Description: CSC is a comprehensive facility providing counseling, referral, outreach services and linkages to social entitlements and welfare schemes to the registered PLHIV. Addressing discrimination is a key aspect of reducing vulnerability as well as fostering quality life of PLHIV community therefore, every CSC has community led Discrimination Response System (DRS) to establish an effective and sustainable mechanism. Under this system, a Discrimination Response Team (DRT) created consist of representation of lawyers, journalist, DLN/CBO/NGOs, district officials, healthcare providers, etc.
A total of 29 DRT are functional and addressing issues in adequately to ensure fundamental rights of PLHIV. The total (282) discrimination cases are reported and resolved by DRT. A gender analysis of data reveals that female (58.51%) reported more stigma and discrimination compare to male (34.40%), and shows vulnerability of women and further followed by children (5%) and TG community (3%). Further from the total the majority of discrimination incidences were reported by Family Members (55.81%) and Health Facility (23.5%). The incidents are responded and resolved further documented to emerge the advocacy efforts for PLHIV.
Lessons learned:
· Disclosure plays immense role and related to Stigma and discrimination
· Sensitization meetings with community and families is needed utmost
· Regular interaction with clients and their family is very important to address issues at the earliest.
· Partnership efforts with CSO,CBO, DLN and Governments system to respond effectively.
Conclusions/Next steps: DRT and dwindling of stigma and discrimination are closely related and plays crucial role in reducing vulnerability as well as fostering quality of life of PLHIV. Hence, it should be a key component of all HIV related programme.

TUPED509

"Stigma and discrimination-free zones": An innovative approach to engaging the private and public sectors in creating more inclusive environments for key populations in Central America

S. Lungo[1], A. Cabrera[1], C. Pineda[2]
[1]Pan American Social Marketing Organization, Strategic Communication, Guatemala City, Guatemala, [2]Pan American Social Marketing Organization, Strategic Communication, San Salvador, El Salvador

Background: Central America's HIV epidemic is concentrated in key populations (KPs): MSM, transgender women (TW), and female sex workers (FSW). Despite existing HIV laws and policies that respond to KP's specific needs, there is evidence of widespread discriminatory attitudes and practices towards these populations, and stigma and discrimination (S&D) continue to be important barriers to accessing HIV services and care. In 2016, under the USAID Combination Prevention Program for HIV in Central America, the Pan American Social Marketing Organization (PASMO) designed an intervention entitled "stigma and discrimination-free zones" as part of a broader initiative known as Generation Zero, contributing to the goal of "getting to zero discrimination".
Description: PASMO developed guidelines and works with public and private sector institutions, companies, and other organizations to meet five criteria that would allow them to become "stigma and discrimina-

tion-free zones": 1) A commitment letter to complete the accreditation process, 2) An internal action plan and system for reporting cases of S&D, 3) An internal employee committee responsible for follow-up, 4) Training and sensitization of staff in human rights, sexual and reproductive rights, gender, masculinities, sexual diversity, HIV/AIDS, S&D and gender-based violence; and 5) An updated HIV, S&D workplace policy. PASMO provides the technical assistance to meet the criteria and facilitates the training and sensitization sessions in coordination with other Generation Zero partners, such as local National AIDS Programs.
Lessons learned: In 2017, PASMO successfully completed the "stigma and discrimination-free zone" process with three major public institutions in El Salvador: The Justice Sector's Technical Executive Unit, the Public Health Superior Council, and the Human Rights Offices of San Miguel and Santa Ana, in which a total of 267 administrative, operational, and other staff were trained and sensitized. In Guatemala and Panama, the initiative appealed to corporate social responsibility efforts aligned with local HIV laws, allowing PASMO to engange two private sector companies and their employees.
Conclusions/Next steps: The "stigma and discrimination-free zone" initiative allows PASMO to engage private sector partners and important public institutions to create sustainable, long-term efforts to reduce S&D towards KPs and persons living with HIV in Central America and to operationalize existing HIV laws and policies.

Experiences of discrimination increase the risk of depression and suicidal ideation among men who have sex with men and transgender in Nepal

K. Deuba[1], U. Shrestha[1], B. Rawal[2], R.P. Khanal[3], R.K. Bhattarai[4], B.D. Pandey[2], R. Shrestha[5], A.M. Ekstrom[6]
[1]National Center for AIDS and STD Control/Global Fund Programs, Kathmandu, Nepal, [2]National Centre for AIDS and STD Control, Ministry of Health, Kathmandu, Nepal, [3]National Centre for AIDS and STD Control/ Global Fund Programs, Kathmandu, Nepal, [4]Save the Children, Kathmandu, Nepal, [5]Public Health and Environment Research Center, Lalitpur, Nepal, [6]Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden

Background: Experiences of discrimination may act as a stressor and result in adverse health outcomes. Still, the extent to which experiences of discrimination increase the risk of depression and suicidal ideation among men who have sex with men (MSM) and transgender people (TG) remains unknown in low-income countries. We examined the prevalence of discrimination experiences on the basis of sexual orientation in different situations among MSM and TG in Nepal, and assessed the association between discrimination and depression including suicidal ideation.
Methods: In this quantitative study, 740 MSM and TG 16 years of age or above were recruited using respondent driven sampling (RDS) between May 2017 and July 2017 from four districts of Nepal. Face-to-face interviews were conducted to collect the information. A modified version of the Experience of Discrimination (EOD) tool developed by Krieger and Center for Epidemiological Studies Depression (CES-D) scale was used. MSM and TG were asked about discrimination in relation to their sexual orientation regarding eight different situations (school, getting hired, work, getting housing, getting medical care, getting service in a store or restaurant, public settings, and to interactions with the police or other security personnel). The assessment of suicidality was based on three dichotomous items asking for lifetime prevalence of suicidal ideation, planned suicide, and attempted suicide. RDS-II estimates were used for the calculation of probability weights and RDS-adjusted prevalence. Statistically significant associations between independent variables and depression including suicidal ideation were computed using multivariable logistic regression.
Results: Experience of discrimination in at least one setting was reported by 47% of all participants (RDS-adjusted estimate: 47%; 95% CI: 42%-52%) and higher among TG than MSM (58% vs 42%). The prevalence of suicidal ideation (9%) and depression (35%) was also high. Experience of discrimination in at least one setting increased the likelihood of depression (4.6 adjusted odds ratio (AOR); 95% confidence interval (CI) =1.5-6.5) and suicidal ideation (3.1 AOR; 95% CI=2.9-7.2).

Perceived Discrimination	MSM (n=513)	TG (n=227)	Overall (n=740)	
	Frequency (%)	Frequency (%)	Frequency (%)	RDS-Adjusted % (95% CI)
At School (Yes)	34(5.5)	20(9.8)	54(6.9)	6.9(4.8-9.6)
Getting hired or Job (Yes)	20(2.3)	20(8.0)	40(4.1)	4.1(2.7-6.3)
At work (Yes)	83(18.3)	46(28.4)	129(21.6)	21.6(17.6-26.1)
Getting Medical Care (Yes)	37(5.0)	16(5.5)	53(5.2)	5.2(3.5-7.7)
In the street or in a public settings (Yes)	165(29.6)	72(40.8)	237(33.2)	33.2(28.7-38.0)
From Police Security Personnel (Yes)	87(6.9)	23(7.0)	110(6.9)	6.9(5.0-9.6)
Getting service in a store or restaurant (Yes)	117(20.4)	51(35.0)	168(25.1)	25.1(21.0-29.8)
Family Rejection (family force them to live outside of home because of their sexual orientation) (Yes)	47(10.6)	18(10.9)	65(10.7)	10.7(7.8-14.5)

[Table 1: Perceived discrimination on the basis of sexual orientation among MSM and TG in Nepal in 2017]

Conclusions: Experience of discrimination increases the risk of depression and suicidal ideation is common among MSM and TG in Nepal. Structural interventions need to be added to the existing HIV programs to mitigate the burden and consequences of discrimination.

TUPED511

Human Rights Violations in the Framework of Mandatory Health Checks for Sex Workers in Austria

C. Nagl
Projekt PiA, Salzburg, Austria

Background: In Austria, registered and voluntary sex work is legal, but regulated differently in each federal state. What is common for all states, however, is the fact that sex workers have to undergo mandatory health checks in order to get a permission to work. Austria is the last state within Europe, which did not abolish mandatory health checks for sex workers. The law is kept for the sake of "national health" (*Volksgesundheit*) and is a remnant of the Hitler-era.
Description: The fact is that these health checks are performed under inhumane conditions and women are neither informed about their health situation, nor do they get sufficient support about possible treatments. A sex worker forum in Vienna submitted a shadow report to the UNCAT (United Nations' Committee against Torture), describing the degrading conditions during the health checks.
Lessons learned: First of all, the health checks are not conducted under circumstances granting doctor-patient confidentiality. Often, women have to put down their trousers before they even enter the examination room and examinations can be heard by third party individuals. Sex workers complain about severe pain after the examinations, sometimes not being able to work for a certain amount of time. It happens that women "pass" the examinations albeit having issues like genital warts. On top of that, women are exposed, since it is known when these checks are performed, so anybody who is looking for specific women knows where to find them. Next to pain and exposure, women have to deal with degrading comments by the staff. Because of these health checks, owners of brothels advertise with "healthy girls", which encourages a lot of clients to ask for unsafe sex practices. In sum, this policy does not only fail in tackling sexually transmitted infections, but pushes women into high risk working conditions..
Conclusions/Next steps: In the framework of PiA, we try to lobby against this inhumane policy, but the state and administrative institutions are not willing to give it up. The main argument is „protecting" sex workers, while seriously putting sex workers in multiple kinds of dangers.

Global trends in HIV criminalisation: Overview, analysis and country ranking

E.J. Bernard, S. Cameron
HIV Justice Network, Brighton, United Kingdom

Background: HIV criminalisation describes the unjust application of criminal law to people living with HIV based on HIV-positive status, either via HIV-specific criminal statutes or general criminal or similar laws. Such state-sponsored stigma and discrimination within the criminal justice system is a barrier to universal access to HIV prevention, testing, treatment and care, and a human rights issue of global concern.
Methods: A global audit of HIV-related arrests, investigations, prosecutions and convictions. Abstract covers October 2015 to September 2017, final data will be presented to April 2018. Despite changes to previous methodology including new regional hubs and use of multi-lingual staff with strong regional contacts, these data should be considered illustrative of a more widespread, undocumented use of criminal law against people with HIV. Countries were ranked based on the total number of cases per 1000 people living with diagnosed HIV during the audit period.
Results: Sixty eight countries have HIV-specific criminal laws. During the audit period, four new HIV-specific criminal laws were proposed (Cameroon, Malawi, Nepal, and Quintana Roo, Mexico); a new law was enacted in El Salvador; proposed problematic statutes were withdrawn in Brazil, Malawi and several United States (US) states; and in Kenya one of two HIV-specific criminal statutes was suspended after being ruled unconstitutional.
At least 69 countries have ever used HIV-specific or general laws to prosecute people with HIV for alleged HIV non-disclosure, potential or perceived exposure or non-intentional transmission. Norway modernised its non-specific law to allow for disclosure and ´treatment as prevention´ defences. Cases were reported for the first time in ten countries: Honduras, Kenya, Kyrgyzstan, Israel, Malawi, Northern Ireland, Nigeria, Paraguay, Somalia and Tajikistan.
The majority of reported cases occurred in the US, Belarus, Russia, Canada and Zimbabwe. Belarus, the Czech Republic and New Zealand had the greatest number of *per capita* cases, although several individual US states (Iowa, Tennessee, Ohio, Michigan, Indiana and Kentucky) ranked higher *per capita* than most countries.
Conclusions: Despite a more co-ordinated approach to national, regional and international advocacy, and to case montoring, HIV criminalisation does not appear to be diminishing fast enough, requiring further urgent attention, focus and funding.

TUPED513

The power of stigma: Experiences of HIV-positive MSM in healthcare services in Puerto Rico

E. Santiago-Rodríguez, R. Vargas Molina, C. Rodríguez-Díaz
University of Puerto Rico, School of Public Health, San Juan, Puerto Rico

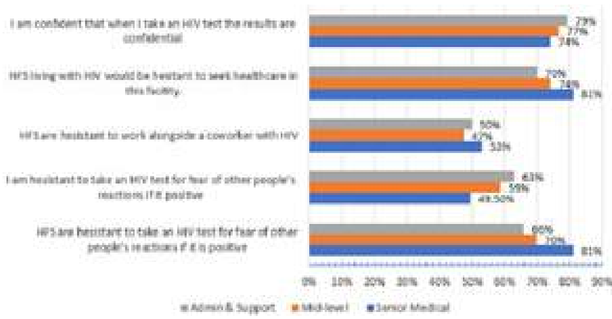
Background: Puerto Rico (PR) has a highly homophobic, patriarchal and extremely religious culture. More than 35 years into the HIV epidemic, stigma is still manifested by many, especially by healthcare providers (HCP). This causes detrimental social and medical implications for people with HIV. Stigma enacted as prejudice and discrimination in the context of healthcare have been associated with challenges in patient's care continuum. This is particularly true for HIV-positive men who have sex with men (MSM) who are otherwise disenfranchised in health services. Greater attention needs to be paid to stigma as a Social Determinant of Health for HIV. However, limited research has been conducted to understand how stigma impacts the retention in HIV care, particularly of HIV-positive MSM in highly-stigmatizing contexts such as PR.
Methods: A qualitative study was conducted using in-depth semi-structured interviews with 19 HIV-positive MSM. Participants were cis-gender males, at least 16yo, and sexually active during the three months prior to the interview. Interviews, conducted in Spanish, included three thematic areas: experiences with HIV testing and treatment, engagement in care, and experiences with HCP. Content analyses were performed using NVivo V-10.
Results: Both HIV stigma and Gay stigma were documented by participants. Issues with confidentiality, poor quality HIV services, disclosure of sexual orientation and HIV status, and linkage to care were among participants' main concerns. They emphasized on discriminating actions by HCP, citing ultraconservative cultural influences for their stigmatizing attitudes. Also, experiences of stigmatization by mental health providers based on their sexual identity was consistently mentioned by participants. The quality of the interaction between HCP and participants greatly influenced the willingness to disclose HIV status and sexual orientation and to choose providers and health care settings.
Conclusions: Experiences of stigma in healthcare settings prevent people with HIV from engagement and retention in continuum of care. Future interventions should invest in culturally-appropriate training for HCP to address stigma and how to provide appropriate services to gay, bisexual men and other MSM. This way we can move forward to eradicating stigma and assuring the quality of life of those affected by HIV/AIDS.

TUPED514

Measuring stigma and discrimination in health facilities in Ghana for intervention design: Fear of HIV status disclosure and lack of confidentiality are key actionable factors

N.A. Addo[1], K. Atuahene[2], E. Gyamera[1], C. Stewart[3], S. Jacinthe[4], E. Essandoh[4], P. Mingkwan[3], L. Nyblade[5]
[1]*Educational Assessment and Resource Center, Accra, Ghana,* [2]*Ghana Aids Commission, Accra, Ghana,* [3]*HP+/RTI International, Washington, United States,* [4]*United States Agency for International Development, Accra, Ghana,* [5]*HP+/RTI International, Global Health Division, Washington, United States*

Background: Health-facility stigma and discrimination (S&D) undermine access to and retention in HIV-services. Health-facility S&D data are essential to tailoring evidence-based S&D-reduction interventions and catalyzing action. In response, the USAID-and-PEPFAR-funded Health Policy Project has partnered with the Ghana AIDS Commission and the Educational Assessment Resource Center, with support from the Global Fund, to measure health-facility HIV-related S&D from the perspective of health facility staff(HFS) and clients. These data have informed the design of a tailored whole-facility HIV-S&D-reduction intervention that engages all levels of staff(medical and non-medical) in improving quality of care while also providing baseline data for an ongoing intervention evaluation.
Methods: Surveys in 20 high HIV caseload facilities in 5 regions with all levels of HFS(1841 female/990 male) and clients living with HIV(192 female/68 male). Key measures included:
1) S&D actionable drivers (fear/attitudes/facility environment) and observed discrimination among HFS;
2) anticipated/experienced S&D, avoidance/delay of health services, and perceptions of health-facility policies among clients.
Results: Fear of status disclosure and lack of confidentiality emerged as a key area to address for S&D-reduction. 36% of clients reported not using their closest HIV facility for HIV care. 74% reported at least one stigma-related reason for not doing so; fear of status disclosure was the most frequently cited(Table 1). 30%(33%female/23%male) of client respondents do not believe their facility keeps HIV records confidential. 7% of clients(female:9%/male:3%) reported that HFS at their regular HIV facility disclosed their HIV status without their consent in the last 6 months. 9% of clients and 27% of HFS reported observing HFS disclosing a client's HIV status without their consent in the past 6 months. Concern over S&D is relected in HFS' own hesitancy to seek HIV testing for fear of stigma, as well as their perception of co-workers' hesitancy to test for HIV, seek treatment if they were living with HIV, and work alongside co-workers living with HIV (Figure 1).
Conclusions: Data from this study were used to tailor whole-facility S&D-reduction interventions. Ensuring confidentiality is an essential part of this approach and critical to reducing anticipated and experienced S&D, and improving service access for and retention of clients living with HIV.



[Figure 1. HIV-related health facility environment for HFS]

	Female (n=192)	Male (n=68)	Total (n=260)
Do not use the nearest facility with HIV services for HIV care	34.9% (67/192)	38.2% (26/68)	35.8% (93/260)
Reasons for not using the closest facility: (n=93)			
1. Fear of HIV status disclosure	70.2% (47/67)	50.0% (13/26)	64.5% (60/93)
2. Fear of discrimination or poor treatment	47.8% (32/67)	30.8% (8/26)	43.0% (40/93)
3. Had a previous negative experience at this healthcare	16.4% (11/67)	7.7% (2/26)	14.0% (13/93)
4. Fear will be denied services	7.5% (5/67)	11.5% (3/26)	8.6% (8/93)
Composite indicator (at least one of the four stigma-related scenarios, items #1-4)	**76.1% (51/67)**	**69.2% (18/26)**	**74.2% (69/93)**
5. Logistical concerns	28.4% (19/67)	30.8% (8/26)	29.0% (27/93)

[Table 1: Percent of respondents not using nearest health facility for HIV services and reasons for not using closest facility, by sex]

TUPED515

"What is not measured is not managed" - implementing a routine technology-based patient feedback system to reduce stigma and discrimination in key population HIV services in Malawi

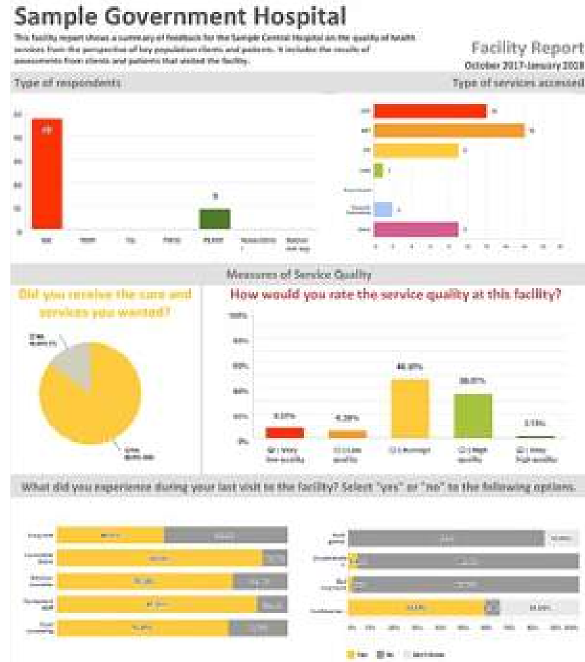
B. Eveslage[1], L. McManus[2], C. Banda[3], S. Kalyati[3]
[1]FHI 360, Global Health Population and Nutrition, Washington, United States, [2]IntraHealth International, Chapel Hill, United States, [3]FHI 360, Lilongwe, Malawi

Background: Stigma and discrimination (S&D) limit key populations' (KP) access to HIV and other health services. However, most HIV programs do not systematically monitor S&D in health settings and are therefore unable to manage and reduce it to improve services.

