[1]Department of Infectious Diseases, Public Health Service Amsterdam, Amsterdam, Netherlands, [2]Department of Dermatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [3]Amsterdam Infection and Immunity Institute (AI&I), Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background: Worldwide, male sex workers (MSW) are at high risk for HIV and other sexually transmitted infections (STI). In 2000 the Netherlands legalized sex work to increase safer and healthier work conditions. In 2008, a specialized care facility for sex workers (SW), the Prostitution & Health Centre (P&G292), was established in Amsterdam with the aim to provide sexual healthcare and social support for SW. P&G292 is funded by the city of Amsterdam and located in the city centre. Even though sex work is permitted, most MSW work at unlicensed (illegal) venues. We aimed to assess STI and HIV positivity rates among MSW seeking care at P&G292.

Methods: P&G292 offers free consultations for MSW at the clinic and at their place of work; MSW may also attend the regular STI clinic. MSW are tested for STIs and HIV at each consultation. We assessed HIV and STI prevalence and incidence among MSW in the period 2011-16.

Results: From 2011 through 2016, 688 MSW had 1,561 STI consultations. The majority had a non-Dutch ethnicity (71%). MSW reported a median of 50 sexual partners in the preceding 6 months (IQR 15-150). Of the MSW who reported anal sex with clients 84% reported consistent condom use. The positivity rate for bacterial STIs was 21% (327/1,561). 25/417 men (6%) reported they had ever injected drugs; 16 of these (3.8%) reported recent drug injecting (in last 6 months). Eighty-four men (12.2%) self-reported to be HIV infected at their first consultation and 26 men (4.3%) were newly diagnosed with HIV at their first consultation. Two men (1.0%) were diagnosed with HIV during a subsequent consultation. Four men (0.7%) declined to be tested for HIV.

Conclusions: Although most MSW report consistent condom use during anal sex with their clients, bacterial STI positivity and HIV prevalence were high. In addition, injecting drugs was not uncommon among MSW. Dutch prostitution laws differ from those in many other countries. The legal nature of prostitution contributes to easy access of MSW to health and social services. The easy assess to healthcare for MSW also enables surveillance of STI and HIV trends among MSW.

TUPEC212

HIV testing and treatment cascade among key populations in Mozambique

W.M. Miller[1], J.L. Manuel[2], F. Mbofana[3], M.E. Herce[4,5], J.K. Edwards[6], F. Rocuts[7], S.S. Weir[1,6]
[1]University of North Carolina at Chapel Hill, Carolina Population Center, Chapel Hill, United States, [2]Centro de Investigação Operacional da Beira (CIOB), Beira, Mozambique, [3]Conselho Nacional do Combate ao HIV e SIDA (CNCS), Maputo, Mozambique, [4]University of North Carolina at Chapel Hill, UNC Institute for Global Health & Infectious Diseases, Department of Medicine, Chapel Hill, United States, [5]UNC Project-Malawi, Lilongwe, Malawi, [6]University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [7]FHI 360, Maputo, Mozambique

Background: The prevalence of HIV in Mozambique is 10.1% among adult men and 15.4% among women from the general population. Given the lack of available data, we aimed to measure the HIV testing and treatment cascade among key populations in Mozambique.

Methods: The University of North Carolina at Chapel Hill, under the USAID/PEPFAR-supported and FHI 360-led LINKAGES project, conducted a biobehavioral survey in five provinces of Mozambique between June and September 2017. Priorities of Local AIDS Control Efforts (PLACE), a venue-based sampling strategy, was used to recruit participants from social venues for a cross-sectional behavioral survey. Based on the behavioral questionnaire, participants were categorized as female sex workers (FSW), men who have sex with men (MSM), or transgender women (TGW). HIV infection was assessed using two rapid tests and HIV viral load from dried blood spots using Abbott M2000. Individuals were assigned weights based on the probability of recruitment. Populations size estimates were calculated from venue informant interviews conducted during venue mapping and adjusted based on participants' venue-frequenting behavior. Participants with a suppressed viral load were assumed to be aware of their infection and on ART.

Results: We recruited 1,194 FSW, 118 TGW, and 517 MSM. HIV prevalence was 19% among FSW, 12% among TGW, and 10% among MSM. 13,000 FSW, 1,310 TGW and 11,500 MSM were estimated of which 2,500 FSW, 160 TGW, and 1,160 MSM were estimated to have HIV. Among HIV-positive participants, 66% of FSW, 53% of TGW, and 23% of MSM already knew they were HIV positive; 63% of FSW, 39% of TGW, and 22% of MSM with HIV reported to be on ART; and 52% of FSW, 30% of TGW, and 18% of MSM with HIV were virally suppressed.

Conclusions: Large gaps exist to reach the 90-90-90 goals among key populations in Mozambique. FSW were most likely and MSM were least likely to know their status. Most people already aware of their serostatus were on treatment and virally suppressed indicating that the Mozambican health system is successful at starting people on treatment. However, TGW were least likely to be on ART, a sign of difficulty in accessing care.

	Population size estimate	HIV prevalence	Estimate of people with HIV	Percent already aware of serostatus*	Percent on ART*	Percent virally suppressed*
FSW (n=1,194)	13,100	19%	2,500	66%	63%	52%
Transgender women (n= 118)	1,310	12%	160	53%	39%	30%
MSM (n=517)	11,500	10%	1,160	23%	22%	18%
* Among all people with HIV

TUPEC213

Characterizing the role of sexual violence in potentiating HIV risks among transgender women in sub-Saharan Africa

T. Poteat[1], B. Ackerman[2], D. Diouf[3], N. Ceesay[4], T. Mothopeng[5], K.-Z. Odette[6], S. Kouanda[7], A. Simplice[8], A. Kouame[9], Z. Mnisi[10], G. Trapence[11], L.L.A. van der Merwe[12], V. Jumbe[13], H.G. Ouedraogo[14], S. Baral[2]

[1]Johns Hopkins School of Public Health, Epidemiology, Baltimore, United States, [2]Johns Hopkins School of Public Health, Baltimore, United States, [3]Enda Sante, Dakar, Senegal, [4]UNAIDS, Mbabane, Swaziland, [5]People's Matrix Association, Maseru, Lesotho, [6]Programme d'Appui au Monde Associatif et Communautaire, Ouagadougou, Burkina Faso, [7]Institut de Recherche en Sciences de la Sante, Ouagadougou, Burkina Faso, [8]ONG Arc-en-Ciel, Lome, Togo, [9]Ministère de la Sante et de l'Hygiène Publique, Abidjan, Cote D'Ivoire, [10]Ministry of Health, Mbabane, Swaziland, [11]Centre for the Development of People, Lilongwe, Malawi, [12]Social Health and Empowerment, East London, South Africa, [13]Malawi College of Medicine, Blantyre, Malawi, [14]Institut Africain de Sante´ Publique, Ouagadougou, Burkina Faso

Background: In 2018, the specific HIV prevention and treatment needs of transgender women remain understudied across sub-Saharan Africa. However, transgender women are known to be disproportionately impacted by HIV, even compared to cisgender men who have sex with men (cis-MSM) in analyses across the continent. Moving forward with effective responses necessitates studying specific determinants of HIV-related risks among transgender women.

Methods: To characterize correlates of HIV infection, we analyzed data from 937 transgender women who completed a cross-sectional, structured questionnaire and rapid HIV testing and as part of a larger study focused on cis-MSM. Study participants were accrued using respondent-driven sampling in Burkina Faso, Togo, Côte d'Ivoire, Senegal, The Gambia, Malawi, Lesotho, and Swaziland. Descriptive statistics, bivariate analyses, and stepwise mixed effects multiple logistic regression modeling, with a random effect for study site, identified the best-fitting multivariable model. The final model included age, depression symptoms in the prior 2 weeks, number of male anal sex partners in the prior 12 months, ever being raped, ever being physically attacked, and ever being arrested.

Results: Depression symptoms, physical violence, and rape were commonly reported by transgender women in this study. Pooled HIV prevalence was 25% [95%CI: 23%, 28%]. In bivariate analyses, HIV-infection was positively correlated with increasing age, depression symptoms, history of a sexually transmitted infection, higher number of anal sex partners, experiencing physical violence (being attacked), sexual violence (being raped) or state violence (being arrested because of perceived sexual or gender identity). In the final multivariable model, only being raped (OR 1.12 [95%CI:1.03, 1.24]) and increasing age (OR 1.02 [95%CI: 1.01 1.02]) remained statistically significant (p< 0.05, Table 1).

Conclusions: Determinants of HIV infection across Sub-Saharan Africa are as complex as anywhere else around the globe. Here, sexual violence emerged as a key HIV-related risk determinant among transgender women across sub-Saharan Africa. While further study of risks will support increased specificity of interventions, there is already enough information to act to ensure that the specific HIV prevention and treatment needs of transgender women are addressed in the region.

Variable	Prevalence, n/N (%)	Bivariate Analysis OR (95% CI)	p-value	Final Multivariable Model adjusted OR (95% CI)	p-value
Age (years)	Mean: 24 Range: 18-56	1.10 (1.07, 1.13)	<0.01	1.02 (1.01, 1.02)	<0.01
Number of anal sex partners (n=276)	Median: 3 Interquartile Range: 2-5	1.05 (1.01, 1.08)	0.02	1.00 (0.99, 1.01)	0.06
Raped	257/932 (28%)	2.2 (1.63, 3.06)	<0.01	1.13 (1.03, 1.24)	0.01
Depression symptoms	535/934 (57%)	2.01 (1.47, 2.76)	<0.05	1.05 (0.98, 1.13)	0.16
Beaten Up	311/936 (33%)	1.47 (1.08, 1.99)	0.02	1.03 (0.95, 1.12)	0.43
Arrested	72/910 (8%)	1.76 (1.06, 2.58)	0.03	0.95 (0.85, 1.09)	0.44

TUPEC214

Village community mobilization is associated with reduced HIV incidence in young South African women participating in the HPTN 068 study cohort

S.A. Lippman[1,2], A.M. Leddy[1], T. Neilands[1], J. Ahern[3], C. MacPhail[4], D. Peacock[5], C.W. Kabudula[2], A. Selin[6], E. Piwowar-Manning[7], K. Kahn[2,8], A. Pettifor[2,6]

[1]University of California, Center for AIDS Prevention Studies, Department of Medicine, San Francisco, United States, [2]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Faculty of Health Sciences, School of Public Health, Johannesburg, South Africa, [3]University of California, Department of Epidemiology, School of Public Health, Berkeley, United States, [4]University of Wollongong, School of Health and Society, Wollongong, Australia, [5]Sonke Gender Justice, Cape Town, South Africa, [6]University of North Carolina at Chapel Hill, Department of Epidemiology, Gillings School of Global Public Health, Chapel Hill, United States, [7]Johns Hopkins University, Department of Pathology, School of Medicine, Baltimore, United States, [8]Umeå University, Division of Epidemiology and Global Health, Department of Public Health and Clinical Medicine, Umeå, Sweden

Background: Adolescent girls and Young women (AGYW) in South Africa bear a disproportionate burden of HIV. Community mobilization (CM), defined as community members taking collective action to achieve a common goal, has been found to be associated with increased HIV testing and condom use and has been called a 'critical enabler' for addressing the HIV epidemic. However, limited research has explored whether CM, or living in a mobilized community, is associated with HIV incidence among AGYW.

Methods: We conducted a longitudinal analysis among 2,533 AGYW (ages 13-21) enrolled in the HPTN 068 cohort in the Agincourt Health and Demographic Surveillance System, South Africa. This analysis includes all participants who lived in 28 villages where we also conducted cross-sectional, population-based surveys among 18-35 year old residents in 2012 and 2014. HPTN 068 participants completed up to five annual visits, receiving an HIV test at each visit (2011-2016). Household-level data were collected from the parent/guardian of each AGYW and census data is collected annually. Mean village-level CM scores were created using a validated CM measure composed of seven components (community social cohesion, social control, collective consciousness, shared concerns, organizations and networks, leadership, and collective action). We used pooled generalized estimating equations with a Poisson distribution to estimate the risk ratios (RR) of incident HIV infection, adjusting for the village-level clustering and key covariates.

Results: There were 177 incident infections over the follow-up period. For every standard deviation increase in village-level CM there was a 14% reduction in HIV incidence (RR: 0.86, 95% CI: 0.74, 0.99, p< 0.05) after adjusting for age, time enrolled in the 068 cohort, education, household assets, and a collated measure of community characteristics (mean community education, proportion of community in highest SES quintile, proportion permanent residents).

Conclusions: These results support that living in a mobilized community, where communities work collectively and organize to address community welfare, can reduce AGYW's risk of HIV acquisition. Community mobilization efforts may be an important component in HIV prevention programs for AGYW.

Characteristics	Unadjusted RR (95% CI)	Adjusted aRR (95% CI)

Global assessment of the availability of condoms and conjugal visits in prisons: Preliminary results of a global prison survey commissioned by UNODC

R. Bosworth[1,2,3], E. Salah[4], R. Lehtovuori[5], S.A. Kinner[6,7], F.L. Altice[8], M. Farrell[3], B. Moazen[9,10], K. Dolan[2,3]
[1]University of New South Wales, School of Public Health and Community Medicine, Randwick, Australia, [2]University of New South Wales, Program of International Research and Training (PIRT), Randwick, Australia, [3]University of New South Wales, National Drug and Alcohol Research Centre, Randwick, Australia, [4]United Nations Office on Drugs and Crime, Adviser. Prisons and HIV, Vienna, Austria, [5]United Nations Office on Drugs and Crime, Adviser Monitoring & Evaluation and Focal Point HIV/AIDS, Vienna, Austria, [6]Centre for Adolescent Health, Murdoch Childrens Research Institute, Melbourne, Australia, [7]Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia, [8]Yale University, School of Medicine, Yale, United States, [9]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [10]University of Heidelberg, Institute of Public Health, Heidelberg, Germany

Background: Condoms are an effective way to reduce the risk of contracting sexually transmitted infections (STIs) such as HIV, hepatitis B and syphilis. Most prisoners are males aged 20-35 years, a period of heightened sexual activity. Unsafe sex occurs in prison between prisoners and between prisoners and staff. Reports of STI cases in prison confirm sex occurs. We aim to assess the availability of condoms and conjugal visits in prisons globally, identifying regions where urgent scale up of condom provision is required.
Methods: In 2017, a global prison survey commissioned by UNODC was disseminated to 197 countries, inviting prison authorities to participate. Data were collected on the availability of the 15 interventions in the UN Comprehensive Package, including condoms, and HIV prevalence/incidence among prisoners.
Results: Of the 35 responses, 27 countries reported on condom availability and conjugal visits spanning six UNAIDS regions (excluding Latin America & the Caribbean). Condoms were available for prisoners and staff in twelve and 3 countries respectively. Fourteen countries did not provide condoms, however, 3 reported distribution upon release. Conjugal visits were permitted in ten out of 27 countries. Of the thirteen countries that did not provide conjugal visitations, nine also did not provide condoms. Both condoms and conjugal visits were reported in six countries. According to survey respondents, prison sex was *'untolerated'* and *'taboo'* with condom distribution at staff discretion. Needing to *'understand provision within the country's political context'* was also reported and recognised as one of the barriers for provision.
Conclusions: Although the survey response rate is low, results show condom availability and conjugal visits are uncommon for these prison systems. When access to preventative health care is obstructed, human rights and public health are compromised. Therefore, we support condom provision as recommended in the UN Comprehensive Package of 15 key interventions to prevent HIV and other infections. Barriers to prison condom provision include; social attitudes towards homosexuality and political opinion. Current prison harm reduction responses must be increased to protect priority populations. Identifying gaps in services may inform policies, supporting countries to develop evidence-based responses, such as condom programs.

TUPEC216

Building bridges, not walls: Prevalence and correlates of injecting with United States residents among people who inject drugs in Tijuana, Mexico

R. Garfein[1], A. Borquez[2], L. Liu[3], D. Abramovitz[1], L. Beletsky[1,4], D. Werb[1], S. Metha[5], G. Rangel[6], P. González-Zúñiga[1], S. Strathdee[1]
[1]University of California San Diego, Infectious Diseases and Global Public Health, La Jolla, United States, [2]University of California San Diego, Infectious Diseases and Global Public Health, San Diego, United States, [3]University of California San Diego, Family Planning and Public Health, La Jolla, United States, [4]Northwestern University, School of Law and Bouvé College of Health Sciences, Boston, United States, [5]University of California San Diego, Medicine, La Jolla, United States, [6]Comisión de Salud Fronteriza México-Estados Unidos, Tijuana, Mexico

Background: In Tijuana, Mexico, HIV prevalence among PWID is 3.4% versus 9.8% in bordering San Diego (U.S.). Characterizing PWID living in Tijuana who inject with PWID visiting from the U.S. is important to prevent cross-border transmission.
Methods: We analyzed baseline data from participants enrolled in 2011-2012 in a cohort study of PWID who live in Tijuana. We calculated prevalence of injecting with PWID from the U.S. while in Mexico and used logistic regression to identify independent correlates of this practice.
Results: Of 730 participants (mean age = 37.4 years; 62% male; 93% born in Mexico; 60% Spanish-only speakers), 132 (18.5%) had injected during the past six months in Mexico with a PWID visiting from the U.S. In multivariable analysis, injecting with PWID from the U.S. was independently associated with higher income (odds ratio [OR]: 2.1, p< 0.01), speaking English and Spanish (OR=1.9, p< 0.001), younger age at first injection (OR=0.97 per yr, p=0.053), receptive syringe sharing in the past 6 months (OR=3.1, p< 0.001) and exchanging sex for money/commodities in the past 6 months among men (OR=2.6, p< 0.01) but not women (OR=0.92, p=0.82). PWID from the U.S. were described as friends (63%), acquaintances (26%), strangers (7%) or sex trade clients (5%). Most reported lending their syringe (67%) or borrowing others' (62%) and sharing cookers/cottons (70%) when injecting with PWID from the U.S.
Conclusions: Nearly one-fifth of PWID in Tijuana reported injecting with PWID from the U.S.; these PWID had a higher risk profile than other Tijuana PWID, which could facilitate cross-border transmission of HIV and HCV. Our findings call into question the U.S. federal government's proposal to reinforce border walls to prevent drug use and disease transmission, given that many U.S. drug users travel to Tijuana of their own volition. This also highlights the need for strengthening HIV and HCV prevention services on both sides of the border.

TUPEC217

The paradox of migration: Assessing protective and risk factors among transgender women in Lima, Peru

K. Moriarty[1,2], E. Segura[1], W. Gonzalez[3], A. Perez-Brumer[4], J. Lake[1,5], R. Cabello[1,3], J. Clark[1]
[1]University of California, South American Program in HIV Prevention Research (SAPHIR), Los Angeles, United States, [2]Brown University Alpert Medical School, Providence, United States, [3]Asociación Civil Via Libre, Lima, Peru, [4]Columbia University, Mailman School of Public Health, New York, United States, [5]University of Texas, Houston McGovern Medical School, Houston, United States

Background: Paralleling global trends, HIV and rectal STIs continue to disproportionately burden transgender women (TGW) in Peru. While migration by TGW to urban centers is common to improve discrimination and economic opportunities, there are few studies assessing the health risks associated with migration. Addressing this gap, we explored the association of HIV and STI risk factors and migration among TGW in Lima, Peru.
Methods: In 2017, 126 TGW participated in a study assessing the relationship between rectal STIs and HIV prevention. Eligibility was limited to HIV-uninfected or serostatus-unknown TGW reporting recent condomless receptive anal intercourse (cRAI). Participants were tested for rectal GC/CT using GenProbe Aptima TMA (Hologic) and screened for HIV and syphilis. Participants completed a bio-behavioral survey on demograph-

ics, sexual behaviors, recent partnerships, and other HIV/STI risk factors. Participants born outside of Lima who lived in Lima at the time of the survey were considered migrants. We explored associations between migration and number of cRAI partners, patterns of drug and alcohol use during sex, problem drinking (AUDIT score), and prevalence of rectal GC/CT, syphilis, and HIV.
Results: Among 125 TGW (median age 29), 29.6% were diagnosed with rectal GC/CT and 12.9% with HIV. 37.6% were migrants. 63.2% of the sample reported transactional sex and 89.5% reported cRAI, in the past 30 days. Migration status was associated with younger age (p=0.01), increased prevalence of rectal GC/CT diagnosis (p=0.04), and increased frequency of anonymous sexual partners (p=0.02). Yet, TGW migrants were less likely to report substance use during sex (p=0.03) or to report alcohol abuse (p=0.05). There was no difference between migrant and non-migrant TGW in total number of recent sexual partners, number of cRAI partners, engagement in sex work or HIV infection.
Conclusions: Further attention is needed to understand differences among TGW that contribute to their HIV/STI vulnerability. Migration emerges as a paradoxical status associated with increased prevalence of rectal GC/CT, but lower alcohol and substance use during sex. Additional research is needed to explore the intersection of migration patterns with sexual networks (e.g, sex work) associated with vulnerability to HIV and STIs.

TUPEC218

Deconstructing the relationship between non-fatal opioid overdose and HIV/HCV risks among PWID in Kazakhstan

L. Gilbert[1], T. Hunt[1], S. Primbetova[2], A. Terlikbayeva[2], M. Chang[3], T. McCrimmon[1], P. Marotta[1], E. Wu[4], N. El-Bassel[1]
[1]Columbia University School of Social Work, Global Health Research Center of Central Asia, New York, United States, [2]Global Health Research Center of Central Asia, Almaty, Kazakhstan, [3]Columbia University School of Social Work, Social Intervention Group, New York, United States, [4]Columbia University School of Social Work, New York, United States

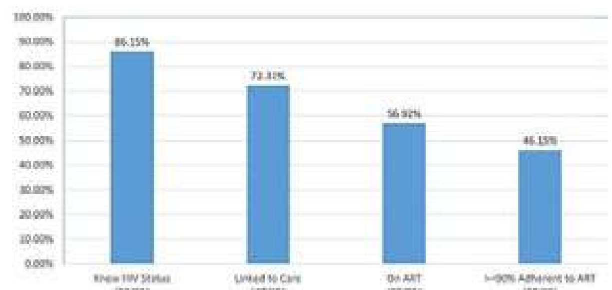
Background: Although opioid overdose is the leading cause of death among people who inject drugs (PWID) in Kazakhstan there remains little research on how opioid overdose may share syndemic risk factors for HIV and HCV among PWID in Kazakhstan or Central Asia. This study aims to examine the relationships between non-fatal opioid overdose and HIV/HCV risks among PWID in Almaty, Kazakhstan.
Methods: We used baseline data from a couple-based HIV study for PWID and their sexual partners, restricting the sample to 580 participants who reported ever injecting drugs. We hypothesized that experiencing opioid overdose in the prior six months would be significantly associated with biological indicators for HIV and HCV and drug and sexual-related risk behaviors after adjusting for age, gender, ethnicity, marital status, education, homelessness and food insecurity. We employed multiple regression analysis with shared couple-level random effects to account for the dyadic structure of the data.
Results: Of the sample, 60% (n=278) identified as male. About one-fifth (20.5%, n=119) reported experiencing a non-fatal overdose in the past 6 months (See Table 1 for socio-demographic characteristics associated with non-fatal overdose). Non-fatal overdose was not significantly associated with biologically confirmed HIV. However, non-fatal overdose quadrupled the likelihood of testing positive for HCV (AOR=4.08, CI=1.32, 12.64). Multiple regression models further supported study hypotheses by identifying significant relationships between non-fatal overdose and any unsafe injection (AOR=1.82, CI=1.01, 3.25); number of people sharing needles (AIRR= 1.73, CI=1.37, 2.19), number of condomless vaginal sex acts (AIRR=1.26, CI=1.11, 1.34), having had vaginal sex under the influence of drugs or alcohol (AOR=2.21, CI=1.06, 4.59) and any condomless anal sex (AOR=5.47, CI=1.28, 23.41).
Conclusions: This study found non-fatal overdose is associated with both sexual and drug-related HIV risk behaviors and HCV. The extremely high rate of recent opioid overdose combined with its association with HCV and multiple behavioral risks for HIV underscore the urgent need to integrate opioid overdose prevention with HIV prevention and treatment as a public health priority to prevent the substantial loss of lives to overdose while achieving 90-90-90 goals among PWID in Kazakhstan.

TUPEC219

Burden of HIV among young transgender women: Factors associated with HIV infection and HIV treatment engagement

H. Jin[1], A. Restar[2], K. Biello[2], L. Kuhns[3], S. Reisner[4], R. Garafalo[5], M. Mimiaga[2]
[1]Brown University School of Public Health, Epidemiology, Providence, United States, [2]Brown University School of Public Health, Providence, United States, [3]Northwestern University Feinberg School of Medicine, Chicago, United States, [4]Boston Children's Hospital and Harvard Medical School, Boston, United States, [5]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, United States

Background: Young transgender women (YTW) are disproportionately affected by HIV, however, little is known about the factors associated with HIV infection and HIV treatment engagement. In this study, we examined correlates of HIV infection and the steps of the HIV treatment cascade, specifically, being aware of their HIV infection, being linked to care, being on ART, and being at least 90% adherent to ART.
Methods: We analyzed the baseline data of Project Lifeskills, a randomized control trial of sexually active young transgender women, which tested participants for HIV and collected self-reported data on HIV treatment engagement. We conducted multivariable logistic regressions to evaluate correlates of HIV infection and the steps of the HIV treatment cascade.
Results: 24.7% of the sample of YTW were HIV infected. Among HIV infected YTW, 86.2% were aware of their HIV status, 72.3% were linked to care, 56.9% were on ART, and 46.2% were at least 90% adherent to ART. HIV infected YTW who avoided healthcare due to cost in the past 12 months had lower odds of being linked to care (OR=0.23, 95% CI 0.06, 0.92) compared to those who did not avoid healthcare, and HIV infected YTW who do not have a primary care provider had lower odds of being on ART (OR=0.08, 95% CI 0.01, 0.48) and being adherent to ART (OR=0.04, 95% CI < 0.01, 0.66) compared to HIV infected YTW who do have a primary care provider.
Conclusions: We observed suboptimal HIV treatment engagement among this sample and our findings highlight the relationship between access to health care and HIV treatment engagement. Our results suggest that improving linkage and retention in care by addressing financial barriers and improving access to primary care providers could significantly improve health outcomes of YTW as well as reduce forward transmission of HIV.



[HIV Treatment Cascade: Engagement in HIV Care by HIV+ Young Transgender Women (n=65)]

TUPEC220

Uncovering a new at-risk group for HIV infection in Ukraine among adults aged 50 and older

I. Zaviriukha[1], O. Zeziulin[1], T. Kiriazova[1], S. Shenoi[2], F. Altice[2], J. Rozanova[2]
[1]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [2]Yale University, Department of Medicine, Section of Infectious Diseases, New Haven, United States

Background: The number of newly registered HIV infections among people older than 50 in Ukraine has been increasing over the last six years: from 1198 in 2011 to 1761 in 2016. Data demonstrates that those

≥50 years constitute the only group where HIV incidence has significantly increased (from 8% to 12% between 2014 - 2016). This study qualitatively explored HIV care providers' perspectives on what facilitates and hinders linking to care of people living with HIV who are older than 50 (PLWH50+).

Methods: We purposively sampled and anonymously interviewed 12 HIV care providers (Infectious Disease physicians and psychologists) in 6 regions of Ukraine. Data were coded using Dedoose qualitative data management software and inductively analyzed for themes using grounded theory.

Results: We found four main themes in providers' accounts. First, older patients newly diagnosed with HIV were perceived by providers as more socially excluded, stigmatized and vulnerable than younger patients, requiring additional efforts to engage in HIV services. Second, providers thought PLWH50+ were largely ignorant regarding HIV, although many newly diagnosed older patients were infected 5-10 years ago according to their medical history and CD4 level. Third, a challenge unique to newly HIV diagnosed individuals ≥50 years was poly-pharmacy. Fourth, providers believed that PLWH50+ got HIV infection predominantly through unprotected heterosexual intercourse (including sex with injection drug users). Providers didn't perceive their clients as MSMs, as clients didn't disclose it.

Conclusions: Our results address the paucity of data in the literature about access to HIV care among older adults in global settings, synergy between HIV stigma and ageing, and continued exclusion of older adults from medical and policy agendas related to sexual health. While Ukrainian Ministry of Health HIV prevention programs prioritize youth, findings suggest that there is awareness among HIV care providers' about increasing role of older adults in HIV epidemic and the need for development of new clinical HIV care and HIV prevention guidelines focused on this group. These guidelines need to pay particular attention to the problem of late case detection and delayed linkage to care.

TUPEC221

HIV prevalence and incidence in adolescent girls and young women in Lesotho: Results from the LePHIA survey 2016-2017

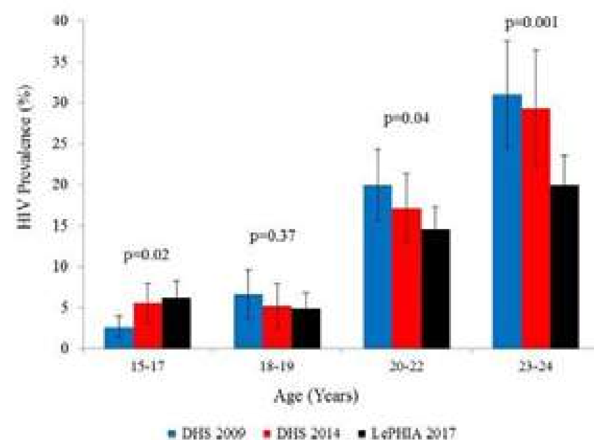
A. Low[1], K. Thin[2], S. Davia[3], J. Mantell[4], M. Koto[2], S. McCracken[5], P. Ramphalla[3], L. Maile[2], N. Ahmed[1], N. Fida[6], A. Schwitters[3], K. Frederix[7]
[1]*ICAP at Columbia University, New York, United States,* [2]*Ministry of Health, Maseru, Lesotho,* [3]*CDC, Maseru, Lesotho,* [4]*Columbia University, New York, United States,* [5]*CDC, Atlanta, United States,* [6]*USAID, Pretoria, South Africa,* [7]*ICAP at Columbia University, Maseru, Lesotho*

Background: Adolescent girls and young women (AGYW, ages 15-24) currently account for 74% of new HIV infections in Southern Africa. A Population-based HIV Impact Assessment conducted in Lesotho (LePHIA) in 2016-2017 provides recent data on prevalence and the first assessment of national HIV incidence in AGYW.

Methods: LePHIA used a two-stage sampling design to select a nationally representative sample of adults. Individuals completed an interview and HIV testing. Incidence was measured using HIV-1 LAg avidity paired with viral load data. The association between demographic and behavioral variables and HIV prevalence and incidence was assessed using logistic regression, incorporating survey weights. A time trend in prevalence and indicators of risk was estimated using weighted data from the Demographic Health Surveys (DHS) in 2009 and 2014.

Results: Of 2708 eligible AGYW, 2358 (87%) were interviewed and tested for HIV. Weighted HIV prevalence was 11.1% (95% CI:9.7-12.5%) overall, 5.7% in 15-19 year olds (64/1156; 95% CI:4.1-7.2%) and 16.7% in 20-24 year olds (209/1202; 95% CI:14.4-19.0%). This translates into an estimated 5862 HIV-positive 15-19 year olds and 16707 20-24 year olds. Annualized incidence was high at 1.8% (95% CI:0.8-2.8%), particularly in urban areas (2.3%, 95% CI:0.7-3.9%). Since 2009, there has been a decrease in prevalence (13.6% to 11.1%), although there was an increase in 15-17 year olds (p_{trend}=0.02, Figure 1), possibly due to increased survival after vertical infection. Compared to 2009, there has been a two-fold increase in odds of secondary/tertiary education (Odds Ratio [OR] 2.21; 95%CI:1.90-2.56), and a 41% reduction in the odds of sexual debut before 15 years (OR 0.59, 95%CI:0.44-.79). However, there has been a significant decline in HIV knowledge (OR 0.72, 95%CI:0.60-0.86). Correlates of prevalent infection include an HIV-positive partner (adjusted OR (aOR) 11.72, 95%CI:6.07-22.62, Table 1), anal sex history (aOR 3.08, 95%CI:1.11-8.57), and having lived outside Lesotho for >1month in past year (aOR 1.82, 95%CI:1.01-3.31). For the 642 AGYW living with parents, maternal education was strongly protective, even after adjusting for household wealth.

Conclusions: HIV prevalence is declining in AGYW, but incidence remains high. Indicators of risk are improving, aside from HIV knowledge, which conveys risk for future acquisition.



[Figure 1. Weighted prevalence in adolescent girls and young women in Lesotho, 2009-2017]

Characteristic	Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)	p-values (determined by logistic regression)

Caregiver depression and child neuropsychological outcomes in an observational study carried out in four sub-Saharan countries

I. Familiar[1], M. Chernoff[2], H. Ruisenor-Escudero[3], B. Laughton[4], C. Joyce[5], L. Fairlie[6], M. Bwakura-Dangarembizi[7], P. Kamthunzi[8], L. Barlow[9], P. Jean-Philippe[10], B. Zimmer[11], K. McCarthy[12], M. Boivin[1]
[1]Michigan State University, East Lansing, United States, [2]Harvard University, FXB Center for Health and Human Rights, Boston, United States, [3]Michigan State University, Psychiatry, East Lansing, United States, [4]Stellenbosch University, Cape Town, South Africa, [5]University of Witwatersrand, Johannesburg, South Africa, [6]Wits RHI Shandukani Clinic, Johannesburg, South Africa, [7]University of Zimbabwe, Harare, Zimbabwe, [8]University of North Carolina - Lilongwe Clinical Research Institute, Lilongwe, Malawi, [9]Makerere University-Johns Hopkins University, Kampala, Uganda, [10]NIH/NIAID, Rockville, United States, [11]IMPAACT Data Management Center, Amherst, United States, [12]FHI 360, Durham, United States

Background: Depression symptoms in caregivers may influence their young children's behavior and cognitive development. Few research studies have focused on Sub-Saharan countries where high prevalence of pediatric HIV may impact child neuropsychological development and caregiver mental health.
Methods: We investigated cross-sectional associations between caregivers' depressive symptoms and child neuropsychological outcomes in P1104s, a multi-center study in sub-Saharan Africa sponsored by the International Maternal Pediatric Adolescent AIDS Clinical Trials (IMPAACT) Network. 611 children between 5-11 years (246 HIV+, 183 HIV exposed, uninfected, and 182 HIV unexposed, uninfected) completed assessments at 6 research sites: South Africa (3), Malawi, Uganda and Zimbabwe. Children were assessed with the BOT-2 total score, the KABC-II mental processing index (MPI) and the TOVA. Caregivers responded to the HSCL-25 depression subscale and evaluated their child with the BRIEF and UNICEF Multiple Indicators Cluster Survey-4 (MICS) Questionnaire for Children. Associations were evaluated with Pearson correlations and with unadjusted and adjusted (for study design, caregiver and child characteristics) linear regression using generalized estimating equations (GEE).
Results: Children's mean age was 7.2 years (SD= 1.4) and 290 (47%) were boys. Most caregivers (68%) were HIV+ and 36% had HSCL-25 score above 1.75. Caregiver depression scores were comparable across groups. Of HIV+ children, 96% had suppressed viral load. In adjusted GEE models, caregivers with high (>1.75 mean score) levels of depression reported higher BRIEF scores (e.g. more executive function problems) by an average 5 to 7 points (p< .001) and almost 3 point lower average MICS development scores (p=0.01; e.g. less development for age). BOT-2 and TOVA scores showed no significant associations with caregiver depression (Table). Exploratory regression models with interactions between caregiver depression and child HIV status showed a trend; adjusted KABC MPI mean scores decreased with increasing levels of caregiver depression in HIV+ children (adjusted p=0.12).

Outcome	Low depressive symptoms (0-1.75)	High depressive symptoms (>1.75)	P-value
KABC Mental processing index	79.2 (77.4,80.9)	78.7 (76.7,80.6)	0.58
BOT-2: Total score	51.8 (50.3,53.3)	51.2 (49.7,52.8)	0.41
BRIEF Behavior Regulation Index	48.9 (46.7,51.1)	56.0 (53.6,58.5)	<0.001
BRIEF Metacognition Index	49.6 (47.0,52.2)	55.3 (52.4,58.1)	<0.001
BRIEF Global Executive Composite	49.2 (46.7,51.6)	55.9 (53.1,58.7)	<0.001
TOVA ADHD	0.01 (-0.53,0.54)	0.08 (-0.48,0.65)	0.76
TOVA D-prime standard score	87.5 (85.2,89.8)	87.0 (84.5,89.6)	0.70
MICS Disability (%)	4.0 (2.2,5.8)	5.6 (3.6,7.5)	0.03
MICS Development (%)	73.8 (71.4,76.1)	70.9 (68.3,73.5)	0.01

[Adjusted baseline predicted means (95% confidence interval) from GEE models for neuropsychological outcomes among school-age children by caregiver dep]

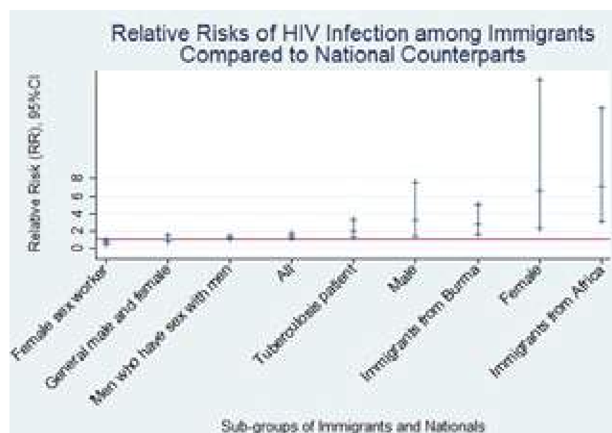
Conclusions: High depressive symptomatology in caregivers was a significant predictor of child behavioral problems and poorer development. Cognitive performance was not associated with symptomatology. Results suggest that depressive symptoms can affect the socioemotional development of children. Considering the mental health of the caregiver should be part of integral neuropsychological evaluations and care in the context of HIV disease.

TUPEC223

Global burden of HIV among Immigrants: A systematic review

X. Wang[1], A. Wirtz[2], C. Beyrer[2]
[1]Chinese Center for Disease Control and Prevention, National Center for AIDS/STD Control and Prevention, Beijing, China, [2]Johns Hopkins Bloomberg School of Public Health, Center for Public Health and Human Rights, Baltimore, United States

Background: Immigrants are vulnerable to HIV due to multiple social and structural factors. Limited HIV research suggests immigration is a risk factor for HIV acquisition and is often associated with increased stigma and reduced access to HIV prevention and care. With increasing globalization, it is imperative to assess the burden of HIV among immigrants to inform responses in HIV prevention and care. We conducted a systematic review and meta-analysis of the global HIV epidemiology among international immigrants.
Methods: Immigrants were defined as non-nationals (foreign born migrants) regardless of citizenship status, including documented migrants legally travelling to or staying in host countries, undocumented migrants legally travelling to but out-stayed in host countries, and illegal migrants illegally travelling to host countries. A systematic review of articles published between 2011 through 2016 and indexed in Pubmed and Embase was conducted to identify information on HIV prevalence, incidence, and prevention and intervention services among immigrants. UNAIDS' website was also searched to identify relevant data in country reports. Extracted data were pooled and analyzed to produce country and regional level estimates. All meta-analysis utilized random effect models due to heterogeneity across studies and locations.
Results: A total of 10,934 articles were identified and 133 were retained for data analysis. HIV prevalence among all immigrants was estimated to be 3% (95% CI: 0.03-0.04), though with significant heterogeneity across countries. Prevalence was especially high among immigrant female sex workers (20%, 95% CI: 0.18-0.23) and tuberculosis patients (17%, 95% CI: 0.07-0.31). Only one study conducted in Denmark reported HIV incidence (2.37%) among African born immigrants, underscoring high post-migration acquisition. Meta-analyses estimated that the burden of HIV is 1.4 times higher among immigrants than nationals globally (RR=1.41, 95% CI 1.14-1.74), especially for immigrants from Africa (RR=7.13, 95%CI 3.16-16.09) and for female immigrants (RR=6.64, 95% CI: 2.28-19.34) compared to nationals. Access to HIV care, treatment and other interventions were reported among a limited number of articles.



[Relative Risks of HIV Infection among Immigrants Compared to National Counterparts]

Conclusions: There is a heightened burden of HIV among immigrants compared to nationals. Coupled with data from other studies that highlight post-migration HIV acquisition, this study suggests that HIV prevention and care services are urgently needed for immigrants.

TUPEC224

Sex work stigma and its effects on healthcare: Data from a large RDS study among FSW in Brazil

I. Dourado[1], M. Drew Crosland Guimarães[2], G. Nogueira Damacena[3], L. Magno[4], P.R. Borges de Souza Júnior[3], C. Landmann Szwarcwald[3], The Brazilian FSW Group
[1]*Federal University of Bahia, Health Collective Institute, Salvador, Brazil,* [2]*Federal University of Minas Gerais, Department of Preventive and Social Medicine, Belo Horizonte, Brazil,* [3]*Oswaldo Cruz Foundation, Institute of Scientific Communication and Information on Public Health, Rio de Janeiro, Brazil,* [4]*Bahia State University, Department of Life Sciences, Salvador, Brazil*

Background: Based on the hypothesis that stigma within health services may be detrimental to health seeking attitudes, this study investigates non-disclosure among female sex workers (FSW) in Brazil and its impact on the utilization of healthcare services.
Methods: Cross-sectional RDS study carried out in 12 Brazilian cities to identify practices related to HIV infection among FSW. Study variables were categorized into four groups to represent social rights, human right violations, health service access and utilization, stigma and discrimination. To investigate the effects of non-disclosure of FSW status on preventive healthcare, we used multivariate logistic regressions for different outcomes: HIV testing in the past year; Pap smear exam in the past two years; awareness of PEP; and PEP use after a risky sexual behavior.
Results: Among 4245 recruited FSW, a high percentage received free condoms (82%) but only 24.4% were counseled on STI. Most FSW used non-specialized public healthcare routinely (62.6%), but less than 40% were tested for HIV in the last 12 months and only 51.5% had a Pap smear exam in the last two years. Among FSW engaged in risky behavior (49.6%), only 8.3% used PEP. Regarding sexual work exploitation, approximately 15% were required to give part of their earnings to owners of workplace establishments and 38% started sex work under 18 years old. Six percent were required to present HIV test results periodically, which is illegal in Brazil. While 21.3% reported having been discriminated in health services, only 24.3% always disclosed their FSW status. Multivariate logistic models indicated significant effects of non-disclosure on the four healthcare outcomes, with lower odds of using preventive health services among women who not always revealed the FSW status to healthcare staff, even after controlling for age, educational level, NGO affiliation, and type of healthcare routinely used.
Conclusions: Our results indicate that sex work stigmatization within health services may be one of the main barriers to STI control and HIV combination prevention among FSW. It is essential to combat stigmatization and discrimination against FSW in health services to guarantee the appropriate uptake of preventive methods available in the public health system in Brazil.

TUPEC225

Gender-affirming genital surgery associated with reduced HIV sexual risk among transgender women: A respondent driven-sampling survey

A. Scheim[1,2], G. Bauer[2]
[1]*University of California San Diego, Division of Infectious Diseases and Global Public Health, La Jolla, United States,* [2]*Western University, Epidemiology and Biostatistics, London, Canada*

Background: Transgender women are a key population disproportionately impacted by HIV globally. Social and medical gender affirmation are theorized to promote health behaviors and health care access among transgender women. Few studies have assessed relationships between gender affirmation and HIV risk, particularly for gender-affirming surgeries, which remain inaccessible in most settings. Drawing on data from Ontario, Canada, where gender-affirming surgeries were publicly funded from the 1970s until 1998, and again from 2008-present, we examined associations between social and medical gender affirmation and HIV-related sexual risk behavior.
Methods: Data were collected through a multi-mode respondent-driven sampling (RDS) study of transgender Ontarians (n=433) in 2009-2010. These analyses were limited to transgender women who had ever had sex (n=171) and weighted using RDS II weights. As half of transgender women were sexually inactive, polytomous logistic regression models estimated odds of past-year high-risk sexual behavior, or reporting sexual inactivity (separately), with low-risk sexual activity as the referent. Condomless vaginal/anal sex outside of a seroconcordant, monogamous relationship was classified as high-risk.
Results: Of sexually-experienced transgender women, 20.9% (95% CI: 11.7, 30.2) reported past-year high-risk sexual behavior. About half (53.3%; 95% CI: 40.8, 65.8) were living full-time in their identified gender, 59.6% (95% CI: 47.0, 72.1) were using feminizing hormones, and 14.8% (95% CI: 6.9, 22.8) had undergone genital surgery. After adjustment for demographics including socio-economic status, genital surgery was associated with lower sexual risk (adjusted odds ratio= 0.08; 95% CI: 0.02, 0.46). This association was robust to sensitivity analysis with a different definition of sexual risk. Genital surgery was also associated with lower odds of sexual inactivity. Neither social gender affirmation nor hormone therapy were associated with sexual risk.
Conclusions: Transgender women in Ontario who had completed gender-affirming genital surgery were at lower HIV risk. Moreover, they were less likely to be sexually abstinent. These results indicate that access to gender affirmation surgeries may enhance transgender women's sexual health, including but not limited to HIV/STI prevention. Longitudinal studies of surgical outcomes should evaluate impacts on sexual risk, and efforts should be made to enhance access to genital surgeries for transgender women who require them.

TUPEC226

Sex work among female workers at the Kokoyo artisanal gold mining site in Mali - results from the ANRS-12339 Sanu Gundo cross-sectional study

C.H. Kounta[1,2], L. Sagaon-Teyssier[1,2], H. Balique[1], M. Mora[1,2], M. Bourrelly[1,2], F. Diallo[3], N. Kalampalikis[4], M. Suzan-Monti[1,2], B.D. Keita[3], B. Spire[1,2], The Sanu Gundo Study Group
[1]*Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France,* [2]*ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France,* [3]*ARCAD Sida, Bamako, Mali,* [4]*University Lyon 2, Institute of Psychology, Social Psychology Research Group (EA 4163), Bron, France*

Background: Female sex workers (FSW) in mining sites are considered to be at very high risk of HIV infection due to risky sexual behaviours associated with migratory work patterns. We aimed to characterize FSW and identify factors associated with their sex work (SW) at the Kokoyo mining site in Mali.
Methods: We used data for FSW and female workers not involved in SW (FNSW) from the ANRS-12339 Sanu Gundo cross-sectional study, conducted in 2015 at the mine by ARCAD-SIDA, a Malian non-governmental organization. People attending prevention activities organized by ARCAD-SIDA (including medical check-ups, HIV testing) were invited to participate in the study's quantitative and qualitative surveys (focus groups). A probit logistic regression was used for data analysis and marginal effects (M-E) were computed to show how predicted probabilities change when the dichotomous explanatory variable changes from 0 to 1.
Results: Of the 101 women recruited, 26.7% reported having SW as their main activity. With respect to FSW 44.4% were unmarried, 44.4 % were uneducated and 55.6% came from other countries. FSW were younger than FNSW. M-E from the multivariate analysis showed that the probability of SW as a main activity decreased by 1% per 1-year age increase (p=0.020). SW was significantly more likely to be reported by single, divorced or widowed women with a probability of 25.4% (p=0.007). FSW were significantly more likely to be non-Malian [36.3% probability (p=0.003)], more likely to have a secondary activity [77% probability (p=0.002)], more likely to work fewer than 56h/week [40.2% probability (p=0.001)] and more likely to have a good health status [12.1% probability (p=0.016)]. In addition, an awareness of STI, a higher consumption of psychoactive products and unprotected receptive anal sex during the previous 6 months were significantly more associated with SW [50.2% (p=0.006), 45.6% (p=0.003) and 7.4% (p=0.016) probability, respectively]. Qualitative findings confirm that poverty and boyfriends' refusal to use condoms remain key barriers to consistent condom use among FSW.

Conclusions: FSW participating in the Sanu Gundo study inconsistently use condoms because of economic and relationship-based factors, and because of drugs and alcohol consumption. Existing targeted prevention interventions should be strengthened in mining sites in Mali.

TUPEC227

Disparities in viral suppression and non-adherence to antiretroviral medicines among women living with HIV infection, 2011 - 2016

A. Geter[1], M.Y. Sutton[1], C. Armon[2], K. Buchacz[1]
[1]Centers for Disease Control and Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD and TB Prevention, Atlanta, United States, [2]Cerner Corporation, Kansas City, United States

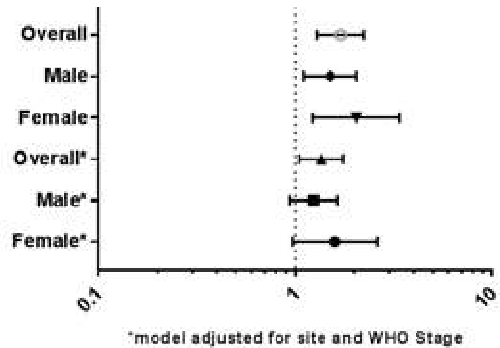
Background: In the United States (US), women accounted for 19% of HIV diagnoses (2016). Black/African American (black) and Hispanic women/Latinas (Latinas) were disproportionately affected; they comprised 61% of women diagnosed with HIV infection. Adherence to antiretroviral therapy (ART) enables HIV viral suppression (VS); a national goal is to have 80% of HIV-infected persons reach VS by 2020. We examined correlates of non-adherence and VS among women to inform HIV care interventions for women.
Methods: We used clinical chart abstraction and audio computer-assisted self-interview (ACASI) data from the HIV Outpatient Study (HOPS), a cohort of adults receiving HIV care at nine US sites. We limited analyses to women aged ≥ 18 years with ≥ 1 HOPS visit, ≥ 1 viral load (VL) test and ≥1 ACASI between 2011 and 2016. We defined non-adherence as missing at least one ART dose in the past three days and VS as VL < 50 copies/mL. Generalized estimating equations were used to assess factors associated with non-adherence and non-VS.
Results: Among 426 women (median age=46 years), 263 (61.7%) were black, 101 (23.7%) were white, 62 (14.6%) were Latina. At last measurement, non-adherence was more prevalent among black women (28.1%) compared with Latinas (21.0%) and white women (12.9%), (p=0.005). VS was less prevalent among black women (63.1%) compared with Latinas (72.6%) and whites (78.2%), (p=0.01). In multivariable analyses, non-adherence was more likely among black women (adjusted prevalence ratio [aPR]=1.86; 95% Confidence Interval [CI]=1.19-2.91) compared with all other; women age ≤ 49 years (aPR=2.72; CI=1.44-5.15) versus older; and women with CD4 < 350 cells/mm³ (aPR=1.56; CI=1.02-2.38) versus ≥ 350 cells/mm³. Non-VS was associated with non-adherence (aPR=2.33; CI=1.51-3.59), age ≤ 29 years (aPR=2.26; CI=1.01-5.02) versus ≥ 50 years, public insurance payers (aPR=2.06; CI=1.19-3.58) compared with private or none, and CD4 < 350 cells/mm³ (aPR=5.18; CI=3.46-7.76) versus ≥ 350 cells/mm³.
Conclusions: Racial/ethnic disparities in VS and adherence persisted among HIV-infected women. Interventions targeting improvement in ART adherence and VS among younger, black, and publically-insured women are warranted.

TUPEC228

Association between serodiscordance status and ART use in the African Cohort Study

D. Reed[1,2], A. Esber[1,2], T.A. Crowell[1,2], C. Polyak[1,2], A. Parikh[1,2], F. Kiweewa[3], J. Maswai[1,4,5], J. Owuoth[1,4,6], L. Maganga[7], Y. Adamu[8], J. Ake[1], African Cohort Study (AFRICOS)
[1]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]Makerere University-Walter Reed Project, Kampala, Uganda, [4]Kenya Medical Research Institute, Nairobi, Kenya, [5]Henry M. Jackson Foundation Research International, Kericho, Kenya, [6]Henry M. Jackson Foundation Medical Research International, Kisumu, Kenya, [7]Mbeya Medical Research Centre, Mbeya, Tanzania, United Republic of, [8]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Abuja, Nigeria

Background: HIV-infected partners of serodiscordant relationships may experience psychological stress that could interfere with antiretroviral therapy (ART) use, or may have increased motivation to prevent transmission. Conversely, seroconcordant relationships are associated with increased social support that may impact ART use. We assessed the association between serodiscordance status and ART use.
Methods: The African Cohort Study (AFRICOS) prospectively enrolls HIV-infected and -uninfected individuals at 12 PEPFAR-supported sites across Uganda, Kenya, Tanzania, and Nigeria. HIV serology, clinical assessments, and sociobehavioral questionnaires are collected. We analyzed enrollment visits of the first HIV-infected individuals (index) within two kinds of sexual dyads, serodiscordant or seroconcordant relationships. Participants were considered a member of a sexual dyad if both partners reported each other as a partner within the study. Dyads were categorized as serodiscordant if only one partner was serologically confirmed HIV-infected. Seroconcordant dyads were defined as having both partners serologically confirmed HIV-infected. Pearson's chi-squared and Fisher's exact tests were used to compare characteristics of indexes between the types of dyads. Poisson regression models with robust error variance were used to estimate the overall and gender-specific prevalence ratio (PR) of ART use while controlling for confounders that changed the prevalence ratio by at least 10%.
Results: As of September 2017, there were 284 sexual dyads; 223 indexes from serodiscordant dyads and 61 indexes from seroconcordant dyads. The majority of the indexes were aged 25-34 years (50.2%), female (53.4%), and married (96.5%). Serodiscordant indexes were more likely to disclose their status to partners than were seroconcordant indexes (96.4% vs. 82.0%, p< 0.001). Additionally, 47.5% of seroconcordant indexes used ART compared to 80.6% of serodiscordant indexes (p< 0.001). After adjusting for site and WHO stage, there was a 36% increased prevalence (95% CI: 1.1-1.8; Figure 1) of ART use among serodiscordant indexes compared to seroconcordant indexes. There were no significant trends by gender.
Conclusions: The prevalence of ART use is greater among serodiscordant indexes. This may be driven by treatment as prevention, and continuing to emphasize ART use in this population is key. Additional emphasis on ART use in seroconcordant partners is necessary even if transmission is not of immediate concern.



[Figure 1. Overall and Gender-specific Adjusted and Unadjusted Prevalence Ratios and 95% CI]

TUPEC229

The need to improve HIV care for migrant populations in Botswana: Addressing the unknowns

D. Escudero[1], T. Marukutira[2,3], A. McCormick[1], S. George[1]
[1]Harvard T.H. Chan School of Public Health, Boston, United States, [2]Burnet Institute, Melbourne, Australia, [3]Monash University, Melbourne, Australia

Background: Botswana has among the highest level of HIV viral suppression in the world, yet maintains HIV incidence >1% per year. Immigrant status has been found elsewhere to correspond to greater risk of infection, and poorer treatment outcomes. Although Botswana provides free antiretroviral therapy (ART) for all HIV-infected citizens, non-citizens are ineligible. Identifying testing/treatment gaps for its large immigrant population may help Botswana achieve greater viral suppression, and reduced transmission.
Methods: We reviewed published scientific/demographic literature to identify potential empirical gaps needed to address the following questions:

- How many non-citizen immigrants reside in Botswana?
- What is the burden of HIV in this immigrant population?
- What proportion of immigrants living with HIV (ILHIV) are on ART?
- Do ILHIV have poorer treatment retention or enrollment compared to citizens?

Results: The United Nations (UN) estimates that 160,000 non-citizens resided in Botswana in 2015, about a 50% increase from census data in 2011. Despite anecdotal accounts of Zimbabweans comprising the largest portion of the immigrant population, estimates were difficult to confirm; the UN estimates 32,000 Zimbabwean nationals were present in 2015, but other estimates reached 100,000. The UN estimates 82,000 non-citizen residents originate from the HIV-endemic countries of South Africa, Zambia and Zimbabwe, suggesting high HIV risk. Data from 30 small communities in Botswana suggest that non-citizens may have similar HIV prevalence as citizens (0.20 vs. 0.22, respectively), however, ILHIV in these communities had a greatly increased risk of undiagnosed infection (63% vs. 16%) and only 29% were enrolled on ART, compared to 71% of citizens. There only exists evidence of sparse HIV testing/treatment services available outside the government's national program; in fact, one study found a majority of Zimbabwean migrants were "afraid" to access HIV testing. Despite early studies suggesting that travel/migration was a significant barrier to HIV testing and a cause of missing ART doses, no data were found contrasting treatment outcomes or adherence in citizens vs. non-citizens.

Conclusions: Although some data suggest significant barriers to HIV testing/treatment for non-citizens in Botswana, comprehensive and nationally-representative data have yet to be collected. Substantial research is needed to inform potential expansions in migrant testing/treatment coverage.

Prevalence and risk factors for unsuppressed viral load among HIV positive female sex workers on antiretroviral therapy in Kampala, Uganda

G. Namale[1], O. Kamacooko[1], D. Bagiire[1], Y. Mayanja[1], A. Abaasa[1], W. Kilembe[2], M. Price[3,4], R. Newton[1,5], J. Seeley[1,6]
[1]MRC/UVRI Uganda Research Unit, Kampala, Uganda, [2]Rwanda Zambia HIV Research Group-Emory University, Zambia Emory HIV Research Project, Lusaka, Zambia, [3]University of California at San Francisco, San Francisco, United States, [4]International AIDS Vaccine Initiative, New York, United States, [5]University of York, York, United Kingdom, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: There is limited information on viral suppression in key populations on antiretroviral therapy in Sub-Saharan Africa. We aimed to assess prevalence and risk factors for unsuppressed viral load (VL) among HIV positive Female sex workers (FSW) on antiretroviral therapy (ART) in Kampala, Uganda.

Methods: We conducted a cross-sectional study between January 2015 and December 2016, using routinely collected data at Good Health for Women Project clinic (GHWP). Plasma samples collected from FSW at least 18 years old on ART were tested for HIV viral load (VL) at the Central Public Health Laboratories (CPHL) in Uganda. Unsuppressed VL was defined as ≥ 1000 copies of viral RNA/mL plasma. Socio-demographic, sexual behaviour, clinical and VL data were extracted from clinic records. We used logistic regression to identify factors independently associated with unsuppressed VL.

Results: Four hundred and thirty two HIV positive FSW on ART were included in the analysis; mean age was 32.5 years (SD=6.5). Of these, 38 (9%) had unsuppressed VL. In the adjusted analysis, unsuppressed VL was independently associated with participant age [young age (18-24)] adjusted odds ratio (aOR) = 5.3 (95% CI: 1.6-17.9), reported ART adherence status [non-adherence] aOR = 2.6 (95% CI: 1.2-5.8) and CD4+ T-cell counts [less than 350 cells/mm³] aOR= 3.1 (95% CI: 1.4-7.0).

Conclusions: Unsuppressed VL at this clinic was relatively low compared to other studies in key populations. Young age, non-adherence and low CD4+ T-cell counts increased the odds of unsuppressed VL. We recommend persistent intensive adherence counselling among FSW with unsuppressed VL for improving adherence to ART. Interventions targeting young FSW to improve viral suppression should be considered in Uganda.

TUPEC231

Factors associated with self-reported utilization of sexual and reproductive health services among Roma women in Macedonia

S. Atanasova[1], B. Pavlovski[2], M. Windle[1], J. Friscik[2], D. Penaloza[1], O. Olawore[1], C. Lyons[1], M. Holtzman[1], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Association for Emancipation, Solidarity and Equality of Women, Skopje, Macedonia, The Former Yugoslav Republic of

Background: The support from Global Fund to Fight AIDS, Tuberculosis and Malaria in Macedonia has phased out at the end of 2017 and the sustainability of the programs is under discussion as Macedonia is transitioning towards governmental funding of these programs. As a result, there is a need to ensure continuous provision of interventions that engage marginalized communities in the health system. Roma population in Macedonia is a highly marginalized community living in poverty with limited access to health services. This study aims to determine factors associated with attendance at preventative gynecological examinations among Roma women in five municipalities in Macedonia.

Methods: Roma women aged 18 or older were included in a standardized cross-sectional study conducted in Macedonia on five different locations, Shuto Orizari municipality and Topaana neighborhood in Chair municipality in Skopje, Delcevo, Vinica and Pehcevo during 2017. We conducted bivariate and multivariate logistic regression to assess the correlates with the attendance at preventative gynecological examinations for all municipalities combined.

Results: : Fifty-six percent (501/891) of the participants had not received a preventative gynecological examination within 3 years. Factors associated with attending preventative gynecological examinations were being married, wedlock or other than being single, divorced and widow (adjusted odds ratio [aOR] = 1.85 95% CI: 1.02-3.35), being currently pregnant or have given birth in the last five years (adjusted odds ratio [aOR] = 2.28 95% CI: 1.29-4.02) and receiving an invitation letter from the gynecologist to attend an examination (adjusted odds ratio [aOR] = 2.05 95% CI: 1.18-3.55).

Conclusions: These results show that there is a need for improving the access to sexual and reproductive health services among Roma women who are not living in partnerships and for women who are not pregnant or have given birth. Furthermore, there is a need to strengthen the implementation of measures that are effective in engaging Roma women in utilizing sexual and reproductive health services.

Correlates of HIV infection among transgender women and men who have sex with men in Peru: Implications for targeted HIV prevention strategies

E. Cyrus
Florida International University, Center for Research on US Latino HIV/AIDS and Drug Abuse, Miami, United States

Background: Men who have sex with men (MSM) and transgender women (TGW) in Peru bear a disproportionate burden of HIV infection. We examined correlates of HIV and sexual risk behaviors among MSM and TGW in Peru, and compared characteristics between the two groups.
Methods: We conducted comparative analyses of HIV/STI prevalence, self-reported sexual risk behavior, alcohol and drug use and demographic characteristics between HIV-infected and uninfected participants, and between MSM and TGW.
Results: Between June and October 2011, 5,148 high-risk MSM were recruited using convenience sampling in five Peruvian cities to participate in a cross-sectional bio-behavioral survey. HIV prevalence among TGW was two-fold greater than among MSM (14.9% vs. 7.0%, p< 0.001) and HIV-infected participants compared to their HIV-uninfected counterparts were significantly (p< 0.001) more likely to be commercial sex worker (CSW; 40.2% vs. 32.9%) and have more mean sexual partners (15.8 vs. 10.3). TGW were also significantly (p< 0.001) more likely than MSM to be CSW, have an alcohol use disorder (69.1% vs. 62.1%) have a higher mean number of sexual partners (36.0 vs. 6.7), and unprotected sex events in the past X months (6.7 vs. 3.2).
Conclusions: Both MSM and TGW in Peru engage in high-risk sexual behaviors, placing them at increased risk for HIV/STI transmission. TGW, however, are more likely to be infected and have even higher risks. Risk behaviors for both groups include commercial sex-work, multiple partners and unprotected sex. Prevention efforts in Peru should continue to target these groups for primary HIV prevention and TGW may require more targeted efforts.This may change after you do the multivariate model.

Perceived undertreated pain is associated with overdose among older HIV-positive people who inject drugs in Vancouver, Canada

P. Voon[1], T. Kerr[1], N. Fairbairn[1], E. Nosova[1], R. Barrios[2], E. Wood[1], M.-J. Milloy[1]
[1]BC Centre on Substance Use, Vancouver, Canada, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada

Background: Pain is common and often inadequately managed among people living with HIV (PLWHA), as has been highlighted in recent clinical practice guidelines for managing chronic pain among PLWHA. Given increasing concerns regarding opioid overdose trends and comorbidities related to aging populations of PLWHA, we sought to explore the impact of perceived undertreated pain on non-fatal overdose among age subgroups of PLWHA who inject drugs.
Methods: Bivariable and multivariable generalized estimating equations (GEE) were used to evaluate the impact of perceived undertreated pain on non-fatal overdose among HIV-seropositive people who reported ever injecting drugs in the AIDS Care Cohort to Evaluate exposure to Survival Services (ACCESS) prospective cohort study in Vancouver, Canada, from June 2014 to May 2016. Participants were considered to have perceived undertreated pain if they reported feeling the need to take more of, or a stronger type of, pain medication than they had been prescribed, based on sub-questions of the Brief Pain Inventory.
Results: In total, 556 participants were eligible for this analysis, of who 359 (64.6%) were male. The median age was 49 years (interquartile range: 43-54 years). In total, 113 overdoses were observed over the study period from 93 (16.7%) unique individuals. Perceived undertreated pain was significantly associated with overdose in bivariable analyses (Odds Ratio [OR]: 2.05, 95% Confidence Interval [CI]: 1.32-3.16) and in a multivariable analysis adjusted for confounding variables (Adjusted Odds Ratio [AOR]: 2.24, 95% CI: 1.40-3.59). In the multivariable analysis, perceived undertreated pain remained independently associated with overdose, while drug use variables (e.g., daily heroin injection) did not. Within age strata, perceived undertreated pain was independently associated with overdose in the oldest stratum aged 50-60 (AOR: 3.73, 95% CI: 1.75-7.94), but not in younger strata aged 30-40 (AOR: 2.51, 95% CI: 0.49-12.86) or 40-50 (AOR: 1.87, 95% CI: 0.86-4.06).
Conclusions: The positive independent association between perceived undertreated pain and overdose in this study highlights the potential role of pain management in mitigating overdose among PLWHA who inject drugs—particularly older subpopulations. These findings also suggest that perceived undertreated pain may be a more significant predictor of overdose than drug use patterns alone.

Risk factors for acquisition, infectivity and transmission of HIV

TUPEC234

Latent profiles of behavioral and sexual risk for HIV-negative and positive young African American men who have sex with men: Implication for HIV prevention and pre-exposure prophylaxis

W. Vincent[1], J. Peterson[2], D. Huebner[1], J. Tan[1], G. Rebchook[1], E. Storholm[3], L. Pollack[1], S. Kegeles[1]
[1]University of California, San Francisco, San Francisco, United States, [2]Georgia State University, Atlanta, United States, [3]RAND Corporation, Los Angeles, United States

Background: Young African American men who have sex with men (YAAMSM) have high HIV risk, but are less likely than other groups to be prescribe pre-exposure prophylaxis if they are HIV-negative and less likely to be retained in care or virally suppressed if they are HIV-positive. Thus, in order to inform HIV prevention and intervention efforts, the present study identified profiles of HIV-related behavioral risks and protective factors and whether these profiles could be distinguished by socioeconomic risk factors and HIV status.
Methods: YAAMSM (*N*=1,808) in two Texas cities completed a survey of sociodemographic characteristics, HIV status, HIV-related behavioral risk and protective factors (i.e.., condom self-efficacy, negative condom

attitudes, being in difficult sexual situation, being in a difficult relationship situation, HIV treatment optimism, perceived HIV stigma) factors. Latent profile analysis was used to identify profiles of behavioral risk and protective factors and whether these profiles could be predicted by HIV status when adjusting for socioeconomic characteristics.
Results: YAAMSM characterized by profile 1 (*n*=1,263) had relatively high scores on condom self-efficacy (i.e., feeling a sense of agency and skill at using condoms in a sexual situation), which is linked to reduced HIV risk, compared to YAAMSM characterized by profile 2 (see Table). In contrast, YAAMSM characterized by profile 2 (*n*=545) had higher scores on all behavioral factors linked to increased HIV risk (i.e., negative condom attitudes, being in difficult sexual situation, being in a difficult relationship situation) (see Table). HIV-positive YAAMSM had greater odds of having a higher risk profile and lower self-efficacy than HIV-negative YAAMSM (*OR*=2.13, $p < 0.0005$).
Conclusions: In this large sample of YAAMSM, men could be distinguished by two profiles of HIV-related behavioral protective and risk factors: one characterized by a relatively high degree of condom self-efficacy and the other characterized by greater HIV-related behavioral risk (e.g., negative condom attitudes, being in difficult sexual relationships). HIV-positive men, who tended to be characterized by the higher risk profile, may require support regarding contextual risk factors (e.g., difficult sexual relationships) and greater efforts to achieve viral suppression given that these men may tend toward negative condom attitudes.

Variable	Overall Item Mean (SD)	First Class: Mean (SE)	Second Class: Mean (SE)
Condom self-efficacy	16.53 (4.20)	18.46 (0.10)	12.14 (0.28)
Negative condom attitudes	5.87 (3.23)	4.40 (0.08)	9.20 (0.20)
Being in difficult sexual situations	20.17 (9.09)	15.92 (0.25)	29.79 (0.49)
Being in a difficult sexual relationship	9.56 (4.44)	8.20 (0.15)	12.65 (0.21)
HIV treatment optimism	7.84 (3.30)	7.00 (0.09)	9.75 (0.17)
Perceived HIV stigma	29.82 (12.44)	28.21 (0.37)	33.41 (0.52)

TUPEC235

The young, the old and the risky: HIV risk factors by age among voluntary medical male circumcision clients in Zambia 2017

O. Chituwo[1], L. Aladesanmi[2], J.Z. Hines[3], M. Lukobo-Durrell[4], M.A. Habel[3], S.M. Davis[3], C. Toledo[3], C. Laube[4]
[1]*Centers for Disease Control and Prevention, Lusaka, Zambia,* [2]*Jhpiego, Lusaka, Zambia,* [3]*Centers for Disease Control and Prevention, Atlanta, United States,* [4]*Jhpiego, Baltimore, United States*

Background: Circumcising men with the highest baseline HIV infection risk achieves the greatest absolute risk reduction from male circumcision. In practice, voluntary male medical circumcision (VMMC) programs have relied on age as a proxy for risk. However, previous studies have not reported risk factors according to VMMC client age. We investigated the association between age and self-reported HIV risk factors among clients in a VMMC program led by the Zambia Ministry of Health and Jhpiego.
Methods: In May 2017, a VMMC program began asking clients aged ≥15 years about several HIV risk factors to better inform counseling during preoperative evaluation. Clients were asked about recent (≤6 month) sex with an HIV-positive partner; multiple concurrent sex partners; sex in exchange for money; treatment for sexually transmitted infections (STIs); sex after drinking alcohol; and illicit drug use. We report on client responses from the first five months of implementation (May-September 2017), comparing risks among clients in five age bands (15-19 years, 20-24 years, 25-29 years, 30-39 years, and ≥40 years) using the chi-square or fisher exact test with a significance level of $p < 0.05$. Data were analyzed only for clients with complete data.
Results: Among 2,846 interviewed VMMC clients during May-September, 2,318 (81.4%) had complete data. Of these, 380 (16.4%) clients reported at least 1 HIV risk factor in the past 6 months, and 153 (6.6%) reported ≥2. The proportion of clients reporting any, ≥2, or any of the six individual risk factors varied by age group ($p < 0.05$), with all but drug use increasing with age (Table).
Conclusions: A substantial minority of clients in a Zambian VMMC program reported recent risk factors for HIV infection, and the likelihood of reporting a risk increased with age. These findings suggest that targeting men aged ≥20 years for VMMC reaches men at higher risk for HIV infection, and demand creation efforts designed to mobilize these men are warranted. VMMC programs that collect risk information should use it to guide demand creation activities (e.g., mobilizing men at shebeens, STI clinics) and to tailor counseling messages for clients.

Factors associated with mother-child HIV transmission in Uruguay: The importance of goals 90-90-90 in the elimination strategy

S. Cabrera[1,2], A. Visconti[1], M. Guirado[2], D. Pérez[1], A. Bálsamo[1], J. Quian[1]
[1]*Ministry of Health, Montevideo, Uruguay,* [2]*Cátedra de Enfermedades Infecciosas, Facultad de Medicina, Montevideo, Uruguay*

Background: There are approximately 130 children per year who are born exposed to HIV-infected women in Uruguay. Although measures to prevent mother-to-child transmission (PMTCT) of HIV have been implemented years ago, it has not yet been possible to achieve sustained elimination of MTCT. An analysis of the national cohort of children exposed to HIV in Uruguay was conducted to evaluate the variables associated with MTCT.
Methods: A cross-sectional study of live births HIV exposed between 2012 and 2016 in Uruguay.
Results: A total of 610 pregnancies resulted in 622 live births exposed to HIV. The overall MTCT rate was 2.7%: 5.3% in 2012, 1.6% in 2013, 3% in 2014, 1.8% in 2015, 1.6% in 2016. The women's average age was 28 ± 7 years, CD4 count 508 ± 311 cells/µl. The median gestacional age and interquartile range of the first pregnancy control was 12 (8-17) weeks, of HIV diagnosis was 17 (11-24) weeks in women without previous diagnosis and, of the start of HAART was 20 (14-27) weeks. The percentage of women with diagnosis of HIV prior to pregnancy and the HAART coverage was 60% and 48%, respectively. An improvement in these indicators was verified from 46.3% to 65.4% and from 27% to 67% between 2012 and 2016, respectively. (figure)
At 18-month follow-up, the MTCT rate was 0% in women with HAART prior to conception or initiating it before 14 weeks, 1% among who started HAART between 14 and 27 weeks, 3.8% among who started at gestational age greater than 27 weeks, and 19% among who did not receive HAART. The factors associated with MTCT in the univariate analysis were: poorly controlled pregnancy, HIV diagnosis late during pregnancy, seroconversion during pregnancy, do not receive any prophylaxis or start HAART late, breastfeeding, virological suppression, newborn without chemoprophylaxis. (table) There were no variables independently associated in the multivariate analysis.

Conclusions: The diagnosis of HIV and HAART coverage prior to pregnancy are the main factors in the PMTCT of HIV; so the achievement of 90-90-90 goals in HIV-infected women would make it possible to achieve the goal of eliminating perinatal HIV transmission.

Variables	OR (CI 95%)	p value
Poor controled pregnancy (< 5 controls)	4.03 (1.11-14.68)	0.045
HIV diagnosis before pregnancy	0.20 (0.07-0.61)	0.002
HIV diagnosis in pregnancy > 28 weeks	20.74 (7.41-58.00)	< .0001

Vulnerabilities to HIV infection among adolescent girls and young women in Selected States in Nigeria

E. Udoh[1], O. Arije[1], K. Ijadunola[1], S. Afolabi[1], J. Arasiola[1], G. Omorige[2], O. Tomori[2], O. Ukeme-Edet[2], A. Onayade[1]
[1]Institute of Public Health, College of Health Sciences, Obafemi Awolowo University, Ile-Ife, Nigeria, [2]Society for Family Health, Global Fund HIV, Abuja, Nigeria

Background: Young women and adolescent girls in particular, account for a disproportionate number of new HIV infections among young people living with HIV. This study identified factors associated with adolescent girls and young women´s vulnerability to HIV infection in Nigeria.
Methods: This was a cross-sectional study conducted among adolescent girls and young women aged 15-24 years in four selected states in Nigeria (Akwa-Ibom, FCT, Kaduna and Oyo). Information on socio-demographic characteristics, risky sexual behaviours and practices, attitudes and perceptions on HIV, STI experience, gender-based violence and related socio-cultural experiences were elicited from 4320 respondents. A total of 14 vulnerabilities factors to HIV were identified in this study and a modified Delphi technique conducted with twenty members of the National Prevention Technical Working Group was used to assign weights between 0 and 1 to each. Cronbach´s alpha coefficient for the 14 factors was 0.55. Composite score for each respondent was calculated and scores above the median score were considered as high vulnerability to acquiring HIV.
Results: Proportion of respondents aged 15-19 years old was 53.1% and majority were never-married. Nearly half of respondents (48.4%) had high vulnerability to HIV infection. High vulnerability was significantly greater (63.4%) amongst respondents aged 20-24 years compared with those aged 15-19 years (35.0%). The greatest proportion of high vulnerability was seen among respondents with no formal education (79.0%), separated/divorced/widowed (88.4%), married/co-habiting (79.0%) and those who had low self-esteem (52.7%). Lower proportion of high vulnerability was seen among those who had never taken an HIV test compared with those that had (43.2% vs. 56.6%) and those who did not have correct knowledge of HIV prevention (40.4% vs. 51.8%) compared with those who did. These findings were statistically significant (p< 0.001 in all cases).

Conclusions: Sociodemographic characteristics of young women are important determinants of vulnerability to HIV. Also knowledge of HIV alone may not always reflect vulnerability to HIV. Interventions targeted to reduce vulnerability to HIV among young women must address behavioural and social-demographic risk factors.

TUPEC238

Comorbidities and antiretroviral therapy treatment failure synergies: A case-control study in low resource settings - Kadoma, Zimbabwe 2017

S. Tapesana[1], D. Chirundu[2], G. Shambira[3], N. Gombe[4], T. Juru[4], M. Tshimanga[3]
[1]Ministry of Health and Child Care Zimbabwe, Centenary District, Harare, Zimbabwe, [2]Kadoma City Council, Health, Kadoma, Zimbabwe, [3]University of Zimbabwe, Community Medicine, Harare, Zimbabwe, [4]Ministry of Health and Child Care, Health Studies Office, Harare, Zimbabwe

Background: Antiretroviral Therapy (ART) treatment failure remains a public health concern threatening the goal of viral suppression. In Kadoma, a concomitant increase in prevalence of comorbidities (non-communicable and infectious diseases) among clients failing ART was noted from 2012-2016. An investigation to determine the role of comorbidities in ART treatment failure was conducted.
Methods: A 1:1 unmatched case-control study was conducted, a case of treatment failure defined as per World Health Organisation clinical, immunological or virological criteria. Cases and controls were randomly selected. Data collection comprised of interviews, records review, screening tests for hypertension, metabolic syndrome, diabetes, hepatitis, syphilis, cryptococosis and depression. Epi Info 7 was used to generate frequencies, proportions and means for descriptive statistics. Bivariate analysis was done to explore relationships between comorbidities and treatment failure. Logistic regression analysis was done to determine the independent factors associated with treatment failure.
Results: One hundred and eighteen cases and 118 controls were recruited. In bivariate analysis, male sex (OR=2.4, CI 1.3-4.2) and having ≥ 2 comorbidities (OR=3.1, CI 1.6-6.2), were risk factors for treatment failure whilst having ≤ 1 sexual partner in previous month (OR=0.47, CI 0.27-0.82) was protective. Tuberculosis infection (OR=2.5, CI 1.3-4.8) and oropharyngeal candidiasis (OR=4.3, CI 1.2-15.8) were predictors of treatment failure. In logistic regression analysis, reported use of dual contraception (aOR=0.44, CI 0.23-0.85) was protective whilst having detectable urobilinogen (aOR=14.82, CI 1.88-117.00) at urinalysis was a risk factor. A stronger dose response relationship was exhibited between coinfections [No coinfection OR=0.42, **1-2** coinfections OR=1.5, **≥3** coinfections OR=3.0] and ART treatment failure.
Conclusions: Although comorbidities have shown to play a role in ART failure, male sex and use of dual contraception have shown a bigger role in ART failure. These findings suggest sexually transmitted HIV drug resistance as being key to treatment failure in this setting. We recommend use of dual contraception, screening and treatment of comorbidities and a study to explore the significance of urobilinogen in treatment failure.

TUPEC239

An increase in rates of HIV infection among people who inject drugs in Petropavlovsk, Kazakhstan, 2016-2017

V. Kazakov[1], M. Izbagambet[2], A. Zhandybayeva[2], B. Baiserkin[1], D. Nabirova[3], D. Moffett[3], A. Mukhamediyev[4]
[1]Republican AIDS Center, Almaty, Kazakhstan, [2]Almaty City AIDS Center, Almaty, Kazakhstan, [3]U.S. Centers for Disease Control and Prevention, Central Asia Office, Almaty, Kazakhstan, [4]Astana City AIDS Center, Astana, Kazakhstan

Background: Drug injection is a major driver of HIV infection in Kazakhstan with HIV prevalence among people who inject drugs (PWID) from 9.3 to 26.5% in different regions. Between July 2016 and May 2017, 256 new cases of HIV were reported among PWID in a northern Kazakhstan region, and local authorities were concerned the cases were linked to an influx

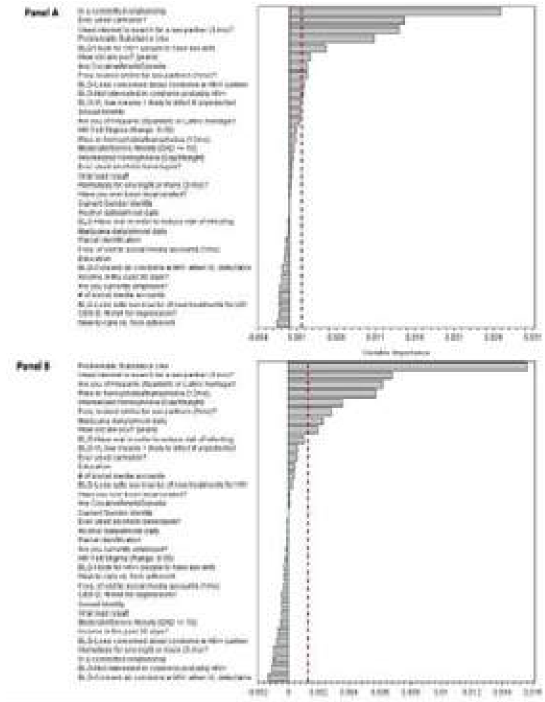
of synthetic drugs ("bath salts"). These cases accounted for 31% of HIV infection attributed to drug injection in the country. Of the 256 cases, 244 (95%) were detected in Petropavlovsk City. We aimed to identify factors associated with this increase in HIV infection.
Methods: Between June and July 2017, we performed a case-control study among PWID aged ≥18 years in Petropavlovsk. Cases with a new HIV+ test after July 1, 2016 and HIV- controls were identified through active surveillance and contact tracing. Participants responded to a questionnaire on demographics and sexual/drug injecting behaviors. Controls received serologic testing for HIV. Logistic regression was used to examine the association of exposures with HIV infection.
Results: Prevalence of risk behaviors was high among 73 cases and 111 controls, with mean duration of drug injection 10 and 12 years (range 3-19 and 4-20) respectively. In multivariate regression, heroin injection (adjusted odds ratio [AOR]=6.9, 95% confidence interval [CI] 1.1-135.1), bath salts use (AOR=3.6, 95% CI 1.4-10.4), sharing syringes (AOR 3.5, 95% CI 1.6-8.1), invasive medical procedures (AOR=3.5, 95% CI 1.4-9.3), and condom use (AOR=0.2, 95% CI 0.1-0.9) were strongly associated with HIV infection.
Conclusions: Heroin and bath salts use, sharing syringes and invasive medical procedures are key factors of HIV infection in Petropavlovsk. Scale-up of unlimited access to harm reduction commodities, HIV testing and treatment for PWID as well as strengthened hospital infection control are recommended to reduce HIV transmission risk in Petropavlovsk.

TUPEC240

Predictors of condomless sex among non-suppressed adolescent MSM and transgender women in the United States

S. Legrand[1], A. Platt[1], K. Muessig[2], J. Egger[1], K. Soni[3], L. Hightow-Weidman[3]
[1]Duke University, Duke Global Health Institute, Durham, United States, [2]University of North Carolina-Chapel Hill, Health Behavior, Chapel Hill, United States, [3]University of North Carolina-Chapel Hill, Medicine/ Infectious Diseases, Chapel Hill, United States

Background: A minority of HIV+ youth in the United States achieve viral suppression, with rates lower for Black young men who have sex with men (YMSM). Elevated viral loads (VLs) increase the likelihood of viral transmission during condomless anal intercourse (CAI).
Methods: From 10/2015 to 9/2016, HIV+ YMSM and transgender women (TW) who have sex with men (age 16-24) with detectable VLs were enrolled in a smartphone app-based antiretroviral therapy (ART) adherence intervention. Baseline data, stratified by any CAI and any serodiscordant CAI, were computed. Random Forests and regression methods were used to determine covariates of importance for predicting each type of CAI. Prevalence rate ratios and 95% confidence intervals were calculated.
Results: 146 participants enrolled; median age was 21.5 years; 50.7% started ART within past 12 months. Median VL was 4096 copies/ml. Most identified as male (93.2%), gay (77.4%) and Black (75.3%). The population exhibited high rates of problematic substance use (49.3%); 32.9% reported daily marijuana use. Half (51.9%) reported engaging in CAI in the past 3 months; 57.1% of those reported serodiscordant CAI. Significant predictors of CAI (Figure 1A) included any marijuana use, problematic substance use and being in a committed relationship. Youth with problematic substance use were 3x more likely to engage in serodiscordant CAI (p=0.001) (Figure 1B). Youth with higher internalized homophobia were more likely to engage in both CAI (p=0.02) and serodiscordant CAI (p=.011). There was no association between HIV transmission beliefs and serodiscordant CAI. Only 47% of participants endorsed the belief that they were less likely to infect another person through CAI if they had a low or undetectable VL.
Conclusions: High rates of CAI and serodiscordant CAI among HIV+ YMSM/TW with detectable VLs is concerning. In addition to being associated with CAI, substance use can negatively impact ART adherence; thus, multifaceted interventions that address conditions impacting HIV+ YMSM/TW is critical. CAI among those in relationships argues for a better understanding of communication patterns, relationship formation and dissolution that could guide interventions to increase protective behaviors among both partners. Addressing internalized homophobia through individual and structural methods, including promotion of messaging reinforcing "undetectable=untransmittable", should be targeted to YMSM/TW.



[Random Forest Variable Importance for Predictors of Any CAI (Panel A) and Serodiscordant CAI (Panel B). Dotted line at absolute value of minimum variable importance score.]

TUPEC241

Key drivers of the changing HIV/AIDS epidemic in North-East of India

R. Adhikary
Consultant - WHO/India, Gurgaon, India

Background: The HIV/AIDS epidemic in North-East of India started in early 1990s and until recently it was mainly driven by injecting drug use. However, some recent research studies as well as new evidences indicate that the epidemic in North-East of India, particularly in the states of Mizoram and Nagaland, is transitioning from an injecting drug use to a heterosexual epidemic. Urgent need was felt to assess and understand the underlying socio-eco-demographic, cultural and epidemiological factors of the HIV epidemic there.
Methods: The methodology of the assessment included three components:
(1) extensive review of existing literature (both published as well as non-published)
(2) in-depth analysis of available secondary data including huge amount of program data e.g. ICTC data, ART data etc. and other data sources like HSS, IBSS etc.
(3) discussions with key policy makers, program managers at national as well as state levels. Mizoram and Nagaland were covered in the first phase of the assessment. The first phase of the assessment was undertaken from Oct 2016 to Jan 2017.
Results: In Mizoram, the key drivers of the changing HIV epidemic include very high HIV prevalence among injecting drug users in some districts, high degree of casual sex, very low condom use, recent disruptions in program interventions, low treatment coverage, high lost-to-follow up of HIV positive cases, non-coverage certain important vulnerable groups and repeal of the Mizoram Liquor Total Prohibition Act. Whereas, in Nagaland, the key identified drivers of the changing epidemic are high STI prevalence among key populations, significant overlap between injecting drug use and commercial sex work, high degree of unprotect-

ed casual sex, late identification of positive cases and absence of Link Worker Scheme, an effective HIV intervention program in rural areas. All these key drivers are identified based on in-depth analysis of program data as well as other available data sources.
Conclusions: The findings clearly indicate that a more comprehensive intervention strategy needs to be adopted immediately to respond to the changing epidemic scenario in North-East of India. The sexual risk behaviours need to be addressed urgently with an equal priority.

TUPEC242

Depressive symptoms, substance use and sexual risk behaviors among Black men who have sex with men (MSM)

F.S. Winterhalter[1], J. Franks[1], Y. Hirsch-Moverman[1,2], H. Ortega[1], Y. Wu[1], J. Knox[2], W. El-Sadr[1,2], P.W. Colson[1]
[1]ICAP, Columbia University, New York, United States, [2]Columbia University Mailman School of Public Health, Department of Epidemiology, New York, United States

Background: MSM experience elevated rates of depression, which is associated with risk factors for HIV infection, including substance use and sexual risk. Depression in racial minority MSM is not well-studied and may contribute to persistently high HIV rates among black MSM in the United States (US). We explore the prevalence and correlates of depressive symptoms in HIV-negative US MSM enrolled in a pre-exposure prophylaxis (PrEP) study.
Methods: Participant inclusion criteria were self-identified black MSM who screened eligible for PrEP. Participants with a CES-D score ≥16 were considered to have depressive symptoms. Problematic drug use was measured with the TCU Drug Screen II (score ≥3), and problematic alcohol use with the Alcohol Use Disorders Identification Test (AUDIT, score ≥8). Structured interviewer-administered questionnaires were used to assess sexual risk behaviors, including transactional sex (giving or receiving goods such as money, alcohol, or drugs in exchange for sex with main sexual partners [MSP] and other partners) and condomless sexual intercourse with MSP and other partners. Comparisons between groups were measured using Student's t-tests, Chi-square tests, or Fisher's Exact tests, as appropriate.
Results: Among 193 MSM enrolled, 44.0% reported depressive symptoms; 16.6% reported problematic alcohol use and 15.0% reported problematic drug use. 17.7% of participants reported condomless sex with MSP and 11.8% reported engaging in transactional sex. Depressive symptoms were significantly associated with problematic drug use (p=0.0002), condomless intercourse with MSP (p=0.02) and transactional sex (p=0.008). Participants with depressive symptoms were at an almost 4-fold higher risk for problematic drug use [RR (95% CI): 3.99 (1.79 - 8.90)] compared to those without, a 1.5-fold higher risk of not using a condom with MSP [RR (95% CI): 1.49 (1.06 - 2.09)], and a 13-fold higher risk of exchanging goods for sex with other partners [RR (95% CI): 13.06 (1.73 - 98.63)].

Outcome	Crude RR (95% CI) for Outcome (Depressive symptomatology as predictor in bivariable association)	Fisher Exact or Chi-Square p-value (* indicates p-value < 0.05)
Problematic Alcohol Use	0.99 (0.52 - 1.87)	0.97
Problematic Drug Use	**3.99 (1.79 - 8.90)***	**0.0002***
Sexual Risk Behaviors:		
Condom Not Used During Last Sex with Main Partner	**1.49 (1.06 - 2.09)***	**0.02***
Last 30 Days:		
Transactional Sex with Main Partner (Receiving goods such as money, alcohol, or drugs in exchange for sex)	Statistic non-estimable due to zero cell counts	-
Transactional Sex with Main Partner (Giving goods such as money, alcohol, or drugs in exchange for sex)	Statistic non-estimable due to zero cell counts	-
Transactional Sex with Other Partner (Receiving goods such as money, alcohol, or drugs in exchange for sex)	2.35 (0.84 - 6.57)	0.09
Transactional Sex with Other Partner (Giving goods such as money, alcohol, or drugs in exchange for sex)	**13.06 (1.73 - 98.63)***	**0.001***

[Associations between depressive symptomatology, substance use and sexual risk behaviors among MSM at baseline (N=193)]

Conclusions: Depressive symptomatology was highly prevalent in this population of black MSM eligible for PrEP and was associated with problematic substance use and sexual risk. Our findings highlight the need for mental health services in this highly HIV-impacted population. Addressing depression and substance use in this vulnerable population may strengthen PrEP and other HIV prevention efforts.

TUPEC243

Factors associated with sexually transmitted infections among sexually active U.S. Navy and Marine Corps personnel across a shipboard deployment

J. Harbertson[1,2,3], P. Scott[4], Y. Li[4], N. Michael[4], B. Hale[2,5]
[1]US Military Research Program, San Diego, United States, [2]Defense Health Agency, Department of Defense HIV/AIDS Prevention Program, San Diego, United States, [3]Leidos, Inc., San Diego, United States, [4]Walter Reed Army Institute of Research, Silver Spring, United States, [5]UC San Diego, La Jolla, United States

Background: Longitudinal data are limited on risk factors associated with sexually transmitted infections (STIs) in deploying military populations who may acquire or transmit STIs transnationally. This study examined factors associated with STIs 12 months prior to international deployment departure (T1), during deployment (T2), and within 3 months of returning from deployment (T3) among US military personnel.
Methods: Data were collected among active duty U.S. Navy and Marine Corps personnel assigned to 11 deploying ships using an anonymous, voluntary, self-report survey, including questions on demographics, chlamydia, gonorrhea, trichomoniasis, or syphilis diagnosis by a healthcare provider, transactional sex, alcohol misuse, and drug use. Descriptive and generalized regression model analyses were conducted to determine the effects of main exposures after adjusting for sex, age, race, marital status and education. When longitudinal data were included, generalized estimating equations were used.
Results: Among 2,400 participants, 2,232 (T1), 649 (T2), and 1,200 (T3) met inclusion criteria (ie, reported age, sex and that they were sexually active in the relevant time interval) and were accordingly included in analysis. The proportion of sexually active individuals with a STI diagnosis was 2.8% (n = 63/2232, T1), 6.8% (n = 44/649, T2), and 2.3% (n = 28/1200, T3). After adjusting for demographics, participants with an STI diagnosis had significantly higher odds of screening positive for severe alcohol misuse, reporting transactional sex, MSM/ MSMW anal sex, and drugs with sex. The association between risk factors and STI diagnosis significantly varied by timepoint.
Conclusions: The majority of STIs were reported before or after international deployment, but there was a higher proportion of STIs reported among those sexually active during deployment. Proportions of STIs were substantially higher among individuals engaged in behaviors that could be screened for before and during deployment. Individuals that screen positive for these risk behaviors could receive differentiated care, more frequent STI testing, and provision of other supportive care (substance abuse or mental health resources, safer sex education) to possibly mitigate STI transmission risk while deployed internationally. These data may be relevant to other militaries who support international peacekeeping or deploying personnel.

TUPEC244

Trajectories of physical intimate partner violence among adolescent girls in rural South Africa: Who is at consistently high risk? (HPTN068)

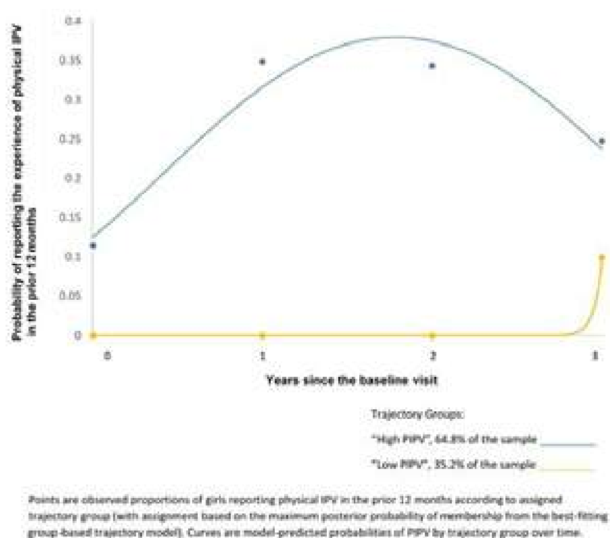
S.M. DeLong[1], K.A. Powers[1], B.W. Pence[1], S. Maman[2], K.L. Dunkle[3], A. Selin[4], R. Twine[5], F.X. Gómez-Olivé[5], C. MacPhail[6], K. Kahn[5], A. Pettifor[1,4,5]
[1]University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Department of Health Behavior, Chapel Hill, United States, [3]South African Medical Research Council, Pretoria, South Africa, [4]Carolina Population Center, University of North Carolina at Chapel Hill, Chapel Hill, United States, [5]MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Faculty of Health Sciences, School of Public Health, University of the Witwatersrand, Johannesburg, South Africa, [6]University of Wollongong, New South Wales, Australia

Background: Adolescent girls are at high risk of HIV in South Africa, and intimate partner violence (IPV) is considered an important risk factor. Little is known about how IPV develops differently across individuals over time and what predicts those experiences.

Methods: We identified longitudinal trajectories and related baseline predictors of physical IPV (PIPV) among adolescent girls in the MRC/Wits-Agincourt Health and socio-Demographic Surveillance Site, South Africa. Data came from HPTN068, a randomized controlled trial of conditional cash transfers for HIV prevention. Adolescent girls in grade 8 or 9 in 2011 (baseline visit) who had at least three annual assessments for PIPV (yes/no in the prior 12 months) were included in the analysis (n=907). We used group-based trajectory modeling to identify latent groups with different temporal patterns of PIPV and simple logistic regression to assess baseline predictors of group membership.

Results: We identified two distinct PIPV trajectories among adolescent girls. A "High PIPV" group, comprising an estimated 64.8% of the population, was characterized by an increase in the predicted probability of PIPV from ~12.5% to ~31.6% over the first year, followed by a probability of ~37.5% and ~23.7% thereafter. The "Low PIPV" group, comprising an estimated 35.2% of the population, had a 0% probability of reporting PIPV for the first two years, followed by an increase to ~10% between years 2 and 3 (Figure 1). Girls in the high group were more likely to report at baseline that they had ever had vaginal or anal sex (unadjusted odds ratio [uOR]= 2.78; 95% CI: 1.88, 4.12); had unprotected sex in the prior 3 months (uOR= 2.52; 95% CI: 1.14, 5.57); had ever had transactional sex (uOR= 7.54; 95% CI: 1.70, 33.37); or had an older partner (uOR= 2.84; 95% CI: 1.24, 6.48).

Conclusions: Longitudinal patterns of PIPV varied among adolescent girls, with nearly two-thirds experiencing a consistently high probability of PIPV. Targeted intervention strategies tailored to those at higher risk could maximize reductions in PIPV.



[Figure 1. Physical IPV Trajectories among Adolescent Girls in the MRC/Wits-Agincourt HIV and socio-Demographic Surveillance Site, South Africa]

TUPEC245

"Probable seroconversion" is associated with having non-tested positive people who inject drugs (PWID) in the referral chain

I. Sazonova[1], P. Smyrnov[2], S. Friedman[3]
[1]Alliance for Public Health, Monitoring and Evaluation, Kyiv, Ukraine, [2]Alliance for Public Health, Kyiv, Ukraine, [3]Institute for Infectious Diseases Research National Development and Research Institutes, Inc., New York, United States

Background: Timely HIV detection to increase the number of people who know they are infected can reduce mortality and new infections. Analysis of PWID network structure may enhance case finding rates.

Methods: We analyzed2013 Ukrainian integrated bio-behavioural surveillance (IBBS) data for PWID for "probable seroconversion", which we defined as a current positive HIV test with a self-reported prior HIV-negative test.

We used logistic regression to analyze association between seroconversion status of PWID and HIV test results of peers immediately adjacent in the recruitment chain. A participant X is adjacent to participant Y if one of them was recruited by the other's coupon.

Results: 9502 PWID participated in IBBS 2013, of whom 6,255 PWID had prior HIV testing experience; 4,860 of these reported their most recent prior HIV test was negative. Comparing them with HIV testing results within the study, 238 probable seroconversions were found. In multivariate logistic regression, having either at least one HIV-positive PWID with previously unknown serostatus (AOR=2.07; CI: 1.46-2.93) was a predictor of probable seroconversion.

Having a PWID in the referral chain who shared syringe during last injection (AOR=2.46; CI: 1.21-5.00), as well as having only female PWID in the recruitment chain (AOR=1.66; CI: 1.03-2.68) also increase the odds for probable seroconversion.