Methods: The USAID- and PEPFAR-supported LINKAGES project developed a technology-based service quality monitoring system called "SMS²" to routinely collect feedback from KP referred to health facilities. In October 2017, the LINKAGES project in Malawi implemented SMS² with 30 community outreach workers (ORW) in 6 districts using online assessments with Survey Monkey, smartphones, and mobile data packages to assess KPs' perceptions of health facilities or experiences of S&D and service quality issues during recent facility visits. Surveys were continuously implemented during routine outreach activities.

Results: From October 2017 to January 2018, KPs completed 1052 assessments (62% from sex workers, 34% from men who have sex with men [MSM], and 6% from transgender individuals). Nine percent of KPs reported living with HIV. Approximately 85% of assessments captured experiences during facility visits and 14% assessed KPs' perceptions of referral facilities they had not yet visited. Of 103 different health facilities assessed using SMS², 13 facilities accumulated 20 or more assessments that could be used to generate live facility-specific dashboards to inform quality improvement activities at those facilities (see Figure 1 for example). Facilities in Mangochi district received the highest average service quality rating (3.75 out of 5), while Lilongwe, Machinga, and Zomba had the lowest score of 2.9 each - but only in Zomba did this correspond with high rates of S&D experienced in facilities. Feedback from sex workers and KPs living with HIV reported the lowest service quality ratings. MSM and transgender people were most likely to report staff gossip and MSM were most likely to report being denied health services. Transgender respondents' perceptions of S&D were much higher than other KPs, however, actual experiences at facilities were comparable with other KPs.

Conclusions: Technology-based and community led-monitoring systems like SMS² can systematically monitor S&D in health settings, thereby allowing programs to manage and reduce S&D and increase patient satisfaction to increase uptake of services.



[Figure 1: Sample Facility Report from Anonymized Government Hospital in Machinga District, Malawi]

TUPED516

HIV related stigma and discrimination among health care providers and people living with HIV In Thailand

T. Siraprapasiri[1], L. Johnston[2], P. KhemNgern[1], K. Srithanaviboonchai[3], J. Chueayen[3], S. Chariyalertsak[4], P. Benjarattanaporn[5]
[1]Ministry of Public Health, Department of Disease Control, Nonthanburi, Thailand, [2]Consultant UNAIDS, Bangkok, Thailand, [3]Chiang Mai University, Research Institute for Health Science, Chiang Mai, Thailand, [4]Chiang Mai University, Faculty of Public Health, Chiang Mai, Thailand, [5]UNAIDS, Bangkok, Thailand

Background: Thailand is committed to zero stigma and discrimination against people living with or affected by HIV (PLHIV) and key populations. We present findings from surveys measuring stigma and Discrimination among Health Care Providers (HCP) and PLHIV.

Methods: Surveys were conducted in Bangkok and Chiang Mai using purposeful sampling of clusters, and in 16 other provinces using multi-level cluster sampling. Data from sampled provinces were extrapolated to unsampled provinces and weighted by HCP or PLHIV population sizes in all provinces (n=77) to calculate a weighted mean average for each indicator.

Results: In the past year, 24% of HCP observed stigma or discriminatory practices towards PLHIV and between 4.2% and 4.8% observed HCP unwilling to care for a patient who is or thought to be a man who has sex with men, transgender or female sex worker, 7.9% observed HCP unwilling to care for a patient who is or thought to be someone who injects drugs and 12.2% observed HCP unwilling to care for a patient who is or thought to be a migrant. 60.9% of HCP experienced personal fear of HIV infection and 53.1% reported using unnecessary precautions to avoid HIV infection from a PLHIV. 84% of HCP felt they stigmatized PLHIV. In the past year, 13% of PLHIV and 12% of females who became pregnant since learning of their positive HIV status avoided/delayed health care because of fear of stigma and discrimination. 5% of PHLIV were coerced/advised to terminate a pregnancy in the past year. 12% of PLHIV experienced stigma and discrimination in a health care setting and 24.5% reported HIV disclosure/non-confidentiality in a health care facility in the past year. 31.4% of PLHIV experienced internal stigma in the past year.

Conclusions: Thailand has been a global leader in formulating national monitoring systems to measure S&D and creating an evidence base for S&D reduction programs. By the time of the 22nd International AIDS Conference data from a larger number of locations using the same questionnaire conducted in late 2017 will be available and presented.

TUPED517

Double stigma affecting HIV-positive people who use drugs in Ukraine and care integration

T. Kiriazova[1], O. Makarenko[1], Y. Sereda[1], N. Rybak[2], A. Chybisov[3], F. Gillani[2], T. Flanigan[2], J.H. Samet[4], K. Lunze[4]
[1]Ukrainian Institute on Public Health Policy, HIV and Addiction Research, Kyiv, Ukraine, [2]Brown University, Warren Alpert Medical School, Providence, United States, [3]Brown University, School of Public Health, Providence, United States, [4]Boston Medical Center/Boston University, CARE Unit, Boston, United States

Background: Stigma related to both HIV and substance use (SU) affects HIV-positive people who use drugs (PWUD) in Ukraine. While integration of HIV and SU treatment improves access to care and care outcomes, its effect on internalized stigma is unknown. This study assessed HIV and SU stigma perceived by HIV-positive PWUD in addiction treatment, and associations of stigma with care integration in Ukraine.

Methods: We conducted a cross-sectional survey of HIV-positive PWUD, receiving opioid agonist treatment (OAT), in six regions of Ukraine, at 3 facilities providing addiction treatment only and 3 integrated facilities providing both SU and HIV care. Primary outcomes were total HIV and SU stigma scores measured with Berger Scale and Substance Abuse Stigma Scale, respectively. We assessed the facilities' user-friendliness and accessibility, on-site support from non-governmental organizations (NGO), regular HIV care visits, receiving ART, receiving OAT, and presence of depressive symptoms as predictors of stigma in linear and logistic regression models.

Results: Study participants (n=191) had the following characteristics: 75% male; mean age 40; 59 % unemployed; mean time in OAT 34 months; and 73% receiving NGO services at OAT site. Levels of HIV stigma (mean 0.39 out of 1; 95% CI:0.36-0.41) and SU stigma (mean 0.41 out of 1; 95% CI:0.38-0.43) were similar. Receiving integrated services was not associated with total HIV stigma (AOR=1.08; 95% CI:0.59-1.98) or SU stigma scores (AOR=1.16; 95% CI:0.60-2.25). SU stigma was the only predictor of HIV stigma (AOR=2.59; 95% CI:1.41- 4.85). SU stigma was associated with high HIV stigma (AOR=3.01; 95% CI:1.58;5.91), depressive symptoms (AOR=2.00; 95% CI:1.01-3.97), and being unemployed (AOR=2.10; 95% CI:1.04-4.32). Receiving NGO services on-site was associated with lower SU stigma (AOR=0.27; 95% CI:0.12-0.59).

Conclusions: In our study, integrated treatment was not associated with a significant decrease in substance use or HIV stigma. Findings indicate that targeted interventions are necessary at integrated and non-integrated care facilities to address both forms of stigma affecting HIV-positive PWUD. Reinforcing protective factors such as NGO support at addiction care facilities, including assistance with employment, might help mitigate the highly persistent stigma related to substance use and its potential interaction with HIV stigma in Ukraine.

TUPED518

HIV and substance use stigma among non-specialized medical care providers in Ukraine

O. Makarenko[1], T. Kiriazova[1], K. Lunze[2]
[1]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [2]Boston Medical Center, CARE Unit, Boston, United States

Background: HIV-positive people and people who use drugs (PWUD) experience multi-level stigma in the community and in health services in Ukraine. Decentralization of services within current health care reform implies that HIV and drug addiction treatment (ART and opioid agonist treatment (OAT)) will be provided at primary care level. With this study, we explored the opinions of HIV-positive PWUD in OAT program and health providers at OAT sites about stigma faced by patients with HIV and addiction at non-specialized health care facilities.

Methods: In August-September 2017, we conducted six focus groups with HIV-positive OAT patients and 13 in-depth interviews with their health providers at six OAT sites in five regions of Ukraine. Interviews were transcribed verbatim, and a thematic analysis was performed.

Results: Forty-seven OAT patients (18 were women, 66% unemployed, aged 30-55 years) and 13 providers (7 narcologists, 3 infectious disease physicians, 2 social workers, 1 psychologist, aged 32-61 years) participated in the study. Across all sites, all participants described stigma towards HIV-positive PWUD, specifically at non-specialized care facilities. While stigma towards HIV-positive patients has been decreasing in Ukraine health care system, this is not the case regarding HIV-positive PWUD. Patients reported referring to their OAT physicians with all kinds of health problems, as providers at other facilities often "did not treat them like humans" and avoided providing services to them. According to providers, physicians of other specialties associate both people in active drug use and OAT patients with criminal behavior, seeing them as non-reliable, non-complient with treatment, and, most important, impecunious patients. However, all respondents admit, that if a PWUD can pay for the medical services, he will be treated differently.

Conclusions: Due to limitations of existing programs, providers at non-specialized health facilities are poorly informed about problems of HIV infection and drug addiction. Education on these diseases is necessary for physicians of all specialties to reduce stigma related with HIV and addiction. The attitude towards patients based on their financial capacity must be taken into account in the context of health care reform, when physicians will be paid depending on the number of patients and the quality of care.

TUPED519

Exploring the mediating effect of HIV-related stigma on the HIV counselling and testing service utilisation in Nigeria - A PLS-SEM approach

F.O. Adekunjo[1], R. Rasiah[1], M. Dahlui[2,3], C.W. Ng[3,4]
[1]University of Malaya, Department of Development Studies, Kuala Lumpur, Malaysia, [2]University of Malaya, Department of Social and Preventive Medicine, Faculty of Medicine, Kuala Lumpur, Malaysia, [3]University of Malaya, Julius Centre, Department of Social and Preventive Medicine, Kuala Lumpur, Malaysia, [4]University of Malaya, Department of Social and Preventive Medicine, Kuala Lumpur, Malaysia

Background: HIV/AIDS is a severe health problem in Sub-Saharan Africa. Globally, Nigeria is second in a number of people living with HIV/AIDS (3.2 million) after South Africa. HIV Counselling and Testing (HCT) is regarded as a critical entry point to other essential HIV/AIDS prevention and intervention programmes**.** However, HIV-related stigma pose severe threat to its success in Nigeria. Although many studies have been carried out on the role of stigma on HIV/AIDS programmes, but studies that explored the mediating impact of the HIV-related stigma on the relationship of willingness to do HIV test, perceived threats of HIV/AIDS and benefits of HCT, and HCT service utilisation in Nigeria is very scarce. The aim of this study is to assess the mediating impact of HIV-related stigma on the relationship of willingness to partake in HIV testing, perceived threats of HIV/AIDS, perceived benefits of HCT and HCT service utilisation in Nigeria using PLS-SEM approach.

Methods: We assessed latent construct of HIV-related stigma as a mediator on the relationship of perceived benefits of HCT, perceived threats of HIV/AIDS, willingness to do HIV test and HCT service utilisation using 768 respondents from cross-sectional survey data collected in three Local Government Areas of Lagos State, Nigeria. We employed Partial Least Square-Structural Equation Modelling (PLS-SEM) method to analyse mediation effects of the research model.

Results: Mediational analysis results revealed that HIV-related stigma was significant and fully mediated the relationship between the willingness to do HIV testing and HCT utilisation (= *0.007; p*=0.049), while on the other hand, it partial mediated the relationship between perceived benefits of HCT and HCT utilisation (=*-0.009; p*=0.018), and perceived threats of HIV/AIDS and HCT service utilisation (=-0.014; *p*=0.008).

Conclusions: In spite of the perception of individuals about the threat posed by HIV and the benefits accrue to having HIV test; fear, rejection, and stigma associated with being tested positive constitute severe hindrances to accessing HCT services in Nigeria. Therefore, for Nigeria to

achieve 90-90-90 HIV targets by 2020 and Sustainable Development Goals (SDGs) in health by 2030, efforts must be geared towards eradication of HIV-related stigma in the society.

TUPED520

The law alone cannot end HIV-stigma and discrimination: Lessons from the Kenya HIV Tribunal Kenya

N. Otwoma[1], P. Anyumba[2], J. Mwilu[3]
[1]NEPHAK, Coordination, Nairobi, Kenya, [2]Kenya Judiciary, HIV Tribunal, Nairobi, Kenya, [3]Ministry of Health, HIV Tribunal, Nairobi, Kenya

Background: Established under Section 25 of the HIV Prevention and Control Act of 2006, the HIV and AIDS Tribunal of Kenya is a HIV-specific statutory body with the mandate to adjudicate cases relating to violations of HIV-related human rights. The Tribunal commenced its work in 2009 and has since kept the promise to advance the human rights of people living with and affected by HIV in Kenya, notably through addressing barriers to access to justice, swift ruling, and purposeful application of the law.
Description: Between 2015 and 2017, the HIV Tribunal received 460 cases seeking redress through litigation based on its mandate to "hear and determine complaints arising out of any breach of the provisions of the Act". Of these, 340 applications met the legal threshold for full-fledged litigation. This means that 120 applications (26%) did not meet the legal threshold required by the Tribunal for litigation. Ten complaints were criminal in nature and referred to the Kenya High Court while 21 could not be litigated because the Tribunal cannot act retrospectively. Of the successfully litigated cases, 62% had to do with discrimination at workplaces, 12% with HIV malpractices that contravened the provisions of HAPCA and 5% with discrimination of young learners living with HIV within learning institutions. Cases stigmatization, verbal abuse and isolation, including by family members did not meet the threshold for litigation.
Lessons learned: Through its composition, mandate, procedures, and decisions, the Tribunal is emerging as a positive mechanism for enforcing HAPCA and for protecting the rights of PLHIV. The tribunal is able to address the challenges relating to access to justice and rights-based judicial decisions for people PLHIV, mainly because it´s sensitive to and knowledgeable on HIV issues, less cumbersome proceedings that protect confidentiality and privacy, and speedy rulings. A positive feature of the Tribunal is its effective referral arrangements to other bodies, including for psycho-social support
Conclusions/Next steps: HIV Tribunal is an excellent mechanism for protecting the rights of PLHIV. However, the high number of complaints received by it but not meeting the legal threshold is reminder that the law alone is not enough to eliminate HIV-related stigma and discrimination.

TUPED521

Status disclosure is closely associated with social HIV discrimination and self-stigma: Lessons learned from the implementation of the people living with HIV Stigma Index in Taiwan

Y.C. Chiu[1,2], T.-S. Wu[1], Y.-T. Lee[3,4], N.-C. Wang[5], W.-W. Wong[6], C.-E. Liu[7], C.-W. Li[8], J.-W. Liu[9], H.-S. Lin[10], Y.-H. Hsiao[1,2], Y.-H. Lin[2], N.-Y. Chen[1]
[1]Division of Infectious Diseases, Department of Internal Medicine, Chang Gung Memorial Hospital Linkou Branch, Chang Gung University College of Medicine, Taoyuan, Taiwan, Province of China, [2]Persons with HIV/AIDS Rights Advocacy Association of Taiwan, Taipei, Taiwan, Province of China, [3]School of Medicine, Chung Shan Medical University, Taichung, Taiwan, Province of China, [4]Chung Shan Medical University Hospital, Department of Internal Medicine, Taichung, Taiwan, Province of China, [5]Tri-Service General Hospital and National Defense Medical Center, Department of Internal Medicine, Taipei, Taiwan, Province of China, [6]Taipei Veterans General Hospital, Taipei, Taiwan, Province of China, [7]Changhua Christian Hospital, Department of Internal Medicine, Changhua, Taiwan, Province of China, [8]National Cheng Kung University Hospital, Department of Internal Medicine, Tainan, Taiwan, Province of China, [9]Chang Gung Memorial Hospital Kaohsiung Branch, Department of Internal Medicine, Kaohsiung, Taiwan, Province of China, [10]Chang Gung Memorial Hospital Chiayi Branch, Department of Internal Medicine, Chiayi, Taiwan, Province of China

Background: Disclosure of HIV positive status is important for getting appropriate medical or psychological supports and for secondary prevention. However, it is generally thought as a sequential decision making process that may involve many factors. The aim of this study is to delineate the relationship between status disclosure and self-, social stigma/discrimination.
Methods: A cross-sectional nationwide survey using the People Living with HIV Stigma Index was conducted in Taiwan in 2017. People living with HIV (PLHIV) who were willing to participate in the survey were referred from HIV-associated NGOs and treatment centers to trained interviewers for face to face private interviews. A total of 842 (3% total PLHIV population in Taiwan) valid questionnaires were collected. Demographic information, self-stigma and social discrimination events were extracted from the pooled data and analyzed.
Results: We found that during the early years of infection (1-4 years), a person was more willing to disclose his/her HIV status to social workers if there was less self-stigma ($p < 0.05$). A person with less self-stigma also tended to talk to his/her friend about his/her HIV infection. In contrast, among those living with HIV for 10-14 years, persons with higher self-stigma were less likely to have disclosed his/her status ($p < 0.05$). Importantly, social discrimination experiences from the partner, family, friends, co-workers, employers, religious leaders and medical staff were all in positive association with the extent of self-stigma ($p < 0.05$). A stronger self-stigma was also related to the fear of potential discrimination events ($p < 0.05$). Among the key populations, participants that used intravenous drugs were associated with higher extent of self-stigma ($p < 0.05$).
Conclusions: Our study showed that status disclosure is closely associated with social HIV discrimination and self-stigma. Building a supportive system without HIV discrimination may facilitate status disclosure of PLHIV and may assist in timely delivering of medical/psychological resources to those in need.

Representations of stigma: social attitudes, media, and public debate

TUPED522

Status of HIV/AIDS-related stigma and its relationship with the mental health of HIV-positive persons in Japan

Y. Inoue[1,2,3], S. Abe[4], T. Togari[1], G. Oshima[5,6], N. Katakura[7], A. Yamauchi[8], Y. Takaku[9], HIV Futures Japan Project
[1]Open University of Japan, Chiba, Japan, [2]Nationcal Cancer Center Japan, Tokyo, Japan, [3]Accelight Inc., Tokyo, Japan, [4]TIS Inc., Tokyo, Japan, [5]Hitotsubashi University, Kunitachi, Japan, [6]Japan Society for the Promotion of Science (JSPS), Tokyo, Japan, [7]Kobe City College of Nursing, Kobe, Japan, [8]Ryotokuji University, Urayasu, Japan, [9]Japanese Network for People Living with HIV/AIDS, Tokyo, Japan

Background: HIV/AIDS-related stigma leads to the unfair, unjust treatment of HIV-positive persons based on discrimination against or biased views on them. Previous quantitative studies in Japan rarely examined their frequency of perceiving or experiencing such stigma. The present study examined the status of HIV/AIDS-related stigma, including changes in its pattern, as well as its influence on the mental status of HIV-positive persons, through 2 online questionnaire surveys separately conducted in Japan.
Methods: Two anonymous, self-administered online questionnaire surveys were conducted by the HIV Futures Japan Project. The first survey (T1) was conducted between 2013 and 2014, and 913 responses were valid for analysis. The second survey (T2) was conducted between 2016 and 2017, and 1,038 responses were valid for analysis. HIV/AIDS-related stigma was quantitatively compared using 3 scales to measure: stigma perception scale (4 items, range: 4-16), stigma-related fear scale (8 items, range: 8-32), and stigma-related behavioral self-restriction scale (6 items, range: 6-24).
Results: At T2, the rate of answering the statement: "I become very cautious when I disclose my HIV-positive status to others" with "Yes" reached 92.8%. The rate was 85.7% for "In general, people reject me after learning that I am HIV-positive", 65.9% for "I am careful to keep my HIV-positive status a secret from others", and 62.9% for "I may lose my position if my employer or superior learns about my HIV-positive status".
In T1 and T2, the mean stigma perception scale scores were 9.40 (SD: 3.28) and 9.69 (3.43), respectively, mean stigma-related fear scale scores were 24.45 (5.33) and 25.32 (4.75), respectively, and mean stigma-related behavioral self-restriction scale scores were 19.63 (5.63) and 19.52 (5.55), respectively.
Using survey data at T1, multiple regression analysis, with scores from the Hospital Anxiety and Depression Scale as a dependent variable, stigma-related behavioral self-restriction scale scores as an explanatory variable, and the gender, age, frequency of perceiving LGBT-related stigma, and stigma perception scale scores as control variables, revealed a significant positive correlation with the explanatory variable (=0.248, p=0.005, R2=0.157).
Conclusions: The results emphasize the necessity of creating detailed plans to implement HIV/AIDS-related stigma reduction measures as a domestic issue to be urgently addressed.

TUPED523

Open conversations on reducing stigma and discrimination in Botswana by using cultural values to foster support to end stigma and discrimination

O. Mosweu
Men For Health and Gender Justice, Policy Advocacy and Project Management, Gaborone, Botswana

Background: Of recent there has been an increase in visibility of Gay Men and Male Sex workers in African countries, and this has been coupled with conversations to decriminalize both same sex sexual activity and sex work done at International level with little work done in country in fear of harassment by law enforcement officials, This has led to gay and male Sex work turning in a burning issue in Africa countries including Botswana. The gay and sex work community has been systematically silenced and face abuse, rejection, stigma and discrimination with the local leaders urging that Gay men and Male Sex workers are cultures adopted from the western culture and therefore "Un-African". This abstract aims to show how the Botswana gay and male sex workers communities' uses native values to foster support towards reducing stigma and discrimination.
Description: The international community often condemns African governments by writing petitions, threats to stop aid and these have often led to the local communities taking the wrath of these action by the Western activists. In Botswana, the gay men and Male sex workers group uses native Botswana culture and values. This approach has been implemented in 5 districts of Botswana through gathering traditional leaders, politicians, Police and using native styles of consultation and consensus - building, We have adopted strategies which are derived from Botswana norms and cultural values such as '*mafoko a kgotla a agelwa mosako*' (Every person's opinion must be respected without stigma). The main aim has been to lobby leaders to end stigma and discrimination in a language Batswana People can understand without referencing much to western arguments.
Lessons learned: This approached proved to work, in the 5 districts in which this was done through traditional consensus building and consultation in native languages and strategies. The dialogues through slow, are indeed building to a conducive environment where gay men and Male Sex workers can engage without discrimination and stigma in addressing issues of health and human rights and inclusion.
Conclusions/Next steps: Going forward, the aim is to continue evaluating these initiatives in-depth and find ways how other communities can implement them to their benefit.

TUPED524

Disclosure of HIV sero-positive status and linkage to care in remote rural and border settings of Mbeya, Tanzania: Qualitative findings of a mixed methods study

E.S. Sanga[1], F. Mukumbang[2], A.K. Mushi[3], C. Zarowsky[2,4]
[1]Mwanza Medical Research Centre, Clinical Research Program, Mwanza, Tanzania, United Republic of, [2]University of Western Cape, School of Public Health, Capetown, South Africa, [3]National Institute for Medical Research, Public Health, Dar-es-Salaam, Tanzania, United Republic of, [4]University of Montreal Hospital Research Centre, School of Public Health, Montréal, Canada

Background: Despite mobile/outreach testing models and anti-stigma efforts, the disclosure of HIV status remains a challenge and significantly impedes linkage to care. In our prospective 2-armed cohort study of 1,012 newly diagnosed individuals testing at mobile/outreach vs facility-based testing sites in remote and hard-to-reach border areas of Mbeya region, Tanzania; participants who disclosed their HIV status had a two and half times earlier rate of linkage to care than those who had not disclosed (p< 0.001). This study describes the reasons for failure to disclose HIV sero-status and its implications for linkage into HIV care.
Methods: We report on the embedded qualitative findings of our sequential explanatory mixed methods study. Between August 2014 and July 2015, eight focus group discussions and ten in-depth interviews were conducted with purposively selected participants from the cohort of 1, 012 newly diagnosed HIV positive individuals from 16 HIV testing sites, complemented by twenty individual interviews with healthcare providers. Data were transcribed verbatim and translated, then thematic content analysis was undertaken, supported by Atlas.ti software.
Results: The major reasons reported to influence individuals' decision not to disclose their HIV positive sero status, were fear of stigma related to HIV/AIDS, lack of trust and fear of intimate partner violence and/or divorce. New relationships or marriages after death of the first partner was also reported to interfere with disclosure to partners. HIV status disclosure to family/relatives was significantly associated with linkage to care (AHR=2.64; 95%CI: 2.05-3.39). They received both financial and moral support from their partners and other family members. Individuals testing at mobile/outreach sites were less likely to expect an HIV+ result and reported more concerns about disclosure and linkage to care.

Conclusions: Lack of disclosure was reported to impede successfully linkage to care and timely initiation of ART due to lack of both practical and emotional support from significant others. Mobile/outreach testing reaches new people but barriers to disclosure, notably stigma and fear of damaging relationships, must be addressed.

TUPED525

Media perpetuation of HIV fear and stigma: A content and textual analysis of coverage of an HIV criminal prosecution

C. Campbell[1], F. Rojo[1], N. Khanna[1,2], S. Dworkin[3]
[1]University of California San Francisco, Department of Social and Behavioral Studies, San Francisco, United States, [2]Positive Women's Network - USA, Oakland, United States, [3]University of Washington Bothell, School of Nursing and Health Studies, Bothell, United States

Background: Research shows that laws criminalizing HIV non- disclosure, exposure or transmission, which currently exist in more than 30 states in the U.S, are rooted in and perpetuate stigma. HIV stigma impedes HIV prevention, testing, engagement in healthcare, and adherence to medication. In 2015, Michael Johnson, a Black gay college student in St. Charles County, Missouri was tried and convicted based on allegations that he did not disclose his HIV status to multiple partners. Media coverage of the case was widespread. While media is known to shape public perceptions of people living with HIV, few studies have examined recent HIV criminalization cases to understand how the media produce conceptions about HIV disclosure, innocence, and guilt.
Methods: We conducted a content and textual analysis of 90 articles and five videos from local and national media sources. Open and axial coding were used to develop a code book. Once the code book was set, four coders coded the data. Inter-rater reliability was over 90%. This analysis focused on the descriptions of Michael Johnson's character and behavior.
Results: Findings revealed consistent framing of innocence and guilt based on cultural assumptions about black gay men who are living with HIV. Michael Johnson was described as dishonest about his HIV status; media frames draw on ideologies of homophobia and racism to present Johnson's sexuality as secretive and hypersexual, evidenced by discussions of secret sex tapes; engagement in consensual condomless sex was framed as deception, placing sole agency and responsibility onto Johnson; and Johnson was presented as lying to medical staff about his sexual behavior.
Conclusions: Media is a key disseminator of facts and ideologies about people living with HIV. Media coverage of this case contributes to racialized, gendered, sexualized notions of HIV fear and stigma. We examine how media can improve upon the accuracy of information presented in HIV related legal cases, discuss the role of media ideologies found in our study in bolstering an environment of HIV stigma and impede prevention efforts, and examine how media narratives promote ideas of HIV-positive people and Black gay men as deceptive and dangerous to broader society.

Experiences and impacts of homophobia and transphobia

TUPED526

Characterizing experiences of conversion therapy among midlife and older MSM from the Multicenter AIDS Cohort Study (MACS)

S. Meanley[1], R. Stall[2,3], O. Dakwar[4], S. Haberlen[5], J. Egan[2,3], M. Friedman[3,6], S. Shoptaw[7], L. Teplin[8], M. Plankey[4]
[1]University of Pennsylvania School of Nursing, Family and Community Health, Philadelphia, United States, [2]University of Pittsburgh Graduate School of Public Health, Behavioral and Community Health Sciences, Pittsburgh, United States, [3]Center for LGBT Health Research (UPitt), Pittsburgh, United States, [4]Georgetown University Medical Center, Department of Medicine, Division of Infectious Diseases, Washington, United States, [5]Johns Hopkins University Bloomberg School of Public Health, Epidemiology, Division of Infectious Disease Epidemiology, Baltimore, United States, [6]University of Pittsburgh Graduate School of Public Health, Infectious Diseases and Microbiology, Pittsburgh, United States, [7]University of California, Los Angeles, Family Medicine and Psychiatry and Biobehavioral Sciences, Los Angeles, United States, [8]Northwestern University Feinberg School of Medicine, Psychiatry and Behavioral Sciences, Chicago, United States

Background: Midlife and older men who have sex with men (MOMSM; 40+ years) in the US came of age during an era when same-sex attractions were stigmatized as pathological disorders amenable to being eliminated by conversion therapies (CT). Leading scientific organizations have denounced CT as harmful to the well-being of sexual minority individuals, yet it remains legally practiced in 41 states in the US. Little data exists regarding the prevalence of lifetime CT (LCT) among MOMSM; therefore, we aimed to describe and characterize LCT experiences in this population. We also examined whether being HIV+ serostatus was correlated with LCT.
Methods: 1,238 MOMSM in the Multicenter AIDS Cohort Study (mean age=61.5 [*sd*=8.56] years, 30% racial minority, 49% HIV+) in Baltimore, Chicago, Pittsburgh, and Los Angeles completed survey questions ascertaining LCT (type, age initiated, frequency, duration, and whether self-initiated) from 2016-2017. We determined the prevalence of LCT and using multivariable logistic regression to estimate the odds of LCT by HIV status, adjusting for age, race/ethnicity, MACS enrollment wave, and education.
Results: (N=219) of participants reported LCT, 58% (N=126) of whom were HIV+. The average age of CT initiation was 22.7 (*sd*=10.56) years. The most common CT types reported were psychotherapy (39%), group-based therapies (23.1%), and religion-based CT (18.4%). 25.8% reported undergoing CT for 6+ months and 37.7% indicated CT session frequencies of 1+ per week. 35.6% reported having little to no control over the decision to initiate CT. Although being HIV+ and older were positively associated with LCT, neither co-factor was statistically significant, however MACS enrollment after 2001 was. There was a statistically significant negative association with being white and having any college education with LCT (See Table).

Socio-demographics	Multivariable model Odds Ratio (95% CI)	p
Age, 10-year increase	1.18 (0.95, 1.47)	0.13
HIV status Negative Positive	 1(reference) 1.14 (0.83, 1.57)	0.41
Race/Ethnicity All other minority White	 1 (reference) 0.54 (0.38, 0.77)	0.0007
Enrollment Wave Pre-1987 Post-2001	 1 (reference) 1.96 (1.32, 2.90)	0.0008
Education Level High School or Less Any College	 1 (reference) 0.64 (0.43, 0.94)	0.024

[Odds ratios with 95% confidence intervals and P values of lifetime conversion therapy estimated with multivariable model]

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

Conclusions: Lifetime CT was not uncommon among MOMSM in this sample. How CT shapes health and well-being over the life course among MOMSM independent of age, HIV status, race/ethnicity, and education remains unknown, warranting further investigation. Continued legislative efforts prohibiting CT may seek to benefit the well-being of future generations of MOMSM as they age into midlife and older adulthood.

TUPED527

Gender-based violence against men who have sex with men (MSM) and transgender persons in humanitarian settings and its impact on their access to health care

R.J. Figueiredo
APCOM Foundation, Bangkok, Thailand

Background: MSM and transgender persons experience humanitarian crises and engage with humanitarian action differently due to a number of reasons. While they may suffer sexual and gender based violence ordinarily in their daily lives, their vulnerability is heightening during man-made and natural disasters. In Asia, this vulnerability is exacerbated because of poor legal protections, blind spots in disaster preparedness and response mechanisms, inadequate training of service providers and responders and the unavailability of data related to MSM and transgender persons in these settings.
With an improved understanding, it will become possible to design responsive approaches to reach out to these communities, before, during and after crises and create an enabling environment for them to access services and articulate their needs.
Description: APCOM conducted an online survey called the Asia Pacific Survey on Gender Based Violence in Humanitarian settings. This survey was promoted through social media channels, community list-serves and through word of mouth. 145 respondents answered the survey from across the region. The majority of the respondents were MSM and transgender persons.
Lessons learned: Some of the key lessons learned from this survey are that transgender persons are more likely to suffer from sexual and gender based violence in humanitarian settings than men who have sex with men. Sexual expression and gender identity continue to pose the most risk to vulnerable communities accessing a broad range of services including health care. A majority of the respondents indicated that they were most likely to suffer from sexual and gender based violence from immediate family members and intimate partners during crises.
Conclusions/Next steps: APCOM in partnership with IPPF Humanitarian, UNWomen and EdgeEffect is hosting a Regional Consultation on LGBTIQ inclusion in Humanitarian Action in May 2018 in Bangkok. This consultation will build on the findings of this online survey to develop a broad based consensus among key stakeholders and stimulate dialogue on how inclusion of LGBTIQ communities in the DRR, response and resilience can reduce sexual and gender based violence when these communities access a broad range of services including healthcare.

TUPED528

Implication of punitive law on HIV/AIDS programming for men who have sex with men in Nigeria

T. Oke[1], A. Ogunbajo[2]
[1]University at Buffalo, State University of New York, School of Social Work, Buffalo, United States, [2]Brown School of Public Health, Behavioral and Social Sciences, Providence, United States

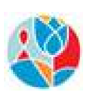
Background: Organizations in homophobic countries with anti-LGBT laws find it extremely difficult to reach an already hard-to-reach population such as men who have sex with men with HIV/AIDS services. In January 2014, the former president of Nigeria signed a same-sex marriage prohibition bill into law, further criminalizing any same-sex amorous relationship with a 14-year imprisonment, and a 10-year prison sentence for organizations who supports same-sex movements/activities. This draconian law made it almost impossible for gay/bisexual men and other men who have sex with men (MSM) to access HIV/AIDS services within the country, and made it particularly challenging for HIV service organizations to reach this key population.
Methods: A qualitative study was conducted to explore the impact of the same-sex marriage prohibition act (SSMPA) on HIV/AIDS programming for MSM in Nigeria. A convenience sampling of two nonprofit organizations working with key populations in Nigeria, and 20 LGBT-identified individuals were selected and interviewed for this study. In-depth interviews were conducted between October to December 2014 with the participants and service organizations, with questions focusing on what has changed since the anti-gay law was enacted. Interviews were transcribed verbatim and assigned into descriptive categories using a coding scheme.
Results: Findings from this study confirmed a significant reduction in HIV/AIDS services for MSM in Nigeria. MSM participants reported concerns to accessing HIV services at healthcare settings for fear of being handed to the police. Reports from the HIV service/LGBT-focused organizations indicate low turn-out of MSM to community events that promote HIV prevention, testing and treatment. Results also confirmed that MSM have been further driven underground, and would rather avoid places and/or services where they could be easily identified as LGBT.
Conclusions: It is pertinent to ensure that key populations regardless of sexual orientation and gender identity have adequate access to HIV/AIDS prevention, treatment and support services. Strategic advocacy is needed towards repealing specific portions of the anti-LGBT law in Nigeria, especially the part that targets HIV service organizations, as this will continue to inhibit HIV services to MSM. The UNAIDS goal of 90-90-90 seems impractical without addressing this issue at the local, national and international levels.

TUPED529

Experienced homophobia and HIV infection risk among U.S. men who have sex with men

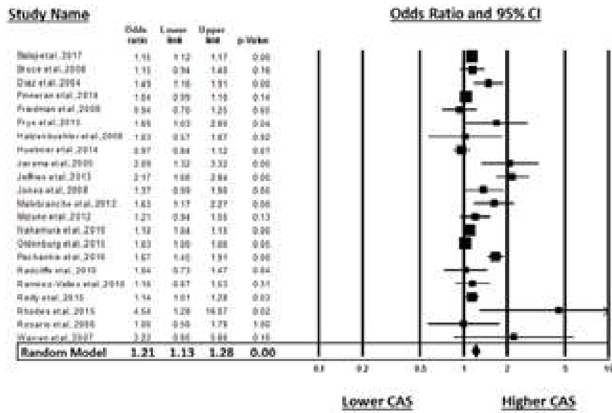
W.L. Jeffries IV[1], S.A. Flores[1], C.R. Rooks-Peck[1], R.J. Wolitski[2], D.J. Gelaude[1], L.A. Belcher[1], P.M. Ricks[3], G.A. Millett[4]
[1]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [2]U.S. Department of Health and Human Services, Office of HIV/AIDS and Infectious Disease Policy, Washington, DC, United States, [3]Centers for Disease Control and Prevention, Field Epidemiology Training Program, Atlanta, United States, [4]amfAR, The Foundation for AIDS Research, Washington, DC, United States

Background: In the United States, men who have sex with men (MSM) compose 2% of the population, but they accounted for 70% of HIV infections diagnosed in 2016. Among MSM, HIV disproportionately affects African American and Latino men. Experienced homophobia—negative treatment that MSM encounter due to their sexual orientations—can promote psychosocial stressors that contribute to sex risk behaviors and antiretroviral therapy nonadherence, which promote HIV infection. Homophobia may be especially harmful for African American and Latino MSM, among whom homophobia interacts with other social factors (e.g., racism) that promote HIV vulnerability. We used meta-analytic techniques to examine experienced homophobia's association with HIV infection and factors that contribute to infection.
Methods: We searched EMBASE, PubMed, PsycINFO, and Sociological Abstracts to acquire data from U.S. studies published during 1992-2017. Studies examined experienced homophobia in relation to: condomless anal sex (CAS), HIV-discordant CAS, number of sex partners—which we combined into an index of sex risk behavior—antiretroviral therapy adherence, viral suppression, and HIV infection. We coded effects for study samples and separately examined samples containing >50% African American, Latino, or white MSM. Random-effects models yielded pooled odds ratios (ORs) and 95% confidence intervals.
Results: Thirty-seven studies provided 146 effect sizes. Experienced homophobia was associated with having CAS (OR=1.21, 1.13-1.28; k=22), HIV-discordant CAS (OR=1.66, 1.29-2.13; k=4), a higher number of sex partners (OR=1.16, 1.13-1.19; k=5), any sex risk behavior (OR=1.32, 1.25-1.40; k=35), and HIV infection (OR=1.34, 1.10-1.64; k=11). Experienced homophobia's association with having any sex risk behavior was stronger in samples containing >50% African American MSM (OR=1.55, 1.28-1.88; k=8) or >50% Latino MSM (OR=1.31, 1.16-1.49; k=13) than in samples containing >50%



white MSM (OR=1.09, 1.02-1.18; k=7). The number of effect sizes for antiretroviral therapy adherence (k=1) and viral suppression (k=1) was insufficient for analysis.