Conclusions: PWID in Ukraine continue to have substantial HIV seroconversion rates, particularly if their peers include HIV-positive PWID who practice high-risk injection behaviour. HIV case finding that incorporates innovative network tracing techniques may be more effective.

TUPEC246

Replicable research on anal sex amongst female sex workers in India towards initiation of effective HIV prevention interventions across continents

A.P. Singh, R. Rani
Global Science Academy, AIDS Cell, Basti, India

Background: Anal-sex between men and women has not received much attention as anal-intercourse between men. However, it plays an important role in HIV transmission amongst heterosexuals. This study attempts not only to explore the occurrence and drivers of anal sex practices amongst Female Sex Workers (FSWs) in India but also to authentically provide new insights and base for future research.

Methods: Pre-tested questionnaire (translated and validated in Hindi and Kannada languages) was administered for interview by involving 120 FSWs from two important states of India namely Uttar Pradesh (UP) and Karnataka representing northern and southern India. Basti district, UP and Belgaum district, Karnataka were the study locations (60 FSWs from each state/district). Mean age of FSWs were 29.6 years (18 years-39 years) for UP while 32 years (20-42 years) for Karnataka. Informed consent was obtained from participants. Overall, study was conducted during 16thAugust 2017 to 15thNovember 2017.

Results: Data analysis revealed that 29% of FSWs had anal sex with clients and 66% used condom during their last anal sex in Karnataka while these ratios were 28% and 62% for UP. Dangerous misconception was observed prevailing amongst FSWs that anal sex is safer in terms of STI/HIV infection for which 56 out of 60 i.e. 93.3 % in Karnataka and 81.6% in UP FSWs considered it safe while this percentile was relatively high amongst illiterate respondents in Karnataka (31.6%) and UP (29.6%).

Multivariate analysis further showed that risk of pregnancy, preserving appearance of virginity, avoidance of contact with menstrual blood, sake of enhanced physical pleasure, experimentation as a matter of taste,

misconception that anal sex was safer, perception that loose vagina after child-birth minimizes pleasure as well as economic coercion were significant reasons of anal sex amongst FSWs.

Conclusions: There observed transactional anal-sex occurrences with FSWs at all the study locations. Findings showed significant anal-sex practices with intermittent condom use, lack of access to appropriate lubricants (for anal sex among FSWs) and low awareness of the associated risks amongst FSWs. This presents a serious threat to the health of FSW, their clients and is likely to be significant contributor to HIV transmission.

TUPEC247

Increased methamphetamine use in Hai Phong, Vietnam and associations with sexual and injection risk behaviors among persons who inject drugs, 2016-2017

J. Feelemyer[1], H. Duong Thi[2], K. Pham Minh[2], G. Hoang Thi[2], T. Thi Tuyet[3], O. Khuat Thi Hai[3], K. Arasteh[1], J.P. Moles[4], V. Vu Hai[5], R. Vallo[4], C. Quillet[4], D. Rapoud[4], L. Michel[6], T. Hammett[7,8], D. Laureillard[4,9], N. Nagot[4], D. Des Jarlais[1]
[1]Icahn School or Medicine at Mount Sinai, Psychiatry, New York, United States, [2]Hai Phong University of Medicine and Pharmacy, Haiphong, Vietnam, [3]Supporting Community Development Initiatives, Hanoi, Vietnam, [4]University of Monpellier, Inserm U 1058, Etablissement Français du Sang, Montpellier, France, [5]Viet Tiep Hospital, Dept of Infectious and Tropical Diseases, Haiphong, Vietnam, [6]Pierre Nicole Center, French Red Cross, CESP/Inserm 1018, Paris, France, [7]Abt Associates, Cambridge, United States, [8]Consultant to Icahn School of Medicine at Mount Sinai, New York, United States, [9]Caremeau University Hospital, Infectious Disease Dept, Nimes, France

Background: Methamphetamine is associated with both injection and sexual risk behaviors. The use of methamphetamine has increased significantly in Vietnam in the last 10 years. This study examines effects of increased methamphetamine use on an existing HIV epidemic among heterosexual persons who inject drugs (PWID) in Haiphong, Vietnam, with specific focus on potential sexual transmission of HIV.

Methods: Using respondent driven sampling (RDS), we recruited persons currently injecting drugs. Participants were administered a quantitative questionnaire on risk behaviors and were tested for HIV and hepatitis C virus (HCV). Bivariate and multivariable logistic regression assessed associations between current (in last 30 days) methamphetamine use, injection risk and sexual risk behaviors.

Results: We recruited 1336 heterosexual PWID in 2016-2017; they were predominately male (94%), injected heroin (~100%) and 51% reported current methamphetamine use. In the previous six months, among those sexually active (54%), 71% reported unsafe sex with any partners and among those with primary partners (45%), 79% reported unsafe sex with their primary partners. In multivariable analysis, current methamphetamine use among HIV seropositives was associated with any unsafe sex (AOR 2.30, 95% CI: 1.20-4.42) and unsafe sex with primary partners (AOR 2.43, 95% CI: 1.15 - 5.10). Current methamphetamine use was not associated with unsafe sex among HIV seronegatives. Methamphetamine use was not associated with injection risk behavior among either HIV seropostives or seronegatives.

Conclusions: The association with current methamphetamine use and potential sexual transmission of HIV in Haiphong is of considerable concern. Methamphetamine increases the likelihood of PWID transmitting HIV to non-injecting primary sexual partners. Methamphetamine use can also reduce adherence to ART and can lead to exhaustion of the immune system. All participants were injecting heroin, and methamphetamine use may interfere with opiate use treatment. Public health efforts should focus on the large increase in methamphetamine use and the associated sexual risk behaviors. Emphasis on sexual risk behavior, particularly among those that are HIV positive, in conjunction with continued monitoring of ART adherence and HIV viral loads will be critical.

TUPEC248

Predictors of abstinence and condom use among rural youth and adults in Malawi

D.L. Jere[1], C. Banda[1], L. Kumbani[1], L. Liu[2], L.L. McCreary[3], C.L. Patil[4], K.L. Norr[4]
[1]University of Malawi, Kamuzu College of Nursing, Blantyre, Malawi, [2]University of Illinois at Chicago, Epidemiology and Biostatistics, Chicago, United States, [3]University of Illinois at Chicago, Health System Sciences, Chicago, United States, [4]University of Illinois at Chicago, Women, Children & Famiiy Health Sciences, Chicago, United States

Background: Abstinence and condom use are effective strategies for reducing new infections, but they are seldom examined together or for both youth and adults. We compared abstinence and condom use predictors among youth and adults in a high-prevalence rural district in southern Malawi.

Methods: Baseline surveys of 544 youth (ages 15-19) and 410 adults from a community HIV prevention study were used. Dependent variables were abstinence and condom use (among sexually active individuals) in the past 2 months. Predictors were age, education, in school (youth only), religion, religious involvement, HIV-related knowledge (9 items), self-efficacy (4 safer-sex items, range 0-12) and partner communication (4 safer-sex topics, range 0-4). Logistic regression and ordinal proportional odds logistic regression models were conducted, for abstinence and condom use respectively, with backward selection, controlling for a two-sided Type I error probability of 0.05.

Results: Mean age was 16 for youth and 35 for adults. Mean education was 8.8 years for youth and 8.1 for adults. 77% of youth were in school. Both youth and adults were half female, 70% Protestant, and had high religious involvement (66%), knowledge and self-efficacy scores. Mean partner communication was 2.8.

Among youth, 48% abstained. Younger age, more education, currently in school and high religious involvement were significantly associated with abstaining. (Table 1). Among sexually active youth, 52% always used condoms and 34% used sometimes. Being older, in school and partner communication predicted more condom use.

Variable	Youth If Abstained (n = 544)	Youth Condom Use (n = 138)	Adult If Abstained (n = 410)	Adult Condom Use n = 302
Age	0.74 (0.65, 0.85)	1.36 (1.02, 1.81)	1.06 (1.02, 1.09)	N.S.
Gender	1.18 (1.08, 1.29)	2.71 (1.26, 5.81)	8.22 (3.24, 20.84)	N.S.
Education (Yrs.)	1.80 (1.13, 2.86)	2.71 (1.26, 5.81)	N.S.	N.S.
In School Now	1.80 (1.13, 2.86)	2.71 (1.26, 5.81)	--	--
Religion	N.S.	N.S.	N.S.	N.S.
Religious Involvement	1.65 (1.15, 2.36)	N.S.	N.S.	1.97 (1.21, 3.21)
HIV-Related Knowledge	N.S.	N.S.	N.S.	N.S.
Self-Efficacy	N.S.	N.S.	N.S.	1.22 (1.04, 1,43)
Partner Communication	--	1.60 (1.10, 2.31)	--	2.06 (1.68, 2.58)

[Table 1. Abstaining and condom use among sexually active persons for rural youth and adults (Odds Ratios and 95% Confidence intervals)]

Among adults, 12% abstained; older adults and females were more likely to abstain. Among sexually active adults, 29% always used condoms and 37% used sometimes. Greater religious involvement, self-efficacy and partner communication predicted more condom use.

Conclusions: Findings have important implications for HIV prevention. Half of youth are abstaining, and being in school is associated with abstinence and condom use. Therefore youth programs and policies should emphasize both prevention strategies and continued education. HIV prevention should emphasize partner communication skills, a modifiable factor affecting condom use regardless of age. Gender related only to adult abstinence, indicating the importance of prevention for both genders. Religious involvement affected youth abstinence and adult condom use, warranting further exploration of collaboration with religious organizations.

TUPEC249

Accuracy of HIV risk perception in east Zimbabwe 2003-2013

R. Schaefer[1], S. Gregson[1,2], R. Thomas[1], C. Nyamukapa[1,2]
[1]Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom, [2]Biomedical Research and Training Institute, Harare, Zimbabwe

Background: Perceiving a risk for HIV infection is an important determinant for engaging in HIV prevention behaviour, particularly for adherence to prevention technologies like condoms and daily pre-exposure prophylaxis (PrEP). However, the degree to which HIV risk perception is accurate, i.e. corresponds to actual HIV infection risks, is unclear and there is a lack of longitudinal studies using objectively determined HIV data to test for associations between risk perception and HIV incidence.
Methods: Interview data and HIV test results from four surveys of a general-population open-cohort study in Zimbabwe were used (2003-2013). Participants (15-54 years) who participated in multiple surveys and were HIV-negative at the start of the period between surveys were included. Reported HIV risk perception (yes/no) at the beginning of the inter-survey period was tested for association with HIV infection in Cox regressions, controlling for age, sex, background characteristics, and sexual behaviour. Interaction terms tested whether associations between risk perception and HIV incidence changed over time or differed by demographic and behavioural variables.
Results: 7198 individuals contributed 31326 person-years and 343 HIV infections. Overall, 13.0% of males (95% confidence interval=11.9-14.1%) and 47.5% (46.4-48.7%) of females perceived a risk of HIV infection, with decreasing trends over time. Risk perception was higher among those with ≥2 sexual risk factors (males: 22.9% [19.6-26.6%]; females: 55.1% [41.9-67.7%]). HIV incidence was higher among those perceiving a risk (HIV incidence=1.27%) compared to those who did not (0.96%) (hazard ratio=1.34 [1.05-1.72], adjusting for age, sex, survey round, and study site). The association remained significant after controlling for background characteristics and/or sexual behaviour (Table) and was stronger among older people (25+ years) and in earlier surveys.
Conclusions: People perceiving a risk of HIV are at an objectively higher risk of infection in east Zimbabwe. However, HIV incidence is also high in those not perceiving a risk and risk perception is low even among those reporting risky sexual behaviour. These results are particularly concerning given that HIV incidence remains high in young women, while accuracy of risk perception is lower in this group. Innovative interventions, such as recently developed applications from behavioural economics, are needed to improve accuracy of risk perception.

		aHR	95% CI	aHR	95% CI	aHR	95% CI
	Infections/pyrs (IR per 100 pyrs)	Model 1 (n=10732)		Model 2 (n=10494)		Model 3 (n=10049)	
Risk perception: No	191/19884 (0.96)	1 (Reference)		1 (Reference)		1 (Reference)	
Risk perception: Yes	144/11348 (1.27)	1.34	(1.05-1.72)	1.41	(1.11-1.80)	1.33	(1.03-1.72)
Values are new HIV infections per person-years (pyrs), crude incidence rates per 100 person-years (IR per 100 pyrs), adjusted hazard ratios (aHR), 95% confidence intervals (CI), and p-values. The covariate results are not shown. Results are based on 30 imputed random dates of HIV infection between surveys. Participants were censored at their 55th birthday. Model 1: Age, sex, survey round, study site; Model 2: Age, sex, marital status, educational attainment, household wealth index, survey round, study site; Model 3: Age, sex, sexual risk factors, condom use (during last sex), partner has other partners

TUPEC250

Drivers of HIV infection in Botswana: Implications for treatment and prevention

J. Okano[1], K. Sharp[1], L. Busang[2], B. Fidzani[2], F. Mwangemi[2], S. Blower[1]
[1]University of California, Los Angeles, United States, [2]African Comprehensive HIV/AIDS Partnership, Gaborone, Botswana

Background: Botswana has one of the most severe HIV epidemics worldwide; in 2013, 23% of 15 to 69 year olds were infected. The population of Botswana is predominantly urban: 16% live in cities, 5% in towns, 43% in urban villages, 35% in rural villages and 1% are nomadic.
Methods: We analyzed data from the Botswana AIDS Impact Survey IV, a national representative survey of 5,415 households conducted in 2013 using a two-stage stratified sampling framework. 3,356 women and 2,745 men were tested for HIV. We conducted a multivariate analysis to identify gender-specific risk factors for HIV infection. We calculated age-adjusted odds ratios (aOR) with 95% confidence intervals (CIs).
Results: In 2013, overall prevalence was higher in women (26%) than men (20%). Prevalence was highest in women 35-39 years old (50%) and men 45-49 years old (42%). Living in cities was found to be much riskier than living in towns for both women (aOR 1.78 [95% CI, 1.04-3.04]) and men (aOR 2.10 [95% CI, 1.13-3.82]). Co-infection with other sexually transmitted infections was also a risk factor for both women (aOR 1.69 [95% CI, 1.24-2.30]) and men (aOR 2.19 [95% CI, 1.41-3.39]). For women, we found an additional risk factor: having a current male partner who was ten or more years older (aOR 1.51 [95% CI, 1.00-2.25]). For men, we found that medical circumcision was effective in preventing HIV infection (aOR 0.52 [95% CI, 0.34-0.79]), but traditional circumcision was not (aOR 0.98 [95% CI, 0.47-1.96]). 22% of men were circumcised, 84% of these medically, Figure. Notably, neonatal levels of circumcision were low (~10%).
Conclusions: There are significant differences in HIV prevalence in Botswana based on geography, gender, and age. HIV prevention, treatment and care services should take these differences into consideration. There is an urgent need to treat STIs, this would both decrease susceptibility to, and transmission of, HIV. Prevention programs need to not only target women with high numbers of partners, but women who are having sex with much older men. Scaling up medical circumcision, a current goal of the government of Botswana, is very likely to have a substantial impact on decreasing HIV transmission.

TUPEC251

Exploring gender-based violence experienced by female sex workers in Gaborone, Botswana

K.M. Maribe[1], A. Geltman[2], K. Francis[3], N.N. Monnapula[1], D.G. Richard-Jackalasi[4]
[1]Nkaikela Youth Group, Program Department, Gaborone, Botswana, [2]Pitzer College, Public Health, California, United States, [3]Nkaikela Youth Group, Coodinator, Gaborone, Botswana, [4]Nkaikela Youth Group, Administration and Procurement, Gaborone, Botswana

Background: Female sex workers (FSW) are disproportionately affected by HIV in Botswana, with an HIV prevalence rate of 61.9% compared to the 19.2% within the female general population. Amongst other variables correlated with HIV, a link exists between Gender Based Violence (GBV) and HIV. In Botswana, 1 in 3 women experience GBV, but little has been documented on the experiences of GBV among sex workers. The objective of this study is to explore the experiences of GBV among FSW's in Gaborone and their subsequent increased risk of HIV infection.
Methods: Overall, 20 FSW's from Gaborone shared their experiences of GBV through 10 in-depth interviews and 2 focus group discussions between November and December 2017. On average each interview session lasted 30 minutes, while focus group discussions lasted 45 minutes. The participants were purposely sampled from Nkaikela Youth Group (NYG), a non-government organization providing FSW friendly services. Data was collected, transcribed, and analyzed using thematic analysis by a NYG social worker and an intern from Pitzer College.
Results: GBV was identified to be one of the variables that promotes entry into sex work. Of the 20 respondents, 25% cite that their introduction into sex work was somewhat influenced by experiences of GBV. In addition, sex work has been found to expose FSW's to abuse, with

100% of respondents having reported experiencing GBV by their clients. Results revealed 70% of FSW's experienced physical violence, while 90% experienced sexual violence from clients. Forced sexual interactions are not perceived as rape by FSW's unless they are not paid afterwards. These experiences are normalized as part of the job and often not reported to the police because of the illegality of sex work in Botswana. Experiencing sexual and emotional violence contributed to FSWs' inability to negotiate safer sex, thus increasing their risk of exposure to HIV. Of the 20 respondents, 55% were HIV positive.

Conclusions: High incidence of GBV and its normalization are key variables influencing the disproportionate prevalence of HIV among sex workers. Targeted violence prevention programs, psycho social support and advocacy interventions for legal reforms are necessary in programming for FSW.

TUPEC252

Relationship between intimate partner violence and risk behaviors for HIV/STIs among Black women accessing publicly funded STD clinics in Baltimore, MD, USA

A.E. Servin-Aguirre[1,2], K. Tsuyuki[2], J. Campbell[3], A. Cimino[3], J. Stockman[2]
[1]*Centro de Estudios Universitarios Xochicalco, Medicine, Tijuana, Mexico,* [2]*University of California, San Diego, Medicine, La Jolla, United States,* [3]*Johns Hopkins University, School of Nursing, Baltimore, United States*

Background: In the United States (U.S.), Black women bear the greatest burden of both HIV infection and sexually transmitted infections (STIs). Further, previous research suggests that intimate partner violence (IPV) is linked to HIV/STI risk and infection among heterosexual women. However, few studies have examined associations between recent IPV and increased HIV/STI risk behaviors among Black women in geographic areas with high HIV prevalence in the U.S. The goal of the proposed study was to examine associations between recent IPV and risk behaviors for HIV/STI risk behaviors among Black women in Baltimore, MD.

Methods: A cross-sectional survey was conducted with Black women ages 18-44 (n=265) seeking health care at government funded STD clinics in Baltimore, MD, USA from November 2014 to December 2017. The survey assessed sociodemographic characteristics, recent and past IPV (physical and forced sex), substance abuse, history of incarceration and HIV/STI sexual risk behaviors. Multivariate logistic regression models were conducted to determine whether recent IPV (physical and/or forced sex) were associated with risk behaviors for HIV/STIs.

Results: The mean age was 26.6 years, 27.2% were married and 64.3% were living at or below the federal poverty level. Furthermore, 1.52% reported being HIV-positive,17% reported not knowing their HIV status and 74% reported ever testing positive for an STI (e.g., chlamydia, gonorrhea, syphilis, hepatitis B, hepatitis C, trichomonas, herpes). Recent IPV (physical violence and/or forced sex in the past 12-months) was reported by 32.3% of the women. In logistic regression models adjusted for age, education, and relationship status women who reported experiencing recent IPV were more likely to report in the past 12-months using illicit drugs (AOR=3.56, 95% IC=1.75,7.23); having an STI (AOR=1.08, 95% IC=1.03, 1.27), engaging in unprotected vaginal or anal sex (AOR=1.32, 95% IC 1.06, 1.64) and having a higher number of concurrent sex partners (AOR=1.80, 95% CI=1.04, 3.13).

Conclusions: IPV was common among study participants and were associated with greater HIV/STI risk behaviors. Future efforts should focus on prevention (e.g. Prep) and advocacy interventions among Black women experiencing and/or at risk for IPV and HIV/STIs when they are coming as they are coming into care at STI clinics.

TUPEC253

Dose-response relationships between substance use frequency, self-reported involvement in sexual HIV transmission behaviors and HIV viral load among men who have sex with men in Los Angeles

B. Quinn[1,2], K. Arfer[3], P. Gorbach[4], S. Shoptaw[5]
[1]*Burnet Institute, Behaviours and Health Risks Program, Melbourne, Australia,* [2]*University of California, Center for Behavioral & Addiction Medicine, Los Angeles, United States,* [3]*University of California, Los Angeles, United States,* [4]*University of California, Department of Epidemiology, Fielding School of Public Health & Division of Infectious Diseases, David Geffen School of Medicine, Los Angeles, United States,* [5]*University of California, David Geffen School of Medicine, Department of Family Medicine, Los Angeles, United States*

Background: Despite demonstrated links between the use of such drugs as illicit stimulants, alcohol and alkyl nitrite and HIV-related outcomes among men who have sex with men (MSM), limited research has explored the possibility of dose-response relationships between substance use and involvement in sexual HIV transmission behaviors and HIV disease progression among this group. We investigated whether more frequent use of methamphetamine, cannabis and amyl nitrites, and a higher frequency of heavy alcohol consumption, was associated with: 1) Self-reported involvement in sexual HIV transmission behaviors (last anal sex partner in past three months) among both HIV-positive and HIV-negative MSM; and, 2) Having a detectable viral load among HIV-positive MSM.

Methods: Data were sourced from the *mSTUDY*, an ongoing prospective cohort mainly comprising men of color who have sex with men in Los Angeles County. We fit three logistic regression models, each with a per-subject random intercept and varying by HIV-related outcome and subsample, and examined how odds ratios (ORs) - varied across frequency categories for each drug.

Results: The sample comprised 485 participants with 1,319 observations (72% provided ≥2 observations). At baseline, the median age of participants was 31 (range: 18-46 years), 51% were HIV-positive, 48% identified as Hispanic/Latino and 45% identified as African American/black.

For self-reported involvement in sexual HIV transmission behaviors, there was evidence of monotonic dose-response relationships for amyl nitrites among HIV-negative participants, and for methamphetamine across the whole sample; among HIV-negative participants, for example, the odds of reporting involvement in sexual HIV transmission behaviors increased with frequency of methamphetamine use from 3.03 (95%CI: 1.08, 8.69) for 'less than monthly' to 8.95 (95%CI: 2.80, 32.93) for 'daily' use. Overall, heavy drinking was not strongly associated with involvement in sexual HIV transmission behaviors among HIV-positive or HIV-negative participants; however, heavy daily drinking was associated with viral suppression.

In general, cannabis trended towards lower odds of reporting involvement in sexual HIV transmission behaviors. There was evidence of a dose-response relationship between methamphetamine use frequency and detectable viral load.

Conclusions: Compared to the use of alcohol (heavily), cannabis and amyl nitrites, methamphetamine had the clearest deleterious dose-response relationships with HIV-related outcomes among our sample.

TUPEC254

The impact of severe drought and HIV in Southern Africa: Results from the LePHIA survey 2016-2017

A. Low[1], K. Frederix[2], S. McCracken[3], E. Gummerson[4], E. Radin[4], S. Davia[5], N. Ahmed[4], S. Findley[6], A. Schwitters[5]
[1]*Columbia University, ICAP, New York, United States,* [2]*ICAP, Maseru, Lesotho,* [3]*CDC, Atlanta, United States,* [4]*ICAP at Columbia University, New York, United States,* [5]*CDC-Lesotho, Maseru, Lesotho,* [6]*Columbia University, New York, United States*

Background: An analysis of the impact of drought in Africa on HIV by Burke, et al (2014) demonstrated an 11% increase in prevalence in HIV-endemic rural areas attributable to local rainfall shocks. The Lesotho Population-Based HIV Impact Assessment (LePHIA) was conducted

November 2016-May 2017, after one of the most severe droughts in Southern African history, allowing for reevaluation of this relationship in a setting of expanded antiretroviral (ART) coverage.
Methods: LePHIA selected a nationally representative sample of adults and children. Individuals completed an interview and HIV testing. Deviations in rainfall for May 2014-June 2016 were measured using precipitation data from Climate Hazards Group InfraRed Precipitation with Station Data (CHIRPS), with severe drought (SD) set at < 15% of the average rainfall from 1981-2016. The association between SD and HIV-related outcomes was assessed using logistic regression, incorporating survey weights and stratified by age, gender and geography (urban vs rural), with a particular focus on young persons.
Results: All of Lesotho suffered from drought, with regions receiving 1% to 31% of their historical rainfall. Only 5.7% (507/8825) of households were in regions without SD, corresponding to 5.9% of children (271/4,291) and 5.8% of adults (742/12,887). In rural areas, 39.5% of households in SD areas reported food shortage in the past four weeks vs. 27.8% in non-drought areas (p=0.01). SD was associated with higher HIV prevalence in 15-19 year old females in rural areas (odds ratio [OR]=2.77, 95%CI:1.19-6.47,p=0.02), and lower awareness of HIV status in urban females aged 15-24 (OR=0.23, 95%CI:0.08-0.70, p=0.01). In rural 15-24 year old females, SD was associated with higher reported transactional sex (OR=3.26, 95%CI:1.78-5.98, p< 0.001), early sexual debut (OR=3.11, 95%CI:1.43-6.74, p=0.004), lower attendance of secondary school (OR=0.44, 95%CI:0.0.25-0.78, p=0.005), and lower condom use (at last sex, OR=0.55, 95%CI:0.31-0.99, p=0.05). In a multivariable model, the impact of drought on HIV prevalence in 15-19 year old females persisted after adjusting for household wealth.
Conclusions: Severe drought was associated with higher HIV prevalence in adolescent girls, lower educational attainment and higher risky sexual behavior. Policy-makers should adopt potential mechanisms to mitigate the impact of income shock from natural disasters on vulnerable populations.

TUPEC255

CD101 Ig-like variants modify the effect of bacterial vaginosis on HIV acquisition

V. Wanga[1], R. Mackelprang[2], K. Thomas[2], C. Cohen[3], N. Mugo[2,4], E. Bukusi[2,5], G. Bryun[6], E. Irungu[4], C. Celum[1,2,7], J. Baeten[1,2,7], J. Lingappa[2,7,8], for the Partners in Prevention HSV/HIV Transmission Study and the Partners PrEP Study
[1]*University of Washington, Department of Epidemiology, Seattle, United States,* [2]*University of Washington, Department of Global Health, Seattle, United States,* [3]*University of California, San Francisco, Department of Obstetrics, Gynecology, and Reproductive Sciences, San Francisco, United States,* [4]*Kenya Medical Research Institute, Partners in Health Research and Development, Thika, Kenya,* [5]*Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya,* [6]*University of the Witwatersrand, Perinatal HIV Research Unit, Soweto, South Africa,* [7]*University of Washington, Department of Medicine, Seattle, United States,* [8]*University of Washington, Department of Pediatrics, Seattle, United States*

Background: Multiple studies suggest that factors eliciting host genital tract inflammation may heighten HIV-1 acquisition risk. For instance, bacterial vaginosis (BV) and variation in the extracellular Immunoglobulin-like (Ig-like) domains of the *CD101* gene both impact host inflammation and are associated with increased risk of HIV-1 acquisition. Studying interactions between these factors could provide insights into the mechanisms underlying this enhanced HIV-1 infection risk. Here we assess whether inflammation associated with *CD101* variation could modify the effect of BV on HIV-1 acquisition risk.
Methods: We used data from two African heterosexual HIV-1 serodiscordant couple cohorts (Partners in Prevention HSV/HIV Transmission Study and Partners PrEP Study) with longitudinal assessment of HIV-1 acquisition (by ELISA) and BV (by Nugent score ≥ 7). As previously published, we genotyped *CD101* for a case-control subset of participants and classified them based on presence of one or more *CD101* functional Ig-like domain variants. Here, we assess effect modification by *CD101* variants on the association of BV with HIV-1 using generalized estimating equations (GEE) extension to logistic regression.
Results: Our analysis included 430 initially HIV-uninfected women with *CD101* genotype and BV data, of which, 38 acquired HIV-1 and 202 had ≥1 visit with BV during follow-up. The presence of *CD101* Ig-like variants was associated with 2.5 times higher odds of seroconversion (95%CI (1.2, 4.9), p=0.01), while the association with BV was OR=1.7 (95% CI (0.9, 3.4), p=0.11), after adjusting for age, study, geographical region and any unprotected sex with study partner. The association of BV with seroconversion was significantly modified by the presence of *CD101* Ig-like variants (p=0.02). Among women without Ig-like variants (N=233), BV was associated with a 5-fold increased odds of seroconversion (OR=4.9 (1.6, 15.2), p=0.01). However, among women with Ig-like variants (N=197), BV was not significantly associated with HIV-1 acquisition (OR=0.8 (0.4, 2.0), p=0.69).
Conclusions: We hypothesize that both BV and *CD101* Ig-like variants facilitate HIV-1 acquisition by augmenting similar genital inflammation pathways. Our results suggest that in the presence of *CD101* Ig-like variants, BV does not increase HIV-1 acquisition risk. Further studies of this may provide insights for a generalized target for HIV-1 prevention interventions.

TUPEC256

Cannabis use and increased risks for HIV among young black sexual minority males in Los Angeles County, California

L.H. D'Anna[1], J. Wood[1], C. Canjura[1], J. Owens[1], T.A. Washington[2], PPOWER Leadership Team
[1]*California State University, Long Beach, Center for Health Equity Research, Long Beach, United States,* [2]*California State University, Long Beach, School of Social Work, Long Beach, United States*

Background: Young black men who have sex with men (YBMSM) are at particularly high risk for cannabis abuse/dependence, with the probability of dependence increasing with frequency of use. Further, when used as a sex-drug by YBMSM, cannabis is associated with condomless and group sex resulting in increased HIV/STI risks. High rates of cannabis use within a sample drawn from Los Angeles County prompted us to explore the relationship between cannabis use and HIV risk factors among YBMSM.
Methods: Survey data were analyzed from a convenience sample of YBMSM (n=161, ages 18-24, mean=22 years) participating in our wellness project from 2016-2018 to explore the influence of peer support on
1) HIV/ hepatitis C testing and
2) Reduction of problem alcohol and cannabis use.
Results: Cannabis/hash was the most commonly used substance; 57.8% reported use in the past 30 days, while 42.2% used cannabis at least 5 days in the past 30 days, and 18.6% used cannabis daily or almost daily (20+ days out of 30). Cannabis smoking in the past 30 days was also related to problem alcohol use measured by the AUDIT problem drinking scale (t=2.743, p=.007), but no other substances. Using a 16 variable composite, cannabis smoking was significantly associated with an overall sexual risk profile (t=4.378, p< .001). Chi-squared tests revealed cannabis use was positively associated with HIV risk behaviors:
1) Ever engaging in anal sex (p = .005),
2) Sex with more than five male partners in the past 3 months (p=.041),
3) Unprotected sex with a partner known or suspected to inject drugs (p= .050),
4) Having sex while under the influence of alcohol or drugs (p < .001), and
5) Exchanging sex for money, drugs or shelter (p < .001).
Conclusions: These initial findings suggest that cannabis may be an important contributor to the overall sexual HIV risk profile for YBMSM and point to the importance of identifying opportunities for developing holistic wellness intervention approaches that take into account the context within which YBMSM engage in high risk sexual behaviors. This is particularly important given the expansion of cannabis legalization in the U.S.

Factors associated with risk HIV-infection among pregnant women in Cameroon: Evidence from the 2016 national sentinel sero-surveillance study

J.D.D. Anoubissi[1], C. Kengne Nde[1], J. Fokam[2,3,4], D.G. Toghoua Tseuko[5], M. Arlette[1], R. Fodjo Toukam[1], Y. Moussa[1], M. Ngo Nemb[1], S. Billong[1,3,4], G. Ekali Loni[1], C. Nguefeu Nkenfou[2,6], D. Kob[7], M.-C. Okomo[5], J.-B. Elat Nfetam[1]
[1]National AIDS Control Committee, Yaoundé, Cameroon, [2]Chantal BIYA International Reference Centre (CBIRC) for Research on HIV/AIDS Prevention and Management, Yaoundé, Cameroon, [3]Faculty of Medicine and Biomedical Sciences (FMBS), University of Yaounde 1, Yaoundé, Cameroon, [4]National HIV Drug Resistance Surveillance and Prevention Working Group, National AIDS Control Committee, Yaoundé, Cameroon, [5]National Public Health Laboratory, Yaoundé, Cameroon, [6]Higher Teachers' Training College, University of Yaounde I, Yaoundé, Cameroon, [7]USAID, Yaoundé, Cameroon

Background: HIV/AIDS remains a major public health concern in Cameroon that requires regular surveillance for informed policy-making toward programmatic interventions. Using the national sentinel surveillance survey in Cameroon, we ascertained HIV prevalence and factors associated with risk of infection among pregnant women.

Methods: A cross-sectional study was conducted throughout 2016 in the 10 regions of Cameroon among 7000 first antenatal care (ANC-1) attendees (4000 from urban and 3000 rural sites) in 60 sentinel sites. HIV serological testing was performed by serial algorithm at the National Reference Laboratory (NRL). Prevalence was determined and multivariate logistic regression was used to assess determinants of HIV infection, with p-value< 0.05 considered statistically significant.

Results: Of the 7000 targets, a total of 6859 first ANC-1 were enrolled (98.0% sampling coverage). Median age was 26 [IQR: 21-30] years and 47,40% had a secondary level of education. Acceptability of HIV test was 99.19% (6513/6566). The national prevalence of HIV was 5.70% (95% CI: 4.93 - 6.4), with 5.58% (95% CI: 95%: 4.88 - 6.35) in urban and 5.87% (95% CI: 5.04 - 6.78) in rural settings. Factors associated with HIV infection were:

(1) age between 20 and 44 years, with risk of being HIV infected increasing with age;

(2) the marital status revealing that pregnant women who were married or living with their partner were less likely to be infected than single ones (aOR: 0.60; 95% CI: 0.46 - 0.78); and

(3) the geographical setting revealing that participants in the Adamawa region were 2 or 3 times less likely to be infected than those living in the Centre, East, North-West and South-West regions.

Conclusions: The burden of HIV infection is still high among pregnant women nationwide, thus prompting the need for interventions in priority populations. Thus, to further decrease new cases of HIV-infection and move toward eliminating AIDS by 2030, preventive actions should prioritize interventions preferentially among single pregnant women, with advanced age, and particularly in the Centre, East, North- West and South-West regions of the country.

TUPEC258

The association of schistosomiasis and HIV acquisition: A review of the literature

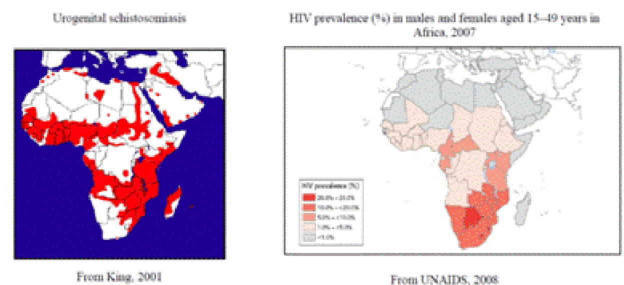
P. Patel[1], E. Townley[2], D.H. Watts[3], W.E. Secor[4]
[1]Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, GA, United States, [2]National Institutes of Health, ColumbusUSA Contractor at Division of AIDS, National Institute of Allergy and Infectious Diseases, Bethesda, United States, [3]Department of State, Office of the Global AIDS Coordinator, Washington DC, United States, [4]Centers for Disease Control and Prevention, Division of Parasitic Diseases and Malaria, Atlanta, GA, United States

Background: Schistosomiasis is an infectious disease that affects more than 230 million people worldwide, of whom 90% are in Africa. Schistosome infection usually occurs in childhood with freshwater contact and recurrent exposures throughout the lifespan. In some regions, particularly sub-Saharan Africa, the epidemics of HIV and schistosomiasis closely overlap; communities with the highest burden of schistosomiasis also have high HIV prevalence (Figure). Furthermore, endemic schistosomiasis, specifically female genital schistosomiasis (FGS), which affects 19 million girls, may increase risk of HIV infection, particularly among adolescent girls and young women (AGYW). FGS, caused by *Schistosoma haematobium*, causes mucosal changes in the vaginal epithelium and alters host immune response, rendering women at higher risk of infertility and potentially, HIV acquisition.

Methods: We examined peer-reviewed literature published between January 1, 2011 and October 18, 2016 to assess currently available evidence regarding effects of schistosomiasis on HIV with a focus on sub-Saharan Africa. The databases searched were OVID/Medline, Embase, and Global Health. Of the 175 abstracts identified, 16 focused on HIV and *S.* haematobium and were reviewed; 4 reported on prevalence of HIV relative to *S.* haematobium.

Results: Three cross sectional studies have shown increased HIV prevalence (2-4 times) among communities endemic for *S.* haematobium infection and an ecological study of 43 sub-Saharan Africa countries demonstrated that for each 100 individuals infected with *S.*haematobium, there was a 2.9% relative increase in HIV prevalence. Mathematical modelling predicted that mass drug administration targeted at school-age children to treat schistosomiasis could reduce HIV incidence by 9-22% and overall HIV prevalence by 6-20%.

Conclusions: The association of schistosomiasis, specifically FGS, with increased HIV acquisition is biologically plausible but research has been suboptimal. Research is needed to understand the effect of FGS and its treatment on HIV acquisition, particularly among AGYW. Furthermore, studies are necessary to understand whether the increased risk of HIV acquisition is substantial enough to warrant offering pre-exposure prophylaxis for HIV among AGYW with FGS and whether treatment of FGS affects the risk of HIV acquisition. Data suggest that uptake of WHO's mass drug administration for schistosomiasis policy may prevent infertility and potentially HIV infection among AGYW.



[Figure. Geographical overlap of urogenital schistosomiasis and HIV infection distribution]

Delayed HIV testing among men who have sex with men in China is common: Findings from the T2T study

H. Zou[1,2,3], X. Meng[4], Y. Lu[2], Z. Wang[2], T. Jia[4], H. Yin[4], Z. Luo[5], Y. Ding[5], W. Chen[5], S. Huang[6], H. Zheng[6], B. Yang[6], A. Grulich[3], The T2T Study
[1]Sun Yat-sen University, School of Public Health (Shenzhen), Shenzhen, China, [2]Sun Yat-sen University, School of Public Health, Guangzhou, China, [3]University of New South Wales, Kirby Institute, Sydney, Australia, [4]Wuxi Municipal Centre for Disease Control and Prevention, Wuxi, China, [5]Shenzhen Nanshan Center for Chronic Disease Control, Shenzhen, China, [6]Dermatology Hospital, Southern Medical University, Guangzhou, China

Background: Guidelines in China recommend yearly HIV testing for men who have sex with men (MSM) and some other countries recommend up to 3-monthly for MSM at higher risk of HIV transmission. We assessed the prevalence and factors associated with delayed HIV testing among MSM in China.

Methods: MSM aged ≥18 years old who had ≥2 male sex partners were recruited between January and August, 2017 in 3 metropolitan cities: Guangzhou and Shenzhen in southern China and Wuxi in eastern China. A self-completed tablet-based questionnaire was collected about HIV/STI testing history, socio-demographic characteristics and sexual behaviors. HIV, syphilis, rectal/urethral gonorrhea, rectal/urethral chlamydia and anogenital warts were tested/checked. Patients were as-

signed "high-risk" status if they had >5 partners or an STI in the past 6 months. Delayed testing status was defined as having no test within the past 6 months for high-risk men, 12 months for non-high-risk men. Mixed effects logistic regression models were used to determine factors associated with delayed testing status.
Results: A total of 603 MSM were enrolled in our study, with a mean age of 27.9 years (SD=7.8). Overall, 81.4% (491/603) had ever tested for HIV. High-risk (27.0%, 163/603) and non-high-risk men (73.0%, 440/603) had similar rates of delayed HIV testing: 31.3% vs 28.2% (X^2=1.118, *P*=0.290). Younger men were significantly less likely to have ever tested (50.0% in < 20 years vs 84.9% in >=20 years, *P*< 0.001) and more likely to have delayed HIV testing (53.3% vs 26.3%, *P*< 0.001). Men with delayed HIV testing status were significantly more likely to have more sex partners (26.3% vs 17.3%, *P*=0.012), have inconsistent condom use with casual partners (54.8% vs 39.7%, *P*=0.009) and be diagnosed with HIV (16.6% vs 5.6%, *P*< 0.001) and urethral chlamydia (10.9% vs 3.8%, *P*=0.002).
Conclusions: Delayed HIV testing is common among MSM in China. Efforts are needed to further decrease delayed HIV-testing among MSM, particularly young men who engage in high-risk sexual behaviors.

TUPEC260

Male partners of adolescent girls and young women in Durban, South Africa: How high is their HIV risk and what groups are most at risk?

A. Gottert[1], S. Mathur[1], C. Cawood[2], J. Pulerwitz[1]
[1]*Population Council, HIV and AIDS Program, Washington, United States,* [2]*Epicentre AIDS Risk Management, Paarl, South Africa*

Background: Adolescent girls and young women (AGYW, ages 15-24) are at high risk of HIV in South Africa. Context-specific data on characteristics, HIV risk and health-seeking behaviors of male partners of AGYW are sorely needed to develop more effective HIV programs.
Methods: We surveyed 962 men ages 20-40 recruited at community 'hot spot' venues (n=649) and HIV service sites (n=313) in two informal settlements in Durban, from May-September 2017. We present descriptive and regression analyses of men's characteristics and their partnership and service-use experiences.
Results: Men's average age was 28, 15% were married/cohabiting, and 61% were employed. Over two-thirds (71%) reported two or more sexual partners in the last year; 24% had five or more. Overall, 75% had AGYW partner(s); 54% had both AGYW partners and partners age 25+. Men's last three partners were 3.4 years younger on average; 8% had partners 10+ years younger. Thirty-two percent reported consistent condom use with their last partner; 14% with each of their last three non-marital partners. Sixty-four percent reported HIV testing in the last year. Among HIV-positive men (n=84), 87% were on treatment, and 24% knew that they were virally suppressed. In multivariate analyses controlling for demographic characteristics, men with more sexual partners in the last year were more likely to have a technical college/university education (p< 0.05), be employed (p=0.01), and be small business owners/entrepreneurs (p< 0.01). Taxi drivers had more age disparate partners (p< 0.001) as well as more partners ages 15-19 in the last year (p< 0.05), and were less likely to have tested for HIV (p< 0.05). Formally employed men were about half as likely to be virally suppressed as informally or unemployed men (p< 0.05).
Conclusions: Men in informal settlements in Durban are at very high risk of both acquiring HIV and transmitting to AGYW due to high numbers of partners, overlapping partnerships of AGYW and older women, inconsistent condom use, suboptimal testing, and low viral load suppression. Engaging men in primary HIV prevention and targeted health services is critical, and in Durban, focusing on reaching men at workplaces, technical colleges/universities, taxi ranks and self-owned businesses may yield the greatest results.

TUPEC261

HIV incidence and treatable STIs among adolescent girls and young women in Swaziland

M. Gorgens[1], S. Ketende[1,2], A. Longosz[1], V. Tsododo[3], M. Dlamini[3], M. Nkambule[4], T. Dlamini[4], M. Mabuza[4], N. Dlamini[4], B. Dube[4], W. Heard[1], K. Sikwibele[3], D. De Walque[1], K. Mabuza[4], Sitakhela Likusasa Study Group
[1]*The World Bank, Health, Nutrition and Population, Washington DC, United States,* [2]*John Hopkins University, Baltimore, United States,* [3]*Institute for Health Measurement Southern Africa, Manzini, Swaziland,* [4]*Swaziland National Emergency Response Council on HIV/AIDS (NERCHA), Mbabane, Swaziland*

Background: Swaziland continues to have the highest prevalence of HIV in the world, and one of the highest HIV incidences among adult populations (aged 15-49). In 2015, the Sitakhela Likusasa Impact Evaluation enrolled 4389 HIV negative adolescent girls and young women (AGYW) aged 15-22, 50% of whom were out of school at enrolment, in a 3-year impact evaluation to test the cost effectiveness of incentives on reducing HIV incidence.
Methods: The Sitakhela Likusasa midline survey - consisting of determining participants' HIV status, syphilis status and *trichomonas vaginalis* status, and administering a behavioural, schooling status, and service coverage questionnaire - of all enrolled study participants was conducted between November 2016 and July 2017.
Results: The loss to follow rate was 15.8%. Of those loss to follow up, participants who were out of school at baseline were 48% less likely to participate at midline. HIV incidence rate per 100 years at midline for AGYW who were under 18 years of age and out of school at baseline was almost identical to AGYW who were 18 or older and out of school at baseline, 3.635 [95%CI: 2.064-6.400] vs. 3.696 [95%CI: 2.851- 4.792]. Prevalence of treatable STI was highest among 15-17 year-olds who were out of school compared to all other AGWY regardless of schooling status. AGWY who were out of school at baseline were more than twice likely to have a treatable STI at midline compares to AGYW who were 18-22 years old and out of school at baseline, OR: 2.36.

Age and schooling status at baseline	HIV Incidence				STI Incidence	
	Person-time	Failures	HIV incidence rate per 100 years	[95% confidence interval]	Prevalence	OR [95% confidence interval]
18-22 and out of school at baseline	1542.08	57	3.696	[2.851- 4.792]	2.56% (36/1431)	1
18-22 and in school at baseline	669.853	11	1.642	[0.909- 2.965]	1.77% (11/621)	0.70 [0.35,1.38]
15-17 and in school at baseline	1455.416	16	1.099	[0.673- 1.794]	1.41% (19/1347)	0.55 [0.32,0.97]
15-17 and out of school at baseline	330.155	12	3.635	[2.064-6.400]	5.73% (17/296)	2.36 [1.31,4.26]
TOTAL	3997.504	96	2.401	[1.966-2.933]		

[HIV incidence and STI incidence amongst study population in Sitakhela Likusasa Impact Evaluation (2017)]

Conclusions: The data presented here highlights the importance of school enrollment as a significant determinant of vulnerability to HIV incidence in Swaziland. The association between school enrollment and HIV incidence is stronger than the association with age, as out-of-school girls AGYW are more vulnerable to HIV incidence irrespective of age. HIV prevention programs for the out-of-school participants are essential, under-served at the moment, yet hard because of the challenges in reaching these mobile, hard-to-reach populations.

HIV incidence and associated factors among men who have sex with men (MSM) in a treatment as prevention environment: Benefits of a prospective cohort study and administrative health data linkage

N.J. Lachowsky[1,2], H.L. Armstrong[1,3], S. Pan[1], N. Bacani[1], G. Olarewaju[1], E.A. Roth[2], R.S. Hogg[1,4], D.M. Moore[1,3]

[1]*British Columbia Centre for Excellence in HIV/AIDS, Division of Epidemiology & Population Health, Vancouver, Canada,* [2]*University of Victoria, Victoria, Canada,* [3]*University of British Columbia, Faculty of Medicine, Vancouver, Canada,* [4]*Simon Fraser University, Burnaby, Canada*

Background: In British Columbia (BC), new HIV diagnoses are stable among men who have sex with men (MSM, 57% of all cases in 2015) despite implementation of Treatment as Prevention since 2010. We measured HIV incidence and associated factors within a prospective cohort of MSM in Vancouver, BC, Canada.

Methods: Sexually-active MSM were enrolled starting 02/2012 in a longitudinal cohort study recruited using respondent-driven sampling. Study visits occurred every six months and included a computer-assisted self-interview on demographics, sex and substance use, and a nurse-administered sexual health check-up with point-of-care HIV testing. Participants consented to data linkages with the BC Centre for Excellence in HIV/AIDS's databases containing all provincial HIV viral load and treatment data. We calculated HIV incidence rates and examined factors associated with HIV seroconversion using Poisson regression (adjusted for follow-up time).

Results: At 02/2017, 497 HIV-negative MSM at baseline contributed a mean follow-up time of 2.32 years. At baseline, 81.7% were gay-identified, 74.5% Caucasian, and 40.2% aged under 30. Of 17 HIV seroconversions, 6 (35.3%) were identified through administrative health data linkage. The HIV incidence rate from observational study follow-up alone was 0.93/100 person-years, but was 1.47/100 person-years with data linkage. Compared with MSM who remained HIV-negative, MSM who seroconverted were more likely to report more recent anal sex partners (median=10 versus 2, RR=1.02, p=0.001), recent condomless sex with an HIV-positive or unknown status partner (64.7% versus 31.9%, RR=3.93, p=0.006), recent group sex (41.5% versus 16.0%, RR=3.61, p=0.008), a lifetime STI diagnosis (41.2% versus 12.5%, RR=4.93, p=0.001), and self-perceived high HIV risk (29.4% versus 7.9%, RR=4.47, p=0.005). There were no differences in HIV Treatment Optimism Scale scores (median=27, p=0.963), awareness of post-exposure prophylaxis (82.4% versus 77.9%, p=0.245), or awareness of pre-exposure prophylaxis (64.7% versus 66.7%, p=0.747). Based on HIV Incidence Risk Index for MSM (HIRI-MSM), 94.1% of seroconverters scored at least 10 points (RR=13.67, p=0.011).

Conclusions: Data linkage identified a third more seroconversions than observational cohort follow-up alone. HIRI-MSM was validated in this sample. Despite no difference in biomedical prevention awareness, only a third of serconverters self-perceived high risk of HIV acquisition indicating need of targeted health promotion and provider-initiated interventions.

Epidemiology of AIDS events (e.g. AIDS-related opportunistic infections and cancers)

Performance of cryptococcal antigen lateral flow assay in postmortem samples of people living with HIV

J.C. Hurtado[1,2], P. Castillo[1,3], F. Marco[1,2], C. Carrilho[4,5], M. Navarro[1,2], I. Casas[1,2], L. Quintó[1], F. Fernandes[4,5], M. Ismail[4,5], A. Sanz[1], I. Mandomando[6], N. Rakislova[1,3], C. Menéndez[1,6,7], Q. Bassat[1,6,8], J. Vila[1,2], J. Ordi[1,3], M. Martínez[1,2], E. Letang[1]

[1]*ISGlobal-Hospital Clínic-Universitat de Barcelona, Barcelona, Spain,* [2]*Hospital Clínic de Barcelona, Microbiology, Barcelona, Spain,* [3]*Hospital Clínic de Barcelona, Pathology, Barcelona, Spain,* [4]*Maputo Central Hospital, Pathology, Maputo, Mozambique,* [5]*Eduardo Mondlane University, Faculty of Medicine, Maputo, Mozambique,* [6]*Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique,* [7]*Consorcio de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBERESP), Madrid, Spain,* [8]*ICREA, Catalan Institution for Research and Advanced Studies, Barcelona, Spain*

Background: There is a need to identify tools providing reliable and robust information on the cause of death at the individual level in sub-Saharan Africa. Cryptococcosis is estimated to cause 15% of AIDS-deaths globally, but remains largely undiagnosed in sub-Saharan Africa. We aimed to validate the use of cryptococcal antigen lateral flow assay (CrAg-LFA) in post-mortem samples from Mozambique in the context of a standardized minimally invasive autopsy (MIA) protocol.

Methods: From November 2013 to December 2015, coupled MIA and complete diagnostic autopsy (CDA) were performed in 223 patients who died at the Maputo Central Hospital in Mozambique, including 109 HIV-infected adult patients. MIA procedures comprised a collection of fluids (blood and cerebrospinal fluid) and puncture of solid organs (lungs, liver and central nervous system) for microbiological and pathological analysis. Molecular microbiology analyses were performed in the MIA and the CDA. To detect *Cryptococcus* a specific real-time PCR were performed in all tissues. Additionally, CrAg-LFA test was done in plasma samples and in cerebrospinal fluid samples of plasma CrAg-positive patients. Histologically, periodic acid-Schiff staining was performed in all organs from cases showing a positive result in the microbiological tests. The performance of CrAg-LFA testing vs. the CDA results in terms of identifying Cryptococcal infections was calculated between HIV-infected adults.

Results: Sixteen (15%) cryptococcal infections (9 male and 7 female) were identified by CrAg-LFA among 109 HIV-infected adults. Cryptococcosis was identified as infection in 15/16 (94%) and assigned as the cause of death in 11/16 (69%) cases in the CDA and the MIA (100% concordance). Clinically, 11/17 (65%) cases had been identified to have neurological symptoms, but premortem diagnosis of cryptococcosis occurred only in 4 (24%) cases. The sensitivity, specificity, and positive and negative predictive value of the CrAg-LFA were 100% (one-sided, 97.5%CI: 78-100), 99% (two-sided, 95%CI: 94-100), 94% (two-sided, 95%CI: 68-100), and 100% (one-sided, 97.5%CI: 96-100).

Conclusions: Cryptococcosis is a relevant and clinically underdiagnosed cause of death in HIV-infected patients in Mozambique. CrAg-LFA testing in post-mortem plasma samples represents a highly sensitive, specific, and affordable approach to accurately assess the contribution of cryptococcosis to AIDS mortality in Africa.

Performance of vaginal self-sampling for HPV testing among HIV-infected women in Botswana

T. Elliott[1], R. Kohler[2,3], B. Monare[1], N. Moshashane[1], K. Ramontshonyana[1], C. Muthoga[1], R. Howett[1], C. Morroni[1,4,5], D. Ramogola-Masire[1]
[1]Botswana UPenn Partnership, Gaborone, Botswana, [2]Harvard TH Chan School of Public Health, Boston, United States, [3]Dana-Farber Cancer Institute, Boston, United States, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]Botswana Harvard Aids Institute Partnership, Gaborone, Botswana

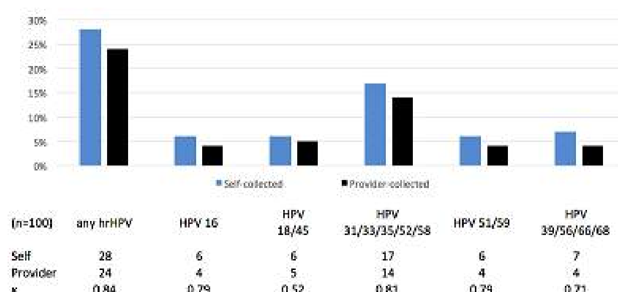
Background: Despite wide coverage of antiretroviral therapy (ART), 26% of adult women in Botswana are HIV-positive and at increased risk for cervical cancer. Multiple professional societies and health organizations recommend testing for high-risk human papillomavirus (hr-HPV) in place of or in addition to visual inspection and pap smear screening. However, in resource limited settings, high screening coverage may not be feasible with provider-collected samples. We conducted the first assessment of self-collected vaginal samples compared to provider-collected cervical samples in Botswana, and report the prevalence of hr-HPV in an HIV-positive population.

Methods: We recruited HIV positive women ≥25 years attending an HIV clinic in Gaborone, the capital city. Participants self-collected vaginal samples using flocked swabs and then had a provider-collected cervical sample taken for comparison. All samples were tested for hr-HPV within 24 hours using the Cepheid GeneXpert HPV assay. Women with any hr-HPV positive result returned to the clinic for colposcopy. Unweighted statistics were used to determine agreement.

Results: A total of 103 eligible women were recruited with a median age of 44 (IQR: 40-51). All participants were on ART with a median CD4 count of 651 (IQR: 451-893), and 97 (94.2%) reported previous cervical screening. Thirty-one (30.1%) women tested positive for any hr-HPV (Table 1), and of these 10 tested positive for more than one genotype. The most common genotypes were HPV 31/35/52/58 (self 16.5%; provider 13.6%) [Figure 1]. Overall agreement for detection of hr-HPV between self and provider samples was 91% with a of 0.79. Excluding three inadequate self-samples, agreement of paired samples was 94% with a of 0.84.

	Positive for any hr-HPV (%) 31 (30.1)	Negative for any hr-HPV (%) 72 (69.9)	Total (n, %) 103 (100)	p-value
Age, median (IQR)	44 (37-48)	44 (40-53)	44 (40-51)	0.24
Single, never married	24 (77.4)	49 (68.1)	73 (70.9)	0.29
Rural residence	17 (54.8)	28 (38.9)	45 (43.7)	0.13
No/Primary education	9 (29.0)	27 (37.5)	36 (35.0)	0.41
Secondary/Tertiary education	22 (71.0)	45 (62.5)	67 (65.1)	
Current/former smoker	0 (0.0)	5 (6.9)	5 (4.9)	0.13
Duration of ART use (yrs), median (IQR)	12 (7-13)	12 (11-14)	12 (9-14)	0.08
Age at first sex	18 (17-20)	19 (17-20)	18 (17-20)	0.55
Concurrent sexual partners	4 (12.9)	2 (2.8)	6 (5.8)	0.04

[Characteristics of women attending HIV clinic by HPV result]



[High-risk HPV genotype prevalence and agreement for paired samples among HIV-positive women in Botswana]

Conclusions: In this well-managed HIV-positive population, hr-HPV prevalence was 30%, and detection was comparable between self and provider samples. Despite a small number of inadequate samples, self-sampling is a feasible and accurate alternative to provider screening. Using self-sampling for HPV testing may play an important role in screen and treat programs for cervical cancer control in high HIV burden settings with limited resources like Botswana.

TUPEC265

CD4/CD8 ratio and risk of Kaposi sarcoma and non-Hodgkin lymphoma in people living with HIV achieving suppressed viraemia on antiretroviral therapy

F. Caby[1,2], S. Grabar[1,3], on behalf of the CD4/CD8 Ratio and Cancer Working Group of the COHERE in EuroCoord
[1]Sorbonne Université, INSERM, Institut Pierre Louis d'Épidémiologie et de Santé Publique, UMR_S 1136, Paris, France, [2]Centre Hospitalier VIctor Dupouy, Infectious diseases, Argenteuil, France, [3]AP-HP, Groupe Hospitalier Cochin-Hôtel Dieu, Université Paris Descartes, Unite de Biostatistique et Epidémiologie, Paris, France

Background: A persistently abnormal CD4/CD8 ratio despite combination antiretroviral therapy (cART) reflects ongoing immune dysfunction and has been inversely correlated with the risk of non-AIDS defining cancer in people living with HIV (PLHIV). However the predictive value of the CD4/CD8 ratio has never been studied for AIDS-defining cancers such as Kaposi sarcoma (KS) and non-Hodgkin lymphoma (NHL) which remain the most frequent cancers in PLHIV receiving cART. Here, we evaluated the impact of CD4/CD8 ratio restoration (≥1) on KS and NHL risks in PLHIV achieving suppressed viraemia on cART.

Methods: PLHIV from the Collaboration of Observational HIV Epidemiological Research Europe (COHERE) were included if they achieved virological control (viral load≤500 copies/mL) within 9 months following cART initiated between 2000 and 2014. Baseline was the time of the first CD4/CD8 measurement after virological control, with persistent suppressed viraemia. Patients with KS or NHL before baseline were excluded. Cox models were used to identify factors associated with KS and NHL risks.

Results: A total of 58308 patients (76% men, median[IQR] age 38 [32-45] years) were followed-up during 59[30-96] months. At baseline, CD4 count, CD8 count and CD4/CD8 ratio were 412[292-550]/mm³, 937[668-1306]/mm³ and 0.43[0.28-0.64] respectively. Overall, 221 KS and 187 NHL were diagnosed, 9[2-37] and 18[7-42] months after baseline respectively. At 2 years, CD4/CD8 ratio was restored (≥1) in 28% (95%CI:27-28). CD4/CD8 ratio restoration, in addition to CD4 restoration, tended to decrease KS risk (see table). High baseline CD8 count was associated with higher NHL risk. Both KS and NHL risks were strongly increased in case of virological failure.

Conclusions: In this population of patients who had achieved suppressed viraemia, restoration of the CD4/CD8 ratio may confer an additional benefit to CD4 restoration with regard to KS risk. For NHL risk, the main immunological associated factor was baseline CD8 count. Furthermore, avoiding virological failure appeared to be key to minimize KS and NHL risks. A closer clinical monitoring should be proposed in patients with high CD8 count despite virological control and/or low persistent CD4/CD8 ratio.

	Kaposi sarcoma		Non-Hodgkin lymphoma	
	Adjusted* HR (CI95%)	p	Adjusted* HR (CI95%)	p

[1]ISGlobal, Barcelona Ctr. Int. Health Res. (CRESIB), Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, [2]Ifakara Health Institute, Ifakara, Tanzania, United Republic of, [3]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [4]Swiss Tropical and Public Health Institute of Basel, Basel, Switzerland, [5]University of Basel, Basel, Switzerland, [6]University of Basel, Molecular Virology, Department Biomedicine Petersplatz, Basel, Switzerland, [7]University Hospital Basel, Departments of Medicine and Clinical Research, Basel, Switzerland

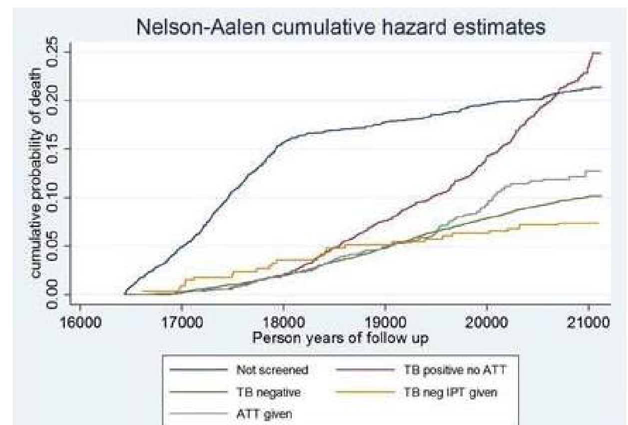
Background: Globally, up to half of people living with HIV (PLWH) have advanced HIV disease (AHD) at diagnosis. However, there is scarce information about AHD in sub-Saharan Africa. We assessed the prevalence, clinical-epidemiological characteristics and predictors of AHD and associated mortality in a rural African cohort of PLWH.
Methods: Prospective cohort study including all ART-naïve adult PLWH enrolled in the Kilombero-Ulanga Antiretroviral Cohort, Tanzania, between Jan 2013 and Dec 2016. AHD was defined as having CD4 count ≤200 cells/µL or WHO clinical stage III or IV at diagnosis. Factors associated with AHD were identified using multivariable logistic regression. Cox regression was used to identify predictors of death among patients with AHD.
Results: Of 1733 participants, 1133 (65%) had AHD. 45% were male, the median age was 40 years (IQR 33-47), and the median CD4 count, 119 cells/µl (IQR 50-206). 75% had symptoms, mostly respiratory (44%) and gastro-intestinal (27%). Independent risk factors for AHD were male gender (adjusted Odds Ratio (aOR) 2.03, 95%CI 1.63-2.52), age >40 years (aOR 1.42, 95%CI 1.15-1.74), living alone (aOR 1.61, 95%CI 1.30-1.99), lower education (aOR 1.53, 95%CI 0.99-2.38) and HIV diagnosis through provider-initiated testing (aOR 1.32, 95%CI 1.06-1.63). 1390/1733 (80%) participants started ART, including 939 with AHD (86%), at a median time of 10 days from enrolment (IQR 5-28).
One year after recruitment, there were 74 confirmed deaths (4.5%), 96% (71/74) among people with AHD($p<$ 0.001). Tuberculosis (26%) and cryptococcosis (24%) accounted for most deaths. After adjusting for age, gender, BMI, CD4 counts and tuberculosis diagnosis, not having started ART (adjusted Hazard Ratio (aHR) 7.48, 95%CI 4.09- 13.68), having a positive cryptococcal antigen in plasma (aHR 4.66, 95%CI 2.39-9.09), and haemoglobin< 8 g/dl, (aOR 1.78, 95% CI 0.96-3.28) independently predicted death among people with AHD.
Conclusions: AHD was prevalent in this rural African population, and most deaths occurred in people with AHD. Prevention and case finding programs should be tailored at older males, living alone, not seeking voluntary HIV testing, and with lower education. To reduce AIDS-related mortality in Africa, ART services need to be differentiated to provide adapted packages of care to people presenting with AHD.

TUPEC267

Impact of TB-related interventions on mortality among people living with HIV on anti-retroviral therapy: A national observational cohort study in Papua New Guinea

S. Miyano[1,2], N. Dala[3], P. Boas[3], G. Anup[1]
[1]World Health Organization, HIV/STI/Hepatitis Programme, Port Moresby, Papua New Guinea, [2]National Center for Global Health and Medicine, Tokyo, Japan, [3]National Department of Health, HIV/STI Programme, Port Moresby, Papua New Guinea

Background: In addition to anti-retroviral therapy (ART), screening for TB, enrolling those screened negative to Isoniazid preventive therapy (IPT), and initiating anti-TB treatment (ATT) for those screened positive and diagnosed as TB have been strongly recommended as standard services for people living with HIV (PHLIV). This study aimed to assess the effectiveness of interventions in reducing mortality in Papua New Guinea (PNG).
Methods: The National HIV Patient Cohort Database (HPDB) was used to analyse the data of PLHIV on ART from 2005 to 2017 coming to clinics focusing on socio-demographics, screening for TB, enrolment of IPT among those found negative and initiation of ATT among co-infected. Cox proportional hazard models were used to compare mortality among 5 different groups.
Results: Over twelve years, 31,997 PHLIV were registered (64,526 person-years; male 40.2%, female 59.7%, transgender 0.1%; mean age 35.5 years and CD4 cell count 236.2 cells/mm³ at first visit). Three-quarters of them were screened for TB, of which 88.4% were found negative, and 3.3% of those initiated IPT. Of those screened positive for TB, 98.2% initiated ATT. PLHIV not screened for TB had twice as high mortality as those screened, found negative and given IPT (HR=2.08; 95%C.I. 0.92-2.17, $p<$ 0.001). Other groups showing higher mortality were those who were TB positive and not on ATT (HR=1.8; 95%C.I. 1.25-2.76, p=0.002), and those who were TB negative and not given IPT (HR=1.15; 95% C.I. 1.05-1.27, p=0.004). The group that were TB positive and given ATT did not show any significant increase in mortality (HR=1.4; 95% C.I. 0.92- 2.17, p=0.12).
Conclusions: This is the first longitudinal cohort analysis reviewing the national HIV/TB programme in PNG. While TB screening rate among PLHIV has been dramatically increasing over the years, the enrolment of IPT still remains extremely low. However, most of the cases diagnosed as TB has been successfully initiated ATT. The statistical analysis showed that not conducting screening, not introducing IPT, and not initiating ATT contributed to statistically higher mortality. It is concluded that screening for TB, enrolment of IPT and initiating ATT were causal to their survival, and should be provided to all eligible PLHIV.



[Nelson- Aalen cumulative hazard estimates]

Epidemiology of non-AIDS infections and communicable diseases (e.g. viral hepatitis, STIs)

TUPEC268

Virological and serological predictors of anal high-grade squamous intraepithelial lesions among HIV-positive men who have sex with men

E. Marra[1], M.L. Siegenbeek van Heukelom[2], A. Leeman[3], T. Waterboer[4], C.J.L.M. Meijer[5], P.J.F. Snijders[5], A.J. King[6], I. Cairo[7], A. van Eeden[8], W. Brokking[8], W. Quint[3], J.M. Prins[2], H.J.C. de Vries[9], M.F. Schim van der Loeff[9]
[1]Public Health Service Amsterdam, Infectious Diseases and Prevention, Amsterdam, Netherlands, [2]AMC, Amsterdam, Netherlands, [3]DDL Diagnostic Laboratory, Rijswijk, Netherlands, [4]German Cancer Research Center (DKFZ), Heidelberg, Germany, [5]VUmc, Amsterdam, Netherlands, [6]RIVM, Bilthoven, Netherlands, [7]OLVG, Amsterdam, Netherlands, [8]DC Klinieken, Amsterdam, Netherlands, [9]Public Health Service Amsterdam, Amsterdam, Netherlands

Background: HIV-positive men-who-have-sex-with-men (MSM) are at increased risk for developing anal cancer. Detection of anal cancer precursor lesions [high-grade squamous intraepithelial lesions (HSIL)] is cumbersome and demanding. Our objective was to identify virological/serological predictors of anal HSIL in HIV-positive MSM.

Methods: Participants, HIV-positive MSM, were recruited from a longitudinal study (2010-2013), during which anal self-swabs and serum were collected at up to five bi-annual visits. Swabs were tested for HPV and genotyped (SPF_{10}-PCR-DEI-$LiPA_{25}$-system-version 1.0). Viral load of high risk HPV (hrHPV) types in anal swabs was determined using a type-specific quantitative (q)PCR. Serum antibodies to E6, E7, E1, E2 and L1 proteins of hrHPV types were analyzed by multiplex serology. 193 participants had a high-resolution anoscopy (HRA) after the last study visit, between 2010 and 2015, and were included in the current analysis. Anal HSIL was diagnosed by histopathological examination of anal biopsies. Causative HPV type(s) of anal HSIL were determined by laser capture microdissection and genotyped as described above.

Univariable and multivariable logistic regression using generalized estimating equations (GEE) was used to study whether persistent HPV infection, HPV16/18 viral load and/or HPV seropositivity were predictors of anal HSIL caused by the same HPV-genotype as detected in swabs and serum.

Results: Of 193 HIV-positive MSM (median age 50 (IQR:45-56) years), 50 (26%) were diagnosed with histologically proven anal HSIL. The mean nadir CD4+ was 245 cells/µl (SD 134), and 94% had an undetectable HIV viral load at time of HRA. HrHPV persistence in anal swabs was common (varying by HPV type between 3-21%). The geometric mean titer of the HPV16 viral load was 47.0 DNA copies per human cell (95%CI 12.7-173.6). For HPV16, in total 19% of the participants were HPV L1 seropositive and 3% were E6 seropositive. In univariable logistic regression using GEE, anal hrHPV persistence and higher anal HPV viral load were associated with anal HSIL ($P< 0.001$, and $P=0.010$, respectively). In multivariable logistic regression only anal HPV persistence was associated with anal HSIL caused by the same HPV type (OR 15.3, 95%CI 6.4-36.5).

Conclusions: Only persistent infection with an HPV genotype was associated with anal HSIL caused by the same type.

TUPEC269

Behavioural profile of viral hepatitis co-infected MSM at HIV diagnosis

T.H. Kwan[1], N.S. Wong[2], K.C.W. Chan[3], O.T.Y. Tsang[4], W.S. Leung[4], K.M. Ho[5], M.P. Lee[6], S.N. Chan[7], G.C.Y. Lui[8], S.S. Lee[2]
[1]Chinese University of Hong Kong, Jockey Club School of Public Health and Primary Care, Shatin, Hong Kong, [2]Chinese University of Hong Kong, Stanley Ho Centre for Emerging Infectious Diseases, Shatin, Hong Kong, [3]Integrated Treatment Centre, Department of Health, Kowloon Bay, Hong Kong, [4]Princess Margaret Hospital, Department of Medicine and Geriatrics, Lai Chi Kok, Hong Kong, [5]Princess Margaret Hospital, HIV & Infectious Disease Centre, Lai Chi Kok, Hong Kong, [6]Queen Elizabeth Hospital, Department of Medicine, Kowloon, Hong Kong, [7]Queen Elizabeth Hospital, Kowloon, Hong Kong, [8]Chinese University of Hong Kong, Department of Medicine and Therapeutics, Faculty of Medicine, Shatin, Hong Kong

Background: Sexual spread of viral hepatitis B and C, apart from conventional bacterial sexually transmitted infections (STI), has gained momentum among HIV+ men who have sex with men (MSM) following widespread introduction of antiretroviral therapy. We hypothesize that viral hepatitis co-infected MSM constitute a community group with a unique profile of sexual behavioural risks.

Methods: All adult patients with newly diagnosed HIV infection attending any one of the 4 public HIV services in Hong Kong were invited to join a prospective cohort study involving a self-administered questionnaire, blood sampling for HIV phylogenetic analysis, and clinical data transcription. Hepatitis B and C infection status (HBsAg, Anti-HCV) at HIV diagnosis, alongside STI history, were noted and analysed.

Results: During a 1-year period since August 2016, 344 newly diagnosed patients were recruited, of which 87% were MSM. The latter's prevalence of hepatitis B and C infection was respectively 5.37% and 3.69%. Totally 191 MSM (median age 31) with completed questionnaire, HIV subtype and clinical data were analysed. Bacterial STI (syphilis, gonorrhoea, and/or chlamydia) occurred in 40% of them. HIV+ MSM with viral hepatitis (B or C) at diagnosis were more likely to have concurrent partners (odds ratio [OR]: 2.98, $p=0.034$), participated in group sex, (OR:4.46, $p=0.005$) and used recreational drugs for sex (chem-sex, OR: 5.79, $p=0.001$). Specifically HIV/HCV co-infected MSM gave a higher odds of history of chem-sex (OR: 8.62, $p=0.026$) and infection with syphilis (OR: 9.86, $p=0.022$) but not the other STIs. All HIV/HCV co-infected patients self-reported local HIV acquisition. There's no difference in the HIV subtype distribution between MSM with or without viral hepatitis. Having sought partners in sauna in the year before infection showed a marginal effect on their hepatitis status (OR: 2.53, $p=0.051$).

Conclusions: Viral hepatitis B and C were markers reflecting the practice of high risk sexual activities among HIV+ MSM. For HCV co-infected MSM, there was also association with chem-sex and concurrent transmission of syphilis but not chlamydia or gonorrhoea around the time of HIV diagnosis. The unique profile suggested that viral hepatitis infected MSM, especially those with hepatitis C, formed a characteristic network in the community.

TUPEC270

Results of a 15-year targeted HBV-vaccination program for high behavioral risk groups

A. Urbanus, A. Meiberg, H. Ruijs
RIVM, Bilthoven, Netherlands

Background: In 2002 the Netherlands started a hepatitis B-vaccination program targeted at high behavioral risk groups in absence of a universal vaccination policy. Universal HBV-vaccination for children was only implemented in 2011. The public health services offer free HBV-vaccination to behavioral risk groups like injecting drug users (IDU), sex-workers (SW), men who have sex with men (MSM) and heterosexuals with multiple sexual contacts (HMS). Here the results of a 15 year unique vaccination program are described (2002-2017).

Methods: The program aims to reach the various risk-groups at outreach locations (e.g. Saunas, festivals, brothels, methadone clinics etc.) and STI clinics and administers free HBV-vaccines. To increase vaccination

coverage and adherence, targeted campaigns are conducted each year via social media, online dating platforms and commercial sex websites. Since vaccination of IDU and HMS was not efficient anymore (i.e. HBV was not circulating in these riskgroups anymore), they were excluded from the program in respectively 2012 and 2007. Since 2012 HIV-positive participants received a double dose of HBV-vaccination in order to increase immunity, conform the Dutch guidelines.

Results: Over a 15-year period over 140,000 (41% MSM, 15% SW, 12.6% IDU 28.8% HMS) participants received their first of three HBV-vaccination, 8137 (5.7%) participants were already immune (anti-HBc positive) and 0.5% were found to be HBsAg positive. In total 336,671 HBV-vaccinations were administered. Compliance varied between risk groups: 72% of MSM finished the complete series, while only 60% of HMS, 57% of IDU and 50% of CSW finished the complete series. Since 2012, 1,604 first double dose vaccines were administered among HIV-positives, of whom most were MSM (96%).

Conclusions: The targeted HBV-vaccination program for high behavioral risk groups has been successful over the past 15 years. In order to increase efficiency of the program policy changes are implemented, like shifting more from offline outreach to online outreach activities, or targeting more younger MSM. Although less cost-effective over the last years, still each year about 4,000 MSM and 1,000 CSW receive their first HBV-vaccination thanks to constant commitment and creativity of enthusiastic health professionals for new approaches.

TUPEC271

Healthcare utilization and STI incidence in young men on pre-exposure prophylaxis (PrEP) compared to young men who are not on PrEP: The PrEPARE Study

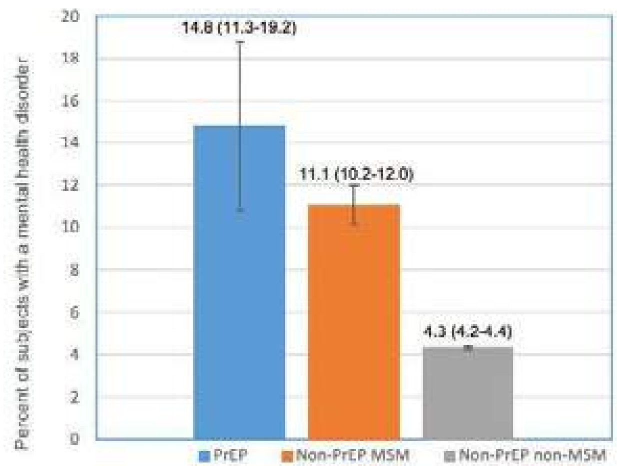
R. Hechter[1], L.-H. Chen[1], K. Yu[2]
[1]Kaiser Permanente Southern California, Department of Research and Evaluation, Pasadena, United States, [2]Kaiser Permanente Southern California, Department of Quality and Infectious Diseases, Pasadena, United States

Background: Many young adult males do not seek healthcare services for a variety of reasons. Regular healthcare visits for pre-exposure prophylaxis (PrEP) prescription required by CDC guidelines may serve as a portal for young male PrEP users to engage in holistic healthcare. In a large, diverse, community-based population, we evaluated the association of PrEP use with healthcare utilization, and incidence of sexually transmitted infections (STIs) among young men.

Methods: Within a large U.S. integrated healthcare delivery system in Southern California, we identified eligible young males (18-34 years) during 07/2014-06/2016. We ascertained demographic characteristics, PrEP use, healthcare utilization, immunization, and STI diagnosis through electronic health records. We evaluated the independent association of PrEP use with healthcare utilization during 6 months following PrEP initiation or study entry, using Poisson regression models with robust variance to sequentially adjust for: baseline utilization, age, race/ethnicity, education, and membership length.

Results: We identified 304 PrEP users, 4,495 men who have sex with men (MSM) without PrEP use and 273,050 other young men. Compared to the two comparison groups, PrEP users were older (27-34 vs.18-26 years), had more primary and urgent care visits, more visits with psychiatry and other specialty care providers (P< 0.001), slightly more ED visits and similar rate of hospitalization. More PrEP users had a diagnosis of mental health disorder (Figure). The coverage of 3 doses of HPV and hepatitis B vaccines was low among all groups, with higher rates among PrEP users (HPV:19%, hepatitis B:18%). Majority of PrEP users received tests for syphilis/ gonorrhea/ chlamydia (97%), hepatitis B (70%), hepatitis C (92%) and HIV (95%) during follow-up, while the testing rates were lower in the comparison groups (MSM:11-23%, other: < 5%). The incidence of syphilis, gonorrhea and chlamydia was 7.6%, 19.7%, and 3.0% among the PrEP users, significantly higher than the comparison groups (P< .001). In multivariable analyses, PrEP use was associated with greater use of primary care, urgent care and ED visit (Table).

Conclusions: Young male PrEP users are more likely to utilize primary and preventive care and undergo STI screening, but have a higher rate of STIs and mental health disorders compared to their counterparts.



[Proportion of subjects who had a mental health disorder diagnosis during 6-month follow-up period.]

Healthcare Utilization	PrEP user vs. MSM (non PrEP user)	PrEP user vs. other young men
No. of primary care visit	1.21 (1.07-1.36)	1.81 (1.61-2.03)
No. of urgent care visit	1.31 (1.07-1.61)	1.99 (1.64-2.42)
No. of ED visit	1.10 (0.78-1.55)	1.42 (1.02-1.96)
No. of hospitalization	0.20 (0.02-1.41)	0.35 (0.05-2.48)

[Multivariable association of PrEP use with healthcare utilization (rate ratio, 95% CI) during 6-month follow-up period.]

TUPEC272

Eliminating hepatitis C as public health threat: Significant increase in HCV direct-acting antiviral therapy and rapid decline in viraemic prevalence among people who inject drugs in Australia

J. Iversen, L. Maher
UNSW Sydney, The Kirby Institute, Sydney, Australia

Background: Australia implemented subsidised access to hepatitis C virus (HCV) direct acting antiviral (DAA) therapy in March 2016, with no restrictions on disease stage, substance use or provider type. Progress towards the WHO HCV elimination goal of 80% of the eligible chronic HCV population treated by 2030 is encouraging, with one in four Australians with chronic HCV initiating DAA therapy by June 2017. However, little is known about people who inject drugs (PWID) initiating treatment, an important consideration in relation to the WHO gaol to also reduce HCV incidence by 80% by 2030.

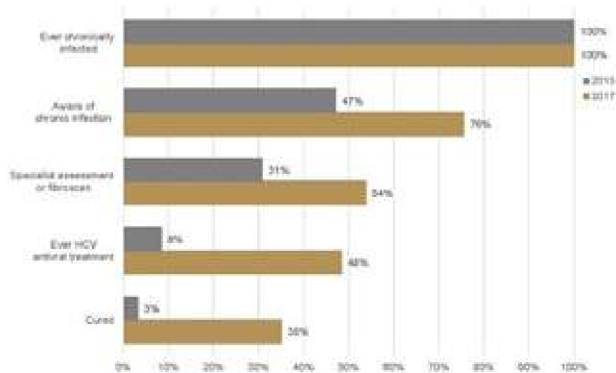
Methods: Annual cross-sectional bio-behavioural surveillance among PWID involved completion of a self-administered questionnaire and provision of a dried blood spot for HIV and HCV (antibody and RNA) testing. Data from 2015 (pre-DAAs baseline) and 2017 (post-DAAs) were used to populate the cascade of HCV care (confirmatory RNA testing, specialist assessment and/or FibroScan®, antiviral treatment and viral clearance/cure) among respondents with a history of chronic HCV infection^.

Results: Samples comprised n=2,304 (2015) and n=2,600 (2017). Just over half were exposed to HCV and ~20% of the exposed group had spontaneously cleared the virus. Among those assessed as eligible for HCV treatment (ever living with chronic HCV), we observed a significant increase (p< 0.001) at all stages of the cascade of HCV care in 2017 compared to 2015 baseline (Figure 1). Prevalence of lifetime treatment uptake increased from 8% in 2015 to 48% in 2017, with a corresponding decline in viraemic prevalence among the overall sample from 45% in 2015 to ~25%^ in 2017.

Conclusions: High levels of HCV treatment uptake are achievable among PWID in settings with no restrictions on access to therapy. Our study also demonstrates that increased uptake of HCV treatment can significantly reduce underlying viraemic prevalence among PWID, the group most at risk of onward transmission, over very short time periods. While results indicate that eliminating hepatitis C as a public health

threat is feasible, challenges remain, including ensuring equity of access among vulnerable sub-populations and preventing reinfection among PWID.

^Laboratory determined (HCV RNA) in 2015, self-report in 2017 (HCV RNA available in May 2018, results will be updated).



[The HCV cascade of care among people who inject drugs in Australia, 2015 and 2017]

Low prevalence and incidence of hepatitis C among men who have sex with men and transgender women in a key population-led Test and Treat cohort in Thailand

R. Ramautarsing[1], J. Jantarapakde[1], S. Pengnonyang[1], R. Meksena[1], N. Teachatanawat[1], T. Sungsing[1], P. Mingkwanrungruangkit[1], N. Mahachokchai[2], S. Samalu[3], T. Nakpor[4], R. Reankhomfu[5], P. Rattakitvijunnanakorn[1], S. Tongmuang[1], S. Charoenying[6], S. Mills[6], R. Vannakit[7], P. Phanuphak[1], N. Phanuphak[1]

[1]Thai Red Cross AIDS Research Center, Prevention Department, Bangkok, Thailand, [2]Rainbow Sky Association of Thailand, Bangkok, Thailand, [3]The Service Workers in Group Foundation, Bangkok, Thailand, [4]SISTERS Foundation, Chonburi, Thailand, [5]Caremat, Chiang Mai, Thailand, [6]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [7]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

Background: Although the prevalence of hepatitis C virus (HCV) in the general population in Thailand is declining, data are lacking on the epidemiology of HCV among men who have sex with men (MSM) and transgender women (TGW). We estimated HCV prevalence and incidence among sexually active, high-risk MSM and TGW in a Key Population (KP)-Led Test and Treat cohort.

Methods: From May 2015 through October 2016, Thai MSM and TGW 18 years and older were recruited from six KP-led clinics in Thailand. Baseline demographics and behavioral risk were assessed using questionnaires. Trained KP health workers provided HIV testing with same-day results every six months, sexually transmitted infection screening every twelve months, and anti-HCV testing at baseline and month 12.

Results: A total of 2,644 participants with a median (interquartile range) age of 24.1 (20.9-29.6) years were enrolled (1,858 [70.3%] MSM, 786 [29.7%] TGW). At baseline, 400 (15.1%) participants were HIV positive, and 6.2% had active syphilis. In the previous six months, participants reported engaging in unsafe sex (77.1%), having multiple sex partners (53.8%), engaging in group sex (11.2%), using any type of illicit drug (18.7%), using amphetamine-type stimulants (7.8%), and using intravenous drugs (IVDs) (3.3%). HCV prevalence (95% confidence interval-CI) was 0.76% (0.49%-1.18%) overall, 0.63% (0.37%-1.06%) among HIV-negative participants and 1.52% (0.68%-3.34%) among HIV-positive participants (p=0.06). HCV prevalence was similar among MSM and TGW (0.71% vs. 0.90% respectively, p=0.61). Independent predictors for positive anti-HCV were age (adjusted odd ratio-aOR [95%CI] 1.09 [1.04-1.15], p=0.001), active syphilis (aOR [95%CI] 4.43 [1.37-14.37], p=0.013) and ever IVD use (aOR [95%CI] 4.11 [1.07-15.84], p=0.04). At month 12, there were two incident HCV cases (incidence [95%CI] of 1.76 [0.44-7.02] per 1,000 person-years). Both were HIV-negative at enrollment, and one seroconverted for HIV at month 12.

Conclusions: We found low HCV prevalence, regardless of HIV status, and low incidence in a cohort of high-risk MSM and TGW enrolled from KP-led clinics in Thailand. MSM and TGW who have active syphilis, report IVD use, or are practicing risk behaviors for HIV should be the target for HCV screening in Thailand.

TUPEC274

High burden of coinfection with HIV and hepatitis C virus (HCV) among people who inject drugs: A respondent-driven sampling study in Jakarta, Indonesia

C. Stoicescu[1], A. Iryawan[2], M. Mahanani[3], E. Nasution[4]

[1]University of Oxford, Social Policy & Intervention, Oxford, United Kingdom, [2]Indonesian Drug Users Network, Jakarta, Indonesia, [3]Atma Jaya University, AIDS Research Centre, Jakarta, Indonesia, [4]Indonesian Drug Users Network, National Coordinator, Jakarta, Indonesia

Background: The intersection of HIV and HCV has numerous detrimental effects on health outcomes. The absence of reliable data on HIV/HCV coinfection among people who inject drugs (PWID) limits the ability to intervene effectively and is a particular concern in resource-limited settings. Given limited surveillance data on coinfection in Indonesia, the Indonesian Drug Users Network implemented a peer-driven intervention with educational, behavioural, and serological components. This study utilises data gathered in the latter two components to estimate the prevalence and predictors of HIV/HCV coinfection in a representative sample of PWID in Jakarta, Indonesia.

Methods: Between August 2015 and January 2016, 326 PWID were recruited using respondent-driven sampling. Eligibility criteria included being ≥18 years of age, injecting illicit drugs in the previous year, residing in Jakarta, and possessing a valid peer recruitment coupon. HCV prevalence was estimated by the presence of HIV and anti-HCV antibodies incorporating RDS-weights. Predictors of coinfection were assessed using weighted multivariate logistic regressions.

Results: Overall HIV prevalence was 53.4%, with higher prevalence among males (53.9%) relative to females (50.0%). HCV prevalence was 89.2% in the entire sample, 90.5% among males, and 80.8% among females (p< 0.05). Coinfection with HIV/HCV was 52.3% in the whole sample, with higher rates among males (53.6%) relative to females (44.6%). Predictors of coinfection included: past-month sharing of injecting paraphernalia (OR=3.99, 95% CIs:1.61-9.94, p< 0.01), lifetime overdose (OR=2.98, 95% CIs:1.28-6.98, p< 0.01), recent tuberculosis diagnosis (OR=3.99, 95% CIs:1.61-9.94, p< 0.01) and history of arrest (OR=1.48, 95% CIs:0.52-4.26, p< 0.01).

Conclusions: The high burden of HIV/HCV co-infection among Indonesian PWID highlights an urgent need for tailored prevention, care and support services. Integration of HCV services within the existing HIV care continuum is essential to curb the dual impact of these epidemics and improve quality of life of PWID.

TUPEC275

Perinatal HIV diagnosis and STI treatment outcomes among HIV positive women in Pretoria, South Africa

L. de Vos[1], M. Mudau[1], D. Olivier[1], C. Bezuidenhout[1], J. Klausner[2], K. Lovero[3], A. Medina-Marino[1]

[1]Foundation for Professional Development, Research Unit, Pretoria, South Africa, [2]Global Health David Geffen School of Medicine, Division of Infectious Diseases, Los Angeles, United States, [3]Columbia University, Department of Psychiatry and New York State Psychiatric Institute, New York, United States

Background: Aside from the physiological implications of the virus on pregnancy, perinatal HIV diagnosis and the processing thereof, may affect health seeking behaviour, treatment adherence and reproductive health including STIs. We aimed to determine the association between perinatal HIV diagnosis and STI treatment outcomes.

Methods: HIV-infected pregnant women attending first antenatal care services (ANC) were enrolled from three primary healthcare facilities in Pretoria, South Africa between June 2016 and September 2017. Eligibility

included >18yrs, ≤34 weeks gestation, intent to stay in Tshwane, willingness to collect a vaginal specimen for STI testing and a documented HIV diagnosis. Participants were tested for Chlamydia, Gonorrhoea and Trichomonas, at first ANC and post-delivery. A test-of-cure was scheduled for women with a positive STI. Date of HIV diagnosis and other relevant clinical information was extracted from maternal records. Data was captured using RedCap and analysed with STATA v. 13.

Results: We enrolled 430 women attending first ANC; mean age=30 years, median gestational age= 21 weeks, 13% primigravida, 37% newly diagnosed with HIV. Women diagnosed with HIV at first ANC, were more likely to experience higher levels of depressive symptoms than those with a previous diagnosis (OR=2.4, 95% CI 1.22-4.81). STI prevalence at first ANC was 40% (N=174), 91% of women newly diagnosed with HIV disclosed their STI status to their partner and overall reported good STI treatment adherence. Among newly diagnosed women who tested positive for an STI during pregnancy, 23/54 were still positive at their test-of-cure (OR=2.4, 95% CI 1.13-4.96). Sixty-three percent (N=20/32) reported using condoms every time since STI diagnosis. Despite these findings, womanly diagnosed with HIV at first ANC more likely to test STI positive at the postnatal visit (OR=2.6, 95% CI 1.24-5.41).

Conclusions: Pre- and post-HIV counselling should ensure sufficient and ongoing support for women newly diagnosed with HIV including STI management. However, future research should further investigate why newly HIV diagnosed women struggle (more) to clear their STI infection despite adherence and disclosure.

Epidemiology of non-AIDS non-communicable diseases (e.g. non-AIDS cancers, CVD)

TUPEC276

Health conditions and use of medications by people living with HIV: The Positive Voices 2017 Survey

M. Auzenbergs[1,2], M. Kall[1], V. Delpech[1]
[1]Public Health England, London, United Kingdom, [2]Watipa, London, United Kingdom

Background: In the UK, the uptake of antiretroviral therapy is high (>97%) among the 91,987 persons seen for HIV care and more than a third (38%) are aged 50 years and older. Population-level estimates of co-morbidities and use of non-HIV related medications are needed to plan the provision of health services, particularly among an aging population.

Methods: Positive Voices is a cross-sectional, probability survey of people with HIV. A representative pre-selected sample of people attending 73 HIV clinics in England & Wales between January and September 2017 was invited to complete a paper or online survey. Participants selected comorbidities (self-reported ever diagnosed) from a comprehensive list of 25 conditions and reported rarer conditions in free text. Use of prescription medication in the past 4 weeks for each condition was collected in addition to ARV medication.

Results: 74% have been diagnosed with at least one chronic condition, rising to 86% among those aged ≥50 (Table 1). Depression (33%) and anxiety (26%) were the most commonly reported co-morbidities overall (with 75% of depression and anxiety diagnoses made at the time of, or after, HIV diagnosis) and the most prevalent in the 18-49 age group. However, among people aged 50+, high cholesterol (45%) and hypertension (36%) were the most prevalent co-morbidities, followed by depression (34%). With the exception of depression and anxiety, most co-morbidities were more common among older adults (Table 1), with the most marked differences being a 4-fold higher prevalence of osteopenia/osteoporosis and a 3-fold higher prevalence of arthritis, peripheral neuropathy and erectile dysfunction compared to under 50s. Overall, 98% of respondents were taking ARVs and 64% of people were taking at least one non-HIV medication, rising to 75% in those 50+ yrs. Differences in rates in co-morbidities and medication use were observed by gender and other demographic characteristics.

		Prevalence Estimates			Percentage of patients on prescribed medication in the last 4 weeks	
	n	Overall % (95% CI)	Age 18-49 years % (95% CI)	Age ≥50 years % (95% CI)	Age 18-49 years % (95% CI)	Age ≥50 years % (95% CI)

At least one co-medication	[illegible]	[illegible]	-	-	[illegible]	[illegible]

[Table 1. Prevalence of selected self-reported ever-diagnosed comorbidities and polypharmacy among people living with HIV, Positive Voices, 2017]

Conclusions: People living with HIV, particularly those over the age of 50, report high rates of comorbidities and medication use. These findings will assist in the modelling and planning of future health and social care services and highlight the need for integrated care for people living with HIV.

TUPEC277

Prevalence and risk factors for hypertension among people living with HIV in Zambia

J. Pry[1,2], M. Vinikoor[1,3], E. Geng[4], M. Roy[4], A. Mody[4], N. Padian[5], C. Bolton[1,3], I. Sikazwe[1], C. Holmes[6]
[1]Centre for Infectious Disease Research Zambia, Lusaka, Zambia, [2]University of California Davis, Davis, United States, [3]University of Alabama Birmingham, School of Medicine, Birmingham, United States, [4]University of California San Francisco, Medicine, San Francisco, United States, [5]University of California Berkeley, Berkeley, United States, [6]George Washington University, School of Medicine, Washington D.C., United States

Background: As the response to the HIV epidemic matures, and people age while on antiretroviral treatment, understanding cardiovascular disease risk factors such as hypertension in this population is key. Our objective was to describe the prevalence, risk factors and trends of hypertension, using routine data, amongst patients in the national HIV treatment program.

Methods: We extracted blood pressure readings for all individuals in the HIV electronic medical record database aged 17-75 years, with at least two measurements between January 1, 2011 and December 31, 2016. Hypertension was defined as two consecutive visits with systolic pressure >140 (mmHg) and/or diastolic >90 (mmHg). Height, weight, age, CD4 count, education, and income were extracted at baseline. We analyzed frequencies, trends and demographic risk factors for hypertension using descriptive statistics and mixed-effects logistic regression.

Results: Among 641,760 patients in the database, 187,620 (29.2%) had at least two blood pressure measures for a total of 1,157,430 visits during the study period. Median age was 37.8 years (IQR: 31.2 - 44.4), 100,721 (64.4%) were female, and median baseline CD4 cell count was 216 (n = 64,184, IQR: 100.5 - 331.5). 186,244 (99.3%) were on ART. Patients included in the analysis had a median of 5 visits (IQR: 2.5- 7.5) and time from first to last visit with a blood pressure measure was a median of 1213 days (IQR: 483.5 - 1942.5). Patients with at least one elevated blood pressure measure totaled 72,877 (38.8%) and 25,477 (13.6%) met the criteria for hypertension. In mixed effects regression analysis (table 1), greater BMI, male sex, increased age, time in care, and higher income were associated with hypertension whereas CD4 and education were not. A minimal, though statistically significant, increase in mean between baseline systolic and diastolic blood pressure at 3 years (n = 11,028 (43.3%)) among hypertensive cases was 1.76 and 1.16 mmHg, respectively.

Conclusions: Hypertension is common among people in HIV care in Zambia. Predictors of hypertension mirror those observed in higher income settings although hypertension screening here was incomplete. The remarkable burden of hypertension in this population suggests a need for greater integration of hypertension management with HIV care in Zambia.

TUPEC278

Opportunities, challenges and implications of m-Health oral cancer screening for HIV-positive individuals in India

S. Joshi[1], I. Marbaniang[2], A. Chandanwale[1], S. Sangle[1], S. Khaire[1], R. Thakur[1], A. Gupta[2,3], R. Chigurupati[4], V. Mave[2,3]
[1]BJ Government Medical College, Pune, India, [2]BJGMC-CRS, Pune, India, [3]CCGHE, Johns Hopkins University, Baltimore, United States, [4]Boston University, Boston, United States

Background: Oral cancer accounts for 30% of all cancers in India. HIV-induced immunosuppression is a risk factor for cancer. Tobacco, alcohol use and oral HPV: risk factors for oral cancer are common among PLWH. Screening for oral cancer in India is sparse and patient to provider ratio high. We evaluated a novel m-Health oral cancer screening approach for PLWH led by non-medical healthcare workers.

Description: Employing a validated oral cancer screening mobile application, PLWH (≥21 years) with no prior history of oral cancer were enrolled June to November 2017 at the ART clinic, Sassoon General Hospitals, Pune, India. Two trained non-medical healthcare workers obtained demographic, HIV, cancer risk factor data and took 8 or more photographs of the oral cavity using a smartphone. Photographs were uploaded to a cloud-based server and reviewed independently by two oral cancer specialists for oral potentially malignant disorders (OPMDs). If disagreement occurred, a third independent senior specialist adjudicated. Image review results were communicated to the healthcare workers. Individuals deemed to have OPMDs were contacted for an in-person clinical evaluation by a specialist and provided additional care as necessary.

Lessons learned: Of 331 enrollees, 50% were male, median age was 40 years (IQR: 34 -45), median CD4 was 529 cells/mm³ (IQR: 366 - 727), 15% ever smoked, 2% currently smoked; 39% ever chewed tobacco, 26% currently chewed tobacco; 35% ever used alcohol and 1% drank currently. Oral sex was reported by 15% and multiple sexual partners by 29%. Of 2648 images reviewed, 99% were deemed adequate for making a clinical diagnosis; 42 participants (13%) were judged to have OPMDs by two clinicians. They were older (p=0.01), more likely to be male (p=0.05). Of the 42, 36% did not return after being contacted. Of 27 who returned, 52% were diagnosed with OPMDs on clinical examination and provided standardized care.

Conclusions/Next steps: In a cohort with high CD4 count, prevalence of oral cancer risk factors was high. While OPMDs were overdiagnosed on image review, m-Health provided an effective and rapid method of oral cancer screening, without overburdening providers.Scaling up of this strategy will however require better risk communication to improve participant follow-up.

TUPEC280

Heart rate variability, HIV and cardiovascular disease risk in rural South Africa

N.G. Godijk[1], A.G. Vos[1,2], V. Jongen[1], R. Moraba[3], H. Tempelman[3], D.E. Grobbee[1], R.A. Coutinho[1], W. Devillé[1,3], K. Klipstein-Grobusch[1,4]
[1]University Medical Centre Utrecht, Julius Global Health, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, [2]University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Faculty of Health Sciences, Johannesburg, South Africa, [3]Ndlovu Care Group, Groblersdal, South Africa, [4]University of the Witwatersrand, Division of Epidemiology and Biostatistics, School of Public Health, Faculty of Health Sciences, Johannesburg, South Africa

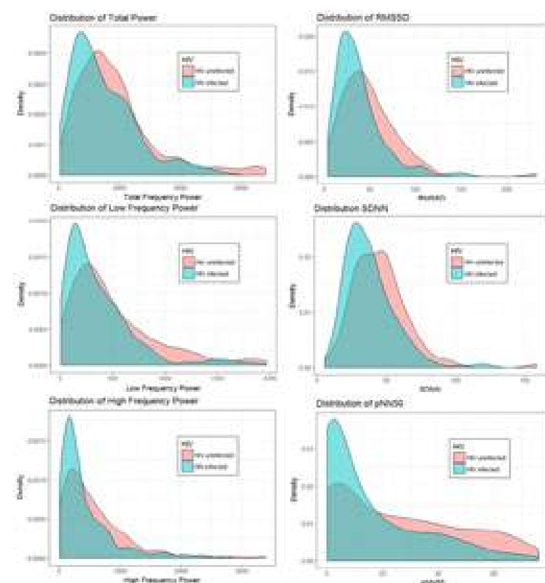
Background: The increased use of anti-retroviral therapy (ART) transformed human immunodeficiency virus (HIV) infection into a chronic disease. Possible HIV-associated complications have emerged including cardiovascular diseases (CVD). Surrogate markers can estimate CVD risk, however data from high HIV-prevalence areas such as rural South Africa are limited. This study aims to determine

1) the distribution of heart rate variability (HRV), a surrogate marker of CVD risk,

2) the association between HIV and HRV and

3) the association between ART and HRV in the rural South African population.

Methods: Participants of the Ndlovu Cohort Study visiting the research centre in Elandsdoorn, South Africa between August and December 2017 were included in this cross-sectional study. HRV was measured using a standardized 5-min resting ECG. HRV was determined using total-frequency (0.04 to 0.5 Hz), low-frequency (0.04 to 0.15 Hz), high-frequency power (0.15 to 0.5 Hz), standard deviation of the normal RR intervals (SDNN), the root of the mean squares of successive RR differences (RMSSD) and the percentage of RR intervals greater than fifty milliseconds different from its predecessor (pNN50). All parameters had a skewed distribution and were log-transformed for multivariable analysis. Information on gender, body mass index (BMI), age, medication use, blood pressure, physical activity, education and income level were obtained using standardized questionnaires. The Kruskal Wallis test was used to test a difference in medians between HIV-infected and HIV-uninfected participants. Multivariable linear regression analyses were performed to identify predictors of HRV.



[Figure 1. The distribution of heart rate variability in a rural South African population]

Model	Variable	Coef.	Std. Error	p-value
Model log RMSSD	Age	-0.02	0.00	0.00
	HIV-infection	-0.16	0.07	0.03
Model log SDNN	Age	-0.01	0.09	0.00
	HIV-infection	-0.11	0.05	0.02
Model log pNN50	Age	-0.02	0.00	0.00
	HIV-infection	-0.11	0.05	0.02
Model log LF power	Age	-0.04	0.00	0.00
	HIV-infection	-0.21	0.10	0.04

[Table 1. Predictors of log RMSSD, log SDNN, log pnn50 and log LF power in a rural South African population]

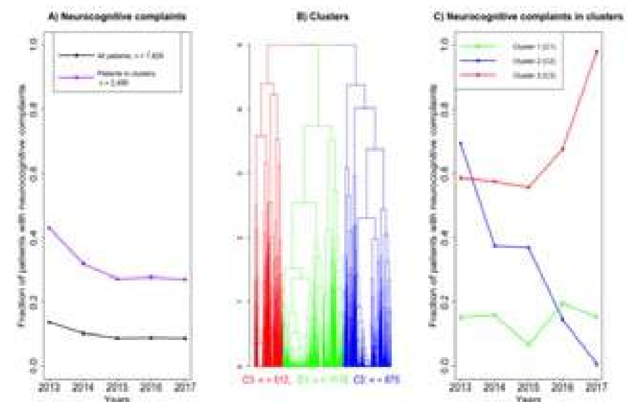
Results: In total 325 participants were included, of whom 202 (62.2%) were HIV-infected. All HRV parameters (median values) were lower for the HIV-infected compared to the HIV-uninfected participants. The multivariate models showed a significant inverse association between HIV and SDNN, RMSSD, pNN50 and LF power, and between age and all HRV parameters. There was no indication of a difference in HRV between participants on ART versus not on ART.
Conclusions: These findings show that HIV-infected participants have a lower HRV, indicating an increased risk of CVD and this suggests that embedding of CVD prevention in HIV-care is necessary.

TUPEC281

Neurocognitive complaints in people living with HIV: Characterizing clusters of patients with similar changes in neurocognitive complaints in the Swiss HIV Cohort Study

K. Kusejko[1,2], L. Salazar-Vizcaya[3], D.L. Braun[1,2], M. Battegay[4], E. Bernasconi[5], A. Calmy[6], M. Cavassini[7], M. Hoffmann[8], R. Du Pasquier[7], J. Böni[2], S. Yerly[6], T. Klimkait[9], M. Perreau[10], A. Rauch[3], H.F. Günthard[1,2], R.D. Kouyos[1,2], and the Swiss HIV Cohort Study
[1]University Hospital Zurich, Zurich, Switzerland, [2]University of Zurich, Zurich, Switzerland, [3]Bern University Hospital, Bern, Switzerland, [4]University Hospital Basel, Basel, Switzerland, [5]Regional Hospital Lugano, Lugano, Switzerland, [6]Geneva University Hospital, Geneva, Switzerland, [7]Lausanne University Hospital, Lausanne, Switzerland, [8]Cantonal Hospital St Gallen, St Gallen, Switzerland, [9]University of Basel, Basel, Switzerland, [10]University of Lausanne, Lausanne, Switzerland

Background: Despite the seminal success of antiretroviral therapy (ART), HIV-associated neurocognitive disorders remain one of the most difficult comorbidities for clinicians to deal with. To date, the pathogenesis and risk factors of neurocognitive disorders are only incompletely understood. We use the extensive, longitudinal data of the Swiss HIV Cohort Study (SHCS) to study self-reported neurocognitive complaints over time.
Methods: Since 2013, SHCS patients are routinely asked twice a year whether they have complaints about memory loss, concentration or slowing down in reasoning. We included patients with at least five follow-up visits at least three years apart in the analysis. A hierarchical clustering algorithm based on the difference of scores calculated from the three questions concerning neurocognitive complaints was applied to detect patients with a similar trajectory of scores. Potential confounders were compared between the clusters using Fisher exact tests.
Results: Of the 7,829 patients included in the analysis, 2,499 reported at least once having frequent neurocognitive complaints, with a decreasing trend over time (Figure A). Via a cluster algorithm, these 2,499 patients were grouped into three main clusters (Figure B), characterized by a constant small fraction (C1), a decrease (C2) and an increase (C3) of neurocognitive complaints over time, respectively (Figure C). There was no significant difference in gender or ethnicity between the clusters. The median birth year in C1 was 1965, in C2 1964 and in C3 1963. Patients in C2 and C3 suffered significantly more often from depression compared to C1 (p< 0.001). Moreover, adherence to ART was worst in C3 (p< 0.001). No difference in mean CD4 cell counts or viral suppression was found, but patients in C3 had more often a history of central nervous system (CNS) opportunistic infections (p =0.007). Differential effects of ART were found with respect to C3.
Conclusions: There is an overall decrease of patients reporting neurocognitive complaints in the years 2013 to 2017 in SHCS patients. However, a cluster of patients with even increasing complaints remains present. Factors associated with being in this cluster (C3) included a slightly higher age, depression, less adherence to ART, history of CNS opportunistic infections and different ART regimens.



[Figure: A) Fraction of patients with neurocognitive complaints. B) The three top clusters. C) Fraction of neurocognitive complaints in the clusters.]

TUPEC282

Frailty-related phenotype, quality of life and non-communicable disease in older Ugandan adults - associations with toxic stress and HIV infection

A.E. Ezeamama[1], N. Nakasujja[2], A. Sikorskii[3], M. Ssonko[4], N. Kaminski[3], D. Guwatudde[5], M.J. Boivin[3], B. Giordani[6]
[1]Michigan State University, Psychiatry, East Lansing, United States, [2]Makerere University School of Medicine, Kampala, Uganda, [3]Michigan State University, East Lansing, United States, [4]Mildmay Uganda, Kampala, Uganda, [5]Makerere University School of Public Health, Kampala, Uganda, [6]University of Michigan, Ann Arbor, United States

Background: Toxic stress may accelerate non-communicable disease (NCD) onset and severity through induction of inflammatory processes and behavioral mal-adaptations. Toxic stress as risk factor for NCD outcomes in older Ugandans with and without HIV-infection is under-investigated.
Therefore, we evaluate the hypothesis that toxic stress is associated with frailty-related phenotype (FRP), low quality of life (QOL) and prevalent NCDs in Ugandan adults at high risk of NCDs.
Methods: We have enrolled, 97 adults ≥50 years with chronic HIV-infection stably linked to HIV-care and 30 age (+/-5 years), sex and village matched HIV-negative community controls from Wakiso District of Uganda. QOL and FRP were defined using the short form Medical Outcomes Study questionnaire and Edmonton frail scale respectively. Number of physician-diagnosed comorbid NCDs (arthritis, depression, ever stroke, diabetes, heart, liver, lung or bone disease) was calculated and dichotomized as none versus any; QOL and FRP outcomes were dichotomized at the mean. Toxic stress was measured using the perceived stress scale and categorized based on tertiles. Odds ratios (OR) and 95% confidence interval (CI) were calculated for HIV- and Stress-related prevalence of low QOL, FRP and presence vs. absence of NCD in SAS v.9.4.
Results: HIV-infected status and stress measures were positively associated with prevalent NCD although neither relationship was statistically significant. The odds of high frailty was 5.2 (95%CI: 1.5, 17.0) times elevated for HIV-infected vs. community controls while low (OR=0.04, 95% CI: 0.1, 1.1) and moderate (OR=0.9, 95%CI:0.3, 2.6) toxic stress level was inversely associated with frailty. High vs. Low QOL was not associated with HIV-infection (OR=0.6, 95%CI:0.2, 2.0) vs. community-control status. However the odds of high QOL was significantly elevated for older adults reporting low (OR = 12.6, 95% CI: 3.8, 41.3) and moderate (OR=11.6, 95% CI:3.7, 36.8) toxic stress.

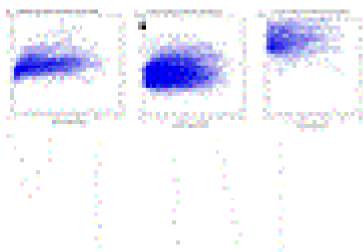
Conclusions: These preliminary data suggest that intentional reduction of Toxic stress could lead to improved QOL and lower frailty in high risk older Ugandans as they age with HIV. We are exploring how to mitigate the effects of toxic stress on these aging adults with HIV.

TUPEC283

Trends of Body Mass Index in HIV positive patients receiving antiretroviral treatment in rural Tanzania

A.V. Kalinjuma[1], H. Hussey[2,3], G. Sikalengo[2], E. Letang[2,4,5], M. Battegay[6,7], D. Paris[5,6], M. Weisser[2,5,6], KIULARCO Study Group
[1]Ifakara Health Institute, Intervention and Clinical Trial Depatment, Ifakara, Tanzania, United Republic of, [2]Ifakara Health Institute, Intervention and Clinical Trial Department, Ifakara, Tanzania, United Republic of, [3]Institute of Tropical Medicine and International Health, Charité-Universitätsmedizin Berlin, Berlin, Germany, [4]ISGlobal, Barcelona Centre for International Health Research (CRESIB), Hospital Clinic Universitat de Barcelona, Spain, [5]Swiss Tropical and Public Health Institute, Basel, Switzerland, [6]University of Basel, Basel, Switzerland, [7]University Hospital Basel, Division of Infectious Diseases and Hospital Epidemiology, Basel, Switzerland

Background: The risk for non-communicable diseases rises with increased prevalence of overweight and obesity in people living with HIV (PLHIV). Simultaneously, low body mass index (BMI) is a predictor of morbidity and mortality in PLHIV. The objectives of this study were to determine the prevalence of underweight and overweight/obesity and to describe the evolution of BMI in PLHIV on antiretroviral treatment (ART) enrolled in the Kilombero and Ulanga Antiretroviral Cohort, Ifakara, Tanzania.
Methods: Prospective cohort study. Consented non-pregnant adults (≥19 years) enrolled from 01/2013-12/2016 were included and follow-up ended in 6/2017. BMI was classified into three categories, according to WHO: underweight: BMI <18.5kg/m²; normal weight: BMI 18.5-24.99 kg/m²; and overweight/obese: BMI ≥25.0 kg/m². Generalized estimated equations with multinomial distribution were adopted to assess the association of BMI and baseline demographic and clinical characteristics.
Results: At start of ART (baseline), 60% of 1,452 participants were female, 87% farmers, 86% with primary school education and 52% had WHO stage III/IV. The median age was 40 years (IQR: 34-49) and CD4 count was 196 cells/µL (IQR: 79-325). Arterial hypertension was diagnosed in 11% and renal impairment in 6%. Prevalence of underweight and overweight/obesity were 21% and 15% respectively. Overweight/obesity was frequent in females (20% vs 8%). The median baseline CD4 count was 99 cells/µL (IQR: 38-228) and 294 cells/µL (IQR: 158-429) in underweight and overweight/obese patients respectively. BMI increased and stabilized in the majority of underweight patients after ART initiation (Figure: Panel (a)). Patients with normal BMI at baseline remained stable within their BMI class during follow-up (Figure: Panel (b)). Baseline WHO stage III and IV had increased odds of being underweight (OR=3.4, 95% CI: [1.9-6.2] and OR=7.4, 95% CI: [3.7-14.5] respectively). Male, patients with CD4 count ≥350 cells/µL and hypertensive patients had OR=0.3, 95% CI: [0.2-0.5], OR=2.3, 95% CI: [1.2-4.4] and OR=2.1, 95% CI: [1.2-3.5] of being overweight/obese respectively.
Conclusions: There exists double burden of underweight and overweight/obesity, even in a rural HIV cohort. We identified gender and clinical baseline factors associated with low and/or high BMI. Measures to address this double burden of malnutrition should be in place.



[Figure: Trends of BMI in patients started ART with all three BMI categories]

TUPEC284

Higher risk of metabolic syndrome among HIV infected women compared to men in Kenya

A. Osoti[1,2], T. Temu[3], S. Page[4], N. Kirui[5], G. Bloomfield[6], C. Farquhar[7]
[1]University of Nairobi, Obstetrics and Gynecology, Nairobi, Kenya, [2]University of Washington, Epidemiology, Seattle, United States, [3]University of Washington, Global Health, Seattle, United States, [4]University of Washington, Division of Metabolism and Endocrinology, Seattle, United States, [5]Moi Teaching and Refferal Hospital, Medicine, Eldorert, United States, [6]Duke University Medical Center, Division of Cardiology Department of Medicine and Global Health, Durham North Carolina, United States, [7]University of Washington, Epidemiology, Global Health, Internal Medicine, Seattle, United States

Background: Antiretroviral therapy (ART) has enhanced life expectancy in resource-constrained settings. Older age, HIV and ART related inflammatory changes might increase gender specific risk of metabolic syndrome (MetS), a risk factor of cardiovascular disease (CVD).
Methods: In a cross-sectional survey among adults receiving HIV-related care in Eldoret, Kenya, cardiovascular risk factors were assessed using the World Health Organization stepwise approach to surveillance (STEPS) questionnaire and MetS was defined according to International Diabetes Federation consensus criteria. Continuous variables were compared using two-sample t-tests and categorical variables using Pearson's chi-square tests or Fisher´s exact tests. We estimated prevalence of MetS overall and of components of MetS (waist circumference, HDL-cholesterol, triglycerides, fasting blood sugar and blood pressure) among women compared to men. Using bivariate and multivariate logistic regression, we obtained unadjusted and adjusted odds ratios (OR) respectively for the association between sex and MetS and tested if the association varied by ART use.
Results: Among 300 participants, 192 (64%) were female. Women were younger compared to men (mean age 39 vs 43 years; p=0.002), had higher mean body mass index (BMI) (26 vs 23 kg/m²; p= < 0.001), were less likely to be on ART (49% vs 65%; p=0.008), and had higher mean waist circumference (87.3 vs 84.7 cm; p= 0.039). Total cholesterol, triglyceride, waist-hip ratio and the blood pressures were not significantly different between men and women. The overall prevalence of MetS was 16% and was three-fold greater in women compared to men (21% vs 7%; OR 3.3; 95% Confidence Interval [CI] 1.5, 7.3, p=0.004). The increased risk remained significant for one or more components (p< 0.001) and when adjusted for age, duration of HIV infection, BMI, viral load and CD4 count (adjusted OR 3.6; 95% CI 1.5, 8.6; p=0.003) and was not different for those taking versus not taking ART.
Conclusions: Compared to men, women living with HIV were younger, less likely to be on ART and had higher waist circumference, BMI, and prevalence of MetS. Risk of MetS was not influenced by ART use. Interventions to reduce CVD risk in HIV infected adults should consider reduction in MetS and central obesity, especially among women.

TUPEC285

Concurrence of unhealthy alcohol use, tobacco use, and depression on all-cause mortality among persons living with HIV

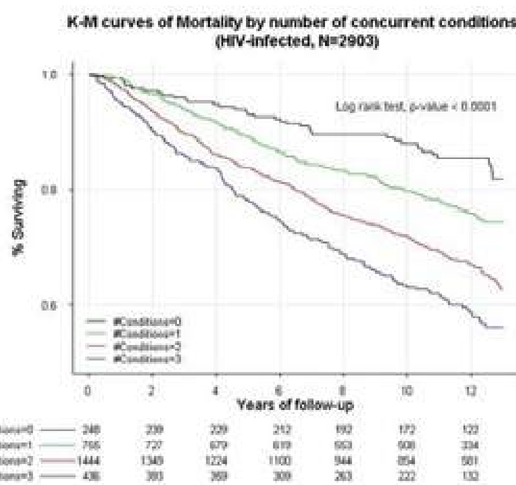
N. Chichetto[1], S. Kundu[2], M. Freiberg[2], A. Butt[3,4,5], R. Cook[6], K. So-Armah[7], H. Tindle[1], Veterans Aging Cohort Study
[1]*Vanderbilt University Medical Center, General Internal Medicine and Public Health, Nashville, United States,* [2]*Vanderbilt University Medical Center, Division of Cardiovascular Medicine, Nashville, United States,* [3]*VA Pittsburgh Healthcare System, Pittsburgh, United States,* [4]*Weill-Cornell Medical College, New York, United States,* [5]*Hamad Medical Corporation, Doha, Qatar,* [6]*University of Florida, Epidemiology, Gainesville, United States,* [7]*University of Boston, Medicine, Boston, United States*

Background: Unhealthy alcohol use, cigarette smoking, and depression contribute independently to preventable mortality. While health effects of these individual conditions are well studied, the combined impact of concurrent unhealthy drinking, cigarette smoking, and depression on mortality are understudied, particularly among persons living with HIV (PLWH). We examined the association between the concurrence of these conditions and all-cause mortality among PLWH.

Methods: Data are from the Veterans Aging Cohort Study (VACS), a prospective, observational multi-site cohort of HIV-infected and uninfected US veterans from 2002-2015. Among HIV-infected (N=2903) patients, we assessed baseline number of concurrent conditions (CC 0-3; unhealthy drinking [Alcohol Use Disorders Identification Test], cigarette smoking [former or current], and depression [Patient Health Questionnaire-9]) and all-cause mortality by the end follow-up. We constructed Kaplan-Meier (KM) survival curves, age-adjusted mortality rates and performed Cox proportional hazards regression to estimate the hazard ratio (HR) and 95% confidence intervals (CI) of number of CC on all-cause mortality, compared to those with no CC.

Results: The majority were male (97.2%) and non-White (66.4% Black, 20.0% White, 13.6% Hispanic/other race/ethnicity), with a median age of 49 years. During the median follow-up period of 11.4 years, there were 851 deaths. Most patients had at least one CC (8.5% 0 CC, 26.2% 1 CC, 49.7% 2 CC, 15% 3 CC). KM curves (Figure) and age-adjusted mortality rates per 1000 person years demonstrated increasing mortality with increasing CC (0 CC: 14.8 [10.0-19.6]; 1 CC: 22.3 [18.9-25.6]; 2 CC: 32.6 [29.9-35.6]; 3 CC: 44.7 [38.0-51.4], p< 0.001). After adjusting for demographics (age, race/ethnicity, education), comorbidities (cardiovascular-related factors, renal disease, hepatitis C infection), illicit substance use, and HIV-specific variables (HIV-1 RNA viral load, CD4+ T-cell count, HAART use), a dose response emerged between CC and mortality (1 CC: HR 1.41 [CI 0.98-2.01]; 2 CC: HR 1.78 [CI 1.26-2.52]; 3 CC HR 2.34 [CI 1.61-3.41]), compared to those with no CC (HRs p< 0.001).

Conclusions: Concurrent unhealthy drinking, tobacco use, and depression was common among PLWH, with 65% having at least 2 CC. Number of CC was incrementally associated with higher mortality risk, underscoring the need to screen and treat these conditions in parallel.



[Figure 1. Kaplan-Meier curves of mortality by number of concurrent conditions]

TUPEC286

HIV nor ART contribute to cardiovascular disease risk proxy in a young urban African population

A. Vos[1,2,3], M. Moorhouse[2], R. Barth[3], D. Grobbee[1], F. Venter[2], K. Klipstein-Grobusch[1,4]
[1]*University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands,* [2]*University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa,* [3]*University Medical Center Utrecht, Department of Internal Medicine, Utrecht, Netherlands,* [4]*University of the Witwatersrand, School of Public Health, Johannesburg, South Africa*

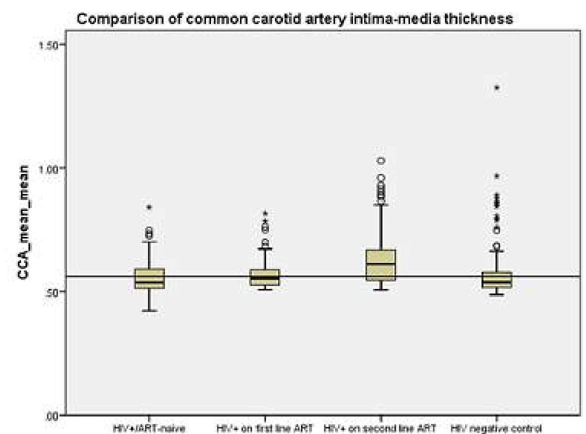
Background: The HIV-infected population is aging with increasing antiretroviral (ART) coverage. HIV and ART are risk factors for cardiovascular disease (CVD) in high-income countries, but the risk in low- and middle-income countries is unknown. This study sets out to investigate the risk of cardiovascular disease, using carotid intima-media thickness (CIMT), an established proxy for CVD risk, in an urban African population.

Methods: A cross-sectional study was performed in Johannesburg, South Africa, comparing four groups of adults: HIV-positive/ART-naïve, HIV-positive on first-line ART, HIV-positive on second-line ART and gender and age matched HIV-negative participants who were recruited by HIV-positive participants. Data were collected on demographics, cardiovascular risk factors, HIV- and ART factors. CIMT was measured as a surrogate marker for CVD. The thickness of the common carotid artery (CCA) wall was measured using B-mode ultrasound. The mean thickness of the right and left CCA near and far wall was used for analysis. The difference in CIMT between groups was analyzed using a generalized linear model.

	HIV+/ART-naïve n = 103	HIV+ on first-line ART n = 94	HIV+ on second-line ART n = 197	HIV-negative n = 153
Age (mean, SD)	33.9 (8.5)	36.9 (6.64)	43.1 (8.0)	34.7 (10.6)
Gender (female) (n, %)	64 (62.1)	59 (62.8)	141 (72.6)	75 (49.0)
Systolic blood pressure (mmHg) (mean, SD)	120.8 (15.2)	125.4 (17.4)	122.6 (19.2)	125.3 (18.9)
BMI (kg/m2)	24.6 (5.4)	25.7 (5.5)	27.9 (6.5)	26.0 (6.5)
Abdominal obesity (n, %)1	53 (51.5)	50 (53.2)	142 (72.1)	79 (51.6)
Current smokers (n, %)	27 (26.2)	12 (12.8)	17 (8.6)	56 (36.6)
Time since HIV diagnosis in months (median, IQR)	0 (0-1)2	47 (37-72)	108 (84-148)	-
CIMT (median, IQR)3	0.54 (0.51-0.59)	0.55 (0.53-0.59)	0.61 (0.55-0.67)	0.54 (0.52-0.58)

1. Waist circumference ≥94 for men and ≥80cm for women, 2. 83 participants (81.4%) were newly diagnosed upon enrolment. 3. Thickness is the mean of left and right CCA measurements; thickness was measured for the near wall and far wall at 3 angles at both sides, mean thickness was used. BMI; body mass index, CIMT; carotid intima-media thickness, CVD; cardiovascular disease, IQR; interquartile range, n; number, SD; standard deviation

[Table 1. Population characteristics]



[Figure 1. Comparison of unadjusted carotid artery intima-media thickness]

Results: 548 participants were included; 103 in the HIV-positive/ART-naïve group, 94 in the group using first-line ART, 197 in the group using second-line ART and 153 HIV-negative controls. The mean age was 37.9

years, 62% were female and almost all were black Africans (>99%). (Table 1) Participants in the group receiving second-line ART were mainly female, older, with a higher BMI and a higher prevalence of abdominal obesity than those in the other groups. Median CCA thickness was significantly higher in this group compared to any of the other groups (P <0.01) (figure 1), but the difference disappeared when adjusting for gender and age.

Conclusions: CIMT (and hence possibly CVD risk) did not differ between HIV-negative and HIV-positive individuals, whether or not on ART, in this urban African population. Further research on CVD risk due to HIV and/or ART with aging is needed. CIMT may need re-evaluation as a proxy for CVD in African populations.

TUPEC287

Association between recommended first-line antiretroviral therapy regimens and chronic kidney disease in HIV-positive adults in Thailand: A retrospective cohort study

N. Paengsai[1], R. Chaiwarith[2], T.R. Cressey[3,4,5], N. Salvadori[3,4], A. Tantraworasin[1,6], N. Kosachunhanun[2], C. Bowonwatanuwong[7], S. Bhakeecheep[8], K. Noppakun[2]

[1]Chiang Mai University, Clinical Epidemiology Program, Faculty of Medicine, Chiang Mai, Thailand, [2]Chiang Mai University, Department of Medicine, Faculty of Medicine, Chiang Mai, Thailand, [3]Institut de Recherche pour le Développement (IRD) UMI 174-PHPT, Chiang Mai, Thailand, [4]Chiang Mai University, Department of Medical Technology, Faculty of Associated Medical Sciences, Chiang Mai, Thailand, [5]Harvard T.H. Chan School of Public Health, BOSTON, United States, [6]Chiang Mai University, Department of Surgery, Faculty of Medicine, Chiang Mai, Thailand, [7]Mahidol University, Department of Medicine, Faculty of Tropical Medicine, Bangkok, Thailand, [8]National Health Security Office Chiang Mai Branch (Region 1), Chiang Mai, Thailand

Background: Antiretroviral therapy (ART) has shifted the causes of mortality for HIV-infected individuals from infectious diseases to non-communicable diseases, including chronic kidney disease (CKD). Other than the known risk factors of CKD, lower CD4 counts, higher HIV RNA viral loads and receiving individual antiretroviral drugs (tenofovir disoproxil fumarate [TDF] and lopinavir/ritonavir [LPV/r]) in HIV-positive patients are also risk factors. However few studies have investigated the association between specific ART regimens and risk of CKD. We investigated the association of World Health Organization (WHO) 2016 and Thailand 2017 recommended first-line ART regimens and the risk of CKD in HIV-positive adults in Thailand.

Methods: We analyzed all records of a large retrospective cohort study of HIV-positive adults within the Thai National AIDS Program from October 1, 2006 to September 30, 2014. Adults who received a first-line ART regimen of

(i) zidovudine(AZT)+lamivudine(3TC)+nevirapine(NVP),

(ii) TDF+3TC+NVP (iii) AZT+3TC+efavirenz(EFV),

(iv) TDF+3TC/emtricitabine(FTC)+EFV (v) AZT+3TC+LPV/r, and

(vi) TDF+3TC+LPV/r were included in this analysis.

CKD was defined as

1) decreased glomerular filtration rate < 60 ml/min/1.73 m^2 for >3 months as per KDIGO 2012; or

2) a confirmed 2010 WHO diagnosis (ICD10 code N183, N184, N185).

CKD incidence was the number of new cases divided by that of person-years of follow-up (PYFU). We used competing risks survival regression models, treating mortality as a competing event, to identify ART regimens associated with CKD, adjusted for sex, age, history of diabetes mellitus and kidney stone, absolute CD4 cell count and propensity scores.

Results: Of 31,997 adults receiving first-line ART, 240 patients developed CKD. With 101,417 PYFU, the overall incidence of CKD was 2.4 per 1,000 PYFU. In the multivariable analysis, using AZT+3TC+NVP as the control group, regimens associated with a higher risk of CKD were TDF+3TC/FTC+EFV (adjusted sub-distribution hazard ratio 1.7, 95% confidence interval 1.2-2.3), TDF+3TC+NVP (3.6, 2.2-5.8) and TDF+3TC+LPV/r (4.8, 2.6-8.9). In a subgroup analysis, TDF+3TC+NVP (2.3, 1.4-3.7) and TDF+3TC+LPV/r (2.6, 1.4-4.7) were associated with a higher risk of CKD, compared to TDF+3TC/FTC+EFV regimen.

Conclusions: Most of the currently recommended TDF-containing first-line ART regimens, particularly with NVP and LPV/r, were associated with a higher risk of CKD compared to AZT+3TC+NVP.

Describing the spread of HIV through molecular epidemiology

TUPEC288

A web-based searching program for nationwide HIV transmission clusters efficiently detected local HIV transmission in the MSM group in Japan

T. Shiino[1], M. Takeyama[2], M. Ishihara[2], R. Minami[3], A. Hachiya[4], Y. Yokomaku[4], W. Sugiura[5], K. Yoshimura[6], The Japanese Drug Resistance HIV-1 Surveillance Network

[1]National Institute of Infectious Diseases, Infectious Disease Surveillance Center, Tokyo, Japan, [2]University of the Ryukyus, First Department of Internal Medicine, Okinawa, Japan, [3]Kyushu Medical Center, Fukuoka, Japan, [4]Nagoya Medical Center, Medical Research Center, Nagoya, Japan, [5]GlaxoSmithKline K.K., Tokyo, Japan, [6]National Institute of Infectious Diseases, AIDS Research Center, Tokyo, Japan

Background: Viral sequence-based transmission clustering of HIV-1 infected individuals among men who have sex with men (MSM) in Japan was conducted using advanced phylogenetic inferences. HIV-1 transmission networks spread with a consistent pattern in MSM groups; therefore, cluster information estimated from viral sequences are useful for an active prevention program. In order to make the transmission cluster (TC) information of newly diagnosed patients readily available to medical staff, we have developed a web-based searching program for HIV nationwide TC based on sequence data (SPHNCS).

Methods: SPHNCS contains reference sequences of the protease-reverse transcriptase region from 4,386 subtype B-infected individuals registered in the Japanese Drug Resistance HIV-1 Surveillance Network between 2003 and 2012 with the associated TC information. The system exhaustively estimates the number of base substitutions per site between a query sequence and the reference using Tamura and Nei's method. TC of the query was identified as that of the most closely linked neighbor, at a distance of less than 1.5%. To verify the quality of the algorithm, we compared the estimated TCs of both the conventional method and SPHNCS for 87 individuals recruited from University of the Ryukyus Hospital in Okinawa from 2013 to 2016.

Results: Using the conventional method, 52/87 individuals from Okinawa were linked to any TCs, 8 were classified as non-B subtypes, and 27 were singletons. SPHNCS accidentally classified two singletons and one newly detected cluster as existing TCs, and failed to detect 18 TC-involved individuals. The specificity and sensitivity of the program were 0.952 and 0.591, respectively. It perfectly detected Okinawa-specific 7 new TCs and 4 sub-clusters of the existing TCs. The specificity was constantly >0.95 until a 1.6% threshold distance, whereas the sensitivity increased linearly from 0.400 to 0.813 in 1% to 2% threshold distances.

Conclusions: Understanding HIV transmission dynamics allows individuals involved public health activities to define a local key population for implementation of prevention strategies. SPHNCS can detect ongoing HIV transmission among MSM populations with high accuracy, achieving on-site targeting for the active prevention program, PrEP, by medical staff in Japan.

TUPEC289

A comprehensive mapping of HIV-1 genotypes in various risk groups and regions across China based on a nationwide molecular epidemiologic survey

Y. Feng[1], H. Xing[1], Y. Ruan[1], L. Liao[1], L. Plessis[2], Y. Shao[1],
Group for HIV Molecular Epidemiologic Survey of China
[1]National Center for AIDS/STD Control and Prevention, Chinese Center for Disease Control and Prevention, Beijing, China, [2]University of Oxford, Oxford, United Kingdom

Background: In the last 30 years, China has experienced several waves of HIV-1 epidemics. The main driving factors of HIV-1 epidemic have shifted considerably, from blood transmission to sexual transmission. It is about 10 years since the last survey has been conducted, there is increasing need for the geographic and demographic distribution of HIV genotypes on present stage.
Methods: We estimated the likely prevalence and distribution of HIV-1 genotypes through 5627 newly diagnosed HIV positive individuals from various risk groups in all of the 31 provinces of mainland China in 2015.
Results: A total of 4817 HIV-1 sample were amplified and sequenced successfully. 20 HIV subtypes or Circulating recombinant forms (CRFs) were detected. In addition, a large number of different types of unique recombinant forms (URFs) or genotypes inconsistent strains, were determined. CRF07_BC, CRF01_AE, CRF08_BC and B were estimated as the predominant HIV-1 subtypes circulating in China and together accounted for 89.2% of all HIV infection (accounting for 41.2%, 32.6%, 11.3% and 4.0% respectively).
We compared the results of the molecular epidemiological studies of 2006 and 2015. The results shown that the growth in reported cases of HIV infection from 2006 to 2015 come mainly from the increase of infection from CRF07_BC and CRF01_AE, which contributed 48.1% and 38.9% respectively. When we give attention to the level of the clusters/categories and the route of transmission, it worth to note that CRF07_ungrouped, CRF01_C1 and CRF08_BC, which were mainly infected through IDUs and Heterosexuals in 2006, had transferred into predominantly heterosexuals in 2015. CRF07_01, CRF01_C4, CRF01_C5 and CRF55_01B, which transmitted predominantly through MSMs, were very few reported cases in 2006, totally contributed 64.3% of increasing from 2006 to 2015.
Conclusions: Our study revealed an unprecedented high level of complexity of the HIV epidemic in China. More various types of CRFs and URFs found in this survey strongly reflects the increasing complexity of HIV in the country. In comparing the survey in 2006, we can conclude that the increase in the number of HIV reports in China over the past ten years is mainly due to the rapid spread of strains through of sexual transmission, especially through MSMs.

TUPEC290

External introductions sustain endemic HIV incidence in South Africa: Implications for public health interventions

C. Coltart[1,2], A. Zhukova[3], A. Tostevin[4], G. Harling[4], O. Stirrup[4], F. Tanser[2], D. Pillay[2], O. Gascuel[3], S. Hue[5], A. Johnson[4]
[1]University College London, Institute for Global Health, London, United Kingdom, [2]Africa Health Research Institute, KwaZulu-Natal, South Africa, [3]Institut Pasteur, Paris, France, [4]University College London, London, United Kingdom, [5]LSHTM, London, United Kingdom

Background: Despite prevention efforts, HIV incidence in rural KwaZulu-Natal (KZN) remains very high. KZN reports high rates of migration, primarily temporary labour and circular migration. Although mobility and migration are both associated with increased HIV acquisition risk, the manner in which these impact HIV dynamics within this area is unclear. This limits our ability to implement preventative measures within the mobile and migrant populations. Therefore, we investigate the contribution of mobility/migration to HIV transmissions within the AHRI Demographic Surveillance Area (DSA).
Methods: We combined epidemiological, phylogenetic and bioinformatics approaches using AHRI data (2010-14) to investigate patterns and rates of HIV transmission between geographical categories (randomly sampled subset: 750 of 2,179 sequences, 250 from each of three geographical categories: individuals residing in 'High' or 'Low' prevalence areas of the DSA, or 'external sources'). We define individuals who changed residence within the last year, or were not registered within the DSA (external sources) as 'migrants'. Phylodynamic analysis used a maximum-likelihood approach to infer a phylogenetic tree and the most likely source (geographical category) of infection of the sampled individuals (repeated x10). The relative rates of transmission between each origin category were calculated by counting and averaging different parent-child state configurations in the reconstructed transmission trees.
Results: We find that external introductions remain a substantial source of HIV infections accounting for over 45% of transmissions, suggesting that mobility/migration play a key role in sustaining this epidemic. We also find that external sources introduce infection to those residing in 'High' prevalence areas within the DSA, who subsequently seed infection in 'Low' prevalence areas (Figure 1). Furthermore, transmission events often remain localised in geographical categories (78.4% external-external, 38.6% high-high and 23.5% low-low transmissions).
Conclusions: Viral imports play a significant and ongoing role in driving and sustaining the HIV epidemic in the AHRI DSA. Since continuous reintroduction of new infections is not captured by traditional public health strategies, the efficacy of existing interventions among those that share sexual networks with migrants is likely to be sub-optimal. There is an urgent need to develop testing and treatment interventions that flexibly support mobile/migrant populations in order to control the ongoing HIV epidemic.

Figure 1: Maximum likelihood tree and estimation of ancestral states, describing the phylodynamics of HIV infection in rural KwaZulu-Natal
The tree for all available sequences was built with RAxML, and pruned to contain an equal number of tips in each state (250 of each, sampled randomly). We used PastML (Ishikawa et al. 2018, submitted) to infer the ancestral states describing the strain origins. PastML uses the maximum likelihood principle and decision theory concepts, to select one or several states for each the tree nodes, depending on the information brought by the node descendants and neighbours. The results show that infection into the AHRI DSA originally came from 'External' sources (green nodes at the top of the tree) and then was spread largely by people from 'External' and 'High' prevalence areas (green and red), before seeding infection to people in 'Low' prevalence areas (blue).

[Maximum likelihood tree and estimation of ancestral states, describing the phylodynamics of HIV infection in rural KwaZulu-Natal]

Modelling the potential impact of prevention strategies on the HIV epidemic

TUPEC291

A mathematical modeling analysis of HIV transmission following release from prisons in the US among participants in the imPACT intervention trial

S. Levintow[1], K. Powers[1], C. Golin[1], K. Knight[2], P. Flynn[2], J. Carda-Auten[1], J. Groves[1], B. Pence[1], B. White[1], S. Napravnik[1], D. Wohl[1]
[1]University of North Carolina, Chapel Hill, United States, [2]Texas Christian University, Fort Worth, United States

Background: Freely accessible antiretroviral therapy facilitates viral suppression for persons with HIV in prison, but if post-release challenges in accessing medication are coupled with resumption of sexual behavior,

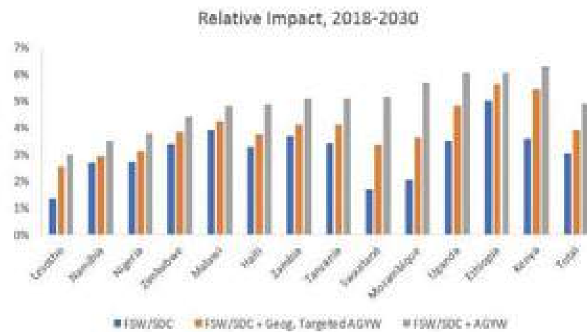
onward HIV transmission can occur. We sought to model secondary sexual HIV transmission in the imPACT (individuals motivated to Participate in Adherence, Care, and Treatment) trial following participants' release from state prisons in North Carolina and Texas.
Methods: 405 virally suppressed persons with HIV awaiting prison release were randomized to standard care (routine discharge planning) or the imPACT intervention (motivational interviewing, linkage to care, medication text reminders). HIV RNA and sexual behavior (frequency of sexual contact and condom use by partner HIV status and act type) were assessed at weeks 2, 6, 14 and 24 post-release. We conducted 10,000 simulations of a Bernoulli process model to estimate secondary transmissions in four intervals (the first 2 weeks after release and the 30 days before weeks 6, 14, and 24), incorporating individual-level viral load and behavioral data. We also modeled a hypothetical scenario of 0% condom use and 0% viral suppression to estimate the potential increase in HIV transmission that could occur under these extreme conditions. In all analyses, we combined study arms and included only the 323 participants who contributed data at ≥1 visit.
Results: In the first six months post-release, 37% of participants reported sex with an HIV-negative or status-unknown partner and 62% were virally suppressed at 24 weeks. Given observed sexual behaviors and viral load, we estimated 1.72 transmission events total (95% CI: 0.92-3.11) across the four post-release intervals. In the hypothetical extreme of 0% condom use and viral suppression, this estimate increased to 7.03 (5.14-9.17) events.
Conclusions: Suboptimal viral suppression combined with reported sexual behavior were predicted to produce approximately two secondary HIV transmissions in the six-month period after prison release, with a predicted increase to seven events under hypothetical elimination of viral suppression and condom use. These analyses highlight the importance of efforts to support care engagement, treatment adherence, and risk reduction for people with HIV who are re-entering their communities from prison.

TUPEC292

Oral Pre-Exposure Prophylaxis (PrEP) modeling for strategic planning: Results from thirteen countries

M. Schnure[1], K. Kripke[2], S. Forsythe[2], M. Hamilton[2], J. Dent[1], M. Reidy[2], R. Glaubius[2], D. Castor[3], C. Pretorius[2]
[1]Health Policy Plus (HP+) Project, Palladium, Washington, United States, [2]Health Policy Plus (HP+) Project, Avenir Health, Washington, United States, [3]USAID, Washington, United States

Background: Many countries are incorporating oral PrEP into their combination prevention strategies following WHO's 2015 guidance on oral PrEP for individuals at substantial risk of contracting HIV. In an effort to inform oral PrEP policy and programs, the USAID-funded Health Policy Plus (HP+) project applied a new mathematical modeling approach to estimate the impact, cost, and cost-effectiveness of providing oral PrEP to different subpopulations in thirteen countries.
Methods: HP+ estimated HIV incidence by risk group and province and considered the impact of oral PrEP through 2030 in the context of the national HIV prevention program using the Incidence Patterns Model (IPM) and an adaptation of the Goals model that incorporated additional risk groups using adjustment factors based on incidence ratios derived from IPM. These two models are linked through a workbook in Microsoft Excel to develop targets and summarize cost and impact modeling results.
Results: In most cases, the vast majority of HIV infections averted by oral PrEP were achieved by focusing on female sex workers (FSW) and sero-discordant couples (SDC) (Fig 1).
In Mozambique and Swaziland, substantial additional impact, without a concomitant decrease in cost-effectiveness, was achieved when medium-risk adolescent girls and young women (AGYW) were also included. Patterns of relative impact and cost-effectiveness by individual risk group varied across countries, with cost per HIV infection averted ranging from US$1,216 in Lesotho for FSW to US$228,694 in Haiti for medium-risk AGYW. When considering oral PrEP in the context of scale-up of other interventions, PrEP is more impactful and cost-effective when scale-up of ART and VMMC is less.
However, scaling up oral PrEP provides additional HIV infections averted even when countries reach 90-90-90 targets for ART and 90% coverage of VMMC among males ages 10-29.



[Additional impact from rolling out oral PrEP, by country and rollout scenario, 2018-2030. Relative impact is defined as the number of HIV infections averted by rolling out PrEP divided by the total number of HIV infections without PrEP. FSW: female sex workers; SDC: sero-discordant couples; AGYW: adolescent girls and young women ages 15-24 years (18-24 for Mozambique]

Conclusions: Oral PrEP is an important component of combination prevention programs, given its potential to protect highly vulnerable and underserved populations. Even in the context of 90-90-90 achievement, our modeling results support oral PrEP scale-up for high-incidence populations. These data will be used to assist countries in rolling out PrEP, while taking into account considerations such as equity, human rights, and implementation realities.

TUPEC293

Determinants of the predicted effectiveness of universal test and treat in a high prevalence generalised HIV epidemic: Insights from the HPTN 071 (PopART) individual-based model

R. Sauter[1], W. Probert[1], M. Pickles[2], A. Cori[3], S. Floyd[4], D. Donnell[5], S. Fidler[3], R. Hayes[4], C. Fraser[1], for the HPTN 071(PopART) study team
[1]University of Oxford, Big Data Institute, Nuffield Department of Medicine, Oxford, United Kingdom, [2]University of Winnipeg, Winnipeg, Canada, [3]Imperial College London, London, United Kingdom, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: HPTN071(PopART) is a three-arm cluster-randomized trial in 12 communities in Zambia and 9 in South Africa, measuring the impact of a combination prevention intervention including universal testing and treatment (UTT) on population-level HIV incidence. Data were collected on the baseline characteristics, and uptake of the intervention. Mathematical modelling informed the trial planning and was developed into an efficient stochastic individual-based simulation model (IBM) of heterosexual HIV transmission in generalised epidemics. Gains in algorithmic efficiency mean that IBM of HIV can be used in fitting to trial data and understanding which determinants are expected to influence the trial outcome.
Methods: Model output was calibrated to historical prevalence and community-level UTT data, identifying the most likely parameter values. Stochastic IBM uncertainty and heterogeneities across communities were assessed by running simulations repeatedly with community-specific parameters. Sensitivity analyses identified the most important determinants of predicted trial impact and long-term effectiveness.
Results: The IBM adequately replicates heterogeneities across sex and age-groups in the trial data. The mean predicted reduction in incidence in the intervention arm was 39% (range 17% to 52%) compared to control communities. The most important determinant of outcome was the uptake of intervention. Conditioning on this, increasing the proportion of infections from individuals in the acute phase, and increasing the number of infections from outside a trial community (both from 10% to 20%) causes on average a 4% decrease in the trial impact. The parameterisation of the sexual contact network explains differences of up to 2%. On average the trial outcome varies by 3% across communities, attributable

to heterogeneities in demography, baseline HIV prevalence, and linkage to care. Differences between Zambia and South Africa can be explained by country-specific differences in the proportion of partners from outside a trial community and the baseline prevalence of male circumcision.
Conclusions: The choice of IBM parameters (some obvious and some less so) has a substantial effect on the predicted trial outcome. Detailed modelling of the trial allows identification of determinants of effectiveness, that will in turn improve long-term modelling projections, offering insight into developments far beyond the trial horizon, relevant for decisions to be taken after trial completion.

TUPEC294

The impact of more frequent HIV testing on HIV transmission among men who have sex with men

M. Reitsema[1,2], M. Visser[1], B. van Benthem[1], J. Heijne[1], M. Xiridou[1]
[1]National Institute of Public Health & Environment, Centre for Infectious Diseases Control, Bilthoven, Netherlands, [2]Leiden University Medical Center, Department of Medical Statistics and Bioninformatics, Leiden, Netherlands

Background: One of the goals of UNAIDS is to increase the diagnosed fraction among HIV-infected individuals to 90% by 2020. To achieve this, efforts are made to promote HIV testing. In this study, we assess the impact of increased HIV testing among men who have sex with men (MSM) in the Netherlands.
Methods: We developed an individual-based model that describes transmission of HIV and N. gonorrhoeae (gonorrhoea) among MSM. The model was fitted to annual HIV diagnoses during 2007-2014. Based on data from STI Clinics, we assumed that, until 2017, 20% of MSM test consistently for HIV every six months. We increased this percentage in 2018 to:
(a) 30%;
(b) 50%;
(c) 50% among MSM with at least 10 partners in the preceding 6 months;
(d) 50% among MSM diagnosed with gonorrhoea in the preceding 12 months.
We calculated the incidence of HIV for each scenario in the subsequent ten years.
Results: With the current 20% six-monthly testing, the incidence of HIV infection is estimated to be 0.300 (interquartile range, 0.186-0.432) infections per 100 person-years in 2027. With 30% or 50% six-monthly testing, HIV incidence in 2027 was reduced by 13% or 37%, respectively. Increasing testing to 50% among MSM with at least 10 partners reduced HIV incidence in 2027 by 23%, while increasing testing to 50% among MSM with diagnosed gonorrhoea resulted in 12% reduction in HIV incidence.
Compared to the current testing rates, the number of extra HIV tests that would have to be carried out to prevent one new HIV infection is 501 with 30% six-monthly testing; 621 with 50% six-monthly testing; 171 with 50% six-monthly testing among MSM with at least 10 partners; and 24 with 50% six-monthly testing among MSM with gonorrhoea diagnosis.
Conclusions: Even small increases in consistent HIV testing can prevent a considerable number of new HIV infections. Increasing HIV testing among high-risk MSM may be less effective than increasing testing among all MSM, but it is more efficient in terms of tests needed to avert an infection.

TUPEC295

Estimating the potential impact of PrEP uptake scenarios on the HIV epidemic in the United States

J. Chou[1], M. Skornicki[1], E. Bendavid[2], O. Diaz[1]
[1]Precision Health Economics, Los Angeles, United States, [2]Stanford University, Palo Alto, United States

Background: The use of tenofovir disproxil fumarate and emtricitabine as pre-exposure prophylaxis (PrEP) for the human immunodeficiency virus (HIV) has been available since 2012, but uptake has been low, even among higher risk populations, such as men who have sex with men (MSM). We simulate the impact of increased PrEP uptake on the HIV epidemic among MSM in the United States.
Methods: We used the HIV Transmission and Progression (HIV TaP) model, a mathematical transmission and progression model, to simulate PrEP usage impact on HIV incidence and progression among Black, White, and Hispanic MSM in the United States.
We modeled three scenarios: "Baseline" in which no patients received PrEP to isolate the impact of PrEP; "Moderate Uptake", with 25%, 300%, and 300% growth; and "High Uptake" with 50%, 600%, and 600% growth in uptake rate by 2025, for White, Black, and Hispanic, respectively. Growth functions were fit using published claims analysis of PrEP usage, 2025 goals, and assuming a plateau by 2025. Anti-retroviral treatment rates were constant across scenarios.
Results: Relative to Baseline, Moderate Uptake resulted in 150,000 avoided infections for White MSM by year 20; Black, 79,000; Hispanic, 77,000; totaling 310,000 avoided infections at an incremental cost of $9,500 per avoided infection. High Uptake resulted in 200,000 avoided infections among White MSM by year 20; Black, 111,000; Hispanic, 100,000; totaling 410,000 avoided infections at an incremental cost of $13,000 per avoided infection. The impact of these avoided infections translated to the following gains in quality-adjusted life years (QALYs) in the Moderate Uptake scenario: White MSM, 120,000; Black, 51,000; Hispanic, 50,000; totaling 220,000 by year 20 at an incremental cost of $13,000 per QALY gained. High Uptake resulted in the following QALY gains by year 20: White MSM, 150,000; Black, 65,000; and Hispanic, 66,000; totaling 280,000 at an incremental cost of $19,000 per QALY gained.
Conclusions: Increasing uptake of PrEP has the potential to help slow the spread of HIV, preventing a significant number of infections over 20 years. These avoided infections and corresponding QALY gains can be achieved at relatively low incremental costs across the total MSM population.

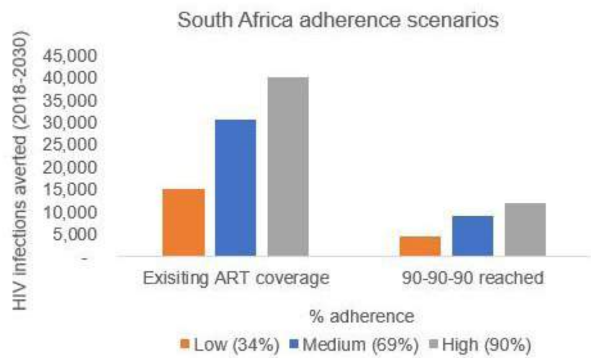
TUPEC296

Modeling the potential impact of the dapivirine ring for HIV prevention

K. Kripke[1], M. Reidy[1], E. Gardiner[2], on behalf of the OPTIONS Consortium
[1]Avenir Health, Washington DC, United States, [2]AVAC: Global Advocacy for HIV Prevention, New York, United States

Background: As the dapivirine intra-vaginal ring, developed by the International Partnership for Microbicides (IPM), moves forward through regulatory review and open-label extension studies, the potential impact and cost-effectiveness of this new longer-acting prevention product is unclear. This study uses mathematical modeling to explore dapivirine ring impact under different scenarios of use. With no comparable products on the market, target coverage levels are informed by proxies, such as contraceptive use.
Methods: This analysis used the Goals module from the Spectrum suite of models to create different scenarios for ART scale-up (including holding constant at 2016 levels and reaching the 90-90-90 targets), oral PrEP, and dapivirine ring coverage for 13 countries (Kenya, Botswana, Lesotho, Malawi, Mozambique, Namibia, Rwanda, South Africa, Swaziland, Tanzania, Uganda, Zambia, Zimbabwe). Within these scenarios, adherence to the dapivirine ring was varied to represent the range of results observed in clinical trials.
Results: The potential impact of the ring varies substantially depending on scale-up of ART and the level of adherence to the ring. In a scenario with all 13 countries achieving the 90-90-90 targets, 52% ring effectiveness (from 75% efficacy and 69% adherence), and a modest peak coverage equivalent to ¼ of each country's modern contraceptive prevalence in the populations of medium-risk women (multiple partners) and female sex workers, we estimate over 39,000 new HIV infections could be averted by 2030. However, if the 90-90-90 targets are not reached and higher levels of ring adherence are achieved with open label use (as seen with oral PrEP), the potential impact of the ring is much greater (see Fig.1 for an example showing South Africa). To illustrate that extreme, if ART coverage is held constant at 2016 levels and 90% ring adherence is achieved, as many as 170,000 HIV infections could be averted.
Conclusions: The dapivirine ring, as a product able to be used discreetly by women, could be a beneficial addition to the HIV prevention toolkit; however, our modeling suggests that its potential impact is highly vari-

able. More understanding of the effectiveness and potential uptake of the intervention would improve our ability to estimate its potential impact.



[Figure 1. New HIV infections averted by dapivirine ring 2018-2030 in South Africa under different scenarios of ART coverage and adherence]

TUPEC297

Modeling projected HIV incidence in the SEARCH study of treatment as prevention in East Africa

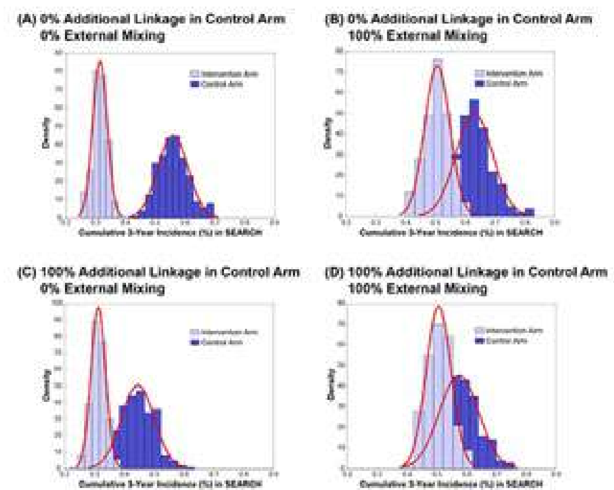
B. Jewell[1,2], L.B. Balzer[3], T.D. Clark[4], E.D. Charlebois[4], S.R. Maddali[4], A. Akullian[2], M.R. Kamya[5], D.V. Havlir[4], M.L. Petersen[1], A. Bershteyn[2]
[1]University of California, Berkeley, Berkeley, United States, [2]Institute for Disease Modeling, Seattle, United States, [3]Harvard University, School of Public Health, Boston, United States, [4]University of California, San Francisco, San Francisco, United States, [5]Makere University, College of Health Sciences, Kampala, Uganda

Background: While mathematical models have predicted that antiretroviral therapy (ART) scale-up via universal test-and-treat (UTT) will reduce population-level HIV transmission, this has not been demonstrated in a randomized trial. SEARCH is a cluster-randomized trial of the UTT strategy for HIV prevention (NCT01864603) taking place in 32 rural communities in Uganda and Kenya. We used a mathematical model calibrated to baseline data in all 32 communities and ART scale-up in 16 intervention communities to predict the cumulative three-year HIV incidence rate ratio (IRR) that might be observed in the study.

Methods: Using data on baseline HIV prevalence, viral suppression, male circumcision, and household demographics (N=146,874 adults ≥15 years), we fit an existing microsimulation network model of HIV transmission, EMOD-HIV v2.5, to the SEARCH population. The 32 SEARCH communities were clustered into six nodes reflecting the trial arm and HIV epidemic pattern. We incorporated data on viral suppression in SEARCH intervention communities in follow-up years one and two as proxies of ART coverage, and used the model to estimate uncertainty about the predicted outcome with respect to two key unknowns: ART scale-up in control communities and sexual mixing with individuals outside intervention communities. Investigators performing the modeling were blinded to interim seroconversion data to preserve the integrity of the prediction.

Results: We estimated that the upper boundary of the IRR in SEARCH, assuming standard ART scale-up in the control arm and no external mixing, was a mean of 0.57 (95% confidence interval 0.47-0.68), a 43% reduction from the control to the intervention arms of the trial. However, if SEARCH intervention communities participate in sexual mixing with a similarly sized population outside of the study or baseline testing increased ART linkage for all eligible individuals in the control arm, the mean estimated IRR was 0.81 and 0.70, respectively. With both maximum external mixing and increased ART linkage in the control arm, the estimated IRR was 0.88.

Conclusions: Based on modeling results, we would expect to see a maximum 43% reduction in HIV incidence in SEARCH, although this observed incidence reduction could be mitigated by increased ART linkage in the control arm or substantial mixing with non-SEARCH individuals.



[Modeled cumulative-3 year incidence in SEARCH control and intervention communities under different assumptions of ART scale-up and external mixing]

Antiretroviral treatment, prevention of transmission and modeling the HIV epidemic: Why the calculated ART effectiveness parameter matters

R. Granich[1], S. Gupta[2], M. Wollmers[3], M. Ruffner[3], B. Williams[4]
[1]Independent Consultant, Potomac, United States, [2]Independent Public Health Consultant, Delhi, India, [3]PEPFAR, Washington, United States, [4]SACEMA, Stellenbosch, South Africa

Background: Human immune deficiency virus (HIV) remains a major public health threat with two million infections, 1 million HIV-associated tuberculosis (TB) cases a year and one million deaths each year. Population-based studies suggest a marked decline in incidence, prevalence and deaths, mostly likely due to treatment expansion, in countries in East and Southern Africa. This calls into question the antiretroviral treatment (ART) related parameters used to project HIV incidence and prevalence.

Methods: We reviewed 2015-2016 global and national mathematical modeling studies regarding ART impact on new HIV infections. We extracted ART and HIV transmission parameters (e.g., proportion diagnosed, on ART, on ART and virally suppressed, on ART and not virally suppressed, reduction in HIV transmission for those on ART and virally suppressed, reduction in transmission for those on ART and not suppressed, and retention). Models assumed varying program implementation rates and we calibrated the derived ART effectiveness to 2020 (see Table 1). Using the extracted parameters, we calculated a model-specific ART Effectiveness percentage for the impact of ART on transmission by 2020. We then compared the two models with the lowest and highest ART effectiveness.

Results: For the 9 models ART effectiveness percentage reduction in HIV transmission by 2020 ranged from 20% to 86%; there were significant disparities between the highest (SACEMA) and lowest (GOALS) models (Figure 1). The GOALS Mozambique model limits ART initiation to 80% of people living with HIV with a CD4+ cell count below 350 cells/mL, assumes 70% retention, and a reduction in HIV transmission of 80% yielding a derived ART effectiveness of 20%. The SACEMA model assumes 90-90-90 by 2020 (i.e., 73% viral suppression of estimated PLHIV), ART reduces transmission by 96% in those virally suppressed, and by 88% in those on ART but not virally suppressed with a derived effectiveness of 86% and consequent decline towards ending AIDS and HIV elimination. ART parameter selection and assumptions dominate and low ART effectiveness translates into lower impact.

Conclusions: Using less pessimistic parameters for ART effectiveness suggests that expanding access to sustainable viral suppression could significantly reduce transmission and eliminate HIV in many settings.

Study	Setting	Parameters	ART effectiveness
Williams (SACEMA model), Current HIV AIDS Research 2015 Epidemiological Trends for HIV in Southern Africa: Implications for Reaching the Elimination Targets	Southern Africa	• Proportion on ART virally suppressed: 90% • Reduction in transmission on ART * virally suppressed 96% * not virally suppressed 88% • Full coverage (2020): People at risk tested on average twice a year and started on treatment immediately	Effectiveness: 86% Calculations (for 2020): On ART: 90% Not on ART: 10% Of those on ART percentage virally suppressed: 90% Of those on ART percentage not virally suppressed: 10% On ART and virally suppressed transmission reduced: 96% On ART and not virally suppressed transmission reduced: 88% Effectiveness: 1-(Proportion on ART(Proportion on ART virally suppressed*Proportion transmission+Proportion on ART not virally suppressed*Proportion of transmission on ART not virally suppressed)+Not on ART)= Equation: 1-(0.9*(0.9*0.04+0.1*0.12)+0.1) =0.86

TUPEC299

Modeling structural changes allowing scale-up of harm reduction and antiretroviral therapy for people who inject drugs on the HIV epidemic in Russia

J. Cepeda[1], P. Vickerman[2], C. Beyrer[3], N. Martin[1]
[1]University of California, Medicine, San Diego, United States, [2]University of Bristol, Brisol, United Kingdom, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: Russia has one of the fastest growing epidemics in the world, fueled primarily by injection drug use. Several regions within the Ural and Siberian Federal Districts have the highest rates of new HIV diagnoses, the majority among people who inject drugs (PWID). Essential harm reduction and HIV services are lacking or prohibited by law: opioid-agonist medically assisted therapy (MAT) is illegal, syringe exchange program (SEP) coverage is minimal, and antiretroviral therapy (ART) for PWID is prohibited. We modeled the impact of structural changes permitting scale-up of harm reduction and ART on the HIV epidemic among PWID in two settings in the Russian Ural and Siberian districts.

Methods: We developed a dynamic deterministic model of HIV injecting and sexual transmission among PWID, calibrated to two Russian settings: Omsk, an expanding epidemic (8% of PWID infected in 2009, 17% in 2011) and Ekaterinburg, a stable but high prevalence epidemic (60% PWID infected). The model was stratified by HIV stage, ART, injecting risk (high/low), and harm reduction status (off/on). No ART or harm reduction was assumed at baseline. We modeled scaled-up harm reduction (combination SEP+MAT, reducing injecting risk by 70%) to 20%, 40%, or 60% coverage among PWID, integrated with ART within harm reduction (recruitment 30%/year) from 2018. We calculated the percentage of HIV cases and HIV-deaths averted by comparing each scenario to the base-case (no intervention) from 2018-2028.

Results: Over a decade, scaling-up harm reduction to 20%, 40%, and 60% coverage integrated with ART in Omsk could avert 35% (2.5-97.5 percentile interval: 22%-36%), 47% (32%-59%), and 60% (43%-73%) of HIV cases, respectively. In Ekaterinburg, scaling up to 20%, 40%, and 60% coverage levels could avert 19% (9%-35%), 28% (15%-45%), and 40% (22%-57%) of HIV cases, respectively. Over half of HIV-related deaths could be averted in the next decade in both settings with 60% harm reduction coverage integrated with ART.

Conclusions: Harm reduction services integrated with ART could have a substantial impact on HIV transmission and mortality among PWID in Russia. Removing legal barriers prohibiting MAT and ART for PWID, alongside scale-up of SEP, is urgently needed in Russia.

TUPEC300

Modeling the impact and cost-effectiveness of oral pre-exposure prophylaxis (PrEP) in Mozambique

J. Dent Hulse[1], K. Kripke[2], T. Hawry[3], N. Gaspar[3], A. Cuoto[4], N. Chicuecue[4], J. Seleme[4], D. Castor[5], C. Pretorius[2]
[1]Health Policy Plus Project (HP+) - Palladium, Washington, United States, [2]Health Policy Plus Project (HP+) - Avenir Health, Washington, United States, [3]USAID, Maputo, Mozambique, [4]Ministry of Health, Maputo, Mozambique, [5]USAID, Washington, United States

Background: Mozambique is a high-burden HIV country with a generalized epidemic. To assist the national HIV program in integrating oral PrEP into the country's existing HIV prevention strategy, the USAID-funded Health Policy Plus (HP+) project developed a new mathematical modeling approach to estimate the impact and cost-effectiveness of different oral PrEP scale-up scenarios.
Methods: Three roll-out scenarios were developed to model the cost and impact of providing oral PrEP to female sex workers, serodiscordant couples, and medium-risk young women ages 18-24. HP+ used the Incidence Patterns Model and the Goals model to estimate HIV incidence by risk group and province and oral PrEP impact in the context of the national HIV prevention program through 2030. We developed an Excel-based tool to link the two models, set scale-up targets, and summarize the cost and impact results. In the modeled scenarios, oral PrEP coverage increased following a logistic growth curve that reached 50% of the target population by 2030.
Results: We estimated that targeting female sex workers, serodiscordant couples, and medium-risk young women will avert the most HIV infections without sacrificing much cost-effectiveness, compared to more narrowly targeted strategies. These estimates were sensitive to changes in oral PrEP adherence; strategies with lower adherence averted fewer infections and were less cost-effective. In terms of individual risk groups, the projected cost per HIV infection averted was lowest (i.e. most cost-effective) for serodiscordant couples and female sex workers at US$22,400 and US$27,700, respectively, and highest (i.e. least cost-effective) for medium-risk young women, at US$33,000. Providing oral PrEP to medium-risk young women was projected to have the greatest impact, averting 13,000 HIV infections. If Mozambique achieves its Fast Track 2030 targets, oral PrEP could avert 13,200 HIV infections; if the targets for other HIV prevention and treatment interventions are not met, the impact of oral PrEP would be higher.
Conclusions: We developed a modeling approach that provides policymakers with impact and cost-effectiveness data to guide decision-making on PrEP. Our modeling results encouraged the Mozambique MOH to consider providing oral PrEP to female sex workers, serodiscordant couples, and medium-risk young women, a high-incidence population not previously prioritized for oral PrEP rollout.

Modelling the evolution of the HIV epidemic through behavioural and PrEP studies

Effectiveness and cost-effectiveness of condomless sex-targeted PrEP in KwaZulu Natal, South Africa: Influence of HIV testing frequency and 1st line ART regimen

A. Phillips[1], V. Cambiano[2], R. Homan[3], T. Rehle[4], G. Meyer-Rath[5,6], L.F. Johnson[4], F. Tanser[7], S. Moyo[8], D. Castor[9], E.S. Russell[9], R.V. Barnabas[10], U. Parikh[11], J. Mellors[11], P. Revill[12]
[1]UCL, Institute for Global Health, London, United Kingdom, [2]UCL, London, United Kingdom, [3]FHI 360, Durham, United States, [4]University of Cape Town, Cape Town, South Africa, [5]Boston University, Boston, United States, [6]University of the Witwatersrand, Johannesburg, South Africa, [7]Africa Health Research Institute, Mtubatuba, South Africa, [8]Human Sciences Research Council, Pretoria, South Africa, [9]USAID, Washington, United States, [10]University of Washington, Seattle, United States, [11]University of Pittsburgh, Pittsburgh, United States, [12]University of York, York, United Kingdom

Background: Cost-effective strategies to start/continue PrEP in adolescent girls and young women (age 15-24; AGYW) and other populations in South Africa are not well defined. The role of drug resistance and appropriate frequency of HIV testing are also not clear.
Methods: An individual-based model was calibrated to KZN,South Africa. Variables indicating condomless sex with new and longer term partners, PrEP use, HIV testing, circumcision and, in people with HIV, variables reflecting HIV clinical status, ART use and drug resistance, were updated 3 monthly. We considered PrEP introduction in various demographic groups targeted according to condomless sex. Assumptions on PrEP are in the Table. We assume introduction of dolutegravir-based first line ART from 2018. Cost /year of PrEP: $206. Cost /year for clinical care for people on ART, including drug costs: $376. 3% discounting per year; 50 year time horizon for cost-effectiveness.

Assumptions around PrEP
PrEP only taken in 3 mth periods in which person has condomless sex
HIV testing performed at baseline and 3 monthly while taking PrEP. Lack of sensitivity of rapid tests to detect recent infection accounted for.
3% (10% in sensitivity analysis) rate of stopping PrEP /3 mths despite continued condomless sex
After stopping, PrEP can be restarted if again eligible (20%/3 months);
Adherence: 11% of people have average adherence <50%, 35% of people have between 50-80% adherence, 54% of people have >80% average adherence. Adherence varies within individuals over periods.
PrEP efficacy: 95%. Effectiveness = efficacy x adherence. Given the adherence, this means effectiveness as implemented is 70% per infected condomless partner per 3 month period.
PrEP 50% as effective against a virus containing both M184V & K65R mutations, fully effective otherwise
15% of people will not consider starting PrEP even if eligible
No increases in condomless sex in the population as a result of PrEP being introduced
People can receive PrEP while living with HIV because of PrEP use when already infected with HIV (due to < 100% test sensitivity (98% assumed) or because they are in primary infection) or because infection occurs despite PrEP (due to sub-optimal adherence or less than 100% PrEP efficacy or presence of M184V and K65R in source partner).
Risk of M184V / K65R by 3 months on PrEP while infected with HIV: 11%/4%

[Table. Assumptions around PrEP.]

Results: With PrEP eligibility/retention such that ~40% of AGYW having condomless sex take PrEP, a >25% reduction in mean HIV incidence 2018-2038 is predicted. If PrEP is targeted at people having new condomless sex partners (or those with a longer term HIV diagnosed partner not on ART) then it is cost-effective, with most DALYs averted when all men/women age 15-64 having condomless sex are eligible. Lower PrEP retention (10% stopping/3 mths instead of 3%) is associated with lower impact (18% incidence reduction in AGYW vs 26% in base case) although PrEP remains cost effective. Less frequent HIV testing while on PrEP (6 or 12 monthly rather than 3) did not have an appreciable negative effect on

impact. If the 1st-line regimen remains efavirenz-containing rather than dolutegravir-containing, increased acquisition and transmission of drug resistance is predicted to undermine ART, leading to an overall increase in AIDS death rate with PrEP introduction.

Conclusions: If retention can be kept high, PrEP targeted at people having risky condomless sex is likely to reduce HIV incidence and be cost-effective in KZN over a long time horizon. These beneficial effects of PrEP may not be realized if 1st-line ART continues to contain efavirenz rather than dolutegravir due to HIV drug resistance.

TUPEC302

PrEP for MSM can result in reductions in HIV transmission and can be cost-effective, even with a small decrease in condom use

M. Reitsema[1,2], A.J. van Hoek[1], J. Wallinga[1,2], B. van Benthem[1], A. van Sighem[3], M. Schim van der Loeff[4], M. Xiridou[1]
[1]National Institute of Public Health & Environment, Centre for Infectious Diseases Control, Bilthoven, Netherlands, [2]Leiden University Medical Center, Department of Medical Statistics and Bioninformatics, Leiden, Netherlands, [3]Stichting HIV Monitoring, Amsterdam, Netherlands, [4]Public Health Service Amsterdam, Amsterdam, Netherlands

Background: Pre-exposure prophylaxis (PrEP) has been shown to be highly effective in reducing HIV transmission among men who have sex with men (MSM). We investigated whether lower condom use (risk compensation; RC) in a nationwide PrEP programme targeted at high-risk MSM in the Netherlands would reduce the impact on HIV incidence and worsen the cost-effectiveness.

Methods: We developed an individual-based model for HIV transmission, which was fitted to annual HIV diagnoses in 2007-2014 in the Netherlands. MSM were eligible for PrEP if they had steady partners with unsuppressed viral load; or had condomless anal intercourse with casual partners in the preceding 6 months; or had gonorrhoea in the preceding 6 months. Eligibility was assessed when MSM got tested for HIV or other sexually transmitted infections. Among eligible MSM, 75% received PrEP for at least one year. We simulated three scenarios in the years 2018-2027: without PrEP; with PrEP and no RC; with PrEP and RC, where RC was modelled by increasing the probability of not using condoms by 75% for those on PrEP. Cost-effectiveness analysis was performed, with healthcare-payers perspective, discounting costs with 4% and health benefits with 1.5%. PrEP costs of €125 per 3 months were assumed.

Results: Due to RC of PrEP users, the number of PrEP-eligible MSM increases in time and the number of PrEP-users is 5,835 without RC and 6,290 with RC, in 2027. The incidence rate of HIV infection in 2027 among PrEP users is 7% higher with RC than without RC. However, since more MSM are on PrEP with RC than without RC, HIV incidence in 2027 with PrEP is reduced by 73% without RC and by 76% with RC, compared to not using PrEP. With or without RC, PrEP is cost-saving. Risk compensation can result in 118 additional QALYs gained and €13 million additional costs (compared to PrEP without RC), reducing the cost-effectiveness of PrEP.

Conclusions: PrEP can be effective in reducing HIV incidence among MSM and can be cost-effective. This holds even with reduced condom use, provided the PrEP programme can be expanded to the additional high-risk MSM who become eligible.

TUPEC303

Evaluating the cost-effectiveness and impact of oral pre-exposure prophylaxis for HIV prevention in Swaziland

S. Forsythe[1], K. Kripke[2], M. Schnure[3], S. Matse[4], N. Gambu[4], D. Castor[5], E. Njeuhmeli[6], C. Pretorius[7]
[1]Avenir Health, Center for Economics & Costing, Cuernavaca, Mexico, [2]Avenir Health, Modelling, Glastonbury, United States, [3]Palladium Group, Washington, United States, [4]Swaziland National AIDS Programme, Mbabane, Swaziland, [5]USAID, Washington, United States, [6]USAID, Mbabane, Swaziland, [7]Avenir Health, Glastonbury, United States

Background: Swaziland has one of the highest HIV prevalence levels in the world (34% among females 15-49 and 19% among males 15-49), along with an HIV incidence of approximately 2% among 15-49-year-old females. Swaziland introduced small-scale pilot programs of oral pre-exposure prophylaxis (PrEP) for HIV prevention in 2017, and the Ministry of Health and PEPFAR sought guidance from modelers at Project SOAR (funded by PEPFAR through USAID) to inform the focus and scale of the national oral PrEP program based on impact and cost-effectiveness.

Methods: We estimated the HIV incidence by risk group and province and considered the impact of oral PrEP through 2030 in the context of the national HIV prevention program using the Incidence Patterns Model (IPM) and an adaptation of the Goals model that incorporated additional risk groups using adjustment factors based on incidence ratios derived from IPM. We developed an Excel-based tool, the oral PrEP workbook, to link these models, set scale-up targets, and summarize the cost and impact results.

Results: We estimated that targeting serodiscordant couples (SDC) and female sex workers (FSW) would be the most cost-effective approach to delivering oral PrEP; although the impact of providing oral PrEP to these populations would be relatively small. While less cost-effective than providing oral PrEP to SDC and FSW, providing oral PrEP to adolescent girls and young women ages 15-29 years and adult males ages 20-34 years could potentially have the largest overall impact in terms of HIV infections averted. Variables that would particularly affect the cost-effectiveness of PrEP include the estimated cost of PrEP services, correct and consistent use of the medication once dispensed, and the scale-up of other interventions (including voluntary medical male circumcision and HIV treatment programs).

Conclusions: We developed a modeling approach that provides policy makers with impact and cost-effectiveness data to guide decision-making on oral PrEP. Our modeling results provided the MOH with data to support providing oral PrEP to general population women and men in the highest incidence age groups. Because of its highly generalized HIV epidemic, Swaziland is considering offering oral PrEP to adult males, a population not prioritized in other countries.

Modelling attempts to end HIV

Mobile multi-disease screening at scale: Modelling the effects in Kenya, Nigeria, and India

P. Kasaie[1], B. Weir[2], D. Dowdy[2], K. Baker[3], L. Holmes[3], S. Labossiere[3], C. Beyrer[2]
[1]Johns Hopkins University, Health, Behavior and Society, Baltimore, United States, [2]The Johns Hopkins School of Public Health, Baltimore, United States, [3]The Johns Hopkins University, Baltimore, United States

Background: Mobile multi-disease screening is effective in increasing diagnosis and linkage to treatment for HIV and other health conditions, yet it has not been widely implemented. We model mobile multi-disease screening in countries with diverse HIV and NCD epidemics (Kenya, Nigeria, and India) to inform dissemination.

Methods: Using intervention and cost data from the SEARCH study and country specific epidemiologic data, we use the Spectrum package and extra-model analyses to estimate the costs and effects of multi-

Author Index

disease screening on HIV, hypertension, and diabetes from 2018 to 2028. We modeled scenarios with 100,000 and 500,000 individuals screened each year and assumed 81% uptake of ART among HIV diagnosed individuals, corresponding to a target level of 90% linkage and 90% engagement in HIV care.

Results: The number of persons initiating ART was highest in Kenya and lowest in India (Panel A), and HIV infections averted was highest in Kenya (7,626 to 37,913 infections averted) and lowest in India (246 to 1,200 infections averted) (Panel B).

The total number of disability-adjusted life years (DALYs) averted was highest in Nigeria (192,361 to 969,087) compared to Kenya (48,683 to 525,099) and India (14,750 to 45,260) (Panel C), and the cost per HIV-related DALY averted was $1,425 in India, $431 in Kenya, and $109 in Nigeria. Adding diabetes screening identified 48,033-240,165 new cases in India ($25 per case identified), 6,580-32,900 in Kenya ($181), and 8,993-44,964 in Nigeria ($132).

Conclusions: Mobile multi-disease screening appears particularly effective for HIV in Kenya and Nigeria, and particularly effective for diabetes in India. Due to low HIV prevalence in India, a more targeted approach focusing on key populations (e.g., men who have sex with men) or using other forms of sampling (e.g., response-driven sampling) can results in more effective outcomes.

The role of social and sexual networks in the spread of HIV

TUPEC305

Evaluating the role of friendship networks and other factors upon participation in couples-based HIV testing and counselling (CHTC) in KwaZulu-Natal, South Africa

M. Johnson[1], L.A. Darbes[2,3], K. Fritz[4], V. Hosegood[5,6], M.O. Johnson[2], T. Ngubane[7], H. van Rooyen[7], N. McGrath[6,8,9]

[1]University of Southampton, NIHR CLAHRC Wessex Data Science Hub, Southampton, United Kingdom, [2]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [3]University of Michigan School of Nursing, Department for Health Behavior and Biological Sciences, Center for Sexuality and Health Disparities, Ann Arbor, United States, [4]International Center for Research on Women, Washington, D.C., United States, [5]University of Southampton, Department of Social Statistics and Demography, Faculty of Social, Human and Mathematical Sciences, Southampton, United Kingdom, [6]Africa Health Research Institute, KwaZulu-Natal, South Africa, [7]Human Sciences Research Council, Durban, South Africa, [8]University of Southampton, Academic Unit of Primary Care and Population Sciences and Department of Social Statistics and Demography, Southampton, United Kingdom, [9]University College London, Research Department of Epidemiology & Public Health, London, United Kingdom

Background: Participation in CHTC is low in SA. While friendship networks have the potential to facilitate the spread of health behaviours, they may influence couples positively or negatively depending upon couple relationship characteristics and the quality and frequency of interactions within networks. This may have implications for couples-based HIV prevention interventions.

Methods: We used data from a randomised controlled trial of a behavioural couples-based intervention designed to increase CHTC uptake in rural SA. Partners individually completed a survey capturing socio-demographic information and measures of relationship characteristics and quality. Self-reported strength of agreement with statements 'I have a supportive group of friends separate from my partner' and 'I have a close friend other than my partner'; were combined and taken together as indicating involvement in friendship networks (hereafter 'social connectedness'). As exploratory analysis indicated that social connectedness did not change significantly during follow-up (9 months), we created baseline average and difference scores for enrolled couples (n=327), and used logistic regression to test for associations with participation in CHTC.

Results: Overall, 27% (n=88) of couples participated during follow-up. Univariately, couples with higher average social connectedness scores were significantly less likely to participate (table). However, after adjustment for other factors, including female religious affiliation (p=0.036), study trial arm (aOR 7.13, p< 0.001) and cohabitation (aOR 2.94, p=0.004), average social connectedness was no longer statistically significant, although association estimates remained similar to univariable estimates. Univariately insignificant factors (including age, partnership length and relationship quality measures) were not considered in model building, although the potential for average social connectedness score to mask partner differences motivated inclusion of each couple's social connectedness difference score (p=0.587) as an adjustment variable.

Conclusions: Although partner cohabitation was more strongly associated with participation in CHTC, couple average social connectedness score may also have a role. No association was found for couple difference score. The suggestion that couples with higher average scores were less likely to participate may reflect greater exposure to stigmatising messages or normative behaviours and attitudes that may undermine HIV prevention activities. Future couples-based prevention interventions should consider the potential effect of social connectedness on participation and engagement.

Hotspots by random chance: Small community size and isolation can explain "patchiness" in HIV epidemics

A. Bershteyn[1,2], A. Akullian[1,2], D. Klein[1,3], B. Jewell[1,4], A. Vandormael[5,6], D. Cuadros[7], F. Tanser[5,8,9], P. Eckhoff[1,3]

[1]Institute for Disease Modeling, Bellevue, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]Bill and Melinda Gates Foundation, Seattle, United States, [4]University of California and San Francisco, Department of Medicine, San Francisco, United States, [5]University of KwaZulu-Natal, School of Nursing and Public Health, Durban, United States, [6]University of KwaZulu-Natal, KwaZulu-Natal Research Innovation and Sequencing Platform (KRISP), Durban, South Africa, [7]University of Cincinnati, Department of Geography and Geographical Information Science, Cincinnati, United States, [8]Africa Health Research Institute (AHRI), Durban, South Africa, [9]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa

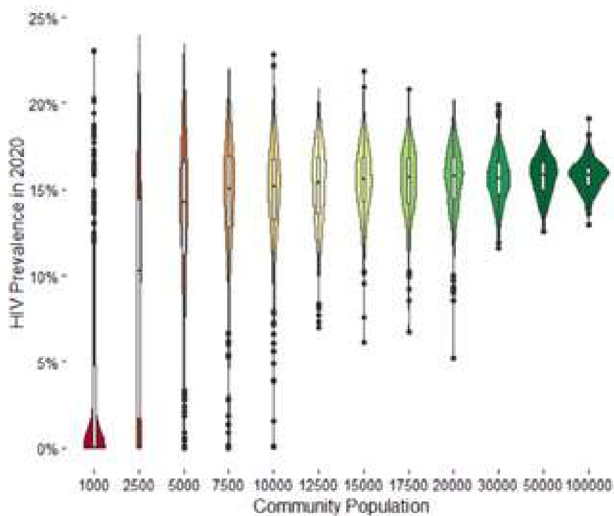
Background: It has long been observed that HIV epidemics are "patchy," exhibiting stable hotspots over spatial scales as small as a few kilometers. While there may be important unobserved covariates that drive HIV hotspots, we hypothesized that some hotspots may arise simply due to chance, because of the auto-correlated nature of HIV epidemic dynamics: areas that start out with more HIV cases by random chance often remain at higher prevalence over time.

Methods: A network model of HIV transmission in South Africa was used to examine the situations in which random chance could account for the "patchiness" of HIV under realistic assumptions about sexual mixing and relationship turn-over. Communities with identical demographic, biological, and behavioral characteristics were simulated, with variations only due to stochastic perturbations of the model.

Results: Epidemic "patchiness" emerges in communities of < 20,000 adults when fully isolated in terms of sexual mixing -- a typical size for a community in highly endemic rural areas. However, the community

size threshold for "patchiness" becomes smaller with increasing sexual mixing between surrounding communities. At the limit of full mixing between communities, without sexual preference for one's own community, hotspots cease to emerge by chance. Our findings also reveal one reason why HIV prevalence was especially "patchy" during the early epidemic, aside from differences in risk among populations. The rapid rate of growth in HIV prevalence accentuated random differences between communities at a fixed point in time, as the vertical distance between parallel lines grows with increasing slope. Simulating interventions such as test-and-treat, VMMC scale-up, and PrEP, we find that these interventions are more effective and cost-effective in hotspots, even when these hotspots came about due to random chance.

Conclusions: HIV hotspots may not always have underlying drivers, especially for smaller communities that are relatively isolated from sexual mixing with outside communities. Even if such communities are simply unlucky, they are nonetheless more effective places to target HIV interventions.



[Variability in HIV Prevalence in Small, Isolated Communities]

TUPEC307

Methods to study network subcomponents of uninfected people during an HIV outbreak among people who inject drugs (PWID): An example from Athens

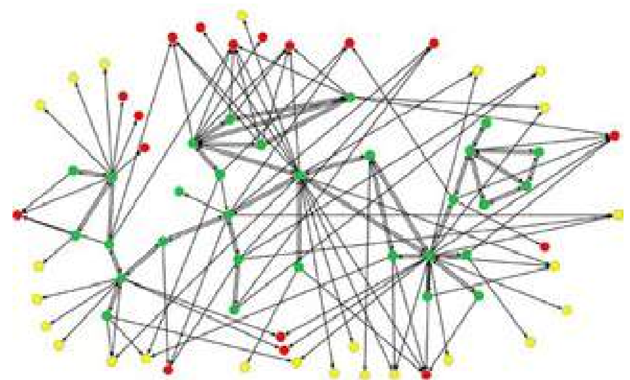
S.R. Friedman[1], L.D. Williams[2], E. Kostaki[3], E. Pavlitina[4], D. Paraskevis[3], A. Hatzakis[3], J. Schneider[5], P. Smyrnov[6], G. Nikolopoulos[7]
[1]National Development and Research Institutes, Institute for Infectious Diseases Research, Highland Park, United States, [2]National Development and Research Institutes, Institute for Infectious Diseases Research, New York, United States, [3]Medical School, National and Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Athens, Greece, [4]National Development and Research Institutes, Athens TRIP Field Office, Athens, Greece, [5]University of Chicago Medical School, Department of Medicine and and Center for HIV Elimination, University of Chicago, Department of Zoology, Chicago, United States, [6]Alliance for Publich Health, Kyiv, Ukraine, [7]University of Cyprus, Medical School, Nicosia, Cyprus

Background: What explains the existence of large pockets of uninfected people connected sexually and/or via injection to larger networks containing many infected people? Explanations include "firewall effects" (Friedman et al 2001; Dombrowski et al 2017) wherein the only HIV+ people they take risks with have low viral loads; the "bottleneck effect" wherein few network paths into the pocket of non-infection exist; low risk behaviors; and impending outbreak. We test each of these.

Methods: TRIP used enhanced risk network tracing methods and referrals to recruit 45 recently-infected, 105 long-term infected and 128 uninfected participants. The largest connected component had 92 members. Within this component there was a subcomponent of 29 connected uninfected PWID. We explored potential explanations for the existence of this large subnetwork of uninfected by considering each possible explanation in turn. Data on risk behaviors in the last 6 months were collected at the individual level. Recent infection was determined by LAg (Sedia™ Biosciences Corporation), data on recent seronegative tests, and viral load. HIV-RNA was quantified using Artus HI Virus-1 RG RT-PCR (Qiagen).

Results: The Figure shows the 29 members (3 were women) of the connected subcomponent of uninfected participants and their risk ties to each other and to the 17 recently-infected and 24 long-term infected participants with whom they have direct risk-network connections. 21 (72%) of these uninfected were linked to recently-infected participants, and 16 (55%) to long-term infected participants. 19 of the 29 (66%) subcomponent members were "extremely high risk": they self-reported syringe sharing and had at least one link to someone who shares syringes and had a viral load > 100,000 copies/ml.

Conclusions: Neither "firewalls" nor "bottleneck" explanations at the network level, nor individual-level low risk behaviors, explains the existence of the large subcomponent of non-infection. Indeed, about two-thirds of subcomponent members were at extremely high risk. These data imply that the epidemic in Athens was not over, but could spread to such uninfected pockets if additional prevention efforts (such as expanded syringe or PrEP access) do not prevent this. The methods developed here provide practical tools to study "bottleneck" and "firewall" network hypotheses in practice.



[Figure. Subnetwork of 29 uninfected participants and the recently- and long-term infected to whom they are linked. Long term positives are marked in yellow. Recently infected are in red. Uninfected are green.]

TUPEC308

Inferring age-assortative mixing patterns by applying phylogenetic methods on the HIV transmission network of the Swiss HIV Cohort Study

K. Kusejko[1,2], C. Kadelka[1,2], A. Marzel[1,2], M. Battegay[3], E. Bernasconi[4], A. Calmy[5], M. Cavassini[6], M. Hoffmann[7], J. Böni[2], S. Yerly[5], T. Klimkait[3], M. Perreau[6], A. Rauch[8], H.F. Günthard[1,2], R.D. Kouyos[1,2], Swiss HIV Cohort Study
[1]University Hospital Zurich, Zurich, Switzerland, [2]University of Zurich, Zurich, Switzerland, [3]University Hospital Basel, Basel, Switzerland, [4]Regional Hospital Lugano, Lugano, Switzerland, [5]Geneva University Hospital, Geneva, Switzerland, [6]Lausanne University Hospital, Lausanne, Switzerland, [7]Cantonal Hospital St Gallen, St Gallen, Switzerland, [8]Bern University Hospital, Bern, Switzerland

Background: Age-mixing patterns are of key importance for understanding the dynamics of HIV-epidemics and target public health interventions. We use the densely sampled Swiss HIV Cohort Study (SHCS) resistance database to study age-assortative mixing using phylogenetic methods. In addition, we investigate whether the mean age difference of pairs in the phylogenetic tree is influenced by sampling as well as by additional distance thresholds for including pairs.

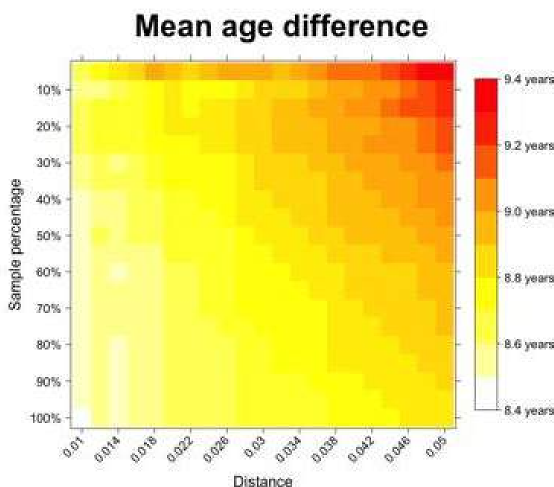
Methods: HIV-1 *pol*-sequences of 11,922 SHCS patients and approximately 240,000 Los Alamos background sequences were used to build a phylogenetic tree. Using this tree, 100% down to 1% of the tips were sampled repeatedly to generate sub trees (N = 500 for each sample proportion), of which pairs of SHCS patients were extracted. The mean of

the absolute age differences of the pairs was analyzed with respect to this sample proportion and a distance criterion for inclusion of the pairs. In addition, the transmission groups men-having-sex-with-men (MSM), intravenous drug users (IDU) and heterosexuals (HET) were analyzed separately.

Results: Considering the tree with all 11,922 SHCS patients, 2,991 pairs could be extracted, with 954 (31.9%) MSM-pairs, 635 (21.2%) HET-pairs, 414 (13.8%) IDU-pairs and 352 (11.8%) HET/IDU-pairs.

Age is significantly assortative for all risk groups considered (p < 0.001, compared to random pairs), meaning that patients of similar age are more likely to be pairs. The mean age difference in the phylogenetic analysis, using a fixed distance of 0.05, was 9.2, 9, 7.3 and 5.6 years for MSM-, HET-, HET/IDU- and IDU-pairs, respectively. Decreasing the cophenetic distance threshold from 0.05 to 0.01 significantly decreased the mean age difference (see Figure). Similarly, repeated sampling of 100% down to 1% of the tips revealed an increased age difference at lower sample proportions.

Conclusions: HIV-transmission is age-assortative, but the degree of assortative mixing detected by phylogenetic analyses depends on both sampling proportion and distance criterion. The mean age difference decreases when using more conservative distance thresholds, implying an underestimation of age-assortativity when using liberal distance criteria. Similarly, overestimation of the mean age difference occurs for pairs from sparsely sampled trees, as it is often the case in sub-Saharan Africa.



[Variation of the mean age difference of pairs extracted from the phylogenetic HIV transmission tree: by distance threshold and sample percentage.]

TUPEC309

"We still get down, but we not together": How Black U.S. heterosexual men's narratives about sexual partner type and condom use disrupt the *main* and *casual* partner dichotomy

I.A. Bowleg[1], J. Massie[1], S. Holt[1], J. Tschann[2]
[1]*George Washington University, Psychology, Washington, United States,*
[2]*University of California, Psychiatry, San Francisco, United States*

Background: HIV prevention researchers routinely use terms such as *main* and *casual* to categorize sexual partner type. Partner type has implications for condom use and HIV risk. This issue is especially pertinent in the U.S. where there is a generalized HIV/AIDS epidemic (i.e., >1%) in urban predominantly low-income Black heterosexual communities. Yet HIV prevention research from the perspective of Black heterosexual men (BHM) is virtually nonexistent. To address this gap, we examined BHM's narratives about main and casual partner types, partnership dynamics, and partner type-specific facilitators and barriers to condom use. We also explored whether condom use differed not just *across* main and casual partner types, but *within* casual heterosexual partner types.

Methods: We conducted individual interviews with 30 Black self-identified heterosexual men recruited from randomly selected venues in Philadelphia, PA. Participants ranged in age from 18 to 44 (M = 31.47, SD = 8.41); were predominantly low income (n = 17, 63% had incomes below the median income of $18,704); and 18 (60%) reported at least two partner types in the last 6 months. After multiple readings, we imported the professionally transcribed interviews into NVivo 10 qualitative analysis software. We analyzed the data using thematic analysis and used our findings to develop a Venn diagram of the reported partner types and partnership dynamics.

Results: Analyses highlighted 6 key themes:

(1) two salient partner types: main and casual; and three casual partner subtypes: primary, recurrent, and one-time;

(2) overlapping partnership dynamics between main partners and primary and recurrent-casuals, but not one-time casuals;

(3) reports of inconsistent condom use with primary-casuals and overlapping partnership dynamics with main partners such as history/familiarity, emotional intimacy, time spent together non-sexually, and knowledge/trust condom use discourses;

(4) consistent condom use with one-time casuals only;

(5) age group differences in reported partner type; and

(6) frequent reports of concurrent sexual partnerships with no reported condom use.

Conclusions: To reduce HIV risk, there is a dire public health need for more behavioral HIV prevention research to understand and inform interventions that effectively address the culturally and contextually-grounded realities of BHM's sexual partner types and partnership dynamics.

TUPEC310

Steady male sexual partner network correlates of forced sex among Black women at risk for HIV in Baltimore, MD, USA

K.K. Gundersen[1], J.K. Stockman[1], N.A. Al-Alusi[1], J.C. Campbell[2], A.N. Cimino[2], A.E. Rudolph[3]
[1]*University of California, San Diego, Medicine, La Jolla, United States,*
[2]*Johns Hopkins University, School of Nursing, Baltimore, United States,*
[3]*Boston University, School of Public Health, Boston, United States*

Background: Forced sex, defined as unwanted sex through physical force or threats, is a risk factor for HIV acquisition. Forced sex has been linked to women's reduced ability to use protection and higher risk behaviors among women and their male partners—some of whom are violent. Research has yet to examine how steady sexual partners' attributes may differ for women who have and have not experienced forced sex. We examined the associations between network characteristics of steady sexual partners and forced sex history since the age of 18.

Methods: Between 2015 and 2018, Black women aged 18-44 years were recruited from STD clinics in Baltimore, Maryland, USA into a retrospective cohort study on sexual assault and HIV risk. Eligible women (n=183) were classified as exposed (n=68) or unexposed (n=115), based on whether or not they experienced forced sex after age 18. Using an audio computer-assisted interview, women were asked to report demographic and relationship-level questions on up to 5 male steady sexual partners within the past year. The 183 eligible women reported a total of 363 recent steady male partners. Log-binomial regressions with generalized estimating equations were utilized to compare the network characteristics of recent steady male partners of exposed women (n=137) to those of unexposed women (n=226).

Results: Controlling for women's age, education, employment, and housing status, steady male partners of the women who experienced sexual violence were more likely to experience the following in the previous 6 months: a male sex partner (adjusted prevalence ratio [APR]=1.61; 95% CI: 1.00, 2.58), another female partner (APR=1.31; 95% CI: 1.12, 1.54), a sexually transmitted infection (APR=1.46; 95% CI: 1.11, 1.94), injected drugs (APR=2.58; 95% CI: 1.29, 5.14), or snorted, sniffed, or smoked illicit drugs (APR=3.03; 95% CI: 1.60, 5.74) compared to steady male partners of women who have not experienced sexual violence.

Conclusions: Study findings provide evidence that steady male partners of women with experiences of sexual violence engage in risky behaviors,

further compounding women's risk for HIV acquisition. Interventions that educate abused women about partner selection as it relates to HIV risk are urgently needed to reduce HIV risk among this marginalized group.

The role of syndemics

TUPEC311

Impact of personality disorders on leaving hospital against medical advice among people living with HIV in British Columbia, Canada

T. Beaulieu[1], T. Li[1], A. Wu[1], V. Lima[1,2], A. Krishnamoorthy[3], J. Montaner[1,2], R. Barrios[1,3], L. Ti[1,2], on behalf of the STOP HIV/AIDS Study Group
[1]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of British Columbia, Department of Medicine, Vancouver, Canada, [3]Vancouver Coastal Health, Vancouver, Canada

Background: Leaving hospital against medical advice (AMA) is a significant source of morbidity, mortality, and a major burden to the healthcare system. Studies have indicated that marginalized populations, including people living with HIV (PLHIV) and those living with a personality disorder (PD), experience high hospitalization rates. Specifically, borderline PD has been shown to be characterized by emotional dysregulation often resulting in high impulsivity, recurrent self-harm and suicidal tendencies. We sought to identify whether being diagnosed with a PD was associated with leaving hospital AMA among PLHIV in British Columbia (BC), Canada.