Conclusions: Experienced homophobia is associated with sex risk behavior and HIV infection among U.S. MSM. Its relationship with sex risk behavior is particularly pronounced among African American and Latino MSM. Future research is needed to understand causality in these relationships, the role of interventions to reduce homophobia, and homophobia's effect on antiretroviral therapy adherence and viral suppression.



[Association between experienced homophobia and condomless anal sex (CAS) among U.S. men who have sex with men]

Laws and policies regarding access to HIV treatment and medical devices, including Intellectual property and trade regimes, competition law, price regulation, etc.

TUPED530

Foreign nationals' access to HIV services in the Republic of Tajikistan: Achievements and challenges

R. Kurbonova
International Organization for Migration in Tajikistan, Migration Health Unit, Dushanbe, Tajikistan

Background: Tajikistan is country of origin, transit and destination for migrants. While research predominantly focused on Tajik migrants' access to HIV services abroad, foreign nationals in the country were left out. The study therefore aimed at analyzing the current practice, regulations and possible gaps concerning foreign nationals' access to HIV services in Tajikistan.

Methods: Data collection and analysis were carried out during 2012 to 2017. Desk research comprised the analysis of official reports, statistical data, international and national legislation, national healthcare programmes, scientific publications, and documents from UN agencies. The findings were supplemented by qualitative interviews with HIV experts, employers, foreign nationals, migration service, NGOs.

Results: Two discriminatory requirements had been abolished from Tajik legislation in the last decade: the deportation of foreign nationals living with HIV (2008), and compulsory HIV testing for migrants who apply for a visa valid for more than 3 months (2014). Moreover, foreign nationals living with HIV were granted access to free antiretroviral therapy (ARVT). The achievement of this policy is that foreign nationals use the services offered: 6,779 underwent HIV testing, 3 migrants from Kazakhstan and Russia receive free ARVT in 2017.[1] At the same time, the study revealed some gaps in applying policy into the practice: the requirement of HIV testing for obtaining a work permit, and the occasional requirement of HIV testing for a visa. Another challenge identified is the lack of knowledge among foreign nationals about their entitlement to use HIV services in Tajikistan, which can be attributed to the lack of cultural mediators and information materials on HIV prevention in the migrants' languages.
[1] Dilshod Saidi, Deputy of the Republic Center on Prevention and Control of AIDS

Conclusions: Tajikistan's policy of guaranteeing migrants' access to HIV testing and free ARVT ensures their right to health. Still, as the study shows, this commitment has to be accompanied by information and education measures and by a thorough application of a discrimination-free legislation on all levels. Moreover, the results suggest enhanced cross border cooperation between Tajikistan and migrants' countries of origin in order to be sure that referred patients continue ARVT at home.

TUPED531

Is it business unusual? Access to medicines for PLHIV in East Africa through using TRIPS flexibilities

M. Mulumba
Center for Health, Human Rights and Development (CEHURD), Human Rights, Kampala, Uganda

Background: The health systems in the East African Countries (EAC) continue to bear a heavy burden of diseases including HIV. A majority of people from these countries can barely afford to access essential medicines required for treatment. A low domestic production of pharmaceutical products within the region and non-willingness of local governments to commit adequate resources continue to frustrate availability of essential medicines to communities in need. Intellectual property rights (IPRs) protecting essential medicines have increasingly been highlighted as one of the factors affecting access to essential medicines including the much needed medicines for persons living with HIV. This paper seeks to highlight the current effort in utilizing the available policy space in IPRs for access to medicines.

Description: While the TRIPS Agreement and the EAC Regional Intellectual Property Policy provide an opportunity for flexibilities in which IPRs in pharmaceutical products can be exploited in public interest, there is very little evidence that the EAC countries are exploiting these flexibilities to improve access to essential medicines for people in their countries. Additionally, there is equally little evidence that stakeholders in the region are dialoguing on the issues which affect the use of flexibilities to promote access to pharmaceuticals. This means that while efforts may be going on to promote the use of trips flexibilities, the isolated manner in which they are being implemented has minimized their ability to create an impact both within their countries and their regions.

Lessons learned: Our past advocacy efforts have indeed confirmed the findings of the High-Level Panel on improving access to medicines, that numerous incoherencies and troubling practices have obstructed sovereign freedom of governments in using flexibilities to promote public health in the East-African Countries.

Conclusions/Next steps: This paper concludes that promoting Access to Medicines for PLHIV in East Africa through Using TRIPS Flexibilities has to move from business as usual to business unusual. This requires that EAC countries should urgently implement the EAC Regional Intellectual Property Policy, build consensus and empower stakeholders to advocate for the exploitation of the TRIPS flexibilities to ensure access to essential and better medicines in the region.

TUPED532

Going to law for PrEP: A case study from England

Y. Azad, D. Gold, K. Smithson
National AIDS Trust, London, United Kingdom

Background: PrEP implementation has been relatively slow in health systems around the world, with cost being a key consideration. In England the relevant decision-making body to commission the drug to be used for PrEP was understood to be NHS England, who have historically commissioned all anti-retrovirals, including for prevention purposes such as post-exposure prophylaxis.

Description: One reason for the argument in England on responsibility to commission PrEP is the separate organisational responsibilities for prevention and treatment in the English health system. Whilst treatment

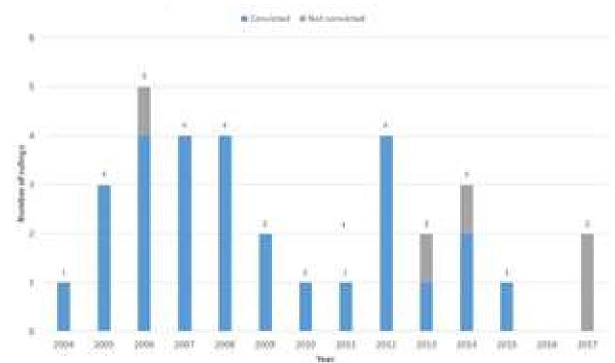
services may be relatively well funded, prevention very often is not. PrEP is therefore a challenge - a prevention intervention, but at treatment prices.
After two and a half years considering the case for PrEP, NHS England suddenly abandoned their process, stating that they did not have the legal powers to commission the drug for PrEP, because it is prevention rather than treatment. NAT took NHS England to judicial review and won. An essential element in this legal victory was the successful framing of PrEP as not only being a preventive intervention, but also treatment. NHS England were forced to recommence consideration of the case for PrEP. In December 2016 they announced plans for a large-scale implementation trial of PrEP as the first stage towards more general roll-out.
Lessons learned: Litigation was immensely effective in removing obstacles to PrEP implementation, when combined with community activism, political engagement and media work. The court case was a key opportunity to explain the effectiveness of PrEP and rebut opposition and HIV stigma across national media. It resulted in a surge in interest in PrEP uptake, in community and media discussion, and in parliamentary pressure. This activity associated with the court case created a political momentum which meant it was very difficult for NHS England not to agree to provide PrEP in some form or other.
Conclusions/Next steps: Advocacy will continue for a timely move from the trial to full roll-out of PrEP.

TUPED533

Did pattern of court rulings in Sweden regarding HIV as a criminal act change in Sweden since new recommendation from The Public Health Agency of Sweden?

E. Blandin, M. Rehn, P. Gröön
Stockholm County Council, Department of Communicable Disease Controle and Prevention, Stockholm, Sweden

Background: HIV infected persons are obliged to inform and protect any sexual partner[1]. It is a criminal offence to risk infecting someone with HIV, with intent „aggravated assault" and "negligence". In 2004, a ruling by the Supreme Court stated that unprotected sex conducted by an HIV-positive person should not be assessed as an act of intent unless the offender had knowledge of a high probability of transmission and/ or reckless behaviour or violence. The Supreme Court also stated that not using a condom should always be regarded as an unaccepted risk. In 2012 the recommendation from The Public Health Agency of Sweden was published regarding what should be defined as "well-treated hiv" with very low risk for transmission.
Methods: Court records for judicial decisions in HIV cases during 2004-2008 were compared with for judicial decisions during 2009-2012 and 2013-2017.We compared the court records from the three time periods with regards to verdict and the courts' analysis of
- well-treated HIV as defined in the recommendation from The Public Health Agency of Sweden
- deportation in the verdict
- concrete risk for transmission
- detention
Results: During 2004-2017 we identified 33 Court records for judicial decisions in HIV cases: 17 during 2004-2008 (mean: 3.4/year), 8 during 2009-2012 (mean: 2.0/year) and 8 during 2013-2017 (mean: 1.6/year). Twenty-eight were convicted and five where not. Four (26%) verdicts in 2004-2008, one (13%) during 2009-2012 and none during 2013-2017 included deportation. The corresponding figures regarding detention was ten (59%), five (63%) and three (38%). Concrete risk of transmission was discussed during all three time periods (71%, 75% and 88 % respectively). In two cases (not convicted) during 2013-2017 the defendant was defined as well treated according to the Public Health Agency of Sweden
Conclusions: Our analyses suggest that the recommendation from The Public Health Agency of Sweden regarding „well-treated HIV" has had a clear influence in court rulings after 2012. This also applies to the number of detainees, deported and convictions



[Court rulings regarding HIV as a criminal act, Sweden 2004-2017]

TUPED534

Safeguarding access to generic treatment: Experience of DNP+ in opposing TRIPS-plus measures in the Regional Comprehensive Economic Partnership Agreement negotiations

H. Shankar Singh[1], A. Royal[2], N. Jina Devi[2], A. Adhikari[2], Delhi Network of Positive People (DNP+) Study Group
[1]The Delhi Network of Positve People, Advocacy, New Delhi, India, [2]Delhi Network of Positive People (DNP+), New Delhi, India

Background: Regional Comprehensive Economic Partnership Agreement (RCEP) negotiations are taking place between 16 Asia-Pacific countries. Leaks of the RCEP intellectual property chapter show provisions that would undermine generic production and supply of HIV, hepatitis C, TB and other medicines from India.
Description: DNP+ has been working on overcoming patent barriers to affordable generic medicines since 2005 including advocacy on trade agreement negotiations such as EU-India FTA. DNP+ followed the RCEP negotiations concerned that it might include provisions in excess of those required by the WTO´s Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPS). TRIPS-plus measures are known to undermine access to generic medicines. DNP+ worked with legal experts to understand the implications of the leaked text of RCEP.
The analysis showed that demands by Japan and South Korea were TRIPS-plus including patent terms longer than 20 years, data exclusivity etc. DNP+ commenced advocacy with law and policy makers and negotiators and sensitisation of general public and media on the implications of RCEP negotiations on access to medicines. In 2017, DNP+ presented their concerns directly to the trade negotiators of RCEP countries at a stakeholder consultation and also courted arrest during a protest at the negotiating venue. The raising of key public health concerns with RCEP resulted in public commitments from the government of India that it would not agree to TRIPS-plus measures that undermine access to medicines.

[RCEP Protests by DNP+]

Lessons learned: People living with HIV are a critical stakeholder in trade agreement discussions as intellectual property demands in such negotiations can undermine access to treatment. Advocacy with law and policy makers is important as they are often unaware of the exact implications of such negotiations. Community advocacy has a strong impact on negotiators. Community literacy on treatment and intellectual property provides a strong foundation for sustained advocacy on trade agreement negotiations that take several years.
Conclusions/Next steps: RCEP negotiating countries have stated that they will sign the agreement in 2018. However, the text of the agreement has not been made public to allow for proper analysis and community consultation. Governments should not agree to any TRIPS-plus measures in RCEP to ensure continued generic production and supply.

TUPED535

Comparing compulsory and voluntary licenses in Brazil: Lessons from efavirenz and atazanavir cases

P.H. Marques Villardi Miranda[1], F. Fonseca[1], M. Vieira[2], C. Alves[1], C. Scopel[1]
[1]Associação Brasileira Interdisciplinar de AIDS, Grupo de Trabalho sobre Propriedade Intelectual, Rio de Janeiro, Brazil, [2]Independent Consultant, Rio de Janeiro, France

Background: Brazil has a public and universal health care system (SUS), that offers free of charge ARV medicines for all those in need. Since 1996 when Brazil changed its law and complied with TRIPS requirements the universal access policy sustainability is under threat. ABIA/GTPI is civil society organization working to reduce the impact of monopolies in public health. Issued in 2007, the compulsory license (CL) for the antiretroviral (ARV), efavirenz is a landmark for the pro-access to medicines policies. However, from 2008 the Partnerships for Product Development (PDP), a policy based on voluntary licenses, technology transfer and prices set in contracts dominated this field in Brazil. A PDP between BristolMyersSquibb (BMS) and Fiocruz to produce atazanavir was signed in 2011. After analyzing the contract's prices and timelines, we compared the two approaches in order to determine which one was the most effective from an access to medicines and guaranteeing the sustainability point of view.
Methods: ABIA/GTPI selected four categories to conduct the comparison: (a) savings to the public health system; (b) percentage of price reduction; (c) months to produce the ARV locally; and (d) royalties to the patent holder. The data used is from published works, public databases and BMS-Fiocruz contract.
Results: The efavirenz CL generated savings of US$ 104 million (2007 to 2011). The atazanavir voluntary license generated US$ 17 million. In relation to percentage of price reduction, efavirenz CL reduced the price paid by SUS in 58%, the reduction in the atazanavir case was 6%. Efavirenz was produced locally in 21 months. The national version of atazanavir was only available 26 months after the contract signature. Regarding royalties, Brazil paid to Merck in the efavirenz CL 1,5%, whereas the royalty paid by Brazil to BMS is set in contract in 4,5%.
Conclusions: The study showed that in the four parameters selected - savings, price reduction, months to produce locally and royalties paid -, the CL was more effective than the PDP. It is possible to say, therefore, that the efavirenz compulsory license was most effective in guaranteeing the sustainability of the access to medicines' policies in Brazil.

TUPED536

Does Brazil pays a fair price for TDF? Civil society struggle to guarantee the sustainability of access universal policies

C. Alves[1], P. Villardi[2], F. Carvalho[2], C. Scopel[2]
[1]Interdisciplinary Brazilian AIDS Association, Working Group on Intellectual Property, Rio de Janeiro, Brazil, [2]Interdisciplinary Brazilian AIDS Association, Rio de Janeiro, Brazil

Background: In 1996, two important legislative changes tool place in Brazil: the law 9.313 established universal access to ARVs and the law 9.276 that changed the intellectual property (IP) laws, allowing patents on pharmaceuticals. ABIA/GTPI is a civil society organization working to reduce the impact of monopolies in public health. Tenofovir (TDF) is a drug to treat HIV, incorporated by the Brazil under monopoly with high prices. ABIA/GTPI struggled in many ways to lower TDF price.
In 2012, the Brazilian patent office rejected the TDF's patent. In the same year, TDF became part the new policy to strengthen the Brazilian pharmaceutical industry by the Ministry of Health (MoH). A Partnership for Product Development (PDPs). A contract setting the API price was signed between a public (FUNED) and private laboratory (NORTEC) to produce TDF locally. After years in the public domain and local produced, ABIA/GTPI expected to see significant reductions TDF prices. That did not happened. Therefore, ABIA/GTPI investigated the composition of the national TDF price and compared it with other prices.
Methods: ABIA/GTPI calculated possible TDF prices, estimating the cost of production and with the different API prices. With this, we compare the prices actually acquired by the MoH with the prices that the medicines produced through the PDP should have and the lowest international prices.
Results: In 2014, the TDF price paid by the MoH was $580.81 ppy. This was 5.5 times higher than the price projected considering the costs and API price fixed in the FUNED-NORTEC contract; 3.4 times higher than the price calculated using the highest price of national available API in 2014; and 12 times higher using the costs and the international lowest generic API price.
Conclusions: The TDF price paid by MoH were at least three times higher than they should be. After all the efforts of civil society and other sectors to put TDF in the public domain in Brazil, even the generic price did not accomplished to contribute to the sustainability of the universal access policies. There is need for further debate on national generic prices from a human rights perspective.

TUPED537

The role of civil society in shaping the political environment for the incorporation of new technologies in Brazil: The cases of dolutegravir and TDF/FTC

F. de Carvalho Borges da Fonseca[1], P. Villardi[2], V. Terto Jr.[2], O. Cerqueira dos Santos[2]
[1]ABIA - Brazilian Interdisciplinary Aids Association, Project Management, Rio de Janeiro, Brazil, [2]ABIA - Brazilian Interdisciplinary Aids Association, GTPI, Rio de Janeiro, Brazil

Background: As Brazil has one of the oldest HIV patient cohorts in developing countries, it anticipates the need to access newer technologies as well as related challenges. However, since 2010, the internal political environment has been undermining the human rights perspective and the ability to confront monopoly powers over key technologies. As result, Brazil is unable to keep its protocols updated, in contradiction to its legacy of reducing the gap between rich and poor countries when it comes to access to the best treatment and prevention options. From 2014 onwards, civil society intensified efforts to reverse this scenario by adopting multiple strategies that involved campaigns, protests, events, patent oppositions, consultations, publications and advocacy. Such efforts lead to the successful incorporation of Dolutegravir as first line treatment for over 100.000 people, despite strong opposition by the government initially. Civil society has also ensured the incorporation of TDF/FTC as a prevention tool, including though the public consultation with the highest number of submission in the history of the National Commission for the Incorporation of Technologies (CONITEC).

Description: ABIA/GTPI championed and documented numerous efforts to promote policy change around treatment and prevention options. The documentation was organized to reveal the chronology of steps taken by civil society, relating them with policy milestones around the incorporation of Dolutegravir (2016) and TDF/FTC (2017).
Lessons learned: As regards to Dolutegravir, civil society efforts were essential for reversing the denial of incorporation and for the expansion in the offer from third-line to first-line through decree 35. Demand creation coupled with public pressure also resulted in price drop from U$ 9.88 per unit to U$1.53. In relation to TDF/FTC, campaigning has led to 3.543 submissions in the public consultation over the protocol for use of TDF/FTC as PrEP, enabling its approval despite opposition by conservative forces. Patent opposition filed by ABIA/GTPI in 2016 led to a patent rejection in 2017, which was instrumental to bring the price down from U$ 752 to U$ 276.
Conclusions/Next steps: Incorporation of technologies relies as much in technical debates as in political debates. Civil society ensures that a rights-based approach prevails in both levels.