Methods: Data were derived from the STOP HIV/AIDS in BC cohort, a provincial-level linkage of a series of surveillance, laboratory, and health administrative databases of all identified PLHIV in BC. Using multivariable generalized estimating equations (GEE), we examined the relationship between diagnoses of PD and leaving hospital prematurely among PLHIV who experienced at least one hospitalization during the study period.

Results: Among 8763 PLHIV included in the study sample, 1321 (15.07%) were diagnosed with a PD. The prevalence of leaving hospital AMA was 8.80%. In multivariable analyses, after adjusting for a range of demographic and clinical confounders, there remained a positive association between being diagnosed with a PD and leaving hospital prematurely (adjusted odds ratio [AOR] = 1.52; 95% confidence interval [CI]: 1.20 - 1.91).

Conclusions: Results showed a significant and independent association between diagnoses of PD and leaving AMA among PLHIV. These findings underscore the importance of identifying specific PD related behaviours which are influencing the acceptance of treatment and addressing these barriers to HIV treatment including managing expectations, and supports to treat behavioural barriers by means of counselling/behavior support approach and medications to manage emotional crisis. Furthermore, these findings suggest a need to develop novel health system interventions to minimize AMA discharge among this population.

TUPEC312

Syndemic conditions of substance use, intimate partner violence (IPV) and incarceration and HIV risk among US-based young Black MSM (YBMSM): Implications for the global HIV epidemic among MSM

A. Maiorana[1], E.A. Arnold[1], S. Brown[2], R. Williams[1], S.M. Kegeles[1]
[1]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [2]University of Texas Southwestern, Community, Prevention, and Intervention Unit, Dallas, United States

Background: Syndemic conditions are psychosocial and structural factors that interact and amplify each other to produce excess burden of disease in a particular population. Quantitative studies internationally have found evidence that syndemics increase HIV vulnerability among MSM. In the U.S. HIV, particularly in the South, disproportionally affects YBMSM, but little is known about how psychosocial and structural factors relate to their HIV risk. In this longitudinal qualitative study, we describe the lived experiences of YBMSM in Dallas, Texas, in relationship to substance use, IPV, and a history of incarceration as syndemic conditions that affect their vulnerability for acquiring or transmitting HIV.

Methods: Guided by grounded theory, we conducted four in-depth interviews every six months in 2015-2017 with a diverse cohort of 30 YBMSM, age 19-29. Qualitative analysts coded the data and identified emergent themes.

Results: Many participants had few marketable skills, were marginalized, and faced challenging circumstances and familiar and social contexts. Six participants were living with HIV at their first interview, and eight other, denoting sexual risk, self-reported seroconversion in subsequent interviews. Methamphetamines use contributed to participants' unstable living situation, job loss, destructive relationships, and HIV risk. Approximately a third of participants, unable to navigate conflict and interpersonal dynamics, reported a history of physical IPV, sometimes related to substance use, in their romantic relationships. About half of the men had a history of incarceration resulting from IPV, substance use, and/or other illegal activities. Many reported that having a criminal record curbed opportunities for employment, housing, and financial stability. Consequently, some engaged in survival means involving HIV risk (sex work, organizing sex parties). For some participants, their socio-economic status fluctuated and did confer protection against HIV risk.

Conclusions: Substance use, IPV, and incarceration as syndemic conditions create vulnerability points related to YBMSM's HIV risk. Using syndemic theory as a framework may elucidate the interaction of structural and individual-level factors that exacerbate HIV among YBMSM in the U.S. These dynamics may also apply to MSM globally, particularly in areas where they are marginalized and highly stigmatized, to inform the development of tailored HIV interventions.

TUPEC313

Effectiveness of an integrated, syndemically-oriented sexual risk reduction intervention among MSM in North India: Findings from a quasi-experimental trial

V. Chakrapani, M. Kaur, R. Kumar
Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India

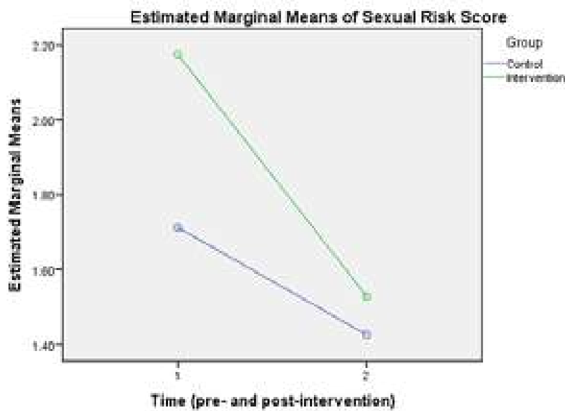
Background: In India, despite a decade of HIV prevention interventions that focus on to condom promotion and distribution, and high levels of HIV knowledge, consistent condom use among MSM remains sub-optimal (about 50%). Given the evidence for co-occurring and mutually reinforcing psychosocial conditions (i.e., syndemics) such as alcohol use, depression and violence victimization, we developed and tested a syndemically-oriented motivational interviewing-based intervention among MSM to promote safer sex, and compared with a standard-of-care control.

Methods: In 2016/17, we conducted a quasi-experimental study with non-equivalent comparison groups design: intervention group had 229 MSM and standard-of-control group had 230 MSM. MSM were recruited through non-governmental agencies in Chandigarh, North India. In the intervention group, MSM received a two-session peer-delivered syndemically-oriented intervention: risk reduction counselling along with screening, counselling and referrals for four syndemic conditions: alcohol use, depression, violence victimization and internalized homonegativity (self-stigma). Participants completed assessments before intervention and at 4th month. The primary outcome measure was sexual risk composite score (that included number of sexual partners, consistency of condom use with male partners and engagement in sex work). GLM repeated measures procedure (in SPSS-23) was used, with control and intervention conditions as between-subjects factor, and time (baseline/endline) as within-subjects factor. Covariates included were: sexual stigma and condom use self-efficacy scores from baseline.

Results: Participants' median age was 26 years (Interquartile range-7) and median monthly income was INR 8000 (IQR-12000). Fifty-one percent had up to secondary education, 68.2% were single, 38.6% engaged in sex work, and had diverse self-identities: kothis-38.6%, giriyas/panthis-17.9%, doubledeckers-16.3%, gay-8.1%, bisexual-12%, and straight/

heterosexual-5%. Of the 459 MSM, 89.9% completed pre- and post-intervention assessments. After adjusting for sexual stigma and condom use self-efficacy, ANCOVA results showed a significant decrease in sexual risk (26% reduction in absolute risk score) among those in the intervention group: F (1, 452)=19.80, p < .001, partial eta squared =.042).

Conclusions: This pilot quasi-experimental study among MSM has demonstrated the feasibility and potential effectiveness of a syndemically-oriented brief intervention to reduce sexual risk. Screening for and addressing syndemic conditions can be integrated into the existing condom knowledge/promotion-based HIV prevention intervention to substantially reduce sexual risk.



[Figure 1. Significant reduction in sexual risk among MSM in intervention group]

TUPEC314

Transactional sex and poverty as syndemic conditions for HIV risk among transgender women

J. Parsons[1], N. Antebi-Gruszka[2], B. Millar[2], D. Cain[2], S. Gurung[2], H.J. Rendina[1]
[1]Hunter College-CUNY, Psychology, New York, United States, [2]Center for HIV Educational Studies and Training, New York, United States

Background: Research has consistently shown a relationship between syndemic factors and HIV transmission risk behavior among men who have sex with men. Little research, however, has examined these syndemic factors among transgender women, nor to what degree different factors are relevant for this population.

Methods: A sample of 215 transgender women, ages 18-65 (M=34.3) were recruited. The majority (75.8%) were women of color. Participants completed measures of HIV transmission risk behavior, four previously established syndemic conditions (polydrug use, depression, childhood sexual abuse, intimate partner violence), and two conditions hypothesized to be relevant for transwomen (transactional sex and poverty).

Results: Only one of the six associations between the four established syndemics conditions (childhood sexual abuse and intimate partner violence) was significant. Transactional sex was positively associated with polydrug use (OR=6.59, 95% CI=1.51, 28.75), childhood sexual abuse (OR=2.80, 95% CI=1.49, 5.24), intimate partner violence (OR=2.14, 95% CI=1.18, 3.88), and poverty (OR=2.22, 95% CI=1.24, 3.97). Only transactional sex was positively associated with HIV transmission risk behavior (OR=2.24, 95% CI=1.16, 4.34). Multivariable logistic regression was used to show the odds of HIV transmission risk behavior explained by all six syndemic conditions. The adjusted odds ratio of the summed six syndemic conditions in the model was significant (AOR=1.33, 95% CI=1.05, 1.68, *p* =0.02).

Conclusions: We found evidence supporting the inclusion of transactional sex and poverty as socioeconomic syndemic conditions related to HIV transmission risk behavior among transgender women, suggesting that syndemic research with transgender women can not rely on the same models used with MSM. In bivariate analyses, transactional sex was significantly associated with three syndemic conditions, and poverty was associated with transactional sex. These findings suggest that transactional sex, and poverty to a lesser extent, co-occur and are co-experienced among transgender women. When we treated these conditions as syndemics, we found a strong positive association between transactional sex and HIV transmission risk behavior.Holistic interventions targeting the identified syndemic conditions in an effort to address the extremely high HIV prevalence among transgender women are especially warranted. This need is even greater in transgender women of color, who experience disproportionately higher rates of exposure to psychosocial conditions exacerbating HIV risk.

TUPEC315

Finding casual sex partners on the internet, and the twin epidemics of methamphetamine use and incident HIV infection in a cohort of MSM in Bangkok, Thailand

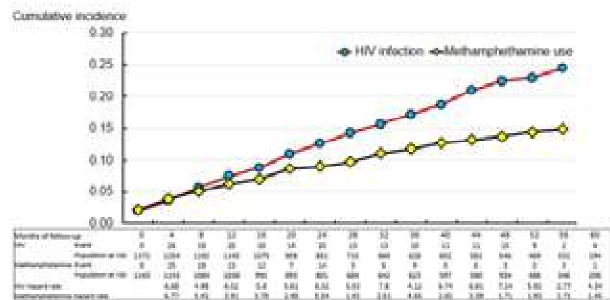
P. Piyaraj[1], P.A. Mock[2], W. Thienkrua[2], J. Tongtoyai[3], A. McNamara[2], W. Chonwattana[2], W. Wimonsate[2], A. Varangrat[2], T.H. Holtz[4], K.E. Nelson[5], F. van Griensven[6]
[1]Phramongkutklao College of Medicine, Bangkok, Thailand, [2]Thailand MoPH-US CDC Collaboration, Nonthaburi, Thailand, [3]Thailand MoPH-US CDC Collaboration, Bangkok, Thailand, [4]US Centers for Disease Control and Prevention, Atlanta, United States, [5]Johns Hopkins University, Baltimore, United States, [6]Thai Red Cross AIDS Research Center and UCSF Department of Epidemiology and Biostatistics, Bangkok, Thailand

Background: Finding casual sex partners on the internet and methamphetamine use have been described as risk factors for HIV infection in men who have sex with men (MSM). However, the interplay between these factors has not been studied prospectively in one design.

Methods: Cohort study of 1,744 Bangkok MSM with follow-up visits every four months from 2006 to 2014. Men were tested for HIV infection at every study visit, and for sexually transmitted infections at baseline. Demographics (at study entry) and HIV risk behavior information were collected by audio computer-assisted self-interview (every visit). Cox proportional hazard regression analysis was used to evaluate covariates for incident methamphetamine use and HIV infection.

Results: Incidence of methamphetamine use was 3·8, and of HIV infection, 6·0 per 100-person years of follow-up (figure). Dual risk factors for both incident methamphetamine use, and HIV infection were younger age and finding casual sex partners online. Ever having received money for sex was found predictive for incident methamphetamine use; living alone, recent anal sex, and ulcerative sexually transmitted infections at baseline were predictive for incident HIV infection.

Conclusions: Twin epidemics of methamphetamine use and HIV infection are occurring among MSM in Bangkok. Finding casual sex partners on the internet, methamphetamine use, and sexually transmitted infections play important roles in sustaining the HIV epidemic in this population. Virtual HIV prevention education, drug use harm reduction, and biomedical HIV prevention methods, such as pre-exposure prophylaxis, may help to reduce or revert the HIV epidemic among MSM in Bangkok.



[Kaplan Meier cumulative incidence of newly reported methamphetamine use and HIV seroconversion in a cohort of MSM in Bangkok, 2006-2014]

TUPEC316
Association of HIV infection with syndemics of psychosocial factors and condomless anal intercourse in MSM in Malaysia

R.X. Ng[1], M.A. Ab Halim[2], T. Guadamuz[3], A. Kamarulzaman[2,4], S.H. Lim[2,5]
[1]University of Malaya Medical Center, Department of Medicine, Division of Infectious Diseases Unit, Kuala Lumpur, Malaysia, [2]Centre of Excellence for Research in AIDS, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, [3]Mahidol University, Department of Society and Health, Faculty of Social Sciences and Humanities, Bangkok, Thailand, [4]University of Malaya, Faculty of Medicine, Department of Medicine, Division of Infectious Diseases, Kuala Lumpur, Malaysia, [5]University of Malaya, Department of Social and Preventive Medicine, Kuala Lumpur, Malaysia

Background: Men who have sex with men (MSM) account for majority of newly diagnosed HIV infection in Malaysia. In Malaysia, sexual activities between men are forbidden by local civil and Shariah laws leading to cultural and social stigmatization and increase vulnerability to psychosocial factors, contributing to HIV infection in a syndemic way. This study aimed to assess the additive effects of multiple psychosocial factors (syndemics), condomless anal intercourse (CAI) and HIV infection among Malaysian MSM in order to inform the development of novel, comprehensive preventive HIV interventions.
Methods: Demographic data, psychosocial factors, CAI and HIV status were collected via an anonymous online survey through MSM social networking sites. Syndemic phenomenon is defined as presence of ≥ 2 psychosocial factors and HIV infection was assessed by self-report. Multivariate regression was used to investigate the independent association between the syndemic factors, CAI and HIV infection.
Results: A total of 483 MSM (whom had anal intercourse in past 12 months) with mean age of 28.7 (range: 18-55) years old completed the survey. Only 320 (66.3%) participants reported ever having taken an HIV test; among them, 88 (27.5%) were HIV positive. Self-reported sexual identity (homosexual versus non-homosexual) was associated with self-reported HIV status (odds ratio (OR) = 2.06, 95% confidence interval (CI) = 1.07-3.97). Prevalence of psychosocial factors were depressive symptoms (61.5%), suicidal ideation (23.6%), history of childhood sexual abuse (CSA) (12.2%), "chemsex" (use of stimulant drugs before or during anal sex) (25.1%) and inter-partner violence (IPV) (19.3%). CAI in the past 3 months was reported by 55.7% of participants and 53.0% experienced syndemic phenomenon. Depressive symptoms (adjusted odds ratio (AOR)=2.19, 95% CI=1.24-3.85), "chemsex" (AOR=2.01, 95% CI=1.19-3.52) and history of CSA (AOR=2.18, 95% CI=1.11-4.67) were associated with self-reported HIV status. The number of psychosocial factors significantly increased the odds of CAI and HIV.
Conclusions: Syndemic phenomenon was present in this sample with large proportion of the participants manifesting significant psychiatric symptoms, experienced childhood sexual abuse and IPV. The results underscore the need for an urgent, comprehensive HIV prevention strategy including addressing mental illness and substance use amongst Malaysian MSM in order to effectively respond to the HIV epidemic.

Syndemic Count n=483		CAI last 3 months n=269		Self-reported HIV status n=88	
	n (%)	n (%)	Odds Ratios (OR) (95% Confidence Intervals (CI))	n (%)	OR (95% CI)

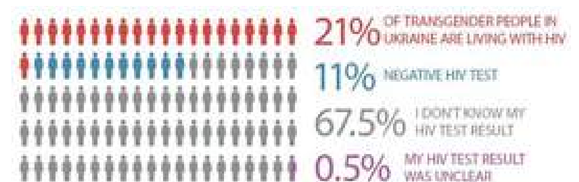
[Association between Syndemic Count, Condomless Anal Intercourse (CAI) and Self-reported HIV status among MSM in Malaysia]

The role of political and structural factors

TUPEC317
Study of behavioral models of transgender people leading to high rates of HIV prevalence in Ukraine

I. Medvid
HPLGBT, Board the HPLGBT, Kyiv, Ukraine

Background: In Ukraine´s current national HIV strategy, there is no targeted intervention or funding for work with transgender people. This is due to a lack of reliable epidemiological and behavioral data on the prevalence of HIV and risky practices among transgender people in Ukraine.
Methods: A quantitative study in 2017 using the RDS method. This is the largest of its kind in the EECA countries: 438 transgender people were surveyed across Ukraine, including Crimea and the eastern regions of the country where military operations are taking place.
Results: 69% of transgender people in Ukraine did not use a condom during their most recent sexual intercourse. The main reasons for this were that sexual partners insisted on sex without condoms (28%) and the lack of condoms (23%).
91% of transgender people in Ukraine have at least once provided sexual services for money and/or other benefits.
According to respondents´ own reports, HIV prevalence among transgender people could be as high as 21%. At the same time, HIV infection specialists and other doctors in AIDS centers in Ukraine do not receive special training to work with transgender people, and transgender people with HIV are registered in health facilities according to their biological gender.
Conclusions: Data obtained suggest that, as in other countries, the risk of HIV transmission among transgender people in Ukraine is 50 times higher than among the general population.
Level of knowledge about HIV/AIDS and STI among transgender people needs to be raised, by means of targeted interventions, and access for transgender people to HIV services needs to improve, including through awareness training for doctors. There is also a need for advocacy work to improve the meaningful participation of trans people and their organizations in national anti-epidemic action.
Next steps should aim to ensure that the state recognizes the vulnerability of transgender people and explicitly includes transgender people in list of groups with an increased risk of HIV infection. Transgender people should be included in national coordination mechanisms, in particular, the National Council for Countering Tuberculosis and HIV/AIDS.



[Transgender people and HIV in Ukraine]

TUPEC318
Are HIV variants from former soviet union countries spreading across the world?

L. Aibekova[1], B. Foley[2], S. Abidi[3], S. Ali[4]
[1]Nazarbayev University, Biological Sciences, Astana, Kazakhstan, [2]Los Alamos National Laboratory, Los Alamos, United States, [3]Aga Khan University, Department of Biological and Biomedical Sciences, Karachi, Pakistan, [4]Nazarbayev University, Astana, Kazakhstan

Background: While cases of new HIV infections among adults have declined globally in recent years, the annual number of new HIV infections in Eastern Europe and Central Asia increased by 60% with an estimated 190,000 new HIV infections in 2016. The number of people living with HIV in these countries reached 1.6 million by 2016. Following the collapse of Soviet Union in 1991, socioeconomic interactions among the former

Soviet Union (FSU) countries facilitated cross-border mobility, leading to the transmission of certain infectious diseases within this region. Initially, HIV outbreaks in the FSU countries were characterized by repeated transmission of HIV variants A_{FSU} and B_{FSU}, which may now be used to track the origin and transmission routes of HIV within and outside the FSU countries. The present study was designed to find distinct signature patterns of HIV variants A_{FSU} and B_{FSU} and using these signatures to track the transmission patterns of HIV subtype A and B in FSU countries and worldwide.

Methods: To this end, phylogenetic analysis of publicly available HIV-1 subtype A and subtype B *pol* and *env* full gene sequences from FSU countries was performed using *MEGA 6.0*. Each cluster from these trees was separately analyzed for A_{FSU} and B_{FSU} signatures using the software *VESPA*. The signature sequences were then used to screen all the subtype A and B sequences, including the ones FSU as well as non-FSU countries, in the HIV Los Alamos database.

Results: Our results revealed that transmission of FSU specific HIV-1 variants has now bridged outside the FSU region.

Conclusions: This analysis elucidates the origins and emerging patterns of HIV transmission within and outside the FSU countries.

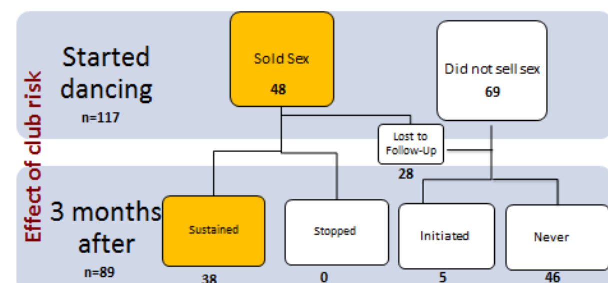
TUPEC319

Sex work trajectories over a 3-month period among a cohort of new female exotic dancers in Baltimore, MD

N. Flath[1], N. Opper[2], J. Park[2], M. Brantley[3], K. Morales[4], S. Sherman[2]
[1]Johns Hopkins Bloomberg School of Public Health, Health, Behavior, Society, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [3]Tennessee Department of Health, Nashville, United States, [4]John Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: Entry into dancing at an exotic dance club (EDC) may be a gateway into initiating, escalating and sustaining sex work. We aimed to determine trajectories of sex work three months after starting to work as a Female Exotic Dancer (FED). Furthermore, we explore the role of structural vulnerabilities including co-occurring social and economic disadvantage, HIV risk factors, and aspects of the club environment on the trajectory of sustaining sex work over time.

Methods: Among a cohort of 117 new FEDs, 89 were followed-up (FU) averaging 3 months after baseline to complete a self-administered survey capturing the role of the EDC on the HIV risk profile in twenty-two EDCs in Baltimore MD; spanning May and October 2014. Trajectories of sex work were characterized as those who sustained sex work from baseline to FU, sold sex at baseline and stopped at FU, initiated only at FU or never sold. Sustaining was the most common trajectory, therefore correlates with structural vulnerabilities and HIV/STI risk factors were estimated with fisher exact tests. A multivariate model was built on the exposure of recent illicit drug use (i.e., heroin, crack, cocaine, and speedball). We adjusted for structural vulnerability indicators and club clustering using GEE logistic regression with robust estimation of variance.



[Trajectories of Sex Work among New Female Exotic Dancers in Baltimore, Maryland]

Results: After following 89 new FEDs, 38 sustained selling sex, 5 initiated, 46 never sold and no dancers stopped. Illicit drug use, housing instability and a history of childhood sexual and physical violence were significantly associated with sustained sex work (respectively, adjusted odds ratio (aOR) 3.4 95% confidence Interval (CI) 1.1,10.6 p< 0.05, aOR 2.2 95% CI 1.1, 4.6 p< 0.05 and aOR 2.5 95% CI 1.2, 5.2 p< 0.01).

Conclusions: The sexual risk trajectory may depend on the structural factors that the dancers walk into the club with. Illicit drug use, histories of violence, and housing instability begin to explain the trajectory of sustained sex work. Identifying modifiable structural and environmental drivers that promote or inhibit HIV/STI risk in a new occupational setting provides insight into the tools of resiliency available to buffer risk and prevent morbidities among women working within the adult entertainment industry.

TUPEC320

Estimating the potential impact of compulsory drug abstinence programs (CAP) on HIV incidence among people who inject drugs (PWID) in Tijuana, Mexico, using mathematical modeling

A. Borquez[1], C. Rafful[1], D. Abramovitz[1], L. Beletsky[1,2], S. Strathdee[1], N.K. Martin[1]
[1]University of California San Diego, Infectious Diseases and Global Public Health, La Jolla, United States, [2]Northwestern University, School of Law and Bouvé College of Health Sciences, Boston, United States

Background: Exposure to CAP has been associated with HIV risk behaviors, HIV infection and fear of accessing HIV services in various settings, including China, Thailand and Malaysia. In Tijuana, Mexico, forceful police referrals to CAP and allocation of government funds for expansion of CAP increased in 2015 to deal with homelessness and drug use. An estimated 5,000-10,000 PWID live in Tijuana among whom HIV prevalence is 3.5% and incidence 1.1%/year. We found exposure to CAP was associated with overdose risk among this population. Here, we extend this work to investigate the potential impact of CAP scale-up, compared with that of opioid agonist therapy (OAT), on HIV incidence among PWID.

Methods: We analyzed data from a cohort of PWID in Tijuana (2011-2020) which bi-annually collects information on sexual and drug-using behaviors and on a range of exposures, including CAP, to inform the parameterization of a deterministic mathematical model of HIV transmission among this population. We investigated temporal trends in exposure to CAP and associations with syringe sharing, controlling for duration of injection, and represented these in the model. We estimated future impact (from 2018-2030) of CAP or OAT scale-up on HIV incidence among PWID.

Results: Exposure to CAP in the past 6 months among PWID in Tijuana was low at baseline (1.4%) and fluctuated between 1.6 % and 5.0% in 2015-2016. Ever being exposed to CAP versus not was associated with an increased risk of receptive syringe sharing in the past 6 months (RR: 1.14 (95%CI: 1.00-1.30)). Modeling estimated that between 2018-2030 CAP could lead to a 9% (95% CrI: 1%-20%) increase in new HIV infections, if peak admission rates were maintained. If OAT was provided instead, an 8% (95% CrI: 4%-13%) reduction in new infections would be expected.

Conclusions: Exposure to CAP has seen recurrent increases in recent years among PWID in Tijuana, likely as a result of current polices. Further scale-up could lead to a rise in HIV incidence among PWID. Instead, OAT scale up could substantially reduce it. A reappraisal of the response to the opioid epidemic in Tijuana, which considers the health and human rights of PWID, is needed.

TUPEC321

Racial microaggressions, not overt racial discrimination, heighten U.S. Black heterosexual men's sexual HIV risk through increased substance use before or during sex

S.L. Holt, A.M. del Río-González, I.A. Bowleg
George Washington University, Department of Psychology, Washington, United States

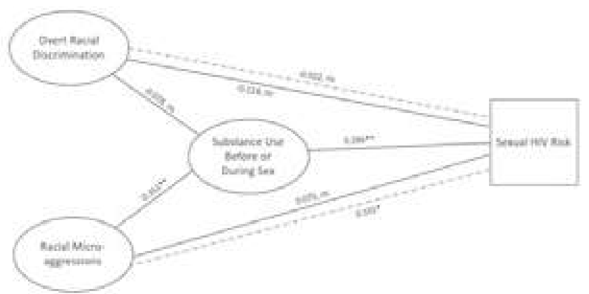
Background: In 2016, Black men represented just 13% of males in the U.S., but 64% of HIV cases among men attributed to heterosexual contact, underscoring a need for more HIV prevention research with Black heterosexual men (BHM). Numerous studies document the impact of racial discrimination — overt discrimination (e.g., not being hired because

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

of your race) and/or more subtle microaggressions (e.g., being looked at suspiciously because of your race) — on Black people's substance use, with evidence of substance use as a coping mechanism. Furthermore, it is well-documented that substance use increases sexual HIV risk. Yet, research on racial discrimination and sexual HIV risk is rare. To address these gaps, we tested a conceptual model in which we hypothesized that racial discrimination would increase BHM's substance use before or during sex and in turn, sexual HIV risk.

Methods: Participants were 722 self-identified BHM living in Washington, DC who reported having sex with women in the past 3 months and ranged in age from 18 to 44 (*M*= 30.4). Field interviewers administered surveys using computer-assisted software within participants' homes in 2015-2016. We used structural equation modeling via Mplus 7 to test the study's mediation model.

Results: Participants reported experiencing microaggressions (*M*= 2.01) more than twice as frequently as overt racial discrimination (*M*= 0.73) (scale 0=Never to 6=Nearly every day). Neither overt racial discrimination nor racial microaggressions were directly associated with sexual HIV risk. Racial microaggressions, but not overt racial discrimination, however, were associated with increased substance use before or during sex, which was in turn associated with increased sexual HIV risk. Furthermore, racial microaggressions were indirectly positively associated with sexual HIV risk through their influence on substance use before or during sex (see Figure 1).



[Figure 1. Structural Equation Model, Depicting Paths and Standardized Estimates among Racial Discrimination, Substance Use, and Sexual HIV Risk]

Conclusions: These results suggest that it is the subtle and mundane racial microaggressions, rather than the more overt but less frequent acts of discrimination, that increase BHM's substance use before or during sex, and in turn their sexual HIV risk. These results highlight the need for individual-level culturally-specific interventions to help BHM positively cope with racial microaggressions as well as structural-level interventions to reduce the frequency of these microaggressions.

Understanding the spread of HIV through behavioural studies

TUPEC322

Coverage of modern contraceptive use and highly active anti-retroviral therapy among women of reproductive age living with HIV in Nigeria

F. Oluwasina[1], B. Onifade[2], K. Ssamula[3], I. Okafor[4], W. Odoke[5], P. Iutung[6], O. Gbadamosi[6], J. Gonzalez Perez[6]
[1]AIDS Healthcare Foundation, Monitoring and Evaluation, Abuja, Nigeria, [2]National AIDS and STIs Control Program, Strategic Information, Abuja, Nigeria, [3]AIDS Healthcare Foundation, Monitoring and Evaluation, Kampala, Uganda, [4]University Teaching Hospital, Community Medicine, Abakaliki, Nigeria, [5]AIDS Healthcare Foundation, Monitoring and Evaluation, Nairobi, Kenya, [6]AIDS Healthcare Foundation, Program Management, Kampala, Uganda

Background: Current levels of contraceptive use in all of sub-Saharan Africa are already preventing 173,000 HIV-positive births annually, even though contraception is not widely used in the region. The practices of contraception by HIV positive women might not be well understood or met. This study aims to assess the coverage of contraceptive use among women living with HIV at ART centres in Nigeria.

Methods: A retrospective cross-sectional study which consist of 746 HIV women, aged 15 to 49 years using systematic random sampling methods at 55 facilities comprising both primary and secondary health care facilities. Data were retrieved from though Electronic Medical Record system between January 2014 and June 2017. The variables obtained included maternal age, number of living children, marital status, religion, the educational level, and the use of antiretroviral treatment (HAART), the knowledge, attitude and practice of contraception. Analyses were done using SPSS 20.1. Fisher exact test was used for comparison. The level of significance was P< 0.05.

Results: Out of a total of 746 HIV positive women who participated in the study, 71% (529) were using modern contraceptive methods and 98% knew at least one method of modern contraception. Twenty-one percent (156) had fallen pregnant whilst on HAART while 81 (51.9%) said that the pregnancy had been unplanned. Factors associated with contraceptive practice were knowledge of HIV status (68.5%) and health worker advice 469 (62.8%). Women ≥28 years consider using contraceptive (OR 2.6, 95%CI 1.3-4.9), on HAART (OR 2.8, 95%CI 0.8-9.2), divorced (OR 1.7, 95%CI 0.8-3.7), had ≥1 living children (OR 1.2, 95%CI 0.6-2.4) and when the women were educated (OR 1.2, 95%CI 0.6-2.4). Condom use was among participants was 49.7%.

Conclusions: Contraceptive use is relatively low among participants in this study. Age and parity were found to be influence the uptake of contraception among these women. Information regarding contraceptive use should therefore be provided at all ART clinics. Integration of Family planning and HIV services should be implemented and more emphasis should be made on condom use even when using other contraceptive methods to ensure dual protection.

TUPEC323

Condomless anal intercourse by partner type among Chinese men who have sex with men in Tianjin

N. Zhou[1], J.A. Bauermeister[2], W. Guo[3], M. Yu[1], J. Yang[4], M. Zheng[5], Y. Guo[1], H. Gong[1], Y. Gao[6], G. Jiang[1]
[1]Tianjin Centers for Disease Control and Prevention, Tianjin, China, [2]University of Pennsylvania, Philadelphia, United States, [3]National Centre for AIDS/STD Control and Prevention, Chinese Centre for Disease Control and Prevention, Beijing, China, [4]Tianjin Dark Blue Working Group, Tianjin, China, [5]Tianjin Centers for Disease Control and Prevention, HIV/AIDS/STD Control and Prevention, Tianjin, China, [6]Tianjin Hongqiao District Center for Disease Control and Prevention, Tianjin, China

Background: HIV prevalence and incidence is high among men who have sex with men (MSM) in China, underscoring the need to support and optimize HIV risk reduction strategies for this population. We sought to estimate the prevalence of condomless anal sex among MSM living in Tianjin, China.

Methods: We recruited 595 HIV-negative MSM (Mean age=29.27 years; 76% gay identified) living in Tianjin to participate in a HIV study between 2013 and 2014. Data were collected after a voluntary counseling and testing session through a face-to-face survey. We used multivariable logistic regressions to examine the association between sociodemographic characteristics and HIV risk correlates (e.g., HIV knowledge, prior STIs) and MSM's likelihood of engaging in condomless anal intercourse (CAI) with main and casual partners in the prior six months.

Results: CAI was prevalent in the sample (N=321; 53.9%), with men reporting CAI with regular (N=233; 39.2%) or casual (N=189; 31.8%) partners. Identifying as gay was the only correlate of engaging in CAI with a regular partner (OR=1.69; 95% CI: 1.09, 2.63). CAI with a casual partner was more likely among men who were older (OR=1.03; 95% CI: 1.01, 1.05), identifying as gay (OR=1.73; 95% CI: 1.08, 2.79), and aware of HIV treatment policies in China (OR=1.40; 95% CI: 1.16, 1.69). MSM with more educational attainment (OR=.65; 95% CI: .50, .85) and greater HIV transmission knowledge (OR=.85; 95% CI: .73, .99) were less likely to report CAI with a casual partner.

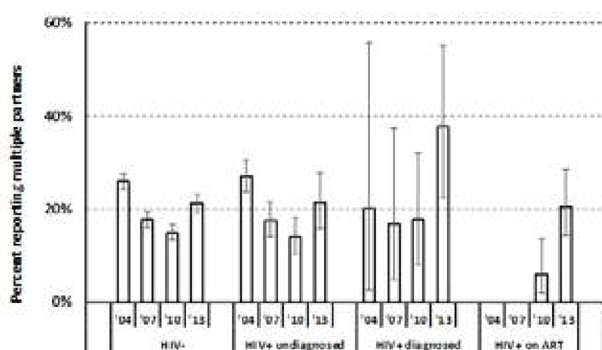
Conclusions: HIV risk reduction efforts should be developed to be sensitive and responsive to the unique experiences of Chinese MSM. We discuss opportunities for future work, including the development HIV risk reduction interventions.

TUPEC324

Could increases in high-risk sexual behaviour contribute to continuing high HIV incidence following the scale-up of ART? Evidence from East Zimbabwe

S. Gregson[1,2], C. Nyamukapa[1,2]
[1]Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom, [2]Biomedical Research and Training Institute, Manicaland Centre for Public Health Research, Harare, Zimbabwe

Background: Slow reductions in HIV incidence have been observed in sub-Saharan African populations despite rapid increases in ART coverage. A contributing factor could be increases in high-risk sexual behaviour at the population level - particularly if concentrated in people living with HIV (PLHIV) not yet on treatment. We test this hypothesis by examining trends in high-risk sexual behaviour disaggregated by HIV infection, HIV diagnosis and ART status in a population in east Zimbabwe with continuing high HIV incidence (0.75%; 95%CI 0.60%-0.95%, 2009-2013).
Methods: Trends in multiple partners in the last year and condom use at last sex were measured using data on approximately 7000 sexually-active adults (15-54 years) in each of four rounds of a general-population open cohort spanning the scale-up of ART services in east Zimbabwe (2003-2013). Levels of sexual risk behaviour by infection, diagnosis and treatment status were compared using multivariable logistic regression adjusted for age and location.
Results: The proportion of adults reporting multiple sexual partners in the last year declined steadily over the first three rounds of the survey but increased in the post-ART period, 2009-2013, particularly in men (men: 14.4% to 21.4%, p< 0.001; women: 1.7% to 2.1%, p=0.1), for whom increases were found in all HIV, HTC and ART sub-groups (Figure). Overall changes in condom use were small but an increase was observed in PLHIV who had been diagnosed or were on ART (44.1% to 59.4%, p=0.057). ART coverage was 36% and 43% in men and women in 2012-2013. PLHIV not yet on treatment were less likely to report 5 or more lifetime sexual partners than those on ART (AOR=0.51, p< 0.001) but were equally likely to report multiple sexual partners (p=0.9) and less likely to report condom use at last sex (AOR=0.34, p< 0.001). Similar patterns were found for men and women.
Conclusions: Increases in high-risk sexual behaviour following the scale-up of ART - particularly in PLHIV not on treatment who may be recently infected and highly infectious - could have limited reductions in HIV incidence in east Zimbabwe. Early ART initiation and improved implementation of efficacious methods of primary prevention could accelerate declines in HIV incidence.



[Figure; Trends in multiple sexual partners in the last year by HIV infection, diagnosis and ART status, in men aged 15-54 years, east Zimbabwe, 2003 to 2013]

TUPEC325

HIV testing among Black heterosexual men in the U.S. capital is linked with social-structural factors at the individual, but not the neighborhood, level

A.M. del Rio Gonzalez, M. Mbaba, S. Holt, I. Bowleg
George Washington University, Psychology, Washington, United States

Background: Black men in the U.S. experience disproportionate poverty, unemployment and incarceration— all of which have been linked to increased HIV rates. In Washington, D.C., Black men represent about half of the male population, yet they accounted for 89% of HIV cases due to heterosexual contact in 2016. Although awareness of HIV status is critical for reducing HIV/AIDS, Black heterosexual men (BHM) are rarely the focus of initiatives promoting HIV testing. Research with other populations (e.g., MSM) have found that social-structural factors both at the individual (e.g., incarceration, poverty) and the neighborhood (e.g., access to HIV-related services, poverty at the census-tract level) levels are significant predictors of HIV testing. We investigated how both individual and neighborhood-level characteristics were associated with being tested for HIV in the last 12 months among BHM in Washington D.C.
Methods: As part of a mixed-methods study examining neighborhood and individual contexts of sexual HIV risk among a predominantly BHM sample, we randomly sampled households from 28 neighborhood clusters in D.C. with >40% Black population. Participants were 810 self-identified BHM between 18 and 44 years old who responded to a computer-assisted survey. We utilized multilevel modeling analysis to assess how individual and neighborhood-level characteristics were associated with HIV testing in the last year.
Results: Most participants reported getting tested in the last year (*n*=456, 67%), and nearly all reported getting tested at least once in their lifetimes (*n*=727; 91%). At the individual level, incarceration history, income, health insurance and HIV concern significantly predicted testing in the last 12 months. Neighborhood-level characteristics, however, were not significantly associated with testing in the last year (Table 1).

	Beta	p
Individual-level characteristics		
Incarceration history	.432	<.001
Income	-.145	<.001
Health insurance	.383	.040
Concern about HIV	.103	.023
Neighborhood-level characteristics (Census tract data)		
Density of HIV clinics	-.385	.122
HIV rate (per 100,000 inhabitants)	.001	.201
Percentage of population under poverty line	-.046	.113

[Table 1. Multilevel model of being tested for HIV in the last 12 months among Black heterosexual men in Washington D.C.]

.

Conclusions: HIV testing among BHM in D.C. is prevalent, independent of where in the city they live. Underscoring the importance of the social-structural context, having a history of incarceration, lower income and having health insurance increased the likelihood of being tested in the last year. Although measured at the individual-level, these factors reflect some of the key social-structural issues that Black men face in the U.S. Understanding how these factors facilitate testing is a critical step in framing HIV testing efforts for BHM.

TUPEC326

Intimate partner violence, depressive symptoms and sexual behaviour among gay, bisexual and other men who have sex with men in the PROUD PrEP trial

A. Miltz[1], F. Lampe[1], L. Bacchus[2], S. McCormack[3], D. Dunn[3], E. White[3], A. Rodger[1], A. Phillips[1], L. Sherr[1], M. Gafos[2], PROUD Study Group
[1]University College London, Centre for Clinical Research, Epidemiology, Modelling and Evaluation, London, United Kingdom, [2]London School of Hygiene & Tropical Medicine, Department of Global Health and Development, London, United Kingdom, [3]University College London, MRC Clinical Trials Unit, London, United Kingdom

Background: Intimate partner violence (IPV) has been found to be associated with depression and with sexual risk behaviour linked to STI/HIV transmission in U.S. studies of gay, bisexual and other men who have sex with men (GBMSM). There is a lack of data in the UK/Europe. This study investigates the prevalence of IPV, associated factors, and relationship with depression and sexual behaviour among GBMSM enrolled in the PROUD trial evaluating pre-exposure prophylaxis (PrEP).
Methods: PROUD was an open label randomised trial (enrollment 2012-2014) evaluating the benefit of PrEP for HIV-negative GBMSM in England who reported recent condomless sex (CLS) with an expectation of subsequent CLS. This analysis included 436 GBMSM with IPV data at the 12- and/or 24-month follow-up. IPV prevalence was assessed at each time-point; associated factors and cross-sectional associations with depressive symptoms (PHQ-9≥10) and measures of CLS and sexual-partner numbers were assessed using Poisson generalized estimating equations combining time-points, adjusted for: age; UK born; sexual identity; education; clinic site.
Results: The majority of men (>70%) reported CLS with ≥2 partners in the past three months. At month-12 (N=410), 44.9% of men reported being a victim of IPV and 19.5% a perpetrator of IPV, in their lifetime. Corresponding percentages at month-24 (N=333) were 40.2% and 18.0%. Internalized homophobia and sexualized drug use were associated with IPV victimization (Table 1).

N=436 GBMSM, observations=743 (data at 12-or 24-month follow-ups in GEE models)		Association of psychosocial factors with lifetime IPV victimization (psychological, physical, and/or sexual)
Independent variables:		Prevalence Ratio [95% CI] p value by Wald test
Had sex after using recreational drugs in past three months	Unadjusted	1.36 [1.08, 1.71] p=0.013
	Adjusted for key socio-demographic factors	1.36 [1.08, 1.71] p=0.010
Age<13 years at anal sex debut	Unadjusted	1.16 [0.73, 1.86] p=0.523
	Adjusted for key socio-demographic factors	1.15 [0.72, 1.84] p=0.565
Negative attitudes towards gay sexuality (marker of internalised homophobia)	Unadjusted	1.28 [1.03, 1.59] p=0.026
	Adjusted for key socio-demographic factors	1.31 [1.05, 1.64] p=0.016
‚Out' to all/almost all friends, work colleagues and close family	Unadjusted	0.96 [0.77, 1.20] p=0.728
	Adjusted for key socio-demographic factors	0.93 [0.74, 1.17] p=0.516

[Table 1: Unadjusted and adjusted associations of psychosocial factors with lifetime IPV victimization in the PROUD trial]

Younger age and sexualized drug use were associated with IPV perpetration. IPV was strongly associated with depressive symptoms (adjusted prevalence ratio [aPR] for IPV victimization: 2.57 [95% CI: 1.71, 3.86]; p< 0.001). IPV was not consistently associated with measures of CLS/partner numbers. However, at month-12, IPV victimization was associated with receptive CLS with an HIV-positive partner not known to be on treatment (aPR 2.84 [95% CI: 1.27, 6.36]; p=0.011) and IPV perpetration was associated with group sex (aPR 1.40 [95% CI: 1.16, 1.69]; p< 0.001).
Conclusions: GBMSM at high-risk of HIV who are seeking/taking PrEP may experience a high burden of IPV, which may be linked to depressive symptoms. It is recommended that training on awareness and selective enquiry for IPV among GBMSM in sexual health clinics, should be enhanced.

TUPEC327

Poor acceptance of HIV diagnosis is a primary barrier to successful engagement in HIV medical care among vulnerable, high-risk heterosexuals in the United States

A. Kutnick, M. Gwadz, N. Leonard, C. Cleland, A. Ritchie, The BCAP Collaborative Research Team
NYU, Rory Meyers, Center for Drug Use and HIV/HCV Research, New York, United States

Background: Current World Health Organization (2015) guidelines recommend persons living with HIV/AIDS (PLHA) engage in medical care and initiate antiretroviral therapy (ART) immediately after diagnosis. However, after HIV diagnosis it is common in the United States for vulnerable (PLHA) to delay engagement in HIV medical care and ART initiation. Further, while past research has shown greater acceptance of one's HIV diagnosis, in contrast to denial or avoidance, is associated with positive HIV health outcomes, little is known about the phenomenon of "acceptance" of HIV among vulnerable PLHA and its relationship to engagement in medical care. The present study, guided by an ecological framework and Critical Race theory, uses an Interpretive Phenomenological Analysis (IPA) to address this gap.
Methods: High-risk heterosexual PLHA of color (N = 140) were recruited through peer referral in Brooklyn, NY in 2012-2015. A subset (N = 28) was purposively sampled for maximum variation for in-depth, semi-structured, qualitative interviews on psychological adaptation to HIV diagnosis and engagement in medical care. Data were analyzed using an Interpretive Phenomenological Analysis. Most participants were male (60.8%); Black (78.6%); aged 47-years (SD=7.12 years) on average; unemployed (92.9%); lacked basic necessities in the past year (75.0%); had histories of homelessness (71.4%) and incarceration (85.7%); and met criteria for lifetime problematic substance use (78.6%).
Results: Analyses revealed that acceptance was a pre-requisite to successful engagement in medical care. However, acceptance was often a lengthy (>3 years), complex and non-linear process, with many participants still struggling with acceptance of HIV status 10+ years after diagnosis. We found six inter-related factors particularly impeded acceptance of HIV status: (1) problematic substance use; (2) past history of trauma; (3) the experience of HIV as abstract in the absence of physical symptoms; (4) social isolation, which amplified feelings of HIV-stigma; (5) receiving HIV testing in settings perceived as harsh and coercive such as prison or mandated treatment; and (6) distrust of the medical establishment.
Conclusions: In light of current HIV treatment guidelines, interventions that facilitate timely acceptance of HIV diagnosis, and consequent engagement in medical care and ART initiation for vulnerable PLHA are sorely needed.

TUPEC328

Disclosure of HIV diagnosis and its relationship to successful engagement in medical care and initiation of ART in the 21st century

A. Kutnick, M. Gwadz, N. Leonard, C. Cleland, A. Ritchie, the BCAP Collaborative Research Team
NYU, Rory Meyers, Center for Drug Use and HIV/HCV Research, New York, United States

Background: To best prevent transmission of HIV and improve HIV health outcomes, it is recommended that persons living with HIV/AIDS (PLHA) both disclose their HIV status to sexual and drug-injection partners and initiate ART soon after diagnosis. However, the relationship among disclosure of HIV status and successful engagement in medical care and initiation of ART remains precarious, particularly among high-risk heterosexual populations. The present study, guided by an ecological framework, uses qualitative methodologies to address this gap.
Methods: High-risk heterosexual PLHA of color (N=140) were recruited through peer referral in NYC in 2012-2015. A subset (N=28) were purposively sampled for maximum variation, for in-depth, semi-structured, qualitative interviews on disclosure of HIV status and en-

gagement in medical care. Data were analyzed using an Interpretive Phenomenological Analysis. Most participants were male (60.8%); Black (78.6%); aged 47-years (SD=7.12 years) on average; unemployed (92.9%); lacked basic necessities in the past year (75.0%); had histories of homelessness (71.4%); incarceration (85.7%); and met criteria for lifetime problematic substance use (78.6%).
Results: Analyses revealed that engagement in HIV medical care varied greatly depending on the tenor (positive or negative) of the disclosure experience. Negative disclosure experiences were common and impeded engagement in medical care and ART initiation, mainly by leading to feelings of shame and alienation that exacerbated avoidance of HIV care. Disclosure to sexual partners emerged as particularly challenging because feelings of betrayal, guilt, and fear of loss of one's intimate relationships often arose. However, we found six inter-related factors facilitated positive disclosure experiences: (1) engagement in substance use treatment; (2) engagement in mental health care; (3) social support from friends and family; (4) positive, long-term relationships with health-care providers; (5) positive experiences with ART (i.e. minimal side-effects and achieving HIV viral suppression); and (6) acceptance of HIV diagnosis, that is the acknowledgement to oneself that one is indeed infected with HIV, in contrast to denial and avoidance, often a lengthy and complex process.
Conclusions: Disclosure of HIV status after diagnosis is challenging and can complicate successful engagement in medical care and ART initiation. However, effective interventions that facilitate positive disclosure experiences exist and should be implemented soon after diagnosis.

Modelling future healthcare needs

TUPEC329

Outcomes of South African mothers living with HIV (MLH) and their children compared to neighborhood peer mothers without HIV (MWOH) and their children over five years

M.J. Rotheram-Borus[1], M. Tomlinson[2], I. le Roux[2], T. Weichle[1], J. Stewart[2], S. Gordon[2], C. Lin[3]
[1]University of California, Department of Psychiatry and Biobehavioral Sciences, Semel Institute, Los Angeles, United States, [2]Stellenbosch University, Department of Psychology, Stellenbosch, South Africa, [3]University of California, Department of Psychiatry and Biobehavioral Sciences, Los Angeles, United States

Background: Recent research examining the children of mothers living with HIV (CMLH) have had conflicting results. Many studies are limited to clinic-based samples in which about one quarter of CMLH are lost within a year.
This study compares outcomes for CMLH and children of mothers without HIV (CMWOH) in multiple domains - physical growth, behavioral adjustment, and cognition - over the first five years of life.
Methods: Almost all (98%) pregnant women in 12 Cape Town neighborhoods (N=594) were recruited in pregnancy and reassessed five times over five years with high retention (83% - 92%); 205 were MLH and 389 were mothers without HIV (MWOH). Comprehensive evaluations of MLH and CMLH were compared over time to MWOH and CMWOH in the same neighborhoods, recruited concurrently. Growth was charted as the World Health Organization Z scores for weight and height; behavior was assessed with the Achenbach Child Behavior Checklist and the Strengths and Difficulties Questionnaire at 36 and 60 months; cognition was assessed with the Bayley Scales at 18 months; Peabody Picture Vocabulary at 36 months; the Kaufman Scales of Mental Development at 60 months and Blair Measures of executive functioning at 36 and 60 months.
Results: CMLH were similar in health care utilization over five years, reflected in the number of hospitalizations and clinic visits; rates of immunizations and influenza were similar over time. Weight-for-age Z scores were significantly lower, but not in the malnourished range, and children were similar in height and stunting. Developmental milestones were similar, as was behavioral adjustment across CMLH and CMWOH. Cognition was similar on the Bayley Scales, and the Peabody Picture Vocabulary Tests, but the Kaufman Scale was significantly lower by about 3 IQ points at five years (p< .05).
Conclusions: CMLH and CMWOH were similar on most outcomes. Children's lower weight and the cognitive scores at five years suggest there may be small cumulative deficits accruing over time. These differences are likely attributable to social factors related to HIV (maternal alcohol abuse or depression, less income, single parenthood), rather than HIV exposure in-utero.

TUPEC330

Quantifying the impact of reduced investments in integrated HIV care delivery in Belgium

S. Vermeersch[1], R. Demeester[2], S. Callens[3], S. De Wit[4], L. Annemans[5], BREACH Consortium
[1]Hict NV, Bruges, Belgium, [2]University Hospital of Charleroi, Internal Medicine and Infectious Diseases, Charleroi, Belgium, [3]Ghent University Hospital, Internal Medicine and Infectious Diseases, Ghent, Belgium, [4]University Hospital St Pierre, Infectious Diseases, Brussels, Belgium, [5]Ghent University, Public Health, Ghent, Belgium

Background: In Belgium, AIDS Reference Centers (ARC) deliver patient-centered, integrated HIV care, leveraging state of the art knowledge and expertise to provide multidisciplinary patient management. We developed an integrated value-centered framework to help drive value-driven financing approaches. The quantification of ARC value drivers is a key framework component. The present study quantifies the impact of disinvestments in ARC.
Methods: We leveraged the published BELHIVPREV model to assess the health and budget impact and return on investment (ROI) in ARC for 5 key value drivers: (i) preventing new infections; (ii) reducing the number of undiagnosed patients; (iii) linkage to and (iv) retention in care and (v) achieving and maintaining virologic control. We simulated 4 scenarios for 2020, which were further extrapolated to 2030 (Table 1). The model scenarios were based on hypothetical, yet realistic, expert estimated parameter settings. Cumulative costs were generated from 2015 to 2030 and assumed an additional 3M€/year investment (+60% of total Belgian ARC costs) in the 'additional effort' scenario and a 2,2M€/year disinvestment (-43% of total Belgian ARC costs) in the 'reduced effort' scenario. For the 'additional' and 'reduced' effort scenarios the ROI was calculated as the ratio of (cumulative budget impact - cumulative investment cost) over (cumulative investment cost).
Results: Table 1 summarizes estimated number of new diagnoses and total annual (pharmaceutical) budget for 2020 and 2030 for the 4 different scenarios. ROI for the 'additional' and 'reduced' effort scenarios were 2,4 and -4,0, respectively; i.e. every € invested in ARC between 2015 and 2030 results in 2,4€ additionally saved by 2030, whereas every € disinvested results in an additional 4,0€ loss to society.

	Current effort	Reduced effort	Additional effort	Additional effort + reinforced outreach
Undiagnosed	11%	12%	10%	8%
Treated	94%	92%	97%	97%
Viral load < 200 c/ml	98%	94%	98%	98%
Linked in care	98,2%	95%	99%	99%
Retained in care	97,9%	97%	99%	99%
PrEP (patients)	1 500	1 000	2 633	2 633
New diagnoses **2020** (patients)	899	1 121	603	513
New diagnoses **2030** (patients)	1 165	1 985	410	319
Annual budget **2020** (euro)	203 M€	202 M€	207 M€	209 M€
Annual budget **2030** (euro)	254 M€	296 M€	211 M€	204 M€

[Table 1]

Conclusions: Assuming reductions in ARC budgets translate to reduced effort on the 5 value drivers included in our analysis. Budget reductions have significant and lasting negative impact on the epidemic and estimated (pharmaceutical) budgets. Likewise, investments in ARC budgets, if translated to increased effort, result in significant and lasting positive epidemic and budget impact. In both cases, costs offsets generated early on (2015-2020) are largely compensated in later years (2020-2030). Investing in integrated care remains critical in managing HIV disease and budget impact.

TUPEC331

Estimating latent tuberculosis infection prevalence in the United States: Back-calculation from active TB cases

A. Mirzazadeh[1], I.E. Fellows[2], A. Parriott[3], H. Ashki[3], A. Readhead[4], P. Barry[4], J. Flood[4], T.R. Navin[5], A.N. Hill[5], S. Reynolds[5], S. Marks[5], D. McCabe[3], J. Mermin[6], J.G. Kahn[3], P.B. Shete[7]
[1]Institute of Global Health Sciences, University of California (UCSF), Epidemiology & Biostatistics, San Francisco, United States, [2]Fellows Statistics, San Diego, United States, [3]Philip R Lee Institute for Health Policy Studies, University of California (UCSF), San Francisco, United States, [4]Tuberculosis Control Branch, Division of Communicable Disease Control, Center for Infectious Diseases, California Department of Public Health, Richmond, United States, [5]Division of Tuberculosis Elimination, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, U.S. Centers for Disease Control and Prevention (CDC), Atlanta, United States, [6]National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, CDC, Atlanta, United States, [7]Division of Pulmonary and Critical Care, UCSF and Zuckerberg San Francisco General Hospital, San Francisco, United States

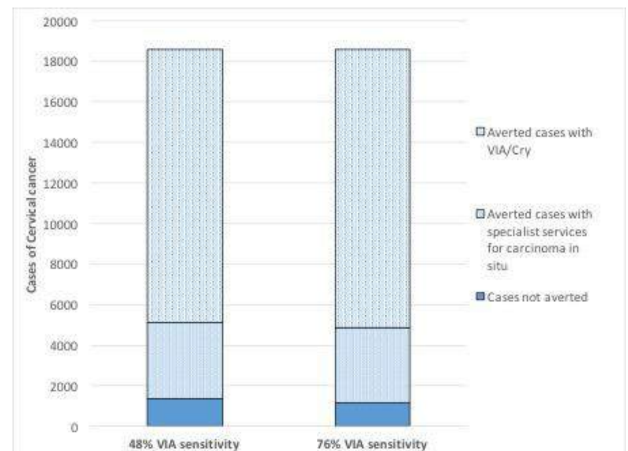
Background: Identification and treatment of latent tuberculosis infection (LTBI) is a critical component of the United States national plan for tuberculosis disease (TB) elimination. However, estimating LTBI prevalence has been challenging. In this study, we present a back-calculation model based on reported active TB disease to estimate the prevalence of LTBI within the United States (U.S.), California, and five counties in California with the highest burden of TB.
Methods: Our model incorporates annual TB cases (1993 to 2016) reported to CDC and annual mortality-adjusted reactivation risks for 85 years following infection to "back-calculate" LTBI prevalence. We used Markov Chain Monte Carlo to calibrate an exponential decay curve fit to surveillance data to estimate reactivation risks, then adjusted the reactivation risks for all-cause mortality risks. Calculations were done using a back-calculation package in R software after accounting for the long lag between LTBI and active disease, and general all-cause mortality as a competing risk. We produced uncertainty limits (UL) using lower and upper bounds for reactivation risks and the LTBI prevalence.
Results: The mortality-adjusted reactivation risk in the first year following infection was 1.42% (UL 1.40 to 1.43), and the lifetime cumulative risk for 85 years was 7.12% (UL 4.70 to 9.54). The back-calculation estimates suggest that 2.36% (UL 1.61 to 4.09) of U.S. population in 2016 were living with LTBI (corresponds to 7.65 million (UL 5.22 to 13.25)]. Estimated LTBI prevalence in 2016 was 4.07% (UL 2.71 to 7.23) in California, 5.29% (UL 3.80 to 8.18) in Alameda County, 5.51% (UL 3.50 to 10.23) in Los Angeles County, 4.13% (UL 2.72 to 7.38) in Orange County, 4.79% (UL 3.22 to 8.28) in San Diego County, and 5.60% (UL 3.97 to 8.81) in Santa Clara County.
Conclusions: Our LTBI prevalence estimates are similar with previous estimates from the 2011-2012 National Health and Nutrition Examination Survey (NHANES) for the U.S. (2.1%) when TST & IGRA combined positivity was used to define the LTBI infection, and in range with NHANES estimates extrapolated to state and county demographics for California (5.99%), and the five counties (5.18%-8.20%). Our model can be used at national, state, and county levels to estimate LTBI.

TUPEC332

Epidemiological benefits of integrating services for the secondary prevention of cervical cancer into HIV care in Kenya: A mathematical modelling study

P.N. Perez Guzman, R. Cassidy, T. Hallett, M. Smit
Imperial College, London, Department of Infectious Disease Epidemiology, London, United Kingdom

Background: Practice guidelines in Kenya recommend secondary prevention of cervical cancer (CC) through a 'screen-and-treat' approach for pre-cancerous lesions of the cervix. The Ministry of Health recognises HIV care as one of the most effective platforms for integrating such services. However, CC screening coverage remains low, at an estimated 3.2% country-wide. We aim to quantify the impact of fully implementing guideline recommendations on CC incidence amongst HIV-positive women in care (HIV-WiC).
Methods: We developed an individual-based multi-disease model of the HIV and HPV epidemics in Kenya. The model was parameterised with and fitted to national and regional surveillance and epidemiological data (Figure 1A). We compared projections of the *status quo* levels of HPV screening to a scenario of 100% coverage of HIV-WiC with visual inspection which acetic acid (VIA) and, if indicated, treatment of pre-cancerous lesions (cervical intraepithelial neoplasia 1 to 3) with cryotherapy (Cry). We assumed VIA sensitivity to range from 48% to 76% and Cry success rates of 87.5% based on literature. Screening intervals were 6-monthly, for the first year, followed by annual, as per national guidelines.
Results: Our model predicts a baseline of 18,600 CC cases (18,078-19,123) between 2018 and 2035 amongst HIV-WiC, with an incidence of 215.35 (208.96-221.76) per 100,000 person-years (py). Integrating screen-and-treat services with VIA/Cry in this population could avert 72% to 74% of cases (13,480-13,700) and reduce CC incidence to 56 to 58 per 100,000py (48-69), depending on VIA sensitivity (Figure 1). Widespread availability of specialised services for the treatment of carcinoma *in situ* could further avert up to 20% of pre-invasive cancer cases, potentially driving CC incidence down to 38 per 100,000py.
Conclusions: In the absence of effective secondary prevention programs, HIV-WiC are at an increased risk of CC than HIV-negative populations. Our modelled projections are in agreement with this. Despite variability in VIA performance, scaling-up VIA/Cry in HIV-WiC in Kenya could forestall a large proportion of HPV-related morbidity.



[Figure 1 - Modelled cervical cancer incidence rate in HIV-WiC from 2018 to 2035, with varying levels of VIA sensitivity from pre-cancerous lesions (ce]

TUPEC333

Characterizing the need for integrated chronic disease healthcare for people living with HIV

B. Osetinsky[1], A. Mwangi[2], E. Sang[3], G. Bloomfield[4], S. Pastakia[5], R. Wamai[6], S. de Vlas[7], J. Hontelez[7], J. Hogan[1], S. McGarvey[1], M. Lurie[1], O. Galarraga[1]
[1]Brown University School of Public Health, Providence, United States, [2]Moi University, Eldoret, Kenya, [3]Academic Model for Providing Access to Healthcare, Eldoret, Kenya, [4]Duke University, Durham, United States, [5]Purdue University, West Lafayette, United States, [6]Northeastern University, Boston, United States, [7]Erasmus MC, Rotterdam, Netherlands

Background: Non-communicable diseases (NCDs) are a significant and growing source of morbidity and mortality among HIV positive people in sub-Saharan Africa. In Kenya, pilot integrated care programs providing services for both HIV and chronic NCDs such as hypertension and diabetes are emerging in some counties, but there is little information about the growth of overlapping conditions at the clinical and population level to provide a basis to assess healthcare needs. The research described within this abstract generates foundational knowledge of potential demand for integrated care in two ways; by assessing development of hypertension among a longitudinal clinical cohort of people living with HIV, and modeling the dual burden of NCD and HIV at the population level.

Methods: The clinical cohort is from longitudinal retrospective clinical data from the Academic Model of Providing Access to Healthcare (AMPATH). The AMPATH patient population included in the analysis was 92,588 HIV-positive adults enrolled in care from 2005-2011. We used multilevel modeling to analyze the change in prevalence of hypertension in the HIV-positive clinical population. To model the spread and control of HIV, we adapted an established microsimulation, STDSIM, to include the disease progression for hypertension, and project trends in HIV and hypertension at the population level in Kenya from 2004 to 2020. The calibration samples for the model are from nationally-representative surveillance surveys and reports of HIV and of NCDs in Kenya of adults ages 18-70.
Results: The hypertension prevalence of the AMPATH HIV positive clinical population grew from 6.5% in 2006 to 10.7% in 2011. When adjusting for age, clinic, WHO stage, and antiretroviral therapy, there is an 3% annual increase in the prevalence of hypertension from 2005 to 2011. The nationally representative model was calibrated to fit Kenya's national estimates of 31% prevalence of hypertension, and 6.2% HIV in 2015. Our model estimated national prevalence of both comorbidities at 2.2% for adults over age 18.
Conclusions: The dual burden of hypertension and HIV is a significant source of morbidity in Kenya. Both HIV positive clinical populations data and the national modeling show an increase in HIV and hypertension as comorbidities as hypertension prevalence increases.

Identifying optimal service models

TUPEC334

Prevalence and predictors of viral suppression among people living with HIV in British Columbia, Canada: Findings from the SHAPE study

A. Bever[1], K. Salters[1], L. Ti[1,2], S. Parashar[1,3], C. Olatunbosun[1,4], G. McGowan[1,5], R. Hogg[1,3], R. Barrios[1], SHAPE Study
[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of British Columbia, Vancouver, Canada, [3]Simon Fraser University, Burnaby, Canada, [4]St. Paul's Hospital Ambulatory Pharmacy, Vancouver, Canada, [5]Ministry of Health, Victoria, Canada

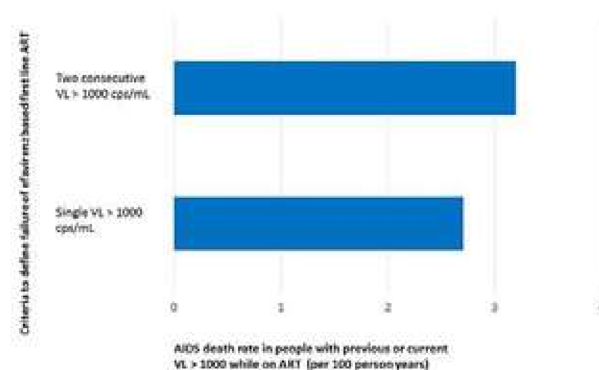
Background: The STOP HIV/AIDS Program aims to improve treatment success among people living with HIV (PLWH) in British Columbia (BC), Canada by expanding access to HIV testing, antiretroviral therapy, and supportive HIV care. The STOP HIV/AIDS Evaluation (SHAPE) study was developed to assess the program's impact, highlight health disparities, and identify barriers to HIV care that disproportionately affect marginalized populations.
This analysis documents the prevalence and examines predictors of viral load suppression (VLS), the final clinical marker of the HIV cascade of care and an important indicator of treatment success.
Methods: The SHAPE study is a longitudinal cohort of PLWH ≥ 19 years of age in BC, initiated in 2016, with clinical follow-up ongoing. Recruitment targets for particular socio-demographic and clinical characteristics were established with the aim of building a cohort that is representative of PLWH in BC. For this analysis, bivariable and multivariable logistic regression models were used to identify predictors of VLS (defined as viral load < 50 copies/mL for ≥ 3 months in the year prior to interview).
Results: Of the 503 participants who completed a baseline survey, 477 met the inclusion criteria (≥ 3 months of VL data available) and 408 (85.5%) achieved VS. In multivariable analyses, being older (>39 years) was positively associated with achieving VLS [ages 40-49: adjusted odds ratio [OR]= 2.11 (95% CI= 1.03, 4.31); ages ³50: aOR=2.45 (95% CI=1.27, 4.72)]. Those who were currently homeless (aOR= 0.21, 95%CI= 0.07, 0.62) or homeless within the last 12 months (aOR= 0.65, 95%CI= 0.30, 1.40) were less likely to achieve VLS. PLWH self-reporting injection drug use (IDU) (aOR= 0.24, 95%CI= 0.12, 0.47), men who have sex with men (MSM) reporting IDU (aOR= 0.24, 95%CI= 0.09, 0.64) and other HIV transmission groups (aOR= 0.49, 95%CI= 0.23, 1.02) were less likely to achieve VLS compared to MSM only.
Conclusions: Strategies for supporting individuals in HIV care must account for intersecting facets of marginalization that influence progression through the cascade of care. Targeted supports may help reduce health inequities experienced by individuals with a history of IDU, younger adults, and those facing housing instability.

TUPEC335

Simplifying switch to second line ART: Predicted effect of a policy of defining 1st line failure of efavirenz-based regimens by a single VL > 1000 in sub-Saharan Africa

A. Shroufi[1], V. Cambiano[2], L. Bansi-Matharu[3], G. Van Cutsem[1], D. Maman[1], A. Phillips[3]
[1]Medecins Sans Frontieres, Medical, Cape Town, South Africa, [2]University College London, HIV Epidemiology and Biostatistics Group, London, United Kingdom, [3]University College London, Faculty of Pop Health Sciences, London, United Kingdom

Background: Many individuals failing first line Antiretroviral Therapy (ART) never receive second line ART, or do so after long delays. For people on ART with a viral load (VL) > 1000 cps/ml WHO recommends VL measurement 3 months after enhanced adherence support, with switch to a 2nd line regimen occurring if VL elevation persists. The need for a confirmatory VL prior to switching to a 2nd line regimen may delay or prevent switching. Here we use an established individual-based model of HIV transmission, progression and the effect of ART which incorporates drug resistance in order to consider this question.
Methods: Using this mathematical model, we compare the effect of a policy requiring one VL > 1000 copies/ml for people failing efavirenz-based regimens to be switched to second line, with one requiring two consecutive values > 1000 cps/ml. We simulated a range of setting-scenarios reflecting the breadth of the epidemic seen in sub-Saharan Africa; taking into account potential delays in defining failure and switching to 2nd line regimens.
Results: The generated setting scenarios had in 2018 19% (13% - 33%) of people on ART with an NNRTI mutation and 88% (77% - 93%) with viral load < 1000 copies/ml. Among those having experienced a VL>1000 copies/ml on ART, using a single VL > 1000 to define failure of efavirenz-based 1st line regimens would lead to a higher proportion of people with NNRTI resistance having been switched to a second line regimen (62% vs 43%; difference 19% (16% - 22%)), resulting in a median (over setting scenarios) 20% reduction in the rate of AIDS death (90% range 2% - 32%; from a median of 3.2 to 2.7 per 100 person years) over 3 years from 2018.
Conclusions: Relaxation of the requirement for two consecutive VL values > 1000 to define 1st line failure of efavirenz-based regimens should be considered.



[Figure 1: AIDS death rate in people with previous or current VL > 1000 while on ART according to criteria to define failure of first line ART.]

TUPEC336

HIV disclosure to partners among pregnant women receiving HIV care in Kenya

D. Matemo[1], L. Osborn[1], K. Ronen[2], J. Unger[2], A.L. Drake[2], G. John-Stewart[2], J. Kinuthia[1]
[1]*Kenyatta National Hospital, Research and Programs, Nairobi, Kenya,* [2]*University of Washington, Global Health, Seattle, United States*

Background: HIV status disclosure by pregnant women to their sexual partner enables partner testing and linkage to care, and can facilitate maternal ART adherence and prevention of mother-to-child HIV transmission. Understanding factors associated with disclosure to partners is critical for developing interventions to expand HIV testing and linkage to care.

Methods: This analysis utilized enrollment data from an ongoing trial evaluating mHealth strategies to improve ART adherence among women living with HIV in Nyanza Region and Nairobi, Kenya (Mobile WAChX, NCT02400671). Women were eligible to participate if they were pregnant, HIV-infected, and had daily access to a mobile phone. A structured questionnaire evaluated disclosure to partner, sociodemographic characteristics, self-reported ART adherence information-motivation-behavior skills (modified Lifewindows IMB, 75 point score), depression (PHQ9) and social support (MOS, 72 point score). Plasma samples were collected for viral load (VL) measurement. Univariate logistic regression was used to evaluate associations with partner disclosure.

Results: :Among 825 participants enrolled, 768 (93%) reported current sexual partners and 570 (74%) of these had disclosed their HIV status to their partner. Participants had a median age 27 years (IQR 23-31) and 84% (695) were cohabiting/married. Median social support score was 63 (IQR 50-72). Median ART adherence IMB score was 58 (IQR 55-62). HIV status disclosure was associated with older participant age (OR 1.06 per year, 95% CI: 1.03-1.09), facility delivery (OR 1.52, 95% CI: 1.01-2.27), duration of current relationship (OR 1.15 per year increase, 95% CI: 1.10-1.20) and co-habitation with partner (OR 4.43, 95% CI: 2.89-6.80). Disclosure was also positively associated with social support score (OR 1.01 per point, 95% CI: 1.00-1.02), IMB score (OR 1.05 per point, 95% CI: 1.00-1.08), and negatively associated with stigma (OR 0.90, 95% CI: 0.83-0.99).

Conclusions: Disclosure among pregnant women on lifelong ART was associated with a number of positive outcomes such as information, motivation and behavioral skills for ART adherence, social support and lower stigma. Relationships between these factors are complex. Women who do not or cannot disclose likely require enhanced support for ART adherence.

TUPEC337

Nigeria needs to prioritize cost effective HIV Testing Services (HTS) strategy and approach to achieve the UNAIDS 90: 90: 90 targets

G.S. Okorie[1], E. Ikomi[2], E. Agogo[1], I. Idika-Chima[3]
[1]*National Agency for the Control of HIV/AID, Program Coordination, Abuja, Nigeria,* [2]*National Agency for the Control of HIV/AID, Policy and Strategy Department, Abuja, Nigeria,* [3]*Teenz Global Foundation, Program Coordination, Abuja, Nigeria*

Background: It is estimated that over 3 million Nigerians are living with HIV. However, only 983,980 are currently on treatment with the implementation of the test and treat strategy. This demonstrates a 65% gap in treatment. The National Agency for the Control of AIDS (NACA) in its co-ordination role provides policy direction in the design and implementation of all HIV activities in Nigerian. After the adoption of UNAIDS targets by the Federal Government, NACA commissioned and monitored the implantation of five (5) HTS approaches. The aim was to present a policy direction regarding HTS strategy and approach that is evidence-based, cost effective, with local content that would fast track the achievement of the set targets.

Description: NGOs provided HTS at 34 locations across Nigeria. The five approaches include; door-to-door; Multi-disease Campaign; Key Population focused; Junction town; In- school. Rapid test kits were used in all the approaches. The different sites were selected based on pre-determined criteria in a developed framework. The project was completed within 4 months. The programmatic data collected from different approaches were validated by the national monitoring and evaluation systems and is reported as part of national dataset for 2015/16. The amount disbursed for implementation was collected from the accounts department of NACA.

Lessons learned: Females constituted 55% of 204,169 clients reached. The door-to-door, Junction town and in school interventions reached more males. The incidence ranged from 0.3% to 18% with clear evidence of more female (0.75%) infection (F: 1,523: M: 494). The costs per client reached were door-to-door $ 3.88; Multi-disease Campaign $ 19.98; key population focused $76.16; Junction town $17.52: In school $ 3.60. Although the focused approach identified more HIV positives, coverage is low. To achieve the set targets, mapping and remodel of approach to reach more people who are living with HIV at less cost is required. Strategic change in strategy to ensure availability of test kits and mitigation of stigma is required.

Conclusions/Next steps: Rebasing of Nigerian HIV prevalence through population survey is required (programmatic results 0.98%, current 3%). Review of HTS algorithm, framework and test run blend of strategy/ies that will improve yield and coverage is essential.

TUPEC338

Identifying components of service delivery and HIV care cascade outcomes: A systematic review of Methadone Maintenance Treatment (MMT)

N.A. Mohd Salleh[1,2], P. Voon[1], M. Karamouzian[1], J. Shoveller[3], E. Wood[1], M.J. Milloy[1,4], L. Richardson[1,5]
[1]*British Columbia Centre on Substance Use, Vancouver, Canada,* [2]*University of British Columbia, Interdisciplinary Studies Graduate Program, Vancouver, Canada,* [3]*University of British Columbia, School of Population and Public Health, Vancouver, Canada,* [4]*University of British Columbia, Department of Medicine, Vancouver, Canada,* [5]*University of British Columbia, Department of Sociology, Vancouver, Canada*

Background: The link between methadone maintenance therapy (MMT) and HIV treatment-related outcomes has been extensively described. Nevertheless, HIV-positive people who use illicit drugs (PWUD) continue to demonstrate poor HIV care cascade outcomes, posing a serious challenge to achieving the UNAIDS 90-90-90 goals. In this review, we aim to assess components of service delivery in optimizing the use of MMT that lead to improvements in the three main stages of the HIV care cascade.

Methods: We searched multiple database platforms for studies that described components of service delivery in conjunction with the provision of methadone in the last 10 years. Outcomes of interest were improved uptake of HIV testing, exposure to ART including initiation and adherence, as well as viral load suppression. Records were screened by title and abstracts independently by two reviewers.

Results: We identified 2186 records after removing duplicates. Title and abstract screening has yielded 438 records which were retrieved as full texts. From this, 18 studies were eligible for this systematic review. Components of service delivery that accommodate MMT provision that improve HIV care cascade outcomes include:
1) routine practices adopted by service providers (admission procedures, physical examinations, co-morbidity screening, referrals to HIV care),
2) strategies to mitigate the impact of stigma associated with HIV testing (voluntary rather than mandatory, self-testing),
3) medication dispensing strategies (directly administered antiretroviral therapy),
4) medication-related factors (simple regimen tablet, adequate methadone doses),
5) clinical management of co-morbidities (HIV care, mental health, hepatitis C and tuberculosis),
6) incorporation of needle and syringe exchange program and
7) social support (case management, counselling sessions to address social issues, counselling on ART and MMT and contingency management).

Conclusions: Evidence in this review has largely pointed out the evidence of a multidisciplinary team to manage comorbidities and strategies to effectively deliver medication to PWUD. There has been an in-

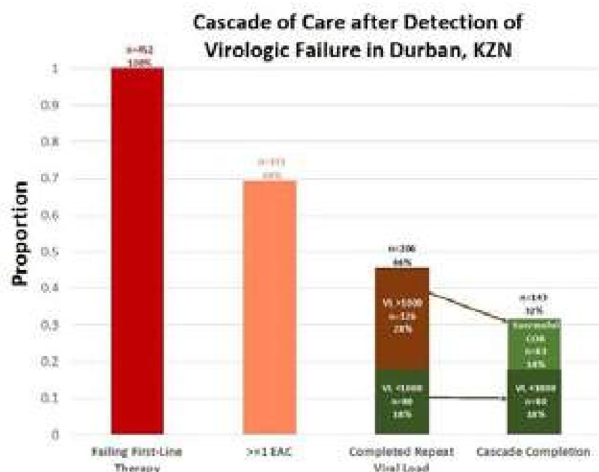
crease in global interest to provide patient-centered services, such that care and treatment would address a wide range of issues affecting this population. However, more work needs to be done to increase the effectiveness of MMT in enhancing HIV-related outcomes among PWUD, especially in determining which areas of social support require further attention.

TUPEC339

The second cascade in the management of adult patients after first line ART failure in public HIV clinics in Durban, South Africa

H. Sunpath[1,2], K. Naidu[3], S. Pillay[1], M.Y.S. Moosa[1], P. Dladla-Msimango[4], V. Marconi[5], K. Naidoo[2], M. Seidner[6,7], D.J. Brijkumar[8]
[1]University of KwaZulu-Natal, Infectious Diseases Unit, School of Clinical Medicine, Nelson Mandela School of Medicine, Durban, South Africa, [2]University of Kwa Zulu-Natal, Centre for AIDS Program of Research In South Africa, Durban, South Africa, [3]MatCH (Maternal, Adolescent and Child Health), School of Public Health, University of the Witwatersrand, MatCH (Maternal, Adolescent and Child Health), Durban, South Africa, [4]Department of Health, Ethekwini Health District, Durban, South Africa, [5]Emory University School of Medicine, Division of Infectious Diseases, Atlanta, United States, [6]Harvard Medical School, Infectious Diseases Unit, Massachusetts General Hospital, Boston, United States, [7]University of KwaZulu-Natal, Africa Health Research Institute, Durban, South Africa, [8]University of KwaZulu-Natal, Infectious Diseases, Durban, South Africa

Background: The identification of patients experiencing first-line ART failure has increased rapidly and will continue to grow as access to viral load (VL) testing improves. At detection of virology failure (VF), most national treatment programs recommend a 3-6 month monitoring period for multiple adherence counseling visits, repeat VL testing, test result dissemination, assesment of comorbidities and regimen decision making. These recommendations create complexities in scheduling and patient follow-up putting those failing therapy at risk for persistent failure and transmission of potentially resistant virus. We sought to evaluate the cascade of care after first-line ART failure in three public clinics in Durban, South Africa.
Description: We conducted a retrospective chart review of patients who had a VL >1000 copies/mL between 01 March and 30 June 2016 and abstracted clinical data from three public clinics. We estimated the proportion of patients failing first-line ART who completed each stage of the care cascade including:
1) completion of at least one adherence counseling visit;
2) repeat viral load testing; and
3) return for results with appropriate maintenance on first-line ART or changes to regimen (COR) for second-line ART.



[Figure 1]

Lessons learned: Among 9782 patients accessing first line ART in these facilities total of 452 individuals were identified as having VF during the three-month period of observation. Of these, 70% (313/452) returned for at least one adherence counseling visit, and 46% (206/452) received a repeat VL test. Of those with a repeat VL, 39% (80/206) re-suppressed their virus to < 1000 and remained on first-line therapy, and of the remaining 126 patients, 50% (63/126) were appropriately switched to a second line regimen. In total, only 32% (143/452) of patients in the sample completed the cascade of VF care; and only 27% (117/452) and 8% (35/452) did so within 180 and 90-days, respectively. (Figure 1)
Conclusions/Next steps: We identified significant delays and management bottlenecks for a majority of patients experiencing VF on first-line ART in South Africa. As access to VL monitoring improves, efforts to strengthen care for this patient population must be prioritized to maintain individual and population-level treatment and prevention goals.

Social and behavioural concepts and theories

TUPED340

Alcohol community's intervention for prevention of HIV risk amongst youth in Pretoria

M.R. Manganye
Sefako Makgatho Health Sciences University, Public Health, Pretoria, South Africa

Background: This study was a randomised, controlled trial to assess the efficacy of a Social Cognitive Theory-based intervention in reducing alcohol-related sexual behaviour among young adults in Mamelodi, Pretoria.
Methods: The individual level randomization was carried out. Simple randomization was applied to the participants into the intervention or control arm. The duration of the study was 12 months with data collected at recruitment, screening, baseline, 3 months and 6 months follow-up.
Results: There was a significant reduction in engagement with multiple sexual partners in intervention group with only 5% reporting having multiple sexual partners, compared with 31% in control group, at month 6 follow-up. On condom use, there was a significant reduction in proportion of the participants in the intervention group (2%) who never used a condom, as against in the control group (41%), at the month 6 follow-up. There was a statistically significant decrease on the proportions of unprotected sex in exchange for money or material things in both the intervention group (from a 12% baseline; 12% month 3, to 8% month 6 follow-up) and the control group (from an 18% baseline; 40% month 3, to 10% month 6 follow-up). The results showed that there was a reduction in alcohol consumption from the baseline through to the month 6 follow-up. However, the difference in alcohol reduction was not statistically significant between the intervention and control groups. Interestingly, a high proportion of the participants moved from gross alcohol consumption to moderate drinking (15 - 21 Units), sensible drinking (08 - 14 Units) and infrequent drinking (0 - 7 Units).
Conclusions: The study findings conclude that Social Cognitive Theory through CLEAR intervention increases the propensity of young adults to reduce alcohol-related HIV-risk behaviour especially in relation to reducing multiple sexual partnerships, transactional sex, and increasing condom use. This propensity is attributable to the application of CLEAR led to the reduction of risk behaviours.

TUPED341

Mediation analysis among peer norms, self-efficacy, and condom use among Chinese men who have sex with men: A parallel process latent growth curve modeling

H. Li[1], J. Tucker[2], C. Wei[3], W. Ma[1], J. Wang[4], G. Marley[1], D. Kang[5], M. Liao[5], W. Tang[2], B. Jiang[1]
[1]Shandong University, Jinan, China, [2]UNC Chapel Hill, UNC Project-China, Guangzhou, China, [3]Rutgers University, New Jersey, United States, [4]George Washington University, Washington, DC, United States, [5]Shandong CDC, Jinan, China

Background: Although norm and self-efficacy are two important constructs in health behavior theories, critical thinking and empirical examinations about the relationship among these two variables are still limited in the literature. The constructs of norm and self-efficacy that apply in one context may not necessarily be applicable in another. This study aims to examine direct and indirect relationships among peer norms, self-efficacy, and condom use among Chinese men who have sex with men (MSM).
Methods: A condom use video promotion campaign with a longitudinal research design, including a baseline survey and two follow-ups, were conducted among online MSM in China in 2015. Given the fact that the content of the video were about sexual activities and condom promotion between men, 804 Chinese MSM who reported having sex with men in the last three months were recruited. Parallel process latent growth curve modeling and mediation analysis were conducted using Mplus 7.4.
Results: Among the 804 MSM, the mean age was 24.9 ±6.5; 58.3% were ≤ 24 years of age; 10.8% were currently married to a woman or engaged; 67.8% had a college diploma or higher level of education; 82% had an annual income less than 9678 USD (60000 RMB).The proposed mediation relationship was examined by correlation analysis and parallel process latent growth curve modeling with a good fit index: RMSEA = 0.043, 90% CI (0.040, 0.045), CFI = 0.968, TLI = 0.968. The initial factor of peer norms was indirectly associated with the initial factor of condom use via the initial factor of self-efficacy (0.40, $p < 0.001$). Also, the growth factor of peer norms was indirectly associated with the growth factor of condom use via the growth factor of self-efficacy (0.331, $p < 0.001$). The model explained 76.7%, 69.7%, and 62.1% of the variances in condom use at the three time points respectively.
Conclusions: Self-efficacy mediated the association between peer norms and condom use. The study has moved the theories forward, indicating a strong potential of casual relationship between norms and self-efficacy among Chinese MSM, thereby justifying the equal importance of enhancing norms and self-efficacy in health behavior promotion in a Chinese cultural context.

TUPED342

Developing a typology of HIV/STI testing patterns and associated motivators: A framework to guide interventions among men who have sex with men

R.K.J. Tan[1], N. Kaur[2], C.S. Wong[2], M.I.-C. Chen[1,2]
[1]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [2]Tan Tock Seng Hospital, Institute of Infectious Diseases and Epidemiology, Singapore, Singapore

Background: Men who have sex with men (MSM) in Singapore are disproportionately represented in prevalent HIV infections, relative to the general population. Notably, voluntary HIV/STI testing rates have remained suboptimal among MSM. While existing research has sought to identify the factors associated with testing behaviors among MSM, few studies have attempted to delineate the mechanisms that underlie different patterns of HIV/STI testing. This study proposes a typology of HIV/STI testing patterns and their associated motivators among MSM.
Methods: We conducted 21 semi-structured in-depth interviews with a purposively recruited sample of self-identified MSM in Singapore. Maximum variation sampling was employed to ensure a diversity of responses from MSM of varying age, socioeconomic status, ethnicity, and HIV/STI status. Topics explored included formative sexual experiences, relationships with other men, experiences of HIV/STI testing, and lived experiences of HIV/STI diagnosis and acquisition. Interviews were audio-recorded, transcribed, coded, and analyzed through an inductive analytical approach.
Results: A typology comprising four distinct HIV/STI testing patterns emerged from the data. Testing patterns are categorized based on the regularity of testing, relative to intrinsic or extrinsic factors that motivate testing behaviors. These include
1) triggered episodic testing, where testing is triggered by a psychological response to HIV/STI symptoms, or as a means to assuage one's own paranoia, fear or other negative emotions that arise from discrete HIV/STI risk events;
2) cued episodic testing, where testing is episodic and influenced by the presence of prompts and cues from friends, community organizations, or sexual health promotion messaging;
3) mandated regular testing, where testing is mandated or directed by healthcare institutions or by employer or government-mandated health screening; and
4) value-based regular testing, where testing is motivated by the value placed by participants on the importance of regular testing, typically driven by engaging in peer support groups, volunteering, or working in the context of sexual health-seeking and promotion.
Conclusions: Participants illustrate the ability to switch between types of testing patterns based on their existing psychosocial and contextual resources. The proposed typology provides policymakers a framework to guide sexual health promotion and behavioural interventions that seek to influence testing patterns among MSM.

		Motivating Factors	
		Intrinsic	Extrinsic
Regularity of Testing	Episodic	**Triggered Episodic Testing** Triggered by a psychological response to manifestations of HIV/STI symptoms, and to assuage paranoia, fear or other negative emotions.	**Cued Episodic Testing** Influenced by the presence of prompts and cues from friends, community organizations, or sexual health promotion messaging.
	Regular	**Value-Based Regular Testing** Motivated by the value placed by participants on the importance of regular testing, typically driven by engaging in peer support groups, volunteering, or working in the context of sexual health-seeking and promotion.	**Mandated Regular Testing** Regular testing directed by employers or healthcare institutions and regimes.

[Typology of HIV/STI testing patterns by regularity of testing relative to factors motivating testing behaviors]

TUPED343

HIV microaggressions: A novel area of stigma research among people living with HIV

L. Eaton, C. Merley, B. Hamilton, T. Grebler, M. Kalichman, S. Kalichman
University of Connecticut, Storrs, United States

Background: Since the beginning of the HIV epidemic stigma has stymied HIV prevention and treatment efforts. Stigma is multi-faceted and directed from many sources, and therefore, remains a challenging social factor to overcome. HIV microaggressions are subtle, negative messages that denigrate people living with HIV (PLWH). Although microaggressions have been researched extensively in other areas
(*e.g.*, race), there are currently no available quantitative assessments of HIV microaggressions.
Methods: We developed an HIV microaggressions scale based on prior microaggressions work and stakeholder/community feedback. We enrolled 106 PLWH living in Atlanta, GA, USA to participate in an assessment of experiences of HIV microaggressions. HIV diagnosis was confirmed for all participants.
A principle components factor analysis with varimax rotation was conducted on all 14 items and scale reliability analyses were completed.
Results: Results demonstrated a five factor solution with 65% of the variance explained, and Cronbach's =.80. Analyses identified the following subareas of our microagressions scale: negative assumptions about

PLWH (example item "people living with HIV shouldn´t have sex"), negative portrayals (example item "you heard about someone being outed about their HIV positive status"), HIV messaging avoidance (example item, "you avoided reading comments section of article on HIV"), subtle mistreatment (example item, "you saw an HIV positive person being portrayed negatively in media"), and negative intrapersonal messaging (example item, "In an online dating profile, someone wrote „drug/disease free, UB2" or „neg for neg only""). All participants reported experiencing at least some instances of HIV microaggressions in the prior month, with variability being observed across the number of instances. The most frequently reported items included: "you heard someone say, I'm HIV negative, I'm clean" (N=96, 91.6%) and "you heard someone say, "but he/she doesn't look HIV positive" (N=99, 93.4%). Further, microaggressions were found to be associated with recent health care access.

Conclusions: Microaggressions are known to impact health outcomes, yet little is understood about microaggressions among PLWH. In the current study, we identified HIV microaggressions as being frequently reported among PLWH. Further research is needed to assess the impact of microaggressions on HIV related health outcomes including heath care engagement and markers of disease progression.

TUPED344

From knowledge to empowerment: A holistic approach to decrease the incidence of HIV among young people globally

W.J. van Enck[1], M. Todesco[2], D. Braeken[3]

[1]Dance4Life, Research & Development, Amsterdam, Netherlands, [2]Dance4Life, Amsterdam, Netherlands, [3]IPPF (former), Amsterdam, Netherlands

Background: To tackle the slow decline in new HIV infections among young people (especially girls), it is necessary to step out of the realm of traditional, knowledge transfer approaches. Instead, empowerment approaches built around the principles of Positive Youth Development (PYD) provide new solutions to existing problems. Based on the insights from over a decade of programming, Dance4Life presents an innovative Empowerment model to tackle the sexual and reproductive health risks of young people globally.

Description: Too often, sexuality education is treated as a scientific topic, resulting in disengagement from information that does not resonate with the daily lives of young people. Dance4Life presents a holistic peer-to-peer PYD approach that helps young people build social emotional learning (SEL) competencies that serve as mediating factors for positive behaviour change, such as increased negotiation skills and use of contraceptives, seeking health services, and voluntary testing and counselling. Young people are empowered to take responsible decisions about their life through increased self-efficacy towards sexual and reproductive health (SRH) issues, robust gender equal attitudes, and awareness of social norms and willingness to change harmful ones.

Lessons learned: The Dance4Life Empowerment model is a contextualized, peer-to-peer approach that enables facilitators to connect to young people and create a safe space where participants feel free to speak out, share and address sensitive issues. UNESCO's key elements for CSE are integrated in the curriculum, while focus shifts from transferring knowledge to experiential learning through creative facilitation of activity-based sessions. Peers refer youth to rights-based sources of information and health services they themselves perceive as youth-friendly. The model ensures that the internal incentive to change is supported by an enabling environment, where quality SRH services are available and accessible, and community support is created through advocacy.

Conclusions/Next steps: Tackling the slow decline in new HIV infections and other SRH challenges can only be accelerated when young people are provided with a positive approach, relevant to their personal lives. The Dance4Life Empowerment model serves as a powerful incentive, and provides a scalable and sustainable intervention for improving the sexual and reproductive health of young people globally.

TUPED345

Using social science methods to understand pathways to impact: A national HIV self-testing intervention targeting men who have sex with men and trans people in England and Wales

T.C. Witzel[1], F.M. Burns[2], A. Rodger[2], C. Bonell[1], F. Lampe[2], A. Speakman[2], D. Dunn[3], D. Ward[3], L. McCabe[3], M. Gabriel[3], M. Gafos[3,4], R. Trevelion[5], S. McCormack[3], A. Phillips[4], P. Weatherburn[1]

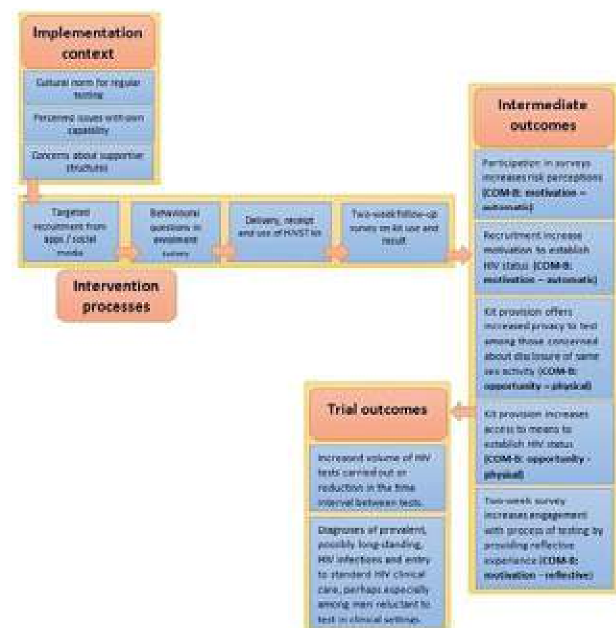
[1]London School of Hygiene and Tropical Medicine, Public Health and Policy, London, United Kingdom, [2]University College London, Institute of Global Health, London, United Kingdom, [3]University College London, MRC Clinical Trials Unit, London, United Kingdom, [4]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom, [5]HIV iBase, London, United Kingdom

Background: Increasing HIV testing among at-risk populations is a global HIV prevention goal. HIV self-testing (HIVST) could expand testing to new populations. SELPHI is an online randomised controlled trial evaluating whether HIVST increases rates and timeliness of HIV diagnoses among MSM and trans people. SELPHI target sample is 10,000, and initial randomisation is to HIVST or standard care.

SELPHI has used the COM-B behaviour change model in intervention development. COM-B theorises alterations in capability, opportunity and motivation as key to successful behavioural interventions.

The aim of this study is to articulate potential pathways to impact in a national HIVST intervention using COM-B.

Methods: Three formative studies investigating attitudes towards HIVST contributed to the logic model: a systematic literature map, six focus groups discussions (FGDs) (July to Nov 2015) with 47 MSM in three cities and 17 key informant interviews (IDIs) (May to Dec 2016) across England. FGDs and IDIs were transcribed and analysed thematically. Themes were extracted from qualitative data and relevant literature, then mapped onto a thematic framework informed by COM-B. The logic model was developed by transposing framework components to contextual factors, intervention processes, intermediate and trial outcomes.



[Figure 1: SELPHI logic model]

Results: As shown in figure 1, contextual factors included a strong norm for regular testing supporting implementation. Perceived capability concerns (low self-efficacy and lack of support) were barriers.

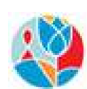
The logic model suggests intervention processes facilitate behaviour change by increasing motivation and opportunity.

Three intervention processes enhance motivation:

i) collection of behavioural information at registration increases risk perception;

ii) a free kit offer enhances the desire to establish HIV status; and

iii) follow-up contact increases engagement with testing.



One process increases opportunity by providing an additional, convenient modality, reducing the burden of time associated with testing while increasing privacy.
In order to address capability issues, advertising should enhance motivation by highlighting facilitators while addressing and minimising capability concerns.
Conclusions: The logic model describes the potential of SELPHI to affect behaviour change. By heightening risk perception and providing HIVSTs and follow-up support, SELPHI increases opportunity and motivation to test. Using COM-B allows us to better understand intervention processes and likely outcomes.

TUPED346

Developing and validating a Safer Sex Empowerment Scale (SSES) for young Black men who have sex with men

S.K. Choi[1], S. Legrand[2], K. Muessig[1], S. Ennett[1], M. Boynton[1], L. Hightow-Weidman[3]
[1]University of North Carolina Chapel Hill, Health Behavior, Chapel Hill, United States, [2]Duke Global Health Institute, Durham, United States, [3]University of North Carolina Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States

Background: Young Black Men who have Sex with Men (YBMSM) experience profound levels of stigma and marginalization which has been shown influence engagement in risky sexual behaviors. Increasing empowerment to engage in safer sex among marginalized groups, in spite of discrimination and stigma, could help reduce rates of HIV infection. Safer sex empowerment is defined by social action that involves participation of individuals, communities, and societies to increase safer sex behaviors. There is currently no published instrument designed to measure levels of safer sex empowerment, thus we developed and validated a Safer Sex Empowerment scale (SSES).
Methods: This study used baseline survey data from 474 YBMSM enrolled in healthMpowerment.org, a mobile-phone-optimized, Internet-based intervention designed to reduce sexual risk behaviors among YBMSM. Based on literature review, common constructs of empowerment included self-efficacy, self-esteem, emotional support and sense of community. At the beginning, 35 items related to these constructs were included in the analysis. Principal components analysis was used to identify an empirically derived set of sub-constructs. Pearson's correlation coefficients were used to examine the validity.
Results: Mean age was 24.3 (SD 3.2), 24% had at least a college degree, and 42% were HIV-positive. The finalized SSES included 29 items with five factors: (1) emotional support: support showing love, empathy, or affection, (2) self-efficacy for condom use: ability to use condoms, (3) negative self-esteem: critical of self-worth, (4) positive self-esteem: appreciating their own merits, and (5) self-efficacy to refuse sexual behavior: ability to refuse sexual behavior. The SSES showed good reliability (Cronbach alpha=0.90) and construct validity was established by examining correlation coefficients for anxiety (=-0.29, p< 0.0001), depression (=-0.53, p< 0.0001) and safer sex intentions (=0.29, p< 0.0001).
Conclusions: Findings support a SSES that includes five sub-constructs; emotional support, self-efficacy for condom use, negative and positive self-esteem, and self-efficacy to refuse sexual behavior. The SSES can be a helpful tool to further quantify the role of empowerment in impacting safer sex behaviors among YBMSM. Measuring these relationships and developing and evaluating interventions based on these relationships could pave the way for empowering YBMSM toward safer sex thereby impacting disparate HIV rates among YBMSM.