Human rights programmes

TUPED538

Combating the great challenge/barrier of ignorance of fundamental human lights among sex workers in Nigeria as it makes them susceptible to violence, abuses, harassment, intimidation and STIs/HIV

A. Anonyuo[1], L. Amadi[2], C. Anidiobi[3], S. Haruna[4,5], C. Anonyuo[1]
[1]Renewed Initiative against Diseases and Poverty (RENAGAIDS), Abuja, Nigeria, [2]Mind Renewal Women Initiative, Lagos, Nigeria, [3]Advocates for Women's Health and Human Rights Initiative, Abuja, Nigeria, [4]Society for Women Development, Abuja, Nigeria, [5]Society for Women's Development, Abuja, Nigeria

Background: Criminalizing sex work/arresting sex workers in Nigeria is not in line with approved government policies to prevent HIV by promoting unfettered access to interventions to general population which includes sex workers who form a fulcrum of Key Affected Population. Nigeria is a signatory to human rights treaties such as Universal Declaration of Human Rights (UDHR), Convention on Elimination of Discrimination against Women (CEDAW) and others but ignorance of fundamental human rights by sex workers have exposed them to all manners of discriminatory and dehumanizing treatments in the hands of the Law enforcement agents, pimps, clients, brothel owners, etc. The ignorance of their Rights have led to law enforcement agents (LEA) continuous raiding and arresting of sex workers coupled with material, financial and sexual extortion which threatens sex workers capability to negotiate safe sex with their clients.
Methods: In a study, a cross sectional study of purposively selected 850 female sex workers working in Jos, Lafia, Makurdi, Lokoja and Kaduna. Data collection technique using InterPersonal Communication (IPC) and Focus Group Discussions (FGD). Their age ranges from 18 - 40. Mean number of years for which they had been in sex work was two years.
Results: Results showed that all of selected 850 sex workers were stark ignorant of their fundamental human rights, this ignorance have given LEA the audacity to carry out uncoordinated raids, arrests, extort money, confiscate valuables and sometimes rape them. They most times demand for unprotected sex even after they pay for their freedom. These raids and arrests have increased their vulnerability to HIV and other STIs. After such raids or arrests, about 80 percent of the sex workers reported having unprotected sex with clients to attract more money to be able to replace some of the lost properties and recover financial losses.
Conclusions: Ignorance of the fundamental human rights by sex workers is undermining HIV prevention efforts and other interventions such as assertive skills, safe sex messages and condom education and distribution. Nigerian Law enforcement tactics, respecting and protection of human rights and other guidelines must be brought into alignment with international best practices to prevent further spread of HIV.

TUPED539

Lesson learned from the global fund's removing legal barriers module in Indonesia

A. Larasati, F. Aotari, R. Gunawan
Lembaga Bantuan Hukum Masyarakat, Jakarta, Indonesia

Background: Key affected populations in Indonesia constantly face human rights violations, creating legal barriers to HIV services. Such barriers discourages and prevents key affected population to access the much needed-health services. Further, it fuels Indonesia AIDS epidemic, of which is already in a high HIV burden. In an effort to remove such barriers, a program was proposed under the Global Fund to Fight AIDS, Tuberculosis and Malaria's New Funding Model grant for Indonesia in 2016.
Description: The program strategy is to work bottom up - by raising human rights and legal awareness of key affected populations, healthcare workers, and legal apparatus; creating community paralegal system; as well as to inform national policy makers and wider relevant actors through some series of research and analysis, and recommendations for policy reform.
Lessons learned: As many as 362 people from key affected populations were trained on legal and human rights issues, where 196 of them were then further trained to be community paralegals. The program also delivered human rights sensitization training for 267 healthcare workers, whom praised the excellence of such initiative. A holistic legal review and documentation on human rights violations against key affected populations were conducted, where it is found that the majority of human rights violations occurred in healthcare settings.
Despite its success in delivering program expectations, challenges were present all the way from program development to the implementation. The negotiating process prior to grant signing lacks the understanding of the unique nature of human rights advocacy and programming, resulting in some key rights programming were deleted from the initial proposal. There was not many rooms created to enable community to address urgent legal issues arose throughout program implementation. The program implementation was also unsuccessful in widening national advocacy networks.
Conclusions/Next steps: Holistic understanding of how human rights advocacy works, the ability to integrate human rights programming with broader HIV program, and continuation of ongoing advocacy efforts are utmost important. When human rights programming within AIDS response is treated as business as usual, it would unlikely contribute in removing legal barriers to access to services for key affected populations.

TUPED540

Outreach legal services - completing the harm reduction response in Kenya

T. Wandera Odunga
KELIN, Key Populations, Nairobi, Kenya

Background: In Kenya, people who use drugs are marginalised, stigmatised and criminalised - negatively impacting upon individuals' ability to access essential health care services or claim their rights. In such environments, the full Constitutional guarantee of the right to the highest attainable standard of health for people who use drugs is impossible. KELIN lawyers believe empowered communities and better access to justice (via a lawyer or paralegal) are essential components of the harm reduction response in Kenya.
Description: Drug use in Kenya is concentrated in Nairobi, and along the coast. People who use drugs in these areas face legal issues including Violence, discrimination and arbitrary arrests. Lawyers tend to be inaccessible to people who use drugs - by virtue of cost, geography and stigma; and community paralegal capacity is nascent. Due to the fear of violence and stigma, persons who use drugs do not come out to report cases of human rights violations, seek legal assistance, and cannot freely access harm reduction services.
Lessons learned: In order to strengthen access to justice and access to harm reduction services for drug users - with the broader objective of improving health outcomes and upholding their rights; KELIN and

Nairobi Outreach Services Trust collaborate to support persons who use drugs. People who face human rights violations can report violations to the legal team, receive legal assistance and pro-bono representation in court where necessary. Monthly legal aid clinics are provided to people who use drugs in safe spaces, where they will be comfortable to open up and report cases of violations, including at the NOSET premises and drug dens.

Conclusions/Next steps: Establishing a referral mechanism between NOSET and KELIN for the purposes of providing legal services and advice to persons who use drugs strengthens access to justice for people who use drugs in Nairobi. Case examples include:

· Mr James Kamau* who had been disinherited by her siblings was able to acquire his rightful inheritance.

· Ms Irene Njeri* who had been assaulted by her neighbour was able to access justice after the perpetrator was arrested

TUPED541

"I feel so safe" flexible emergency support in Botswana for sex workers in case of violence

K. Shabane[1,2,3], U.A. Mashumba[4], I. Van Beekum[3], S. Hendriks[3], N. Jagessar[3]

[1]SISONKE Botswana, Programs, Gaborone, Botswana, [2]Botswana Network on Ethics, Law and HIV/AIDS, Gaborone, Botswana, [3]AIDS FONDS, Amsterdam, Netherlands, [4]BONELA, Programs, Gaborone, Botswana

Background: The Emergency Fund aims to provide more flexible financial support to (individual) sex workers in cases of emergency that are related to violence. The fund is part of the Hands Off! programme, aiming to contribute to the reduction of violence against sex workers in Southern Africa Violence is one of the most significant factors affecting the vulnerability of sex workers to HIV& AIDS. Due to their position in society and criminalizing laws, sex workers are vulnerable to physical, sexual and emotional violence from clients, police and the community.

Description: the rapid response system focuses on building mechanisms to respond to cases of violence for the protection of the sex worker community as a whole, the Emergency Fund is for individual cases of violence. It provides flexible financial support to sex workers through sex worker-led organisations, like shelter money in case of rape, urgent applications at court, post trauma counseling, funeral costs as a result of violence or hospital emergency - for example initial consultation During the implementation of previous sex work programmes,sex worker-led organization Sisonke often sent requests to donors for small funding to assist sex workers in need of emergency to no avail. Normally, these are never thought of as possibilities when developing proposals and workplans as they are not predicted. Through the Emergency Fund 9 sex workers received support .

Lessons learned: We learnt that with the emergency fund system it helps sex workers to be able to report cases as they know they will be helped with certain costs for redress or even help them with their costs at the hospital. This helps with fighting the spread of STI's and they can access services such as PEP. Furthermore it should be promoted more widely so that SW are better aware and less reluctant to report a case.

Conclusions/Next steps: In Botswana violence is aggravated by criminalization, as sex workers lack access to justice. Laws and policies, including those who criminalize sex work, leave sex workers very vulnerable to physical and sexual abuse. Decriminalization of sex work is necessary to increase access to justice for sex workers.

TUPED542

Changing the situation with human rights violations of people who use drugs. What is really needed

A. Basenko[1], A. Tolopilo[2], P. Skala[1], M. Andrushchenko[1], S. Tkalya[3], E. Kuvshynova[4], L. Hripkova[5], O. Dymaretskyi[6]

[1]Alliance for Public Health, Policy and Partnership, Kyiv, Ukraine, [2]Odessa Human Rights Group 'Veritas', Odessa, Ukraine, [3]CF 'Hope and Trust', Kyiv, Ukraine, [4]Convictus Ukraine, Kyiv, Ukraine, [5]CSO 'Our Help', Slovyansk, Ukraine, [6]CF 'Meridian', Poltava, Ukraine

Background: Ukraine has the second-largest HIV epidemic in Eastern Europe and Central Asia. The epidemic is closely associated with injecting drug use. Human rights violations and legal barriers for people who inject drugs are still the case. Ukraine is is one of the 9 countries in international advocacy program PITCH: Partnership to inspire, transform and connect HIV response.

Methods: To evaluate the actual situation with human rights violations of PWID including OST patients and to estimate the need in legal support there was carried out a investigative research based on tne next methods: questioning - 250 respondents (including 47 young IDUs); studying the registration journals of the OST and Druguse Hotline and other database materials; focus-groups (3 groups of PWID/OST), in-depth interviewing (25 community, NGO, medical national and local experts); studying of human rights violation cases.

Results: 92% of adult IDUs and 65% of young IDUs (15-24 years) feels the full absense of their human rights protection. 82% of OST patients reported the denial in access to medical services in public hospitals and clinincs. 86% of OST patients reproting the violations from law-enforcers. 73% of OST reprorted about the problems in employment and 60% have lost their employment as a result of receiving information by the employer about the OST or druguser registration. At the same time as a reply on the question „Where do they appeal in case of human rights violations?" 24% of adult IDUs and 25% of young IDUs respondents reported „nowhere because they don´t know where or don´t trust in help".

Conclusions: Actual legal protection of IDUs is extremely low; Most IDUs are confident that they do not have the actual opportunity to obtain qualified legal assistance; A significant problem is the lack of basic legal knowledge of the IDUs; there is a significant demand for IDUs in obtaining legal knowledge; highly demanded are such forms of legal assistance as legal advice, assistance in drafting legal documents, legal support in contact with the police and treatment in medical institutions, as well as representation in the court.

TUPED543

The Human Rights Defenders Program: Mobilizing cisgender and transgender female sex workers for advocacy, outreach and service delivery

S.B. Shianian, V.X.H. Ho, M. Siew, W.Q.A.b. Wan Daud, L.B. Musa

Project X, Singapore, Singapore

Background: According to WHO, community empowerment is an "absolutely necessary component" of sex worker interventions (WHO, 2012). Research further shows that empowering the community to take charge of HIV intervention programs can contribute to a reduction in HIV by 32% (Lancet, 2014). However, due to multiple intersecting reasons, it is a constant challenge to get sex workers involved in our community and advocacy work.

Description: We created a 16-session capacity building program after three years of research and one feasibility study. The program ran over four months and topics included Digital Storytelling, Human Rights and Feminism, Racial Justice, Sexual and Mental Health, Drugs, Counselling Skills, Suicide Intervention, Financial Literacy, Law, and Project Management. Each session functioned as a platform for participants to exchange ideas and opinions, as well as to increase their knowledge of the issue at hand.

We received sign-ups from 10 current and former sex workers.

The program culminated with participants forming groups to craft a mini project that addresses an issue they are passionate about. These projects were funded by us.

A key feature of this program is that participants were provided a scholarship to attend this program so as to lessen the opportunity costs required to participate.
Lessons learned: The scholarship was crucial to enabling our participants to attend the program. The need to provide for family or personal survival should not be undermined. At the end of the day, participants did not have to make the choice between advocacy or survival.
Most sessions allowed for participants open discussion about the topics and this helped to foster greater understanding between different types of sex workers.
The culmination in group work was crucial to ensure the long-term impact of the program as this provided yet another opportunity for people to work together towards a common goal.
Conclusions/Next steps: Human rights activism in Singapore is highly frowned upon. It is important to destigmatise human rights work and to show that it is multi-faceted. Advocacy is needed for long term change, and it is important to empower sex workers to be part of the fight. We will be running the program again in 2018.

TUPED544

Preserving human rights through involvement of the judicial system and law enforcers

L.A. Okello[1,2], A.K. Karisa[3,4], D.N. Ateka[5]
[1]Reachout Centre Trust, Mombasa, Kenya, [2]Anyones Child, London, United Kingdom, [3]Reach out centre trust, Mombasa, Kenya, [4]Anyones Child, Mombasa, Kenya, [5]HAKI Africa, Mombasa, Kenya

Background: People who use drugs work and live in complex environments dominated by power structures within family, community, workplace and state. They are highly stigmatized and categorized as immoral and a threat to the moral fabric of society. The Kenyan legal frame work and county by laws criminalize behaviours related to pwids exposing them to punishing acts.
Description: Mombasa is a drug trafficking route, making heroin readily available. It estimated that Kenya has 18,327 People Who Inject Drugs (PWID) who have 18.3% HIV prevalence. Over 1730 Cases reported since in the county courts are related to drug use,218 cases of violence,10 cases of mob justices were reported at Reachout since 2016 to November 2017.
From January 2016 to July 2017, Reach out Centre Trust (RCT) engaged the justice system through a Justice Actors conference where 70 Judge, magistrates, lawyers, law enforcers, probation and CSOs were brought together under the theme clemency for social justice for people who use drugs. 140 Law enforces were sensitized on Harm Reduction and social inclusion Health rights. RCT raised awareness through: radio talk shows, 15 religious leaders Muslim,Christian, and 230 family members of MAT client on Human rights for PWIDs.
Lessons learned: Through training and sensitization of law enforcers, judicial system many petty crimes related cases to the PWUDs have been given alternative sentence through the community services from the probation.
Law enforces have been engaging with the RCT paralegals officers hence MAT clients are released without being taken to court.
RCT has been included in the sitting in court users committee where it gives its views and suggestion.
All sentenced MAT clients are able to access treatment without hinderance.
Conclusions/Next steps: There is a need to advance legal protection of people who inject drugs and this can only be achieved through the support of the judiciary. Members of the judiciary should assert their crucial role in advancing justice through use of evidence-based judgments towards the said population. In putting into consideration, there is a need to have a common understanding of people who inject drugs by the judiciary hence the need to have a continuous engagement with the judiciary.

TUPED545

Collaborative efforts of partners through small grants to key population-led organisations on human rights protection

F.A. Iyamu[1], Y.F. Anoemuah[1], O. Ndubuisi[2], N. Turpin[3], M. Egemba[1], F. Esor[1], A. Okorukwo[1]
[1]National Agency for the Control of AIDS, Programme Coordination, Federal Capital City, Nigeria, [2]United Nations Development Programme, Governance & Peace Building, Federal Capital City, Nigeria, [3]ENDA Sante, Gender and Human Rights, Dakar-Fann, Senegal

Background: Legislations in general, particularly in Africa, strongly condemn the activities of Key Population - sex workers, men who have sex with men, and drug users. In the context of HIV, punitive laws in Nigeria penalize these groups, thus creating barriers to access to HIV/AIDS services which impedes effective HIV/AIDS response in the country. Three decades of experience has shown that promoting and protecting human rights are essential for preventing HIV transmission and reducing the impact of HIV/AIDS. Thus, a meaningful partnership and collaboration among partners such as the National Agency for the Control of AIDS (NACA), UNDP Country Office and ENDA Santé, a regional NGO to support KP in defending their rights and improve their access to adequate information and health services is a key strategy to ending AIDS by 2030.
Description: In 2017, the Africa Regional HIV Grant was provided to three rigorously selected national key populations-led organizations (YouthRise, COLaHR and ICARH). These organizations organized capacity building meetings for sex workers, men who have sex with Men and persons who inject drug and other key stakeholders on issues related to HIV/TB and human rights. Issues harnessed were quite different as the different populations had their specific peculiarities and human right issues affecting them from accessing HIV services. Group discussions were used to identify issues under different contexts areas, how it affect their human rights, access to HIV services and proposed advocacy strategies to address the issues.
Lessons learned: The capacity building meetings which used nationally standardized tools were instructive for strengthening key populations associations, documentation and reporting of human rights violations. The support also produced an evidence-based policy brief for advocacy on current quality of service provision, barriers to HIV services and strategies to address them for key and vulnerable populations.
Conclusions/Next steps: The collaboration of development partners and government institutions is a strategy that could positively be harnessed and expanded. This would provide the much-needed civil society institutional strengthening for key population led and focused institutions for a human rights responsive HIV programmes towards ending AIDS by 2030.

Legal advocacy tools and strategies

TUPED546

The activities of the patients' community to improve access to treatment of HIV-positive patients: The role of communications in legal advocacy

Y. Chechotkina[1], M. Rovinskyi[1], K. Rivera[1], A. Leonova[1], S. Dmytriiev[2]
[1]CO 'All-Ukrainian Network of PLWH', PR-Department, Kyiv, Ukraine, [2]CO 'All-Ukrainian Network of PLWH', Advocacy, Kyiv, Ukraine

Background: It is estimated that 238 000 people live with HIV (PLWH) in Ukraine; 88 270 PLWH receive ARV therapy, and 42 150 of them are treated at the state expense. About 40% of the state budget is spent only for the Lopinavir/Ritonavir (LPV/R) drug which has a 13-year monopolistic position in the market. The abolition of the patent for LPV/R will open access to generic versions of the drug and give the state up to $ 13 million in savings. This will allow additionally 125 000 people to be treated. Ukrainian courts are reluctant to hear cases against one of the largest pharmaceutical companies *AbbVie*, that is why and the risk of corrupt decisions always exists.

Description: In May 2016, *the Network* created a precedent by filing a patent opposition to recognize the LPV/R patent as invalid as not novel and obvious. The court refused to examine the patent, and a number of high-profile actions were held to follow each court session during 2017. The judges and the *AbbVie* management were the target audience of these actions. The largest online media (*Ukrainska Pravda, Censor.net, and RBC-Ukraine*) published *the Network*'s experts' blogs on case progress, and *the Network's* website has all related information in Ukrainian, Russian, and English. The information was also distributed to the English-speaking audience through the *Make Medicines Affordable* partnership coalition.

Lessons learned: Correct media messages for judges in combination with vivid and effective promotion campaigns allowed keeping media attention to the trial during a year. The maximum publicity did not allow the court to delay the hearings further and contributed to reducing the influence of the pharmacy's lobby. The court delivered a judgment in favour of the patients' organization under public pressure and appointed patent re-examination in 2018.

Conclusions/Next steps: The milestone of the patent re-examination is achieved. The first such a precedent in Ukraine provides the basis for future demands to increase access to treatment. Challenges related to patent oppositions initiated by patient's organizations could be successfully overcome by bringing public attention using media instruments.