TUPED347

Motivation matters! Using qualitative research to develop an mHealth intervention to support antiretroviral adherence among HIV-positive female sex workers in Mombasa, Kenya

F.M. Aunon[1], G. Wanje[2], L. Masese[3], T.A. Odeny[4], W. Jaoko[5], J. Simoni[1], R.S. McClelland[3,6,7]
[1]University of Washington, Department of Psychology, Seattle, United States, [2]University of Nairobi Institute of Tropical & Infectious Diseases (UNITID), Nairobi, Kenya, [3]University of Washington, Department of Medicine, Seattle, United States, [4]Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya, [5]University of Nairobi, Department of Medical Microbiology, Nairobi, Kenya, [6]University of Washington, Department of Global Health, Seattle, United States, [7]University of Washington, Department of Epidemiology, Seattle, United States

Background: While mHealth interventions have been identified as innovative approaches to addressing antiretroviral (ART) adherence challenges, theory-driven interventions remain limited. We conducted focus group discussions (FGDs) grounded in Information, Motivation and Behaviour (IMB) theory to design a personalised, interactive, text-based intervention to support ART adherence among HIV-positive female sex workers (FSWs) in Mombasa, Kenya.
Methods: Qualitative FGDs with 23-positive FSWs were used to iteratively develop an SMS-based intervention (Motivation Matters!). FSW were purposively sampled across two stages of treatment: ART-naïve (one group) and ART-initiated (two groups). Two rounds of FGDs were conducted with each group, for a total of six FGDs. The first round of FGDs was used to identify culturally appropriate treatment content grounded in IMB theory (e.g., identifying information and misconceptions influencing decisions, eliciting sources and types of motivation, and identifying cues promoting ART adherence). A second round of FGDs was then used to determine intervention format and structure. All FGDs were recorded, transcribed and translated, and analysed according to the IMB model. From these broad IMB themes, grounded theory approach was used to identify subthemes and key content areas used to develop text messages.
Results: Text messages were developed based on IMB themes generated by FGDs. Based on FGDs, information-oriented texts addressed women's concerns about responding to missed doses, taking ART while drinking alcohol, and the influence of religion on adherence. Motivation-oriented texts reflected the women's desire to feel healthy enough to engage in everyday activities and provide family support. Based on FSWs' feedback, behaviour-oriented texts suggested strategies to remember taking ART, especially if there was a disruption in schedule. In addition, messages were personalized based on religion, language, and the time of day sent. Women appreciated the proposed interactive texting and requested more frequent messages shortly after ART initiation.
Conclusions: The theory-driven approach described above has the potential to inform development of culturally-tailored interventions to support ART adherence among key populations. This study begins to explore the extent to which application of theory and feedback from target populations during intervention development provides more efficacious interventions. The developed intervention is now being tested with a cohort of FSWs newly initiating ART.

TUPED348

The roles of behavioral and social sciences research in the fight against HIV/AIDS: A functional framework

P. Gaist[1], M. Stirratt[2]
[1]National Institutes of Health, Office of AIDS Research, Rockville, United States, [2]National Institutes of Health, National Institute of Mental Health Division of AIDS Research, Rockville, United States

Background: Though there have been significant biomedical advances in HIV/AIDS prevention and treatment, the public health crisis of HIV/AIDS persists. This persistence has led researchers to more closely examine the inter-related roles of behavioral and socio-structural factors that impinge, improve, and/or otherwise impact HIV/AIDS prevention, treatment, and care at both the individual and population levels.
Methods: To support the future application of behavioral and social sciences research (BSSR), authors Gaist and Stirratt created a functional framework for HIV/AIDS-related BSSR. The framework consists of 4 primary domains: (1) Basic BSSR to understand vulnerable populations and the context of risk; (2) Elemental BSSR to improve behavioral and social approaches to risk reduction, prevention, and care; (3) Supportive BSSR for strengthening the design and outcomes of biomedically focused research in HIV/AIDS treatment and prevention; and (4) Integrative BSSR to attend to effective implementation of HIV/AIDS interventions in real-world settings.
Results: Basic, Elemental, Supportive, and Integrative BSSR culminate to create a figurative table of HIV prevention, care, and cure research and practice. As shown in the figure below, Basic BSSR provides a sturdy foundation for the other 3 domains and guides future efforts to improve HIV-related health outcomes. Each of the components are integral to fully understanding behavioral and social aspects acting as barriers or facilitators to HIV prevention and treatment.
Conclusions: These 4 domains illustrate the important role of BSSR in current and future efforts to address HIV/AIDS on a global scale. The successful development and delivery of effective, evidence-based HIV prevention and treatment requires BSSR in each of the domains. All 4 domains benefit by research to further identify structural determinants of HIV, help individuals/communities navigate the expanding and changing HIV prevention and treatment landscape, and scale intervention endeavors. Significant progress has been made in identifying and addressing behavioral and social aspects that impact HIV prevention, care, and treatment interventions. However, future application of BSSR within and across these domains are necessary to ultimately end the HIV/AIDS epidemic. This functional framework provides a useful perspective and approach to assist researchers, program implementers, policy-makers and other HIV/AIDS-focused communities.

[A Functional Framework for HIV/AIDS Behavioral and Social Sciences Research]

Strengthening social and behavioural data collection and analysis

TUPED349

Novel measures of personal and cultural themes likely to affect HIV risk when large-scale economic or sociopolitical change occurs

S.R. Friedman[1], E.R. Pouget[2], M. Sandoval[3], G.K. Nikolopoulos[4], P. Mateu-Gelabert[5], D. Rossi[6,7]
[1]National Development and Research Institutes, Institute for Infectious Diseases Research, Highland Park, United States, [2]Brooklyn College, Biostatistics, New York, United States, [3]Brooklyn Legal Services Corporation A (BKA), New York, United States, [4]University of Cyprus, Medical School, Nicosia, Cyprus, [5]National Development and Research Institutes, Institute for Infectious Diseases Research, New York, United States, [6]Intercambios Civil Association, Buenos Aires, Argentina, [7]University of Buenos Aires, Social Work, Buenos Aires, Argentina

Background: Social and cultural groups differ cross-sectionally and over time in the extent to which people make decisions based on altruism, solidarity and the necessities of daily survival. We developed measures of these cultural themes as part of ongoing research on how large scale sociopolitical and economic change affects HIV epidemics. We have previously published these measures' reliability and validity for people who inject drugs in New York City. Here, we study their reliability and validity among high-risk heterosexuals (HRH) and men who have sex with men (MSM).
Methods: 298 HRH and 256 MSM, recruited by referral from an RDS study and by chain recruitment by study participants, were interviewed in New York City in 2013 - 2015. All were 18 years old or older and provided informed consent. Questions and scales on cultural themes and related behaviors were based on two years of qualitative research. Scale reliability is assessed with Cronbach's alpha and construct validity assessed by Pearson's r with selected criterion variables.
Results:
Within the HRH sample, 49% were women. Cronbach's alpha for the cultural orientations were 0.86 for altruism, 0.70 for solidarity and 0.86 for survival orientation. Validation: Altruistic orientation correlated 0.45 with frequency of helping others; solidarity 0.52 with competitiveness (which included items for group solidarity to increase group competitiveness) but only 0.05 with helping others, survival cultural orientation -0.57 with traditional values.
Within the MSM sample, Cronbach's alpha for the cultural orientations were 0.77 for altruism, 0.80 for solidarity and 0.89 for survival orientation. Validation: Altruistic orientation correlated 0.42 with frequency of helping others; solidarity 0.49 with competitiveness and 0.33 with helping others, but survival cultural orientation was not correlated with traditional values.
Conclusions: In New York, the measures of altruistic cultural orientation, and probably of solidarity orientation, seem reliable and valid for both HRH and MSM, and survival orientation for HRH. Future research should determine psychometric properties of these measures in other locations and, particularly, should study their role in mediating between large-scale sociopolitical and economic change and changes in HIV risk behaviors, risk networks, and HIV incidence.

Mixed methods, integrated approaches and synergies in HIV research and intervention

TUPED350

Effecting change in research and policy for women living with and vulnerable to HIV through the women's research initiative on HIV/AIDS (WRI)

D. Averitt[1], J.D. Auerbach[2], G.M. Brown[3], J. Conley[1], L. Fitzpatrick[4], J. Kates[5], C.R. Wira[6], K. Martel[1]
[1]The Well Project, Brooklyn, United States, [2]University of California, San Francisco, United States, [3]Office of AIDS Research, NIH, Bethesda, United States, [4]George Washington University School of Public Health, Washington, United States, [5]Kaiser Family Foundation, Washington, United States, [6]Geisel School of Medicine at Dartmouth, Department of Microbiology and Immunology, Lebanon, United States

Background: The WRI was founded by The Well Project in 2003 in response to the historic exclusion of HIV-positive women from clinical trials and the overall lack of focus on women in HIV prevention and treatment research. Since its inception, the WRI has employed a unique model of stakeholder engagement to elevate, enhance, and expedite research on women and HIV.
Description: The WRI hosts a small (< 40) annual meeting on a salient topic (e.g., HIV cure, U=U, the HIV care continuum) focused on women. By bringing together key stakeholders from clinical care, research, advocacy, policy, government, and the pharmaceutical industry, as well as women living with HIV, the WRI comprehensively identifies research and policy gaps in treatment and prevention for women. Invited presentations and moderated discussions yield a series of action items that WRI members commit to undertake in their respective sectors. A summary report from the WRI deliberations is disseminated through The Well Project's website and by WRI members to their networks.
Lessons learned: The WRI has been instrumental in effecting change in research for women and HIV. Efforts include the development and successful implementation of the GRACE Study and the *Women Living Positively* Survey, the FDA meta-analysis of HIV clinical trials funded by the Office of Women's Health, and input by WRI members in the annual development of the NIH Plan for Women and Girls. Additionally, WRI members have formed collaborations, implemented fellowships, developed protocols to address novel basic science questions, created multidisciplinary teams for enhanced study hypotheses and design, mentored young investigators, and worked with policymakers to ensure that the needs of women living with HIV are consistently addressed.
Conclusions/Next steps: The WRI has created a uniquely multidisciplinary model of engagement for work in HIV among women. This model has successfully built relationships, influenced research, policy and advocacy efforts, and affected the direction of HIV treatment, prevention and cure research. The WRI model has the potential to be replicated across diseases and demonstrates the value of bringing diverse voices and perspectives together to address complex issues.

TUPED351

Trade and health. Emergence of local drug markets, HIV and injected drugs in Hermosillo, Sonora México. Results from a mixed study

A.M. Ospina Escobar[1], C. Magis Rodriguez[2]
[1]UNAM. Programa de Becas Posdoctorales en la UNAM, Becaria del Instituto de Investigaciones Sociales, Asesorada por la Doctora Marina Ariza, Instituto de Investigaciones Sociales, Mexico City, Mexico, [2]Centro Nacional para la Prevención y el Control del SIDA (CENSIDA), Atención Integral, Mexico City, Mexico

Background: Hermosillo, a middle-sized city in Northern Mexico has become an important site for drug-trafficking (DT) in the last decade. Official data show unprecedented expansion of heroin and methamphetamine use and HIV among people-who-injected-drugs (PID) in this city. We aim to identify characteristics of local drug market that could explain the emergence of injected drugs (ID) and HIV in Hermosillo.
Methods: This is a mixed study design. We analyzed quantitative data from a survey conducted in 2012 in sites where PID gathered in Hermosillo. We described patterns and contexts of drug use and risk behaviors. To understand the emergence of ID and HIV among PID, we conducted ethnographic work in 2014 and collected 13 biographies of drug use among PID from three different generations (1960, 1980, 1990). We trace generational changes in patterns, dynamics and context of drug use and trafficking in this city.
Results: 392 PWID were recruited. Their HIV prevalence was 5.2%. Most participants were polydrug users, 53% 42% of participants declared using methamphetamine and cocaine and 40% declared using china-white-heroin. Patterns of drug use reveal faster transition to injected drug use (5 years since the onset of drug use) but a relatively lower prevalence of syringe sharing (31%). Ethnographic findings revealed limited harm reduction programs and the arrival of criminal groups who boosts local drug market by promoting methamphetamine and china-white heroin use, controlling drug use dynamics and using violence in the neighborhoods. Younger drug users initiated with more addictive drugs (heroin and meth) and showed more compulsive patterns of drug use. PID are encouraged to work for criminal groups to pay debts which enhance risky practices for HIV.
Conclusions: Emergence of drug injection and HIV among PID is contingent with the arrival of criminal groups to Hermosillo. Mixed research design, combining quantitative data, ethnographic data and documentary research, allowed us to understand how changes in drug trafficking dynamics, along with an insufficient institutional increase HIV risks and injected drug use. Relationship between local drug markets and risk injection practices need to be contextually understood and has to be addressed in the debate of drug policy reform.

Qualitative and ethnographic methods in HIV research

TUPED352

Mapping the intersections of space, place, and health: Geo-narratives of living with HIV in San Francisco, California

A. Martinez[1], X. Liu[2]
[1]San Francisco State University, Center for Research and Education on Gender and Sexuality, San Francisco, United States, [2]San Francisco State University, Geography, San Francisco, United States

Background: The use of geographic information systems (GIS) to visualize the HIV/AIDS epidemic have produced maps and statistics that inform programmatic and policy efforts to reduce the burden of new infections in both resource limited and resource rich settings. Integrating GIS into qualitative methods opens up new possibilities for interpreting and understanding the treatment and care experiences of people living with HIV. This study seeks to advance qualitative GIS methodologies and contribute geo-narratives of managing treatment and accessing health care among persons living with HIV (PLWH) in San Francisco.
Methods: We conducted 30 qualitative interviews with PLWH who lived in San Francisco, California. We purposively recruited participants from clinics and hospitals between 2015 and 2017 by targeting neighborhoods with lower rates of viral suppression in San Francisco. We used the HIV continuum stages of care to structure our interview guide and elicit geographic data on the experiences of managing treatment and accessing care. After interviews were transcribed and integrated into GIS software, narrative analysis was used to produce geo-narratives of being HIV positive in San Francisco and managing treatment.
Results: PLWH in our sample were 75% men, 20% women, and 5% transgender. Three-quarters of the sample reported being LGBTQ and one-quarter reported a history of substance use. 100% of the sample reported being linked to care and currently receiving anti-retroviral therapy. Housing emerged as a theme that adversely impacted engagement in care, especially for those who lived in neighborhoods perceived as chaotic sites of violence, drug use, heightened police activity, and lack

of empathy for those living with HIV. Participants also highlighted a perceived reduction in availability of non-HIV related goods and services essential to overall well-being.
Conclusions: Integrating GIS into qualitative research is useful for illuminating how our PLWH participants´ experiences of particular spaces and places impact their engagement in HIV care. San Francisco is a health resource-rich city in which participants reported receiving excellent care for their HIV, yet struggled to remain engaged in care due to changes in the availability of housing, food, and community in a wealthy city with shrinking spaces for those on the social and economic margins.

TUPED353

Critical reflections on the use of repeated collages to understand the experiences of young women living with HIV in urban Zambia

C.R.S. Mackworth-Young[1,2], A. Wringe[3], A. Stangl[4], K. Sievwright[4], V. Bond[2,5]
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Zambart, Department of Social Science, Lusaka, Zambia, [3]London School of Hygiene and Tropical Medicine, Department of Population Health, London, United Kingdom, [4]International Center for Research on Women, Washington, United States, [5]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom

Background: Participatory and art-based research methods, including collages, can be an effective tool to involve young people living with HIV (LWH) in generating data. However, critical reflections on using arts-based methods with young people are lacking.
Methods: 24 young women LWH aged 15-19 years were recruited from two health facilities in Lusaka, and participated in two workshops in January 2015. Another participatory workshop was held in November 2017 with 7 participants purposively sampled from the original group.
In each workshop, participants were given A3 card, magazines, pens, scissors and glue to create a collage telling a story about themselves (n=31). Participants described their collages in participatory workshops (n=3), and subsequent in-depth interviews (n=17) and participant observations (n=46). The collages were analysed visually, alongside inductive analysis of transcripts from the IDIs and observation notes.

[Collage by 18-year old young woman living with HIV, created in workshop in November 2017, revealing optimism, high ambitions and importance of family]

Results: Participants enjoyed the opportunity to physically construct their stories, recognising that collages "*held meaning*". Collages captured expressions of optimism and ambition, regardless of their HIV status, such as: "*HIV will not stop me from achieving my dreams*". This contrasted with in-depth interviews that typically captured stories of adversity.
Collages allowed visual representation of participants' lives, including demonstrating the importance of family and beauty. However, this was limited by the magazines provided, on fashion, travel, food and home. Participants noted that "*more [material] on aspirations for career and for the future*" would have enabled them to better express their aspirations.
Comparing collages with the same participants at two time points presented a progression from the central importance of school to college and careers, reflecting participants transitioning life stages. Some participants made direct before-after comparisons. One participant expressed: "*I now have so much confidence in myself*", which helped with disclosure.
Conclusions: Collages provide a feasible, engaging and effective method to involve young people in the production of data to understand their experiences LWH. They allowed participants to express more optimism, and, for repeated collages, transitions over time. Collages need to be used reflectively, including understanding how materials provided influence the representations presented. Collages can be an important tool, for research and beyond, in engaging young people LWH to visually tell their stories.

TUPED354

Online focus group discussions with transgender women in the Eastern and Southern United States: An emerging qualitative method for HIV research

E. Cooney[1], S. Reisner[2,3,4], D. Pardee[4], A. Wirtz[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Harvard Medical School, Pediatrics, Boston, United States, [3]Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States, [4]The Fenway Institute, Boston, United States

Background: Technology-based methods are increasingly common in survey research. Qualitative research, however, has been slower to embrace technology frequently used by its target populations. The LITE American Cohort is a multi-site cohort examining HIV outcomes among transgender women in the eastern and southern United States. We examined the utility of using computer-mediated technology for formative, qualitative research (i.e. "online focus groups") to inform recruitment, marketing, and survey development for the cohort.
Methods: Seven online focus group discussions („online FGDs"; 5 English, 2 Spanish) were conducted between August 2017 and January 2018 using a secure web-conferencing platform (Zoom). Participants joined via landline, mobile phone, mobile application, or web browser and were given the option of using a pseudonym and to turn on/off video conferencing. Electronic gift cards were emailed to participants at the conclusion of each online FGD.
Results: Overall, 70 adult transgender women were eligible and scheduled for an online FGD; 41 attended (see Table 1). The most common reason for non-attendance was forgetting or having a scheduling conflict. Online FGDs facilitated geographic diversity, perceptions of anonymity, and flexibility in scheduling by eliminating challenges related to traveling to a data collection site. Several issues with traditional in-person FGDs remained with online FGDs such as overlapping conversations, variable audio quality, and prior connections between participants. Online FGDs raised additional considerations of technological literacy, acceptability of non-cash incentives, feasibility of distributing incentives, and imperceptibility of non-verbal communication. Participants with limited technological literacy, inconsistent access to a phone and/or cellular data/service, and circumstances necessitating immediate cash incentives may require additional support and accommodation.

	Attendees (n=41)	Non-Attendees (n=29)	Total Eligible (n=70)
Age: Mean (Range)	39.3 (21-59)	40.1 (22-65)	39.6 (21-65)
Race			
White	34%	10%	24%
Black	34%	55%	43%
Asian	5%	0%	3%
More than one race or other	27%	34%	30%

Unknown	n/a	31%	n/a

[Table 1: Eligible Participant Demographics]

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

Conclusions: This study highlights several considerations for technology-enhanced qualitative research. Online FGDs with multiple secure phone or Internet access options have the potential to improve the feasibility of conducting research with hard-to-reach populations and to meet participants "where they are" in terms of their use of technology without significantly affecting data quality. In the context of HIV research, it is important to continue to find ways to ensure that individuals with inconsistent cellphone access, inability to utilize electronic gift cards and varying levels of technological literacy are included in research.

TUPED355

Construction of HIV-infected Lithuanian female drug users' identity in biographical narratives

G. Aleksaitienė
Vytautas Magnus University, Department of Social Work, Kaunas, Lithuania

Background: Most of PLHIV in Lithuania are injecting drug users suffering from psychosocial stress, stigma and discrimination. People with HIV infection, often experience multiple stigmatization because they use drugs, provide sexual services, have criminal record (Čaplinskas, 2010). Due to dominant Catholic faith in Lithuania the most stigmatized are drug-dependent women living with HIV. Assistance for PLHIV in Lithuania is medicalized, there are no dedicated psychosocial programmes guaranteed by the state (Sultan, 2013).
To improve the state programme for psychosocial work with women it is necessary to understand how drug-dependent HIV-infected women construct identity in the past, present and future.
Methods: The objective is to disclose how HIV-infected female drug users construct personal identity in biographical narratives.
The study is based on constructivist, existential and critical feminist theories and on interpreted constructive-ontology and subjectively-interpreted epistemology. 16 drug-dependent HIV-infected Lithuanian women between the age of 28 and 52 were interviewed in the format of biographic narrative and "life line" visualization. Data analysis was carried out using Creswell (2007) analysis.
Results: Construction of identity among survey participants unravelled as reconstruction of past events and social bonding reflecting the present and projecting the future with moments of impact throughout the entire "life line." As children women suffered distress due to unformed safe sense of attachment and trying to avoid suffering and loneliness started using drugs. This led to personality destruction subsequently leading to "breakdown in the biography" at the time of hearing the HIV diagnosis. This crisis has become the starting point for positively-oriented recovery of identity. Women not using drugs anymore and those still using drugs project the present and the past differently. Abstinence is a vital factor allowing women to create more close social relationships, who are highly significant for all survey participants. Psychosocial assistance at the time of hearing the HIV diagnosis was very helpful.
Conclusions: Reconstruction of life has vital positive impact on reconstruction of identity, HIV treatment and consumption/non-consumption of drugs. This method can be used in social work with drug-dependent, HIV-infected women and has already been proposed by the author to the Ministry of Health for the Programme to work with PLHIV.

TUPED356

A qualitative analysis of sexual communication and uncertainty management among participants in Taiwan CDC PrEP demonstration project

P. Huang[1], H.-J. Wu[2], F.-M. Jan[3], L.-W. Mao[4], N.-Y. Ko[5], C.-W. Li[4], C.-Y. Cheng[6], C. Strong[2], S.W.-W. Ku[7]
[1]University of California San Diego, Department of Communication, La Jolla, United States, [2]National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Department of Public Health, Tainan, Taiwan, Province of China, [3]Taipei Veterans General Hospital, Department of Medicine, Division of Infectious Diseases, Taipei, Taiwan, Province of China, [4]National Chang Kung University Hospital, Department of Internal Medicine, Tainan, Taiwan, Province of China, [5]National Cheng-Kung University, Department of Nursing, College of Medicine, Tainan, Taiwan, Province of China, [6]Taoyuan General Hospital, Ministry of Health and Welfare, Department of Internal Medicine, Taoyuan, Taiwan, Province of China, [7]Taipei Veterans General Hospital Hsinchu Branch, Taiwan, Department of Medicine, Division of Infectious Diseases, Hsinchu, Taiwan, Province of China

Background: In 2017, the Taiwanese CDC recruited 321 individuals in a national PrEP demonstration project to assess key populations' acceptance. However, little is known about how PrEP users - predominately men who have sex with men (MSM) - incorporate PrEP in communicating with their sexual partners. This paper reports the result of the interviews with participants enrolling in the demonstration project.
Methods: Based on the framework of Dale Brashers's Uncertainty Management Theories, this research aims to determine whether being „On-PrEP" decreases MSM's perceived uncertainty in communicating with their sexual partners. Through online flyers and snowball sampling methods, we conducted in-depth, semi-structural interviews with 40 MSM. We accessed their: motivations of taking PrEP; perceived barriers of maintaining in PrEP regime, inclinations of specifying "on PrEP" on their online profiles, and strategies for applying PrEP into their communication with sexual partners.
Results: Among the interviewees who are currently on PrEP, only less than 20% reported being willing to reveal their On-PrEP status either to their sexual partners or on smartphone apps. Reasons of not-disclosing On-PrEP status include "protecting one's privacy" and "avoiding awkwardness," suggesting that social stigma around AIDS remains the biggest barriers for PrEP's rollout. While the interviewees had better health awareness, having more prevention tools paradoxically increased their perceived uncertainty. We have categorized four types of uncertainty regarding their biomed matching and strategies for safe sex.

1. Uncertainty about one's literacy in interpreting scientific data and jargons;
2. Uncertainty about one's skills in negotiating condoms use with sexual partners;
3. Uncertainty about sexual partners' awareness, attitudes, and acceptances about PrEP;
4. Uncertainty about the cultural gap and language barrier, such that how the idea of *prophylaxis* should be properly represented in the local context.

Conclusions: PrEP is an effective prevention tool for HIV infection. However, during its initial rollout in Taiwan, MSM reported increasing perceived uncertainty regarding their literacy, skills of negotiating condom use, sexual partners' awareness, attitudes, and acceptance, as well as the cultural and language barrier regarding translation. To facilitate its implementation, we suggest policy makers, PrEP providers, potential PrEP users, and AIDS advocates focusing on above uncertainties and tailoring messages in the future campaigns.

TUPED357

Psychosocial barriers to HIV care in Uganda

S. Lofgren[1,2], L. Atuymbe[3], N. Nakasujja[4], P. Kirumira[2], R. Rajasingham[1], D. Meya[2], D. Boulware[1]
[1]University of Minnesota, Medicine, Division of Infectious Diseases and International Medicine, Minneapolis, United States, [2]Makerere University, Infectious Disease Institute, Kampala, Uganda, [3]Makerere University School of Public Health, Kampala, Uganda, [4]Makerere University, Psychiatry, Kampala, Uganda

Background: Despite success of HIV treatment roll out in sub-Saharan Africa, 20-25% of patients still present with advanced HIV disease. These late presenters experience higher morbidity and mortality. To better understand the reasons for late presentation, we conducted a qualitative study in Kampala, Uganda.
Methods: People living with HIV (PLWH) who had newly presented to HIV clinic within the last 3 months and healthcare workers (HCW) from the same clinics performed in-depth interviews. Patients were grouped as:
1) antiretroviral therapy (ART) defaulters,
2) ART naïve CD4 count< 100 cells/uL "late presenters" or
3) ART naïve CD4 count>350cells/uL "early presenters".
Interview topics included:
a) barriers for HIV care,
b) facilitating factors,
c) mental illness,
d) drugs and alcohol,
e) stigma, and
f) social support.
Themes were grouped by category.
Results: Between May and August 2017, 58 PLWH and 21 HCW were interviewed at 5 HIV clinics. HCWs reported stigma as the primary barrier for HIV testing and care. Denial of diagnosis, time-consuming clinic appointments, or lack of transport funds were other barriers. The HCWs noted alcohol abuse contributed to men not engaging in care. HCWs noted fear of abandonment or domestic abuse contributed in women. Barriers around clinics being inefficient and lacking privacy were also themes.
Among ***early presenters*** themes included incidental HIV testing during febrile illness, after a partner develops AIDS or partners are non-monogamous. Many noted a friend/family member who encouraged them to engage in care. A few tested for HIV to check on the status of their health. ***Late presenters*** nearly all waited until they were ill/symptomatic. A major theme among men and some women was alcohol abuse. Themes among ***defaulters*** include denial, stigma, and alcohol use. Most had a major life event, which interrupted their care such as travel, incarceration, or neighboring country civil wars.
Conclusions: Our findings suggest interventions to reduce stigma, educate the community, and reduce alcohol abuse would reduce late presentation. Efforts to do contact tracing and partner disclosure would be of value. Improving clinic efficiency and privacy would be useful. Finally encouraging healthy individuals to have periodic HIV tests would likely help reduce late presentation of HIV.

TUPED358

AIDS in action: Researching a new movement led by Canadians living with HIV

C. Hui[1,2]
[1]Ryerson University, School of Social Work, Toronto, Canada, [2]Canadian Positive People Network (CPPN), Toronto, Canada

Background: Utilizing an anti-oppressive and intersectional approach to qualitative research, a co-founder of the Canadian Positive People Network (CPPN), a new network formed by Canadians living with HIV and HIV co-infections, conducted a GIPA-centerd graduate level social work study aimed at exploring
1) the challenges and opportunities faced by this peer-led group as they reassert PLHIV back to the forefront of the Canadian national HIV response; and
2) establishing key factors to inform the strengthening the young network.
Methods: The study developed an original theoretical framework, the "Positive People Centred Perspective", by combining GIPA with theories on anti-oppressive social work practice, citizenship and rights, and social movement to comprehensively ground the HIV response. To ensure the views and needs of key populations are not left behind, the study utilized purposive sampling and conducted qualitative one-on-one "activist dialogue" interviews with 5 key Canadian activists living with HIV representing an intersection of MSM, sex worker, drug user, migrant, transgender people, incarcerated people, and Indigenous people. Interviews were audio-recorded and transcribed.
Thematic analysis was performed with N-Vivo. Results were member-checked with interviewees for accuracy.
Results: Challenges and barriers facing the Canadian PLHIV movement include the shifting of the epidemic to marginalized key populations groups and the professionalization of the sector. Key themes include the importance of the network to champion the right agenda that is informed by all affected communities, and to proactively challenge and resist structural violence and oppression, colonialism, racism, whiteness, and neo-liberalism to create transformative change. Institutional considerations include making a proactive commitment and create policies on equity, inclusion, anti-oppression, and non-discrimination. For minoritized groups, true equity means working in culturally-safe ways and supporting their specific goals and objectives within the network´s broader agenda.
Conclusions: An anti-oppressive, positive-people centered, intersectional approach to research has informed a nascent Canadian PLHIV network the importance to break systemic and structural barriers for PLHIV and key populations and proactively build bridges to support the changing needs of PLHIVs. The HIV sector, including PLHIV networks and organizations serving PLHIV, must proactively commit to equity, inclusion, anti-oppression, non-discrimination, cultural-safety, decolonization, and resist neo-liberalization to end the epidemic for all.

TUPED359

'Being healthy' as a factor for both accepting and refusing to initiate ART: A cross-sectional qualitative study in the era of *Test and Treat* in Mozambique

A. Magaco[1,2], K. Dovel[3,4], F. Cataldo[5], P. Nhassengo[2], J. Tique[6], A. Couto[6], R. Hoffman[4,7], L. Nerua[2], M. Saide[2], E. Samo Gudo[2], S. Chicumbe[2]
[1]National Institute of Health, Health Systems Program, Maputo, Mozambique, [2]National Institute of Health, Maputo, Mozambique, [3]Partners in Hope, Lilongwe, Malawi, [4]University of California, Los Angeles, United States, [5]Institute for Global Health and Development, Edinburgh, United Kingdom, [6]National STI, HIV and AIDS Control Program, Maputo, Mozambique, [7]Research Department, Partners in Hope, Lilongwe, Malawi

Background: In mid-2016, Mozambique began phased implementation of the "Test-and-Treat" (T&T) approach, which enrols HIV positive clients into antiretroviral treatment (ART) immediately, regardless of clinical stage. The aim of this study was to describe perceived barriers and facilitators to the implementation and uptake of T&T. We examined the relationship between the lived experience of patients initiating ART in the context of T&T and how 'good health' influences their perception of care.
Methods: A cross-sectional qualitative study was conducted across 10 health facilities in 4 provinces in Mozambique that initiated the implementation of T&T. Data were collected through in-depth interviews with HIV+ clients (n=60 initiated/20 did not initiate ART within T&T) and 9 focus group discussions with health care workers (n=53). The analysis used a deductive and inductive approach to develop analytic categories and transcripts were coded using NVIVO-11.
Results: Feeling 'healthy' functions both as a barrier as well as a facilitator for ART initiation. Clients in „good health" found it hard to believe a positive HIV diagnosis and, if they believed in the validity of the test, did not understand why they were asked to start ART right away. Patients also reported concerns about ART side effects, fear of inadvertent HIV disclosure, as well as discrimination, limited privacy at health facilities, and long waiting times as barriers. In contrast, being in „good health" was also a key motivator for clients to remain healthy, maintaining responsibilities and caring for their families, and avoiding unwanted disclosure. Other facilitators included being well enough to take care of dependents as well as the positive perception of the quality of ART services.

Conclusions: Our study provides an in-depth understanding of the complexity and dynamics of the perception of 'health' among newly diagnosed HIV positive clients and how individual perceptions of 'being healthy' may influence ART initiation in T&T. Engaging with the priorities and experiences of individuals in relation to the notions of health and illness are key to improving future HIV interventions especially in the era of T&T.

TUPED360

Understanding motives for initiating PrEP amongst adolescent girls and young women (AGYW) in South Africa and Tanzania

S. Lees[1], F. Scorgie[2], E. Mashauri[3], N. Khoza[2], L. Ramskin[2], D. Baron[2], S. Delaney[2], S. Harvey[1]
[1]*London School of Hygiene and Tropical Medicine, PHP, London, United Kingdom,* [2]*University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa,* [3]*Mwanza Intervention Trials Unit, Mwanza, Tanzania, United Republic of*

Background: Very few studies have been conducted with AGWY in Tanzania and South Africa on motives for initiating PrEP. We conducted a qualitative sub-study as part of the EMPOWER study, which evaluates the feasibility and acceptability of offering oral PrEP alongside an HIV and violence prevention package for AGYW in South Africa and Tanzania.
Methods: In-depth interviews were conducted with participants 3 months after accepting PrEP in Johannesburg (n=25) and Mwanza (n=14). Data were transcribed and translated into English and coded in QSR Nvivo taking an inductive thematic approach. Key themes relating to participants' motives for PrEP-use were elicited.
Results: In Mwanza, participants were working in bars or as local food vendors where sexual transactions are common. They acknowledged the higher HIV risk of their work environment but also were concerned about regular partners' infidelity. Initial concerns about PrEP safety were assuaged following receipt of product information from study staff. Motives also focused on 'being safe', and that using PrEP would offer them reliable HIV protection in contrast to condoms.
Participants in Johannesburg were students in the inner-city, a social context where multiple concurrent partnerships are the norm. Virtually none trusted their partners, who were considered promiscuous and at high HIV-risk. Most participants recognised their risk was heightened by low condom use and cited fear of sexual assault. In both sites, experiences of family living with HIV and dying of AIDS also motivated women to use PrEP.
Conclusions: In both sites, motives for initiating PrEP reflected a desire to protect their health and future. In Mwanza, the main narrative was one of 'safety'; PrEP was considered a safe drug with high efficacy, reflecting trust in the research study context and confidence that HIV could be conquered. In Johannesburg, PrEP aligned with the 'independent, urban woman', an aspiring image in this setting; participants understood PrEP does not guarantee efficacy in preventing HIV and had some safety concerns, but awareness of their heightened personal risk was greater.
Our study confirms the high acceptability of PrEP among two contrasting populations of African AGYW, but cautions that repeated messaging about multiple protection methods are still needed.

TUPED361

Person-focus analyses of resilience among newly diagnosed HIV positive men who have sex with men: Results from an ethnographic study in China

H. Li[1], E. Holroyd[2]
[1]*Shandong University, Jinan, China,* [2]*Auckland University of Technology, Auckland, New Zealand*

Background: Limited studies have examined the dynamic interplays of risk and resilience in the context of HIV-infected men who have sex with men (MSM), and very few studies have examined this issue within a Chinese cultural context using a longitudinal research design. This study aims to explore resilience-related experiences among newly diagnosed HIV positive MSM in a Chinese cultural context.
Methods: Longitudinal in-depth interviews at two time points in a 3 months interval were conducted within a lager ethnographic study in Shenzhen, China. Purposive sampling was used to recruited 31 participants with diverse social economic status. Inclusion criteria were 18 years of age or older, received a diagnosis of HIV infection within the last 6 months, identified as a MSM. A person-focus approach and cross-case analysis were adopted in data analysis.
Results: At time point one, most participants (29/31) reported symptoms of depression and/or anxiety when they were diagnosed HIV positive. At time point two, most participants (17/31) expressed resilience, with eleven participants being back to normal functioning and six participants even experiencing growth. This group of participants integrated negative experiences and recovered in both cognitive and activity levels, using resources such as social support and optimism. However, three participants (3/31) still reported severe symptoms of suicidal ideation, major depression, and anxiety. Other participants (11/31) reported being resilient to some degree while encountering such problems as not accepting their diagnosis, rejecting available healthcare services, and practicing unsafe sex. These were seen to be related to their original psycho-social wellbeing further deteriorating with an HIV diagnosis, such as being put into the centre of gossips and threatening, lack of hope for the future, perceiving increased living pressure, in conflict with CDC/hospital, etc.
Conclusions: Resilience was seen to be created from positive person-situation interaction. Resilience and setbacks concurred in tandem, switching back and forth, and only participants who continued to make an effort to deal with their setbacks could grow continuously. In order to facilitate the development of resilience and personal growth among these HIV positive MSM, community developments, including increased social support, routine mental health services, stigma reduction and intentional activity campaigns, are needed.

TUPED362

HIV: Once a crisis, now undetectable? An ethnographic study of ageing gay men´s long-term experience of HIV

C. Zraunig[1], E. Moyer[2]
[1]*University of Amsterdam, Medical Anthropology, Amsterdam, Netherlands,* [2]*University of Amsterdam, Anthropology, Amsterdam, Netherlands*

Background: The psycho-social wellbeing of men-who-have-sex-with-men (MSM) is increasingly recognized as vital to public-health interventions, however little research has been conducted on how aging gay men's views on current HIV-interventions are shaped by history and memory.
This qualitative study examines how memories of the AIDS-crisis, i.e. the era before HAART (highly active antiretroviral therapy), shape the contemporary emotional states of self-identifying gay men in New York City and questions what the consequences might be for public health interventions.
Methods: Data was gathered in New York City between August and December 2017 through ethnographic research methods with 43 respondents born between 1945 and 1965. Methods included participant-observation, focus-groups, interviews and walk-along-discussions focusing on the urban landscape and HIV/AIDS related memories and memorials. Additionally, a discourse-analysis of contemporary HIV prevention campaigns was completed, focusing on the NYC Health Department's conceptualization of HIV, both as a pathogen and a historical event of crisis.
Results: The findings from the ethnographic methods show that memories about the AIDS crisis become *present* in informants' relations with their urban surrounding: As bearers of personal memory, buildings of friends lost to AIDS and commemoration sites evoke melancholia and thereby influence people's present-day emotional states. The discourse-analysis focused on the public health department's strategy "EtE" (Ending-the-Epidemic) with interventions such as PrEP (Pre-Exposure-Prophylaxis) or U=U (Undetectable=Untransmittable). These interventions render HIV invisible, both as a biological presence and as a historical event of crisis. Informants' experiences and ongoing relation

with their memories inscribed in the urban landscape transcend the timeline of HIV as "crisis" (the era before HAART) and an "ending epidemic" (contemporary discourse). As a result, informants often experience feelings of alienation in the context of public health interventions.
Conclusions: Reflecting on the results, an assemblage approach to memory is proposed. Conceptualizing memory as assemblages of material and immaterial components (the urban landscape and personal biographies) can enable public-health strategists to better understand how emotional states of ageing gay men are shaped by their experiences of the multiple temporalities of HIV and how this can lead to feelings of alienation in the context of contemporary public-health interventions.

Knowledge translation and dissemination of research and programme outcomes

TUPED363

The Dance4Life youth empowerment model: A catalyst to foster the role of young people in promoting sexual lives and relationships

S. Adhikari[1], A. Mishra[2]
[1]Restless Development, Programme, Kathmandu, Nepal, [2]Dance4Life, Business Development, New Delhi, India

Background: Nepal has been able to make some substantial progress in HIV and AIDS response from the period 1988, when the first case of HIV infection was identified. In line with the SDGs, Nepal Government has set a national target of reducing HIV prevalence among men and women aged 15-24 years to 0.01 (by 2030) from 0.03 (2015). Government of Nepal has also acknowledged the role of civil society organizations in this substantial decrement of HIV prevalence in the country.
Being one and only international NGO working in Nepal, Restless Development has focused its' activities for harnessing the leadership of young people and to engage them as 'Young Leader' to change their community by giving right information at right time, by providing counseling and psychosocial support and to guide the young people for positive transformation of society.
Methods: As a partner of Dance4Life, Restless Development works in Nepal to capacitate young people as leaders and develop platforms to engage them to empower community. It pilots the 'Youth Empowerment Model' among the young people since November 2017. In this course, Restless Development has been piloting the 'Journey4Life' (18 sessions curricula) to impart socio emotional competencies, SRH Knowledge, gender equal attitudes, awareness and willingness to change harmful norms to foster behavior change among young people. The curriculum is delivered by 'champions4life' (peer leaders) among 600 young people. Rigorous monitoring and evaluation has been in-built during this process to capture the learning and best practices so as to build the model to empower millions of young people.
Results: Empowerment model, builds with the critiques that knowledge only is not sufficient to change the behavior and scientific SRHR education is not enough to challenge the deep rooted SRHR taboos and increase confidence, gender equality and desire to challenge harmful norms. Hence, empowered young people lead the journey that starts from the self 'me' (building confidence), pass through the 'me & you' (relationships) and goes to 'me & society' (challenging norms).
Conclusions: Empowerment model has been effectively working to change young people for having healthy sexual lives and relationship.

TUPED364

Using archival materials, art and poetry to improve sexual and reproductive global health training and programs

K.A. Stewart[1], M. de Bruyn[2], R. Ingold[3], K.K. Swain[4]
[1]Duke University, Global Health, Durham, United States, [2]Independent Scholar, Chapel Hill, United States, [3]Duke University, Durham, United States, [4]Oxford University Museum of Natural History, Oxford, United Kingdom

Background: Since 2000, critiques of international clinical research have emphasized the need to prevent unnecessary duplication, reduce wastage of results and learn from the past. This also applies to global health research and work. A university course now trains global health students to use archival materials to avoid "re-inventing the wheel", while applying lessons on what works and identifying coverage gaps. Published and grey literature can identify how HIV and AIDS, gender, sexual orientation and reproductive rights have been tackled through behavior communication, education, training, activism. Insights gained lead to re-use and updating of successful approaches, inform new approaches and take into account the needs and desires of the people affected.
Description: Trainees apply „concrete poetry", an art technique best illustrated by Tom Phillips´ Humument project, to process materials from a sexual and reproductive health and rights (SRHR) archive, culminating in reflective writing and public presentations. After choosing a page from archival materials, participants use the word-based art technique, effacing most of the text using color markers, fabric, stickers, ephemera, etc.; they leave words, phrases, and letters on the page which flow together to create an entirely new story and artwork.

[Example: HIV and AIDS Archival Data After Humument Art Treatment]

Lessons learned: The course helps trainees learn the importance of archival material for the future of global health and SRHR. We offer a description of participant learning through an analysis of both the resulting Humument artwork and the written reflective essay. A common theme was transforming negative narratives associated with challenges related

to HIV, violence and stigma into messages of hope and increased agency on the part of affected persons. Participants also reflect on how the evolution of global health approaches can be seen through both successes and failures of interventions and health programs.
Conclusions/Next steps: We hope future trainees and workers in SRHR will incorporate successful past approaches into their programs, giving space to the perspectives of people affected. A new grant will develop training materials, such as a graphic novel, based on archival material showing how the treatment of women living with HIV has changed over the past three decades and how women have confronted HIV transmission in different parts of the world.

TUPED365

Listen to the experts; how policymakers and influencers like to receive evidence

J. Koch
Mott MacDonald, EHPSA, Johannesburg, South Africa

Background: Evidence points towards the importance of strategic approaches to communication for research uptake in policy, moving beyond simple "dissemination" models towards facilitating joint interpretation and dialogue. This abstract provides key insights into how policymakers like to receive evidence related to HIV prevention for key populations and vulnerable groups in eastern and southern Africa.
Methods: The study triangulated three sources of evidence: a knowledge synthesis of 63 published papers and 14 case studies on the role of evidence in health policymaking in the ESA region; survey responses policymakers (N=19), and interviews with key HIV policymakers (N=9).
Results:
· Policymakers prefer receiving evidence in face- to-face meetings, encouraging two-way engagement that allows for joint interpretation of results and identifying implications.
· Policymakers prefer a series of engagements and dialogues rather than a one-off event.
· Policymakers appreciate evidence briefs/policy briefs and PowerPoint presentations. These should be clear, brief, jargon-free, and provided as part of face-to-face interactions.
· The 'messenger' matters: policymakers showed sensitivity to the approach of individuals who present research results.
· Messaging around HIV prevention for key populations is particularly challenging and sensitive.
· There are risks involved in communicating evidence. These include misinterpretation of results and negative perceptions among policymakers about researchers' motivations.
· Mass media are influential in debates about HIV prevention for key and vulnerable populations. National TV, print and radio were the most popular sources of media. Misinterpretations by the media are a concern and media are sometimes seen as a more appropriate channel for influencing public opinion rather than targeting policymakers.
· Social media did not appear to be a significant channel of communication.
Conclusions:
· To have maximum impact, messages around HIV prevention for key populations should be practical and consider taking a health rather than a rights-based approach.
· Effective communication is about relationships. Start early and engage continuously and responsibly throughout the research continuum. Effective engagement is a series of dialogues in which policymakers and researchers work together.
· Poorly managed relationships with policymakers can not only damage research uptake from a specific programme, but also affect other researchers.

TUPED366

Setting the global research agenda on faith sector engagement for HIV service delivery and HIV prevention services

M.T. Teijema[1], M.O. Kok[2], S.L. van Elsland[1,3], D.R. Barstow[4], A.M. van Furth[1]
[1]VU University Medical Center, Department of Paediatric Infectious Diseases, Amsterdam, Netherlands, [2]Erasmus School of Health Policy and Management at Erasmus University Rotterdam, Department of Health Care Governance, Rotterdam, Netherlands, [3]Stellenbosch University, Paediatrics, Cape Town, South Africa, [4]EMPACT Africa, Corvallis, United States

Background: The faith sector is expected to play a crucial role organizing community based services and achieving the UN Fast Track goals to ending AIDS. While numerous reports and some empirical studies are available, robust primary research is needed to find the most effective and efficient strategies through which the faith sector can contribute in achieving these goals. The aim of this study was to set an inclusive global research agenda reflecting priority research questions from key international and national organizations and stakeholders at the intersection of HIV healthcare and religion.
Methods: To develop a socially robust research agenda, we combined the Delphi method and CHNRI methodology. Between March 2016 and January 2018, we interviewed 58 purposively selected key-informants, including leading policy makers, health care providers, faith leaders, academics, HIV activists and NGO and FBO representatives. Based upon these interviews a first list of main themes and priority questions was developed. This list was distributed as part of an online questionnaire to a large internationally representative group of 110 key-stakeholders. In addition, focus group discussions (2) served to prioritize emerging questions and themes and identify data gaps. Field notes and interviews were transcribed verbatim.
Results: Respondents to the questionnaire worked in 54 different countries, were mostly male (56%), had research experience (84%) and identified themselves as religious (79%). Nine research themes were filtered from the interviews: agenda setting, funding, evaluation of faith/health collaborations, stigma, advantage of faith initiatives, gender roles, specific populations, combined prevention, and counselling/disclosure. Improving engagement of faith communities in tackling stigma and addressing combined prevention (including sexuality), were prioritized for future research by most respondents. The prioritization of research aims and questions was related to stakeholder's professional experience, background, years of experience and work region.
Conclusions: A wide range of respondents participated in developing a research agenda, which represents a variety of international, national and local stakeholders. It is now important to implement this agenda together with researchers, funders and other key stakeholders. In order to align new research to the most urgent needs, enhance coordination, reduce research waste and increase the likelihood that results are being used.

Community engagement in research and research dissemination

TUPED367

"I'm doing something that matters, that might change the world we live in":cCommunity perspectives on advancing the HIV cure research agenda

A.K. Johnson[1], J. Pickett[2], J. Holliman[1], R. Fierro[2], G.J. Greene[3]
[1]Ann & Robert H. Lurie Children's Hospital of Chicago, Adolescent Medicine, Chicago, United States, [2]AIDS Foundation of Chicago, Chicago, United States, [3]Northwestern University, Medical Social Sciences, Chicago, United States

Background: Developing a cure for HIV requires a combination of innovative techniques and interventions, as well as the collaboration of multiple sectors and key stakeholders. It is imperative to gather input from

key populations living with HIV to advance a cure agenda. Early engagement of stakeholders is critical to navigating complex ethical issues, including risks and benefits, and ensuring proposed cure approaches are acceptable to target communities to promote future participation in cure research and therapies.

Methods: A series of focus groups were conducted with key stakeholders living with HIV in the United States to explore barriers and facilitators to participation in HIV cure research. Focus groups were conducted using a semi-structured script and were audio recorded, transcribed and coded using a directed approach to content analysis.

Results: A total of 18 people participated in 4 focus groups, all were living with HIV and represented diverse stakeholder groups: young men who have sex with men, men who have sex with men of color, trans and cis gender women. Participants, across populations, reported the need for concrete information about risks and benefits to participation in HIV cure trials as well as the need to have someone reliable to discuss options with (peer navigator, doctor). Facilitators included: incentives, helping others, and the possibility of being cured; barriers to participation included: health concerns, fear of disclosure, stigma and distrust of researchers/doctors. All participants expressed concern with experimental treatment and its impact on their current health and treatment options. Additionally, those who had been living with HIV for 10+ years discussed feeling like cure research was not for them.

Conclusions: Community perspectives should inform the advancement of an HIV cure research agenda. Our findings highlight areas of opportunity-particularly in addressing barriers to participation, as well as illuminate attitudes towards and interest in cure research from a community perspective. Increasing communication, transparency and collaboration between communities living with HIV and cure scientists is essential for the future of cure research and implementation.

TUPED368

Improving HIV cure clinical research engagement: Voices from stakeholders

A. Mathews[1,2], E. Valera[3], C. Harding[4], S. Day[2,5], M. Blumberg[2], S. Rennie[2,6], J. Tucker[7,8], D. Margolis[9]

[1]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Disease, Durham, United States, [2]University of North Carolina at Chapel Hill, Social Medicine, Chapel Hill, United States, [3]University of North Carolina at Chapel Hill, CARE Community Advisory Board, Chapel Hill, United States, [4]University of North Carolina at Chapel Hill, SCEED, Center for AIDS Research, Chapel Hill, United States, [5]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Disease, Chapel Hill, United States, [6]University of North Carolina at Chapel Hill, Center for Bioethics, Chapel Hill, United States, [7]University of North Carolina, Institute for Global Health and Infectious Disease, Chapel Hill, United States, [8]University of North Carolina at Chapel Hill, UNC-Project China, Guangzhou, China, [9]University of North Carolina at Chapel Hill, UNC HIV Cure Center, Chapel Hill, United States

Background: Clinical trials towards an HIV cure have begun in multiple sites around the world. Stakeholder engagement is essential for the ethical conduct of clinical trials. We define stakeholders as potential participants, medical professionals, community advisory boards, and researchers. Given that many cure studies have high individual risks and no individual benefits, this also presents a compelling rationale for strong community stakeholder engagement related to HIV cure research. This project identified stakeholders' priorities to improve HIV cure research engagement using a series of workshops.

Description: A collaboration of North Carolina researchers, community advisory board members, and a research engagement office members developed and conducted three stakeholder workshops (September to November 2017) lasting 4 to 6 hours each. A lead facilitator and two notetakers moderated workshop activities and reconciled detailed notes to identify overarching discussion themes. Workshops featured creative activities, didactic sessions explaining clinical research, invited speakers, small group brainstorming sessions, and larger group discussions. The overall purpose of the workshops was to improve informed consent processes for vulnerable populations, address stigma, and identify HIV cure communication strategies. Larger group discussions produced a consensus list of priorities for HIV cure research engagement.

Lessons learned: Thirty-seven stakeholders attended the workshop series, including community members (n=9), HIV cure community advisory board members (n=3), cure clinical trial participants (n=2), people living with HIV (n=10), healthcare providers (n=3), and researchers/university representatives (n=10). Participants prioritized ways to improve HIV cure research engagement:

1) use accessible language describing participant eligibility, study procedures, and risks/benefits
2) improve compensation mechanisms,
3) provide expanded mechanisms to file confidential complaints, and
4) provide access to wrap-around services for participants.

Many stakeholders noted a need for improved HIV cure literacy among people living with HIV and potential trial participants.

Conclusions/Next steps: Stakeholder workshops focused on HIV cure research are useful in understanding local concerns about clinical trial participation and setting priorities for improving engagement. Future work should focus on developing accessible materials that foster cure literacy among people living with HIV. Further stakeholder engagement is needed related to ongoing and planned HIV clinical trials towards a cure.

TUPED369

Women and the International AIDS Conference: Will anything change? An analysis of women living with HIV as abstract presenters at AIDS2016

M. Tholanah[1], M. Musiiwa[1], E. Bell[2], F. Hale[2], A. Welbourn[3]

[1]ICW Zimbabwe, Harare, Zimbabwe, [2]Salamander Trust Associate, London, United Kingdom, [3]Salamander Trust, London, United Kingdom

Background: The new WHO Guideline on the Sexual and Reproductive Health and Rights (SRHR) of women living with HIV (Section 6.2.1) calls for women living with HIV as equal partners in research. We sought to review data from AIDS2016 in this light.

Methods: The AIDS2016 Abstract Book was searched, containing keywords 'Women living with HIV'; 'WLHIV'; 'WLWH'. We discarded abstracts presented by academics and others only, and counted those (co) authored by a representative of an organisation of people/women living with HIV.

We also read all abstracts accepted for oral presentation sessions, to ensure inclusion of those co-authored by an organisational representative of people (including women) living with HIV and relevant to women living with HIV, even if they did not contain our keywords.

We triangulated this with International AIDS Society (IAS) data on AIDS2016 abstracts by women living with HIV.

Results: 43 abstracts contained our keywords, and of these the following were (co)authored by an organisational representative of people living with HIV: Poster Exhibition: 8 Poster

Discussion: 2 Oral Abstract: 1.

Further review of all oral abstracts revealed 4 additional abstracts co-authored by an organisational representative of people/including women living with HIV. None of these was explicitly gendered or women-focused.

IAS data showed that 2% of 1048 women presenters at the conference self-identified as HIV-positive. 142 self-identified HIV positive women submitted abstracts. Of these, 21 (15%) abstracts were selected, 120 (85%) were rejected, 1 (< 1%) accepted but withdrawn.

Abstracts from all 17 self-identified positive trans people were rejected (100%).

Of 137 invited women speakers. 15 (11%) identified as HIV positive.

Conclusions: Our review of all abstract co-authors mirrors the IAS data, which shows a marked scarcity of abstract presenters who self-identify as living with HIV.

Further, women living with HIV are almost completely absent from presenting research beyond a Poster Exhibition.

We will compare these findings with representation of all women living with HIV, including trans women, at AIDS2018. This will support the future improved involvement of women living with HIV in abstract-driven sessions presented at AIDS2020 and beyond, to uphold the recommendation in the new WHO Guideline.

TUPED370

Qualitative and community-based approaches to maternal disclosure in the pediatric HIV/AIDS cohort study (PHACS)

C. Berman[1], D. Kacanek[2], M. Nichamin[1], M. Reznick[3], K. Sanders[4], S. McCann[5], E. Chadwick[6]
[1]Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States, [2]Harvard T.H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [3]Westat, Rockville, United States, [4]Baylor College of Medicine, Houston, United States, [5]University of California San Diego, San Diego, United States, [6]Northwestern University Feinberg School of Medicine, Chicago, United States

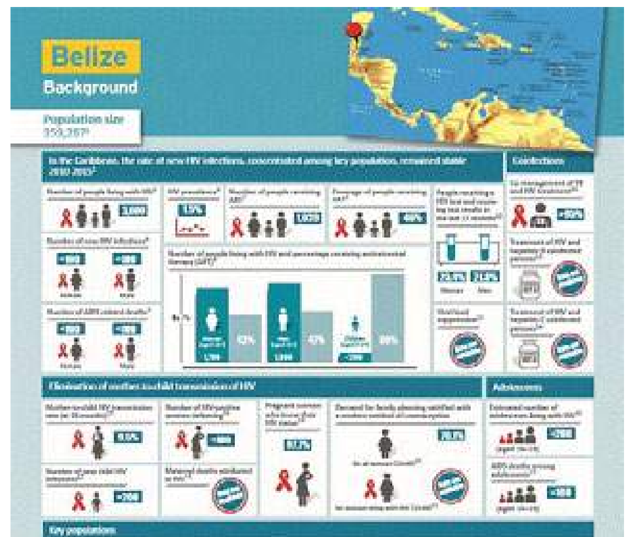
Background: In order to consent to participate in long-term research about their perinatal exposure to HIV and antiretrovirals, and to discuss these topics within their own health care, perinatally HIV-exposed but uninfected (PHEU) young adults (YAs) must be aware of their mother's HIV diagnosis. Understanding factors contributing to successful maternal disclosure is critical for this process. In the U.S.-based Surveillance Monitoring for ART Toxicities (SMARTT) protocol of PHACS, which studies long-term safety of in utero antiretroviral exposure, many PHEU participants are approaching adulthood, yet only 30% of participants ≥12 know their mother's HIV status. To identify and address families' needs around disclosure, we investigated caregiver and YA experiences of maternal HIV disclosure through qualitative and community-guided approaches.
Methods: In 2013-2014, at 8 PHACS clinical sites, we conducted in-depth interviews with 7 PHEU YAs who were 18-24 years old and aware of their mother's status (71% female, 57% Black) and 13 caregivers (75% female, 83% >40 yo, 50% Black) about their perceptions/experiences regarding participation and communication preferences in HIV research. Thematic analysis of coded transcripts using Atlas.ti revealed maternal disclosure to be a salient topic for both caregivers and YAs. Additionally, we engaged YA and Adult Community Advisory Board (CAB) members and PHACS clinical staff in facilitated interviews, story circles, and focus groups.
Results: Caregivers, CAB members, and clinical staff shared key factors regarding disclosure decisions, including HIV stigma as a primary barrier, disclosure as a process over time, the impact of disclosure on family units, and choosing age-appropriate information for children. They identified education, peer support, and culturally relevant resources as important tools for making informed disclosure decisions. PHEU YAs described varied responses to learning of their mother's diagnosis and attitudes towards connecting with peers affected by HIV. Disclosure comics to facilitate family discussions and staff guidelines were developed and have been positively received: https://phacsstudy.org/Education-Hub/HIV-Disclosure-Comics.
Conclusions: Results from qualitative and community-guided approaches to maternal disclosure can guide researchers and practitioners in supporting caregivers to make informed disclosure decisions. These approaches could positively impact research acceptance and retention to support a better understanding of the long-term safety of perinatal exposure to HIV and antiretroviral regimens.

TUPED371

Using robust, evidenced based infographics in 6 Caribbean countries to inform community advocacy, and illustrate the reforms necessary to meet UN sustainable development goals, and show the human rights challenges

J. Shepherd[1], W. Tannis-Abbott[1], S. Jiwan[2], J. Hows[3]
[1]Caribbean Regional Network of People Living with HIV (CRN+), Diego Martin, Trinidad and Tobago, [2]Global Network of People Living with HIV (GNP+), Amsterdam, Netherlands, [3]Development Research Advocacy Governance (DRAG), Amsterdam, Netherlands

Background: The Caribbean Regional Network of People Living with HIV (CRN+), supported by the Global Network of People Living with HIV (GNP+) and the Robert Carr Network Fund identified a need to show linkages in a clear way between all of the issues that impact upon the HIV response in countries in the Caribbean; to promote working between sectors, to support synergies for action, and to engage communities in a easily understandable way.
Methods: In 2016/7 we developed a series of environmental scans; they cover some 200 key indicators under 10 main page headings - fully referenced in a partner document.
These heading are: Population and demographics; Policies, strategies and laws; TB, viral Hepatis, and cervical cancer; Stigma, discrimination and gender based violence; Children and adolescents; Key Populations; EMTCT; HIV testing counselling and treatment; Human resources, service coverage, stock-outs and rapid assessments; Spending and funding.
Currently we have covered 6 countries - Belize, Dominican Republic, Guyana, Haiti, Jamaica, Trinidad and Tobago, The data was collected through desk review and Key informant interviews with National AIDS Programs, people living with HIV, key populations and partner organisations.
Results: A snapshot of the results for one country - one page:



[Belize environmental scan]

The wealth of data able to be displayed clearly and accessible to all by this method is incredible- especially when each graphic representation is fully referenced by footnotes showing the source of the information - with the appropriate links. The scans have been extensively used in countries by many agencies and sectors - as well as being invaluable as a tool in CRN+ and others in assessing the strategic needs and priorities for action at all levels of the response.
Conclusions: It is true that a picture is worth a thousand words- working in this way has made sometimes ´impenetrable´ data accessible; this has enhanced the response and allowed for synergies between sectors. The next steps are to develop more data scans - and put some of the key data that drives the infographics onto a searchable and publicly accessible and searchable database.

TUPED372

Community and provider attitudes towards treatment interruptions in HIV cure trials

J.S.Y. Lau[1,2], M.Z. Smith[3,4], B. Allan[5,6], C. Martinez[7], J. Power[8], S.R. Lewin[3,4], J.H. McMahon[1,2]
[1]The Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia, [2]Monash University, Melbourne, Australia, [3]The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [4]Melbourne University, Melbourne, Australia, [5]International Council of AIDS Service Organizations, Toronto, Canada, [6]Australasian Society for HIV, Viral Hepatitis and Sexual Health Medicine, Sydney, Australia, [7]National Association of People Living with HIV Australia, Sydney, Australia, [8]Australian Research Centre for Sex Health and Society, La Trobe University, Melbourne, Australia

Background: Analytical treatment interruption (ATI) is being used increasingly to assess effects of interventions aimed at curing HIV or achieving antiretroviral therapy (ART)-free HIV remission. While a critical outcome in cure trials, ATI poses potential risks. Understanding of ATI acceptability and how ATI should be conducted amongst people living with HIV (PLHIV) and their HIV healthcare providers (HHP) is limited.
Methods: Two online surveys for PLHIV and HHP assessed understanding and acceptability of different monitoring strategies during ATI (frequency of CD4, viral load (VL) and clinical assessment), potential risks of ATI and the prospect for HIV cure. The PLHIV survey also assessed motivation for enrolling in cure trials and the HHP survey assessed support for ATI trials for PLHIV in their care. Responses were collected from July 2017-January 2018. Survey results were compared using ^{2} test between PLHIV and HHP for ATI monitoring strategies and perceptions of cure research.
Results: 442 PLHIV completed the survey: 21% female, 61% ≤ 50 years old, 24% identified as heterosexual, 95% on ART and 83% reported undetectable VL. 55% believed an HIV cure would be achievable within 10 years. The commonest preferred frequency of CD4, VL and clinical monitoring during ATI was monthly (31%, 35%, and 39% respectively). 59% stated they would be more willing to undergo ATI if home based VL testing was available, 51% if nurses could perform home visits, and 54% if pre-exposure prophylaxis was offered for HIV negative partners. 144 HHP completed the survey: 72% practiced in Australia, 51% work in teaching hospitals, 24% in community based family practices and 15% in sexual health clinics. 19% HHP believed a HIV cure would be achievable within 10 years.
Responses from questions comparable in both surveys demonstrate: higher optimism for cure amongst PLHIV, higher awareness of ATI in HHP, decreased acceptability of sustained viremia in PLHIV and similar acceptability of changes in CD4 (Table).
Conclusions: PLHIV were more optimistic about the potential for HIV cure than HHP, but were less aware of ATI or willing to have periods of sustained viraemia. Clear education messages in relation to ATIs should be developed for both PLHIV and HHP.

Survey Question	People living with HIV (PLHIV)^ (n=442)	HIV Healthcare Providers (HHP)^ (n=144)	P-value*
HIV cure achievable in next 10 years	226/410 (55)	26/140 (19)	<0.01
HIV cure not achievable in lifetime	58/410 (14)	23/140 (16)	0.4
Ever participated/enrolled a patient in HIV cure-focused trial	21/412 (5)	25/140 (18)	<0.01
Aware of ATI	182/399 (46)	86/138 (62)	<0.01
Would not allow a sustainable period with a detectable viral load (recommence after a detectable viral load)	136/387 (35)	24/136 (18)	<0.01
Would allow ATI for long as necessary to test trial intervention if remained well	99/387 (26)	37/136 (27)	0.7
Want CD4 to remain >350 during ATI	286/359 (80)	120/137 (88)	0.04

NOTES: ATI, analytical treatment interruption
* compared using χ^2 test
^ proportion of participants who responded to the question (%)

TUPED373

The InvestiGAYtors program: Developing research capacity among young gay, bi and other men who have sex with men

S. Nam[1,2], D. Brennan[2], A. Ablona[3], F. Ibanez-Carrasco[4], B. Adam[1,5], M. Gilbert[6], A. Kroch[1], N. Lachowsky[7], O. Ferlatte[8], J. Morgan[9]
[1]Ontario HIV Treatment Network, Toronto, Canada, [2]University of Toronto, Toronto, Canada, [3]University of British Columbia, Vancouver, Canada, [4]St. Michael's Hospital, Toronto, Canada, [5]University of Windsor, Windsor, Canada, [6]BC Centre for Disease Control, Vancouver, Canada, [7]University of Victoria, Victoria, Canada, [8]University of Bristish Columbia, Vancouver, Canada, [9]Community Based Research Centre for Gay Men's Health, Vancouver, Canada

Background: The epidemiological monitoring of the sexual health of gay, bi, and other men who have sex with men (GBMSM) is often developed and implemented in a top-down manner, and results can be communicated in stigmatizing ways. Modelled after a program developed by the Community-Based Research Centre for Gay Men's Health in Vancouver, a diverse volunteer group of GBMSM youth (ages 18 to 29) were mentored in Toronto, Canada to do the formative work toward proposing a sustainable, community-led periodic sexual health monitoring survey for GBMSM.
Description: The InvestiGAYtors met weekly, and they received over 114 hours of instruction by a volunteer faculty of academics and community leaders. Curriculum included basics of HIV epidemiology, research methodology, qualitative interviewing, and presentation skills. They also learned about the history of GBMSM health research in Canada and basics of knowledge transfer and exchange (KTE). To apply research skills they learned, the InvestiGAYtors conducted 10 interviews with well-established HIV researchers around the world who are conducting major monitoring surveys of GBMSM, and analyzed the data to identify best practices to implement a periodic sexual health monitoring survey for GBMSM in Ontario.
Lessons learned: Seven InvestiGAYtors completed the program. Their learning and progress in acquiring knowledge and skills were measured at pre and post-training points using one self-reported instrument (ranging from "novice" to "experts") and one civic leadership skills measure. Two focus groups were also conducted to assess key features of the program. Most Investigaytors reported an increase in knowledge, skills and experiential areas (e.g., meeting diverse queers), an enhanced team spirit and increased engagement with the GBMSM communities. By learning about key aspects of research such as sampling, survey design, community input, the investigaytors reported having developed a critical lens towards GBMSM health research.
Conclusions/Next steps: Our program successfully engaged GBMSM youth in the fundamentals of sexual health surveys for GBMSM. The process of engaging communities affected by HIV became opportunities for community capacity building and development. Our graduates became enthusiastic proponents of queer sexual health and health research in their communities. Following the success of the pilot cohort, a new cohort of thirteen InvestiGAYtors has started in 2017.

TUPED374

Engaging young Tanzanian women in participatory research to understand structural drivers of HIV and disseminate results to the community

P. Balvanz[1], J. Wamoyi[2], A. Pettifor[1], K. Atkins[1], S. Maman[1]
[1]University of North Carolina, Chapel Hill, United States, [2]National Institute of Medical Research, Mwanza, Tanzania, United Republic of

Background: Young women in sub-Saharan Africa are disproportionately affected by HIV and their vulnerability is exacerbated by poverty and inequitable gender norms. With limited access to income, young women depend on partners, thus reducing their decision making power in relationships. Photovoice, a participatory research method, gives agency to vulnerable populations to describe problems in their own voices and to lead actions to promote change. We used Photovoice with young women to explore factors influencing their HIV risk, and voice these concerns to local leaders.

Methods: We engaged two groups of young women (rural n=7, urban n=8) aged 17-24 from Western Tanzania in a Photovoice project in October 2017. Across four sessions participants used photography to document the role, aspirations and challenges of young women in their community, and the impact of having resources. Based on the discussions that followed the photo elicitation young women described key factors that affect their vulnerability to HIV, as well as their ideas for how to combat HIV. Following the fourth session, rural and urban participants met to share findings and develop an agenda and an invitation list for a community forum to discuss their findings with community stakeholders. The young women invited local and regional government officials, NGO and development workers, community leaders, role models, and medical personnel.
Results: Young women identified the following structural factors driving HIV risk for women in their communities: limited access to education which increases dependence, cultural norms that minimize options for earning or borrowing capital, and laws that disproportionately punish girls for adolescent pregnancy. Community forum breakout sessions highlighted these key drivers of HIV risk. Key recommendations from participants included: involvement of men in sexual health programming and addressing gender norms that lead to adolescent pregnancy and cause young women to feel responsible.
Conclusions: Photovoice empowered young women to explore structural factors that put them at risk for HIV acquisition, and to discuss these factors with decision makers in the community. These young women highlighted the role of gender inequity and lack of access to professional development in increasing their HIV risk.

TUPED375

Data difficulties encountered in crowdsourcing information on legal & regulatory barriers to accessing HIV services (testing and care) for key populations across Europe

J.V. Hows[1], L. Power[2], S. Jakobsen[3], L. Sprague[4], A. Von-Lingen[5], M. Dutarte[5]
[1]DRAG, Development Research Advocacy Governance, Amsterdam, Netherlands, [2]HIV Justice Network, Amsterdam, Netherlands, [3]CHIP, Department of Infectious Diseases, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [4]GNP+ Global Network of People Living with HIV, Amsterdam, Netherlands, [5]EATG European AIDS Treatment Group, Brussels, Belgium

Background: Crowdsourcing information about service conditions can be a useful tool for both information gathering and community engagement. It is important to be aware of its uses and limitations.
Methods: Between 2015-2107 OptTEST researchers compiled a European country survey of legal and regulatory barriers to HIV services, in English and Russian. They solicited activist/NGO responses alongside governmental/legal ones through mailing lists and listservs. Responses were checked for internal consistency and against each other and external verified data sources where these existed. Most responses came from NGO and PLHIV organisations and a few individual activists. The website was published in 2017 and continues to be updated on an iterative basis.
Results: Initial responses were received from 32 countries. 18 had single respondents and others between 2 and 8. While all the responses were helpful and most were rigorous, 11/32 had identifiably inaccurate or contradictory responses e.g. 5 stated that treatment was free to all but subsequently reported not to some or all migrants. One country had 7 respondents, none of whom fully agreed with any other. As a result, all responses were subsequently checked by further research. Laws relating to migrants and sex workers had the least accurate responses, while regulations about who could test for HIV and access to HCV testing were frequently disputed between different respondents from the same country. Causes of variations included: federal systems with devolved healthcare and laws; disparities between national regulations and local practices; lack of familiarity with laws affecting some key populations.
Conclusions: While crowdsourcing data has many benefits, its drawbacks must be managed. Respondents should be encouraged not to offer helpful guesses and desk research should be used to cross check reliability. NGOs and community organisations aiming to help all PLHIV and other affected populations should be supported to increase their understanding and knowledge of laws which may impede access for some key populations to be able to act on it at the appropriate level.

Role of social and behavioural science in biomedical responses

TUPED376

Level of knowledge and attitude of medical students to the problem of TB and HIV

N. Kolisnyk
Dnepropetrovsk Medical Academy, Phthisiology, Dnipro, Ukraine

Background: Tuberculosis and HIV infection affect the most active, young part of the population, contributing to the creation of a serious threat to the demographic situation in Ukraine.The purpose of our study was to determine the degree of awareness students of Dnipropetrovsk Medical Academy in various issues on HIV / AIDS and tuberculosis.
Methods: 388 students of IV and VI courses aged from 20 to 30 of medical faculties in the Academy took part in our study, All respondents filled out a questionnaire, which included questions for assessing students' awareness about diagnosis, prevention, relevance of the problem of HIV / AIDS and tuberculosis.
Results: Most students (89.7%) consider the problem of TB and HIV infection very relevant.The most of the fourth and sixth year students were correctly oriented in relation to the risk factors for HIV infection, clinical manifestations of the disease. At the same time, students were not sufficiently knowledgeable about HIV, believing that the main mode of transmission is currently injecting (91.8% of fourth-year students and 96.3% of sixth-year students). About a quarter of respondents underestimated the likelihood of the spread of HIV infection during manipulations with the use of manicure, dental instruments. The overwhelming majority of students in courses 4 and 6 (92.7% and 87.1%, respectively) do not trust the means of mechanical contraception, as reliable, at sexual contacts.Students are also not sufficiently informed about the treatment of tuberculosis and HIV infection. More than a third of the students surveyed (38.5%) believe that tuberculosis can not be cured. Negative attitude to antiretroviral therapy was expressed by 89 (22.9%) respondents, considering it ineffective and dangerous due to adverse reactions.
Conclusions: Despite the fact that students note the relevance of TB and HIV infection to society, medicine, they are not sufficiently informed in the modern mechanisms of the spread of diseases, individual remedies, prevention and treatment of diseases.

Research data disaggregation by factors such as sex, age, race/ethnicity, sexual orientation, etc.)

TUPED377
Gender based differences in clinical characteristics and social barriers to HIV care among HIV-infected participants in four African countries

K. Ganesan[1,2], A. Esber[1,2], T.A. Crowell[1,2], C. Polyak[1,2], E.H. Lee[1,2], P. Coakley[1,2], E. Bahemana[3], Y. Adamu[4], F. Kiweewa[5], J. Maswai[1,6,7], J. Owuoth[1,7,8], J. Ake[1]
[1]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]Mbeya Medical Research Centre, Mbeya, Tanzania, United Republic of, [4]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Abuja, Nigeria, [5]Makerere University-Walter Reed Project, Kampala, Uganda, [6]Henry M. Jackson Foundation Medical Research International, Kericho, Kenya, [7]Kenya Medical Research Institute, Nairobi, Kenya, [8]Henry M. Jackson Foundation Medical Research International, Kisumu, Kenya

Background: Gender-based differences in social barriers and clinical outcomes that affect HIV care can be attributed to strong cultural gender norms in Africa. We assessed gender-based differences in social barriers to HIV care among HIV-infected adults in Uganda, Tanzania, Kenya and Nigeria to identify and target gender-specific interventions.
Methods: AFRICOS is an ongoing cohort that enrolls adults at 12 PEPFAR-supported HIV care facilities. Clinical evaluations were conducted and socio-demographic data was collected using questionnaires at enrollment to evaluate social barriers for HIV-infected participants. Participants were asked to report any history of HIV-related stigma, HIV-related stigma disrupting HIV care, sexual assault, physical assault, and displacement due to violence in the home. Socio-demographic and clinical characteristics were compared across gender using Chi-squared and Kruskal-Wallis tests. Binomial logistic regression was used to estimate adjusted odds ratios (AOR) and 95% confidence intervals (CI) for each social barrier comparing men and women at enrollment, controlling for age and facility.
Results: Between January 2013 and September 2017, 2,683 HIV-infected participants were enrolled, including 1,579 (59%) women. The median age at enrollment for women was significantly younger than men (36.8 vs. 41.8 years of age). Women had a younger median age of HIV diagnosis, higher median enrollment CD4 counts, and lower frequency of advanced HIV disease (CD4< 200 or WHO stage 3 or 4) (Table 1). Women were more likely to have experienced HIV-related stigma (AOR 1.34, 95% CI 1.04-1.73), sexual assault (AOR 3.91, 95% CI 1.33-11.52) and physical assault (AOR 1.81, 95% CI 1.37-2.42) (Figure 1). The odds of stigma interfering with HIV care and displacement due to violence was not significantly different between men and women.
Conclusions: Both men and women are underserved in different aspects of HIV care. Despite experiencing more social barriers, women are diagnosed and engaged in care earlier in their disease process, which may be due to availability of women-centric services such as prenatal care. Implementation of targeted support services will be key in mitigating social barriers that may adversely impact clinical outcomes despite engagement in care. Targeted interventions to engage men in HIV care earlier are also needed.

	Male (N=1104)	Female (N=1579)	Total (N=2683)	P-value
Median Age (IQR)	41.8 (34.8-49.5)	36.8 (30.2-43.8)	38.7 (31.8-46.3)	<0.001
Median Age at Diagnosis (IQR)	38.1 (31.8-45.1)	32.7 (27.2-39.9)	35.0 (28.8-42.3)	<0.001
Median Viral Load, copies/mL (IQR)	49.0 (TND*-28679.0)	64.5 (TND*-19131.0)	56.0 (TND*-21977.0)	0.85
Median CD4, cells/mm³ (IQR)	326.0 (209.0-486.3)	434.0 (272.0-619.0)	388.6 (236.0-570.0)	<0.001
Advanced HIV Disease (n,%)	502 (45.5%)	541 (34.3%)	1043 (38.9%)	<0.001

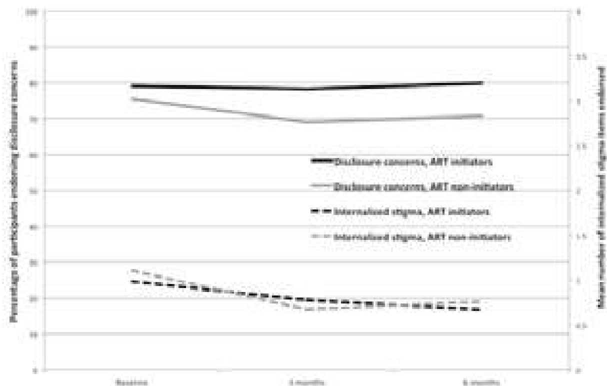
TUPED378
Trajectories of HIV-related internalized stigma and disclosure concerns among ART initiators and non-initiators in South Africa

B. Chan[1,2], B. Maughan-Brown[3], L. Bogart[4], V. Earnshaw[5], J. Dietrich[6], C. Orrell[7], G. Gray[6,8], D. Bangsberg[9], I. Katz[1,2,10]
[1]Brigham and Women's Hospital, Medicine, Boston, United States, [2]Harvard Medical School, Boston, United States, [3]University of Cape Town, Southern Africa Labour and Development Research Unit, Cape Town, South Africa, [4]RAND Corporation, Health Unit, Santa Monica, United States, [5]University of Delaware, Department of Human Development and Family Science, Newark, United States, [6]University of the Witwatersrand, Perinatal HIV Research Unit, Faculty of Health Sciences, Johannesburg, South Africa, [7]University of Cape Town Medical School, Desmond Tutu HIV Centre, Cape Town, South Africa, [8]South African Medical Research Council, Cape Town, South Africa, [9]Oregon Health & Science University-Portland State University School of Public Health, Portland, United States, [10]Massachusetts General Hospital, MGH Global Health, Boston, United States

Background: HIV-related stigma among people living with HIV (PLHIV) is associated with poor mental health and reduced adherence to anti-retroviral therapy (ART). Engagement in HIV care and ART initiation may attenuate stigma through ART-related counseling and improvements in health that restore economic viability and social connectedness. Most of the data supporting this hypothesis have been derived from qualitative studies. We used longitudinal data from a clinic-based sample of black South Africans to assess changes in stigma among PLHIV after engagement in care and whether ART initiation is associated with stigma reduction.
Methods: We administered the Internalized AIDS-Related Stigma Scale (IARSS, a six-item dichotomous scale questionnaire) at baseline, 3 months, and 6 months to newly diagnosed ART-eligible participants between 2014-2015. A confirmatory factor analysis indicated that the IARSS contained a four-item internalized stigma factor (=0.80) and a two-item disclosure concerns factor (=0.75). Thus, we examined the relationship between ART initiation and internalized stigma/disclosure concerns while adjusting for sociodemographic characteristics, using generalized estimating equations (GEE) to estimate model parameters.
Results: Of the 500 participants (187 men and 313 women) who were enrolled, 308 (62%) initiated ART. Internalized stigma declined over 6 months among both ART non-initiators (mean score, 1.1 to 0.8, p=0.02) and ART initiators (1.0 to 0.7, p< 0.01). However, disclosure concerns did not decrease over the study period, either among ART non-initiators (percentage endorsing either disclosure concern item, 76% to 71%, p=0.34) or ART initiators (79% to 80%, p=0.90). Using GEE regression models, we estimated a statistically significant positive association between ART initiation and disclosure concerns (b=0.13; 95% Confidence Interval [CI], 0.04-0.21) but not between ART initiation and internalized stigma (b=0.14; 95% CI, -0.02 to 0.31).

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

Conclusions: Among black South African PLHIV engaged in HIV care, internalized stigma modestly declined over time among both ART non-initiators and initiators. However, disclosure concerns persisted, with ART initiators more likely to have persistent disclosure concerns over time compared with non-initiators. Policymakers should consider interventions to create environments in which PLHIV, especially ART initiators, can safely disclose and obtain social support.



[Disclosure concerns and internalized stigma among ART initiators and non-initiators in South Africa at baseline, 3 months, and 6 months in care]

TUPED379

Health-related quality of life of people living with HIV in Spain

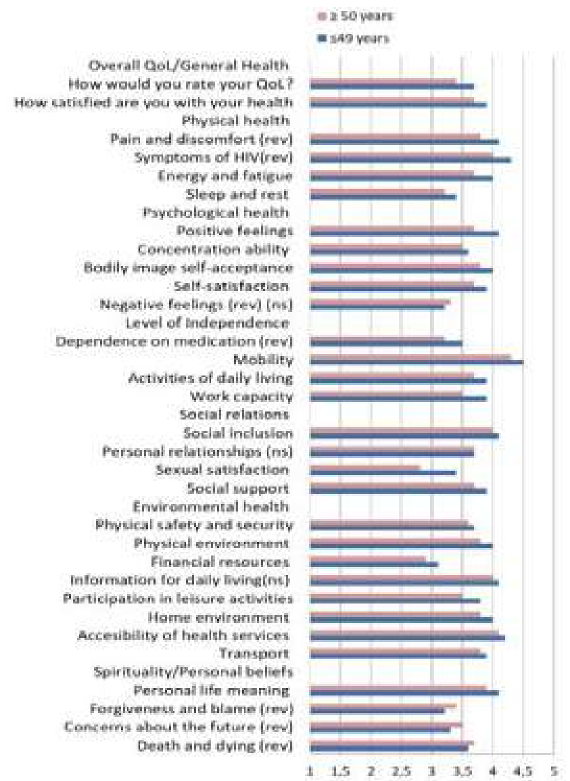
M.J. Fuster Ruiz de Apodaca[1], A. Laguia[2], J. del Amo[1,3], P. Arazo[4], D. Dalmau[5], R. Font[1,5], J.C. Lopez[1,6], F. Lozano[1,7], E. Negredo[1,8], M. Pastor[1,9], S. Cenoz[10], M.J. Galindo[1,11]
[1]SEISIDA, Madrid, Spain, [2]UNED, Madrid, Spain, [3]Instituto de Salud Carlos III, Madrid, Spain, [4]Hospital Miguel Servet, Zaragoza, Spain, [5]Hospital Mutua Terrassa, Barcelona, Spain, [6]Hospital Gregorio Marañón, Madrid, Spain, [7]Hospital Valme, Sevilla, Spain, [8]Hospital Germans Trias i Pujol, Badalona, Spain, [9]Bizcaisida, San Sebastián, Spain, [10]ViiV Healthcare, Madrid, Spain, [11]Hospial Clínico Universitario, Valencia, Spain

Background: Improving the health-related quality of life (HRQoL) of people living with HIV (PLHIV) has been proposed as an additional goal ('the fourth 90'), together with testing and treatment targets ('90-90-90'). This study aimed to examine how is HRQoL in PLHIV in Spain, describe which facets are more impaired, and identify those PLHIV with the most vulnerable profiles. Besides, associations between HRQoL with health-related questions were examined.

Methods: A total of 1462 PHIV participated in an observational cross-sectional study conducted between October 2016 and April 2017. Data were collected throughout 33 Spanish HIV centers (clinics and NGOs) through an online self-administered survey. HRQoL (WHOQOL-HIV-BREF), treatment adherence (CEAT-VIH), psychological well-being (GHQ-12), self-reported health status questions, and demographics were measured. Pearson's correlation, T-test, and one-way variance analyses were used to examine HRQoL differences and associations.

Results: Most participants were men (79.3%), and 52.5% were homosexual. Mean age was 45.0±10.2. The HRQoL facets showing lower scores were *financial resources, sexual satisfaction, sleep and rest, negative feelings,* and *forgiveness and blame*. Across domains, the Physical Health and the Level of Independence showed the higher scores while the Spiritual domain presented the lowest score. To be a woman ($p< .0001$), heterosexual ($p< .0001$), to have a low socio-economic ($p< .0001$) and educational status ($p< .0001$), having acquired HIV through injection route ($p< .0001$) and be living with HIV for a longer time ($p< .01$), were all related with poorer HRQoL. PLHIV older than 50 presented lower scores in several HRQoL facets (displayed in the figure), but the higher size differences were found in *sexual satisfaction* and *work capacity* (Cohen's d = 0.47 and 0.37 respectively). Those with higher CD4+ T cell counts showed significantly higher HRQoL scores in eight facets ($p< .05$). Positive correlations were found between all the HRQoL dimensions and treatment adherence ($p< .05$) and psychological well-being ($p< .05$).

Conclusions: This study presents the more recent data on HRQoL in PLHIV living in Spain. Long-term survivors, older adults, and women are key populations to pay more attention in research and interventions.



[Figure. Differences in WHOQOL-HIV-BREF facets scores according to age. Note. (rev): reverse item. All differences were significant at p<0.05 except (ns): no significant difference.]

TUPED380

Factors influencing quality of life of persons living with human immunodeficiency virus (HIV) infection in Almaty, Kazakhstan

B. Zhakipbayeva[1], Z. Nugmanova[2], M. Tracy[3], G. Birkhead[3], G. Akhmetova[2], J. DeHovitz[4]
[1]Asfendiyarov Kazakh National Medical University, Department of Epidemiology, Almaty, Kazakhstan, [2]Asfendiyarov Kazakh National Medical University, Division of HIV-infection and Infection Control, Almaty, Kazakhstan, [3]University at Albany, State University of New York, Department of Epidemiology and Biostatistics, Albany, United States, [4]Downstate Medical Center, State University of New York, Department of Medicine, Brooklyn, United States

Background: Health-related Quality of life (HRQoL) is recognized as a significant medical outcome measure for people living with HIV (PLWH) infection. Identification of potentially modifiable determinants of HRQoL could help target people in need of additional health care and social services in order to improve their HRQoL. The objective of this study was to determine the factors with the strongest impact on HRQoL in PLWH.

Methods: A cross-sectional study among adult PLWH registered at the Almaty City AIDS Center was conducted in 2013. HRQoL data were collected using the World Health Organization's Quality of Life HIV brief (WHOQOL-HIV Bref) questionnaire. Depression data were obtained using the Patient Health Questionnaire-9. Socio-demographic data were collected with self-administered questionnaire. Clinical data were retrieved from medical records. Multivariate logistic regression and Tobit censored regression were used to examine the relationship of socio-demographic, behavioral and clinical factors with overall quality of life and WHOQOL-HIV Bref domain scores.

Results: A total of 531 people participated, of whom 55.4% were male, 87% were with high school or lower education, 66.5% were unemployed, 48% had a history of injection drug use (IDU), 57.8% had CD4+ count < 350

cell/mm³, 53.9% were on antiretroviral therapy, 48.6% were diagnosed with hepatitis C. Mean age was 37.4±8.7 years. 35.8% had poor HRQoL. In the regression analysis, the following variables were identified as independent predictors of poor overall HRQoL: probable depression (adjusted odds ratio (AOR) 13.42, 95% confidence interval (CI): 4.56 - 39.52); history of IDU (AOR 2.10, 95% CI: 1.40 - 3.14); CD4+ T cell count < 200/mm³ (AOR 2.17, 95% CI: 1.30 - 3.62); previously married status (AOR 1.26, 95% CI: 1.16 - 4.28), and presence of co-infection (AOR 1.59, 95% CI: 1.06 - 2.39). Additionally, age ≥50 years, higher school or lower education, history of ART, more ≥1.5 year since HIV diagnosis, and HIV viral load ≥500 copy/mL were associated with poorer HRQoL at least in one domain.
Conclusions: HRQoL of PLWH in Almaty was independently influenced by several factors (psychological, clinical, social, behavioral). An interdisciplinary approach is needed in planning healthcare and social services addressing HRQoL improvement of PLWH.

TUPED381

Voluntary drug addiction treatment at community level in Viet Nam

D.T. Ninh Xuan
Center for Supporting Community Development Initiatives, Hanoi, Vietnam

Background: Center for Supporting Community Development Initiatives (SCDI) contributed to a national Programme on reviewing addition treatment through focusing on transferring drug addiction treatment since 2014. This is a completely new approach on drug addiction treatment in Viet Nam that drug users will voluntary go to the treatment settings and will not be discriminated and continue to receive services if they relapse.
Description: The pilot model has been implemented in 22 treatment settings in 22 districts of 5 provinces through two main interventions: capacity development for staff working in treatment settings and policy advocacy on voluntary treatment for drug users at community level with the operation budget allocated fully from the state budget at the district and provincial levels.
Lessons learned: After four years, SCDI strengthened the capacity of 200 staff working in the treatment settings (80% are female) through providing knowledge on addiction mechanism, detoxification period, basic mental health treatment, motivation interviewing, cognitive behavioral treatment, behavioral management... One advantage of this new model is the active participation of CBOs' drug users in providing treatment services. As a result, more than 2,000 clients have received services at community level; and they reduced using drug and have better jobs. The evaluation showed that the drug users have better family and social relationship, reduce number of violation cases related to drug addiction. The staff working in the treatment settings have more interest in their work because their contribution have changed lives of drug users and reduce the community's discriminatory attitude toward drug users. SCDI advocated successfully for related drug addiction policy to ensure the stability of this SDCI model at community. As result of SCDI efforts, these policies were approved at the provincial level in 2016 and now the government has considered as a role model in the national policy on drug voluntary treatment in the community.
Conclusions/Next steps: If this is accepted, the model will be implemented in the whole country of Viet Nam and it is estimated that at least 50,000 drug addicts will benefit from this initiative and save at least 80% of expenditure for the drug addicts compared with the compulsory treatment.

TUPED382

Effect of psychosocial group intervention on social support among depressed HIV infected perinatal women in Dar es Salaam, Tanzania: A cluster randomized controlled trial

M. Somba[1], E. Larson[2], H. Siril[3], A. Kaale[1], A. Minja[1], A. Mwimba[1], A. Komba[1], F. Ngakongwa[4], J. Kamala[1], Z. Aloyce[1], M.C. Smith Fawzi[5], S.F. Kaaya[4]
[1]Africa Academy for Public Health, Dar es Salaam, Tanzania, United Republic of, [2]Harvard T. H Chan School of Public Health, Global Health and Population, Boston, United States, [3]Management and Development for Health, Dar es Salaam, Tanzania, United Republic of, [4]Muhimbili University of Health and Allied Sciences, Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of, [5]Harvard Medical School, Global Health and Social Medicine, Boston, United States

Background: The prevalence of depression among HIV infected pregnant women in sub Saharan Africa is estimated to be 40%; much higher than in men living with HIV and in the general population. Low social support is among the major contributing factors.
Psychosocial support group interventions have been widely reported to increase social support and facilitate elimination of depressive symptoms.
We explore the effect of such an intervention on perceived social support among HIV infected depressed women.
Methods: A total of 16 public health facilities providing PMTCT services were randomly assigned to intervention and control groups in 2015 to 2016. A total of 742 HIV-infected depressed pregnant women were recruited using locally validated cut point of PHQ-9 tool to measure depression. Women were placed in structured psychosocial groups with problem solving (n=7 sessions pre-delivery), cognitive behavioral (n=8 sessions post-delivery) components, facilitated by lay providers. Enhanced Standard of Care (ESC) was offered to providers at all study sites. Data was collected at baseline, six weeks and nine months post-delivery. Social support was assessed using ten-item scale ranging 1-4; a score of "1" indicating receiving support "as much as I would like" and "4" "never receiving support". We compare average scores on social support in intervention and control groups using a linear regression model with robust standard errors to account for clustering.
Results: Among 742 women who participated in the study the average age was 29.6, ranging from 18-43 years. At baseline (13%) had less than basic education, 73% were married or living with sexual partners and 54% were employed. Average social support score at baseline was 2.9 (standard deviation (sd) 0.7) and increased to 3.3(sd=0.6) and 3.6(sd=0.4) at six weeks and 9 months post-delivery respectively; but there was no significant effect of the intervention on social support (P=0.27 and P=0.17) respectively.
Conclusions: The intervention did not have a direct association with social support among depressed HIV infected pregnant women. Although this could be in part related to the potential effect of ESC, which improves access to mental health care. More studies using other approaches of increasing social support in this key group should be considered.

TUPED383

Does stigma really impact health and well-being in persons living with HIV (PLHIV)?

Background: HIV-related stigma is a phenomenon where PLHIV are viewed or view themselves as tainted by being HIV-infected. The Health Stigma Framework (HSF) posits that there are distinct HIV-related stigma mechanisms by which PLHIV experience and respond to stigma namely: internalized, enacted, and/or anticipated stigma. Although, there is evidence that HIV-related stigma has a negative effect on the health and well-being of PLHIV, less is known about how different stigma mechanisms affect specific health and well-being outcomes. We investigated whether internalized, enacted, and/or anticipated stigmas are associated with distinct physical (physical function, fatigue, pain), mental (anxiety and depression), and social (social health) indicators of health and well-being in PLHIV.

Methods: We recruited PLHIV (N=702) from seven geographically diverse sites in the United States and Thailand for a cross-sectional study on physical activity in PLHIV. Participants completed validated measures of physical, mental, and social health-related domains (PROMIS-29) and stigma (HIV Stigma Mechanism Scale). We used descriptive statistics to calculate mean PROMIS-29 t-scores (higher scores indicate greater levels of specific constructs, e.g. greater anxiety, depression, pain, etc.), and for internalized, enacted, and anticipated stigma (higher scores indicating greater level of stigma). Multiple regression was used to examine the relationship between stigma mechanisms and physical, mental, and social health indicators.

Results: The majority of participants resided in the US (14% in Thailand). Fifty-five percent identified as male (40% female and 4.5% transgendered/queer). All stigma mechanisms and health indicators were significantly associated. Specifically, internalized (r=.447, p=.000) and anticipated stigmas (r=.371, p=.000) were most closely associated with depression. Enacted stigma was most closely associated with pain (r=.293, p=.000). Regression analyses revealed that for PLHIV, internalized stigma was the most significant predictor and accounted for the most variance in all physical, mental, and social health indicators of health and well-being with the exception of pain.

Conclusions: Different stigma mechanisms are associated with distinct health outcomes in the study sample. Distinguishing between different stigma mechanisms and their impact on health outcomes is particularly important to informing the design and development of interventions that have potential for the effective mitigation of stigma and its effects on health outcomes.

TUPED384

Burden of HIV-related stigma and associated factors among prenatal women living with depression accessing PMTCT services in Dar es Salaam, Tanzania

A. Minja[1], E. Larson[2], A. Komba[1], A. Mwimba[1], A. Kaale[1], J. Kamala[1], M. Somba[1], Z. Aloyce[1], H. Siril[3], S.F. Kaaya[4], M.C.S. Fawzi[5]
[1]Africa Academy for Public Health, Programs, Dar es Salaam, Tanzania, United Republic of, [2]Harvard T.H. Chan School of Public Health, Global Health and Population, Boston, United States, [3]Management and Development for Health, Dar es Salaam, United States, [4]Muhimbili University of Health and Allied Science, Dar es Salaam, Tanzania, United Republic of, [5]Harvard Medical School, Global Health and Social Medicine, Boston, United States

Background: In Tanzania and similar resource-limited settings, the burden of HIV-related stigma is high and can have a significant impact on well-being and quality of life. The social isolation experienced with stigma can increase the risk of depression, which can also have a negative effect on survival and prognosis of HIV disease. The aim of this study is to assess the level of HIV-related stigma among women living with HIV and depression accessing PMTCT services and examine factors associated with stigma in this context.

Methods: We administered a questionnaire for prenatal women with depression accessing PMTCT services in Dar es Salaam that included measures of HIV-related stigma, depression, social support, and related factors. Women's exposure to stigma was assessed using a questionnaire with a five-point Likert scale ranging from one to five, with one indicating no stigma and five representing a high level of stigma. We conducted univariate analyses and linear regression models to examine factors associated with HIV-related stigma.

Results: A total of 742 women were enrolled in the study with an average age of 26.9 years old (range 18-43). Over one-third of the women indicated having problems with food security in the past six months (33.2%) and 27.3% reported owing money at shops where they buy food. The average value on the HIV stigma scale was 2.07. HIV-related stigma was positively associated with food insecurity (= 0.24, 95% CI: 0.02, 0.46) and negatively correlated with hope (= -0.20, 95% CI: -0.30, -0.10).

Conclusions: Our study demonstrated a significant level of stigma among perinatal women living with HIV and depression. Socioeconomic factors, such as food insecurity, increased the risk of HIV-related stigma, whereas hope demonstrated a protective effect. This suggests a need to account for economic stressors when addressing HIV-related stigma among high risk groups such as perinatal women living with depression and HIV in resource-limited settings. A more holistic approach addressing psychological, such as hope, as well as economic characteristics should be considered when developing interventions to enhance well-being in this vulnerable population.

TUPED385

Determinants of mental health problems among children living with HIV in Malawi: A cross-sectional study

F.W. Kalembo[1,2], G.E. Kendall[2], M. Ali[2]
[1]Mzuzu University, Nursing and Midwifery, Mzuzu, Malawi, [2]Curtin University, Nursing and Midwifery, Perth, Australia

Background: Approximately 10% of people living with HIV in Malawi are children under the age of 15 years. Although the survival rate of children living with HIV in Malawi has increased due to the increased availability of antiretroviral medications, these children continue to experience numerous challenges negatively impacting on their physical and mental health. These challenges include: high levels of poverty, stigma, discrimination, bullying, and the loss of one or both parents. This study was conducted to investigate the prevalence and determinants of mental health problems in children aged between 6 and 12 years living with HIV in Malawi.

Methods: A random sample of 429 primary caregivers of children living with HIV drawn from the three main administrative regions of Malawi was recruited in a cross-sectional study. Reliable instruments translated

into the local Chichewa language were used to collect data on child's demographic factors, clinical factors, and emotional and behavioural problems as well as family socio-economic and psychosocial factors, including stressful life events, the impact of illness on the family, and caregiver support. Data were analysed using descriptive statistics and logistic regression.
Results: Using the newer band categorisations of the Strengths and Difficulties Questionnaire (SDQ), parent version, 31 per cent of primary caregivers reported that their child had a slightly raised to very high level of total difficulties. Factors that independently predicted difficulties were primary caregivers' young age (aOR 3.6; 95% CI: 1.4-9.5), primary school level of education (aOR 2.6; 95% CI: 1.2-5.7), and lack of employment (aOR 2.7; 95% CI: 1.2-5.9), as well as impact of the illness on the family (3.1; 95% CI: 1.5-6.5) and a low level of functional support (aOR 2.0; 95% CI: 1.1-4.1). Neither non-disclosure nor any of the child demographic or clinical factors were significant in multivariate analysis (p>.0.05).
Conclusions: Close to one-third of children living with HIV in this study had high SDQ scores indicative of mental health problems. Mental health problems in children living with HIV are associated with some family demographic and psychosocial factors. Effective policies and programs that promote the mental wellbeing of children living with HIV in Malawi are indicated.