TUPED547

David against Goliath: How concerted action among stakeholders in Brazil overturned a draft bill that aimed to classify HIV transmission as heinous crime

G. Braga-Orillard[1], D. de Castro[2]
[1]UNAIDS, Brazil Country Office, Brasilia, Brazil, [2]UNAIDS, Brasilia, Brazil

Background: Amidst political turmoil, the legislature of 2015 initiated bringing back to vote the text of a bill dated 1999, re-packaged into what was named PL198/2015. It stated that 'the intentional transmission of HIV is a heinous crime'. If the bill became law, all efforts of the country in the response to HIV would have been in vain. Simultaneously, news outlets were pouring out fake news of PLHIV ´gathering in clubs to infect others on purpose´. Therefore, concerted action was key to put pressure in Congress and retract the bill.

Description: By virtue of an active partnership, the Ministry of Health (MoH), UNAIDS and civil society, were expedient in setting-up a strategy to target parliamentarians to bring down the PL198/2015. The strategy was composed of:

(i) production of well-argumented documentation against the bill. Two technical notes were produced by UNAIDS and MoH. They were presented in conjunction with a repudiation note from civil society (ANAIDS) to the President of the Constitution and Justice Committee;

(ii) usage of mechanisms of the legislative process to stall the vote: members of the Parliamentarian Front against AIDS were mobilized to comment the bill and adjourn the vote. The Family and Social Security Committee also presented a motion to reject the bill;

(iii) Mobilization of media outlets and counter argumentation: UNAIDS and partners launched an active social media campaign against the text to influence public opinion;

(iv) use of personal networks to reach out to key parliamentarians: members of civil society sensitized Congressmen to finally have the bill retracted.

Lessons learned: It is arduous to break barriers, it is easier to stop them from being built.

The whole process took two years, amidst the impeachment of President Rousseff. Despite the political turmoil, attempts to reduce the rights of PLHIV did not stop. Building on the strength of each partner was the key to success.

Conclusions/Next steps: A permanent legislative watch has been put in place by UNAIDS to monitor closely proposed bills that can affect negatively and positively the rights of people living with HIV and other key populations. Today, more than 190 bills are being monitored on a weekly basis.

[Images from social media campaign]

TUPED548

Dangerous desires: The criminalisation of HIV endangerment in Victoria, Australia

P. Kidd[1,2]
[1]La Trobe University, La Trobe Law School, Melbourne, Australia, [2]HIV Legal Working Group, Melbourne, Australia

Background: The criminalisation of HIV transmission and exposure represents a controversial expansion of the scope of the criminal law to encompass disease transmission as a criminal subject. In the state of Victoria, Australia, the principal mechanism for HIV criminalisation has been via reckless endangerment laws, however their application to HIV has not been extensively studied.

Methods: A series of HIV-related criminal cases employing the endangerment laws were identified, and access to court records was sought from the County Court of Victoria. The Court granted access to five of the six cases requested. A review of academic and judicial commentary on the endangerment laws was undertaken, as well as a doctrinal analysis of the application of the laws to people with HIV over two decades. The Court-provided materials were analysed to critically examine the practical application of the laws in HIV cases.

Results: This analysis shows that general endangerment laws have been used as a ´proxy charge´ in HIV transmission cases; that highly prejudicial evidence about HIV transmission is routinely put before juries despite not being a fact in issue; and that in some cases, defendants appear to have been sentenced as if they were on trial for causing another´s HIV infection rather than endangering it. This represents a significant departure from the scope and intent of the endangerment laws as they were passed.

Moreover, the broad scope of Victoria´s endangerment law has resulted in an unreasonably high rate of criminalisation of HIV compared to equivalent jurisdictions without similar laws.

Conclusions: The use of laws criminalising reckless endangerment in cases where HIV transmission is alleged represents a problematic exercise of prosecutorial discretion which has the potential to lead to greater

criminalisation of, and injustice against, people with HIV. Legislative and policy reform is needed to ensure prosecutions are in the public interest and do not counteract public health efforts.

TUPED549

Intimate conviction: The role of churches in the (de) criminalization of sodomy

M. Tomlinson[1], S. Ka Hon Chu[1], R. Elliott[1], P. Wong[2], J. Butler-Mcphee[3], J. Terry[3]
[1]Canadian HIV/AIDS Legal Network, Research and Policy, Toronto, Canada, [2]Canadian HIV/AIDS Legal Network, Development, Toronto, Canada, [3]Canadian HIV/AIDS Legal Network, Communications and Advocacy, Toronto, Canada

Background: Despite advances for LGBTQI rights in some countries, 73 states still criminalize consensual same-sex activity. 36 of these countries are in the Commonwealth of Nations: former British colonies, many in Africa and the Caribbean, where anti-sodomy laws were mostly imposed during the period of British colonial rule. Despite decades of independence, the statutes have been difficult to dislodge and contribute to the overwhelmingly disproportionate HIV burden in Africa and the Caribbean.
Description: The British anti-sodomy law reflected Victorian morality based on narrow Church of England theology. While the Church of England played a significant role in decriminalizing same-sex activity in the UK, a similar process has not occurred in the Commonwealth. With the support of local and international partners, the Canadian HIV/AIDS Legal Network hosted "Intimate Conviction" — the first-ever discussion of the role (past, present and future) of the church in the decriminalization of sodomy.
From October 12-13, 2017, 25 Christian leaders (12 women and 13 men), including many senior clergy and academics from former British colonies, met in Jamaica. The sessions were all open to the public, and although some local conservative church pastors called for a boycott, there were significant interventions by Christians opposed to decriminalization who attended and took opposing views.
Lessons learned: Topics covered included the distinction between Global North and Global South churches regarding decriminalization, the role of criminalization on the church's response to HIV, and the impact of criminalization on women. There was also a rich discussion of the history of church involvement in criminalization and the challenge for church leaders to support decriminalization. Most participants reported that the conference was timely, as the issues of religion and homosexuality were topical in Jamaica after two local senior preachers made public calls for decriminalization.
Conclusions/Next steps: The conference concluded with recommendations on how to encourage more churches to endorse decriminalization, including holding similar dialogues in criminalized contexts, and encouraging more Global South participation in these exchanges. An edited volume of the conference presentations will be produced for use and research by Commonwealth lawyers working on decriminalization, as well as NGOs seeking to engage and partner with faith leaders.

TUPED550

Using the HIV and AIDS tribunal in Kenya to protect rights of PLHIV: A compendium of cases

T. Makokha[1], L. Ghati[2], A. Maleche[2]
[1]Kenya Legal and Ethical Issues Network on HIV and AIDS, HIV & TB Thematic Area, Nairobi, Kenya, [2]Kenya Legal and Ethical Issues Network on HIV and AIDS, Nairobi, Kenya

Background: The *HIV & AIDS Tribunal* in Kenya was established in 2009. The *Tribunal* was established to adjudicate and give appropriate redress in cases on HIV violations; and prevent an irrational, panicky and fear-driven response to HIV. The *Tribunal* adjudicates cases on breach of privacy and confidentiality; testing without consent; disclosure of status; stigma and discrimination; loss of employment due to status, among others.
The Tribunal has endeavored to
- Enhance access to justice for PLHIV;
- Interpret the Kenyan law in line with the international best practices; and
- Provide a flexible and friendly forum for resolution of HIV and AIDS disputes.

In 2016 KELIN, with support from UNDP Kenya, embarked on documentation of cases decided by this Tribunal, resulting in a first ever *compendium of cases*. KELIN, has over the years, through its pro bono lawyers, supported clients with cases at the *Tribunal*.
Description: This *Compendium* was produced with an aim of supporting lawyers, judges, legal researchers, students, and the general public in understanding and appreciating how the law has been applied and interpreted to protect and promote the rights of PLHIV. It aimed at igniting legal discourse on HIV and AIDS laws and policies in Kenya.
Lessons learned: Cognizant of the fact that HIV stigma, discrimination, bastardization and other forms of rights violations pose the greatest threat to the fight against HIV and AIDS, the tribunal has committed itself to addressing these challenges, and has endeavored to develop and improve HIV jurisprudence in Kenya taking into account the development of HIV law worldwide. This is reflected in the decisions it has made as documented in the *compendium of cases*.
Conclusions/Next steps: The *compendium* will be useful in advancing the human rights agenda of PLHIV in Kenya and beyond and can help eradicate the rampant HIV related stigma and discrimination.

TUPED551

Aristotle was right - the sum is greater than the whole of its parts: How collaboration increased capacity in the fight against HIV criminalisation

S. Cameron, E.J. Bernard, S. Beaumont
HIV Justice Network, Amsterdam, Netherlands

Background: HIV criminalisation is the unjust application of criminal law to people living with HIV based solely on HIV status - either via HIV-specific criminal statutes or by applying general criminal laws that allow for prosecution of unintentional HIV transmission, potential or perceived exposure, and/or non-disclosure of known HIV-positive status. Despite recommendations from global normative agencies to severely limit the use of the criminal law to rare cases of malicious, intentional transmission, the overly broad and unjust use of the criminal law to control and punish people living with HIV is a growing, global phenomenon that has been generally overlooked and under-funded.
Description: In 2016, seven civil society networks, funded by the Robert Carr Fund, formed the HIV Justice Worldwide coalition to shape the global discourse on HIV criminalisation, share information and resources, build capacity, mobilise advocacy, and cultivate a community of transparency and collaboration. Today, HIV Justice Worldwide includes more than 70 partners globally and is led by a ten-agency steering committee. HIV Justice Network serves as its secretariat.
Lessons learned: Collaboration between civil society and other key stakeholders has delivered a diverse range of strategies to address HIV criminalisation including: stronger civil society relationships with international agencies and representative bodies of HIV scientists and clinicians; the reporting and analysis of more accurate global data on HIV laws and prosecutions; development of a centralised online advocacy resource consolidating all current HIV criminalisation resources; development of a compendium of legal precedents listing all known HIV criminalisation cases where a successful legal defence was mounted; development of shared communication strategy to promote expert scientific opinions on HIV transmission risk and harms; large-scale training events for community leaders, defence lawyers and media; and sharing of cross-jurisdictional legal expertise to mount successful legal challenges including constitutional challenges to amend laws or acquit those unjustly accused of HIV-related crimes.
Conclusions/Next steps: Funding international collaboration on HIV criminalisation for the first time has increased capacity and galvanised agencies and NGOs to develop evidence-based advocacy and undertake targeted interventions to improve the legal environment and increase access to justice for people living with HIV.

TUPED552

HIV related cognitive impairments and criminal law - barriers accessing justice for people living with HIV and HIV-associated neurocognitive disorder

A. Stratigos[1], V. Parwani[2]
[1]HIV/AIDS Legal Centre, Surry Hills, Australia, [2]HIV/AIDS Legal Centre, Sydney, Australia

Background: The HIV/AIDS Legal Centre has recognised an increase in the need for legal representation in criminal law matters for people with HIV with HIV-associated neurocognitive disorder (HAND). Many clients do not even have a recollection of having committed any offence and/or are in denial of their actions an their HAND has directly resulted in their offending behaviour.
The *Mental Health (Forensic Provisions) Act* in the Australian state of New South Wales allows for the dismissal of some criminal offences where the person has a cognitive impairment, case law requires that the defendant also enter into a treatment plan as proposed by an appropriately qualified physician. The application of the case law and legislation poses challenges for those facing criminal charges as a result of HAND.
Description: Representation of people with HIV with HAND in criminal law requires competent counsel to ensure that: clients remain empowered and engaged; the judiciary and the prosecution are educated on HIV and HAND, and people with HIV are not stigmatised and that the public do not form a view that all people with HIV will develop HAND.
Lessons learned: Case studies revealed that it is difficult to assist clients with HAND to have charges dismissed under the mental health legislation. The first challenge is establishing whether the client has sufficient legal capacity to provide instructions. Secondly the judiciary and the prosecution need to have the condition explained to them in a sensitive and non-stigmatising manner. The result of the challenges mean that appeals processes are often utilised and/or people with HAND face criminal penalties in circumstance where the mental health legislation should have been applied.
Conclusions/Next steps: Representation of people with HIV with HAND assists to ensure that the individual is not subject to criminal law penalties where it is not appropriate, but also educates the judiciary on the challenges faced by people living with HIV.
Outcomes achieved in the courtroom demonstrate that judicial and prosecutorial training is necessary to ensure greater success and greater sensitivity to protect not only the individual before the court but all people with HIV.

TUPED553

Community health advocates championing realization of the right to health in Kenya

L. Ghati[1], H. Ochieng[1], T. Wafula[2], A. Maleche[2], T. Saoyo[2]
[1]Kenya Legal and Ethical Issues Network on HIV & AIDS (KELIN), HIV and TB, Nairobi, Kenya, [2]Kenya Legal and Ethical Issues Network on HIV & AIDS (KELIN), Nairobi, Kenya

Background: Realization of the universal health coverage, achievement of the Sustainable Development Goals and the global targets of 90:90:90 in HIV interventions will remain a pipe dream if the community level health care systems are not adequately addressed. Every year, TB kills 1.4 million people and is the number one killer opportunistic infection amongst persons living with HIV. This is largely due to various social, legal and structural factors such as stigma and discrimination, inadequate drug regimens, poor drugs adherence to treatment and a large proportion of people with active TB disease who are missed by health systems.
Article 27 of the Constitution of Kenya 2010 has provisions that outlaw discrimination on the basis of one's health status. Many affected communities are not aware about the useful provisions in the Constitution.
Description: KELIN, with support from ARASA, has engaged 30 Community Health Advocates (CHAs) from five counties in Kenya to raise awareness on HIV and TB rights, increase treatment literacy, and demand for quality health care services contributing to strengthening community health facility linkages.
The CHAs have documented and reported cases of health human rights violation, the most recent is detention of lactating mothers in a public health facility for nonpayment of maternity fees. With KELIN's intervention, the mothers were release from the facility without paying a cent. The CHAs hold regular feedback meetings and conduct community outreaches by leveraging on existing community platforms including chiefs *barazas*, religious gatherings, and in health facilities. They receive technical support from KELIN, who has linked them to local partners working on HIV and Human Rights.
Lessons learned: Community health advocates, adequately trained, supported and motivated, are better champions of health rights in their respective communities. This kind of intervention has proved necessary, useful and easy to implement and can be replicated in other areas of similar and comparable settings to yield positive results.
Conclusions/Next steps: The CHAs will continue with the community based outreaches to increase awareness and document cases of rights violations to ensure that communities enjoy their health rights.

TUPED554

Working with parliamentarians on rights of PLHIV: Safeguarding access to treatment in the HIV/AIDS Act 2017

M. Gahlot[1], J. Prakash[2], E. Chinrimoi Haokip[2], Delhi Network of Positive People (DNP+) Study Group
[1]The Delhi Network of Positive People, Advocacy, New Delhi, India, [2]Delhi Network of Positive People (DNP+), New Delhi, India

Background: PLHIV networks have been advocating for the adoption of an HIV anti-discrimination law drafted through community consultations in India since 2003. Since the Bill was submitted to the government in 2007, DNP+ being the network of PLHIV in Delhi where the Indian Parliament meets, met members of Parliament (MPs) to advocate for the Bill. In 2014 an amended version of the Bill was presented in Parliament without a legal commitment to provide HIV treatment.
Methods: Between 2015-2017, DNP+ worked with MPs on the treatment clause in the HIV/AIDS bill which stated that government would provide treatment „as far as possible;" a vague phrase according to legal experts. DNP+ with other PLHIV networks and legal experts commenced a legislative advocacy campaign including:
(1) Submissions, testimony and evidence to Parliament Standing Committees
(2) One-to-one advocacy with MPs from the ruling and opposition parties
(3) Public/media sensitisation and advocacy: Direct actions like protests in front of Minister of Health´ residence, press releases and press conferences were also held.

NATIONAL

Remove the words 'as far as possible' from HIV Bill: patients

SPECIAL CORRESPONDENT

Members of the People Living with HIV group protesting outside the residence of Union Health Minister J.P Nadda. | Photo Credit: Vidya Krishnan

[Advocacy on HIV Bill Treatment Clause]

Results: As a result of the strong advocacy of PLHIV networks, during the debate on the HIV Bill several MPs including from the ruling coalition requested the government to remove the vague clause on treatment.

Despite these efforts, „as far as possible" remains in the HIV/AIDS Act. However, not only did the pressure from PLHIV networks result in raising this issue in Parliament, it also resulted in a clear commitment from the Health Minister on providing treatment and his announcement of „Test and Treat" as the new policy of the government.

Conclusions: With the Bill being passed with the vague treatment clause still in it, DNP+ and other positive networks are committed to continuing advocacy for its proper implementation, to raise awareness among the community on their rights and to ensure comprehensive access to treatment for PLHIV. As the Act requires rules and regulations and guidelines on access to treatment for implementation, PLHIV networks are continuing their advocacy with Members of Parliament, the Ministry of Health and the National AIDS Control Organisation on these processes to ensure that the government continues to provide and expand access to HIV treatment.

TUPED555

My body, my right! The power of women's advocacy in defeating HIV criminalisation in Malawi's HIV Bill

A. Raw[1], C. Banya[2], C. Chijozi[3], S. Chisala-Tempelhoff[4], M. Clayton[5], M. Luba[6]

[1]Southern Africa Litigation Centre, Johannesburg, South Africa, [2]International Community of Women Living with HIV, Lilongwe, Malawi, [3]Centre for Human Rights Education, Advice and Assistance, Blantyre, Malawi, [4]Women Lawyers Association, Lilongwe, Malawi, [5]The AIDS and Rights Alliance for Southern Africa, Windhoek, Namibia, [6]The Malawi Network of AIDS Service Organisations, Lilongwe, Malawi

Background: Based on a 2008 Law Commission report, Malawi's HIV (Prevention and Management) Bill was tabled in mid-2017. It combined coercive and punitive approaches on the management of HIV with crucial administrative provisions to institutionalise the National AIDS Commission. This paper describes key interventions by civil society, activists and, prominently, the role of women living with HIV, in ensuring the removal of criminalising and rights-infringing provisions from the law.

Description: In 2017 Malawian and regional civil society organisations (CSOs) conducted joint advocacy, raising human rights and public health concerns on coercive and punitive provisions in the draft HIV law. This joint, cumulative advocacy resulted in Parliament's HIV Committee proposing a range of amendments. Their amendment report addressed many civil society concerns but retained section 43, criminalising the "deliberate transmission" of HIV. In weeks before the Bill went to vote, Malawian women activists, led by women living with HIV, directly engaged Parliamentarians, protested and delivered statements condemning section 43 as a threat to human rights. On 28 November 2017, Parliament passed the Bill into law, adopting the HIV Committee's amendment report in full and going further to exclude section 43, thus comprehensively rejecting criminalisation of HIV.

Lessons learned: Manufactured urgency to enact the law left little space for meaningful engagement with affected communities. Adopting the slogan, "My body, my right", women activists, led by women living with HIV, achieved a fundamental shift in the understanding of and attitude towards HIV criminalisation by lawmakers and the executive. The technical objections and support of lawyers and human rights CSOs were effective in a supporting capacity, legally empowering the affected community with the language to implicate the proposed law in their lived realities. This grounded the discourse and powerfully challenged the abiding patriarchal and stigmatising underpinnings of the law's purported protections. Ultimately, the ability of "ordinary" women living with HIV to articulate what the law meant in real terms directed Parliament's response.

Conclusions/Next steps: The feminisation of HIV criminalisation in Africa demands a response led by women living with HIV. This requires the active engagement, participation and full legal empowerment of affected communities.