TUPED386

Working together to promote the physical and psychosocial wellbeing of children living with HIV through the safe and effective disclosure of HIV status: A qualitative study

F.W. Kalembo[1,2], G.E. Kendall[2], M. Ali[2]
[1]Mzuzu University, Nursing and Midwifery, Mzuzu, Malawi, [2]Curtin University, Nursing and Midwifery, Perth, Australia

Background: Approximately one tenth of people living with HIV in Malawi are children under the age of 15 years. While the World Health Organisation recommends that healthcare workers, teachers and community leaders should work with primary caregivers to disclose HIV status to children living with HIV. Research assessing the involvement of these adults in the disclosure process in Malawi is limited. This study was conducted to assess the involvement, practice, challenges, and support needed by primary caregivers, healthcare workers, teachers and community leaders to disclose HIV status to children aged between 6 and 12 years living with HIV in Malawi.
Methods: Focus group discussions and one-on-one interviews were used to collect data from primary caregivers, healthcare workers, teachers and community leaders across all three administrative regions of Malawi. Information regarding involvement, practice, challenges, and support needed to disclose of HIV status to children was collected. Data were analysed using thematic analysis.
Results: Twelve focus group discussions and 19 one-on-one interviews involving a total of 106 participants were completed. Three main themes namely talking about HIV disclosure, open communication, and shared responsibility were identified. The first theme 'talking about HIV disclosure' was identified through participants' expression of the need for all stakeholders to talk about HIV disclosure despite being constrained by the complexity and potentially negative consequences of the disclosure process. The second theme 'open communication' emerged after many participants emphasized the need for stakeholders to have an open communication regarding disclosure of HIV status to the child. Hierarchical relationships and misunderstandings were reported as barriers to open communication. The last theme 'shared responsibility' emerged after most participants expressed that each stakeholder had a role to play in the disclosure process. Nonetheless, many participants reported that there was little attempt to share responsibility for care. The three themes had a common concept of 'working together as most participants emphasized the need for them to work together to break down the barriers to effective disclosure.
Conclusions: Disclosure of HIV status to children is a complex issue that require all stakeholders to work together to meet the health, psychosocial and academic needs of children living with HIV.

TUPED387

We are much more than our HIV status: Uniting HIV+ women in Kyiv to address HIV-related stigma using immediate intervention model

V. Varyga[1], I. Nerubaieva[2]
[1]Positive Women of Ukraine, Kyiv, Ukraine, [2]ICF 'AIDS Foundation East-West' (AFEW-Ukraine), Program Department, Kyiv, Ukraine

Background: HIV-related stigma and lack of social support are crucial factors that undermine ART adherence among HIV-positive women in Ukraine. Self-help group proved to be a good method of overcoming stigma and improving the quality of life. Empowerment given in such groups increase the self-esteem and self-efficacy of its participants helping them to (re)build meaningful relationships in their life and better cope with the on-going life challenges. Using Immediate Intervention Model in 2014 several HIV-positive women created unique self-support and empowerment group for HIV-positive women in Kyiv now nationally well-known as "Kyianka+".
Description: Immediate Intervention Model used by "Kyianka+" is based on the principles of meaningful involvement of people living with HIV/AIDS and implies immediate support of women who have just discovered their HIV-positive status and those who struggle to accept their status by creation of small peer support networks.
The key components of this model:
- Phone hotline.
- Monthly meetings of self-help groups.
- Online counseling and peer support via facebook secret group "Kyianka+".
- Monthly joint events, such as master classes, trainings and leisure activities.
- Skill trainings and professional education with further assistance in employment.
- Informal meetings with doctors.
- Joint creative arts activities.

Lessons learned: The self-help group had an immediate positive effect on women´s health. During 2014-2017 "Kyianka+" provided support to 158 HIV+ women in Kyiv. The number of women who started ARV treatment during this period has significantly increased by 62% - 82 out of 131 participants on ART started treatment empowered by peers in "Kyianka+". There were additional 12 cases of those who re-started to take ART. 10 of 53 women with hepatitis C were supported to start and complete HCV treatment.
Conclusions/Next steps: Women from support group indicated that key unifying factor was not HIV-positive status of its participants, but their belonging to the female community, which demands specific gender-focused approaches in designing interventions. Most of HIV+ women also reported that round the clock peer support and regular informal meetings with doctors helped them the most to overcome the internal stigma. Currently it is planned to disseminate this experience from Kyiv to other regions of Ukraine.

TUPED388

The impact of social support on HIV care attendance and ART adherence in PLH social networks in St. Petersburg, Russia

Y. Amirkhanian[1,2], J. Kelly[1], A. Kuznetsova[2], A. Meylakhs[2], A. Yakovlev[2], V. Musatov[2]
[1]Medical College of Wisconsin, Psychiatry and Behavioral Medicine, Center for AIDS Intervention Research (CAIR), Milwaukee, United States, [2]Botkin Hospital for Infectious Diseases, Interdisciplinary Center for AIDS Research and Training (ICART), St. Petersburg, Russian Federation

Background: A wide body of research shows that social support is strongly associated with HIV care engagement indicators including medical care enrollment, adherence, and retention. In Russia—where ART uptake remains very low—there is a need to identify specific contextual issues related to ways in which social support impacts HIV care.
Methods: Seven egocentric social networks of PLH (n=40) were recruited in St. Petersburg Russia. Interested PLH responded announcements placed online and in service venues. PLH not treatment adherent

or nonengaged in care were recruited as "seeds" (initial network access persons) and invited the participation of their PLH friends. Each network attended a focus group to elicit details of social support provided within the network as well as supports from outsiders such as parents, partners, HIV- friends, or service providers.
Results: Almost all participants (93%, n=37) indicated that other members of their PLH networks provided support for HIV care. Among other significant persons providing care-related supports were relatives (78%, n=31), treating doctors (50%, n=20), and others (53%, n=21). 25% (n=10) of participants indicated that they mostly rely on themselves to support their HIV care. The most common support types were:
(1) a variety of tangible supports,
(2) sincere interest shown in one's heath and to remind about care appointments or the need to take pills;
(3) emotional support;
(4) being a positive model and sharing personal experiences in overcoming care-related barriers; and
(5) motivational support that emphasizes one's personal responsibility to care for family, children, relatives, or themselves.
A set of supports types felt not to be helpful included inappropriate care recommendations, advice too direct and insensitive to one's lifestyle, and—finally—advice from AIDS deniers seen untrustworthy.
Conclusions: This study identified specific types of support that PLH perceive as helpful and those that are perceived negatively. Interventions to improve HIV care outcomes that increase support—both within PLH networks and among others—hold particular promise. While PLH may support one another as peers, supports for care from family members, care providers, friends, or sexual partners are important and can be mobilized and utilized to achieve HIV care-related goals.

TUPED389

A dyadic investigation of relationship dynamics and depression in HIV-positive couples from Malawi

A. Conroy[1], E. Tuthill[2], T. Neilands[1], M. Johnson[3], N. Mulauzi[4], J. Mkandawire[4]
[1]University of California, Center for AIDS Prevention Studies, San Francisco, United States, [2]University of California, School of Nursing, San Francisco, United States, [3]University of California San Francisco, Center for AIDS Prevention Studies, San Francisco, United States, [4]Invest in Knowledge, Zomba, Malawi

Background: Among HIV-infected individuals, depression is associated with suboptimal adherence to antiretroviral therapy (ART), worsening disease progression, lower CD4 counts, higher viral load, increased risk of comorbidities, and decreased quality of life. Primary partnerships such as marriage could be protective against depression through partner social support. Most studies have examined depression on the individual level, which ignores interpersonal dynamics such as interdependence between partners. In this study, we used a dyadic perspective to examine whether relationship dynamics (e.g. trust, unity, communication, social support) were associated with couple-level depression among HIV-affected married couples in Malawi.
Methods: Couples were eligible if they were in a non-polygamous relationship for at least six months, age 18 or older, and had at least one partner on ART for at least two months who had disclosed HIV status to their primary partner. Using validated scales, both partners were asked about relationship dynamics and symptoms of depression (CES-D). We computed couple-level means for all variables and constructed a dyadic dataset with one row per couple. We then fit linear regression models predicting couple-level depressive symptoms, controlling for relationship length, alcohol use, shared children, health status, couple HIV status (discordant or concordant positive), and other demographic covariates.
Results: All participants (211 couples) were married and most had a primary school education or less (81%). Approximately one-third were serodiscordant. Over one-quarter of participants (28%) had a CES-D score of 16 or higher, indicating probable depression. The mean CES-D score at the couple-level was 11 (range: 0-48). The adjusted models showed that couples with higher levels of intimacy, trust, equality, satisfaction, unity, and commitment had lower levels of depressive symptoms. In contrast, couples with higher levels of maladaptive communication had higher levels of depressive symptoms.

Measure of relationship quality (couple-level)	Unadjusted Coef. (95% CI)	Adjusted Coef. (95% CI)
Intimacy	-1.81 (-3.28, -0.33)*	-2.01 (-3.60, -0.44)*
Trust	-0.20 (-0.37, -0.03)*	-0.24 (-0.44, -0.04)*
Equality	-0.35 (-0.54, -0.17)***	-0.42 (-0.62, -0.22)***
Relationship satisfaction	-1.95 (-3.55, -0.34)*	-2.31 (-4.02, -0.61)**
Unity ("We-ness")	-1.72 (-2.61, -0.82)***	-1.87 (-2.83, -0.92)***
Relationship commitment	-1.99 (-4.08, 0.09)	-2.65 (-4.86, -0.45)*
Maladaptive communication (avoidant)	1.52 (0.48, 2.56)**	1.68 (0.60, 2.77)**
Adaptive communication (constructive)	-1.27 (-3.01, 0.46)	-1.83 (-3.70, 0.02)
Partner social support	-0.08 (-0.20, 0.04)	-0.12 (-0.24, 0.01)

*[Linear regression coefficients for relationship quality and depressive symptoms among couples with HIV in Malawi (*p<.05; **p<0.01; ***p<0.001)]*

Conclusions: High levels of depressive symptoms were reported by married couples with HIV, which has the potential to hinder optimal HIV clinical outcomes. Couples-based interventions that encourage positive relationship dynamics and couple communication could be key in the prevention and treatment of depression, particularly in settings with low access to anti-depression medications and mental health services. This may result in enhanced HIV treatment outcomes.

TUPED390

Does social support serve emotion regulation function in death anxiety among people living with HIV/AIDS?

J. Chukwuorji[1], C. Uzuegbu[2], C. Chukwu[2], C. Ifeagwazi[2]
[1]University of Nigeria, Nsukka, Department of Psychology, Nsukka, Nigeria, [2]University of Nigeria, Nsukka, Nigeria

Background: A growing body of research supports low social support quality as a key predictor of death anxiety, but knowledge of the underlying processes by which social support impacts death anxiety is limited. The major goal of this study was to examine whether social support predicts multidimensional death anxiety as a function of emotion regulation strategies (cognitive reappraisal and expressive suppression) among people living with HIV/AIDS (PLWHA).
Methods: Participants were 186 PLWHA (mean age = 34.16 years, SD = 11.16; 43.5% men and 56.5% women) drawn from the HIV/AIDS care unit of a tertiary healthcare institution in south-eastern Nigeria. Many of them (*n* = 108, 58.1%) had attended higher institutions. Data was obtained by means of self-report questionnaires containing the 17-item Death Anxiety Inventory - Revised (DAI-R), the 12-item Multidimensional Scale of Perceived Social Support, and the 10-item Emotion Regulation Questionnaire (ERQ). A serial mediation analysis for test of hypotheses was conducted using Model 6 of the Hayes' PROCESS macro for SPSS which applies two mediators for each single analysis in a regression-based, path-analytical framework.
Results: There were no gender, age and educational status differences in social support, emotion regulation and death anxiety. The indirect pathway from social support to death anxiety through the emotion regulation strategies were found to be significant for death acceptance and death thoughts, but not for externally generated death anxiety and death finality. Apparently, emotion regulation strategies, especially expressive suppression mediates the process by which social support is linked to reductions in death anxiety among PLWHA.
Conclusions: Findings support existing mental health research and theories elucidating core social mechanisms of emotion regulation in relation to psychopathology. Thus interventions for the improvement of mental health for PLWHA needs to recognise this link.

TUPED391

Psychosocial support for people living with HIV in Burkina Faso through SMS

M. Geldof[1], N. Wagner[1], B.A. Thiombiano[2]
[1]Erasmus University Rotterdam, International Institute of Social Studies, The Hague, Netherlands, [2]Univsersité Polytechnique de Bobo-Dioulasso, Institut du Développement Rural, Bobo-Dioulasso, Burkina Faso

Background: As part of a larger nation-wide study about the impact of SMS reminders on the ARV adherence by people living with HIV in Burkina Faso, a qualitative assessment of the impact of the SMS messages on beneficiaries was undertaken to complement the mostly quantitative data collected through questionnaires. The aim of the assessment was to better understand how the beneficiaries perceived the SMS reminders.
Methods: The qualitative inquiry was done through semi-structured interviews and focus groups with beneficiaries and surveyors taking part in the SMS reminder intervention in both 2016 and 2017 (a total of 37 interviews and 13 focus groups with 76 beneficiaries and 24 surveyors) across 10 different places across Burkina Faso about their experiences with the SMS reminders.
Results: The qualitative inquiry revealed some evidence that the SMS reminders are indeed leading to better ARV adherence, particularly when people are away from their homes and get reminded. However, more importantly the assessment provided strong evidence that the SMS messages were perceived as an important psychosocial support, even if beneficiaries couldn't read or understand them. Simply the fact that someone was thinking about them and making the effort to send a reminder, made people feel that there is someone caring about them and therefore that their life matters.
Conclusions: Typically interventions that use SMS messages for people living with HIV have a functional nature, such as to remind patients of appointments, taking medication or for communication. This qualitative study in Burkina Faso demonstrated that SMS messages can also play an important role in providing psychosocial support to patients, particularly in countries where people living with HIV still face stigmatization and isolation. Such psychosocial support can potentially have an indirect positive impact on health behaviour and ARV adherence, because patients feel more worthy and appreciated.

TUPED392

What do we know about reducing self-stigma among people living with HIV (PLHIV) and key populations affected by HIV? A systematic review of interventions from low and middle-income countries (LMIC)

M. Pantelic[1,2], J. Steinert[2], J. Park[3], F. Murau[4], S. Mellors[4]
[1]International HIV/AIDS Alliance, Secretariat, Oxford, United Kingdom, [2]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [3]University of British Columbia, Department of Experimental Medicine, Vancouver, Canada, [4]International HIV/AIDS Alliance, Brighton, United Kingdom

Background: Self-stigma is a major impediment to the UNAIDS 90-90-90 targets. Self-stigma can hamper HIV testing, treatment and prevention by compromising people's quality of life, mental health, healthcare use and adherence to anti-retroviral treatment (ART). We synthesized existing evidence of interventions aiming to reduce self-stigma experienced by PLHIV and key populations in LMIC.
Methods: Studies were identified through bibliographic databases, grey literature sites, study registries, back referencing, and contacts with researchers, following PRISMA and Cochrane guidelines. Two independent investigators screened abstracts according to inclusion criteria pre-specified in the study protocol https://www.crd.york.ac.uk/prospero/display_record.php?RecordID=83972. The data extraction form was adapted from Cochrane Collaboration guidelines and forms used in previous relevant reviews.
Results: Of 5850 potentially relevant titles, 15 studies were included in the review. Represented in these studies were 7,131 people (67% women) from Ethiopia, India, Kenya, Lesotho, Malawi, Nepal, South Africa, Swaziland, Tanzania, Thailand, Uganda, and Vietnam. The vast majority (13/15) of interventions targeted adults living with HIV with four being evaluated in women only. Only two interventions specifically targeted key populations: young men who have sex with men (YMSM) in Thailand and female sex workers (FSW) in India. Approaches to self-stigma reduction included group and individual psycho-educational sessions (sometimes combined with poverty alleviation components), ART initiation with counseling or food assistance, ART adherence counseling (either through peers or community health workers) and food assistance. 11 interventions resulted in reductions in self-stigma. ART initiation and psycho-educational sessions with economic strengthening components consistently resulted in reduced self-stigma, but psycho-educational approaches that did not include economic strengthening had mixed effects.
Conclusions: Structural interventions such as scale-up of ART, prevention of medication stock outs and economic strengthening may help substantially reduce self-stigma among PLHIV, potentially by improving physical and mental health outcomes. It should be noted that only two tested interventions for key populations were identified, of which the one for YMSM did not appear to be effective in reducing self-stigma. More research is urgently needed to understand how to reduce self-stigma among young people and key populations particularly in contexts where they are heavily discriminated and/or criminalized.

TUPED393

The young people living with HIV stigma survey UK: Self-image related to an HIV diagnosis

I. Lut[1], C. Smith[2], A. Hudson[3], V. Delpech[4], C. Foster[5]
[1]Family Planning Assciation, HIV, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Family Planning Association, London, United Kingdom, [4]Public Health England, London, United Kingdom, [5]Imperial College Healthcare NHS Trust, London, United Kingdom

Background: HIV-related stigma affects self-esteem and quality of life among people living with HIV. We report on HIV-related self-image among young people (YP) aged 15-24 living with HIV in the UK.
Methods: *The Young People Living with HIV* Stigma Survey UK was co-produced by a diverse range of young people living with diagnosed HIV (YPLWH), clinicians and researchers. A cross-sectional study was conducted, exploring stigma and discrimination experienced by YPLWH in the UK. Participants were recruited through cross-sector organisations supporting PLWH and HIV clinics. Descriptive and multivariate analyses are presented on positive and negative feelings over the past 12 months.
Results: Data from 300 YP was analysed; median age 20 years (IQR 17,22) with 47% aged 15-19 and 53% aged 20-24. 53% identified as male (including trans men) and 39% of sexually active participants were men who have sex with men (MSM). 79% of YP identified as Black, Asian or Minority Ethnic. 65% of YP acquired HIV at birth and 29% were infected sexually. 92% of participants were currently on ART, 70% self reported an undetectable viral load. Reported feelings in relation to HIV status are presented below:

N=300	No ART and/or detectable VL currently	ART & undetectable VL currently	p-value	Adjusted OR (95% CI)*
In control of health	66 (69.5%)	187 (91.2%)	0.012	3.36 (1.36-8.32)
As good as anyone else	70 (73.7%)	182 (88.8%)	0.008	3.24 (1.35-7.75)
Blame self	37 (39%)	53 (25.9%)	0.018	0.48 (0.26-0.88)
Blame others	31 (32.6%)	34 (16.6%)	0.005	0.43 (0.24-0.77)
Positive self-image	46 (48.4%)	133 (64.9%)	0.031	1.82 (1.06-3.1)

[Feelings and positive self-image score]

YP who are currently on treatment and undetectable (self-reported) reported feeling more in control of their health and as good as anyone else and less feelings of blame compared to others. They were also more likely to report a high positive self-image score.
Conclusions: YP on suppressive therapy report feeling significantly more in control of their health and feeling as good as anyone else while reporting less feelings of blame in relation to their diagnosis. Strategies that translate positive youth self-efficacy into improved health behaviours and reduced risk-taking require further exploration.

TUPED394

Influence of harmful alcohol drinking on anti-retroviral therapy adherence and health-related quality of life in HIV-positive people in Nepal: A community-based cross-sectional study

S. Pokhrel[1], V.D. Sharma[2], K. Gaulee[3], K. Pokhrel[4]
[1]*Integrated Development Foundation Nepal, HIV, Nutrition, and Mental Heatlh, Kathmandu, Nepal,* [2]*Institute of Medicine, Mental Health and Psychiatry, Kathmandu, Nepal,* [3]*Royal Tropical Institute, Public Health, Netherlands, Netherlands,* [4]*Integrated Development Foundation, Kathmandu, Nepal*

Background: HIV-positive people often endure alcohol use disorders resulting in their poor health and treatment outcomes. Little is known about the association of harmful alcohol drinking with their adherence to anti-retroviral therapy (ART) and health related quality of life (QOL) in low-resource settings. Additionally, such evidence is not available according to the gender differences worldwide. This study aimed to investigate the association of harmful alcohol drinking with adherence to ART and health-related QOL of HIV-positive people stratified by gender in Nepal.

Methods: A cross-sectional study was conducted among HIV-positive people on ART in Nepal from March to April 2016. Harmful alcohol drinking was measured using a validated AUDIT scale. Non-adherence to ART was measured using AIDS Clinical Trial Group questionnaires. We also measured their health-related QOL using WHOQOL-HIV BREF scale. The association of harmful alcohol drinking with non-adherence to ART was examined using multiple logistic regressions. Additionally, multiple linear regressions examined the association between harmful alcohol drinking and QOL.

Results: Harmful alcohol drinking was associated with non-adherence to ART among men (AOR: 2.48, 95% CI: 1.50, 4.11, p < 0.001) and women (AOR: 2.52, 95% CI: 1.32, 4.80, p = 0.005). Men were more likely to have lower score for psychological domain (= -0.55, p = 0.021) and level of independence (= -0.68, p = 0.018) domains when they had harmful alcohol drinking. Moreover, women were more likely to have lower scores for physical (= -1.01, p = 0.015), social relation (= -0.82, p = 0.033), environmental (= -0.88, p = 0.011), and spiritual (= -1.30, p = 0.005) domains of QOL when they had harmful alcohol drinking.

Conclusions: Harmful alcohol drinking was an overlooked threat to ART adherence and QOL of both HIV-positive men and women in Nepal. Screening for alcohol use disorders and community-based counseling services should be provided while delivering ART services to improve treatment adherence and QOL. Additional studies are warranted to explore the co-morbid effect of mental health and alcohol use disorders on treatment adherence.

TUPED395

Linking perceived stigma and mental health in adults living with HIV: The mediating effect of self-compassion and psychological flexibility

A. Martins, C. Chaves, M.C. Canavarro, M. Pereira
University of Coimbra, Faculty of Psychology and Educational Sciences, Coimbra, Portugal

Background: Stigma remains one of the biggest challenges for people living with HIV, and has been consistently related to poor mental health. Although scarcely studied in HIV context, self-compassion and psychological flexibility are psychological processes that have shown positive associations with psychological health. In an effort to identify the mechanisms to reduce perceived stigma and its negative consequences, the objective of this study was to assess the association between perceived stigma, self-compassion, psychological flexibility, and mental health outcomes (anxiety and depression); and examine the mediating role of self-compassion and psychological flexibility in the association between perceived stigma and mental health outcomes among adults living with HIV.

Methods: The sample of this cross-sectional study comprised 95 adults living with HIV (53.7% male) with a mean age of 41.65 years (range:19-65). Participants completed an online survey, between January 2016 and June 2017, which included a self-reported questionnaire on sociodemographic and clinical information, the Stigma Scale Revised, the Self-Compassion Scale, the Acceptance and Action Questionnaire-II, and the Hospital Anxiety and Depression Scale.

Results: Perceived stigma was positively correlated with both anxiety (r=.30, p< .01) and depression (r=.44, p< .001), and negatively correlated with self-compassion (r=-.43, p< .001) and psychological flexibility (r=-.47, p< .001). These processes were significantly associated with lower psychological symptoms (r range: -.60 to -.67, p< .001). A serial mediation model was tested. For both anxiety and depression, the total effect was significant, but the direct effect was not. All indirect paths (through each mediator and the two mediators sequentially) were significant. The model for anxiety explained 50% of the variance, F(3, 91) = 30.34, p< .001; and the model for depression explained 47% of the variance, F(3, 91) = 26.86, p< .001.

Conclusions: Our findings demonstrate mediating effects of self-compassion and psychological flexibility, sequentially or not. Adults living with HIV reporting higher levels of perceived stigma showed higher levels of psychological symptoms, especially when they reveal lower levels of self-compassion and psychological flexibility. These preliminary findings suggest that these processes may be important targets of psychological interventions to reduce the negative impact of perceived stigma on individual's mental health.

TUPED396

Emotional wellbeing, drug and alcohol use, and their relationship with adherence to anti-retroviral therapy among MSM living with HIV in Guatemala

K.M. Guzman Guevara[1], J.P. Alvis Estrada[1], R. Santa Luce[1], D.A. Davis[2], I. Loya-Montiel[1], C. Barrington[2]
[1]*Universidad del Valle de Guatemala, Centro de Estudios en Salud, Guatemala, Guatemala,* [2]*University of North Carolina, Department of Health Behavior, Gillings School of Global Public Health, Chapel Hill, United States*

Background: Emotional wellbeing and substance use can influence adherence to anti-retroviral therapy (ART) but little is known about these relationships in Guatemala. We assessed the association between emotional wellbeing, substance use, and ART adherence among men who have sex with men (MSM) living with HIV.

Methods: From January to May 2017, 397 MSM living with HIV participated in a socio-behavioral survey for the baseline assessment of a multi-level intervention in Guatemala City. Eligibility criteria included ≥18 years old, male, ever had sex with men, diagnosed with HIV, enrolled in HIV care, and spoke Spanish. We used the AIDS Clinical Trials Group measures of adherence and DSM-5 for alcohol use disorder. We also measured prevalence of illicit drug use and emotional wellbeing (anxiety, worry, depression). We used descriptive statistics and bivariate analysis to contrast groups and estimate odd ratios.

Results: Among participants who had started ART (88%, 350/397), 93% reported being adherent, defined as not having missed a dose in the last 4 days. However, only 59% reported always taking their medication as prescribed. Most reported anxiety (64%), worry (64%), and depression (62%) two weeks prior to the survey, though these symptoms were not significantly associated with adherence. Twenty-eight percent of participants met the criteria for alcohol use disorder; these participants were half as likely to be adherent to ART compared to those who did not (OR 0.42, 95% CI: 0.18-0.99). Twenty-nine percent reported having ever used drugs; of these, 23% had used drugs in the last 30 days most frequently marijuana and cocaine. Those who used drugs in the last 30 days were approximately a quarter as likely to be adherent to treatment than those who did not (OR 0.21, 95% CI: 0.04-1.02).

Conclusions: While overall adherence was high among participants in this study, there is a need to reinforce taking ART as prescribed. The negative association between substance use and adherence highlights the need to integrate referral and support services into HIV care to improve and sustain treatment outcomes and wellbeing within this vulnerable population. Future research should continue to explore the pathways between emotional wellbeing, substance use, and ART adherence.

TUPED397

Invisible no longer: Exploring the experiences of women living with and at risk of HIV in the UK through two national surveys and six workshops

J. Stevenson[1], E. Bell[1], F. Hale[1], L. Kwardem[2], D. Laycock[2], J. Lennon[2], F. Obadeyi[2], J. Shepherd[2]
[1]Sophia Forum, London, United Kingdom, [2]Terrence Higgins Trust, London, United Kingdom

Background: Around a third of people living with HIV in the UK are women and every year 25% of new diagnoses are in women. Yet women living with and affected by HIV have been mainly invisible in the narrative and response to HIV in the UK.
Methods: Two online surveys were used, one for women living with HIV, and one for women interested in HIV prevention. Both were open to any women (including trans women) living in the UK aged 18 and over. Six participatory workshops were also held, five attended by women living with HIV and one for women who do not identify as heterosexual.
Results: Data from 308 surveys and the output of six workshops attended by 32 women were taken forward for analysis.
Living with HIV: 27% of women felt health services missed an opportunity to diagnose their HIV earlier. 41% felt they had been diagnosed late. A third had no-one to turn to for support post diagnosis. 58% had experienced violence in their lifetime. 1 in 6 never or rarely had enough money for basic needs. 17 felt their immigration status had affected their ability to manage HIV. Over 40% felt HIV had affected their choice to have children and 54% felt their HIV status affected their sex lives. Awareness of U=U was high (96%) but many women did not believe or fully trust U=U.
HIV prevention: Women in stable relationships, women resident in London and women born outside the UK were more likely to worry about HIV. Three used blood donation to test for HIV. 46% would like to try online HIV testing services and 30% would like more opportunities to test within community settings. 48% had not been offered information about HIV prevention at their last HIV test. Women who do not identify as heterosexual felt HIV and sexual health services did not meet their needs.
Conclusions: There remains a lack of understanding of who women at risk of HIV are and what factors put women at risk of HIV. More research and service focus is needed to identify and meet the needs of women living with HIV.

TUPED398

'I know where my tribe is': An online social network for people living with HIV

N. Holas
Institute of Many, Fitzroy, Australia

Background: Accessing peer and social support is a key stage in the process of coming to terms with a HIV diagnosis for most people living with HIV (PLHIV). Traditionally, peer support has been delivered via facilitated groups meeting in physical space, however there is increasing interest in the use of digital technology to deliver social support programs.
Description: The Institute of Many (TIM) is a peer-run platform for HIV-positive people and their allies, founded in 2012. With a membership over 1700, TIM is the largest digital gathering space for PLHIV in Australia. The organisation focuses on social support for PLHIV, primarily through a Facebook group and social networking events in major Australian cities, as well as delivering innovative health promotion programs. Over a 3.5 month period, TIM averaged 6.5 posts, 38 comments, and 116 reactions per day. Its membership is diverse but, in line with other online services, tends to have greater uptake among younger people, newly diagnosed PLHIV, those disconnected from traditional services, and digital natives.
Lessons learned: In 2017, living with HIV online could be seen as just one aspect of what for many people is an increasingly online/digitised life. For digital-native PLHIV, accessing support via online fora comes as naturally as online banking, shopping and dating. While the traditional 'circle of chairs' model for peer support remains relevant for many PLHIV, online services complement and extend the accessibility of traditional services. The TIM Facebook group delivers social support via a digital medium that users are comfortable with and access frequently - it goes where people are rather than asking them to come to it. TIM users employ the service in diverse ways and report high levels of perceived support, a key building block of resilience.
Conclusions/Next steps: Despite operating without substantial funding, TIM has been enthusiastically adopted by Australian PLHIV as a source of social support, and has outperformed online initiatives delivered by traditional organisations. There is a role for independent social support services to operate alongside traditional models.

TUPED399

PozQoL - a short quality of life measure for people living with HIV

G. Mikolajczak[1], G. Brown[1], A. Lyons[1], J. Power[1], F. Drummond[2], A. Cogle[3], B. Allan[4,5], C. Cooper[6], S. O'Connor[7], S. Malhotra[8]
[1]Australian Research Centre in Sex, Health, and Society, La Trobe University, Bundoora, Australia, [2]ViiV Healthcare Australia, Abbotsford, Australia, [3]National Association of People with HIV Australia, Newton, Australia, [4]International Council of AIDS Service Organizations, Toronto, Canada, [5]Australian Society for HIV, Viral Hepatitis and Sexual Health Medicine, Surry Hills, Australia, [6]Positive Life NSW, Surry Hills, Australia, [7]Queensland Positive People, East Brisbane, Australia, [8]Living Positive Victoria, Southbank, Australia

Background: Advances in HIV medical treatment are driving major changes in HIV policy and practice, including the encouragement of uptake and maintenance of antiretroviral treatment by people living with HIV (PLHIV) for both personal and public health benefits. However, achieving these goals requires a concurrent focus on the broader quality of life (QoL) of PLHIV, including psychological and social wellbeing. Current QoL measures are either long, complex, restricted in their use, or expensive which makes it difficult to monitor QoL to inform strategic policy and program evaluation. To address these shortcomings, the PozQoL study aimed to develop, test and validate a short and freely available scale assessing QoL among PLHIV, that could be used by HIV community, support and healthcare services.
Methods: The initial pool of items was developed drawing on a literature review and consultation with PLHIV community groups across Australia. The items covered health concerns, psychological, social, and functional wellbeing. Testing involved a baseline and a follow-up online survey of 465 adult PLHIV. The survey included the pilot PozQoL scale and other validated measures of health and wellbeing.
Results: Guided by an Exploratory Factor Analysis and conceptual considerations, a 13-item scale was developed. The PozQoL scale demonstrated high levels of fit in a Confirmatory Factor Analysis ($^{2}_{(61)}$ =74.42, *p*=.116; CFI=.992, SRMR=.036, RMSEA=.034 [.000, .059]), very good internal consistency (: 0.82-0.94), test-retest reliability (ICC: 0.83-0.95), and concurrent validity with other measures that approximated different aspects of QoL (*r*: 0.45-0.87).
Conclusions: The PozQoL scale has been tested in a diverse sample of adult PLHIV living in Australia, demonstrating very good reliability and validity. The insights from PLHIV and other stakeholders supported the balancing of statistical rigour and conceptual accuracy. The scale is currently being field-tested by15 community, support and healthcare programs for PLHIV in Australia. The measure will make a significant contribution to the evaluation and enhancement of programs for PLHIV. The PozQoL scale is now being considered for a national indicator of QoL in the Australian National HIV Strategy and has been implemented in a national study in the US.

TUPED400

Relationship between perceived stress, depression and self-efficacy among female sex workers in Southern India

S.K. Patel[1], M. Battala[1], B. Mahapatra[1], N. Saggurti[2], Y. Atmavilas[3]
[1]Population Council, HIV and AIDS Program, New Delhi, India, [2]Population Council, New Delhi, India, [3]Bill and Melinda Gates Foundation, New Delhi, India

Background: Female sex workers (FSWs) in many countries are at elevated risk of reproductive and mental health problems, HIV/AIDS, and have low self-esteem due to the stigma and discrimination they experience. Further, psychological health issues have been a largely neglected issue among FSWs and have not been given proper attention, particularly in developing nations. This study examines the prevalence of perceived stress and investigates its relationship with self-efficacy for health service utilization and condom use, and mental health status among FSWs in southern India.

Methods: Data were drawn from the needs assessment study under Avahan-III program, conducted among FSWs (N=694) during May-June 2017 in Karnataka, a southern state of India. The survey collected information on the FSWs' reproductive health needs, self-efficacy for service utilization and condom use, validated self-perceived stress scale, and depression (assessed using CESD-R10 scale). Descriptive statistics, frequency, bivariate and multivariate logistic regression techniques were used for analysis.

Results: About one-half of FSWs (55%) were found to have high perceived stress, while 67% were found to have at least one depressive symptom. About half (46%) scored high for self-efficacy of condom use and 25% scored high for self-efficacy for service utilization from a health facility. FSW's age, educational attainment, typology, living status and experience of sexual violence were associated with high perceived stress. FSWs, those who had high levels of perceived stress were eight times more likely to report any depressive symptoms (86% vs. 43%, AOR: 8.0, 95% CI: 5.4-12.0) than their counterparts. FSWs, who had high levels of perceived stress were less likely to have high self-efficacy for condom use (41% vs. 53%, AOR: 0.6, 95% CI: 0.5-0.9) as compared to others.

Conclusions: The study highlighted that greater stress is associated with lower general self-efficacy and lower mental health status among FSWs. The current HIV prevention activities in India require an integrated program approach to focus on addressing the psycho-social issues as well. To support this, mental health intervention programs and research-based evidence will be highly needed to ensure that mental health issues are properly addressed among high-risk groups.

TUPED401

The prevalence and correlates of depression in a cohort of HIV-Infected pregnant women in Kenya

L. Osborn[1], K. Ronen[2], D. Matemo[1], J. Unger[2], A. Drake[2], J. Kinuthia[1], G. John-Stewart[2]
[1]Kenyatta National Hospital, Research and Programs, Nairobi, Kenya, [2]University of Washington, Global Health, Seattle, United States

Background: Depression is the leading cause of disability globally and is associated with poor HIV clinical outcomes. Risk of depression is higher in HIV-infected individuals and in peripartum women, but few studies have characterized depression in pregnant HIV-infected women in sub-Saharan Africa.

This study evaluates the prevalence and correlates of depression in pregnant HIV-infected women in Kenya.

Methods: We conducted a cross-sectional analysis of enrollment data from participants in a trial evaluating mHealth strategies to improve ART adherence (Mobile WAChX, NCT02400671). Participants were age ≥14, HIV-infected, pregnant, and had daily access to mobile phone. Participants were recruited from 6 public MCH clinics in Nairobi and Nyanza region. Self-report questionnaires were administered, including assessment of depression (by PHQ9) and social support (by MOS). Correlates of depression were assessed by ^{2} test, univariable and multivariable logistic regression with standard errors clustered by clinic.

Results: Among 825 women enrolled, median age was 27 (IQR 23-31), median gestational age was 24 weeks (18-30), median time since HIV diagnosis was 2 years (IQR 0.08-5.00), and 452 (55%) had an intended pregnancy. Overall, 244 (29.6%) reported at least mild depression (PHQ9 score ≥5) and 71 (8.6%) reported at least moderate depression (PHQ9 score ≥10). Prevalence of ≥mild depression varied significantly by clinic site (range 7.8%-36.5%, p< 0.0001). Compared to women without depression, women with ≥mild depression had lower income, education, and were less likely to have had an intended pregnancy (p< 0.05 for each). In addition, women with ≥mild depression had a more recent HIV diagnosis (median 1 vs. 2 years, p=0.006), more enacted stigma (21.5% vs. 9.3%, p< 0.001), IPV (20.5 vs. 7.2%, p< 0.001) and less social support (58 vs. 66, p< 0.001). In adjusted analysis, depression remained associated with poor social support (aOR=0.98, 0.97-0.99), unplanned pregnancy (aOR=1.35, 1.07-1.71), less than primary education (aOR=1.45, 1.03-2.04), and IPV in the last 12 months (aOR=2.89, 2.45-3.40).

Conclusions: Prevalence of depression in HIV-infected pregnant women in Kenya was substantial, and was associated with pregnancy intention, IPV, education level and social support. The findings highlight the need for improved depression screening and treatment for pregnant HIV-infected women.

TUPED402

Understanding anxiety during sex among women living with HIV in Canada: A cross-sectional analysis of social, psychological, and relational factors

A. Carter[1,2], S. Greene[3], D. Money[4], M. Sanchez[5], K. Webster[2], V. Nicholson[2], L.A. Brotto[4], C. Hankins[6,7], M. Kestler[4], N. Pick[4,8], K. Salters[1,2], K. Proulx-Boucher[9], N. O'Brien[6,9], S. Patterson[10,11], L. Wang[1], L. Tiamiyu[1], A. de Pokomandy[6,9], M. Loutfy[12,13], A. Kaida[2], CHIWOS Research Team
[1]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]Simon Fraser University, Burnaby, Canada, [3]McMaster University, Hamilton, Canada, [4]University of British Columbia, Vancouver, Canada, [5]ViVA, Positive Living Society of British Columbia, Vancouver, Canada, [6]McGill University, Montreal, Canada, [7]University of Amsterdam, Amsterdam, Netherlands, [8]British Columbia Women's Hospital and Health Centre, Vancouver, Canada, [9]McGill University Health Centre, Montreal, Canada, [10]Simon Fraser University, Vancouver, Canada, [11]Wirral University Teaching Hospital, Birkenhead, United Kingdom, [12]Women's College Research Institute, Toronto, Canada, [13]University of Toronto, Toronto, Canada

Background: Sustained use of antiretroviral treatment (ART) with an undetectable viral load effectively eliminates risk of sexual HIV transmission. Awareness of the scientific facts about HIV transmission may reduce anxiety during sexual activity, although trauma and power inequity remain prevalent forces in the lives of women with HIV. We investigated what factors predict self-reported high sexual anxiety among Canadian women with HIV.

Methods: Data were drawn from the baseline questionnaire of the Canadian HIV Women's Sexual and Reproductive Health Cohort Study (2013-2015). Women who reported sex in the past month (n=478) were asked, "Overall, how frequently have you become anxious or inhibited during sexual activity with a partner?" Awareness of ART prevention benefits was measured via the question, "How do you think taking ART changes your risk of transmitting HIV?" and defined by the response "makes the risk a lot lower." Logistic regression identified factors associated with sexual anxiety.

Results: Median age of women was 39 (interquartile range: 32-45), with 5.7% identifying as trans, 14.2% lesbian/queer, 24.5% Indigenous, 27.0% African/Caribbean/Black, and 41.6% White. 72.4% were aware of ART prevention benefits. 58.6% reported feeling no anxiety during sex, while 26.8 % said that they "sometimes/seldom" and 14.6% said they "always/usually" became anxious during sex. Among women aware of ART prevention benefits, 13% "always/usually" felt anxiety compared to 18% of women not aware (p=0.508). Women reporting depression [AOR: 1.11 (95% CI: 1.05-1.16)], previous illicit drug use [2.32 (1.278-4.212)], and current sex work [4.89 (1.32-18.15)] had increased odds of sexual anxiety. Those reporting higher emotional closeness [0.31 (0.14-0.69)], more equitable relationship power [0.95 (0.91-1.00)], and greater ability to communicate

sexual desires to partners [0.52 (0.28-0.95)] had reduced odds. We found no association with being aware of ART prevention benefits [0.95 (0.45-2.01)].
Conclusions: Awareness of ART's HIV prevention benefits was not associated with lower anxiety during sex for women in this study. Instead, correlations were found with social status, mental health, and the quality of sex and intimate relationships. These results highlight a need to gender the HIV treatment as prevention paradigm and address complex social inequities in order to promote positive sexual health among women with HIV.

TUPED403

Psychological and socio-cultural effects of forced and coerced sterilisation on women living with HIV (WLHIV) in Namibia

K. Bakare, S. Gentz
University of Namibia, Human Sciences, Psychology, Windhoek, Namibia

Background: The forced and coerced sterilisation of women living with HIV (WLHIV) is one of the most serious forms of fundamental human rights violations. While, the litigation of Namibia's forced and coerced sterilisation cases has been successful for the women involved, aspects of their well-being have not been fully addressed. The aims of the study were to explore the negative psychological symptoms resulting from forced and coerced sterilization, to describe the socio-cultural effects of forced and coerced sterilization as well as to investigate the meanings that individuals attach to the circumstance of being forced and coerced into sterilization and how these influence coping.
Methods: This study was conducted in Windhoek, Namibia in 2017 using a qualitative research methodology. The target population for this study was the 40 WLHIV who were victims of forced sterilisation in Namibia. Convenience sampling was used to select a sample of seven research participants. The researcher made use of semi-structured interview schedules and content analysis was used to interpret meanings and derive themes.
Results: Results indicated negative psychological and socio-cultural effects on the lives of research participants succeeding forced sterilisation. The findings indicated negative psychological symptoms, particularly those associated with anxiety and depression. These symptoms include withdrawal, overthinking or ruminating, fear, sleep disturbance, change in weight, loss of interest, self-blame, shame, feelings of helplessness, hopelessness, worthlessness, sadness and anger. Additionally, themes of negative health effects, poor state health care services, gender based violence, discrimination, victimisation and unemployment emerged. It was noted that, cultural principles and values regarding reproduction, marriage and decision making also contribute to negative socio-cultural and psychological effects. Another finding was that coping has been difficult, with some psychological and socio-cultural challenges still significantly affecting the women's lives.
Conclusions: The findings of this research point to the need for a strong and sustained HIV support program for WLHIV, especially where human rights violations have occurred; in this particular case, WLHIV who were forced or coerced into sterilisation. It reveals that while financial compensation and policy reform maybe the immediate goals of advocacy efforts, the psychological, social, physical and financial well-being should be prioritised.

TUPED404

Hope in HIV infected depressed perinatal women participants of a psycho social group intervention in urban Tanzania

A. Mwimba[1], E. Larson[2], A. Komba[1], A. Kaale[1], A. Minja[1], J. Kamala[1], M. Somba[1], Z. Aloyce[1], M.C. Smith Fawzi[3], S.F. Kaaya[4]
[1]Africa Academy for Public Health, Program, Tanzania, Tanzania, United Republic of, [2]Harvard T.H Chan School of Public Health, Department of Global Health and Population, Boston, United States, [3]Harvard Medical School, Department of Global Health and Population, Boston, United States, [4]Muhimbili University of Health and Allied Sciences, Department of Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of

Background: Facilitating hope may be important in the provision of comprehensive care for persons living with HIV (PLHA); yet little is known about levels of hope in this population. The purpose of this paper is to describe levels of hope in perinatal women accessing PMTCT-plus services and identify factors associated with hope.
Methods: .A cluster randomised trial was conducted in 16 PMTC-plus providing facilities in urban Dar es Salaam, which recruited perinatal depressed women using a locally validate cut point of the PHQ-9. A total of 742 women with HIV and comorbid depression were enrolled at baseline and 87.5% (n=649) and 86.6% (n=643) followed up at 6 weeks and nine months post-partum respectively. A composite indicator of hope was developed as the average of responses for 20 locally derived idioms of hope from narratives with PLHA in Dar es Salaam from a previous study. Each item had a 4-point response scale from "definitely false" to "definitely true" with lower scores indicating less hope and higher scores more hope. We assessed the level of hope at each survey time point. We used linear models with standard errors clustered at the facility level to assess the association between hope and correlates of interest at baseline.
Results: Women had mean age of 29.6 years (sd 5.42), and most (65.2%) had completed primary education. The average score at baseline on the hope scale was 3.51 (range 1.55-4.00) compared to 3.72 (range 2.10-4.00) at follow-up 1, and 3.78 (range 2.05-4.00) at follow-up 2; this increase in hope over time being statistically significant ($p< 0.001$). At baseline, older women were more hopeful than younger women (=0.01, 95% CI; 0.00, 0.01). Women with high scores on a general self-efficacy measure, also showed higher scores on the hope scale (=0.25, 95% CI; 0.16, 0.33).
Conclusions: Using locally derived idioms signifying hope, perinatal women had above average scores for hope at baseline, that significantly increased with follow-up. The positive correlation with self-efficacy suggests the utility of the hope measure in future analysis.

TUPED405

Risk factors for relapse of depressive symptoms after a psychosocial group intervention for depressed perinatal women attending PMTCT-plus services in Dar es Salaam, Tanzania: A cluster randomized controlled trial

A. Komba[1], E. Larson[2], A. Mwimba[1], A. Kaale[1], A. Minja[1], J. Kamala[1], M. Somba[1], Z. Aloyce[1], M.C. Smith Fawzi[3], S. Kaaya[4], H. Siril[5]
[1]Africa Academy for Public Health, Programe, Dar es Salaam, Tanzania, United Republic of, [2]Harvard T.H. Chan School Public Health, Global Health and Population, Boston, United States, [3]Harvard Medical School, Global Health and Social Medicine, Boston, United States, [4]Muhimbili University of Health and Allied Sciences, Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of, [5]Management and Development for Health, Programe, Dar es Salaam, Tanzania, United Republic of

Background: Depression is common in women living with HIV/AIDS attending antenatal care-based services for preventing mother-to-child transmission of HIV (PMTCT-plus). While relapse of depressive symptoms after treatment may occur, few interventions have identified risk factors for relapse in a low-income country context.
Methods: A cluster-randomized controlled trial compared a psychosocial group intervention utilizing problem solving (PS) and cognitive behavioural (CB) components facilitated by lay community-based health-

care workers to standard of care among women with elevated PHQ-9 depressive symptom scores comparable with major depressive disorder. In addition to baseline, follow-up assessment was at six weeks (T1) and nine months (T2) post-delivery. Relapse of depression was defined as a woman who was not depressed at first follow-up and depressed at second follow-up as determined by a PHQ-9 score of nine or above. We first conducted univariate analysis of depression at each time point, then assessed potential predictors of relapse using generalized estimating equations with a log link and standard errors adjusted for clustering at the facility level.
Results: We enrolled 742 women at baseline, interviewed 649 (87.5%) at T1 and 643 (86.7%) at T2. At baseline women were on average 29.6 years old (range 18-43) and 72.5% were married or living with their partner. At T1 25.2% of women were depressed, compared to 10.2% at T2. Of the 429 who were not depressed at T17.2% relapsed and had an elevated depression score at T2. Women who were younger or single were more likely to relapse; however, higher levels of hope at baseline reduced the risk of relapse by 57% (RR=0.43; 95%CI: 0.23-0.79). Intimate partner violence and HIV-related stigma increased the risk of relapse. In particular, women who reported food insecurity were 3 times more likely to relapse compared to those who did not report this risk factor (RR=3.29; 95%CI:1.62-6.69).
Conclusions: Psycho social support groups utilizing PS and CT components have proven effective in treating depression however, a number of factors can increase the risk of recurrence. In order to sustain the reduced risk of depression related to treatment, contextual factors such as intimate partner violence and food insecurity need to be addressed.

TUPED406

The Young People Living with HIV Stigma Survey UK: An intergenerational comparison of self-image related to an HIV diagnosis

I. Lut[1], C. Smith[2], A. Hudson[1], V. Delpech[3], C. Foster[4]
[1]*Family Planning Association, London, United Kingdom,* [2]*University College London, London, United Kingdom,* [3]*Public Health England, London, United Kingdom,* [4]*Imperial College Healthcare NHS Trust, London, United Kingdom*

Background: HIV-related stigma affects self-esteem and quality of life among people living with HIV. We report on the intergenerational differences in HIV-related self-image among adults and young people (YP) living with HIV in the UK.
Methods: *The People Living with HIV* Stigma Surveys UK were co-produced by a range of people living with diagnosed HIV (PLWH), clinicians and researchers. Two cross-sectional studies [adults (18+) and YP (15-24)] were conducted, exploring stigma and discrimination experienced by PLWH in the UK. Participants were recruited through cross-sector organisations supporting PLWH and HIV clinics. A composite binary self-image score was created from responses to 9 questions on positive (4) and negative (5) feelings in the past 12 months. Descriptive and multivariate analyses are presented.
Results: Data from 1,450 adults and 300 YP was analysed; median ages 45 years (IQR 37,52) and 20 years (IQR 17,22) respectively. 76% and 53% identified as male (including trans men) and 67% and 39% of sexually active participants were men who have sex with men (MSM). 62% of adults identified as White British while 79% of YP identified as Black, Asian or Minority Ethnic. 65% of YP acquired HIV at birth and 29% were infected sexually. 92% of participants in both studies were currently on ART. Reported feelings in relation to HIV status and positive self-image scores are presented below:

	Adults (N=1,450)	Young People (N=300)	p-value	Adjusted OR (95% CI) YP vs Adults
In control of health	900(62.1%)	223(74.3%)	<0.001	1.57 (1.08-2.29)
As good as anyone else	857(59.1%)	220(73.3%)	<0.001	1.75 (1.2-2.58)
Shame	710(49.0%)	65(21.7%)	<0.001	0.29 (0.21-0.39)
Guilt	670(46.2%)	50(16.7%)	<0.001	0.29 (0.21-0.4)
Positive self-image	720(49.7%)	211(70.3%)	<0.001	2.95 (2.11-4.12)

[Feelings and positive self-image score]

Conclusions: YP report significantly more feelings of control over their health and feeling as good as anyone else while reporting less feelings of shame or guilt about their diagnosis compared to older adults. They are more likely to have a positive self-image and better adjustment to their diagnosis. Strategies that translate positive youth self-efficacy into improved self image for older adults require exploration.

TUPED407

Prevalence and factors associate with common mental health problems among people living with HIV/AIDS in Dar es Salaam, Tanzania

S. Likindikoki[1], V. Fonner[2], E. Steven[1], F. Chiwanga[3], J. Mbwambo[1], M. Sweat[4]
[1]*Muhimbili University of Health and Allied Sciences, Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of,* [2]*Medical University of South Carolina, Psychiatry and Behavioural Sciences, Charlestown, United States,* [3]*Muhimbili National Hospital, Internal Medicine, Dar es Salaam, Tanzania, United Republic of,* [4]*Medical University of South Carolina, Division of Global and Community Health, Charlestown, United States*

Background: People living with HIV/AIDS (PLWHA) are at risk of getting mental health problems such as depression, alcohol and tobacco use. These conditions can negatively impact on the disease progression and overall quality of life (QOL). This study aims to determine the prevalence and risks factors for depression, alcohol and tobacco use among people currently receiving care for HIV in Tanzania.
Methods: A total of 359 adult HIV-positive patients were recruited and interviewed between August and October 2017. We sampled every third HIV Care and Treatment Clinic (CTC) client receiving care at the Muhimbili National Hospital situated in Dar es Salaam. Patients Health Questionnaire-9 (PHQ-9) was used to assess for depression, WHO-STEPS survey to assess tobacco and alcohol use. Structured questionnaire was used to assess predictors of interest like social support, social demographic status and anti-retroviral (ART) adherence. Frequencies and percentages were used to describe the prevalence, chi-square test to examine differences in prevalence and bivariate logistic regression for depression and predictors of interest.
Results: Participants were predominantly female 277/359 (77.2), the mean age was 45.8 (SD=9.8) more than half of the participants had primary education 207 (57.7%) and a majority reported clinic attendance for the past five years (71.8%). Of 359 participants, 9 (2.5%) were classified as having depression (phq9 score>=10). Rates of depression were similar comparing males (2/82, 2.4%) and females (7/277, 2.5%), chi-square=0.96. 36/359 (10%) and 18/359 (5%) reported to ever use tobacco products and current tobacco use, respectively. As for alcohol use, 217/359 (60.5%) and 70/359 (19.5%) reported to ever drank alcohol and having drunk alcohol in the past 12 months, respectively. Men were found be more likely to have ever used tobacco (OR=17.4, 95% CI: 7.5-40.3, p< 0.001) and alcohol (OR=2.6, 95% CI: 1.5-4.7). Alcohol use was also associated with receiving no family support related to HIV (OR=2.1, 95% CI: 1.0-4.2, p=0.05).
Conclusions: Alcohol and tobacco use are common among PLWHA and despite the reported low prevalence of depression, it is imperative to screen for common mental health problems at CTC to be able to intervene and reduce comorbidities as well as improve QOL for PLWHA.

	Overall (n=359)	Males (n=82)	Females (n=277)	Chi-Square
Depression (PHQ-9>=10)	9(2.5%)	2(2.4%)	7(2.5%)	0.96
Current Tobacco use	18(5%)	12(14.6%)	6(2.2%)	<0.001
Ever Tobacco use	36(10%)	28(34.2%)	8(2.9%)	<0.001
Current alcohol use (In past 12 months)	70(19.5%)	21(25.6%)	49(17.7%)	0.11
Ever alcohol use	217(60.5%)	63(29.0%)	19(13.4%)	0.001
ART adherent	350(97.5%)	79(96.3%)	271(97.8%)	0.45
ART non adherent	9(2.5%	3(3.7%)	6(2.7%)	
Family support for HIV care - YES	316(88%)	73(89.0%)	243(87.7%)	0.75
Family support for HIV care - NO	43(12%)	9(11%)	34(12.3%)	

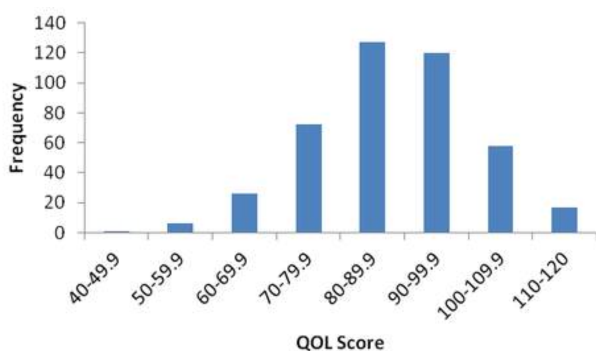
[Table 1. Prevalence of depression and risk factors, stratified by sex]

TUPED408

Cross-sectional study of Quality of Life (WHO HIV-QL31) of HIV patients in the Philippines

C. O'Connor[1,2], K. Leyritana[1], H. Elsayed[3], S. Cox[2,3], J. Lewis[2], E.M. Salvana[4]
[1]*Sustained Health Initiatives of the Philippines (SHIP), Madaluyong City, Philippines,* [2]*London School of Hygiene and Tropical Medicine, London, United Kingdom,* [3]*Nagasaki University, Nagasaki, Japan,* [4]*National Institute of Molecular Biology and Biotechnology National Institutes of Health University of the Philippines Manila, Manila, Philippines*

Background: Philippines has the fastest growing HIV/AIDS epidemic in the Asia Pacific region. In the past six years the Philippines has seen a 140% increase in the number of new infections, and 83% of new cases are in men who have sex with men (MSM). As the burden of HIV increases, assessing the quality of life (QOL) of PLHIV is important in order to provide appropriate care and treatment. Currently, no data are available regarding the QOL in HIV patients in the Philippines.
Methods: A cross-sectional analysis was conducted using data from the baseline visit of a cohort study of patients at a nonprofit private clinic in Metro Manila. Data were collected from October, 2016 to December, 2017. Patients completed the World Health Organization HIV QOL questionnaire (WHO HIV-QL31) in English. Data were entered into Excel and descriptive analysis was conducted in STATA 14.
Results: The study enrolled 463 patients, 91% were MSM. 427 completed HIV-QL31 questionnaires. The range, IQR, mean, and standard deviation for each of six domains and the total score are detailed in the Table. The distribution of total QOL scores is detailed in the histogram in the Figure. The mean QOL score in the cohort was 88.3 (maximum possible total = 120, max possible per domain = 20). The domain with the lowest mean QOL was Environment (13.4) followed by Spirituality (14.3).
Conclusions: The QOL scores of our cohort are somewhat higher than those of cohorts from Thailand and from India, suggesting that QOL for PLHIV in the Philippines may be somewhat better than it is in other countries throughout the Asia Pacific region. The cohort in our private clinic is of higher socioeconomic status than the average Filipino, however, so these data may not be representative of QOL for most Filipinos living with HIV.
Further analysis should be conducted to examine the independent predictors of QOL and also to determine how QOL impacts outcomes. Understanding which domains patients have poorer QOL may help officials to plan targeted interventions to improve patient outcomes.



[Quality of Life Score Distribution (WHO HIV-QL31)]

QOL Domains	Minimum Observed	IQR 25%	IQR 50% (Median)	IQR 75%	Maximum Observed	Mean Score	Standard Deviation
D1 Physical	7.0	13.0	15.0	17,0	20.0	15.1	2.7

QOL Total	47.9	80.4	88.7	97.0	116.7	88.3	12.5

[Quality of Life of HIV Patients by Domain (WHO HIV-QL31)]

TUPED409

Is the PHQ-8 an efficient screening tool for depression among HIV positive pregnant women attending antenatal and postnatal care?

L. de Vos[1], D. Olivier[1], M. Mudau[1], C. Bezuidenhout[1], J. Klausner[2], K. Lovero[3], M. Wainberg[3], A. Medina-Marino[1]
[1]*Foundation for Professional Development, Research Unit, Pretoria, South Africa,* [2]*Global Health David Geffen School of Medicine, Division of Infectious Diseases, Los Angeles, United States,* [3]*Columbia University, Department of Psychiatry and New York State Psychiatric Institute, New York, United States*

Background: South African primary care guidelines stipulate that all pregnant women should be screened for depression at every antenatal care visit (ANC). Previous studies have shown high depression levels among HIV-infected pregnant women. Depression contributes to various adverse maternal health outcomes, supporting the need for a feasible and validated screening tool for detection at PHC-level in South Africa. We aimed to determine the reliability of the 8-item Patient Health Questionnaire (PHQ8) and quantify depressive symptoms among this population.
Methods: From June 2016 to September 2017, HIV-infected pregnant women attending ANC at three primary healthcare facilities in Tshwane were recruited. Participants were screened for symptoms of depression during pregnancy, after delivery and six weeks post-delivery. Scores were categorized into depression levels: none (0-4), mild (5-9), moderate (10-14), moderately severe (15-19), severe (20-24). A cut-off score of 10 for depression was used in accordance with previous studies. Women with high symptoms of depression were referred for further care. An inter-item scale reliability analysis was conducted to demonstrate internal consistency of the PHQ-8.
Results: We recruited 845 women. Twenty-eight percent (N=236) experienced mild to severe depressive symptoms; 6.9% (N=58) were classified as depressed. Fifty-one percent (N=430) of participants were attending first ANC. Of those, 37% (N=159) were newly diagnosed with HIV. Women diagnosed with HIV on day of enrolment showed higher levels of depression than women previously diagnosed (OR=2.6, CI 1.49-4.6). Higher symptoms of depression (score ≥ 10) were positively associated with younger age, education level and multiple partners during pregnancy. Only 1.3% (N=6/461) were classified as depressed after delivery and only one participant at six weeks post-delivery. The Cronbach alpha for the PHQ-8 was 0.72 in ANC, 0.72 after delivery, and 0.68 at six weeks post-delivery.
Conclusions: Higher depression rates among those newly diagnosed shows the importance of early screening and ongoing mental health support. Internal consistency rates were acceptable when administering the PHQ-8 during pregnancy. However, it should be validated against a gold-standard to confirm depression rates found here.

TUPED410

Associations between HIV-related stigma and socioemotional competencies: Evidence for psychosocial and psychotherapeutic interventions

P.D. Radusky[1,2], I. Aristegui[2,3], V. Zalazar[2], O. Sued[2], I.M. Mikulic[1]
[1]*University of Buenos Aires, Department of Psychology, Buenos Aires, Argentina,* [2]*Fundación Huésped, Buenos Aires, Argentina,* [3]*Universidad de Palermo, Buenos Aires, Argentina*

Background: HIV-related stigma has a negative emotional impact on people living with HIV (PLH), ranging from emotional distress to depression and anxiety disorders and ultimately leading to adverse outcomes on health and well-being. Socioemotional competencies (SEC) can be resources to adequately perceive, express and manage these negative emotions, reducing their adverse impact. The purpose of this study was to explore the association between stigma (internalized, anticipated and enacted) and SEC and to analyze the existence of predictive relations between these variables.
Methods: A cross-sectional study was conducted between June-November 2017. The Socioemotional Competencies Inventory (SECI) and the HIV-Related Stigma Inventory (EI-HIV) were administered. The

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

analysis included Pearson correlations, to identify associations between SEC and dimensions of stigma, and regression analysis, to test predictive relations between variables.

Results: The final sample consisted of 83 PLH (66% men, 34% women). Mean age was 41 years (SD=13.40). Half were MSM and half were heterosexual men and women. All significant correlations between SEC and HIV-related stigma were negative. Emotion regulation and optimism were the only SEC significantly associated with the three dimensions of stigma. Having experienced stigma and discrimination (enacted stigma) negatively affected the levels of self-efficacy (R^2=.11, F(1,81)=10.75, p< .01, ß=-.34, p< .01), optimism (R^2=.12, F(1,81)=11.25, p< .001, ß=-.34, p< .001) and emotion regulation (R^2=.11, F(1,81)=10.07, p< .01, ß=-.33, p< .01). These last two SEC significantly predicted internalized (R^2=.22, F(2,80)=11.58, p< .001) and anticipated stigma (R^2=.18, F(2,80)=8.82, p< .001).

	IS	AS	ES	IS		AS	
				ß	p	ß	p
Emotional Regulation	-.32**	-.37**	-.33**	-.21	.046	-.30	.006
Optimism	-.43**	-.31**	-.34**	-.36	.001	-.22	.041
Self-efficacy	--	--	-.34**	--	--	--	--

*[Table 1. Pearson correlations and multiple regression analysis between SEC and dimensions of HIV-related stigma. Note: IS: Internalized stigma; AS: Anticipated stigma; ES: Enacted stigma; **p<0.01]*

Conclusions: Participants with higher levels of SEC exhibited lower levels of HIV-related stigma. Results support previous evidence showing that experiences of HIV-related stigma and discrimination negatively affect certain SEC, especially emotion regulation and optimism. This may contribute to the increment of internalized and anticipated stigma. These specific SEC might play a particularly important role in coping with the negative emotional impact of stigma. An integrative model including them should be tested in future studies. This evidence supports the relevance of promoting and developing SEC (focusing on emotion regulation skills and optimism) in psychosocial and psychotherapeutic interventions aimed at PLH, to enhance individuals' resources to cope with HIV-related stigma and reduce its negative impact on health and well-being.

TUPED411

A place to belong: Findings from a mixed-methods examination of housing as a health intervention for LGBT young adults age 18-24

S. Ali[1], M. Stanton[2], P. Andrews[2], V. Shubert[2], T. Ghose[3]
[1]University of Houston, Houston, United States, [2]Housing Works, Brooklyn, United States, [3]University of Pennsylvania, Philadelphis, United States

Background: Young age and housing instability independently predict virologic failure, driving heightened HIV risk among unstably housed lesbian, gay, bisexual, transgender and/or queer (LGBTQ) youth (18-24). Congregate, supportive housing can promote viral load suppression among marginalized groups. However, little is known about the impact of housing on health outcomes for LGBTQ youth, who are living at the intersection of social marginalization and late-adolescent development stage. The aim of this study is to examine a unique congregate, supportive housing program for young LGBTQ adults living with HIV.

Methods: A mixed-methods study initiated upon the housing program's opening was designed to assess the effect of the program on HIV management, mental health, substance use, sexual health, HIV stigma, and self-esteem. Data collected to date include descriptive statistics from baseline resident surveys (N=13) and in-depth semi-structured interviews (N=8) conducted approximately 3 months following program enrollment.

Results: Most residents (average age 21.8 years) identify as male (85%), black (69%) and unemployed seeking work (62%). 77% moved more than three times in the past two years, 62% experienced homelessness, and most were staying temporarily with a family member or friend (38%) or residing in emergency housing (23%) prior to program entry. Two-thirds (62%) have histories of incarceration, 54% have experienced intimate partner violence in the past year, and 100% report perceived HIV stigma. Interviews revealed that the housing program promotes medication adherence and viral load suppression among youth through:

1) shielding residents from the risk environment;
2) connecting residents to a range of culturally appropriate physical and behavioral health services; and
3) developing a sense of community which fosters mutual support, prosocial health norms and mitigates the negative effects of internalized stigma.

Conclusions: Lack of affirming, safe housing for LGBTQ homeless youth with HIV contributes to poor health outcomes. Quantitative findings reflect volatile residential instability and high internalized stigma. Qualitative data reveal how supportive, congregate housing can promote environmental predictability and foster positive peer relationships. These factors influence LGBTQ youth's development of sense of self and health and point to critical components of housing as a structural intervention with this group.

Adaptation to living with HIV for individuals, families, and communities

"It is our time": Confronting internalized stigma to empower young people living with HIV

B. Nanyonjo[1], B. Nabuuma[2], P. Senteza[3]
[1]Busega Adolescent Sexual Health Program (BUSHEP), Outreach, Kampala, Uganda, [2]Reproductive Health Uganda, Advocacy and Community Development, Kampala, Uganda, [3]Makerere Institute of Social Development, Research, Kampala, Uganda

Background: Young people living with HIV do not have access to resources required to keep them healthy, and to access HIV and sexual reproductive information. YPLWHA are further marginalized because of their status as HIV is linked to sex which is a taboo issue - creating a double stigma.

Description: Busega Adolescent Sexual Health Program (BUSHEP), an affiliate to the Reproductive Health Uganda (RHU) engaged 74 youth and adolescents living with HIV aged 18 - 25 in advocacy and empowerment training initiatives. Through funding from Ministry of Health, BUSHEP facilitated two programs in Kampala district between August 2016 and August 2017. YOU-STOP a health promotion and sexual education group for youth living with and affected by HIV, and YOU-CAN+ a private space for HIV+ youth. The programs address the misconceptions around HIV and sexual health, and also build capacity to respond to stigma and discrimination. Activities for the programs include radio talk shows, HIV testing campaigns, and life-experience sharing.

Lessons learned: After data analysis, it was reported that YLWHA were more proactive to confront internal fear and speak about against stigma. "It is our time to be part of the HIV response. Involve us at all levels to fight stigma and discrimination" one participant said. Empowerment was also seen with increased disclosure and building alliances with other groups (e.g., youth with disabilities) to collectively address stigma. In the one year of intervention, the 74 youth had also expanded their base to engage other community members to talk about HIV and sexual reproductive health.

Conclusions/Next steps: BUSHEP engaged YLWHA as a way of empowering youth to be active partners in HIV response. The project also empowered YLWHA to fight internal stigma, and to create networks for addressing stigma and improve wellness. This research recommends more involvement of YLWHA and allies to increase HIV knowledge and sexual health information.

TUPED413

The effect of social stigma on drug adherence for HIV positive secondary school teenagers in St. Kizito SSS Katikamu, December 2017

K.C. Richard, Secondary School Teenagers 13-19 years
St. Kizito S.S.S. Katikamu Kisule Wobulenzi, Guidance and Counseling Department, Kampala, Uganda

Background: Recent statistics show, 3.8 Million Youth are living with HIV globally, 76% of whom are in Sub Saharan Africa. In Uganda, HIV is still a national problem, especially among the youth. Alarmingly, with all the efforts made, prevalence has increased from 6.4 in 2004 to 7.4 in 2016. This study therefore, sought to find the extent to which Social Stigma affected drug adherence of Secondary School Teenagers in Katikamu Sub- County, Luwero District, Uganda. The objective was to ascertain whether the close interaction with the school community, does not significantly interfere with adherence to ART.
Methods: A sample of 45 teenage students, between the ages of 13 and 19, living with HIV, was selected for the study. A cross section survey design was adopted and data was collected through questionnaires. Data was analyzed quantitatively using the SPSS.
Results: Out of 45 students, 10 kept their situation in total concealment; they had a lot of difficulty taking their drugs since they did it in secrecy. Many times they missed their drugs. 30 had never disclosed their HIV status to any other student. These took their drugs under the supervision of the school nurse or counselor. They still some times missed their drugs. On the other hand, 4 had disclosed their status to at least one or two of their friends. These had the opportunity of taking their drugs in the company of those who knew, and they could even be reminded, they rarely missed their drugs. Exceptionally, one had publicly disclosed his HIV status and had overcome the stigma attached. He had the freedom of taking his drugs freely and he never missed.
Conclusions: It was therefore concluded that social Stigma was a big barrier in drug adherence among teenage youth in School, in Katikamu Sub County, Luwero District. The youth in schools should be encouraged to disclose their HIV status in order to fight stigma and be able to adhere to ART. Youth communities should be sensitized more on the need to give social and moral support to those living with HIV, and not to stigmatize them.

TUPED414

Filial piety as a risk factor for self-stigma and poor mental health among HIV-positive men who have sex with men (MSM) in China

R.C.H. Chan[1], A. Restar[2], R. Cheng[3], W. Mak[3]
[1]University of Hong Kong, Department of Social Work and Social Administration, Hong Kong, Hong Kong, [2]Brown University School of Public Health, Providence, United States, [3]Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: HIV-positive men who have sex with men (MSM) face double stigma of being HIV-positive as well as having same-sex attraction and behavior. Such stigma may be particularly pronounced in traditional Chinese cultural context, with filial piety as its core value. Chinese people are obligated to fulfill the filial duty to their parents and bring grace to their family and ancestors. Under the influence of Confucianism, it is also important for people to have children to carry on their family name. These filial obligations may impose considerable psychological burdens on HIV-positive MSM. The present study examined the endorsement of filial piety among HIV-positive MSM in China, and investigated its effects on their self-stigma and mental health.
Methods: A sample of 234 mainland Chinese HIV positive MSM (mean age = 30.43, SD = 7.61) was recruited from a non-governmental organization providing services to people living with HIV (PLHIV) in Shanxi province, China. They were asked to fill in a questionnaire on filial piety, self-stigma of being PLHIV, self-stigma of being MSM, and mental health.
Results: Findings of structural equation modeling showed that filial piety was positively associated with self-stigma as PLHIV and self-stigma as MSM. Self-stigma as MSM was related to lower level of mental health. Filial piety was found to have an indirect negative effect on mental health via self-stigma as MSM, while the mediating effect of self-stigma as PLHIV was not significant.
Conclusions: Understanding HIV and sexual stigma within the Chinese cultural context are pivotal in controlling the HIV epidemic in China. Given the double stigma and the cultural norm of filial piety, HIV-positive MSM in Chinese societies are highly vulnerable to negative mental health outcomes. They face substantial pressure to manage the stigma surrounding their sexual desire and the sociocultural expectations. Self-stigma reduction intervention in China should always take cultural factors into consideration, supporting HIV-positive MSM to develop strategies for negotiating filial obligations.

TUPED415

Roles of employment status and emotion regulation in death anxiety among people living with HIV/AIDS

J. Chukwuorji[1], C. Chukwu[2], C. Uzuegbu[3], C. Ifeagwazi[2]
[1]University of Nigeria, Department of Psychology, Nsukka, Nigeria, [2]University of Nigeria, Nsukka, Nigeria, [3]University of Nigeria, Department of Social Work, Nsukka, Nigeria

Background: Death anxiety is one of the most commonly observed mental health sequelae of HIV/AIDS. However, there is limited research on contributions of employment status and emotion regulation strategies in death anxiety. This study examined the moderating role of emotion regulation strategies on associations of employment status and death anxiety among people living with HIV/AIDS (PLWHA). Death anxiety was operationalised based on its four dimensions - Death Acceptance, Externally Generated Death Anxiety, Death Finality, and Thoughts About Death. Cognitive reappraisal and expressive suppression were the emotion regulation strategies considered to be of interest in this study.
Methods: Participants were 186 PLWHA (mean age = 34.16 years, SD = 11.16; 43.5% men and 56.5% women) from the HIV/AIDS care unit of a tertiary healthcare institution in south-eastern Nigeria. Many of them (*n* = 108, 58.1%) had attended higher institutions. Employment status were as follows: Unemployed (n = 58, 31.2%), self-employed (n = 59, 31.7%) and currently employed (n = 69, 37.1%). They completed self-report measures of the variables and provided some demographic information including their employment status.
Results: Employed persons had lower scores on all death anxiety dimensions, than self-employed and unemployed persons. Self-employed persons did not differ from unemployed persons in any dimension. Cognitive reappraisal was not associated with any death anxiety dimension. Those with high expressive suppression were more accepting of death. Moderation analysis showed that unemployed and self-employed PLWHA were more vulnerable to higher thoughts about death when they adopt low and moderate expressive suppression than when they adopt high expressive suppression.
Conclusions: Findings underscore the benefits of formal employment and the utility of expressive suppression in effective interventions to reduce death anxiety and improve quality of life of PLWHA.

TUPED416

The impact of serostatus disclosure on the spousal relationship between wives and HIV-positive husbands who have sex with men in China: A qualitative study

W. Cao, H.M. Wong
University of Hong Kong, Hong Kong, Hong Kong

Background: Men who have sex with men (MSM) is classified as a key population in HIV epidemic, and the HIV prevalence among MSM was high. An overall of 38-70% of MSM enter into heterosexual marriage during the lifetime. Disclosure of HIV-positive status to wives is inevitable along with the disease progression and the necessity to test the wife's HIV status. However, acknowledgment of the husband's HIV-positive status may change the spousal relationship, which is rarely investigated in the literature. This study aimed to describe the impact of serostatus disclosure on the spousal relationship from the perspective of wives.

Methods: A qualitative study using semi-structured interviews was conducted among wives (n=31) who had known their husbands' HIV-positive status in China. Their husbands were infected by HIV through homosexual behavior. Participants were identified by a non-governmental organization and a Center for Disease Control and Prevention who provide routine services for people living with HIV and their family members. Qualitative data underwent a detailed content analysis.
Results: Both positive and negative impacts on the spousal relationship were expressed by wives. Six themes were identified:
(1) reduced sexual activities;
(2) changes in intimacy;
(3) limited communication on HIV-related issues but improved communication on other topics;
(4) increased instrumental support but decreased emotional support;
(5) developed spousal relationship resilience; and
(6) shared privacy management rules regarding HIV-positive status.
Moreover, the acknowledgment of the husband's homosexual behavior hurt the spousal relationship more serious than the HIV infection, and an irremediable marriage was observed among wives who knew both.
Conclusions: Disclosure of HIV-positive status had a great impact on the spousal relationship, and such impact varied across individuals. Tailored counselling is recommended to meet personal needs and contextual situations.

TUPED417

HIV-related stigma and proactive coping processes among HIV-positive clinic patients in Philadelphia, Pennsylvania

S. Meanley[1], B. Yehia[2,3,4], J. Hines[2], R. Thomas[2,3], D. Calder[2,3], B. Carter[2], B. Dube[5], J.A. Bauermeister[1]
[1]*University of Pennsylvania School of Nursing, Family and Community Health, Philadelphia, United States,* [2]*University of Pennsylvania Perelman School of Medicine, Department of Medicine, Philadelphia, United States,* [3]*Penn Medicine Program for LGBT Health, Philadelphia, United States,* [4]*University of Pennsylvania, Leonard Davis Institute of Health Economics, Philadelphia, United States,* [5]*University of Pennsylvania Perelman School of Medicine, Department of Psychiatry, Philadelphia, United States*

Background: Interpersonal HIV stigma continues to burden the well-being of people living with HIV/AIDS (PLWHA), often shaping their ability to cope and integrate disease management into their lives. Extant literature on managing HIV/AIDS stigma has focused primarily on engaged (e.g., social support seeking) and disengaged (e.g., denial) coping styles. Few research efforts have explored PLWHA's proactive coping, which refers to regulating one's behavior in anticipation of stigma to prevent/minimize its impact. Understanding proactive coping strategies are important for contextualizing the methods undergone to reduce PLWHA's HIV-related stress.
Methods: We conducted 19 in-depth, qualitative interviews with PLWHA recruited at a university-based HIV clinic in Philadelphia, Pennsylvania. Our sample was predominantly middle-aged or older (40+ years, 74%), racial/ethnic minority (74%), sexual minority (52%), cis-male (74%), and had 5+ years since diagnosis (74%). We conducted a thematic analysis guided by the *Stages of Proactive Coping* to understand participants' recognition of HIV-related stigma, perceived consequences of stigma, and proactive coping efforts.
Results: Anticipated stigma regarding HIV status disclosure remained the most commonly described stressor. Manifesting as anticipated rejection, participants assuaged these stigma-related perceptions through proactive coping strategies including selective disclosure and limited pursuit of romantic/sexual partnerships. Additionally, internalized stigma manifested as fear of transmitting the virus to others and subjecting them to similar stigmatizing circumstances. Participants discussed a variety of proactive coping strategies to mitigate internalized stigma, including sexual abstention, minimizing physical contact with others, and not sharing kitchenware and utensils.
Conclusions: Despite integrating HIV diagnoses into their daily lives, PLHWA endure on-going HIV-related stigma and seek proactive coping strategies to mitigate anticipated and internalized stigma as chronic stressors. Seeking to mitigate these experiences, PLHWA relied on avoidant behaviors as proactive coping strategies. Our findings provide implications for clinical practice, elucidating the importance of classifying PLWHA's health beyond metrics like viral load and CD4+ counts. Future efforts should seek to understand how proactive coping strategies impact the health and social well-being of PLWHA. Lastly, individual-level strategies that elicit alternative coping strategies to build resiliency in the contexts of stigma and disclosure may complement continued structural/interpersonal-level initiatives that directly address HIV-related stereotypes and misinformation.

TUPED418

Longitudinal efficacy trial of a disclosure intervention (TRACK) for HIV+ mothers

M. Schulte[1], L. Armistead[2], D. Murphy[1], W. Marelich[3]
[1]*University of California, Santa Monica, United States,* [2]*Georgia State University, Atlanta, United States,* [3]*California State University, Fullerton, Fullerton, United States*

Background: Mothers living with HIV (MLH) often do not disclose their HIV status to their young children due to concerns of burdening them and lack of confidence in their ability to disclose. However, concealment can negatively impact maternal health and child development. The Teaching, Raising, And Communicating with Kids (TRACK) program was a full-scale longitudinal efficacy trial of a previously successful pilot intervention aimed at assisting MLH with disclosure. Based on Derlaga's disclosure model and Bandura's theory of self-efficacy, the current study examined TRACK's impact on MLH disclosure.
Methods: MLH and their young children (6-12 years) were recruited in Los Angeles, California and Atlanta, Georgia (March 2013 to November 2017) and randomized to intervention or wait-list control (N = 175) conditions. Participants were assessed at baseline, 3-, 9-, and 15-month follow-ups regarding HIV disclosure, disclosure self-efficacy, and parenting practices. Growth curve modeling was used to examine differences between the TRACK and control groups across time.
Results: MLH (mean age = 39.3, SD 7.9) were 33.7% Latina, 56% African-American, 5.1% White, and 5.1% other/multiracial. Those in the intervention group were 4.27 times (1.9 to 9.5; 95% CI) more likely to disclose their status compared to the control group, with 34.52% disclosure in the TRACK group compared to 10.99% in the control group. Although the greatest proportion of disclosures happened within the first three months, the TRACK group continued to disclose at a much higher rate at all follow-ups. Based on growth curve modeling, intervention MLH showed a significant increase in disclosure self-efficacy, with increased self-efficacy associated with a greater likelihood to disclose. In addition, positive parenting significantly improved among the intervention TRACK mothers compared to controls.
Conclusions: TRACK helped MLH disclose their HIV status to their young children and increased positive parenting practices. By boosting confidence to effectively disclose serostatus, disclosure interventions can increase the likelihood of initial disclosure as well as improve mothers parenting skills for how to approach subsequent questions and conversations regarding HIV with their children. Increased positive parenting can serve as a protective factor that mitigates risk for psychological disturbance among children.

TUPED419

Can HIV counselors be supported to attain better outcomes for their child clients and their caregivers? The case of *Stepping Stones with Children*

E. Mkolokoti[1], A. Welbourn[2], S. Holder[2]
[1]*Pasada, Counseling, Dar es Salaam, Tanzania, United Republic of,* [2]*Salamander Trust Fund, London, United Kingdom*

Background: Children affected by HIV and their caregivers face many physical, psycho-social and material challenges, which can lead to poor health outcomes. Salamander Trust and PASADA developed transformative participatory workshop materials, to enable children aged 5-8 and 9-14 to realise and build on their strengths, and create happier, healthier and safer ways of being. We also developed a parallel guide to

counselling children affected by or living with HIV and their caregivers, and used it to train PASADA's counsellors, to improve their effectiveness.
Description: The materials were developed and tested during 2012-14 in Tanzanian coastal regions. Community workshops and counsellor training then took place during 2015. 185 people participated in the community workshops, comprising 23.8% children aged 5-8, 28.6% aged 9-14, and 47.6% caregivers. 56.7% of the children and 78.4% of the caregivers were female. 88.7% of the children were clients of PASADA living with HIV. 80.6% of the 31 counselors trained were female.
Lessons learned: Working with children and their caregivers *and* with the counsellors produced beneficial synergies:
§ Caregivers and counsellors learned the importance of and skills for listening to children and involving them in decision-making, and children became better at expressing their thoughts and feelings to others, including to their counselors. This led to improved relationships between family members and with the counselors (see table).
§ Caregivers and children learned about managing living with HIV, leading to greater willingness among caregivers to share their child's serostatus with them, while counsellors improved their skills in supporting decision-making around disclosure, and supporting caregivers and child clients in that process. The proportion of children knowing their status increased from 27% to 93%.
§ Greater understanding of HIV and increased attendance at counseling sessions linked to improved adherence to HIV treatment and statistically significant clinical outcomes.
§ All parties learned about puberty, sexuality and sexual abuse, and grief, and became less inhibited about discussing sexual matters and death.
Conclusions/Next steps: Working only with child clients or their caregivers or HIV counselors would likely be beneficial, but working with all parties produces important synergies that support and compound the outcomes.

Experiences and impacts of antiretroviral therapy

TUPED420

Partners of people living with HIV (PLHIV): Findings from the positive perspectives survey

D. Garcia[1], B. Spire[2], S. Marcotullio[3], M. Muchenje[4], A. Namiba[5], K. Parkinson[6], B. Young[7], B. Allan[8], Y. Punekar[9], A. deRuiter[9], F. Barthel[10], J. Koteff[11], A. Ustianowski[12], A. Murungi[9], V. Carr[9]
[1]European AIDS Treatment Group, Madrid, Spain, [2]French National Institute for Medical Research (INSERM), Paris, France, [3]Nadir Onlus, Rome, Italy, [4]Women's Health in Women's Hands Community Health Centre, Toronto, Canada, [5]Salamander Trust, London, United Kingdom, [6]Beacon Project, St Louis, United States, [7]International Association of Providers of AIDS Care, Washington DC, United States, [8]ICASO and Australasian Society for HIV, Viral Hepatitis and Sexual Health Medicine, Victoria, Australia, [9]ViiV Healthcare, Brentford, United Kingdom, [10]GlaxoSmithKline, London, United Kingdom, [11]ViiV Healthcare, Research Triangle Park, United States, [12]Pennine Acute Hospitals NHS Trust, Manchester, United Kingdom

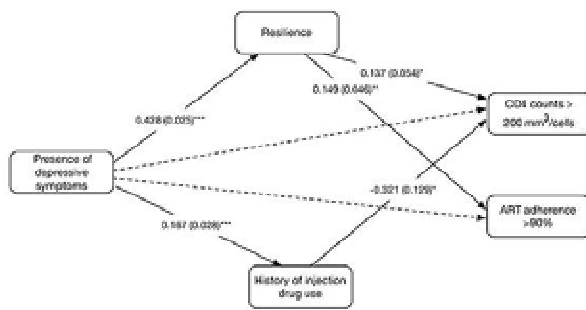
Background: While studies have been conducted to evaluate the psychosocial effect of treatment and the support available to People Living with HIV (PLHIV), there remains a gap in understanding their influence on partners. We conducted an international survey of partners of PLHIV to explore the support offered specifically to them and their partner's perception of their HIV management.
Methods: Qualitative in-depth interviews were performed with PLHIV and their partners to identify key hypotheses. A steering group developed the survey questions which were fielded online from November 2016 to April 2017 in 9 countries across North America, Europe & Australia. A mixed sampling/recruitment approach was used to ensure a broad cross-section of PLHIV, and partners of PLHIV were recruited where possible.
Results: 250 partners of PLHIV completed the survey from Europe (55%), North America (43%) and Australia (2%). 91% were male, 26% aged ≥50 years, 30% HIV+ themselves, and 77% lived with their partner. Results differed between HIV+ and HIV-ve partners: emotional support available to partners of PLHIV was rated as 'quite good' or 'very good' in 78% HIV+ partners but decreased to 53% in HIV- partners. Partners of PLHIV stated that they provided emotional support (87%) and encouraged their partners to raise concerns with their main HIV healthcare provider (80%), yet over half of partners would like to be more involved in these areas and 20% feel they sometimes lack the information needed for this role.
Of those whose partners were on ART (98%), 63% had helped their partner prepare for an appointment with their HIV HCP and had raised concerns about side effects (82%), strategies to reduce long-term impact of ART (62%) and the possibility of switching regimen (59%).
Conclusions: In this international survey, nearly two thirds of partners were involved in discussions on treatment and were most often concerned about side effects and the long-term impact of ART. Partners represent an important support system for PLHIV, and dedicated resources to inform partners could enable them to become more involved in the support of PLHIV.

TUPED421

A psychosocial approach to understanding pathways from depression to HIV care cascade outcomes among women living with HIV in Canada

C.H. Logie[1], C. Williams[1], Y. Wang[1], N. Marcus[1], M. Kazemi[2], L. Cioppa[2], A. Kaida[3], T. Conway[2], K. Webster[3], K. Beaver[2], A. de Pokomandy[4], M. Loutfy[2], Y. Persad[5]
[1]University of Toronto, Toronto, Canada, [2]Women's College Hospital, Toronto, Canada, [3]Simon Fraser University, Vancouver, Canada, [4]McGill University, Montreal, Canada, [5]519 Community Centre, Toronto, Canada

Background: Women living with HIV (WLWH) experience stressors, including stigma and discrimination, that may contribute to a higher prevalence of depression in comparison with HIV-negative women. Adaptive and maladaptive coping strategies for depression, and depression severity, may account for differences in HIV care cascade outcomes. Yet psychosocial approaches to understanding pathways from depression to cascade outcomes such as ART adherence and CD4 count are understudied. We examined pathways from depressive symptoms to ART adherence and CD4 count among WLWH in Canada, exploring resilience and injection drug use history (IDU) as mediators in this relationship.
Methods: Baseline survey data were analyzed for WLWH (≥16 years) enrolled in a community-based cohort study in British Columbia, Ontario, and Québec, Canada. Using the Center for Epidemiologic Studies Depression 10-item Scale, we assessed depressive symptoms (score: ≥10) and severe depressive symptoms (score: ≥15). Structural equation modeling using weighted least squares estimation methods was used to test the direct effects of depressive symptoms and severe depressive symptoms on ART adherence and CD4 count, and the indirect effects via resilience and IDU history, adjusting for socio-demographic factors.
Results: Most participants (n=1342; mean age: 42.77, IQR: 35-50) were currently taking ART (82.91%). Nearly half (48.61%) reported depressive symptoms and one-quarter (26.90%) severe depressive symptoms. Approximately one-third (31.55%) reported an IDU history. Resilience fully mediated the relationship between depressive symptoms and ART adherence (B=0.019, p<0.01). The combination effects from resilience (B=0.018, p<0.05) and IDU history (B=-0.219, p<0.05) fully mediated the relationship between depressive symptoms and CD4 count. The direct path from severe depression to ART adherence (B=-0.274, p<0.01) was significant, accounting for the mediation effects of resilience and IDU history. Resilience (B=0.015, p<0.01) and IDU history (B=-0.159, p<0.01) partially mediated the relationship between severe depression and ART adherence. Resilience fully mediated the relationship between severe depression and CD4 count (B=0.016, p<0.05).
Conclusions: Findings underscore the importance of a psychosocial approach to understanding how WLWH manage depressive symptoms, and how coping strategies may be associated with ART adherence and CD4 count. Harm reduction approaches, depression interventions, and strategies to foster resilient coping, have the potential to improve the HIV care cascade among WLWH.



[Figure 1. Final model for depressive symptoms and HIV care cascade outcomes among women living with HIV in Canada]

TUPED422

Barriers to linkage and retention in HIV care among adolescent girls and young women (AGYW) in communities around Lake Victoria in Western Kenya

Z. Kwena[1], K.R. Amico[2], K. Ngure[1], J. Mantell[3], R. Remien[4], N. Nguyen[5], B. Young[6], T.B. Masvaure[5,7], J. Zuniga[6], P. Ochwal[1,8], E. Stacey[6], D. Ochola[5], E. Bennett[5], T. Navalta[5], Z. Simpson[5], P. Ryland[5], P. Valente[5], J. Wallw[5], E. Bukusi[1]

[1]Kenya Medical Research Institute, Center for Microbiology Research, Nairobi, Kenya, [2]University of Michigan, Department of Health Behavior and Health Education, Ann Arbor, United States, [3]HIV Center for Clinical and Behavioral Studies at the New York State Psychiatric Institute, Psychiatry, New York, United States, [4]HIV Center for Clinical & Behavioral Studies, NYS Psychiatric Institute and Columbia University, Psychiatry, New York, United States, [5]HIV Center for Clinical and Behavioral Studies at the New York State Psychiatric Institute, New York, United States, [6]International Association of Providers of AIDS Care, Washington, United States, [7]College of the Holy Cross, Sociology and Anthropology, Worcester, United States, [8]Impact-IRDO, Nairobi, Kenya

Background: AGYW in sub-Saharan Africa experience delayed linkage to and poor retention in HIV care. Identifying and addressing specific barriers in HIV care programming is important in achieving the UNAIDS 90-90-90 targets and epidemic control. We sought to explore barriers to linkage and retention in HIV care among AGYW in communities aroung Lake Victoria in western Kenya.

Methods: As part of a larger qualitative study to identify drivers of HIV testing and HIV-care utilization in key populations, we conducted 103 in-depth interviews with HIV+ AGYW in and out of HIV care. We coded and analyzed resultant transcripts for theme and content using inductive methods.

Results: Barriers to linkage and retention in HIV care that emerged fell into five broad themes: confidentiality and privacy, stigma and discrimination, provider attitudes, antiretroviral treatment side effects and costs and distance to health facilities. Participants voiced concerns about disclosure of their HIV status to community members either by being seen at clinic or through breaches in confidentiality by clinic staff. Participants also highlighted pervasive fears of stigma and discrimination by friends and family, and particularly sexual partners. Participants reported being dismayed by poor quality counseling they received from providers who they said were often rude and not prepared to deal with patients´ issues. They cited cases where clinical staff ´punished´ patients for missed appointments by asking them to return on a different day for their clinic. Challenges with treatment included side effects (medications making them feel worse), especially if taken without food, the pills being too big and difficult to swallow, and daily routine of medication-taking being disruptive to their lives. Additionally, participants expressed concerns about the long distance to health facilities and associated transportation costs, and time spent at these facilities. They anticipated that these costs and time associated with their clinic attendance may pose challenges in the future since treatment is a lifelong commitment.

Conclusions: In these communities where concerns about confidentiality, stigma, provider attitudes, treatment side effects and costs associated with clinic attendance are still prominent, linkage and retention in care requires innovative approaches that are tailored to the individual needs and circumstances of patients.

TUPED423

Coping with antiretroviral therapy related stressors among HIV-positive men who have sex with men in China

C. Li[1], H. Jiang[2,3], G. Lei[4], W. Dong[1], E. Fisher[1], C. Golin[1,5], P.Y. Tang[1], K. Muessig[1]

[1]University of North Carolina at Chapel Hill, Department of Health Behavior, Gillings School of Global Public Health, Chapel Hill, United States, [2]Sichuan Provincial People's Hospital, Institute for Emergency and Disaster Medicine, Chengdu, China, [3]University of Electronic Science and Technology of China, School of Medicine, Chengdu, China, [4]Aibai Culture & Education Center, Chengdu, China, [5]University of North Carolina at Chapel Hill, Department of Medicine, Chapel Hill, United States

Background: In China, despite availability of free testing and treatment, the HIV epidemic is increasing among men who have sex with men (MSM), in contrast to stabilizing or decreasing prevalence for other key populations. Improving engagement in HIV treatment (e.g. antiretroviral therapy (ART) initiation and adherence) is critical for individual patient outcomes and preventing secondary transmission. We aimed to understand how Chinese HIV-positive MSM coped with ART-related stressors.

Methods: We conducted in-depth interviews and demographic surveys (PHQ-9 for depression) with HIV-positive MSM (n=30) recruited through clinics and a community-based organization (CBO) in Chengdu, China. Interviews focused on ART-related stress, coping strategies, social support, challenges, and well-being. Data were collected and analyzed by bilingual researchers. The Transactional Model of Stress and Coping informed thematic analyses of ART-related stress (primary stressor), identifying appraisals, coping efforts, resources, and outcomes.

Results: Average age was 31.5 years old. Length of time on ART was between 1 and 7 years (mean, 3.3 years). Over half of participants reported symptoms consistent with mild or moderate depression. Appraisals of ART-related stress included side effects, difficulty of daily adherence, and fear of developing drug resistance to free regimens. Coping efforts focused on improving physical health (e.g. increased exercise, regular physical exams) and actively seeking ART information (e.g. internet searching, querying providers), while also protecting privacy and social standing (e.g. concealing medications, limiting HIV status disclosure). While coping with ART-related stressors, participants faced challenges navigating contradictory information sources, experiencing stigma and discrimination within medical and non-medical settings, and managing financial concerns. ART initiation and continuity of HIV care was complicated by systems barriers such as required documentation (e.g. residency permit, CD4 results). Though several participants received support from family/friends after disclosing their HIV status, CBOs, peer support groups, and healthcare providers were more salient sources of social support.

Conclusions: Participants' narratives of stress and coping with ART-related stressors revealed multi-level intervention opportunities including at the individual (e.g. mental health services), institutional (e.g. provider anti-discrimination training), and policy (e.g. changing ART eligibility requirements) levels. CBOs are well-poised within China's gay community to expand and advocate for these interventions to meet existing needs of HIV-positive MSM.

TUPED424

Adherence misfits: Divergent perspectives on ART-defaulting among healthcare providers and HIV-positive adolescents

R. Hodes[1,2], L. Hatane[3], L. Gittings[4], A. Ronan[3], S. Malunga[5], L. Cluver[6], D. Mark[3], E. Toska[1,2], K. Bloch[3], R. Haghighat[2]
[1]University of Cape Town, AIDS and Society Research Unit, Cape Town, South Africa, [2]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [3]Paediatric Adolescent Treatment Africa, Cape Town, South Africa, [4]University of Cape Town, AIDS and Society Research Unit & School of Public Health and Family Medicine, Oakville, South Africa, [5]University of Cape Town, Department of Public Health and Family Medicine, Cape Town, South Africa, [6]University of Oxford, Department of Social Policy and Intervention, Oxford, South Africa

Background: HIV is the leading cause of death for young people (ages 10-24) in Africa. Adherence to antiretroviral treatment (ART) is commonly understood as the greatest healthcare challenge facing HIV-positive adolescents. Terms such as 'defaulting' and 'non-adherent' define the extent of non-compliance to ART, delinkage from care, and related clinical consequences. A growing literature identifies structural and clinical factors for ART non-adherence among adolescents. Less is known about how adolescents themselves understand non-adherence, and how this may differ from their healthcare providers.
Methods: This research combines the qualitative datasets of the Mzantsi Wakho study and Paediatric-Adolescent Treatment for Africa (PATA). Mzantsi Wakho is the largest longitudinal, community-traced study of ART adherence among adolescents living with HIV (n=1057). PATA constitutes a network of healthcare providers in 24 African countries, collecting data from health providers and HIV-positive peer-supporters within 289 facilities.
Different perceptions of the term 'defaulting' were explored through qualitative interviews with HIV-positive adolescents (n=56) and healthcare providers (n=13), and through clinic observations, in the Mzantsi Wakho study. PATA data constituted semi-structured interviews with peer supporters (n=6), health facility surveys (n=218) and programme reports with those providing adolescent services (n=289).
Results: Terms for non-adherence are used widely in research and programming for tracking and improving the health of young people with HIV. Within this diagnostic framework, the term 'defaulting' is used by healthcare providers to refer to patients with the worst adherence outcomes and the weakest retention in care. However, adolescents themselves do not use or identify with these terms (apart from youths working as treatment supporters). Instead, they understand non-adherence as temporary ('I'll go back') and necessary ('I need a break').
Conclusions: Combining qualitative datasets from research studies and HIV programming offers a valuable opportunity for triangulating findings across settings, and for critically evaluating research hypotheses and findings in relation to programming and implementation. Through integrating qualitative research between datasets, including with adolescents and healthcare providers, popular and practicable understandings of adolescent ART adherence emerge. To improve adolescent ART-related outcomes, it is crucial to address the disjuncture between adolescent and healthcare provider understandings of non-adherence.