TUPED556

Impact of the ARASA online short courses on criminalisation of HIV transmission, exposure and non-disclosure

B. Tushabe

AIDS Rights Alliance for Southern Africa, Training, Cape Town, South Africa

Background: The AIDS and Rights Alliance for Southern Africa is a partnership of over 117 civil society organisations working together in Southern and Eastern Africa to promote a human rights response to HIV and TB.

Description: The criminalisation of HIV transmission, exposure and non-disclosure, which is often referred to as 'HIV criminalisation', is the unjust application of criminal law based solely on HIV status - either by enacting and applying HIV-specific criminal laws, or by applying general criminal laws exclusively or disproportionately against people with HIV.
Law makers who try to enact HIV-specific laws to criminalise HIV transmission are often driven by public pressure to be seen to be doing something about HIV in their country without stopping to consider the effects of HIV criminalisation on the spread of HIV.

Lessons learned: The course has equipped participants in Africa to advocate for laws that do not criminalise HIV transmission, exposure and non-disclosure and respect the rights of people living with HIV and promote universal access or for the repeal or amendment of laws that do criminalise

Ø Increased understanding on criminalisation of HIV transmission, exposure and non-disclosure is and the difference between transmission, exposure and non-disclosure

Ø Increased understanding of the disproportionate impact of criminalisation on women and key populations

Conclusions/Next steps: Monitor existing and proposed laws on HIV non-disclosure, exposure and transmission. Advocate that any criminal law provision applicable to HIV be informed by the best scientific and medical evidence relating to HIV, and uphold generally applicable criminal law and human rights principles.

Ø Support people living with HIV through programmes such as legal assistance and "know your rights" campaigns, to challenge overly broad criminalisation of HIV non-disclosure, exposure or transmission

Ø Support monitoring and research to further inform an appropriately limited application of criminal law in the context of HIV in order to support public health, justice and human rights. Such research should investigate the content and impact of HIV-related laws on public health and human rights, as well as the effectiveness of alternatives to criminalisation of HIV non-disclosure, exposure and transmission.

Ethical aspects and standards in research, including clinical trials

TUPED557

Ethical considerations in HIV phylogenetic research

A. Hoppe[1], C. Coltart[2], M. Parker[3], L. Dawson[4], J.J. Amon[5], M. Simwinga[6], G. Geller[7], G. Henderson[8], O. Laeyendecker[9], J.D. Tucker[8], P. Eba[10,11], V. Novitsky[12], A.-M. Vandamme[13,14], J. Seeley[15,16], G. Dallabetta[17], M.K. Grabowksi[18,19], P. Godfrey-Faussett[10,16], C. Fraser[3], M.S. Cohen[8], D. Pillay[2,15], On behalf of the Ethics in Phylogenetics Working Group
[1]University College London, Infection and Immunity, London, United Kingdom, [2]University College London, London, United Kingdom, [3]University of Oxford, Oxford, United Kingdom, [4]DAIDS, Bethesda, United States, [5]Princeton University, Princeton, United States, [6]Zambart, Lusaka, Zambia, [7]Johns Hopkins University, Baltimore, United States, [8]University of North Carolina, Chapel Hill, United States, [9]NIH, Bethesda, United States, [10]UNAIDS, Geneva, Switzerland, [11]University of KwaZulu-Natal, Pietermaritzburg, South Africa, [12]Harvard T.H. Chan School of Public Health, Boston, United States, [13]KU Leuven - University of Leuven, Leuven, Belgium, [14]Universidade Nova de Lisboa, Lisbon, Portugal, [15]Africa Health Research Institute, Durban, South Africa, [16]London School of Hygiene & Tropical Medicine, London, United Kingdom, [17]Bill & Melinda Gates Foundation, Washington, United States, [18]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [19]Rakai Health Sciences Program, Kalisizo, Uganda

Background: Phylogenetic analysis applied to pathogen genetics is a powerful tool with the potential to help reduce the spread of epidemics, including HIV. Phylogenetics allows the deduction of historical relationships between groups of organisms based on their pathogen genomes, which can be used to help infer transmission chains among infected individuals. The application of phylogenetic approaches to public health programmes has rapidly increased in the last five years and present unique ethical, legal and social issues which are not well addressed by the existing bioethics literature.
Description: A multidisciplinary meeting was convened to explore the issues arising from the design, conduct and use of results from HIV phylogenetic studies, and additionally to propose recommendations to minimise the associated risks both to individuals and groups. The meeting focused on phylogenetic studies of HIV in Africa, the epicentre of the global HIV pandemic.
Lessons learned: We identified eight critical ethical domains which provide a framework through which to consider the issues:
(i) risk-benefit assessment;
(ii) protection of the rights and interests of study participants while in pursuit of scientific progress;
(iii) local social and legal context, including human rights violations;
(iv) risk mitigation strategies;
(v) valid informed consent and other safeguards;
(vi) community engagement;
(vii) communication and
(viii) equitable data sharing.
Within each domain, we highlighted factors that make phylogenetic research unique, such as the fact that both individuals who participate in studies as well as social and geographic groups are linked in phylogenetic networks.
Conclusions/Next steps: We endeavoured to provide a framework to assist researchers, public health practitioners, and funding institutions to ensure that HIV phylogenetic studies are designed, conducted and disseminated in an ethical manner.

TUPED558

PLHIV data sovereignty in research: Empowerment and inclusion in the Australian context

D. Toborek[1], C. Cooper[2], L. Sutherland[3]
[1]Positive Life NSW, Research & Peer Support, Sydney, Australia, [2]Positive Life NSW, Chief Executive Officer, Sydney, Australia, [3]Positive Life NSW, Manager, Sydney, Australia

Background: Research conducted by academic institutions is rarely directed, owned or controlled by PLHIV, and university research agendas do not always align with the PLHIV community's need to research issues in a timely and targeted manner, influencing policy and service systems. To redress these issues Positive Life NSW has increasingly turned to community driven, owned, and promoted electronic surveys (Anal Cancer Awareness Survey, Immediate Start to HIV Treatments Survey) to provide a more effective mechanism to consult with community. We have demonstrated that our surveys are faster, more in depth data in greater quantities, and more responsive to emerging PLHIV concerns and needs. This data and PLHIV representative advice adds to and compliments the research published by universities and clinical services.
Description: Produced by Positive Life on behalf of the national Australian HIV peer-led organisational grouping, Poz Action, the document establishing the principles, objectives and guidelines of the PLHIV-led human research ethics committee (HREC) was drawn from local and international examples. The guiding document will now enable Australian HIV peer organisations to include PLHIV at all stages of the research process and inform the HIV research agenda.
Lessons learned: Not all jurisdictions have a dedicated PLHIV-led organisation and varied levels of skills and resources to dedicate to development; however, the desire to progress this project has led to stronger ties, skill development and knowledge transfer between PLHIV community organisations throughout the collaboration stages. As PLHIV become more involved and the issue of data sovereignty, coordination and participation impact researchers and clinicians, a culture shift in management process and education will need to occur.
Conclusions/Next steps: Formal establishment of the HREC. Engagement with all Australian HIV researchers and research facilities and jurisdictional/national health agencies. As per Australian Aboriginal research precedent, seeking State/Territory legislation requiring HIV research to be reviewed by a PLHIV-led HREC.
Funded by ViiV Healthcare Australia.

TUPED559

A study of violations of human rights of PWUD and PLHIV in Kazakhstan resulted from an unethical governmental research

D. Matyushina-Ocheret[1], M. Golichenko[2], E. Bilokon[3], A. Pak[4]
[1]Eurasian Harm Reduction Association, Moscow, Lithuania, [2]Canadian HIV Legal Network, Toronto, Canada, [3]Community Crisis Center Moi Dom (My Home), Temirtau, Kazakhstan, [4]NGO 'Ty Ne Odin' (You Are Not Alone), Pavlodar, Kazakhstan

Background: Among post-Soviet states, Kazakhstan has one of the biggest populations of people who inject drugs (PWID), which amounts to 128700 persons, 8.2% of them living with HIV. Around 98,000 of Kazakhstan PWID are opiate users, which means that the spread of HIV can be substantially decreased through opioid substitution treatment (OST). However, OST programs in Kazakhstan are available to only 2.69% of those in need, and even these treatment slots are currently under the threat of being closed. In 2017 Kazakhstan government initiated an assessment of the effectiveness of OST programs. The study explored human rights violations among PWID and PLHIV resulted from the governmental assessment.
Methods: In November - December 2017 three group interviews with 30 OST patients (most of them PLHIV) in Pavlodar and Temirtau were conducted.The study was organised by an independent international group. Local PLHIV community groups were involved as gatekeepers and in interpreting the study results.

Late Breaker Abstracts
Publication Only Abstracts
Author Index

Results: Analysis of interviews revealed the following violations of research participants' and patients' rights:
(1) Patients participated in the assessment on non-voluntary basis and under threat of termination of the OST program;
(2) Patients were not provided with full information on research to participants;
(3) Patients were forced to provide urine for non-anonymous drug testing;
(4) No single patient gave informed consent to medical doctors to disclose information about their diagnosis to any assessment group members or other government bodies;
(5) Assessment group members often spoke to patients in a disrespectful, loud tone, and were present when male and female patients collected urine samples without permission;
(6) Former patients were approached at their homes by police to provide details about the reasons they had quit OST program.
Conclusions: The governmental assessment of OST was organised with rude noncompliance with international bioethical standards. It is recommended that the governments of Kazakhstan rejects the results of the assessments as of poor quality and ensures that in future any research with the involvement of PLHIV and PWUD is organised according to international bioethical standards.

TUPED560

Identifying ethical issues in HIV positive adolescents research: Zimbabwe National Ethics Committee experiences

S. Sithembile, M. Kanengoni, M. Phiri-Shana, P. Ndebele
Medical Research Council of Zimbabwe, Research Oversight, Harare, Zimbabwe

Background: There remains reluctance to involve adolescents in clinical trials, in general, yet they remain at high risk of the HIV disease. When such a protocol is submitted to an Ethics Committee for review, contradictory legal and ethical requirements remain a challenge. Because of this myriad of challenges, it is necessary for Ethics Committees to identify, during protocol review, as much as possible, ethical issues that might arise during research involving HIV positive adolescents. We share our experiences as the National Ethics Committee on ethical issues raised during review of research protocols involving HIV positive adolescents.
Methods: Monthly protocol review meetings were held in order to cope with the review workload. Protocols involving HIV positive adolescents are never reviewed through the expedited process as per Standard Operating Procedures. This allows a wide range of face-to-face opinions from committee members. Stipulations and recommendations raised are communicated to the researcher through written letters and these are addressed before protocol approval.
Results: In 2017, a total of 54 HIV research protocols were reviewed, clinical trials and social sciences research inclusive. Out of the 54, fifteen protocols involved recruiting HIV positive adolescents research participants. Some of the ethical issues identified during review included, when adolescent child can consent independently, logistic challenges of child and parent/guardian consent, confidentiality issues on the side of the child, justice not done to the child whose parents /guardian refuses their participation when they can benefit, principle of autonomy not honored, adolescents treated as vulnerable patients, and that protectionist attitude impedes human rights.
Conclusions: Protocols involving HIV positive adolescents need attention to detail when reviewing. It is prudent to adopt and adapt to localized context-dependent strategies. There is need for flexibility in reviewing HIV positive adolescent research so as to meet community needs, thereby ensuring ethical research practices.

TUPED561

"Free testing and PrEP without outing myself to parents:" barriers and facilitators for oral and injectable PrEP clinical trial participation among adolescent men who have sex with men

C. Fisher[1], L. Ibrahim Puri[1], A. Fried[2], K. Macapagal[3], B. Mustanski[3]
[1]Fordham University, Center for Ethics Education, New York, United States, [2]Midwestern University, Glendale, United States, [3]Northwestern University, Feinberg School of Medicine, Chicago, United States

Background: Adolescent men who have sex with men (AMSM) account for high numbers of new HIV diagnoses. Non-adherence to daily use limiting the effectiveness of oral PrEP (Truvada) has led to current trials with adult MSM testing Cabotegravir, a long-term injectable medication. AMSM trials will begin once adult studies have established relative safety and efficacy of these medications. Recruitment of AMSM under 18 has been a barrier in prior HIV prevention research due in part to guardian permission requirements. This has created pressures to waive guardian consent and develop alternative research protections. This study examined factors influencingAMSM attitudes toward participation in oral/injectable PrEP RCTs to inform protections of youth's rights and welfare in future studies.
Methods: We administered to 198 ethnically diverse U.S. AMSM, 14 - 17 years a web-based survey including demographic and sexual health questions, description of a year-long oral versus injectable PrEP RCT and 20 Likert-type and open-ended items assessing motivations for and against participation including: perceived benefits and risks of PrEP and HIV/STI testing; benefit to others; random assignment; and confidentiality concerns.
Results: Sixty-two percent indicated they were likely to participate in the study. Over 80% endorsed daily HIV protection, HIV/STI testing, sexual health counseling, not having to rely on partner's condom use, and altruism as reasons to participate. Reasons against participation included medication side effects (48%), fear of learning they had HIV (42.5%) and concern taking the pill daily would reveal their sexual orientation to parents (61%). Many (60%) erroneously assumed they would be assigned to the
condition best for them and 39% indicated free access to services would lead them to participate even if they did not want to. Multiple regression indicated these factors accounted for 55% of the variance in participation choice. Nether age or ethnicity yielded significance.
Conclusions: Results suggest future biomedical HIV prevention research will need to address AMSM's confidentiality concerns and develop procedures to enhance youth's understanding of random assignment, the continued importance of partner condom use during trial participation, and availability of alternative sexual health services to avoid the potentially undue influence of access to free sexual health services.

TUPED562

Participating in biomedical HIV prevention trials while pregnant: Women´s views about enrolling in Pre-Exposure Prophylaxis (PrEP), vaginal ring, and randomized comparison trials

K. Sullivan[1], C. Zimba[2], S. Gilbert[3], T. Mtande[2], E. Jaffe[1], M. Gross[4], J. Coleman[4], I. Hoffman[5], L. Rahangdale[6], N. Rosenberg[2,7], J. Anderson[4], R. Faden[3], A. Lyerly[1]
[1]University of North Carolina at Chapel Hill, Center for Bioethics, Department of Social Medicine, Chapel Hill, United States, [2]UNC Project Malawi, Lilongwe, Malawi, [3]Johns Hopkins University, Berman Institute of Bioethics, Baltimore, United States, [4]Johns Hopkins Medical Institutions, Division of Gynecologic Specialties, Baltimore, United States, [5]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States, [6]University of North Carolina at Chapel Hill, Department of Obstetrics and Gynecology, Chapel Hill, United States, [7]University of North Carolina at Chapel Hill, Department of Health Behavior, Chapel Hill, United States

Background: Despite the significant need for effective HIV prevention during pregnancy, the widespread exclusion of pregnant women from clinical trials has resulted in limited data on biomedical HIV prevention

methods in pregnancy. Failing to study these methods in pregnancy has important implications for equitable access to prevention modalities and their safe and effective use. The PHASES project is developing engagement-driven guidance on how to responsibly expand the HIV evidence base for pregnant women. Pregnant women´s views on participation in research are critical to informing the development of this guidance which must be responsive to pregnant women's needs and values.

Methods: Seventy semi-structured, in-depth interviews were conducted with pregnant or recently pregnant women at risk for HIV; 35 in the U.S. and 35 in Malawi. Questions explored decision-making around enrollment while pregnant in 3 hypothetical HIV prevention clinical trial vignettes testing

(1) PrEP,

(2) a vaginal ring, and

(3) a randomized trial comparing the two.

Thematic analysis informed the analytic approach. Interviews were transcribed, translated when necessary, coded and emergent themes identified.

Results: The majority of women in Malawi reported willingness to join at least one trial. Reasons included the potential benefit of preventing HIV in themselves and their offspring, access to enhanced medical care, helping other women in the future, and low perceived risk of the medications during pregnancy. Overall, U.S. women were more reluctant to participate, citing general avoidance of medications during pregnancy, unwillingness to assume potential risk to offspring, and low perceived personal risk for HIV exposure, with some exceptions.

Conclusions: We identified diverse considerations shaping decision making around potential participation in HIV prevention trials during pregnancy. Perceptions of HIV risk and the safety of medications in pregnancy were significant drivers of women´s decisions and appear to be influenced by underlying epidemiological and cultural contexts. These findings indicate that the current HIV research agenda, which largely excludes pregnant women, is misaligned with the views of some of these women; consideration of such views, situated within cultural contexts, may lead to a more ethically responsible and inclusive approach.

TUPED563

Ethical research with indigenous populations: Translating standard ethical guidelines to strengthen indigenous community involvement in research

C.R. Pearson[1], M. Parker[2], C. Fisher[3]
[1]University of Washington, Indigenous Wellness Research Institute, Seattle, United States, [2]University of Washington, Seattle, United States, [3]Fordham University, Psychology, New York, United States

Background: American Indian and Alaska Native (AIAN) community partner informed engagement in the review of HIV/AIDS research protocols helps ensure community-based research (CBPR) serves community interest, enhances recruitment and study retention and avoids cultural misunderstandings, stigmatization, or culturally inappropriate, irrelevant, and disrespectful science. Although review boards and researchers are trained to minimize risks to participants, all parties must also know how to apply research ethics principle that are culturally responsive, at a community level, and weigh studies' potential pathologizing effects for entire social groups. Traditional ethics training curricula have yet to keep pace with the rapid expansion of CBPR and have failed to address the unique situations across AIAN communities. We brought together national panels of AIAN community members, AIAN academic scholars and allies, and policy leaders to co-design and evaluate a culturally tailored online human subjects training curriculum.

Methods: In a national randomized sample of 490 AIAN community members, we compared our AIAN ethics training curriculum (n= 244) with a standard nationally used online curriculum (n= 246). We assessed pre-and post-test measures in group differences in ethics knowledge. Analysis of regional tribal differences assessed curriculum generalizability.

Results: The AIAN curriculum, as compared to the standard curriculum, achieved significantly higher levels of participants' research ethics knowledge at first attempt (78.9% quiz items correct versus 65.3%, t= 8.09, p < .001), acceptability (4.2 versus 3.8, t= 6.21, p < .001), satisfaction (4.1 versus 3.7, t= 5.26, p < .001), ease of responding to curriculum and completion of the training requirements. There were no regional, urban, or rural differences.

Conclusions: We produced a validated research with human subject training curriculum and a trainer's toolkit with case studies and quiz items that is ready for immediate use. Culturally-grounded training curricula may help remedy the impact of historical research ethics abuses involving minority communities that have contributed to mistrust of research and lack of community engagement in research.

TUPED564

Data regarding the ethical issues in HIV+ to HIV+ solid organ transplantation

J. Sugarman[1,2,3], S. Rasmussen[2], A. Eno[2], J. Bollinger[1], S. Seaman[2], A. Nguyen[3], D. Brown[2], M. Henderson[2], A. Tobian[2,3], D. Segev[2,3], A. Wu[2,3], C. Durand[2]
[1]Johns Hopkins University, Berman Institute of Bioethics, Baltimore, United States, [2]Johns Hopkins University School of Medicine, Baltimore, United States, [3]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States

Background: Clinical trials involving transplantation of HIV+ organs into HIV+ recipients are now being conducted. If proven safe and effective, HIV+/HIV+ transplants will provide another source of organs for people living with HIV (PLWH) facing high mortality on transplant waitlists and alleviate organ shortages generally. However, HIV+/HIV+ transplantation raises ethical issues related to risk, consent, and fairness, among others, that must be addressed.