TUPED425

Does involving people in treatment decisions reduce barriers to adherence to antiretroviral therapy? Results from the Positive Perspectives study 2016 - 2017

J. Guitart[1], V. Cooper[2], H. Lycett[1], T. Kenny[1,3], E. Raebel[1], J. Koteff[4], S. Barthel[5], Y. Punekar[6], A. de Ruiter[6], A. Murungi[6]
[1]Spoonful of Sugar Limited, London, United Kingdom, [2]UCL School of Pharmacy, Centre for Behavioural Medicine, London, United Kingdom, [3]Bournemouth University, Bournemouth, United Kingdom, [4]ViiV Healthcare, Research Triangle Park, Raleigh, United States, [5]GlaxoSmithKline, London, United Kingdom, [6]ViiV Healthcare, Brentford, United Kingdom

Background: Involving patients in decisions about their treatment has the potential to improve health outcomes, enhance the quality of care and reduce costs. The aim of this analysis was to determine whether people living with HIV (PLHIV) who perceive they are more involved in making decisions about their treatment have fewer perceptual barriers to adherence to antiretroviral therapy (ART) and are more satisfied with their treatment.
Methods: As part of the Positive Perspectives study 2016-2017, a cross-sectional, multi-country survey, PLHIV completed the Treatment-related Empowerment Scale (TES) which measures patients´ perceived degree of involvement in decisions about their medicines; the Beliefs about Medicines Questionnaire (BMQ) ART-specific version, which measures perceptual barriers to ART adherence and consists of two scales - ART-Necessity, which measures participants´ beliefs about their necessity of ART, and ART-Concerns, which measures participants´ concerns about side effects of ART; and questions about treatment satisfaction and whether participants had discussed concerns about side effects and long-term effects of ART with a healthcare professional (HCP). Spearman's rank correlation was used to determine the relationship between variables (TES, BMQ and treatment satisfaction). The Kruskal-Wallis test was used to compare TES scores between those who had discussed their concerns with an HCP and those who had not.
Results: 1078 patients (75% male, median age 45 years) from nine countries across Europe, North America and Australia completed the study questionnaires. There was a general perception of treatment empowerment as indicated by 86% of participants scoring above the TES scale midpoint, with no differences in scores by age, gender or sexual orientation. PLHIV who perceived a high level of treatment empowerment were more convinced of their necessity for ART (r_s=0.102; p< 0.001), had fewer concerns about side effects (r_s=-0.317; p< 0.0001) and were more satisfied with their treatment (r_s=0.238; p< 0.0001). Those who had discussed their concerns about side effects and long-term effects with an HCP had significantly higher TES scores than those who had not (H=9.621; p< 0.01).
Conclusions: The findings indicate that involving PLHIV in decisions about their treatment may reduce perceptual barriers to adherence to ART, facilitate discussions about treatment concerns and improve satisfaction with treatment.

Growing up with HIV: specific needs and interventions for children and adolescents

Community-health facility care system linkages increase beaming faces of children living with HIV: Findings of 'Towards an AIDS Free generation in Uganda' studies on paediatric HIV care

D. Bitira William[1], D.'. Hart[2], M. Musinguzi[3], J. Rujumba[4], Children Living with HIV, People Living with HIV
[1]Community Health Alliance Uganda, Monitoring, Evaluation and Learning Manager, Kampala, Uganda, [2]Aidsfonds, Programs, Amsterdam, Netherlands, [3]Aidsfonds, Programs, Kampala, Uganda, [4]Makerere University, Paediatrics and Child Health, Kampala, Uganda

Background: Even with Anti-Retro viral Treatment (ART) scale-up countrywide, 37% of children under 14 years living with HIV in Uganda miss life-saving treatment; few (25%) exposed infants receive ARV prophylaxis. 30% HIV positive children are lost to follow up before and more after enrollment in care. To address this gap, Aidsfonds and its partners in Uganda implemented a30-month (2015-2017) 'Towards an AIDS Free generation in Uganda' (TAFU) program in five rural districts.
Methods: Aidsfonds, implementing partners and Makerere University conducted TAFU baseline (2015) and end-line (2017) studies. Studies assessed changes in children enrolled in care between start and end of the program in all 22 target health facilities in Serere, Moroto, Napak, Mubende and Mityana program districts. Data on number of children in care were obtained from health facility health management information system while on project interventions were from program monitoring reports using check list. Further conducted 42 key informant interviews with health facility, district and program officials; and 53 focus group discussions with parents/caretakers. Quantitative data were analyzed using Epidata. Content thematic approach analyzed qualitative data.

Results: Overall, TAFU trained and engaged 1,378 community resource persons including Village Health Teams and expert clients. These conducted community sensitization on paediatric HIV, home visits and referred suspected children living with HIV to health facilities for HIV testing. Children who tested HIV positive or had been lost to follow-up were linked to care. Children in care increased from 459 at base line to 1,017 by end of the program. Trained community resource persons and health workers conducted dialogue meetings to increase community awareness on paediatric HIV. Sixteen peer support groups for children and 28 Village Savings and Loan Associations (VSLA) for their parents/caregivers were formed; and financially supported. These enhanced treatment adherence and retention of children in care.
Conclusions: TAFU strengthened community systems for tracing, referral and follow-up of children living with HIV.
.Number of children living with HIV enrolled and retained in HIV care significantly increased.
·Peer support groups for children and VSLAs for caregivers are key in meeting economic and real needs of children living with HIV and retaining them in care.

TUPED427

"These families did their research" a qualitative study of healthcare provider perspectives of US families who internationally adopt children with HIV

C. Fair[1], S. Alger[2]
[1]Elon University, Public Health Studies, Elon, United States, [2]George Washington University, Milken Institute School of Public Health, Washington, United States

Background: Emerging evidence suggests that an increasing number of US families are adopting children with HIV born outside the country. Little is known about the medical or psychosocial wellbeing of internationally adopted children with HIV (IACH), or experiences of their adoptive families. This exploratory qualitative study seeks to understand healthcare providers´ perspectives on international adoptee and family needs.
Methods: A purposive snowball sample was recruited from clinicians who attended a US think tank on adolescents with HIV and had experience caring for IACH. Eligible providers were asked to refer other experienced providers to participate. In 2017 we conducted hour-long, semi-structured, recorded interviews with 6 social workers and 5 medical providers representing 11 hospitals in 7 states. Providers were asked about adopted children's medical status and psychosocial wellbeing. Two researchers coded transcribed interviews guided by grounded theory to identify emergent themes.
Results: Providers had a mean of 14.9 years of experience in the field of HIV and followed an average of 18 children with HIV in their clinics adopted from 22 countries. Providers described considerable variation in the families who adopted children. Some had grown biological children while others pursued adoption due to fertility problems and several adopted multiple children with special needs. Most were connected to communities of faith which served as an inspiration to adopt and offered support. Medical issues included growth concerns, parasites, and other infectious diseases such as tuberculosis. International adoptees were typically treated for HIV before arrival in the US. HIV-related medical issues were uncommon. Psychosocial concerns were more common and included attachment, adjustment, sleep, and behavioral issues. Several participants noted that adoptive parents were well informed about HIV, but less prepared for cognitive delays and emotional challenges. Some providers experienced or expected to have challenges offering sexual and reproductive health (SRH) to adolescent adoptees due to their adoptive parents' religious beliefs on sexuality.
Conclusions: IACH are a growing population in the US. Our study provides initial documentation that this population has unique challenges. While serious medical issues were uncommon, adjustment and attachment issues emerged as pressing concerns. Additional support around SRH may be needed as IACH transition into adolescence.

TUPED428

Social-support needs of adolescents living with HIV in transition from pediatric to adult care: Findings from a cross-sectional study in Cambodia

S. Yi[1], G. Toth[2], S. Tuot[1], V. Khol[3], P. Chhoun[1], G. Mburu[4]
[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]Touro University California, Public Health Program, Vollejo, United States, [3]National Center for HIV/AIDS, Dermatology and STD, Phnom Penh, Cambodia, [4]Lancaster University, Division of Health Research, Lancaster, United Kingdom

Background: Understanding the circumstances of adolescents living with HIV is critical in designing adolescent-friendly services. This study describes the different aspects of social support adolescents aged 15—17 living with HIV have and may need during the critical period preparing them to transition from pediatric to adult care in Cambodia.
Methods: A cross-sectional study was conducted among 328 adolescents, randomly selected from 11 antiretroviral therapy (ART) clinics across the country. Descriptive analyses were conducted to summarize their characteristics, access to social support, stigma experience and barriers to ART access. Gender differences were explored using Chi-square or Fisher's exact tests for significance. This study was approved by the National Ethics Committee for Health Research.
Results: Mean age of study participants was 15.8 (SD= 0.8) years. More than half (55.2%) were male, and 40.8% were living with parents and 49.3% with either grandparents or relatives. Almost half of them (48.4%) reported that their family had received social support for their health care, including food support (78.7%), school allowance (64.8%), transport allowance for going to ART clinic (55.6%), emotional counseling (32.4%), vocational training (25.9%) and home visit (10.2%). A third came from families with an ID poor card, and over half (55.0%) reported that their family had no ability to cover health expenses. Of these, 87.6% were covered by health insurance, and 38.4% had access to the health equity fund. About a third of respondents (13.7%) had been asked to come back earlier than their scheduled appointment, and 2.7% had been asked to purchase their own drugs. A third (32.0%) had experienced stigma, and 8.2% had been denied housing or food as a consequence HIV infection. Additionally, 16.8% had not attended school within the past month, and 22.9% reported having issues with school attendance.
Conclusions: Social protection mechanisms are reaching some adolescents in need, but the majority remain without aid due to significant discontinuities in health and social care. Multicomponent interventions, supporting school attendance, reductions in child employment, mitigation of stigmas associated with HIV infection, peer support groups and improve coverage of social protection interventions are required for successful transition.

TUPED429

Internationally adopted children with HIV in the U.S.: Exploring parent and provider views on anticipated sexual and reproductive health challenges in adolescence

S. Alger[1], C. Fair[2], E. Gibson[3]
[1]George Washington University, Milken Institute School of Public Health, Washington, United States, [2]Elon University, Public Health Studies, Elon, United States, [3]Orange County Department of Social Services, Hillsborough, United States

Background: The number of U.S. families pursuing the international adoption of children with HIV infection has steadily increased since 2010. The majority of internationally adopted children with HIV (IACH) are under the age of 12 and adopted by parents who commonly work with faith-based adoption agencies. Adopted children may have additional educational needs as they mature into adolescence, particularly related to sexuality.
Methods: We conducted hour-long, semi-structured, audio recorded interviews with a purposive snowball sample of 13 mothers of IACH and 11 providers who work with this population. Parents were asked about motivations to adopt their child, medical and psychosocial needs, and potential challenges that may occur as the child moves into adolescence.

Providers were asked about their current or anticipated experiences providing care to IACH. Interviews were coded for emergent themes using standard qualitative methods.
Results: All mothers identified as white (mean age 37 years) and 12 as Christian. Mean age of their adopted child with PHIV was 7 years (range 3-15, 9 females, 7 from African countries). Faith was a guiding factor that influenced most parents' decisions to adopt of a child with HIV from another country. Immediate adoption-related issues such as pre-adoption trauma, loss, and language barriers often took priority over HIV-related medical or psychosocial concerns. The majority of parents felt their religious beliefs would guide decisions to share sexuality-related information during adolescence. Several parents viewed sex before marriage as immoral and did not want their child to have access to comprehensive sex education as a teenager. Providers (6 social workers and 5 medical providers with a mean of 14.9 years of experience in the field of HIV) corroborated these findings and reported that some adoptive parents often sought to delay provider-initiated sexuality conversations including those focused on reducing HIV transmission and pregnancy risk. One provider noted, "I've had to be respectfully slower with some families about sex education."
Conclusions: All adolescents with HIV should be informed on ways to prevent HIV transmission and unintended pregnancy. Parents of IACH could benefit from the support of healthcare providers to better understand the importance of sexual and reproductive health during adolescence.

Closing the gap: Increasing the availability of child- and youth-focused antiretroviral therapy (ART) at non-state health facilities in Nairobi, Kenya

J. White[1], M. Bunyi[1], L. Kagasi[2], D. Kinuthia[3], E. Oywer[4], N. Gitonga[5], P. Mutua[6], D. Nyaboke[7], C. Karanja[8], S. Eagan[9], J. Pearson[9], D. Sullivan[10], J. Tayag[10], L. Weir[11]
[1]Abt Associates Inc., International Health Division, Bethesda, United States, [2]Independent Data Consultant, Nairobi, Kenya, [3]Kenya Pediatrics Association (KPA), Secretariat, Nairobi, Kenya, [4]Kenya Ministry of Health, Nursing, Nairobi, Kenya, [5]Insight Health Advisors, CEO, Nairobi, Kenya, [6]Abt Associates Inc, Nairobi, Kenya, [7]Independent Consultant, Nairobi, Kenya, [8]Healthstrat Data, Nairobi, Kenya, [9]JSI, Washington, United States, [10]USAID, Washington, United States, [11]Abt Associates Inc, Rockville, United States

Background: Despite significant investment in the Kenyan HIV response, the number of new HIV infections and treatment needs among children, adolescents, and young people (CAYP) continues to increase. Engaging non-state (private) health providers to deliver HIV testing services (HTS) and antiretroviral therapy (ART) targeted to CAYP could be an effective strategy to augment government efforts to reach this population.
Description: From 2016 to 2018, the USAID-funded Strengthening High Impact Interventions for an AIDS-free Generation (AIDSFree) Project assisted a broad consortium of Kenya-based partners to create a public-private alliance (PPA) aimed at increasing the availability of high quality CAYP-focused ART services among private providers in Nairobi county. The PPA—which included the National AIDS and STI Control Programme, the Kenya Pediatrics Association, and the Kenya Healthcare Federation—trained more than 135 nurses and clinical officers representing 31 separate private clinics, facilitated government supply of HTS and ART commodities, and connected clinics to ongoing clinical mentorship.
Lessons learned: The project demonstrated that private providers in Kenya share a strong commitment to addressing HIV among CAYP. The alliance format addressed multiple public-private concerns in an open forum, facilitated dialogue among previously disconnected health stakeholders, and from January to April 2016, was able to quickly scale up government-supported pediatric ART services to more than 26 private facilities. From April 2016 to September 2017, PPA-affiliated clinics tested 15,755 CAYP (64% female) for HIV and initiated 203 (52% female) CAYP on treatment. The clinics also enrolled 197 CAYP in pre-ART care, indicating that continued efforts are needed to operationalize test-and-treat protocols at the facility level. Working through established partners, such as the Kenya Pediatrics Association, was critical in ensuring ongoing quality improvement of services throughout the monitoring period.
Conclusions/Next steps: Through collaborative public-private action, private providers can be capacitated as critical sources of HIV and ART care for CAYP. The model underscored the need for ongoing investment in clinical mentorship to build private provider confidence and quality while implementing pediatric ART services. Following AIDSFree investments in 2016 and 2017, the Kenya Healthcare Federation and Kenya Pediatrics Association now spearhead the partnership.

TUPED431

Whether and why caregivers adhere to oral lopinavir/ritonavir pellets: Lessons for scaling up an innovative pediatric HIV treatment in Kenya

C. Noestlinger[1,2], A. Nebot Giralt[1], O. Ouma[3], I. Nyamongo[3], O. Salami[4], M. Lallemant[4], J. Lee[4], B. Marchal[1]
[1]Institute of Tropical Medicine, Public Health, Antwerp, Belgium, [2]University of Vienna, Faculty of Psychology, Vienna, Austria, [3]University of Nairobi, Institute of Anthropology, Nairobi, Kenya, [4]Drugs for Neglected Diseases Initiative, Nairobi, Kenya

Background: Globally, only 43% of 1.8 million children living with HIV have access to antiretroviral therapy (ART), and few adequate pediatric formulations are available. Oral pellets containing lopinavir/ritonavir may be better accepted by infants and children than liquid formulations. They can be used with liquids/soft foods, taste better and do not require cool storage. Pediatric adherence is complex, involving daily supervision, practical skills and age-appropriate negotiations skills. It is also influenced by health-systems and contextual factors. To scale-up the use of the pellets, in-depth understanding of treatment initiation, adherence and underlying mechanisms is needed.
Methods: This extensive qualitative study adopted a realist evaluation approach. Nested in a clinical trial to assess the pellets' efficacy, caregiver-child dyads were purposively selected in three Kenyan settings (Kenyatta Hospital, Gertrude's Children Hospital, Nairobi; Faces Clinic, Kisumu). Between 01-09/2017, trained interviewers conducted in-depth interviews with care-givers (n=42), health care providers (n=12), and observations of pellet administration (n=17 at home; n=17 clinic observations). Data were analyzed in two stages with Nvivo 11: inductively, using a data driven code-book and employing retroductive inference according to realist approaches for drawing conclusions. Ethics approval was obtained.
Results: The pellets' taste and storage facilitated easy administration, simplifying initiation of treatment. While study staff gave standardized information, caregivers developed their own best way to deliver the treatment, particularly when specific problems occurred, e.g. just-weaned babies, food shortage linked to poverty. Visible treatment effects enhanced caregivers' motivation to continue. Tailored support by providers was perceived to improve adherence. Caregivers who had received support from providers, family and informal networks developed active coping strategies for creating a daily routine. This also enabled them to deal with HIV disclosure and (self-) stigma, contributing to better adherence. For many, stigma remained a barrier reducing access to social support outside the clinic setting.
Conclusions: The study setting was supportive for the initiation of and adherence to using pellets. Pellets may mark a major step towards better treatment for HIV positive children. When scaling up pellets, tailored support by clinic staff should consider the influence of contextual factors, such as HIV-related stigma, informal peer support networks and poverty.

'In their shoes': Limited disclosure amongst young people living with HIV stifles their ability to contact others in the same situation, a qualitative cohort HPTN071 (PopART) study in Zambia

M. Mbewe[1], C. Mackworth-Young[1,2], D. Ziba[1], R. Ndubani[1], B. Chiti[1], M. Simuyaba[1], M. Gondwe[1], K. Shanaube[1], G. Hoddinot[3], V. Bond[1,2]
[1]*Zambart, Lusaka, Zambia,* [2]*London School of Hygiene and Tropical Medicine, Department of Global Health and Development, Faculty of Public Health and Policy, London, United Kingdom,* [3]*Desmond Tutu TB Centre, Faculty of Medicine, Stellenbosch University, Department of Paediatrics and Child Health, Cape Town, South Africa*

Background: Support for Young people aged between 16-24 years living with HIV (YPLHIV) is critical but remains limited in Zambia, partly because YPLHIV are often hidden within communities, having disclosed to very limited networks.
Methods: A qualitative cohort of 8 purposively sampled YPLHIV (4 women, 4 men) in four communities in Zambia. Over a 10-month period in 2017, each participant was involved in three research activities (carried out at three-month intervals), including participant observations, individual in-depth interviews and a participatory workshop. Within these methods, visual tools included social network diagrams that explored geographical and 'close in feeling' networks and how these linked to disclosure. Qualitative analysis carried out by a team of social scientists reviewed the data and identified disclosure, secrecy and desire to share experiences with other YPLHIV as inductive key themes.
Results: YPLHIV, like other participants, had a wide network of friends and family, but only an extremely restricted number of people (and largely close family members) knew their HIV status. Parents/guardians often actively and strongly discouraged disclosure, regulated who knew the adolescents' HIV status and rarely spoke about HIV within their homes. "Mum said I shouldn't tell them otherwise they will start using it against me, like they do to her", explained one young woman living with HIV, aged 19. However, YPLHIV expressed their desire to speak with, share experiences with, and get support from others who are "in their shoes". The weight of not telling others about their HIV status sometimes led to feelings of loneliness and fatigue, exacerbated by the continuous secrecy of taking their antiretrovirals in private. Fears about unintended disclosure (usually linked to ART), coupled with silence about HIV in their homes stifled opportunities to be connected with other YPLHIV. One participant had attended a support group and found this contact fulfilling, and supportive for adherence.
Conclusions: YPLHIV were isolated by limited disclosure and being 'hidden' by parents/guardians. Drawing on this research and literature, interventions targeting YPLHIV should address relationships in the home and the benefits, challenges and strategies for disclosure YPLHIV to allow them to share experiences, concerns and feel less alone.

TUPED433

"We decided not to tell him because he would tell everyone else." Care-giver and young people's experiences of disclosure in Kinshasa, Democratic Republic of Congo

E. Manziasi Sumbi[1], R. Harrison[1], E. Kanumay[1], J.L. Chalachala[2], M. Garcia[3], K. Iakovidi[3], G. Van Cutsem[3], E. Venables[3,4]
[1]*Médecins Sans Frontières, Kinshasa, Congo, Democratic Republic of the,* [2]*University of North Carolina, Carolina Population Centre, Chapel Hill, United States,* [3]*Médecins Sans Frontières, Southern Africa Medical Unit, Cape Town, South Africa,* [4]*University of Cape Town, Division of Social and Behavioural Sciences, School of Public Health and Family Medicine, Cape Town, South Africa*

Background: It is estimated that 42,000 children ≤15 are living with HIV in DRC (UNAIDS 2015). WHO recommends disclosure for HIV-positive children of school-going age, but the process remains challenging for health-care workers and care-givers. Non-disclosure is probably associated with poor outcomes during adolescence; including increased risk of poor adherence and retention, and treatment failure. Médecins Sans Frontières has been working in Kinshasa since 2002, providing treatment and support to children/adolescents living with HIV, and their care-givers. Children in DRC can only be informed of their HIV status with the approval of their care-giver, which, along with the age of consent for HIV testing being 18, can cause delays in disclosure.
Methods: Thirty in-depth interviews were conducted with care-givers (n=20) and HIV-positive children/adolescents (n=10) to understand their experiences of disclosure. Ten care-givers who had disclosed to their children and 10 who had not were purposively selected. Care-givers included biological parents, grandmothers, siblings and community members. Interviews were conducted in Lingala, translated, transcribed, then coded and analysed using NVivo.
Results: Several children suspected they had HIV before disclosure, commonly asking why they had to take medication or were '*always ill*'. Care-givers and children perceived benefits of disclosure to include improved adherence and improved behaviour at home. Care-givers who had not disclosed to their children wanted to protect themselves and their families from stigmatisation, and were fearful their children could tell others. HIV positive care-givers were reluctant to disclose to perinatally infected children because they felt guilty and did not want their children to blame them. There was also a perception amongst interviewees that there could be a risk of suicide relating to disclosure. Many children had more than one care-giver, often due to being orphaned, which delayed disclosure and made adherence support more challenging.
Conclusions: The fear of stigmatisation and not wanting to upset their children prevented several care-givers from disclosing. HIV-positive care-givers, particularly mothers, need additional support to overcome their fears and help their children understand their status. Attention should be given to non-primary care-givers involved in adherence support and disclosure as they also play a significant care-giving role for children living with HIV.

TUPED434

"New horizons" in taking care of perinatally HIV-infected adolescents and young people

V. Boscolo[1,2], C. Novello[1,2], O. Rampon[1], V. Ortolan[2], C. Giaquinto[1,2]
[1]*Hospital - University of Padua, Women's and Children's Health Department, Padua, Italy,* [2]*Penta Foundation, Padua, Italy*

Background: Since 1984 the Paediatric Department of Padua University has been following 180 perinatally HIV-infected children and families. In 1992 a multidisciplinary team was created to improve the quality of the children's life. Nowadays, HIV infection turned into a chronic disease. Children are now more likely to survive and to reach adolescence and adult age. Consequently, the focus moved from the centrality of medical therapies to ensure survival, to a growth oriented view, with its psycho-socio-educational complexity.
Description: Since 1992, the psycho-educational programs have involved 75 subjects in paediatric age. In the last few years, a deficit in the acquisition of self-efficacy has emerged and so in taking care of their own health.This was confirmed by an observational study on the psychosocial and behavioral features of 23 vertically HIV-infected adolescents followed by the site. In the questionnaire, the T-scores exceeded the cut-off for items concerning Activity competences, Social skills and Positive Qualities. Rather than a significant vulnerability to psychopathology, the data describes a clinical difficulty in recognizing one´s own skills and adapting to the social environment. These difficulties are also involved in the compliance. For these reasons, in 2016, an educational experimental project with formative features for young adult called „New Horizons" started. The first involved group was made by 10 young people. It was held by professional educators and volunteers appropriately trained. Every second month, it provided residential weekends where interactive workshops were conducted by extra-team professionals. The topics (self-esteem and self-efficacy, counselling about work/study, affective relationship and sexual behavior, pregnancy and reproductive health) were chosen considering the needs expressed by the attendees filling in a self-reported questionnaire.
Lessons learned: The recorded difficulties of HIV-infected adolescents in building their personal and relational autonomy, psychological distress and behavioral problems, have negative impacts on the infection

awareness, compliance and management of risky behaviors. The continuity of psycho-educational care has supported the implementation of proactive behaviors.
Conclusions/Next steps: Changes in the characteristics and treatment of HIV lead to changes in care of adolescents and young adults. The project aims to develop maturation from adolescence to adulthood as a basis for an effective transition from pediatric care to adult care.

TUPED435

Adolescent transwomen face additional barriers to ART adherence than cisgender peers

A. Edeza[1], M. Mimiaga[1,2,3], B. Grinsztejn[4], N. Fernandes[4], L. Kamel[4], K. Biello[1,2,3]
[1]Brown University School of Public Health, Behavioral and Social Health Sciences, Providence, United States, [2]Brown University School of Public Health, Department of Epidemiology, Providence, United States, [3]The Fenway Institute, Fenway Health, Boston, United States, [4]Instituto de Pesquisa Clinica Evandro Chagas-Fiocruz, Rio de Janeiro, Brazil

Background: Brazil has implemented a comprehensive HIV treatment program with broad access to ART, but challenges remain in addressing adherence challenges for adolescents, a group with poor adherence. Adolescents account for the largest number of incident HIV infections in Brazil. It is imperative to supplement current ART distribution efforts with medication adherence interventions.
Methods: We conducted three focus groups with 24 Brazilian adolescents (age 15-24) living with HIV in the Rio de Janeiro metro area, Brazil, separately for gay- or bisexual-identified cis-gender young men, heterosexual-identified cis-gender young men and women, and young transwomen (TW) of any sexual orientation. Thematic analysis identified key themes regarding barriers and facilitators to ART adherence.
Results: On average, participants were 22 years old (SD=2.3). One quarter had a less than a high school education. Five were perinatally-infected, and the remaining were infected via sex with an HIV-infected person. Twenty-two individuals were currently taking ART. All participants reported that transportation costs, understaffed clinics, and medication shortages impact their ability to fill an ART prescription. Additionally, they agreed that depression, complex medication schedules, and side effects discourage daily adherence. Motivations to remain adherent include a desire to be healthy, to look physically attractive, to meet life goals, and to protect partners. Compared to cisgender peers, TW expressed more gaps in HIV, AIDS and ART knowledge, higher uncertainty about disclosing HIV status to peers or family, and strong societal stigma as substantial deterrents. Additionally, unpredictable schedules, late nights, and concerns about interactions with recreational drugs were cited as barriers. There was a perceived lack of specialized clinicians that could meet the unique needs of TW, as well as a pronounced interest in medication adherence programs for adolescent TW exclusively led by a cis- or transwoman living with HIV.
Conclusions: All participants reported substantial barriers to ART adherence; however, TW face distinct barriers to ART adherence than their cisgender peers, which are not currently being addressed by the ART distribution system in Rio de Janeiro. These barriers limit HIV testing and ART medication adherence, and it is imperative to incorporate additional support systems into the current SUS framework which accommodate these unique needs.

Ageing with HIV: evolving and additional needs and responses

TUPED436

Sexual behaviors among older adults living with HIV in Chiang Mai, Northern Thailand

K. Srithanaviboonchai[1,2], K. Rerkasem[1,2], A. Tangmunkongvorakul[1], W. Sitthi[1], P. Masika Musumari[3], P. Kowal[1]
[1]Chiang Mai University, Research Institute for Health Sciences, Chiang Mai, Thailand, [2]Chiang Mai University, Faculty of Medicine, Chiang Mai, Thailand, [3]Kyoto University School of Public Health, Department of Global Health and Socio-epidemiology, Kyoto, Japan

Background: Worldwide, the number of older adults living with HIV (OALHIV), defined as HIV infected persons aged 50 years or older, is increasing due to effective antiretroviral therapy (ART) programs and ongoing HIV transmission in elderly. Little is known about sexual behaviors and HIV sexual risk behaviors among this population, especially OALHIV who reside in developing countries. The current study describes HIV sexual risk behaviors in OALHIV in Thailand.
Methods: This cross-sectional quantitative study was conducted between November 2016 and April 2017. Participants were enrolled from ART clinics at 12 community hospitals in Chiang Mai Province, Northern Thailand. Behavioral information was collected through face-to-face interviews and clinical data were retrieved from the medical records by trained researchers upon permission from the participants and the hospital staff.
Results: Of the 328 participants, 42.4% (139) were males, with an average age of 58.8 years (range: 51-84). The majority of participants 93.9% (308) had undetectable viral load (< 40 copies/µl). During the past 12 months, 31.4% of the participants (52.2% among males and 16.7% among females, $p < 0.001$) reported having had sex. Men had sex outside of stable relationships more than women (11.8% vs 0.5%, $p < 0.001$). All participants reported always using condoms during sexual intercourse that occurred outside of stable relationships while 91.4% reported doing so during sexual intercourse that occurred with their stable partners. Of the sexually active participants, 48.5% (54.9% among male and 34.4% among female) had sex with sexual partners who were HIV-negative or of unknown HIV status. Three participants, all of whom had undetectable viral load, had sex without a condom during the last 12 months with sexual partners who were HIV-negative or of unknown HIV status.
Conclusions: While having sex was common among OALHIV in Northern Thailand, risk of spreading the HIV virus through sexual intercourse was low due to effective ART programs and safe sex practices. The prevalence of condom use was very high regardless of the type and HIV status of the sexual partner. The situation might vary considerably in other locations and specific studies are needed to understand this issue in particular localities.

TUPED437

Younger age of HIV diagnosis correlated with early menopause among a cohort of canadian women living with HIV

G. Gao[1], P. Duff[2,3], M. Braschel[2], N. Pick[3,4], G. Ogilvie[3,4], K. Shannon[2,3], on behalf of the SHAWNA Study (Sexual Health and HIV/AIDS: Women's Longitudinal Needs Assessment)
[1]Queens University, Medicine, Kingston, Canada, [2]Gender and Sexual Health Initiative, Vancouver, Canada, [3]University of British Columbia, Medicine, Vancouver, Canada, [4]Oak Tree Clinic, British Columbia Women's Hospital and Health Centre, Vancouver, Canada

Background: As women living with HIV (WLWH) live longer and go through the aging process, healthcare considerations and priorities need to evolve to address WLWH's needs over the life course. Currently, there is limited evidence on age at menopause and correlates of early menopause in Canadian WLWH. The purpose of the study was to identify correlates of early menopause among WLWH in Metro Vancouver.
Methods: This analysis used baseline data (2014-2017) from the Sexual Health and HIV/AIDS: Women's Longitudinal Needs Assessment (SHAWNA) study, an ongoing community-based, open prospective co-

hort consisting of WLWH, aged 14+ who live and/or access HIV services in Metro Vancouver. Our analytic sample was restricted to cis-gender WLWH who reported being diagnosed by a physician as having undergone menopause. Bivariate and multivariable logistic regression were used to examine correlates of early menopause (≤45 years).
Results: In total, 101 women who have undergone menopause were included in the analysis with a median age of 49.0 (Interquartile ratio (IQR): 44.4 - 53.0). The median age of menopause was 45.0 years (IQR: 41.0-49.0), with 54.5% experiencing early menopause. In multivariable analysis, the odds of early menopause decreased by 9% for every year older a woman was diagnosed with HIV (Adjusted Odds Ratio= 0.91, 95%CI: 0.86 - 0.97), after adjusting for confounders.
Conclusions: In our study of WLWH within Metro Vancouver, older age at HIV diagnosis decreased the odds of early menopause. WLWH who are diagnosed with HIV at a younger age may be more progressed in their disease and exhibit HIV clinical factors (lower CD4 counts and CDC Class B or C disease) correlated with menopause. Our results suggest that changes to healthcare practice may facilitate more timely diagnosis, such as confirming menopause using biochemical markers which is not routinely done in the general population. The timely detection of menopause in WLWH is vital for appropriate care of peri-menopausal/menopausal health issues, such as treatment for vasomotor symptoms and prevention of osteoporosis and cardiovascular disease, leading to improved quality of life and longevity.

TUPED438

Women ageing with HIV: "I was not meant to be here, and I´m still here." How women have adapted to living long-term with HIV

J. Stevenson[1], J. Smith[1], E. West[1], P. Keogh[2]
[1]University of Greenwich, London, United Kingdom, [2]Open University, Milton Keynes, United Kingdom

Background: Women ageing with HIV potentially face a range of social, emotional and health challenges. Their experiences are relatively under-researched, yet as the population of people living with HIV ages, there is urgent need for greater efforts to understand their specific experiences. In the UK, over 34% of people accessing HIV care in 2015 were aged 50 and over. Many women in this age cohort have lived long-term with HIV, and were diagnosed in the pre-treatment era, creating a unique experience of living with HIV.
Methods: As part of a study exploring the experiences of women ageing with HIV in London, UK, 14 women aged over 50 participated in a life story interview. Participants were recruited to reflect the diversity of women living with HIV in the UK, and included 5 White British, 1 White Other, 1 Black British, 7 Black African. 12 were aged 50-60, 2 aged 60-70. 2 bisexual women, 1 trans woman. One diagnosed less than 5 years, 3 for 6-10 years, 1 11-15 years, 2 16-20 years, 2 21-25 years and 5 26-30 years. The interview was open and unstructured, with participants invited to tell the story of their lives however felt appropriate to them, with some broad prompts used to facilitate story-telling. A participatory data analysis workshop was held with four women living with HIV aged over 50, to analyse the life story data and identify key themes.
Results: Women shared a range of experiences, including both challenges and coping strategies for ageing with HIV. The particular experience of surviving a terminal diagnosis emerged as a significant theme, as both impacting on life choices and chances, and health and wellbeing, while also being a cause for celebration and gratitude. Participants in the analysis workshop described this phenomenon as 'survivor conflict', capturing the complex feelings associated with the challenges both physically and emotionally of unexpectedly reaching older age.
Conclusions: Women diagnosed before effective treatment became accessible have unique needs and experiences that are not adequately understood or addressed. Living with HIV is an ongoing, evolving experience that brings challenges that can be hard to reconcile with simple constructs of 'survival'.

Prevention interventions and their effects on the lives and relationships of people living with HIV

TUPED439

Determinants of antiretroviral adherence in Myanmar

S. Aung[1], J. Larkin[1], F. Zervou[2], A. Rana[3], N. Htun[4], A. Kyaw[5], M.S. Tun[6], K.W. Aung[4]
[1]Brown University Alpert Medical School, Infectious Diseases, Providence, United States, [2]Brown University Alpert Medical School, Internal Medicine, Providence, United States, [3]University of Alabama School of Medicine, Infectious Diseases, Birmingham, United States, [4]Pyi Gyi Khin, Yangon, Myanmar, [5]National AIDS Programme, Yangon, Myanmar, [6]Myanmar Positive Group, Yangon, Myanmar

Background: Antiretroviral therapy (ART) adherence ensures suppression of the HIV virus and reduces transmission. Determinants that influence adherence may vary by region and cultural norms. Such factors have not been formally assessed in Myanmar.
Methods: A crosssectional study was conducted utilizing questionnaires administered between May to October 2016 to 1,022 HIV-infected patients across four cities in Myanmar. Variables of interest included HIV knowledge, social support, structural barriers to care, enacted stigma, internalized stigma, and peer-to-peer HIV counseling (PC). The dependent variable was medication adherence. These variables were assessed using validated scales. A logistic regression analysis was used to determine the correlation between the above independent variables and ART adherence using total scores. The statistical significance threshold was 0.05.
Results: Among 1,022 participants, mean age was 38.6 years and 55% were females. Majority of patients (55%) reported heterosexual intercourse as their mode of transmission. The median CD4 count was 351- 500 cells/mm3, and 16% of participants had CD4 counts < 200 cells/mm3. Five hundred patients (49%) received PC and the remaining participants received standard counseling (HIV negative counselor). Enacted stigma (OR 0.87; 95% CI 0.82-0.94; p< 0.01), internalized stigma (OR 0.96; 95% CI 0.94-0.99; p< 0.01), and social support satisfaction (OR 2.19; 95% CI 1.10-4.38; p=0.03) were independently associated with medication adherence. With each increasing enacted stigma and internalized stigma score the odds of adherence was 13% and 4% lower, respectively. Participation in PC had a moderately significant association with adherence (OR 1.40; 95% CI 0.97-1.98; p=0.07) and increased the odds of adherence by 60%. Interestingly, participants with lower social support satisfaction had increased odds of adherence compared to other categories. Patients who identified doctors or nurses as their biggest source of support had higher odds of adherence (OR 1.72; 95% CI 1.03-2.86; p=0.04), but type of support was not an independent determinant. HIV knowledge and structural barriers to care were not independently associated with adherence.
Conclusions: Significant correlations were found between PC, enacted stigma, internalized stigma, and social support with ART adherence. The results overall promote reducing stigma and utilizing peer-to-peer counseling as a means to improve medication adherence in Myanmar.

TUPED440

Christain Marriage Counsellors practices relating to pre-marital counselling and HIV counselling and testing for intending couples in Ibadan, Nigeria

A. Adegbola[1], F. Oshiname[1], A. Ogunwale[1,2]
[1]University of Ibadan, Department of Health Promotion and Education, Faculty of Public Health, Ibadan, Nigeria, [2]Oyo State College of Agriculture and Technology Igboora, Department of General Studies, Igboora, Nigeria

Background: HIV Counseling and Testing (HCT) is a strategy for controlling HIV, an infection which constitutes a public health challenge in Nigeria. There are Church-based Marriage Counselors (CMCs) in most churches in Ibadan who prepare Intending Couples (IC) for marriage solemnization. These counselors can play pivotal roles in facilitating adop-

tion of HCT by IC. However, there is dearth of baseline information relating to their counseling practices. This study was therefore designed to explore practices of CMCs relating to HCT in Ibadan South-West Local Government Area (LGA), Nigeria.

Methods: The cross-sectional survey involved the use of a three-stage random sampling technique to select 660 CMCs from Christian Association of Nigeria districts, denominational categories and parishes in the LGA. Respondents' churches consisted of indigenous Churches and Non-Indigenous Churches. A pretested questionnaire was used for data collection. Descriptive statistics and Chi-square test were used to analyse data at p=0.05.

Results: Respondents' age was 45.0±8.6 years, 60.3% were males, 84.1% had tertiary education, 65.0% performed only CMC roles while 35.0% were pastors as well. Majority (81.2%) were members of indigenous churches. Many respondents (68.9%) performed at least one wedding ceremony per month and 87.9% stated that pre-marital courses for ICs, with infused elements of HIV, existed in their churches. The mean duration of their counseling related courses was 9.6±6.8. Majority (73.2%) of the respondents usually requested ICs to undergo compulsory HCT. Proportions of respondents in non-indigenous and indigenous churches who recommended mandatory HCT for ICs were 93.5% and 85.3% respectively (P≤0.05). Mandatory HCT for ICs was highest among those who had an average of more two weddings per month (100.0%) (P≤0.05). Respondents adopted different ways of handling HCT results when one of the intending partners is HIV positive. These included counseling ICs (33.5%), leaving ICs to decide on their own (32.1%) as well as cancellation of weddings (7.8%).

Conclusions: Mandating ICs to undergo HCT was common in churches especially in churches with high frequency of wedding programmes. Some CMCs indulged in the unethical practice of cancelling of ICs wedding based on HIV sero-postive. Training and other relevant health education interventions are needed to address these issues.

Sexual and reproductive health, fertility, family planning, pregnancy, and abortion

TUPED441

Breaking barriers and building bridges: Women living with HIV leading the way through the 4M+ peri-natal peer mentoring project, to complement clinical care in East Africa

A. Namiba[1], E. Bajenja[1], N. Osborne[1], A. Welbourn[2], T. Otieno[3], B. Ogolla[3], J. Alessi[4], R. Nalwanga[4], N. Niwagaba[4]

[1]Associate Salamander Trust, London, United Kingdom, [2]Salamander Trust, London, United Kingdom, [3]Personal Initiative for Positive Empowerment (PIPE), Nairobi, Kenya, [4]Uganda Network of Young People Living with HIV (UNYPA), Kampala, Uganda

Background: Through scientific advancements, vertical HIV transmission risk is potentially < 2%. However, pregnant women living with HIV face many complex issues. These are now recognised to act as key barriers to treatment access, affecting women and their children alike. To overcome this, three peer-led organisations conducted training workshops with Mentor Mothers (MMs). The training sought to build MMs' capacity to support their pregnant peers. 4M stands for *My Health My Choice, My Child My Life*.

Description: The 3-day training, led by a woman living with HIV, was practical and interactive. Held in 4 urban and rural areas, in East Africa, topics included pre-conception planning, ante- and post-natal care, safe motherhood, and creative writing. Participants created books based on their experiences, ideas and plans. A steering group of in-country healthcare professionals (HCPs), peers and staff shaped the programme.

Lessons learned: 65 MMs were trained. 24 (37%) were < 24 years. 12 (18%) were pregnant. Immediate pre- and post-training evaluation was conducted.

MMs in Nairobi continued sharing through a WhatsApp group. A 6 month post-training evaluation sampled MMs in both countries.

HCPs in both countries reported increased attendance and adherence by those supported.

Peer-led participatory training is key to establishing safe spaces for MMs to share without fear; and to understand what support can, and should, be offered to pregnant women, from community and HCPs.

Some MMs reported challenges from intimate partners, including lack of economic and decision-making autonomy and critical attitudes and behaviour.

Some MMs also reported challenging behaviour from HCPs in some facilities.

MMs' confidence to challenge negative behaviours from partners and HCPs was strengthened.

Wider awareness amongst HCPs of this programme's value is urgently needed.

Funding and geographic spread of the project also need improvement.

Conclusions/Next steps: Training Mentor Mothers to support peers proved to have a marked impact on skills, confidence and aspirations. It can also complement clinical care, improving health outcomes of young women/mothers living with HIV.

Engagement of men/partners is key to the success and continued engagement of MMs, many of whom felt restricted by limited financial and social autonomy.

Next steps also include raising awareness among HCPs regarding anti-discriminatory behaviours.

Successes and challenges within a safer conception intervention for men living with HIV in South Africa

M.N. Mathenjwa[1], L. Greener[1], H. Khidir[2], N. Mosery[1], C. Psaros[2,3], K. O'Neil[4], A. Harrison[5], D.R. Bangsberg[6], S.A. Safren[7], J.A. Smit[1], L.T. Matthews[2,4]

[1]MatCH Research Unit, Durban, South Africa, [2]Harvard Medical School, Boston, United States, [3]Behavioural Medicine, Department of Psychiatry, Massachusetts General Hospital, Boston, United States, [4]Center for Global Health, Massachusetts General Hospital, Infectious Disease, Boston, United States, [5]Brown University School of Public Health, Department of Behavioural and Social Sciences, Providence, United States, [6]Oregon Health Sciences University and Portland State University, School of Public Health, Portland, United States, [7]University of Miami, Psychology, Miami, United States

Background: Many men living with HIV (MLWH) want to have children. Safer conception strategies such as ART, PrEP, limiting condomless sex to fertility, and sperm washing allow men to meet reproductive goals while minimizing transmission to partners. We piloted an intervention to support MLWH to adopt safer conception behaviors. Exit qualitative in-depth interviews (IDIs) explored successes and challenges based on an ecologic conceptual framework.

Methods: Between 2015-2017 we enrolled MLWH in Ethekwini, KwaZulu-Natal, South Africa. Eligible men were 20-45 years old, with HIV-serostatus known ≥1 month, ART naive or on ART < 3 months, and planning to have a baby with an HIV-negative or unknown-serostatus partner in the next year. Men participated in a five-session safer conception intervention over 12 weeks. One-on-one counseling sessions provided HIV and safer conception education and cognitive behavioral therapy for behavioral change. A subset completed an IDI upon study exit to explore participant experiences with the intervention, and challenges and successes with implementing their safer conception plan. Translated transcripts were analyzed using thematic analysis.

Results: Eleven black South African MLWH with median age 32 years (range 27-37) completed exit IDIs. At intervention entry, 6 (54%) had completed secondary school, 5 (45%) reported multiple sexual partners, all reported a single desired pregnancy partner. Two (18%) had disclosed to pregnancy partner and five (45%) were employed.

Successes described at the structural-level included confidence in this clinic-based intervention and community-demand. However, employment made it challenging for men to attend clinic sessions. Men also described contradictory clinic counseling emphasizing condoms regardless of reproductive goals. At the individual-level, men learned the safer conception methods and tried adopting the strategies (principally ART, sex timed to peak fertility, and disclosure). At the dyadic-level, men

found it challenging to implement safer conception strategies without disclosure. While problem solving and role plays helped some, disclosure remained difficult for most.

Conclusions: MLWH are able to learn and willing to adopt safer conception strategies. Providing safer conception care at the community level during non-working hours may be necessary to meet demand for services. Creative approaches to promote disclosure are needed to support MLWH to safely meet reproductive goals.

TUPED443

Assessment of SRH needs of women living with HIV In Pakistan

K. Zahra
Association of People Living with HIV-Pakistan, Islamabad, Pakistan

Background: Women living with HIV [WLHIV] in Pakistan face significant challenges in accessing sexual and reproductive health [SRH] services. One of such challenge is the lack of sensitivities and skills among health care workers. The care workers are not trained in providing SRH services and address SRH needs of WLHIV. There is also widespread stigma and discrimination towards WLHIV in primary and secondary heath care settings. WLHIV are not well aware about their SRH Rights. This study aimed to establish their SRH&R needs in Pakistan.

Methods: This was a cross-sectional descriptive study. Structured questionnaire were used to document the needs of WLHIV, related to SRH&R. The study participants were WLHIV, who self-reported diagnosed with HIV infection prior to their participation in the study. The sample size of 120 women living with HIV was taken from four major cities of the country.

Results: Among the participants 96% identified the need of Integrated SRH/HIV services. The participants identified that gaps in training of HCPs prohibit them from providing sexual and reproductive health information and services; they expressed a desire for better access to respectful providers who are willing to care for their needs. All participants agreed that some level of service integration is necessary. Only 19.2% of the participants were aware of their sexual and reproductive health rights. Gynecological examination was prioritized as a need by 72.5% participants. Several of the interviewed women indicated that they were most comfortable receiving comprehensive services from NGOs. Almost all the participants identified that they fear being stigmatized or discriminated at a health care setting.

Conclusions: The Study recommends training of care providers on SRH along with capacity building of WLHIV, for improved leadership in addressing SRH&R needs. Strengthening of human resource through training, combating widespread stigma and discrimination and development of a national strategy and guidelines, backed with an operational plan for providing sexual and reproductive services at the ART clinics or at the linked primary health care facilities, within the same premises and through NGOs. Empowerment of WLHIV, education on their rights and bridging the communication gap through a NGO setting may provide a working solution.

TUPED444

The effect of fertility intentions on HIV clinical care attendance among HIV-positive women on ART in Johannesburg, South Africa

K. Rucinski[1,2], S. Schwartz[3], K. Powers[1], B. Pence[1], B. Chi[4], V. Black[2,5], H. Rees[2], A. Pettifor[1]
[1]University of North Carolina-Chapel Hill, Epidemiology, Chapel Hill, United States, [2]Wits Reproductive Health Institute, University of the Witwatersrand, Johannesburg, South Africa, [3]Johns Hopkins School of Public Health, Department of Epidemiology, Baltimore, United States, [4]University of North Carolina-Chapel Hill, Department of Obstetrics and Gynecology, Chapel Hill, United States, [5]Clinical Microbiology and Infectious Diseases, University of the Witwatersrand, Johannesburg, South Africa

Background: Poor HIV care retention impedes optimal treatment outcomes in HIV-infected women. Women trying to become pregnant may be motivated by horizontal transmission concerns and PMTCT to have a more consistent relationship with HIV care than women who are not trying to conceive. We estimated the effect of fertility intentions on clinic attendance over 12 months in non-pregnant, HIV-positive women.

Methods: 850 non-pregnant, HIV-positive women aged 18-35 on or initiating ART in Johannesburg, South Africa were enrolled into a prospective cohort study (2009-2010). We assessed both current and future fertility intentions at enrollment. Current fertility intentions assessed whether or not a woman was trying to conceive at the time of interview (yes/no). Future fertility intentions assessed whether or not a woman planned to conceive within the next 12 months (yes/no). Attendance was assessed dichotomously (any attendance vs. none) in 90-day intervals. We used generalized estimating equations to estimate the effect of current and future fertility intentions on the odds of attending clinic visits over the 12-month study period.

Results: At enrollment, 105 (12.4%) women reported they were already trying to conceive; 396 (46.6%) reported their intention to conceive in the next 12 months. The proportion of women attending a scheduled visit decreased from 93.2% in month 3 to 80.6% in month 12. Neither trying to conceive at enrollment (aOR: 0.92, 95% CI 0.56, 1.53) nor planning to conceive in the next 12 months (aOR 0.87, 95% CI 0.60, 1.26) was associated with clinic attendance (Table).

Conclusions: We found no association between fertility intentions and attendance at HIV clinical care visits in the pre-conception period. Integrating safer conception services with other HIV prevention, care and treatment services could offer opportunities to further improve care retention in HIV-positive women and their partners who are planning to conceive.

	Unadjusted OR % (95% CI)	Adjusted* OR % (95% CI)
Current Fertility Intentions		
Trying to conceive	0.82 (0.51, 1.31)	0.92 (0.56, 1.53)
Not trying to conceive	1	1
Future Fertility Intentions		
Plan to conceive, next 12 months†	0.78 (0.56, 1.09)	0.87 (0.60, 1.26)
No plan to conceive, next 12 months	1	1

Abbreviations. OR: Odds Ratio; CI: Confidence Interval

*Models were adjusted for a minimally sufficient set of confounders including age (continuous), relationship status (yes/no), time on ART (continuous), partner fertility intentions (no partner, partner does not desire a/another child, partner unsure, partner desires a/another child), any prior living children (yes/no), and provider discouraged future childbearing (yes/no).

†Women who were planning to conceive in the next 12 months comprised both those who were currently trying and those who planned to try in the next 12 months.

[Unadjusted and adjusted ORs for the effect of fertility intentions on attendance at HIV clinical care visits among HIV+ women on ART in Johannesburg.]

TUPED445

Unmet need for modern contraception: Challenges reaching female sex workers without a prior pregnancy in Swaziland

A. Rao[1], S. Schwartz[1], Z. Mnisi[2], D. Kochelani[3], M. Mavimbela[4], S. Baral[1]
[1]Johns Hopkins Universtiy, Department of Epidemiology, Baltimore, United States, [2]Ministry of Health, Mbabane, Swaziland, [3]Johns Hopkins Universtiy, Center for Communication Programs, Mbabane, Swaziland, [4]Swaziland National AIDS Program, Mbabane, Swaziland

Background: Female sex workers(FSW) are disproportionately affected by HIV and have sexual and reproductive health needs like other women. Family planning has the potential to mitigate risks to mother and child, especially in the context of high HIV prevalence and inadequate access to care. This study explores predictors of unmet need for modern contraception among FSW in Swaziland.

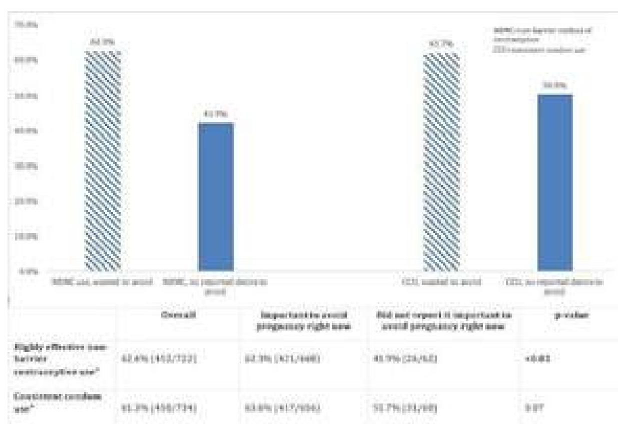
Methods: This is a secondary analysis of a study of FSW in Swaziland between Oct/2014-Dec/2014. Women were excluded if they were currently pregnant(n=9) or trying to get pregnant(n=28). Due to inconsistent condom use, women were classified as having unmet need for modern contraception if they

1)reported it important to avoid getting pregnant and

2)were not currently using a non-barrier method of contraception(e.g. oral contraceptives,intrauterine device). Log binomial regression models evaluated predictors of unmet need.

Results: The median age of the included women was 27(IQR 23-30) and FSW had a median of two children(IQR 1-2). Among the 744 eligible FSW, 676(91%) reported it was important to avoid getting pregnant now. One-third of women reported inconsistent condom use during vaginal sex in the past 12 months(270/722), and nearly 40% of those who reported it important to avoid getting pregnant had an unmet need for modern contraception(247/668). Never having been pregnant compared with attending ANC during last pregnancy was independently associated with higher prevalence of unmet need for contraception(aOR 1.48[1.19,1.84], p< 0.001). Older age(aOR 1.44[1.07, 1.94], p=0.02) and identifying with a non-Christian religion(aOR 1.40[1.01, 1.92], p=0.04) were also all independently associated with increased prevalence of unmet need for contraception, while education was not.

Conclusions: A large gap exists in effective family planning coverage for those FSW who wish to control and time pregnancy. Given the HIV burden among FSW in Swaziland, high unmet contraceptive need and inconsistent condom use contribute to increased risk for adverse maternal and child outcomes, including vertical transmission risk. Women with no previous pregnancy had a higher prevalence of unmet need compared to women attending ANC, suggesting a possible linkage to reproductive health services of a previous pregnancy. Finding strategies to promote and ensure access to reproductive services among FSW-including those without children-is crucial.



[Figure 1. Highly effective non-barrier contraceptive use and consistent condom use comparing female sex workers in Swaziland by how important it was]

TUPED446

Fertility desires, contraceptive preferences and practices of women living with HIV in the South West region of Cameroon: A qualitative study

L.H. Foglabenchi[1,2], V.N. Mbome[3], G. Halle-Ekane[4], A.M. Tebah[5], S.A. Ndeso[6]

[1]Cameroon Baptist Convention Health Services, AIDS Care and Prevention Program, Bamenda, Cameroon, [2]University of Washington, Department of Global Health, Seattle, United States, [3]Ministry of Health, Regional Delegation, Buea, Cameroon, [4]University of Buea, Research and Cooperation, Buea, Cameroon, [5]University of Yaounde, Sociology and Anthropology, Yaounde, Cameroon, [6]St Monica University, International Health, Buea, Cameroon

Background: With the rapid expansion of antiretroviral therapy (ART) and Prevention of Mother-to -Child-Transmission (PMTCT) of HIV programs in sub-Sahara Africa and Cameroon in particular, women living with HIV are desiring children to meet up with personal and societal expectations. Evidence on the extent and drivers of these desires is scanty. This study therefore, explores the extent and drivers of fertility desires and provides in-depth understanding on the contraceptive preferences and practices of women living with HIV in Cameroon.

Methods: A qualitative research approach through a combination of 4 focus group discussions (FGDs) and 29 in-depth interviews (IDIs) was used. Sampling was purposive and primary research subjects were HIV-infected women of reproductive age currently attending care in four facilities in the South West Region of Cameroon. The Thematic framework approach was used for data analysis and interpretation.

Results: Participants' narratives indicate that, a complex mix of personal (beliefs and motivation), medical (ART effectiveness) and societal factors (social validation and expectations) appear to influence the fertility desires of Cameroonian women living with HIV. Procreation in this sub-population is seen as a means for women living with HIV to normalize their social status, rebrand their identities and secure their marriages. We also found that desires for pregnancy are not moderated with family planning as majority of study-subjects reported the use of traditional and less effective methods like salt and whisky for family planning. The use of modern contraceptive methods among a minority of study subjects was influenced by myths, perceived side effects, ease and frequency of use.

Conclusions: Our findings suggest that for the sustained engagement of women of reproductive age in HIV care, the Ministry of Public Health in Cameroon needs to employ a comprehensive approach to PMTCT and target all prongs to ensure that every pregnancy is planned and timed to optimize maternal and infant health and to reduce the risk of HIV infection to infants and partners. Interventions should aim to integrate preconception counselling and family planning into HIV care services and reduce the operational barriers of accessing Family planning commodities.

Living with HIV and co-infections and/or co-morbidities

TUPED447

"Blood pressure can kill you tomorrow but HIV gives you time": Illness perceptions among HIV-infected individuals with hypertension

M. Hing[1], R.M. Hoffman[1], J. Seleman[2], F. Chibwana[2], K. Phiri[2], D. Kahn[1], K. Dovel[1,2], C. Moucheraud[3], EQUIP Innovation for Health

[1]David Geffen School of Medicine at the University of California, Los Angeles, United States, [2]Partners in Hope Medical Center, Lilongwe, Malawi, [3]University of California, Fielding School of Public Health, Los Angeles, United States

Background: Despite the rise in non-communicable diseases among individuals living with HIV, there is limited knowledge about the experience of patients with comorbid chronic illnesses in low-resource set-

tings. This study sought to investigate disease and adherence experiences among patients with HIV and hypertension (HTN).

Methods: Semi-structured interviews were performed between June-December 2017 at an urban, non-profit PEPFAR-USAID ART facility in Malawi. HIV-infected adults ≥18 years, and taking ART and ≥1 antihypertensive for at least 1 year, were interviewed about their experience with the two conditions and treatments. Interviews were recorded, transcribed and translated into English. A codebook was developed based on the interview guide; iterative codes were added as needed. Analyses used theories from the public health literature to identify themes related to disease perceptions and treatment adherence.

Results: Seventy-five participants were interviewed (64% female, median age 53). Median duration on antihypertensives was 4 years with participants taking on average 2 antihypertensives (range:1-4). Most (84%) participants had elevated blood pressure (systolic >140mmHg, and/or diastolic >90mmHg) at their most recent clinic visit. Although most respondents (63%) viewed HTN and HIV as equally important chronic diseases, nearly half (45%) reported having greater fear of HTN compared to HIV, mainly due to the perceived suddenness and severity of HTN complications versus the perceived slow and visible progression of HIV (Table 1). Despite increased fear of HTN, participants found adherence to antihypertensives more challenging than adherence to ART: 77% of participants reported missing ≥1 dose per week of their antihypertensive medicine(s) (versus 7% who missed ≥1 dose per week of ART). Barriers that uniquely affect HTN treatment included medication costs (mentioned by 61% of respondents) and lifestyle changes (30% of respondents) like diet and exercise required for HTN management.

Conclusions: Participants living with HIV and HTN recognized the importance of controlling HTN to prevent future severe complications, but barriers such as costs of medications and lifestyle changes impeded adherence to treatment. Areas of commonality and difference in perceptions of HIV and HTN may inform future efforts to improve outcomes in comorbid patient populations.

Improving care for people in Ukraine who have tuberculosis and HIV: Findings from a qualitative analysis of integrated services

Z. Charyeva[1,2], S. Curtis[1], S. Mullen[1,3], R. Teal[4], O. Zaliznyak[5], T. Senik[5], S. Eagan[3]
[1]*MEASURE Evaluation, University of North Carolina at Chapel Hill, Chapel Hill, United States,* [2]*Palladium, Chapel Hill, United States,* [3]*JSI, Washington, United States,* [4]*Consultant, Chapel Hill, United States,* [5]*IFAK Institut, Kyiv, Ukraine*

Background: Ukraine is one of the 10 countries with the highest incidence of multi-drug resistant TB; about a quarter of all TB patients are also infected with HIV. The USAID-funded Strengthening Tuberculosis Control in Ukraine project aims to improve the integration of TB and HIV services to reduce mortality through early diagnosis and treatment of TB- and HIV-coinfected clients. This study examined changes in the integration of TB and HIV services, and factors that facilitate or impede timely access to testing and treatment services for TB- and HIV-coinfected clients in project intervention regions.

Methods: We conducted 53 in-depth interviews with three stakeholder groups: 30 TB- and HIV-coinfected clients; 17 infectious disease and TB providers; and six coinfection specialists. We also conducted six focus group discussions with providers. All discussions were digitally recorded, translated, and transcribed. Using ATLAS.ti, we synthesized data based on key themes that were identified using deductive and inductive coding, and then presented results using direct quotes to support themes.

Results: The HIV-TB integration program affected several positive changes in the integration of services, especially around availability of diagnostic tests across facilities, training of providers, and improved communication and collaboration across services. However, client databases are not consistently shared across all TB and HIV services, which makes coordination challenging and further increases travel costs for patients, as they have to travel between TB and HIV clinics. Providers spoke of clients' inability to accept their HIV diagnosis and follow treatment instructions, short-staffed facilities, and infrastructure issues such as buildings that needed repair as key barriers. From the clients' perspective, barriers to accessing care included: dealing with HIV-related stigma; long lines at facilities; high out-of-pocket costs associated with travel, inpatient stay, laboratory work, and medications; confusion about where to go to receive treatment; and confusion about medication regimens and their debilitating side effects.

Conclusions: The study suggests that while improvements in diagnostic testing and coordination across TB and HIV facilities is well underway, factors such as stigma, emotional burden, adequate education to deal with the side effects of the medication, and high patient out-of-pocket costs still need to be addressed.

TUPED449

Countering double trouble - PLHIV community led intensified case finding of TB cases amongst PLHIV in India

M. Balani[1], R. Chauhan[1], V. Arumugam[1], H. Rosenara[1], U. Chawla[1], S. Mehta[1], R.S. Gupta[2], M. Barmotiya[2]
[1]*India HIV/AIDS Alliance, Program, Delhi, India,* [2]*National AIDS Control Organization, Ministry of Health and Family Welfare, Delhi, India*

Background: TB is the most common opportunistic infection among people living with HIV (PLHIV). TB being a major public health problem in India accounts for 20-25% of deaths among PLHIV. It is known that nationally about 5% TB patients registered under the Revised National Tuberculosis Control Programme (RNTCP) also have HIV infection. There is a need to scale up the early detection of TB presumptive cases amongst PLHIV and link them to treatment for effective management of HIV-TB co-infection.

Methods: The Global Fund-supported Vihaan care and support programme is implemented by India HIV/AIDS Alliance as a principal recipient. As a core component of India's national HIV strategy, 361 care and support centres (CSCs) have been established, most of them implemented by PLHIV networks (80%) and other civil society organisations (20%). CSCs promote treatment adherence, enhance positive living and create an enabling environment for an effective HIV response in India. Intensified case finding (ICF) for TB is one of the key activity carried out by the staff of CSCs who are mostly from the PLHIV community themselves. Through ICF, symptomatic TB cases are referred to ART centres from where TB testing is done and linked to if confirmed TB positive. Peer counselors and outreach workers from the PLHIV community provides follow up services to those identified HIV-TB co-infected. Some CSC provides nutritional support to such clients by mobilising locally available resources.

Results: Peer led ICF and follow up services is effective for early detection and linkage with TB treatment.1,025,304 PLHIV were screened for TB, of which 149,976(15%) PLHIV were found with at least one symptom are referred for TB testing, of which 10,075 (6.7%) PLHIV were diagnosed with TB and out of this 9,067(90%) were linked for TB treatment.

Conclusions: Complementing the national collaboration on HIV-TB activities, Vihaan care and support programme will continue strengthening the PLHIV led ICF and follow up of identified HIV-TB co-infected PLHIV

to treatment adherence and course completion. The program will also emphasise on tracing of family members of the PLHIV co-infected with HIV-TB.

TUPED450

"You change who you hang out with": Understanding hepatitis C risk behaviours and attitudes among HIV-diagnosed gay and bisexual men

S. Schroeder[1], M. Stoové[1,2], P. Higgs[1,3], A. Pedrana[1], M. Hellard[1,2,4], J. Doyle[1,2,4]
[1]Burnet Institute, Disease Elimination, Melbourne, Australia, [2]Monash University, School of Population Health and Preventive Medicine, Melbourne, Australia, [3]La Trobe University, Department of Public Health, Melbourne, Australia, [4]The Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia

Background: Due to sexual and/or parenteral exposure, gay and bisexual men (GBM) are at increased risk of hepatitis C (HCV)/HIV co-infection. In Australia, the advent of subsidised direct-acting antivirals (DAA) for HCV treatment has made eliminating HCV among co-infected GBM possible; however, high reinfection rates could threaten this elimination goal. To gain an understanding of the factors influencing HCV reinfection risk and identify post-treatment support needs, this study explored HCV risk perceptions and attitudes among HIV-diagnosed GBM recently cured from HCV.
Methods: Fifteen in-depth interviews were conducted with HIV-diagnosed GBM in Melbourne post DAA-treatment success. Interviews focused on participants' experiences related to HCV risks and attitudes towards reinfection avoidance. Data collection, analysis and interpretation were guided by constructivist grounded theory.
Results: Three categories conceptualise participants' experiences:
Rejecting the junkie label
Contrary to feelings of inevitability associated with HIV seroconversion, a lack of HCV risk awareness coupled with perceived knowledge about safe drug use meant that HCV-diagnosis came as a shock to most participants. Despite high prevalence of injecting drug use, participants did not identify with populations typically at risk for HCV.
Risk environments and fear of social isolation
Interviewees implicated the micro-social environments in which they were socially and sexually engaged as risk environments, where sexualised drug use was perceived as ubiquitous. Removal from high-risk environments and sexual activity to avoid HCV reinfection resulted in disengagement from their communities, leaving many feeling socially isolated.
Beyond cure
HCV was experienced as highly stigmatising and many jumped at the opportunity to achieve cure. Treatment was identified as a catalyst for substantial lifestyle changes among those who had become critical of their use of methamphetamines. A key narrative was the commitment to avoiding HCV-reinfection; conceptualising reinfection as representing a personal failure and manifest of an inability to maintain their current, healthier lifestyles.
Conclusions: Tailored HCV prevention campaigns need to take account of the intersectionality between multiple stigmatised social identities. An understanding of HCV-infection as both behavioural and social should form the basis of treatment support. Establishing peer support networks could mitigate social capital loss following a commitment to behaviour change and contribute to avoidance of HCV reinfection.

TUPED451

Qualitative study on the experiences and perspectives of public sector patients in managing workload of demands of HIV and type 2 diabetes co-morbidity in Cape Town and Polokwane, South Africa

H. Onya, Health Promotion Group
University of Limpopo, Public Health, Polokwane, South Africa

Background: In South Africa, little is known about how chronic patients with multi-morbidities currently experience the (re)-organisation of health services as suggested by the Integrated Chronic Disease Model (ICDM); and what their perceived needs are in order to enhance the management of their conditions both at point of healthcare and in their daily lives. Shippee´s Cumulative Complexity Model (CCM) was used as a testing tool to explore patient workload and capacity to manage HIV and type two diabetes (T2D)] and how this impact on their capacity for effective self-management.
Methods: 28 qualitative in-depth interviews (10 Cape Town patients; 12 Polokwane patients; 6 Cape Town and 6 Polokwane patients' health providers were conducted) and health facilities document review in Khayelitsha and Mankweng hospitals. Convenience and purposive sampling (people living with HIV and T2D; and key informant health providers) were utilised in respondents 'selection. Grounded Theory method was used in the data analysis.
Results: Patients' Workload demands were transport challenges/costs to health facilities and frequent visits. Patients´ capacity to deal with burden of illness were physical and mental functioning challenges, financial resources, social support and problems with the health system. Facilities access barriers included long waiting periods and queues to consult and collect medication, health worker attitudes and confidentiality. Some patients were no longer using the facilities and receive their medication elsewhere or consult traditional healers. Prolonged waiting at outpatient departments in hospitals, creates problems for diabetic patients who cannot stay for a long time without a meal.
Conclusions: There is tremendous demand related to the amount of patients' workload (collecting medication, clinic appointments, medication intake, job demands, and self-management). As patients' physical, emotional capacity and other aspects deteriorate they are unable to cope with managing their conditions. Health education and counselling related to management of co-morbid conditions and adherence to treatment need to be intensified.

TUPED452

Outcomes of HCV treatment with DAAs in key groups HIV/HCV co-infected patients in Ukraine

S. Filippovych[1], O. Burgay[2], S. Antoniak[2], S. Antonyak[3], Z. Tsenilova[2], N. Ivanova[2], D. Marunko[2]
[1]ICF, TPSM, Kyiv, Ukraine, [2]ICF 'Alliance for Public Health', TPSM, Kyiv, Ukraine, [3]Gromashevsky Institute of Epidemiology and Infectious Diseases within the Academy of Medical Sciences of Ukraine, Viral Hepatitis and HIV/AIDS Department, Kyiv, Ukraine

Background: According to UNAIDS in 2016 Ukraine numbered 240 000 persons living with HIV; 346 000 people who inject drugs with HIV prevalence of 21.9%. Estimated hepatitis C virus (HCV) prevalence in Ukraine is 2-5% (~1-2 million people). 78% of newly registered with HIV were tested for HCV, 28.8% out of them had positive results.
Since 2015 Alliance for Public Health is implementing the Project aimed at scaling up accessible and effective HCV treatment with directly active antivirals (DAAs) for key populations (KPs) - people who inject drugs (PWID), men having sex with men (MSM), commercial sex workers (CSW). Among Project's main objectives are to develop and implement innovative community-based HCV treatment model for KPs in resource constrained Ukraine; to render intensified social support to the patients and integrated services.
Description: Project was implemented in 25 medical settings, located in 19 regions of Ukraine. 1400 HIV co-infected patients from KPs (73.5% of 1907 totally enrolled) received DAA-based HCV treatment, including 1360 (97.1%) on ART 70.3% (n=984) were men, median age 39 years (18-68).

Treatment regimens included sofosbuvir+pegylated-Interferon+ribavirin 12weeks; sofosbuvir+ribavirin 12-24weeks; sofosbuvir+daclatasvir+/-ribavirin 12-24weeks; ledipasvir/sofosbuvir+/-ribavirin 12weeks.
Multi-disciplinary teams (MDT) consisting of doctor, nurse, social worker from local NGOs were operational at each Project site. Every enroller was covered with social support. Case managers served as a link to integrated services (HCV-HIV-TB diagnostics, treatment and opioid substitution therapy management, prevention of HCV re-infection).
Among 1400 HIV/HCV co-infected patients, 1373 completed full treatment course, 27 (1.93%) discontinued treatment (12 - adverse reactions; 8 - refused to continue treatment; 5 -non-related to HCV deaths; 8 - other). Treatment results are available for 1325 patients who were tested for HCV RNA at 12 weeks after end of treatment. 1261 (95.2%) patients achieved sustained virologic response (SVR12).
Lessons learned: KPs' high adherence to treatment is evidenced by few treatment discontinuations and high treatment success. Adherence indicator was conditioned by the patient-centred approach practiced by MDTs when delivering integrated services within community-based HIV/HCV treatment model.
Conclusions/Next steps: Implemented by Alliance innovative community-based HCV treatment model is regarded as paradigm of best practices and evidence-based solutions for HCV treatment policy decisions for HIV/HCV co-infected patients.

TUPED453

Understanding the burden of mental health among persons living with HIV in Northern Indiana, United States

H. Beidinger[1], A. Scott[1], D. Aragon[1], R. Ghiassedin[1], L. Hopper[2]
[1]University of Notre Dame, Eck Institute for Global Health, Notre Dame, United States, [2]AIDS Ministries/AIDS Assist, South Bend, United States

Background: Indiana has one of the highest rates of HIV and ranks as one of the worst states for mental health well-being. In collaboration with AIDS Ministries/AIDS Assist (AM/AA), HIV care organization, we need to determine the following in order to improve services:
(1) the prevalence of MHDx among PLWH,
(2) their mental health care seeking behaviors and
(3) the relationship between viral load status, mental health care seeking behaviors and type of mental health provider.
Methods: A cross-sectional, quantitative study was performed utilizing AM/AA's anonymized client database (N= 366). Variables included were: gender, race, ethnicity, MSM, viral load status (below 20 copies/mL of blood was deemed undetectable), MHDx, and mental health provider (was the client in the care of a licensed mental health provider).
Results: Of the 366 clients, 140 (38.3%) clients had a MHDx. Of the 140 clients, 110 (78.6%) clients sought mental health care (85 male; 25 female). A chi-square test revealed a significant difference in viral load status of those seeking mental health care and those who did not (p = .007). Those who sought care were more likely to have an undetectable viral load. There was also a significant difference in viral load status between those seeking care from a licensed mental health provider, seeking care from a non-licensed provider and those not seeking care (p=.028). Black MSM with a MHDx were more likely not to seek care (p = .037).
Conclusions: While many clients are seeking care for their MHDx, there remains a group that is not seeking care which may be negatively affecting their viral load status resulting in possible HIV transmission. However, because of the positive relationship between seeking care from a licensed mental health provider and an undetectable viral load, providing access to a licensed provider should be made a priority. The implications of this study are significant; access to a licensed provider is important for quality of life, more likely to achieve an undetectable viral load, and reduce HIV transmission.

TUPED454

First experience of viral hepatitis C screening, diagnostic and treatment in HIV-infected patients of the penitentiary sector

O. Burgay[1], E. Khaniukov[2], S. Filippovych[3], N. Nedashkovska[4], T. Gaborets[5], Z. Tsenilova[6], S. Antoniak[3], N. Ivanova[3], D. Marunko[3]
[1]ICF 'Alliance for Public Health', TPSM, Kyiv, Ukraine, [2]GFATM Head of PIU Center of Public Health Ministry of Health of Ukraine, Kyiv, Ukraine, [3]ICF 'Alliance for Public Health', Kyiv, Ukraine, [4]GFATM PIU Center of Public Health Ministry of Health of Ukraine, Kyiv, Ukraine, [5]The State Penitentiary Service of Ukraine, Kyiv, Ukraine, [6]ICF 'Alliance for Public Health', Treatment, Kyiv, Ukraine

Background: As of January 2018 prison population in Ukraine reached 57 456 with 6,7% HIV prevalence (3 830 HIV+ persons). No reliable data on the numbers of Hepatitis C virus (HCV)-infected patients in prisons in Ukraine was available till the end of 2017. HCV treatment was unavailable as well. With the support of the Global Fund to Fight AIDS, TB and Malaria HCV screening program in HIV+ prison population with further HCV diagnostic and treatment was first initiated in November 2017 by the Alliance for Public Health, Ukraine, and implemented in close cooperation with penitentiary sector.
Description: The main goal of the study was to create an algorithm of granting access to HCV screening, diagnostic and treatment to HIV-infected imprisoned patients. 1000 express tests were distributed to 23 penitentiary institutions. Screening was performed among HIV-positive prisoners by penitentiary service medical staff. 1000 HCV express tests gave 742 positive results (74,2%/). 139 random patients out of 742 with HCV positive antibodies results were further diagnosed for viral load (quantitive) and genotyping (G). Genotyping results distribution: 53 persons with G1a/1b; 6 persons with G2; 56 persons with G3, mixed G was detected in 2 persons, undetectable G in 22 persons. 50 available 12 weeks ledipasvir/sofosbuvir treatment courses were granted to the first 50 patients with G1a/1b in two penitentiary medical settings late December 2017. Treatment was prescribed and provided by the doctors from the hospitals mentioned, previously trained in HCV management.
Lessons learned: Results of the first ever HCV screening showed dramatic levels of HCV antibodies prevalence among HIV+ prison population in Ukraine. The model applied (HCV screening followed by HCV diagnostic and further HCV treatment) opened the window of opportunity for the prison population in Ukraine to get access to HCV testing, diagnostic and innovative short-course treatment with directly active antivirals.
Conclusions/Next steps: Implemented for the first time innovative model of HCV screening, diagnostic and treatment among HIV+ prison population of Ukraine is considered to be valuable evidence for filling in the challenging gap of the health care system in screening, diagnostics and treatment of HIV+ population co-infected with HCV in the penitentiary sector.

Human rights of people living with HIV and key and vulnerable populations

TUPED455

Accessing universal health care for all by 2030 - improving legal environments to ensure equitable access to HIV and SRHR services for young key populations (YKPs) in Africa

S.F. Ntshangase[1], M.G. Getahun[2], A. Saha[2]
[1]United Nations Development Programme, Health HIV Department (HHD), Istanbul, Turkey, [2]United Nations Development Programme (UNDP), HIV Health Department, Istanbul, Turkey

Background: Young key populations (YKPs) continue to face enormous challenges to access HIV and SRH services despite global and regional commitments. Data on YKPs remains limited resulting in poor planning

for YKP-oriented services including for HIV, STIs, teenage pregnancies, access to contraception, drug use, etc. and policies and legal frameworks for young people are not aligned with international and regional obligations.
Description: Recognising that a third of the population in sub-Saharan Africa are young people aged 10-24 years, the Government of Netherlands supports a project in 5 countries to
(a) harmonise their national laws and policies with international and regional commitments to enable them to improve access to HIV and SRH services for YKPs;
(b) strengthen capacity of YKPs as active participants in law and policy reform processes;
(c) assist SADC to develop inclusive guidelines to increase HIV/SRHR services among YKPs;
(d) create an environment conducive for legal reform; and
(e) to establish indicators to measure increased service uptake by YKPs in the region.
AMSHeR, HEARD and UNDP are implementing partners in this project in Angola, Madagascar, Mozambique, Zambia and Zimbabwe. Interventions include assessment of law, policy and national strategic plans, development of engagement scans for policy advocacy; capacity building of YKP groups on advocacy and policy change, and evidence-based research on access to SRH services for YKPs.
Lessons learned: Multisectoral advocacy approach resulted in the adoption of the SADC Key Population Strategy by Member States; SRH Scorecard developed to monitor KP interventions at national and regional level. Government, CSO and KP community capacitated on HIV, law and human rights resulting on a government led undertaking of Legal Environment Assessment; One LEA report finalised in Zimbabwe.
Conclusions/Next steps: Using a participatory multisector approach in the analysis of law and policies involving governments, key populations and CSOs is vital as it sensitises stakeholders on HIV/TB/SRH rights of YKP and builds national consensus on priority actions to be taken forward. Additionally, such approach creates a pace for dialogue and assists duty-bearers to change their perceptions on issues affecting YKPs and their access to services and justice.

TUPED456

Advancing human rights in the HIV response in Africa: The case of the report on HIV, law and human rights of the African commission on Human and Peoples' Rights

B.D. Nibogora[1,2], E. Durojaye[3,4], A. Bagona[4], P. Eba[4,5], H.-J. Kim[6]
[1]African Men for Sexual Health and Rights (AMSHeR), Law and Human Rights Advocacy Programme, Johannesburg, South Africa, [2]Global Fund to Fights AIDS, Tuberculosis and Malaria, Developing Country NGO Delegation, Geneva, Switzerland, [3]University of Western Cape, Dullah Omar Institute - Law Centre, Cape Town, South Africa, [4]African Commission on Human and Peoples' Rights, Committee on the Protection of the Rights of People Living with HIV and those at Risk, Vulnerable to or Affected by HIV (HIV Committee), Banjul, Gambia, [5]UNAIDS, Human Rights and Law, Geneva, Switzerland, [6]ARASA, Regional Advocacy, Windoek, Namibia

Background: Advancing human rights in the HIV response in Africa: The Case of the Report on HIV, Law and Human Rights of the African commission on Human and Peoples' Rights.
Methods: Following the adoption of Resolution 290, the Commission undertook a consultative process based on the terms of reference for the Study Report. Inputs were received from a wide range of stakeholders in a session held on December 1st, 2015 at the margin of the 18th International Conference on AIDS and STIs in Africa in Harare, Zimbabwe. The civil society voices emphasized that the study process needs involvement of civil society and other stakeholders. Between December 2015 and November 2017, five face-to-face consultations were held in Harare, Banjul, Durban and Abidjan, online submissions were opened for December 2016. Submissions of testimonies and technical inputs were received from United Nations experts, International NGOs and affected communities from all regions of Africa.
The report, with strong and unprecedented recommendations on human rights and key populations, was adopted on November 2017 by the Commission.
Results: The process demonstrated the potentials, benefits of a healthy collaboration between the Commission, the UN agencies, governments and civil society, including representatives of key populations in the development policy standards at the regional level. This multi-stakeholders' engagement model is commendable and allows for ownership, legitimacy and swift progress in policy formulation and implementation at all levels.
Conclusions: Through its inclusive and multi-stakeholder process, the report provides a strong model for engagement between African regional bodies, civil society and the UN on HIV-related issues. Country-focused initiatives were identified at the launch of the report to support the implementation of the bold recommendations to advance zero discrimination and rights for all in the HIV response.

TUPED457

Africa regional grant on HIV: Removing legal barriers - emerging results

D. Patel[1], D. Owolabi[2]
[1]UNDP, HIV and Health, Istanbul, Turkey, [2]UNDP, Istanbul, Turkey

Background: The Africa Regional Grant on HIV: Removing Legal Barriers aims to address human rights barriers faced by vulnerable communities in Africa, and facilitate access to lifesaving health care. The grant is the first of its kind and covers 10 countries, including Botswana, Côte d'Ivoire, Kenya, Malawi, Nigeria, Senegal, the Seychelles, Tanzania, Uganda and Zambia. The programme also works at the continental and regional levels with the African Union Commission and key Regional Economic Communities (SADC, ECOWAS, EAC) to promote alignment of national laws and policy with regional and international human rights commitments.
Description: The programme is supported by the Global Fund to Fight AIDS, Tuberculosis and Malaria. UNDP is the Principal Recipient of the grant and implements in collaboration with four sub-recipients - the AIDS and Rights Alliance for Southern Africa (ARASA), ENDA Santé, KELIN, and the Southern Africa Litigation Centre (SALC) - with recognized expertise in documenting human rights violations, strategic litigation, advocacy and capacity-strengthening. The goal of the programme is to strengthen the legal and policy environment to reduce the impact of HIV and TB on key populations in Africa, including men who have sex with men, sex workers, transgender people, people who use drugs and prisoners.
Lessons learned: Now that the grant is in the third and final year of implementation, many results have been achieved. Sharing lessons across the 10 countries has proven invaluable in removing legal barriers. Specifically, the successes in strategic litigation in Kenya, Malawi, Botswana shows that integrated capacity strengthening of critical stakeholders (lawyers, judges, CSOs etc) in HIV/TB and human rights is key to preventing and addressing human rights violations of KPs; reinforcing the implementation of supportive laws and strengthening the evidence base for law reforms. Advocacy efforts have also resulted in integration of TG into NSPs, and adjudication for women living with HIV, and sex workers.
Conclusions/Next steps: To ensure sustainability, UNDP will follow up at both the regional and national levels including working towards institutionalizing such efforts in formal training institutes and curricula.

TUPED458

„Bringing science to justice": How advocacy in Sweden is resulting in modernising its HIV-related laws and prosecutions/sentences of people living with HIV

A. Berglöf
RFSU (The Swedish Association for Sexuality Education), Stockholm, Sweden

Background: Under the general criminal law of assault, people with HIV can be prosecuted for unprotected sex even when there was prior disclosure and when no transmission has occurred. Some shouldn't even have been prosecuted because of no risk of transmission. Especially so

Tuesday 24 July

Wednesday 25 July

Thursday 26 July

after the "Swedish statement" on infectiousness was published October 2013 that says that the risk of transmission of HIV from a well-treated person is minimal. With the Swedish statement the Supreme Court needs to come up with a new precedence.

Description: In 2010, RFSU partnered with RFSL and HIV-Sweden on a project that aimed to educate and inform politicians and the justice system on advances in HIV science, and the negative impact of overly broad HIV criminalisation on public health.

Since then we have kept fighting for that the unjust prosecutions and sentences of people living with HIV should stop. We have done so via debate articles in relevant papers and magazines. We have also had discussions with The Public Health Agency of Sweden, government officials and with people in the Parliament.

Lessons learned: In 2016 where a well-treated person with HIV was prosecuted despite no transmission, the person was acquitted in lower court and later on also in the court of appeal. For us it was very important to try and get this case all the way to the Supreme Court to get a new presedence. The Supreme Court eventually announced its decision to take the case. The case haven't been dealt with so far (February 2018) so we don't have the result from the Supreme Court yet.

Conclusions/Next steps: Even if the Supreme Court does come up with a new good and relevant precedence, we will keep on monitoring human rights for people living with HIV. The violations of people living with HIV takes place not only in court rooms, but also in society overall from time to time. Not least because there is still a lack of sufficient knowledge about HIV and how it is to live with HIV. It is getting better, but we are not yet there.

TUPED459

Utilizing African national human rights institutions in promoting and protecting the rights of key populations

N. Mokoena
ARASA, Cape Town, South Africa

Background: In most countries in the African region, the rights of key populations are often seen as
controversial. Key population groups often struggle to carry out their work because they work in criminalised settings. NHRIs can serve as key players in creating enabling legal environments to ensure access to affordable, accessible and quality HIV prevention, treatment and care services. NHRIs, due to their powers and mandates, have a duty to speak in defense of the rights of key populations.

Description: Recognising that National Human Rights Institutions (NHRIs) have a significant role to play in creating an enabling legal environment for HIV and TB prevention, treatment, care services for Key Populations, the AIDS and Rights Alliance for Southern Africa (ARASA) under the Africa Regional Grant on HIV: Removing Legal Barriers, has implemented a number of interventions and activities to strengthen the capacity of NHRIs in promoting and protecting the rights of key populations;

- Annual Regional Capacity Strengthening Meeting for NHRIs
- Media briefs for NHRIs focusing on the role of NHRIs in the HIV response
- National Advocacy meetings in Malawi and Kenya in collaboration with the NHRIs.

Lessons learned:

A. Regional Lessons learned: Key population groups were asked why they do not utilise complaint mechanisms put in place by NHRIs. A number of issues were identified:

(1) Lack of trust in government institutions
(2) Discriminatory attitudes by NHRI staff members
(3) Reluctance of NHRIs to speak out against human rights violations on key populations
(4) The (lack of) strength and influence of NHRIs

B. Collaborative partnerships: Two national meetings were organised by key population groups and NHRIs. The collaborative approaches formed a bridge between the NHRIs and the key populations, thus addressing the regional lessons stated above.

Conclusions/Next steps: NHRIs are perfectly placed to advise governments on laws and policies that serve as legal barriers to accessible HIV prevention, treatment and care. Strengthening the capacity of NHRIs, increases their capacity to advise governments on law review and reform. The Annual Regional Capacity Strengthening Meeting for NHRIs, will continue to increase the capacity and knowledge of NHRIs around HIV, TB and the law.

TUPED460

Facilitating access to justice for communities of people living with HIV in Kenya

T. Makokha[1], L. Ghati[2], A. Maleche[3], E. Makona[3]
[1]Kenya Legal and Ethical Issues Network on HIV & Aids, HIV & TB Thematic Area, Nairobi, Kenya, [2]Kenya Legal and Ethical Issues Network on HIV & Aids, Nairobi, Kenya, [3]Kenya Legal and Ethical Issues Network on HIV and Aids, Nairobi, Kenya

Background: Since 2012, Kenya Legal and Ethical Issues Network on HIV and AIDS (KELIN), with support from UNDP Kenya, has been implementing the project focusing on *Enhancing the legal environment for an effective HIV response*.

The project aimed at enhancing the legal environment for an effective HIV response in Kenya through:

(i) Strengthening capacities of legal professionals, law enforcement officers, judges, magistrates, healthcare workers, PLHIV, key affected populations, youth, religious leaders and traditional elders;
(ii) Improving access to justice and legal services by communities of PLHIV
(iii) Engaging in advocacy for change to HIV related law, policy and practices.

Description: Interventions of this project included:

§ Empowering lawyers on the link between HIV and human rights, and creating a pool of lawyers available to offer free legal services on HIV related cases. KELIN trained 233 lawyers in Kenya, 54% female and 46% male.

§ Development of a *compendium of cases* decided by the HIV and AIDS Tribunal as a documentation of HIV related cases, and raise awareness on violations facing PLHIV.

§ Sensitization of judicial officers on HIV since they are key players in the justice system through judicial dialogues and colloquium. A total of ninety one (91) judges and magistrates and one hundred and twelve (112) other judicial officers were sensitized through this project.

§ Public Interest Litigation to challenge government policies that violated human rights of PLHIV. One such case involved an unconstitutional presidential directive that would violate the right to privacy of children living with HIV.

Lessons learned: It is important to mobilize and empower communities of key and affected populations to ensure their direct involvement in influencing responses that address problems in the justice system.

Conclusions/Next steps: There is a need to support countries to take steps to strengthen legal frameworks to protect PL HIV and key populations. This is critical in promoting universal access to HIV prevention, treatment, care and support in keeping with international guidance and national human rights commitments.

TUPED461

Breaking the legal barrier for sex workers justice. Alternative dispute resolution grass root system for sex workers

S. Mwangi, J. Mtende, P. Mwangi
Bar Hostess Empowerment and Support Program, Program, Nairobi, Kenya

Background: Bar Hostess Empowerment and support program(BHESP), a woman led organization, being in the forefront in advocating for the human rights of sex workers in Kenya. Despite this effort, Sex workers continue to face significant layers of GBV/SGBV on account of repressive patriarchal structure, misogynist interpretation of law, culture and morality, stigma and discrimination, preventing them from accessing reproductive health service, HIV prevention and care and other social services.

One worrying report revealed by the Polling Booth Survey 2016 is that the proportion of FSWs who had experienced physical violence increased significantly from 44% to 48%.
Significant number of sex worker prefer giving of bribes rather than pursuing the case through litigation due to prolonged and tedious judicial processes in Kenya. With this fact BHESP started employing Alternative Dispute Resolution(ADR) which is a process for resolving disputes other than litigation.
Methods: BHESP has engaged the judicial service commission and government representatives from ministry of health in four progressive dialogues after presenting a proposal to them the urgency of strengthening the grassroots ADR system to reduce procedural delay of cases and assist speedily access to justice and support for SGBV survivors. These meetings were held with identified Judicial members, sensitized on special needs of sex workers as a means of lobbying. BHESP is making a case on GBV/SGBV response for sex workers in Kenya through breaking the legal barrier in ensuring that sex workers access justice.
Results: 27 incidences have been successfully resolved through grassroots Alternative Dispute Resolution (ADR) system. Members of Judicial service commission sensitized by BHESP have been very supportive in the effort of ensure that sex workers cases that are in court are handled without delay. Most sex workers have found this as the best option and sustainable way to address Human Rights Violations challenges they face day to day.
Conclusions: Removing legal barriers against sex workers in Kenya will be paramount to fully accessing of sex workers Rights. It is paramount to Creation of progressive jurisprudence which advances human rights for sex works. BHESP recommends that sex workers to seek redress for human rights violation in quasi-judicial bodies and courts.

TUPED462

Documenting sex workers' human rights violations in Kyrgyzstan Shah Ayim network

D. Bakirova, G. Sarybaeva
Shah-Aiym, Bishkek, Kyrgyzstan

Background: The goal of the project is to strengthen the advocacy platform of sex workers community and their allies to increase the effectiveness of counteracting violence, illegal law enforcement practices against sex workers and legislative initiatives that criminalize sex work.
Description: In Kyrgyzstan, adult sex work has been decriminalized since 1997. Based on the data of the first national survey „Observing the Human Rights of Sex Workers in the Kyrgyz Republic" 2012 supported by Soros Foundation Kyrgyzstan, Shah-Aiym network began documenting sex workers' human rights violations in 2013. Trained employees from the community and friendly lawyers were recruited for human rights violation documentation, counseling and support. The documentation data was used to prepare the Alternative Reports to the CEDAW Committee, to inform key agencies whose activities affect sex workers and are related to the implementation of international human rights obligations. Quarterly analysis of documented cases is distributed through e-mails to all NGOs in Kyrgyzstan, engaged in HIV, human rights NGOs, international organizations whose activities concern sex workers, rights and gender.
Kyrgyzstan´s experience in documenting sex workers' human rights violations is transmitted to members of Shah-Aiym network from other countries.
Lessons learned: Documented cases in Bishkek and Jalal-Abad:
In 2016 - 364 cases, in 2017 - 306 cases reported by 249 people (of which 11 are trans sex workers). Police officers are the main source of violence and human rights violations.
The main types of violations:
- arbitrary detention 89%
- money extortion 81%
- threat, blackmail and pressure 68%
- degrading and inhuman treatment 61%

Outcomes of detentions: sex workers who could not pay the police are registered on charges of petty misdemeanor or for disobeying police officers and are brought to court. Judges convict sex workers without reviewing the case.
Conclusions/Next steps: 1. Discriminatory application of administrative articles to sex workers represents the actual criminalization of sex work
2. To continue to document and collect data on violations and violence against sex workers in order to collect the evidence.
3. Advocate for the improvement of the legal status of sex workers in Kyrgyzstan at the national, regional and international levels.

TUPED463

HIV criminalization in California: Policing sex work and women´s bodies

A. Miyashita Ochoa[1], B.D.M. Wilson[2], A. Hasenbush[2], I.W. Holloway[1]
[1]UCLA Luskin School of Public Affairs, Department of Social Welfare, Los Angeles, United States, [2]UCLA School of Law, Williams Institute, Los Angeles, United States

Background: HIV criminalization laws target individuals living at the intersection of multiple oppressions. In California, women and people of color are disproportionately impacted by such criminalization. Additionally, almost all (95%) of those criminalized came under the felony targeting those engaged in sex work, or suspected of doing so, while living with HIV (Cal. Penal Code §647f). We sought to better understand whether trends in HIV criminalization were related to trends in the policing of sex work.
Methods: Data from 2005-2013 from the U.S. American Community Survey, California Department of Public Health, and California Department of Justice, including de-identified Criminal Offender Record Information (CORI), was analyzed. We compared CORI data for all individuals that were arrested under Penal Code §647f to general demographic data and frequencies of arrest for prostitution over the same time period. Inferential statistics were used to test differences between racial/ethnic subgroups.
Results: From 2005-2013, women made up 12 percent of the people in California living with HIV but accounted for 37 percent of those arrested for Penal Code §647f; Black women made up 4 percent of all HIV-positive women in California but accounted for an average 22 percent of the arrests for Penal Code §647f. Of all HIV-positive people living in California, Black women were the most overrepresented subgroup arrested under Penal Code §647f. Despite a decrease of overall number of arrests for sex work statewide, Black women made up an increasing proportion of those arrested in California. Across 2005 and 2013, Black women were arrested for prostitution at a rate of 11 to 14 times their rate in the general population.
Conclusions: Efforts of advocates led to the repeal of the felony solicitation law in California as of January 1, 2018. However, 30 U.S. states and over 70 countries still have criminal laws that target people living with HIV. Further attention must be paid to the impact of criminalizing HIV and sex work and the resulting policing of vulnerable communities. Understanding criminalization, and its role in underscoring societal bias and discrimination, is integral to understanding what may contribute to the rising rates of HIV especially among Black women.

TUPED464

Reacting to reality, using Rights-Evidence-Action (REAct) to support HIV response and take action on human right violations against KPs

R. Lusimbo[1], D. Wamala[2], P. Njanje[3], R. Paulo[4], C.D. Defferary[5]
[1]Sexual Minorities Uganda - SMUG, Research, Kampala, Uganda, [2]Icebrekers Uganda, Programs, Kampaa, Uganda, [3]ISHTAR, Kenya, Nairobi, Kenya, [4]Lambda, Maputo, Mozambique, [5]International HIV AIDS Alliance, Brighton, United Kingdom

Background: Human rights violations remain a harsh and persistent reality for KPs, including within the context of programmes for HIV and SRH. LGBTI communities face harassment, discrimination and violence, denying their fundamental rights and restricting their access to vital health services. Yet KP led organisations often lack a systematic and evidenced based way to document abuses, identify responses and advocate for change.

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

Description: LGBTI organisations in Uganda, Kenya, Mozambique and Zimbabwe are using a Rights-Evidence-Action (REAct), a secure IT based human rights monitoring and response system owned by grassroots organisations. Focusing on the Ugandan experience, **Sexual Minorities Uganda and Icebreakers Uganda,** have since 2014 adopted safety and security measures in KP service delivery programming and used **REAcT to successfully** support and respond to community members affected right at the onset of the Anti-homosexuality act being passed. They documented evidenced-based human rights-related barriers, including gender violence, to accessing HIV and health services. SMUG has used the evidence generated to review and strengthen its human rights-based programming, such as with the introduction of *Know Your Rights* campaigns for LGBTI people. The data and case studies have also been critical for advocacy work. The ground-breaking publication *And That's How I Survived Being Killed,* was based on 264 violations conducted against the backdrop of the 2014 Anti-Homosexuality Act and on-going political and social oppression against community members.

Lessons learned:

· REACT has improved skills and human rights knowledge among KPs increasing their ownership to document and analyse to shape and demand action.

· REACT has generated an unprecedented body of evidence of the reality of human rights violations against LGBTI communities and its link to accessing HIV services, prevention, treatment and care.

· The importance of advocacy focused peer-to-peer support to LGBTI organizations in multiple African countries, offering a wealth of learning and practical experience.

· The importance of including safety and security on KP programming.

Conclusions/Next steps: REACT is a powerful and safe mechanism to empower KP led organisations, to inform human rights-based and HIV **programmes on treatment, care and support** as recommended by the UNAIDS. The REAct database provides a unique and powerful body of **evidence for advocacy.**

TUPED465

Provision of legal aid to key populations and people living with HIV in Eastern Europe and Central Asia - the case of the Regional HIV Legal Network

J. Macauley[1], R. Kumwenda[1], A. Mukanova[2]
[1]*United National Development Programme, HIV, Health and Development, Istanbul, Turkey,* [2]*Regional HIV Legal Aid Network, Kharkiv, Ukraine*

Background: Guided by work of the Global Commission on HIV and the Law, UNDP as UNAIDS co-sponsor works on protecting and promoting the rights of key populations at higher risk of HIV (KP). EECA is the only region that did not achieve MDG 6, and continues to experience a growing epidemic[1]. Only 28% are on treatment, and in many cases punitive laws and policies continue to fuel stigma towards KPs, driving them away from health seeking behaviors. The SDG-framework guiding principle to *"leave no one behind"* creates opportunities to re-invigorate the AIDS response.

[1] UNAIDS 2017 Factsheet Update - http://www.unaids.org/sites/default/files/media_asset/UNAIDS_FactSheet_en.pdf

Description: In 2012, UNDP supported establishment of the Regional HIV Legal Aid Network and its work to remedy the lack of legal services for PLHIV and KPs. It unites organisations, lawyers and activists to provide legal aid.

Lessons learned: The network serves as the umbrella organization for 36 members in 10 EECA countries. In 2017, through its online platform received 78 requests from KPs requesting legal support compared to 64 in 2016. Its website was visited 23,150 times compared to 22,979 visits in 2016. 71 strategic litigation cases were successfully supported by members in 2017.

The Network offers a range of legal services - from brief consultations to full legal representation. Many clients often require minor legal assistance and information about their rights. Many organisations provide training for legal professionals and healthcare workers on the effects of stigma, discrimination and rights violations towards PLHIV and KPs, and their consequences for public health. Members have different structural models and approaches. Some employ full-time legal professionals, others contract private firms/lawyers to provide services as needed. It is important to ensure that potential clients are made aware of these services to increase up-take.

Conclusions/Next steps: The Network is a novel platform, which contributed to the development of strategic litigation cases leading to precedents and further protection of the rights of PLHIV and KPs.

Scaling-up geographic coverage and thematic scope is important. Cross-regional discussions with legal-aid organizations in Africa and Arab States initiated in 2017, will open channels for inter-continental initiatives, activities and lessons learnt to leave no one behind.

TUPED466

Human rights barriers to access TB and TB/HIV perceptions by mine workers in 10 Southern Africa Countries (Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Swaziland, Tanzania, Zimbabwe and Zambia)

L. Busang[1], B. Fidzani[1], B. Mbambo[2], M. Ndhlalambi[3], J. Mafeni[4], F. Mwangemi[5]
[1]*ACHAP, DREAM, Gaborone, Botswana,* [2]*Aquity Innovations, Pretoria, South Africa,* [3]*World Bank, Pretoria, South Africa,* [4]*ACHAP, Administration, Gaborone, Botswana,* [5]*ACHAP, Programmes, Gaborone, Botswana*

Background: It is reported that "the mining industry is among southern Africa's largest employers. In such an environment, it is expected that Human Rights and Gender issues will be amongst the key challenges faced by this industry particularly concerning access to health. The objective of this Survey was to identify the human rights and gender barriers to accessing to TB, TB/HIV and occupational lung diseases by mine workers their families in ten (10) Countries of Southern Africa Region (Botswana, Namibia, South Africa, Swaziland, Lesotho, Zimbabwe, Zambia, Tanzania, Malawi and Mozambique).

Methods: This study was a regional cross-sectional survey of miners. Probability proportional to size criteria was used to distribute miners by country, mineral and mine size. The target sample size for current miners was 1,068. Data Management was done in CSPro while data analysis was done using SPSS. Clearance approval was applied for and received in each respective country Ethical Review Boards/committees except in Mozambique which was then dropped.

Results: Only 12.0% of miners were female. Lesotho had the highest proportion of females in mining at 22.6%, while Tanzania had the lowest (3.4%). Unavailability of comprehensive package of services (44%), was the main barrier followed by service providers' attitudes (38%), long waiting times (38%) and overcrowding (32%). In addition, where services were available, access became a barrier due to distances, costs, service acceptability and relevance. When respondents were asked if TB treatment is accessible, only 25.8% said yes.

Conclusions: Quality of services in general is a barrier to accessing TB, TB/HIV and occupational lung diseases services in the mines. This therefore requires that existing health care services to miners should be periodically assessed for availability, accessibility, acceptability and their quality. Governments should consider provisions for health insurance systems that would help decongest public facilities, but also affordable. Funders, Mine Unions and Civil Society Organizations in the region should recognize and prioritize TB in the Mining Sector as a critical gap that needs and deserves prioritization given that TB ultimately affects the general population.

TUPED467

Long overdue: HIV-related discrimination in immigration and the need to repeal the "excessive demand" regime

S.K.H. Chu[1], M. Tomlinson[1], M. Johnston[2], A. Smith[3], R. Elliott[1]
[1]Canadian HIV/AIDS Legal Network, Toronto, Canada, [2]HIV & AIDS Legal Clinic Ontario, Toronto, Canada, [3]Jordan Battista, Toronto, Canada

Background: Since before Confederation, Canada has excluded immigrants with disabilities, beginning with a prohibition on admitting persons with disabilities who were believed to impose financial burdens on the state or charities. Similarly, today's *Immigration and Refugee Protection Act* stipulates that foreign nationals are inadmissible to Canada if their health condition, or that of a family member, might reasonably be expected to cause an "excessive demand" on health or social services. Due to the high cost of HIV medications, people living with HIV are generally medically inadmissible.

Description: Human rights advocates, immigration and HIV organizations, and people with disabilities have long argued that the "excessive demand" regime is discriminatory, rooted in the outdated idea that people with disabilities are a burden on Canada, and unjustifiably violates the human rights of newcomers with disabilities. This prompted Canada's Parliamentary Committee on Citizenship and Immigration to study the law, during which advocates for people living with HIV described the regime as a complex and dehumanizing process that reduces people living with HIV to the cost of their medications. Advocates also questioned the government's cost-savings estimates and described how HIV-related discrimination in immigration violates Canada's obligations under international human rights law.

Lessons learned: During the study, the Immigration Minister acknowledged that the excessive demand regime "simply does not align with our country's values on the inclusion of persons with disabilities in Canadian society." Committee members also learned that numerous countries do not have any laws or policies that deny migration based on health status, the excessive demand regime undermines many of the objectives of Canada's immigration legislation, and the regime is rife with operational flaws.

Conclusions/Next steps: In December 2017, the Committee released its study recommendations, in which it emphasized "the dignity and human rights of those applying to enter Canada play a central role in the selection of a policy path forward" and recommended an historic repeal of the excessive demand regime. While the recommendation is a tremendous first step, a repeal of the discriminatory provision is long overdue and advocates must continue their work to ensure parliamentarians heed this recommendation.

TUPED468

When health systems collapse: Strengthening the advocacy and accountability role of people with HIV in Venezuela

A. Nieves[1], M. Torres[2]
[1]Acción Ciudadana Contra el SIDA (ACCSI), Caracas, Venezuela, [2]ICASO, Toronto, Canada

Background: In the last five years, Venezuela has lost 1/3 of its GDP and inflation rates have reached 1,600%. Economic collapse has made accessing medicines impossible for most. As a result, the number of AIDS-related deaths has risen nearly 75% since 2011. In this context, with support from ICASO and UNAIDS, a project was launched to strengthening the leadership of the Venezuelan Network of Positive People (RVG+), increase the evidence-base of Venezuela's health crisis, and improve advocacy for health service delivery.

Description: The 1-year project had three phases:
(1) Training;
(2) Monitoring;
(3) Advocacy.
In the Training Phase, multi-stakeholder consultations assessed the state of the crisis (including human rights violations). During the Monitoring Phase, tools were designed and implemented in 39 health centers across 12 states, gathering information on health infrastructure, human resource gaps, and ARV stock-outs. The results were analyzed and published. During the Advocacy Phase, RVG+ discussed the reports with high-level health authorities and UN-agencies. A social media campaign was targeted at the Minister of Health. Technical and financial support was leveraged from a network of international NGOs.

Lessons learned: The project enabled activists living with HIV to be leaders in the process of building peer knowledge, identifying problems affecting HIV services, and developing evidence-based reports and advocacy strategies. Activists revealed a 100% stock-out rate of ARVs, OI medicines, HIV test-kits, and viral load monitoring reagents. Health infrastructure is in critical condition, staffed with insufficient personnel. But, the project is also a success story. Linked to the project's data-driven advocacy, short-term supply of ARVs for 15,000 people was secured through the international community. The resilience of communities working in challenging operating environments was also highlighted. They faced and overcame fears of constant attacks, reprisals and threats from the government, ultimately achieving progress for their community.

Conclusions/Next steps: This project revealed that the Venezuelan government continues to violate human rights of people living with HIV, rooted in its persistent denial of the collapse of the public health system and refusal to receive aid. In this context, it is imperative that international agencies and organizations continue to invest in community-led solutions.

TUPED469

After the repeal: Prosecution of HIV exposure after the removal of specific offences in Colorado, USA and Victoria, Australia

J. Manwaring[1], P. Kidd[2,3]
[1]Department of Health and Human Services, Melbourne, Australia, [2]HIV Legal Working Group, Melbourne, Australia, [3]La Trobe University, La Trobe Law School, Melbourne, Australia

Background: The use of HIV-specific criminal offences to prosecute people living with HIV (PLHIV) has been extensively criticised, and achieving repeal of such laws has been a target of sustained advocacy in many countries. Following extensive grassroots advocacy campaigns, HIV-specific criminal laws were repealed by the legislatures of the Australian state of Victoria (2015) and the US state of Colorado (2016). PLHIV still face possible prosecution in both jurisdictions under other, unrepealed, laws however, which raises the question of the degree to which these repeals have alleviated the burden of HIV criminalisation.

Methods: The repeal of HIV-specific criminal laws is argued to be a significant step in reducing HIV stigma as well as having practical benefits for people who might otherwise face criminal prosecution. We compared the frequency of charge/prosecution and the range of sentences in the pre- and post-repeal environments in the two jurisdictions.

Results: A review of pre-repeal prosecutions shows the laws were in fact infrequently charged or prosecuted. When compared to prosecutions that have occurred since reform, under substitute offences, there appears to be no significant change in the frequency of charge or prosecution. Our analysis suggests police and prosecutors may instead be increasing prosecutions of HIV-related cases under general provisions that were previously unutilised. In Victoria, there has been a problematic increase in prosecutions under a provision that criminalises procurement of sexual penetration by fraud.

Conclusions: The repeal of HIV-specific offences, while a worthwhile goal, may have little practical utility beyond stigma reduction. It may have the perverse effect of increasing prosecution under substitute offences, as penalties are less than before. It may also see prosecutors utilising other provisions that are difficult to monitor in regard to HIV because they are not specific to the virus. Continued monitoring of arrests and prosecutions under the new provisions should continue, to provide an accurate understanding of the long-term impact of law reform.

TUPED470

Advocacy for preventing violence against PLHIV and PWUDs among law enforcement, civil society, religious leaders and family members

W. Muhammadi
OHRA, Hardm Reduction & HIV Prevention, Chelsetoon, Afghanistan

Background: Afghanistan is among one of the countries that produces more than 90% of the world's opium, that shows it is also among the countries that are more likely at the high risk of HIV and BBDs. Drug use and crime both have a direct relationship which cannot be avoided, although it is a crime to manufacture, distribute and possess drugs in Afghanistan, but due to high demand of drugs by PWUDs and the high rate of drug production, it is almost impossible to prevent the drug use, directly resulting on user's negative behavior by generating illegal activities that causes people and members of communities performing violence against them.
Methods: A research conducted by OHRA's advocacy team in 2017, concluded the violent cases performed on PWUDs by people in Kabul hotspots, mostly in (Pol Sokhta, District #6). A number of 100 questionnaire distributed and interviews were conducted with PWUDs by outreach team. The aim of the following interviews was to collect the data of violence acted on PWUDs in one month.
Results: The collected data from 100 questionnaires showed 40% of different types of violence against PWUDs acted by community members, religious leaders, Law enforcement and family members. OHRA conducted regular awareness raising campaigns throughout 2 months for 400 individuals from community members, law enforcement, family members, religious leaders etc.
After the campaigns, OHRA team distributed another Questionnaires and collected data from 100 more PWUDs on the same target area which shows a result of 28% violence against PWUDs, resulting a 12% decrease in violence cases comparing to the data collected before the campaigns.
Conclusions: The surveys finding shows that by conducting awareness raisings and advocacy campaigns for the rights of people who use drug, could be an effective tool for preventing violence against PWUDs and PLHIV.

TUPED471

"Global advocacy to end Duterte's war on people who use drugs in the Philippines" - the first won battle

B. Gurung, A. Chabungbam, R. Kafle
Asian Network of People who Use Drugs, Bangkok, Thailand

Background: In June 2016, the world witnessed the beginning of the Philippines war on people who use drugs under President Duterte's regime. In a year, over 13,000 people - many of them children - ostensibly suspected of using or selling drugs were brutally killed. It destroyed millions of lives of people who use drugs, including thousands who are imprisoned and the families and children of those who were killed.
Amid such crisis, numerous games were made available through Apple App Store that promoted the war on people who use drugs in the Philippines. Some of the games had over a million download. The Asian Network of People who Use Drugs (ANPUD) led a global petition demanding Apple Incorporation's CEO to urgently perform a formal review and remove all the apps.
Description: A call for sign-on page was developed on the ANPUD website and extensive use of social media and other online platforms was made. The petition aimed for a global coverage. ANPUD coordinated with the global, regional and national networks/organizations in the whole process. On October 10, 2017, the letter was submitted to the Apple CEO and made public in a media release.
Lessons learned: The petition was endorsed by 131 organizations, including community, human rights and drug policy reform organizations from across 35 countries globally. The media release was featured by CNN Philippines, BBC, Philstar, Reuters, Inquirer, ABS CBN News and many others, with global coverage.
Apple removed most of the games from their app store. A case study of the advocacy effort was developed and disseminated to inform and inspire more community-led advocacy at different level. The case study recaptured attention of wide range of online media.
Conclusions/Next steps: The petition was one of many advocacy efforts against Dutere's war. It brought the Philippines human rights crisis back into the attention of the global community. The achievement was more than the removal of apps in that this collaborative approach made by ANPUD brought the activists, organizations and media from around the world together. The Philippines drug war continues and only global unity can put an end to it.

TUPED472

Organizing PLHIVs on ART for collective advocacy: Assessing its impact on the human rights, participants and the environment in urban India

R. Singh[1], P. Varma[1], P. Prabhughate[1], R. Verma[1], S. Schensul[2]
[1]*International Center for Research on Women (ICRW), Navi Mumbai, India,* [2]*University of Connecticut, Community Medicine, Hartford, United States*

Background: Interventions to change knowledge, attitudes and behavior that negatively affect the health and mental health status of persons living with HIV (PLHIV) have largely focused on providing individual education, counseling, group mobilizations and clinical care. This paper describes the testing of a less utilized approach; the organization of PLHIV to collectively address structural barriers and issues of human rights.
Methods: The research and intervention described in this paper is drawn from a US National Institutes of Health-funded study (2014-2019) focused on male PLHIV treated at five ART Centers in greater Mumbai who have habit of consuming alcohol. Three centers were randomly selected for experimental interventions that consist of individual counseling, group interaction and collective advocacy with two centers as controls; a total sample of 940 (188 from each center) was recruited. The collective advocacy intervention consisted of six, two-hour sessions conducted on monthly basis with a group of 10-15 PLHIV on ART and CST centers. The curriculum covered the benefits of collective action, promotion of human rights, selection of a structural issue of stigma and implementation approaches to collective advocacy.
Results: An extensive survey instrument was administered at baseline and follow-up in year gap to assess the impact of collective actions on the participating PLHIV. In comparison with the PLHIV in the two control centers, those who participated in collective action showed improve reported alcohol drinking frequency, less reasons for drinking ($p < .001$), less experiences with external stigma ($p = .01$) reduced self-stigma ($p < .001$) improved CD4 count, reduced viral load and risky behavior. Qualitative process data showed better response from public service sector on PLHIV rights, expanded social networks, improved relationship with spouse and family and a greater sense of collective capacity to affect change.
Conclusions: The results indicate that collective advocacy not only play a complimentary role in human rights, but also promote environmental change and individual empowerment.

TUPED473

Study of the key open national data aimed at improving the quality of programs for PLHIV / PWUD, CSW and MSM implemented jointly by NGOs and government authorities

S. Uchayev[1], E. Korotkova[2], D. Mahmudova[3]
[1]*PLWH|/PWUD, NGO Ishonch va Hayot, Tashkent, Uzbekistan,* [2]*WLH, NGO Ishonch va Hayet, Tashkent, Uzbekistan,* [3]*Sociologist, Tashkent, Uzbekistan*

Background: As of 01 January 2016, 32 967 people living with HIV (PLHIV) and 13 186 under ART were registered in Uzbekistan. Less than half of PLHIV reached viral suppression, half of PLHIV are not covered by treatment.
To reach the 90-90-90 objectives a transition plan has been approved to implement ART for all patients regardless of the immunosuppression

level by 2018. For the plan to be effectively implemented a quality analysis of regulatory framework and the needs of key groups is required.
Methods: Overview of secondary data - laws, national plans, protocols, resolutions, etc. in HIV/AIDS context. Five in-depth interviews (20 persons) and 2 focus groups (10 persons each) with representatives from communities of PLHIV and key groups (KG) from government institutions, specialists and key informants.
Results: Present day legislation on HIV/AIDS prevention generally complies with international standards. The state declares involvement, transparency and responsibility of political resolutions on HIV problem through coordinated efforts of all society spheres. However international standards change rapidly and new Uzbekistan laws fail to keep up. Low tolerance towards PLHIV is still observed in the society in general as well as within professional communities. This is due to generally low level of population awareness about HIV. Such key needs of KG as syringe/needle exchange points, distribution of alcohol wipes and contraceptives, information materials, express testing, counselling, referrals are not satisfied.
Conclusions: Owing to the survey of PLHIV/KG community we were able to identify dimensions for development of Strategic Action Plan.
1. Change of regulatory framework through direct participation in the dialogue with decision makers.
2. Acknowledgement of existence of special needs of PLHIV and key groups and alignment of standards for services to PLHIV and KG with WHO recommendations.
3. Ensure tolerant treatment of PLHIV and KG through implementation of de-stigmatization programmes with the general public and professional community.
Programmes for prevention, harm reduction, care and support need to be reinforced through the Makhalley network public fund financed by the state and involved in prevention activities and services at all levels with involvement of key groups.

TUPED474

Women, ART and the criminalization of HIV non-disclosure (WATCH): Mapping criminalization's creep into the health and social care of women living with HIV in Canada

J. Cotnam[1], S. Greene[1], A. Ion[1], L. Birungi[1], K. Dunn[1], M. Frank[2], S. Glum[3], R. Gormley[2], M. Muchenje-Marisa[4], V. Nicholson[2], J. Odhiambo[1], K. Shore[1], A. Symington[5], A. Kaida[2]
[1]McMaster University, Hamilton, Canada, [2]Simon Fraser University, Vancouver, Canada, [3]Saskatoon Health Region, Positive Living Program, Saskatoon, Canada, [4]Women's Health in Women's Hands Community Health Centre, Toronto, Canada, [5]Pro Bono Students Canada, Toronto, Canada

Background: People living with HIV in Canada are legally obligated to disclose their HIV status to sexual partners in specific circumstances under the *Criminal Code*. In Canada, the criminalization of HIV non-disclosure falls under sexual assault law and consequently stigmatizes people living with HIV while disregarding the realities of women's lives. The WATCH study explored how the socio-legal context in which women can be criminalized for not disclosing their HIV status to sexual partners impacts their sexual and familial relationships, and their interactions with legal, health, and social services.
Methods: WATCH is a participatory arts-based research study. Seven Body Mapping workshops with 48 women and trans women across 4 Canadian provinces were co-facilitated by peer researchers (women living with HIV). Utilizing a variety of art materials, women visually expressed experiences of the impact of the criminalization of HIV non-disclosure on their everyday lives. Sharing circles were co-facilitated for the purpose of sharing and recording each women's unique criminalization of HIV narrative. Narratives underwent a process of participatory thematic analysis.
Results: Women expressed concerns about the criminalization of HIV non-disclosure in the context of historical and current experiences of HIV stigma and other marginalized social positionings. Women identified concerns about how the law characterizes them as sexually deviant and does not account for their commitments to cultural, personal and social responsibilities. Connections were made between the stigma inherent in the criminalization of HIV non-disclosure and other experiences of HIV stigma including access to health and social services. Concerns about having a sexual relationship raised fears about how the law could be applied in circumstances outside of the current legal precedent.
Conclusions: WATCH illuminates how legal obligations to disclose one's HIV status uniquely impacts the lives of women living with HIV in Canada. Importantly, the law positions women living with HIV as irresponsible, which perpetuates stigma and increases surveillance in all aspects of their lives. Canadian women living with HIV and their advocates require global support for legal reform.

TUPED475

Thorny track to teens' wellbeing: findings from an HIV and SRHR baseline study conducted among adolescents most affected by HIV in Uganda

D. Bitira William[1], G. Caswell[2], C. Kihara[3], E. Dyke[4], M. Cassolato[5],
Adolescents Selling Sex, Living with HIV, Using Drugs
[1]Community Health Alliance Uganda, Monitoring, Evaluation and Learning Manager, Kampala, Uganda, [2]International HIV/AIDS Alliance, Programs, Cape Town, South Africa, [3]International HIV/AIDS Alliance, Programs, Brighton, United Kingdom, [4]Advisem, Consultant, Edmonton, Canada, [5]International HIV/AIDS Alliance, Programs, Brighton, United States

Background: Adolescents most affected by HIV face many barriers accessing healthcare. 44-54% adolescents 15-19 years old ever tested for HIV. New HIV infections, lifelong ill-health, AIDS-related deaths higher among teenagers.
READY Teens project empowers adolescents most affected by HIV to make healthier life choices and demand their sexual and reproductive health rights. The abstract presents findings from baseline study that informed and shaped READY HIV and SRHR programming in Uganda.
Methods: CHAU, Advisem, International HIV/AIDS Alliance conducted quantitative and qualitative baseline study in two rural Ugandan districts between January-May 2017. Purposively selected four health centers, six hotspots as study sites.
Survey obtained quantitative data from 190 adolescents (10-19 years) living with HIV, selling sex, using drugs; employed cluster and systematic sampling; structured questionnaire.
Conducted 15 key informant interviews, 8 focus group discussions with adolescents, parents, health workers, community leaders. Stata and Nvivo used for data analysis.
Results: 78.9% respondents attained upto primary school education. 54.7% adolescents have comprehensive knowledge about HIV prevention; lower proportion (43.4%) among 10-14 than (59.1%) 15-19 year. 59.8% adolescents satisfied with HIV/SRHR information they received; less (54.2%) among girls than (66.7%) boys; 10-14 (47.2%) than (78.1%) 15-19 year. 71.6% adolescents are confident and hardly influenced on HIV/SRHR issues; lower (70.7%) proportion of girls than (72.5%) boys, half (41.5%) among 10-14 as (83.2%) 15-19 year.
Community leaders' perceptions of teenagers, parents' beliefs about adolescent sex education; health workers' attitudes towards teens' right to HIV treatment information are negative. Health workers' lack of confidentiality and privacy were barriers to adolescents accessing health services.
Conclusions:
· Half of adolescents have comprehensive knowledge about HIV prevention. HIV and sexuality education needs to be tailored to especially most affected adolescents with little education.
· Negative beliefs and perceptions impede adolescent HIV/SRHR programs. Dialogues to promote positive HIV/SRH influence in families, communities and facility level are required.
· Adolescent-friendly services are key for teenagers' security and satisfaction. Need for sustainable adolescent-friendly integrated HIV/SRHR services at family, youth support group, health facility, school levels.
· Adolescents should be more empowered to increase their confidence and resilience on HIV/SRHR issues, adopt healthier choices, practices, behaviours and to demand for their rights.

TUPED476

Preserving human rights through involvement of the community, judicial system and law makers

A. Karisa, T. Abdulrahman
Reachout Centre Trust, Harm Reduction, Mombasa, Kenya

Background: Most People Who Use Drugs (PWUDs) in Kenya have been discriminated and stigmatized hence have been living in an isolated areas e.g. Streets, drug dens and parks and involve in criminality and sex work as their primary means for survival. Hence have been the targets of neglect, arrests by county Inspectorate and national police service units, harassment and mob justice by the community.
Description: It's estimated that Mombasa has 3000 People Who Inject Drugs (PWID) who contributes 18.3% HIV prevalence for PWIDs in Kenya. 70% of all cases reported yearly at the county Law courts are related to drug use, 225 cases of violence, 41 cases of mob justices& 8 cases of death as a result of mob justice were reported at Reachout since 2016 to November 2017. From January 2016 to November 2017, Reach out Centre Trust (RCT) engaged the judicial system through a Justice Actors conference where 70 Judges, magistrates, lawyers, law enforcers, probation and civil society organizations were brought together under the theme clemency for social justice for PWUDs.140 Law enforces and 20 members of the county Assembly on Health were sensitized on Harm Reduction and social inclusion Health rights. RCT raised community awareness through 96 radio talk shows, 5public bazaras, and 40health workers, 15 religious leaders and 230 family members on Human rights for PWUDs. RCT organized Media Awards, where 23 media fraternity participated in Positive reporting on Harm Reduction and Drug Policy reform.
Lessons learned: Through the training and sensitization of law enforcers and the judicial system, 600 cases of petty crimes related PWUDs were given alternative sentence through the community service order.100(both MAT clients &PWUDs) cases were intervened by RCT Paralegals and released at the police cells. RCT has a representation at the Court Users Committee and Discharge Board Committee in prison .All sentenced MAT clients access MAT services and treatment without hindrance Media fraternity partnered with RCT in advocating for Harm Reduction and drug policy reforms in Mombasa.
PWUDs accesses heath care with minimal assistance.
Conclusions/Next steps: There need to change the narcotic drugs and psychotropic substances act 1994 and the existing by- laws of the Mombasa county.

TUPED477

Assessment of the protection needs of key refugee populations in access to health and other services

K. Ordek[1,2,3], Y. Selcuk[4], C. Harmanci[5], S. Ilaslaner[1], G. Yildirimkaya[6], F. Hacioglu Saridag[6]
[1]Red Umbrella Sexual Health and Human Rights Association, Ankara, Turkey, [2]SWAN Foundation for the Rights of Sex Workers in Central-Eastern Europe and Central Asia, Budapest, Hungary, [3]International Committee on the Rights of Sex Workers in Europe, Amsterdam, Netherlands, [4]Social Policies, Gender Identity and Sexual Orientation Studies Association, Istanbul, Turkey, [5]Positive Living Association, Istanbul, Turkey, [6]UNFPA, Ankara, Turkey

Background: Key refugee populations (KRPs); namely LGBTI people, sex workers and PLHIV in Turkey, experience high levels of stigmatisation, discrimination and violence which hinders their access to all forms of services;such as, health, protection, housing, justice/redressal, etc. Protection needs of KRPs are invisibilised and not served by public or other institutions.This situation increases the risk of HIV and other STIs against KRPs. Health as well as human rights situation of KRPs are negatively impacted on.
Description: UNFPA Turkey, in collaboration with Red Umbrella, SPoD and Positive Living Association, carried out a joint project between January - December 2017, to assess the needs of KRPs and to provide services to them. Outreach work in Istanbul and Mersin was carried out towards LGBTI, sex worker refugees and refugees who live with HIV in order to share information on the services they need, to refer them to services and to further gather data on their needs especially in relation to SRHR. Within the scope of this project, partners have reached out to 1000 KRPs members, through outreach work, legal counseling and psychosocial support.
Lessons learned: - KRPs are systemtically excluded from all forms of services, including SHR services.
- KRPs do not have Access to information on specific health services; such as HIV/AIDS and STIs testing, counseling and treatment.
- KRPs have higher burden of HIV in comparison to the host community. Therefore, programs must be designed in accordance with the specific sensitivities and needs of KRPs.
- Advocacy intervention programs must be designed and implemented through direct involvement and ownership of KRPs members in order to better the overall human rights and health situation.
Conclusions/Next steps: Partners have decided to empower KRPs through service provision, outreach and advocacy in order to strengthen their capacities to access to information and services in 2018. As next steps, the partners will establish 5 service units in Istanbul, Ankara, Eskisehir and Mersin where legal counseling, PSS support, HIV counseling, SGBV counseling, referrals will be provided to beneficiaries (11000 refugees in total in 2018). Advocacy workshops with local stakeholders (health service providers, public officials, local administrations, NGOs, etc.) will be organized.

TUPED478

Migratory status, gender and HIV/AIDS Continuum of Care Navigation Experiences among Hispanics immigrants in Puerto Rico

M. Rivera Diaz[1,2], A. Suarez[3]
[1]University of Puerto Rico, Social Sciences Research Center, San Juan, Puerto Rico, [2]University of Puerto Rico, Clinical & Translational Research, San Juan, Puerto Rico, [3]City Math de Puerto Rico, San Juan, Puerto Rico

Background: Longer delays in the diagnosis of HIV, treatment interruptions, and lack of health care access could influence AIDS disease progression and increase new HIV infections. There is lack of research to understand barriers that keep Hispanics immigrants from successfully navigating the HIV/AIDS continuum of care, specially in the US owned territory, Puerto Rico (PR). This is the first research on the Continuum of Care outcomes among the growing immigrant population living with HIV in this Caribbean island.
Methods: The aims are: To identify and characterize differences in the HIV/AIDS continuum of care experience between Dominicans of varying migratory status and genders. Specially differences on:
a. HIV/AIDS diagnosis and link to care;
b. retention/engagement in HIV/AIDS care;
c. access to prescribed HIV/AIDS antiretroviral therapy &
d. achieved viral suppression.
An exploratory and descriptive national cohort study on data from immigrants receiving HIV/AIDS services through Department of Health, Ryan White Program (RWP) in HIV/AIDS Clinics of PR during the period of January 2010 to December 2016 was conducted. Data was obtained from the PR HIV/AIDS Surveillance System, and matched with RWP, Part B database of patients in care and validated with the case management component to analyze the navigation's outcomes at each step of the continuum of care and late diagnosis. Associations with gender and migratory status were applied.
Results: Among 77 Dominican immigrants diagnosed with HIV/AIDS during the period of 2010 to 2016, 62% were linked to care, 71% of those were retained in care, 97% of those were on ART, of whom 88% achieved suppression of VL (< 200 cp/ml). For non-authorized immigrants diagnosed, only 53% were linked to treatment and 27% achieved viral suppression. Statistical significances differences suggest that non-authorized Dominican immigrants show lower success linking to care (p=0.03), retaining in care (p=0.01), in ART (p=0.00) and achieving viral suppression (p=0.01).
Conclusions: No statistical significance difference was observed between gender and the different phases at the continuum of care. Despite USA federal government efforts to link Hispanic immigrants to their HIV/

AIDS continuum of care, immigrants still show lower success navigating the HIV continuum of care in PR, especially for non-authorized Dominican immigrants.

TUPED479

Showing the problem in Perú: We create an app to complaint the lack of antitetroviral drugs

M. Castillo Castro[1,2], J.L. Ppati Izaguirre[1]
[1]Sí, da Vida, Lima, Peru, [2]GIVAR, Lima, Peru

Background: Since 2004, peruvian goverment offers HIV´s treatment for free in several national hospitals. Today, this service benefits around 47,000 people living with HIV. However, during last years, the lack of medicines for this illness became a great problem, due the patient´s fear to complaint about that. So, in 2010, we created the group of organization named GIVAR, as a response of this crisis, picking up information in order to probe the lack of antiretroviral medicines.
The result was a better relationship between the authorities and the society´s organizations. Also, the population´s mind about complainting was changed, due the patients now have a real knowledge about their rignts.
Description: Because of the increasing number of cell phones and the low cost of internet service in my country; last year, GIVAR developed the app called DENUNCIA GIVAR, as a support tool that improves the website for complaints. This app is free and can be downloaded to android cell phones. The users have 4 ways to complain, according to the nature of their case. On the other hand, DENUNCIA GIVAR allow them to probe the outrage by showing pics or videos, recorded by the acusser.
So far, it has been reported around 700 complaints by Givar. Twenty of them were possible thanks to the app.
Also, DENUNCIA GIVAR have a virtual pill box that provides the users a schedule for monitoring the antiretroviral dosis.
Lessons learned: The revelation of the shortage, based on arguments and statistical data, alows the society negotiate with goverment and improve the supply of medicines. Society´s Watchfulness and goverment attention, must be supported by technologic tools, mobilization of society and media campaigns in order to diffuse the patient´s rights.
Conclusions/Next steps: DENUNCIA GIVAR is the only enterprising action from the society to watch the complet and real supply of antiretroviral medicines in Perú. One of the achievements is the benefit of 61 babies, whose mothers are living with HIV. So, they could obtain infant formula milk, after a regulation of the goverment denies them that product. The achievement alows the mothers to save 400 dollars per month to feed their children.

TUPED480

Delivering legal interventions for key populations in Nigeria through HIV prevention and treatment programs

T. Jaiyebo[1], A. Yusuf[1], G. Emmanuel[1], O. Olabosinde[1], C. Nwofor[1], B. Ochonye[1], C. Trout[2], P. Umoh[1], A. Kalaiwo[3]
[1]Heartland Alliance International, Programs, Abuja, Nigeria, [2]Heartland Alliance International, Programs, Los Angeles, United States, [3]United States Agency for International Development, Abuja, Nigeria

Background: Men who have sex with men (MSM), female-sex-workers (FSW) and people who inject drugs (PWID) - key populations (KPs) are highly affected by HIV in Nigeria. They are subject to acts of violence due to discriminatory laws criminalizing their behavior, and further face barriers to accessing legal services for redress. Barriers such as the fear of reprisal and prosecution can play a role in heightening their vulnerability to HIV by driving them further underground and limiting their access to HIV care and support services. This paper appraises legal intervention services under the Integrated MARPs HIV prevention project (IMHIPP) implemented by Heartland Alliance in Nigeria.
Methods: IMHIPP provides legal intervention services to KPs who have suffered violations as part of its comprehensive HIV package in Akwa Ibom, Benue, Cross River, Lagos, Nasarawa and Rivers states and the FCT. Quantitative data was collected using the standardized violation reporting tools across the program states. This paper accessed the types of violations suffered that necessitated legal intervention, provided between July and December 2017.
Results: 29% (419) - (FSW: 249, MSM: 102, PWID: 68) of KPs who reported violence (1435 KPs - FSW: 959, MSM: 335, PWID: 141) needed and were provided legal intervention services between July and December 2017. A majority-75% of violations were related to police raids, arbitrary arrest and detention, and this trend cuts across all KP groups, but highest numbers from female-sex-workers who suffer from frequent brothel raids and arrests.

[Graph 1: Breakdown of violations requiring legal intervention]

As shown in table 1 and consistent with the violations suffered, facilitated release from police custody made up the majority of legal interventions provided. Other interventions include legal and human rights education with safety and security counselling to avoid recurrent violations, and support to file police reports as many feared further reprisals by the law enforcement agencies.

Type of intervention	Total #	Total %
Facilitated release from custody	271	64.7%
Legal education/ safety and security counselling	39	9.3%
Litigation	32	7.6%
Support to file police report	32	7.6%
Other legal support	24	7.6% 5.7%
Alternate dispute resolution e.g. mediation	21	5%

[Table 1: Types of intervention provided]

Conclusions: Findings show an alarming average of 2 KPs in HIV programs per week needing some sort of legal intervention, most likely arising from the law enforcement agencies meant to provide redress. Engagement of law enforcement agencies in the HIV response is therefore essential to improving access of KPs to HIV services.

Gender equity

TUPED481

Results of the community efforts in mitigating violence and discrimination among TG/Hijra community in Lahore, Pakistan

Z. Kadirov, B.P. Dahal, K. Achebe, C. Tara, I. Mohammad, T. Ur Rehman, M. Ali
Save the Children International, Global Fund Program, Kathmandu, Nepal

Background: Lahore, a city in Pakistan is home to nearly *4455 Hijras**[1]***. This socially stigmatized community faces abuse from their families, clients, male sex partners and public. The abuse and violence are the main cause of emotional distress and mental agony among the *Hijras*. Despite gaining the legal identity from Pakistan Supreme Court in 2009, the legal environment supporting the co-existence of *Hijars* in the society is ill-defined due lack of domestication of law, internalization of rights law enforcement instrumentation and access to legal remedy. Theses non

supportive circumstances compel almost 80% of *Hijras* to earn from sex work making them vulnerable to HIV. Save the Children and Khawaja Sira Society through Multi Country South Asia Global Fund HIV program has implemented an HIV advocacy project to minimize the cases of perpetration and also providing the key HIV prevention services in Lahore.
[1] Official figures on size of Hijra population in Pakistan are yet to be counted as Hijras has been included into the national census in 2017 only, for the purposes of the abstract author used draft IBBS report (dated April 2017).
Methods: The project adapted a multi-faceted approach to mitigate the challenges of violence reduction using a comprehensive advocacy strategy that included mass media sensitization, community activist motivation and public awareness to protect and promote the rights of *Hijras*. Data from routine monitoring of the project advocacy activities was analyzed quantitatively.
Results: After the intervention made under MSA Grant/Global fund since 2012, substantial decrement in number of perpetration is notably observed. Latest reading shows that number of rape cases decreased from 1774 in 2013 to 160 cases in 2016. Empowering *Hijra* on their rights and voicing their need for health services induced conducive environment to secure the rights of Hijra community.
Conclusions: The participatory approach involving government, religious scholars and parliamentarians along with media mobilization contributed significantly in conquering violence against *Hijras* in Lahore. Neatly tailored community-based HIV programs with emphasis on capacity building and advocacy contribute to the quality of life of them, thereby facilitating their access to health and legal services and reducing their HIV vulnerabilities.

Sexual and reproductive health and rights

TUPED482

Improving the access to sexual and reproductive health and rights among women who use drugs in Ukraine. Where are we now?

S. Tkalya[1], A. Basenko[2,3], P. Skala[2], M. Andruschenko[2], M. Kasianchuk[4], G. Kornienko[1]
[1]Charitable Foundation 'Hope and Trust', Kyiv, Ukraine, [2]Alliance for Public Health, Policy and Partnership, Kyiv, Ukraine, [3]PITCH Program, Country Focal Point, Kyiv, Ukraine, [4]ECOM, Talin, Estonia

Background: Ukraine has the second-largest HIV epidemic in Eastern Europe and Central Asia. The epidemic is closely associated with injecting drug use. The estimated number of injecting drug users are 346,000 people, of whom 75% are men and 25% are women. In Ukraine, HIV prevalence among people who inject drugs was estimated at around 21.9% in 2016. HIV prevalence was higher among women who inject drugs (23.6%) than men who inject drugs (20.8%).
Methods: The assumption is that WUD are constantly faced with stigma and discrimination by medical personnel and have a number of problems in obtaining reproductive health services. Within the PITCH project the CBO of WUD carried out the intelligence study (in-depth interviews) on sexual and reproductive health rights of women who use drugs including OST patients in Ukraine. The main points of the questionnaire were the accessibility of medical services (in particular, gynecologists), medical registration and access to women consultation during pregnancy, cases of patients´ interaction with the police and social services, as well as cases of violence.
Results: 77 women from five regions of Ukraine aged 26 to 55 were interviewed, mostly have secondary education with a predominantly low average monthly income and a long (over 5 years) experience in the use of psychoactive substances. It was shown that 80% had problems with registering in the case of pregnancy and only a quarter received completely satisfactory medical services in case when doctor knew that the patient was taking drugs and had a positive status for hepatitis C or HIV. 63% were faced with a refusal to provide medical care. 33% used drugs during pregnancy. The majority of interviewed women indicate problems when applying for assistance to the National Police of Ukraine. One third has experience of domestic violence, physical, psychological or economic.
Conclusions: Due to stigma and discrimination, women are not registered in the women´s consultation, and as a result, only during the birth will learn about existing infections and accordingly do not undergo vertical transmission. Wider range of NGO services is necessary. There is a need of national campaign to protect sexual and reproductive health rights.

TUPED483

Awareness-raising on sexual and reproductive health and rights among school-going adolescents for services access in Tanganyika province, Democratic Republic of Congo

N. Eliya Nduelib
Sauve la Femme et la Jeune Fille du Katanga, SAFEKA, Senior Management, Kalemie, Congo, Democratic Republic of the

Background: Based on the 2016 report from the Tanganyika Provincial Educational Division, 25% of adolescent girls dropped out of schools between 2013 and 2016 due to reproductive health problems. 35% of cases were due to risky sexual behavior while 65% were caused by SGBV in school settings and communities. Prevailing social norms sustain the disregard of SRHR and condone SGBV among adolescent boys and girls. Our project aimed at empowering the latter with appropriate knowledge and skills on SGBV and SRHR in order to respectively enable them to manage such violence and make informed choices regarding their sexual life.
Description: Funded by AmplifyChange, the project (May 2016- April 2018) started with the creation of 50 secondary school-based SRHR/SGBV youth clubs, each consisting of 25 members (13 girls; 12 boys or vice versa) aged 12-16. Then, 250 were trained as trainers in SGBV management, SRHR promotion and Participatory Theatre. Under SAFEKA coaching, trainees taught back their 1000 peers before all of them engage in mass sensitization in both schools and communities from November 2016 to date. Last August, a provincial conference brought together 250 adolescents to amplify voice for advocacy around SGBV and SRHR.
Lessons learned: From routine data we found out that 625 young boys are currently supporting girls' SRHR and acting as role models; 792 persons (495 female; 297 male) believe that women and girls are equal to men and boys; estimated 66 282 sensitized community members are aware of comprehensive sexual education benefit for young girls and boys; reported cases of SGBV from school settings have gone up; and the number of adolescents accessing such services as HIV testing, ART, contraceptives and legal support has increased respectively in 30%, 5%, 15%, and 25%. A Provincial SRHR/SGBV Youth Network was created as well. Yet, shifting social norms that undermine SRHR and condone SGBV still remains a big challenge because adolescents' reference networks have been overlooked.
Conclusions/Next steps: The project has created a space for dialogue around SGBV and SRHR among Tanganyika adolescent girls and boys whose participation is increasingly high. Project extension is needed with additional focus on norms change and reference networks.

TUPED484

Health, rights and well-being: A practical tool for HIV and sexual and reproductive health programmes with young key populations in Eastern Europe and Central Asia

J. Butler[1], J. Baer[2], I. Zhukov[3], N. Zakareishvili[4], C. Egeshova[5], L. Luyckfasseel[6], D. Kalajdjieski[7], D. McCartney[8]
[1]UNFPA, Bangkok, Thailand, [2]Consultant, Boston, United States, [3]UNFPA, Guttenberg, United States, [4]UNFPA, Tbilisi, Georgia, [5]UNFPA, Bishkek, Kyrgyzstan, [6]IPPF, Brussels, Belgium, [7]UNFPA, Skopje, Macedonia, The Former Yugoslav Republic of, [8]IPPF, London, United Kingdom

Background: The Tool is based on the experience of young key populations in eight countries in the region who participated in focus group discussions organized by UNFPA and IPPF in 2015. Key publications underpinning this tool are the four technical briefs on young key populations and HIV (UNAIDS Interagency Working Group on Key Populations, 2015), and the four key populations implementation tools (the SWIT, MSMIT, TRANSIT and IDUIT) published by WHO, UNFPA, UNDP and UNODC in 2013-2017.
Description: This tool contains practical advice on implementing HIV and sexual and reproductive health and rights (SRHR) programmes with young key populations—sex workers, men who have sex with men, transgender people, people who inject drugs and people in detention (prison or other closed settings)—in Eastern Europe and Central Asia. Health, Rights and Well-Being is designed to support UNFPA, IPPF and their partners in the region in developing rights-based and evidence-based programmes for HIV prevention and sexual and reproductive health for young key populations. It is intended for use by public-health officials and managers of HIV and SRHR programmes; nongovernmental organizations, including community and civil-society organizations; and health workers. It may also be of interest to international funding agencies, health policy-makers and advocates.The tool describes the context of young key populations and HIV in Eastern Europe and Central Asia and outlines the importance of sexual and reproductive health and rights; discusses community empowerment, participation, rights and social inclusion, and the importance of comprehensive sexuality education; and explores the legal and policy environment for young key populations, including issues of parental consent, stigma, discrimination and violence. The comprehensive package of services for HIV and SRHR is described, and issues of effective service delivery are discussed. Examples from programmes in the region and further afield are given to show how challenges may be addressed.
Lessons learned: The tool became possible only due meaningful participation of young key populations throughout the development of this tool and in the development of country-level action plans: their experiences inform much of the text.
Conclusions/Next steps: The global tool will be developed in 2018 based on this regional one.

TUPED485

Using legal and policy mapping for advocacy, by women with HIV in Latin America (LAC)

M. Arends[1], A. Cano[2]
[1]Hivos Latin America, San Jose, Costa Rica, [2]ICW Latina, Managua, Nicaragua

Background: Since 2016 the International Community of Women Living with HIV in Latin America (ICW Latina) and Hivos have been implementing a Global Fund grant aimed at strengthening the participation and advocacy of women with HIV in regional and national decision making processes, in order to achieve political, legal and regulatory changes that improve their quality of life.
Description: ICW Latina commissioned a mapping of the legal and policy framework regarding HIV, gender violence, gender inequality and SRR&H for women with HIV in Latin America. The mapping analyzes 37 criteria, and has been the basis for the development of an online tool (http://mapeo.icwlatina.org/map) that shows a comprehensive legal and policy landscape, with a human rights perspective, in 18 countries: Bolivia, Colombia, Costa Rica, Ecuador, El Salvador, Guatemala, Honduras, Nicaragua, Panama, Peru, Dominican Republic, Argentina, Chile, Brazil, Cuba, Mexico, Uruguay and Venezuela.

[ICW General MAP LAC]

The mapping has served as input for the development and implementation of national advocacy plans in 11 countries. The mapping also served for the development of a regional political agenda that prioritizes actions to comply with human rights of women with HIV in LAC (http://icwlatina.org/wp-content/uploads/2018/02/Documento-Estrategico-ICW.pdf).
Lessons learned: A clear picture of the gaps in legislation and policies has been useful to focus the political and advocacy agenda of women with HIV in LAC, both regionally and nationally.
During the process alliance building with the feminist movement has been key to include the needs of women with HIV in regional documents on SRR&H and VAW and to further national policies.
However, the capacity of the women in the network to analyze, use and monitor the SRR&H and VAW rights framework effectively, is limited to few of them, which is a limitation to defend the demands of the network.
Conclusions/Next steps: The mapping is an important but not sufficient tool to ensure the defense and monitoring of women with HIV´s health and rights. Individual and collective training of HIV+women about their SSR&H rights and VAW, alongside with training about the national and international human rights framework, is needed to traduce the information into effective and sustained advocacy efforts and civic monitoring by women with HIV.

TUPED486

The importance of harmonizing laws and policies to fulfill adolescents sexual and reproductive health rights: Good practices, gaps and opportunities in 23 countries in Africa

R. Tallarico
UNFPA, East and Southern Africa Regional Office, Johannesburg, South Africa

Background: UNFPA with the University of Pretoria conducted an analysis of the legal and policy environment that affects adolescents' sexual and reproductive health rights (ASRHR) in 23 countries in Africa. The study focused on 10 main rights such as:
1. Age of consent to sexual activity;
2. Age of consent to marriage;
3. Criminalization of consensual sexual activity;
4. Age of consent to health services, including HIV and contraception;
5. Access to sexual and reproductive health services, including abortion;
6. Sexual and reproductive health rights of adolescents and youth;
7. Criminalization of HIV transmission;
8. Harmful cultural, religious or traditional practices;
9. Learner pregnancy and re-entry laws and policies and
10. Comprehensive sexuality education.
Methods: The assessment includes:
1. a review and analysis of the laws and policies in place in each one of the 23 countries that influence directly or indirectly ASRHR;
2. An in-depth analysis of the laws and policies and how they affect young people and adolescents' sexual and reproductive health rights and access to services in six countries (Malawi, South Africa, Swaziland, United Republic of Tanzania, Uganda and Zambia).

Publication Only Abstracts
Author Index

Results: The study indicated the existence of overall disjuncture between the relevant policies and laws in the majority of the 23 countries while identifying some good practices. It demonstrated that many countries' laws do not comply with international and regional commitments. A particular challenge in the region is the co-existence of customary law and civil law. The harmonisation of these legal systems on the issues under review is a difficult task, but essential for the fulfilment of ASRHR. The field study also demonstrated that adolescents, young people, medical practitioners, teachers and counsellors generally lacked knowledge about laws pertaining to ASRHR both from a right holder and a right bearer perspective. The rights bearers were unaware of their rights, and the service providers - while often working diligently - also did not work within the law.
Conclusions: Efforts need to be made to go beyond piece-meal actions but look at adolescents' sexual and reproductive health rights in a holistic manner in order to harmonize national legislations and policies accordingly while ensuring their implementation.

TUPED487

Linking HIV and gender based violence: A critical analysis of the dis-proportionate burden on Kenyan women and girls

T. Saoyo
Kenya Legal and Ethical Issues Network on HIV, Sexual and Reproductive Rights, Nairobi, Kenya

Background: In 2016, UNDP Kenya, in collaboration with KELIN conducted a baseline survey titled '*common forms of gender based violence against women living with HIV*'. The study revealed that whereas approximately 1.6 million people are living with HIV countrywide, a larger proportion of this population, 58%, constitutes women. Women living with HIV regularly face discrimination and are more likely to experience violence as a direct result of their HIV diagnosis. Living with HIV exposes women to new sites of violence, not only from partners, family members and the wider community, but also within institutional settings, particularly health care institutions. Further compounded is the area often given less attention, particularly women from key populations, such as female sex workers, and drug users, who are even more likely to experience violence.
Description: In 2016, premised on the above findings, UNDP, in collaboration with local partners including KELIN and the Network of people living with HIV, NEPHAK, embarked on a one year long campaign to sensitize duty bearers such as police, judiciary and court users committees on their role in safeguarding the rights of women living with HIV. The overall aim of the trainings was to create an understanding of the linkages between sexual violence & HIV, ensure revamped, professional, and accountable duty bearers with the primary mandate to institute and undertake prosecution of criminal matters and all other related incidents occasioned against women living with HIV in an aim to foster justice.
Lessons learned: This rights based approach model of trainings was crucial in not only advancing the rights of women but also ensured that stigma generally associated with HIV was addressed by combining informative lectures with case studies, experience sharing, statistics, practical exercises and group work that enriched the learning experience of duty bearers to be able to see the real life issues in practice.
Conclusions/Next steps: KELIN aims to continue working with the Employment and Labour Relations Court as well as the HIV Tribunal to address the common forms of violence meted on women living with HIV as well as develop IEC materials that heighten awareness on SGBV and HIV.

TUPED488

The HIV epidemic among young women: Overcoming human rights violations and gender inequality to achieve the SDGs

T. McGovern[1], J. Fine[2], C. Crisp[3], E. Battistini[3]
[1]Mailman School of Public Health, Columbia University, Heilbrunn Department of Population and Family Health, New York, United States, [2]Center for Reproductive Rights, New York, United States, [3]Mailman School of Public Health, Columbia University, New York, United States

Background: Global efforts to curb the HIV epidemic among young women and girls are persistently challenged by gender inequality and human rights violations. In 2015, women in Sub-Saharan Africa accounted for 56% of new infections among adults over the age of 15. Lack of sexual and reproductive health services, economic insecurity, and limited educational access contribute to the high prevalence of HIV. The SDG 5 - to achieve gender equality and empower all women and girls - promises to address these determinants of health.
Description: We analyzed the progress towards and current challenges in achieving the SDG 5 through a legal framework. We described the links between gender inequality, policies, and health outcomes, and reviewed the state of national, regional and global policies that support women and girls' rights. We discuss the human rights barriers that must be addressed to achieve the SDGs and aim to generate action and accountability around women and girls' human rights.
Lessons learned: There are widespread gaps in implementation of comprehensive sexuality education, access to safe and legal abortion, and the development of special protection measures for adolescents and youth regarding their sexual and reproductive health. States with plural or multiple-legal systems, which allow customary, religious and tradition or practice to rule, present a challenge in measuring the SDG 5.6. Ensuring that data collection and validation incorporates relevant laws and commentaries by human rights bodies and civil society organizations will be necessary to achieve the SDG's promise. An integrated human-rights approach to assess compliance with human rights obligation and measures key issues areas in sexual and reproductive health and rights and their implementation is necessary to overcome these challenges.
Conclusions/Next steps: Improving access to sexual and reproductive health services is necessary to achieve the SDGs. The provision of these services fundamentally relies on the fulfillment of human rights. A human-rights based approach is needed to adequately document and address the political barriers individuals face in plural and multi-legal systems, correctly measure our progress towards the SDG 5, ensure compliance with SDG commitments, and reduce the burden of HIV in women in Sub-Saharan Africa.

TUPED489

Leveraging social media as a tool to promote SRH/HIV information among visually impaired persons in Lagos State, Nigeria

E. Okotie[1], A. Familua[2], O. Akanni[3], D. Ayinla[3]
[1]Nigeria Association of the Blind, Lagos, Nigeria, [2]Nigerian Association of the Blind (NAB), Lagos, Nigeria, [3]Journalists Against AIDS (JAAIDS) Nigeria, Lagos, Nigeria

Background: Negative myths and misconceptions continue to impact on the sexual and reproductive health rights (SRHR) of Persons with Disabilities (PWDs). These state that PWDs are asexual, not sexually active and unable to contract HIV/ STIs; PWDs engage in sexual activity by chance, not by choice and women with disabilities who are pregnant must have been impregnated as a result of abuse. Thus, PWDs often shy away from discussions about their SRH needs.
Description: Journalists Against AIDS [JAAIDS) Nigeria in collaboration with Nigeria Association of the Blind (NAB) with support from the AMPLIFY CHANGE is working on a project titled *Voices for Change: Promoting increased uptake of SRH services among PWDs in Lagos State* which seeks to equip PWDs with SRH knowledge and skills to enable them make informed SRH decisions. After training the leadership of the

PWDs clusters in Lagos State on SRHR issues in June 2017, trainees were required to conduct step down trainings among members. The NAB cluster opted to utilise their existing WhatsApp and Facebook platforms to share SRH information. Since September 2017, NAB leadership has been training group members at a dedicated hour every weekend. SRH topics are posted on the WhatsApp group, NAB Lagos and Southwest Facebook pages. The sessions are interactive and the SRH series reaches 461 members weekly. Topics addressed have included: Basic concepts of SRH; Sexuality, Gender; SRH as a Human Right; Menstrual hygiene, Ovulation, Fertilization, STIs and Family Planning.
Lessons learned: Based on the series, individual members have reached out to the moderators for guidance on dealing with personal SRH challenges ranging from poor erection, irregular menses to coping with a HIV positive partner in a discordant relationship. Using social media has created the space for members within and outside Lagos to better understand their SRH rights, and discuss their SRH concerns in a non-threatening space.
Conclusions/Next steps: PWDs can be better equipped to make informed SRH decisions. Stakeholders need to explore innovative ways of reaching PWDs with appropriate and user friendly information in formats that will support their uptake of SRH services.

TUPED490

Prevention of pediatric HIV/AIDS and AIDS orphans: Celebrating 35 years of hope, fear, innovation and courage among women living with HIV in the early years of the pandemic

K. Beckerman[1], R. Denison[2]
[1]Icahn School of Medicine at Mt Sinai Medical Center, Obstetrics & Gynecology, New Rochelle, United States, [2]Redwood Day, Oakland, United States

Background: Pediatric HIV/AIDS was first reported in New York City in1983. Ten years later, HIV/AIDS had become a "Health Care Crisis of Women and Families" increasing at "alarming" rates. During those years, effective HIV prevention and treatment were absent, and in this absence, even HIV testing of women of reproductive age, pregnant or not, was greeted with fear, ambivalence and ignorance. For those infected, recommendations were clear: no woman with HIV should have children.
Description: Twenty-five to 30 years ago, most women living with HIV did so in isolation, and did not know whether they would live to see their children go to kindergarten. Their providers had limited resources: Until 1994 zidovudine was the only available antiretroviral. Until 1996 viral load testing, even when available, had a limit of detection of 10,000 copies/mL. Women all over the world demonstrated courage and determination to protect their families. We present four women who exemplify the courage and determination of women all over the world to confront their own family's health care crisis.
Personal Stories:
Mom #1: Taking on the United States Congress and FDA.
Mom #2: Rebecca's story: Creating WORLD and a family.
Mom #3: I never gave up on myself or my family. Today I'm a grandmother.
Mom #4: Surviving genocide to fight for health.
Lessons learned: We celebrate here heroic pioneers who lived with the virus in the 1980s and early 1990s, dared to assert their human rights, and fought the long, hard fight for their own health and the health of their families. In so doing, these women changed the course of the pandemic. Today, the right of women living with HIV to found a family has been incontrovertibly established, and the rights of children to receive life-saving health care is part of a broad, if imperfect, national agenda.
Conclusions/Next steps: None of these achievements came easily. The HIV/AIDS innovations of health care advocacy at community and personal levels must be acknowledged and remembered. Those of us who lived through those years have a duty to celebrate one of the great victories of 20th century medicine, so that these lessons are not forgotten.

TUPED491

Facilitating access to sexual and reproductive justice for orphaned and `vulnerable adolescent girls

N.A. Were[1], J.A. Oluoch[2], G. Otieno[3]
[1]KELIN, Sexual and Reproductive Health and Rights, Nairobi, Kenya, [2]KELIN, Women, Land and Property Rights, Kisumu, Kenya, [3]KELIN, Sexual and Reproductive Health and Rights, Kisumu, Kenya

Background: Young people (15-24) contribute significantly to Kenya's HIV burden accounting for 51% of all the new infections with adolescent girls and young women (AGYW) accounting for a disproportionate amount of this burden.The intrinsic connections between HIV and sexual and reproductive health and rights (SRHR) are well established given that HIV is a predominantly sexually transmitted or associated with pregnancy.
Informed by this, the Kenya Legal and Ethical Issues Network on HIV and AIDS (KELIN) is implementing a project: "*facilitating access to sexual and reproductive justice for orphaned and vulnerable adolescent girls*", aimed at securing sexual and reproductive justice as an avenue to reduce the HIV prevalence among AGYW.
Description: The two-year project which begun in 2016, is being implemented in Homa-Bay and Kisumu counties,[1] is structured to address individual and societal barriers of access to health, information and justice through:
a) Increased knowledge and understanding on SRHR, HIV and women land and property rights by AGYW.
b) Addressing structural barriers of access to services and justice through engagements with key stakeholders including: elders and widows; the Judiciary and its structures; and policy makers and legislators.
c) Nurturing AGYW through sports and drama. One of the foundational discussions in this project is "realising your dreams" and dismantling stereotypes on what spaces AGYW should or ought to belong in.
[1] Rationale for counties: HIV burden, 26% and 21%; rates of unintended pregnancy; and KELIN's existing relationships in the region through its Cultural Structures Project.
Lessons learned:
a) Programmatic interventions for HIV fail to explore the intrinsic connection with SRHR leaving a gap in information for AGYW.
b) Limited understanding on the SRHR component and its relation to HIV.
c) Empowerment of AGYW without cognizance of their societal contexts may not yield intended results because structural and cultural barriers have an overarching impact on their vulnerability to HIV.
Conclusions/Next steps: There is a need to replicate intervention models that seek to address both structural and individual barriers. Interventions solely aimed at addressing the individual needs of AGYW fail to address the societal contexts in which AGYWs come from and the areas of vulnerability that individual empowerment cannot shift.

Children's rights and HIV

TUPED492

Findings from violence against children survey in Nigeria: Inferences for HIV programme for abused children and young people

A.P. Okorukwu[1], Y. Falola-Anoemuah[2], M. Egemba[1], A. Okorukwu[3], Gender and Human Rights Team Study Group
[1]National Agency for the Control of Aids, Programme Coordination Department, FCT, Nigeria, [2]National Agency for the Control of Aids, Directorate of Community Prevention and Care Services, FCT, Nigeria, [3]National Agency for Control of AIDS (NACA), Directorate of Community Prevention and Care Services, FCT, Nigeria

Background: Globally, Nigeria ranks second in the number of people living with HIV/AIDS. Although more than 90% of Nigeria's 15-to-24 years old had heard of AIDS, only 24.2% females and 33.5% males had a comprehensive and correct knowledge of HIV/AIDS while an estimated

325,900 of them are living with HIV in the country. A National Survey on Violence Against Children was conducted in 2014 by National Population Commission, in collaboration with FMWASD, NACA, UNICEF Nigeria and United States Centers for Disease Control and Prevention. The study provided strong justification for improved HIV programmes for young people.

Methods: A multi-stage cluster design was used for the Nigerian Violence Against Children Survey (VACS). Data collection included interviews with 1,766 girls and young women and 2,437 boys and young men. The survey examined the link between exposure to violence in childhood and subsequent sexual risk-taking behaviours of males and females aged 18-24 who had experienced sexual violence in childhood. Data from this population provides estimates of the prevalence of violence ever experienced in childhood, while data from 13-17-year olds estimate the prevalence of violence experienced in the 12 months prior to the survey.

Results: According to the VACS findings, violence against children is highly prevalent in Nigeria, 1 in 4 females and 1 in 10 males between the ages of 18-24 reported ever experienced sexual violence in childhood. Almost half of females and males who experienced sexual violence reported that their first incident of sexual violence occurred before the age of 16. A majority of females and males who experienced sexual violence in childhood reported never having been tested for HIV (51% of females and 60% of males).

Conclusions: Based on the findings of the Nigeria VACS, priority actions were developed through a consultative and participatory approach by the Technical Working Group on VACS. The TWG developed and is implementing a comprehensive, holistic and multi-sectoral response which focused on adopting and implementing laws and policies that prevent and respond to violence, encouraging children to speak out and enhancing access to youth-friendly HIV Testing Services and other services for young people.

Stigma and discrimination regarding people from key populations

TUPED493

Reaching key populations within the East African Community: Rhetoric unsupported by policy

A. Gatome[1], M. Costa[2]
[1]Swiss Tropical and Public Health Institute of Basel, Basel, Switzerland, [2]Abt Associates Inc, 10 Fawcett Street, Cambridge, United States

Background: The East African Community (EAC) partner states-Burundi, Kenya, Rwanda, South Sudan, Tanzania and Uganda, have approximately 13% of the global people living with HIV (PLHIV) population. Significant resources mobilized for HIV prevention and treatment services in the EAC have contributed to a decline in HIV prevalence and access to antiretroviral therapy for 48% of PLHIV. Spread of HIV in these countries is concentrated among key and vulnerable populations particularly criminalized groups: commercial sex workers, men who have sex with men, and people who inject drugs. Therefore achieving 90-90-90 will require interventions focused on key populations and a supportive legislative and policy framework.

The EAC HIV and AIDS Prevention and Management Act 2012, provides a harmonized framework to guide HIV responses in partner states and provides protection for key and vulnerable populations. This study sought to identify if partner states' legislation is consistent with the objectives of EAC legislation, specifically protection of key populations.

Description: USAID funded Cross-Border Health Integrated Partnerships Project conducted a desk review in 2016 of EAC and partner states´ HIV related legislations, policies, and strategies focusing on points of convergence and divergence, and fundamental issues affecting key populations.

Lessons learned: In summary, the EAC and partner states have substantive HIV laws, policies and strategies. The legislation across countries aspire to a rights based approach, and include constitutional provisions to guarantee access to health and HIV services. However, some partner states' laws are regressive with regards to key populations which limit progress towards epidemic control.

Among partner states' laws, positive elements include mandating provision of HIV services and prohibiting discrimination in employment and admission to academic institutions based on HIV status. Regressive elements include disclosure to third parties without consent; criminalization of intentional transmission; criminalization of key populations; and mandatory testing of some populations which contradicts EAC legislation.

Conclusions/Next steps: Strides have been made to align country legislation to EAC legislation, but gaps remain. To reach 90-90-90, lobbying and advocacy to address decriminalization, stigma and discrimination challenges facing key populations is needed. Otherwise, available services may not be used and impact on the HIV concentrated epidemic among key populations will not be realized.

TUPED494

A qualitative study of intersectional stigma and discrimination of transgender women living with HIV: Implications for HIV vulnerability and access to HIV-related care

A. Lacombe-Duncan[1], Y. Persad[2,3]
[1]Factor-Inwentash Faculty of Social Work, University of Toronto, Toronto, Canada, [2]The 519 Community Centre, Toronto, Canada, [3]Women's College Hospital, Toronto, Canada

Background: Transgender (trans) women experience a disproportionate HIV prevalence relative to cisgender women, due to social and structural contexts of inequity, including intersectional stigma and discrimination. Scant stigma literature has focused on trans women as a unique key population, separate from women or LGB populations. Studies have also failed to document the strengths of trans women in navigating intersectional stigma. This exploratory study sought to understand:

(1) How does intersectional stigma influence HIV vulnerability and access to HIV-related care for trans WLWH?

(2) How do women exhibit resiliency and empowerment in relation to intersectional stigma?

Methods: Semi-structured in-depth individual interviews lasting 30-90 minutes were conducted with 10 trans WLWH purposively sampled based on HIV-related healthcare access, transition situations, and intersecting identities from 3 Canadian cities (Toronto, Montreal, Vancouver) between May 2017 and January 2018. Interviews were audiorecorded and transcribed verbatim. Qualitative data analysis was conducted using framework analysis, a qualitative content analysis method, which includes line-by-line coding using an inductive approach to develop themes, development of an analytic framework, application of the analytic framework to subsequent transcripts, charting of the data, and interpreting the data with key stakeholders. Data analysis was supported through the use of NVivo10.

Results: Women's narratives highlight intersectional stigma and discrimination, including transphobia, gender non-conformity stigma, and HIV stigma, among others experienced by trans WLWH. These intersecting stigmas resulted in pervasive violence which increased HIV vulnerability and decreased access to HIV-related care. However, findings also suggest that trans WLWH exhibit resiliency and empowerment through multiple mechanisms, such as setting boundaries (e.g., refusing care), becoming self-advocates (e.g., informing providers of how/why their actions or words are discriminatory), supporting each other in accessing competent, stigma-free care (e.g., sharing experiences with other trans women), and becoming public advocates for the rights of trans women living with/affected by HIV
(e.g., volunteering at AIDS service organizations).

Conclusions: Future research should develop/adapt, implement, and evaluate stigma reduction interventions to address HIV vulnerabilities and healthcare access disparities for trans WLWH, which take into context the lived realities of trans women's daily lives and acknowledge their many strengths as individuals and as a community.

TUPED495

Stigmatization of HIV and barriers to health service use for men who have sex with men with HIV in Manila, Philippines: A qualitative study

A. Adia[1], M. Callahan[2], A. Restar[1], L. Hernandez[3], R. Imperial[3], D. Operario[1]
[1]Brown University School of Public Health, Providence, United States, [2]Hofstra University, Hempstead, United States, [3]University of the Philippines, Manila, Manila, Philippines

Background: The Philippines currently has one of the fastest growing HIV epidemics in the world. Despite recent expansions in free testing and treatment services for PLHIV, the growth of the epidemic continues to increase. In other settings, HIV-related stigma has proved to be a substantial deterrent to accessing health services.
The objective of this study was to describe experiences of stigma among HIV-positive men who have sex with men (MSM), a subpopulation that accounts for the vast majority of sexually transmitted cases of HIV.
Methods: Using purposeful sampling, 21 in-depth interviews with MSM with HIV (n=15) and with NGO workers (n=6) were conducted in Manila. Data were analyzed using a thematic analysis framework to illustrate the ways stigma influenced health service use-related behavior for participants both pre- and post-diagnosis.
Results: Drivers of stigma included connotations with injection drug use, extramarital sex, homosexuality, and sex work, leading to a "dirtiness" attached to MSM with HIV. Perceived and indirect experiences of stigma drove participants´ fear of HIV more than any direct experience of stigmatization. The deep-rooted collectivism and Catholic culture in the Philippines heightened participants´ awareness and internalization of stigma. Overall, these stigma-related fears created reluctance to get tested, often leading to late diagnoses. Post-diagnosis, participants discussed fears of accessing treatment, despite the fact that it was free, because of the stigma attached to potentially being seen at clinics and hospitals that treat HIV patients. Medication adherence was also challenging because of the fatalistic attitudes regarding health created by internalization of HIV stigma.
Conclusions: Overall, this study illustrates the ways in which stigma can play a role in decision-making regarding health service use for MSM with HIV in the Philippines. Despite awareness of free testing and treatment services, stigma provides a substantive deterrent to access. This effect may be particularly strong in the Philippines, which has deep-rooted cultural factors like strong Catholic traditions and collectivism that may exacerbate the impacts of stigma. As such, programs designed to specifically target the drivers of stigma and mitigate the impacts of stigma on the lives of PLHIV are needed in the Philippines.

TUPED496

Reporting, prevention and response of gender based violence against key populations in Côte d'Ivoire

A. Ambeu[1], M. Ouedraogo[1], C. Trout[2]
[1]Heartland Alliance International, Abidjan, Cote D'Ivoire, [2]Heartland Alliance International, Chicago, United States

Background: Men who have sex with men (MSM) and female sex workers (FSW) in Côte d'Ivoire have HIV prevalences that are 3 to 5 times higher than the general population. They are also frequent victims of gender-based violence (GBV). The experience of GBV has been associated with higher vulnerability to HIV among key populations (KP) in the scientific literature. To prevent GBV and mitigate its effects on HIV outcomes and to promote well-being of its KP participants, HAI has implemented GBV activities within a large-scale HIV prevention, treatment and care program in Côte d'Ivoire since 2013.
Description: HAI's GBV reporting, prevention and care program component promotes a dynamic of empowerment of KPs and debate in various community fora based on the transformative justice model. First, we use psychosocial education and legal listening sessions to strengthen KP's knowledge of the Ivorian legal environment in the fight against GBV as well as de-normalize the violence that they experience frequently. KPs who have been victims of GBV receive medical and psychosocial services and are assisted to report and prosecute if they wish. KP leaders hold advocacy sessions with authorities.
Lessons learned: From 2013- 2017, 617 cases of physical, sexual, social and emotional GBV were reported by KPs: 53 against MSM and 564 against FSW (Figure 1). In 2017, 187 persons of authority participated in advocacy sessions and 660 and 570 KPs participated in legal listening sessions and psychoeducation, respectively. Also, a new strategy "Circles against violence" was rolled out in 2017 and 133 FSW participated. (Table: 2017 GBV Services offered)

Table: 2017 GBV Services offered		
Services	Number of session/Sites	Number of participants
Advocacy sessions	13	185 authorities
Legal "Listening sessions"	42	630 KP
Psycho-education	38	570 KP
Circles against violence	20 Sites	133 FSW

[Table: 2017 GBV Services offered]

A FSW from Santa Maria de Gagnoa confided in a "circle against violence" that: „now when a violent client comes, we blow in our whistles and he leaves".
Conclusions/Next steps: Unfortunately GBV continues to be a barrier to HIV prevention and treatment for KPs in Côte d'Ivoire. In 2018, HAI plans to extend the "Circles against Violence" to all sex work sites of the project for a better reference of GBV survivors to medical, legal and social support services and to promote the systematic documentation of violence to nourish local, national and even international advocacy.

TUPED497

Determinants of HIV and substance use stigma among people with a history of substance use who are living with HIV in Russia

K. Lunze[1], S. Lodi[2], N. Gnatienko[3], C. Lloyd-Travaglini[2], S. Bendiks[3], M. Vetrova[4], O. Toussova[4], N. Bushara[4], E. Blokhina[4], M. Ekstrand[5], J. Luoma[6], E. Krupitsky[4], D. Lioznov[4], J. Samet[1]
[1]Boston University School of Medicine/Boston Medical Center, Boston, United States, [2]Boston University School of Public Health, Boston, United States, [3]Boston Medical Center, Boston, United States, [4]First St. Petersburg Pavlov State Medical University, St. Petersburg, Russian Federation, [5]University of California, San Francisco, United States, [6]Portland Psychotherapy, Portland, United States

Background: Persons with substance use and living with HIV are affected by stigma. Although stigma related to HIV and substance use is considered to be widespread in Russia, little is known about individual and contextual factors that influence its severity.
Methods: We used data from a cohort study of HIV-positive people who reported a lifetime history of substance use in St. Petersburg, Russia. We focused on two outcomes: perceived HIV stigma (10-item Berger Stigma Scale) and substance use stigma (score on 21 questions). Multivariable linear regression was used to examine the cross-sectional association of each stigma outcome with the following potential risk factors: perceived level of social support, gender, recent (past month) substance use, depressive symptoms (CES-D score ≥ 16), alcohol dependence, and ever selling sex.
Results: Participants (n=249) had the following characteristics: mean [standard deviation (SD)] age 34 [6] years; 168 (68%) male; 113 (46%) depressive symptoms (CES-D); 137 (55%) alcohol dependent; 97 (39%) recent substance use; and 149 (60%) low social support. Mean (SD) HIV stigma score and substance use stigma score were 21 (6) and 55 (16), respectively. Alcohol dependence and presence of depressive symptoms were associated with increased HIV and substance use stigma (Table). Recent substance use was associated with higher substance use stigma, but not with HIV stigma. We did not detect an association between social support and either stigma outcome.

	HIV stigma score		Substance use stigma score	
Risk Factor	β (95% CI)	p-value	β (95% CI)	p-value
Social Support	0.35 (-1.06, 1.76)	0.6272	-1.97 (-5.61, 1.67)	0.2870
Male vs. Female	-1.18 (-2.62, 0.27)	0.1107	2.14 (-1.68, 5.95)	0.2716
Depressive Symptoms	3.87 (2.49, 5.25)	<.0001	7.03 (3.44, 10.62)	0.0001
Alcohol Dependence	1.34 (-0.05, 2.73)	0.0598	5.46 (1.83, 9.10)	0.0034
Ever Selling Sex	2.16 (-0.41, 4.74)	0.0987	5.95 (-0.69, 12.58)	0.0786
Recent Substance Use (past month)	-0.33 (-1.74, 1.09)	0.6509	9.89 (6.18, 13.60)	<.0001

[Analysis of risk factors of HIV and substance use stigma. Estimated using multivariable linear regression in Russian cohort.]

Conclusions: Stigma related to HIV and substance use continues to affect people with a substance use history living with HIV in Russia. Depressive symptoms and alcohol dependence were associated with both HIV and substance use stigma. Further research, including qualitative studies, needs to examine whether these associations are causal and to explore further sources of stigmatization of HIV and substance use in Russia, such as provider stigma or public attitudes around HIV and substance use.

TUPED498

Getting to the root: Addressing the barriers to HIV service access among the LGBT community in Lesotho

L. Mohasoa
Phelisanang Bophelong, Programs, Hlotse, Lesotho

Background: The right to health is considered universal. However, in countries like Lesotho, exclusion of minority groups, such as Lesbians, Gays, Bisexuals and Transgender (LGBT), continues to affect health access. LGBT-led organisation Matrix are aware of approximately 315 LGBT people in Leribe district and report that many avoid or delay care because of perceived or real homophobia and discrimination by health care providers, impacting on their general and sexual health. Against this backdrop, in 2015, national NGO Phelisanang Bophelong began focusing on empowering LGBT people to access HIV services and have their rights recognized through Bocha Ke Palesa youth project.
Description: The project took a two-pronged approach (2015-2017):
Improving self-efficacy to encourage HIV service take-up: Two safe spaces established in Hlotse / Maputsoe for LGBT members to share information, talk about their sexual health and rights, and encourage HIV service access. Groups are led by trained peers to provide a mutually supportive environment.
Building social capital to improve the context for LGBT service access: Building relationships with influential stakeholders (e.g. District Administration, Police, community leaders, health staff) to improve social relations at community level and promote inclusion of LGBT members. This included gender and sexual diversity training to raise awareness and allow open dialogue with LGBT community. LGBT members were empowered to share information and be more visible in the community to reduce social stigma, through community sensitization and awareness events. This included a training of trainers on key population stigma reduction.
Lessons learned: There is a general community shift in attitude towards LGBT people, they have improved self-worth, reduced self-stigma and feel able to come forward for services.
- 268 LGBT reached through safe spaces
- 20 health providers sensitized to provide LGBT-friendly HIV services
- 28 stakeholders trained on gender and sexual diversity
- 25 community leaders engaged in discussions and awareness events.
- First Pride event held in Hlotse
Conclusions/Next steps: The interventions have improved the general environment for LGBT people in Leribe district. The project will build on progress to date, taking learning to enhance interventions to change mindsets and create a more conducive environment for LGBT people to access services.

[LGBT pride event 2017]

TUPED499

Stigma is still a problem: Experiences of HIV and gay-related stigmas and coping among young HIV+ GBMSM in Puerto Rico

S.M. Malavé-Rivera[1], R. Vargas-Molina[1], E. Santiago-Rodríguez[1], C.E. Rodríguez-Díaz[1], S.D. Rhodes[2]
[1]*University of Puerto Rico, Graduate School of Public Health, San Juan, Puerto Rico,* [2]*Wake Forest University, Social Sciences & Health Policy, North Carolina, United States*

Background: Despite significant advances in biomedical and socio-behavioral sciences to improve the health outcomes of people living with HIV (PLWH), HIV and gay-related stigmas still persist. Both types of stigmas negatively impact HIV prevention efforts, linkage and retention in care, and quality of life of PLWH. Young gay, bisexual and other men who have sex with men (YGBMSM) are at increased risk for HIV in the United States and Puerto Rico (PR). In 2015, youth 13 to 24 y/o accounted for 22% of new cases and 81% of those were GBMSM. Latino GBMSM are among the most vulnerable and disenfranchised from care.
Methods: We conducted a qualitative study in PR to understand how YGBMSM experience stigmas and how they cope with those experiences. We conducted 5 focus groups with n=29 HIV+ YBGMSM ages 18 to 29. Audio files were transcribed and organized in NVivo v11 for content analysis.
Results: Results suggest that HIV+ YGBMSM in PR experience enacted, perceived and internalized HIV and gay-related stigmas, and intersections between stigmas exist. Accounts of enacted HIV stigma include experiences of discrimination at work and healthcare settings. Participants also perceive that many Puerto Ricans are uninformed about the routes of HIV transmission; thus, they act negatively towards PLWH. Participants also perceive that other GBMSM have negative opinions about those with HIV, based on notions of personal responsibility of infection and "slut shaming", which foster exclusion. Feelings of shame about being GBMSM and being HIV+ were also found. Active and passive coping strategies to deal with stigmas were identified, including confronting stigmatizers and concealing one's HIV status and/or sexual orientation/behavior.

Conclusions: In the era of PrEP, undetectability, and LGBT rights, HIV and gay-related stigmas still hinder HIV prevention and care globally. It is important to understand current manifestations of HIV and gay-related stigmas and the effects on wellbeing and health outcomes. Developing interventions to address stigmas must acknowledge the complex intersections between various forms of stigmas. In addition, it is important to incorporate the voices from younger generations into the development of responses to eliminate stigmas.

TUPED500

Impact of social stigma on the mental health outcomes of female sex workers and men who have sex with men in Cameroon

O.M. Olawore[1], S. Ketende[1], S. Zadrozny[2], I.M. Njindam[1,3], G. Fako[3], A. Rao[1], C. Lyons[1], G. Turpin[1], U. Tamoufe[3], A. Bowring[1], G. Fouda[4], F. Ndoko[4], D. Levitt[5], A. Bissek[6], O. Ndoya[7], S. Billong[8], S. Baral[1]
[1]Johns Hopkins University School of Public Health, Epidemiology, Baltimore, United States, [2]University of North Carolina, Chapel Hill, United States, [3]Metabiota, Yaounde, Cameroon, [4]CARE Cameroon, Yaounde, Cameroon, [5]CARE USA, New York, United States, [6]Ministry of Health, Department of Operational Research, Yaounde, Cameroon, [7]University Hospital Center, Yaounde, Cameroon, [8]Group Technique Central (CNLS), Yaounde, Cameroon

Background: Social and sexual-related stigmas affecting key population (KP) have been shown to limit engagement in care including through their impacts on mental health. Here, we assess the association between stigma, self-reported HIV status and the mental health status of men who have sex with men (MSM) and female sex workers (FSW).
Methods: 2255 adult FSW (median age 28 years) and 1323 adult MSM (median age 23 years) were recruited by respondent-driven sampling in five urban centers of Cameroon and completed a structured instrument and biological testing. A positive depression screen defined as a Patient Health Questionnaire (PHQ-9) score of 10 or greater. Social stigma experienced, perceived or anticipated as a result of being a FSW or MSM was measured by asking the study participants a series of validated indicators. Logistic regression models stratified by population were used estimate the odds of depression associated with any experience of stigma and self-reported HIV status with adjustments for demographic, social and behavioral factors.
Results: The prevalence of depressive symptoms was 70.4% among FSWs (aPr= 71.8%, 95% CI: 69.5-74.0) and 71.2% among MSM (aPr=79.1%, 95% CI: 76.4-81.6). Stigma was significantly associated with depression in both the crude and adjusted analysis for both FSW (OR=1.58, 95% CI: 1.28-1.96, aOR= 1.34, 95% CI: 1.04-1.72) and MSM (OR=2.85, 95% CI: 2.22-3.67, aOR= 1.63, 95% CI: 1.21-2.19). For FSW, however, the significance of the association was negated after adjusting for RDS sampling. In these analyses, self-reported HIV status did not appear to be associated with depression. Among FSW, disclosure to a healthcare worker about KP membership and age remained significantly associated with depression after all adjustments. Finally, transgender women were found to have higher levels of depression as compared to cis-gender MSM
Conclusions: There are consistent relationships observed between mental health and stigma among key populations in Cameroon. Currently, HIV and stigma mitigation programs offer limited mental health services and existing mental health services offer limited HIV prevention and stigma mitigation services suggesting the need for better integration of these services as a means of providing comprehensive and evidence-based services for key populations in Cameroon.

Make us feel safe: Discrimination and disclosure of sex work status in healthcare settings and implications for HIV harm reduction strategies among US-based sex workers

J. Brown[1,2], B. Robinson[1]
[1]Call Off Your Old Tired Ethics Rhode Island (COYOTE RI), Providence, United States, [2]Brown University, Alpert Medical School, Providence, United States

Background: Sex workers (SWs) of all gender identities remain a key population that face disproportionately high rates of HIV in the US. The criminal status of sex work, many structural barriers to healthcare and support across other sectors, and widespread discrimination against SWs create an environmental in which it is difficult for SWs to obtain healthcare. Many harm reduction strategies target SWs but are often unsuccessful due to the many intersecting forms of marginalization SWs face in the US. A nationwide SWs rights organization, COYOTE RI, carried out a study for four months in 2017 through which they looked to understand how healthcare systems and those attempting to conduct harm reduction programs with SWs could better connect with this key population.
Methods: This community-based research was carried out by organizations that have advocated for SWs rights for many decades. This study surveyed people working in various areas of the sex industry in all regions of the US [n = 1,496]. Analysis of the data utilized qualitative and quantitative methodologies and key findings were developed through the use of grounded theory.
Results: This study found that there are many ways in which clinicians, healthcare workers, and harm reduction programs can better serve US SWs. Retaining absolute confidentiality, eliminating moral judgments, showing respect, treating SWs the same way other patients are treated, listening to and inquiring for facts, avoiding assumptions about sex work, reading publications by SWs, and publicizing the fact that programs are SW-friendly would allow SWs to be less hesitant in seeking and continuing HIV care.
Conclusions: There is much work to be done in the US to remedy the discrimination that SWs face in healthcare settings. Understanding and taking into consideration the experiences and perspectives of SWs is key in connecting with and providing effective, long-term HIV care for this key population.

Stigma and discrimination in specific settings, including family, community, work place, education, and healthcare settings

Fear of workplace HIV transmission, an unrecognized and actionable driver of stigma and discrimination in health facilities

N. Skyers[1], R. McLean[2], L. Nyblade[3], S. McLeish[4], T. Clough[4], J. Knight-Johnson[5], I. Cruickshank[6], D. Chevannes-Vogel[7], C. Stewart[3]
[1]Ministry of Health, Jamaica, HIV/STI/TB Unit, Health Promotion and Protection Branch, Kingston, Jamaica, [2]University of the West Indies, HIV and AIDS Response Programme, St. Augustine, Trinidad and Tobago, [3]HP+/RTI International, Washington D.C., United States, [4]The Palladium Group, Health Policy Plus Project, Kingston, Jamaica, [5]USAID, Kingston, Jamaica, [6]Caribbean Vulnerable Communities, Kingston, Jamaica, [7]National Family Planning Board, Kingston, Jamaica

Background: Stigma and Discrimination (S&D) are barriers to uptake and retention in HIV prevention, care, and treatment programs and particularly damaging within health systems. Measuring key actionable S&D drivers is a critical first step to reducing S&D and improving access, linkage, and retention in HIV services. One key actionable driver is worry about HIV transmission in the workplace, which can lead to unnecessary

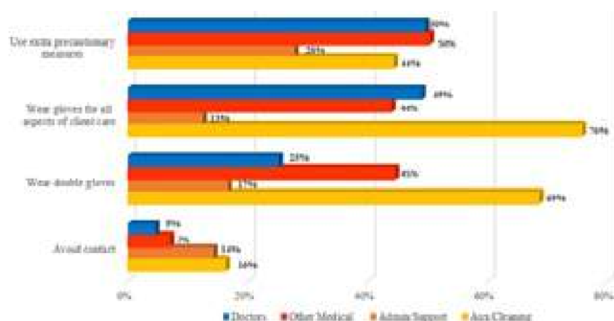
infection control behaviors. These are not only stigmatizing behaviors but can lead to breaches of confidentiality, signaling to others that a client is different in a dangerous way. The USAID-and-PEPFAR-funded HP+ project and UWI-HARP with the MOH and the National Family Planning Board are applying a total-facility approach to S&D-reduction. The first step in Jamaica was collection of baseline data that is informing tailored facility-based S&D-reduction activities and will support evaluation.

Methods: Quantitative survey data was collected in three facilities (July-Sept 2017) with all levels (medical and non-medical) of public sector healthcare workers (HCWs)(n=446) and 292 clients living with HIV. Data on key drivers (fear of HIV transmission/attitudes/health facility environment) and manifestations of S&D were collected from HCWs, while clients reported on experienced discrimination, anticipated stigma and its relationship to health seeking behaviors.

Results: When asked about worry of contracting HIV when conducting five routine activities within the purview of their occupational requirements, doctors (60%) and other medical staff (58%) reported concern/fear of at least one activity (Table 1). Self-reported routine uses of stigmatizing avoidance behaviors with clients living with HIV was high across all categories of staff (Figure 1). For example, HCWs reported using precautionary measures with clients living with HIV that are not used with other clients (48%). HCWs also reported high rates of training in infection control. Clients reported lower levels of experiencing double gloving (8%) in the past 6 months than staff reported using.

Conclusions: Data revealed that despite significant training or other knowledge building interventions, the attitudes or behaviors of key HCW towards PLHIV continue to reflect stigmatizing tendencies. Strengthening understanding and enforcement of the universal application of standard precautions can reduce one common type of S&D in facilities—stigmatizing avoidance behaviors.



[Stigmatizing Avoidance Behaviours Towards Clients with HIV by Staff Classification]

Areas of Concern		Doctors (N=108)	Other Medical (N=178)	Admin/ Support (N=43)	Aux/ Cleaning (N=88)	Total (N=417)
Touched the clothing of a client living with HIV	Worried	4.6%	6.2%	14.0%	20.5%	9.6%
Dressed the wounds of a client living with HIV	Worried	51.1%	42.1%	0%	0%	45.5% (N=242)
Drew blood from a client living with HIV	Worried	54.6%	55.8%	0%	0%	55.3% (N=217)
Took the temperature of a client living with HIV	Worried	0%	2.5%	0%	0%	1.6% (N=243)
Gave an injection to a client living with HIV	Worried	39.8%	50.3%	0%	0%	46.4% (N=239)

"Self-stigma is the worst kind of stigma": Internalised stigma and navigating HIV care amongst health workers living with HIV in Zambia and South Africa, the HPTN071 (PopART) stigma ancillary study

V. Bond[1,2], M. Mwamba[1], N. Vanqa[3], D. Ziba[1], D. Milimo[1], L. Vilijoen[3], T. Mainga[1], H. Ayles[1,4], M. Steinhaus[5], J. Hargreaves[6], G. Hoddinott[3], T. Nicholson[3], A. Stangl[5]

[1]Zambart, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, Faculty of Public Health and Policy, London, United Kingdom, [3]Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Faculty of Medicine and Health Sciences, Stellenbosch, South Africa, [4]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [5]International Center for Research on Women, Washington, United States, [6]London School of Hygiene and Tropical Medicine, Department of Social and Environmental Health Research, London, United Kingdom

Background: Sub-Saharan African health workers are looked up to as knowledgeable professionals and leaders. This assigned professional status may heighten feelings of shame, guilt or worthlessness stemming from the acceptance, or internalisation, of negative attitudes about HIV, making it harder for this group to reveal an HIV-positive status. We explore the prevalence of internalised, or 'self', stigma amongst Zambian and South African health workers living with HIV (HW-LWH) and implications for accessing care.

Methods: Health facility (n=963), community health workers (n=281), and trial-specific community health workers (n=631) across 21 urban health facilities linked to a cluster randomised trial HTPN071 (PopART) completed a self-administered survey in 2015. Questions included self-reported HIV status, ART status, and reported internalised stigma for HW-LWH. Fifty HW-LWH were then interviewed about their experiences in 2016-17.

Results: Of all health workers, 87.8% self-reported their HIV status. Across the health worker cadres, reports of positive HIV status ranged from 15.3% to 28.5% in Zambia, and from 8.3% to 19.6% in South Africa. Compared to South Africa, all Zambian HW-LWH cadres reported higher internalised stigma, particularly health facility workers, with 25% agreeing with one of three internalised stigma items, and 10.5% reporting not taking ART.

In qualitative data, the term 'stigma' was often aligned with *'self-stigma'*. Health facility workers discussed fearing gossip, co-workers using their status against them, and client reactions. Community health workers (both types) were more open about living with HIV, drawing on their experiences to support clients. They were also more likely to access HIV clinic services at the local clinic. If health facility workers accessed ART at their workplace, they employed tactics to 'fast-track' care and avoid identification. Experienced stigma, youth and pregnancy heightened internalised stigma. Interviews evoked poignant stories of HW-LWH dying rather than risking their professional reputation. Participant strategies to navigate internalised stigma included "acceptance" of status, avoiding identification, covert social support, and sometimes public testimony and challenging stigma.

	Health facility workers n %	Zambia Community health workers n %	CHiPs n %	Health facility workers n %	South Africa Community health workers n %	CHiPs n %
Sample: Those who self-reported their HIV status Living with HIV	n = 620 95 15.3	n = 123 35 28.5	n = 377 105 27.9	n = 222 27 12.2	n = 112 22 19.6	n = 193 16 8.3
Sample: Those living with HIV Not currently taking ARV drugs	n = 95 10 10.5	n = 35 0 0.0	n = 105 4 3.8	n = 27 3 11.1	n = 22 4 18.2	n = 16 1 6.2
Sample: Those living with HIV who answered all three internalized stigma questions Agreed or strongly agreed with one of the three items reflecting internalised stigma	n = 88 22 25.0	n = 35 7 20.0	n = 102 19 18.6	n = 26 3 11.5	n = 20 2 10.0	n = 15 2 13.3

[Table. Internalised stigma and ARV drug adherence among health care workers living with HIV in Zambia and South Africa]

Conclusions: Most health workers reported their HIV status. HW-LWH reported concerning levels of internalised stigma, particularly Zambian health facility workers. Interventions are required to support those at the heart of HIV service delivery.

TUPED504

The good use of alternative modes of settlement of disputes in the fight against discriminations and stigma towards PLWHIV: Case of Cameroon

J.N. Tamekue Tagne[1], F. Fogue[2], C. Chemgne[3]
[1]Positive-Generation, Law and Human Rights, Yaounde, Cameroon, [2]Positive-Generation, Yaounde, Cameroon, [3]Positive-Generation, Research, Development and Communication, Yaounde, Cameroon

Background: Discriminations against PLWHIV is still numerous in Cameroon whether in urban or rural areas. POSTIVE-GENERATION, have conducted a survey among a sample of 560 person who sought the services of its legal clinic during the year 2017. According to the results of the survey, 90% of PLWHIV reported having been discriminated after disclosure of their status. Women were the most affected with 70%. Discriminations concern family, work place and hospital environment. The investigation carried out informs us that the victims prefer resign themselves than to seize the courts for fear of being more stigmatized and discriminated, the justice being on principle made public. It´s in this context in order to preserve the confidentiality of the victims and to encourage them to seek justice and improve their lifestyle and their state of health that the Legal Clinic of Positive-generation has set up a model of alternative dispute settlements.
Methods: - Reception and listening at the headquarters of the association - Registration and statement of facts on a tracking sheet - Transmission of the file to the legal clinic - Legal support by a team of lawyers and paralegals - Bailiff´s summons - Conciliation or mediation within the legal clinic - Approvals of the terms of the arrangement by the President of the competent court in closed session.
Results: -150 cases accompanied from January to December 2017
- 64 cases of mediation (discriminatory dismissal).
- 23 cases of conciliation (inheritancce, land and properties rights).
Conclusions: This alternative system of dispute resolution has the advantage of being fast, accessible, and concerned about the privacy of victims who fear the advertising encountered in the classic pattern of institutional justice. The latter is still not accessible because of its cost, its slowness and sometimes procedural requirements and techniques that almost always recommend the services of a lawyer, which is a luxury for most victims in financial vulnerability. We started with three regions of Cameroon: the center, the east and the far north. We aim to cover by 2025 the entire national territory with its ten regions.

TUPED505

The HIV stigma landscape in sub-Saharan Africa: Baseline findings of a mixed-method, comprehensive evaluation nested in the HPTN 071 (PopART) trial

J. Hargreaves[1], A. Stangl[2], G. Hoddinott[3], T. Mainga[4], S. Floyd[1], K. Sabapathy[1], H. Jones[1], L. Viljoen[3], T. Pliakas[1], S. Krishnaratne[1], C. Mubekapi-Musadaidzwa[3], V. Bond[4], HPTN (071) PopART Team
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]International Center for Research on Women, Washington D.C., United States, [3]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [4]University of Zambia, Zambart, School of Medicine, Lusaka, Zambia

Background: HIV stigma involves interactions between (at least) PLHIV, community members (CMs), health workers (HWs) and members of key populations (KPs). HIV stigma may change in prevalence and form over time, as might its impact on HIV prevention and treatment. However, evaluations of stigma that include these multiple perspectives are rare. We set out to comprehensively describe the stigma landscape in 21 communities in South Africa and Zambia at baseline in the HPTN 071 (PopART) trial.
Methods: Synthesis of baseline HIV stigma data from a large, mixed-method, longitudinal study. Quantitative data came from a representative population cohort (3859 PLHIV, a subsample of 5088 CMs not living with HIV, and 1558 HWs). Stigma was categorised into three domains using 11 items: experienced in communities, in health settings and internalised stigma (self-stigma). Qualitative data came from observations and key informant interviews.
Results: 1371/3859 (35.5%) of PLHIV reported at least one of 11 types of stigma. Reported stigma was more frequent in the community (22.1%) than in health settings (7.3%). Internalised stigma was common (22.5%). There was more internalised but less experienced stigma in health settings in Zambia than in South Africa. Structures and client-flow patterns identifying HIV status in clinics sometimes made PLHIV uncomfortable. Among PLHIV on treatment before the start of the trial, experienced community stigma was more commonly reported by those who had been non-adherent (aOR:1.52 95% CI:1.12-2.07). Stigma was experienced most acutely close to time of diagnosis.
Few CMs reported stigmatising attitudes, but many perceived that stigma was present. HWs rarely reported they would be ashamed if a family member was living with HIV (76/1439, 5.2%). In contrast, high proportions reported they would be ashamed if a family member were a man having sex with men (1065/1366, 80.0%), a woman selling sex (1100/1408, 78.2%) or a young woman falling pregnant before marriage (653/1432, 45.6%), especially in Zambia. However, HWs supported the rights of these groups to access health services.
Conclusions: HIV stigma remains a commonly experienced phenomenon for PLHIV. Going forward, it may be particularly important to address any negative effects of HIV stigma on treatment success, and to reduce stigma toward KPs.

TUPED506

'They are not responsible enough to use protection': The blind spot of stigma and discrimination towards young people in healthcare settings

D. Mark[1,2], K. Bloch[1], A. Ronan[1], H. Chorlton[1], L. Hatane[1]
[1]PATA, Cape Town, South Africa, [2]University of Cape Town, Psychology, Cape Town, South Africa

Background: Efforts to reach the 90-90-90 treatment targets in young people living with HIV (YPLHIV) are failing, with HIV testing, treatment and viral suppression rates worse than adults. UNAIDS warns that HIV-related stigma and discrimination in healthcare settings discourages YPLHIV from accessing HIV services. Confronting marginalisation in HIV care is critical to ensuring service access and positive treatment outcomes for YPLHIV.
Methods: In 2016-2017, Paediatric Adolescent Treatment Africa (PATA), a network of frontline health workers, conducted semi-strutured knowledge, attitudes and practices (KAP) surveys with 54 health providers from 29 health facilities across Kenya, Malawi, Uganda, Zambia and Zimbabwe, and 68 YPLHIV from Cameroon, DRC, Ethiopia, Malawi, Tanzania, Uganda, Zambia and Zimbabwe. Data were analysed using descriptive statistics and thematic coding to describe central tendencies and identify themes.
Results: Providers were most frequently nurses (41%), predominantly female (67%), and had a mean age of 38 years. Participating YPLHIV were predominantly female (59%), with a mean age of 22 years. Eighty-seven percent of providers reported training in care and support for YPLHIV, and most providers (85%) reported that YPLHIV do not receive inferior care. Ninety-eight percent of providers reported being comfortable talking about sexual and reproductive health (SRH) with YPLHIV, but 41% of YPLHIV reported fear discussing SRH with providers. While two-thirds of providers (76%) reported that they did not scold YPLHIV for requesting SRH services (76%), 41% of YPLHIV reported that they had been scolded.
Conclusions: Results indicate a discrepancy between health provider versus YPLHIV accounts of youth services. Providers seem to have little awareness of young people's experience of services as discriminatory. Fundamentally there remains a blind spot in providers' insight and willingness to provide services without judgement. To mitigate stigmatising health provider attitudes and practices, we recommend urgent and intensified health provider education, sensitisation and training on peo-

ple-centred healthcare and the rights of YPLHIV, as well as routinized engagement with YPLHIV. In particular, integration of YPLHIV as peer supporters within health facility teams and active YPLHIV patient feedback mechanisms build trust between YPLHIV and providers, improve YPLHIV service experiences and increase provider confidence.

TUPED507

Creating an enabling environment for equal employment opportunities at the workplace for sexual minorities and People living with HIV

T. Chopade, K. Roy, A. Kavi
The Humsafar Trust, Advocacy Unit, Mumbai, India

Background: Congenial employment conditions and fair working environments play an important role in determining a country's economic progress. Discrimination and non-inclusion of LGBTQ employees and People living with HIV (PLHIV) result in reduced job performance, employee disparity, lack of job security and limited access to health care services. The adverse legal environment in India also contributes to employment inequality, marginalization and socio-economic alienation for LGBTQ persons and PLHIV.
Description: The Humsafar Trust is a Community Based Organisation (CBO) and Sub-Recipient for Global Fund Round-9 funded Projects working in 27 states of India which focuses on sensitization of key policymakers and stakeholders. The advocacy initiative undertakes capacity building of organizations and emphasizes on having non-discriminatory policies in workplaces to curb violence and harassment faced by LGBTQ and PLHIV. Different methodologies including discussions, presentations, and theatre activities are employed to engage corporates and non-corporates into LGBTQ-friendly policy development and innovative initiatives to create safe workplaces.
Lessons learned: As a result of discussions with 38 corporates on the violence and discrimination at the workplace, crucial insights were obtained. There are very few corporates who have LGBTQ friendly policies in place. Those who have non-discriminatory policies do not proactively engage with LGBTQ and PLHIV inclusion due to the stigma attached to the subject. Furthermore, employees are not necessarily aware of existing policies and senior management is often not sensitive to LGBTQ issues. There were reports of instances of LGBTQ and persons living with HIV being denied access to health care, equal opportunities due to their sexual orientation and/or gender identity and HIV status.
Conclusions/Next steps: We need pro-active non-discriminatory and inclusive policies that specifically address issues around gender and sexuality. There is an urgent need for correct implementation of HIV AIDS law 2016 to maintain inclusivity that extensively addresses the varied dimensions of inequality. There is also a need for corporates, particularly multi-nationals who champion LGBTQ cause globally, to come forward and proactively advocate for LGBTQ-friendly policies through their Indian counterparts and franchisees.