Description: Given the novelty of these transplants, we are conducting a set of empirical ethics projects that include: a survey of PLWH on a transplant waitlist about HIV+/HIV+ transplants; a survey of a general PLWH population regarding willingness to donate organs; in-depth interviews with early recipients of HIV+/HIV+ transplants; in-depth interviews with independent recipient advocates (which are required for HIV+/HIV+ transplants in the US); and developing patient reported ethical outcome measures (PROM) to prospectively capture ethical issues among future HIV+/HIV+ transplant recipients.

Lessons learned: Preliminary data suggest that most (44/46) PLWH on an organ waitlist are willing to accept an HIV+ deceased donor organ. Most of the 114 general PLWH population survey respondents expressed willingness to donate (79.8% after death and 62.3% as living donors). However, only 21% were registered organ donors. Interviews with six transplant recipients revealed general satisfaction with the consent process and absence of regret over their decision to undergo transplantation, but some were concerned about stigma. Nine independent recipient advocate interviews revealed marked variability in practice among medical institutions and a desire for additional information and specification of their roles. We developed a draft PROM based on these results and existing scales. After cognitive and pilot testing with 27 PLWH it includes 29 items in five domains: emotions, trust, decision-making, transplant, and decision satisfaction.

Conclusions/Next steps: Overall our preliminary findings are encouraging, but there are opportunities to enhance current approaches. Organ donation registration rates may pose a barrier to these transplants and independent recipient advocates need additional guidance. We are continuing these data collection activities as well as nesting our PROM in a multicenter trial of HIV+/HIV+ kidney transplants to obtain generalizable information about the ethical issues related to these transplants.

Ethical aspects and standards in prevention programmes

TUPED565

Ethical pitfalls of phylogenetic approaches to HIV prevention

M.K. Smith[1], A.M. Dennis[2], S. Rennie[3], G.E. Henderson[3]
[1]*University of North Carolina, Infectious Diseases, Chapel Hill, United States,* [2]*University of North Carolina Chapel Hill, Medicine, Chapel Hill, United States,* [3]*University of North Carolina Chapel Hill, Social Medicine, Chapel Hill, United States*

Background: Advances in molecular network analysis are providing unprecedented levels of granular insight into HIV transmission patterns. Through sequence similarity or phylogenetics, analysis of these molecular data can reveal potential transmission patterns among HIV-infected people. Although they cannot prove direct transmission, use of these methods to inform prevention targeting can inadvertently confer greater epidemiological significance to these data, raising ethical questions regarding the appropriate balance of personal risk and public health benefit.

Methods: We conducted a review of six known studies taking place in Europe, North America, and sub-Saharan Africa that are utilizing molecular data to identify and target individuals with elevated HIV transmission risk. Data were gathered through direct communication with investigators and attendance at an international conference on this topic organized by the Bill and Melinda Gates Foundation in May 2017. This review focuses on study design, risks, benefits, and informed consent procedures used in these interventions.

Results: By targeting people or groups who are not only HIV-infected but also identified as having higher transmission risk, molecular and network-driven prevention approaches may introduce new risks to already vulnerable populations. These interventions could also backfire if fear of criminalization, stigma, or other harms cause people to withdraw from studies or the HVI care continuum. Consent procedures that convey appropriate amounts of scientific complexity and uncertainty for lay audiences pose significant implementation challenges. The ethical implications of these methods will continually evolve as technologies and analytical techniques develop.

Conclusions: Public health ethics dictate that any tool capable of more rapid or effective HIV control be utilized. Yet decisions on whether and how to implement molecular and network tools must carefully consider tradeoffs between population benefit and individual-level risks Community-wide input will be necessary to ensure that indications of transmission risk (e.g. cluster membership, network centrality, etc.) are not conflated with evidence of a transmission, particularly in settings that criminalize HIV transmission. Design of acceptable and sustainable interventions will need to involve communities from the most formative stages. Lastly, better methodological consensus can be expected as our understanding of their particular limitations improves.

TUPED566

Supporting patient rights and informed consent in the context of HIV testing and treatment scale-up: Experiences of female sex workers living with HIV in Bali, Indonesia

P. Duff[1,2,3], C. Supriyadinata[4], E. Rowe[5], L. Maher[3], N.G.A. Nanditha[2], T. Sarahdita[5], K. Shannon[1,2]
[1]*Gender and Sexual Health Initiative, Vancouver, Canada,* [2]*University of British Columbia, Medicine, Vancouver, Canada,* [3]*Kirby Institute for Infection and Immunity, University of New South Wales, Sydney, Australia,* [4]*Yayasan Gaya Dewata, Denpasar, Indonesia,* [5]*Yayasan Kerti Praja, Denpasar, Indonesia*

Background: Access and coverage of combination prevention strategies for key populations continues to lag behind/remains sub-optimal. The role of HIV testing and treatment scale up for key populations as part 'Treatment as Prevention' (TasP) has drawn criticism and concern by community groups, with fear that patient rights and informed consent may be compromised. In a setting with government-sponsored HIV TasP roll-out, this study sought to capture female sex workers (SWs) experiences around informed consent (i.e., information, comprehension, voluntariness).

Methods: Data were drawn from ETHICS (2016-2017), a community-based qualitative study aimed at exploring a broad range of ethical questions surrounding HIV service scale-up in Bali, Indonesia. In-depth interviews with 25 female SWs living with HIV were conducted by a trained Peer Research Associate and analyzed using participatory coding techniques.

Results: Informed consent around HIV testing varied widely by venue, with most SWs who were tested at Yayasan Kerti Praja, a non-profit HIV clinic serving marginalized communities, indicating they were able to make an informed decision to test. In contrast, many SWs who were tested for HIV via outreach to sex work venues (e.g., by government-sponsored mobile health clinics) described having their blood 'stolen'; many were not informed, did not understand the purpose of the test and felt unable to refuse authority figures, or in the presence of managers/co-workers. Overall, SWs were satisfied and comprehended the information received around ART, though some described having been sold on the idea of one-pill-per day, only to have the pill burden increase (to 3+ pills/day) months later. Peer navigators (SWs living with HIV) and support groups were suggested to help support patient rights and the ethical scale-up of HIV services.

Conclusions: Our findings highlight a need for services, developed and delivered together with SWs themselves (including peer navigators), that better support SWs' right to informed consent. Aligned with WHO/UNAIDS sex work guidelines, consideration of laws, confidentiality and labour rights of workers must be considered before rolling out venue-based HIV services and supports (e.g., housing & work environments), and must be in partnership with SWs.

National financing analyses and initiatives

TUPEE567

Investing in the HIV Workforce: Government Capacity and Willingness to Increase HRH Spending in Response to Increased Needs for HIV in Uganda

C. Barker Cantelmo[1], M. Schnure[1], C. Shumba[2], R. Berger[3]
[1]*Palladium, Washington, United States,* [2]*HRH2030 consultant, Kampala, Uganda,* [3]*Chemonics International, Washington, United States*

Background: Uganda may need additional human resources for health (HRH) to achieve national HIV goals, yet the country faces HRH constraints, including inadequate skills mix, maldistribution, and a 36% vacancy rate in public facilities. As a result, the HRH2030 program, funded by USAID, through PEPFAR, assessed the capacity and willingness of the government to make more strategic investments in facility- and community-based HRH for HIV.

Methods: We projected HIV workforce salary costs and fiscal space and conducted a political economy analysis involving literature review and interviews with 52 stakeholders. The cost analysis estimated how many facility- and community-based health workers are needed and the corresponding salary/stipend costs for reaching national HIV targets, including 90-90-90. We analyzed costs for HIV treatment under two service delivery model scenarios: status quo versus national roll-out of differentiated care models (DCMs). The fiscal space analysis estimated how much funding may be available for HIV HRH salaries from the government and PEPFAR from 2016 to 2020.

Results: An estimated $20.3 million is needed in 2020 for select facility- and community-based HRH salaries to reach national HIV targets under 2016 HIV treatment models. The HIV HRH funding gap under this scenario could be as high as $6 million in 2020, even if the government increases HRH salary spending in line with its national recruitment plan - which may not be feasible due to macroeconomic projections and limited political will to invest in HRH - and PEPFAR's salary support for

HRH remains constant. Community-based health workers (CHWs) face the largest gaps. However, DCMs that change the frequency of facility visits and the types of laboratory monitoring conducted by patient group could save an estimated $1.7 million in HIV HRH salary costs in 2020 alone.

Conclusions: Increasing investment in HRH and improving efficiency in HIV service delivery are essential to reach national HIV goals and sustain achievements. The analysis suggests that there are financial and political constraints to increasing investment in HIV HRH in the short term, but national roll-out of DCMs for HIV treatment has the potential to improve efficiency, lowering the average HRH cost per patient.

TUPEE568

Mobilizing domestic financing for HIV through health insurance

B. Lee, S. Prabhakaran, E. Lang, A. Dutta, S. Bowsky
Palladium, Washington, United States

Background: Integrating HIV services into health insurance schemes can sustainably increase domestic resources available for HIV, though regulatory and financial mechanisms must be in place. A package of HIV services must be in the minimum benefits package of the insurance scheme. Results from select countries can illuminate options applicable for both generalized and concentrated epidemics.

Methods: In Tanzania and Indonesia, the PEPFAR- and USAID-funded Health Policy Plus project (HP+) assessed these options. Based on basic vs. comprehensive packages of HIV services, HP+ projected utilization rates through insurance. This involved analyses of the current proportion of people living with HIV (PLHIV) enrolled in schemes. Costs to the scheme of selected HIV services were estimated based on underlying unit costs to project the scheme's total annual expenditure on HIV. This additional liability was compared to scheme revenues and expenditures, to assess sustainability. Sensitivity analyses considered variations in enrolment, utilization, reimbursement mechanisms and service delivery efficiency.

Results: In Tanzania, a basic package (excluding commodity costs) of ART, PMTCT, and HTC is estimated to cost an additional $23 million in Year 1 ($33 million with commodities). A comprehensive package of HIV services (including HIV support services and VMMC) would cost $34 million ($45 million with commodities). In Indonesia, a basic package may only include opportunistic infection prophylaxis, screening and treatment; while a comprehensive one includes ART, PMTCT and HTC. These packages would decrease projected scheme surpluses by 26%-34% in Year 1.

Conclusions: Based on the current cost of HIV services, our results suggest the financial impact on insurance schemes is manageable within the scope of existing pooled resources or through minor premium increases. While insurance schemes differ in design and implementation, this approach to analyzing integration of HIV services can be consistently applied in countries with established health insurance schemes and declining external resources for HIV. A key requirement is ensuring PLHIV are adequately covered and served by insurance schemes, especially key populations. The governments of Tanzania and Indonesia should adopt a two pronged approach - concurrently integrating HIV services into, and scaling up enrolment of PLHIV in, their major insurance schemes.

TUPEE569

Optimal allocation of resources for HIV services in Ukraine: Findings from a model-based study

J. Pearson[1], A. Latypov[2], R. Dierst-Davies[3], M. Duda[2], N. Avaliani[2], C. Kerr[4,5]
[1]Deloitte Consulting LLP, Strategy & Operations Practice, Arlington, United States, [2]Deloitte Consulting LLP, The USAID HIV Reform in Action Project, Kyiv, Ukraine, [3]Deloitte Consulting LLP, San Francisco, United States, [4]Optima Consortium for Decision Science, Sydney, Australia, [5]University of Sydney, Sydney, Australia

Background: Ukraine has one of the most severe HIV epidemics in the region, with an estimated 238,000 infected persons (prevalence ~1.0%) in 2017. Globally, Ukraine is among 30 fast-track-strategy countries, which generated more than 89% of new HIV infections in 2014. To investigate the most efficient way to achieve the UNAIDS 90-90-90 HIV eradication goals, a forecasting and resource allocation analysis was conducted.

Methods: A secondary analysis of data from a study of HIV expenditures among selected facilities in three regions (Mykolayiv, Poltava, and Zhytomyr) of Ukraine was conducted. First, sample data were interpolated to all facilities in study regions. The Optima HIV model was then applied to determine allocative efficiency across regions. This model estimates how changes in funding allocations to individual programs impact overall epidemic outcomes. The effects of multiple funding scenarios on disease progression through 2030 were explored: baseline, each oblast optimized independently (with C&T services either unconstrained or constrained), and geospatial optimized between oblasts
(C&T unconstrained and constrained).

Results: Over the past 10 years, both new incidence cases and HIV-related deaths have decreased sharply among all key populations, a trend that is expected to continue, albeit at a slower rate, until 2030. Compared to the current mix of funding, Ukraine can achieve a more cost-effective impact by shifting a greater portion of funding to ART and NSP programs, as well as increasing funding in Mykolayiv and Poltava. At current funding levels the total cost of services will be $115.1M in 2016-2030, resulting in 5,800 deaths, 5,300 infections, and 91,500 DALYs averted. To achieve 90-90-90 goals by 2020 and sustain the current funding mix is estimated to cost $184.5M by 2030. Applying a more cost-effective funding mix, 90-90-90 goals can be achieved for $155.9M (a cost savings of $28.6M), resulting in additional decreases in new infections (12,200 to 8,300) and deaths (10,800 to 7,800) by 2030.

Conclusions: With the anticipated reduction in donor funding, Ukraine may consider reallocating available resources to more cost-effective interventions. Reallocating more funding towards ART has the greatest impact on new infections and deaths averted and will play a crucial role in achieving the 90-90-90 benchmarks.

TUPEE570

The end of the golden age of HIV/AIDS funding? Trends in HIV/AIDS spending by financing source and spending category in 188 countries, 2000 - 2015

M. Moses[1], A. Haakenstad[2], T. Tao[1], A. Chapin[1], J. Dieleman[1]
[1]Institute for Health Metrics and Evaluation, University of Washington, Seattle, United States, [2]Harvard T.H. Chan School of Public Health, Boston, United States

Background: Development assistance provided by donors to combat HIV/AIDS in low- and middle-income countries decreased by 6.6% between 2012 and 2017, following a decade of 19.6% in annual growth. These decreases are concerning because little is known about the magnitude of domestic resources spent on HIV/AIDS across the globe and within each country. There is also little evidence about whether declines in funding threaten the reductions in HIV/AIDS incidence and mortality achieved since 2000. We addressed this critical knowledge gap by quantifying HIV/AIDS spending, identifying the source of these funds, and measuring HIV/AIDS spending on prevention, care and treatment, prevention of mother-to-child transmission of HIV/AIDS (PMTCT), and antiretroviral therapy (ART).

Methods: We collected and extracted data from five main sources: the AIDSinfo online database, Global Fund proposals, National AIDS Spending Assessments, National Health sub-Accounts, and the AIDS

Wednesday 25 July

Thursday 26 July

Friday 27 July

Late Breaker Abstracts

Publication Only Abstracts

Author Index

data hub. A spatiotemporal Gaussian process regression model was used to estimate HIV/AIDS expenditure by source and function from 2000 to 2015. All currencies were converted to 2017 purchasing power parity dollars.

Results: In 2015, global HIV/AIDS spending amounted to $48.1 ($45.7-$52.1) billion, a decrease of $800 million from 2013. Governments financed 62.2% (56.6%-66.7%) of total HIV/AIDS expenditure and out-of-pocket expenditure financed 5.6% (4.9%-6.3%). Development assistance for HIV/AIDS comprised 30.2% (27.8%-31.7%) of total spending in 2015. Among low-income countries, $0.11 in government health spending for HIV/AIDS is spent for each dollar of development assistance. In high prevalence countries, development assistance constituted 76.6% (73.6%-79.4%) of HIV/AIDS spending. Since 2000, expenditure on prevention has increased by 273% to 11.2 billion, while spending on treatment increased by 271% to 23.6 billion. In 2015, total expenditure on ART and PMTCT was $6.3 and $7.7 billion respectively.

Conclusions: Government resources played a substantial role in growth in global HIV/AIDS spending. Still, development assistance remains a major portion of spending on the prevention and treatment critical to millions living with HIV/AIDS. This makes these programs susceptible to future cuts in spending. High prevalence countries reliant on international assistance must plan strategically so that drops in external financing do not alter progress towards an AIDS-free generation.

TUPEE571

Domestic financing of HIV prevention programs for key populations in Thailand

R. Rahman[1,2], S. Talawat[1], P. Lertpayup[1], P. Panitchpakdi[1]
[1]Raks Thai Foundation, Bangkok, Thailand, [2]Duke University Hart Leadership Program, Durham, United States

Background: Between 2015 and 2019, over 70% of new HIV infections in Thailand are projected to occur among key populations, including men who have sex with men, transgender women, people who inject drugs, and female sex workers. Civil society organizations (CSOs), reliant on international donor support, have played an important role in ensuring access to HIV services among key populations. However, declines in international funding threaten the sustainability of CSO engagement in HIV prevention in Thailand.

Description: Starting in 2015, Thailand established the THB200 million (6.4% of national AIDS budget) HIV Prevention Fund, a national program aiming to fund CSOs working in HIV prevention and to overcome dependence on international donors. Under this program, CSOs work to reach key populations, recruit them into HIV testing and treatment, and retain them in the continuum of care.

Lessons learned: In the first year of implementation (2015-2016) of the HIV Prevention Fund, only 38% of targeted key population individuals (27,157/72,285) were reached with HIV prevention services. CSOs reported many challenges in accessing funding under this program: 1) Legislative frameworks, which had only allowed for government health funds to be provided to hospitals, had to be revised to allow funding to be directly allocated to CSOs. 2) The cost of reaching and providing HIV services to hard-to-reach key population communities was not fully accounted for by the initial compensation packages offered to CSOs. Despite these difficulties, open communication between government, CSOs, and key population communities allowed for identification of key challenges and gradual reform in the second year of implementation.

Conclusions/Next steps: Integrating CSO participation into the national AIDS program may require restructuring of health financing channels that traditionally support hospital-based care alone. Global Fund and PEPFAR exit strategies must include tailored discussions between government and civil society to identify feasible options for domestic financing.

TUPEE572

Funding for HIV/AIDS and TB: Producing evidence for a successful donor transition in Cambodia

F. Sophie[1], B. Johns[1], H. Nguyen[2]
[1]Abt Associates, Bethesda, United States, [2]Abt Associates Inc, Hanoi, Vietnam

Background: In Cambodia HIV/AIDS and TB have historically been financed by donors, the Ministry of Health, and out-of-pocket spending. However, in recent years donor funding has been declining and upcoming social health protection reforms may increase the likelihood that the National Social Security Fund (NSSF) might cover HIV/AIDS and TB services. In this context, the objective of this study was to estimate unit costs/cost components and identify the sources of funding for HIV/AIDS and TB services. Such information aim to help the government better understand the financing of these services to prepare for donor transition; and help the NSSF shape future purchasing mechanisms and inform reimbursement rates.

Methods: Cost data were collected for the year 2016 from a sample of 21 health facilities in four high burden provinces in Cambodia. Total and unit costs were calculated using a step-down approach. Additionally, the sources of financing were tracked, and a variance analysis was performed to identify cost-drivers.

Results: The cost per VCCT visit ranged from $8.79 to $14.03. For first-line ART it ranged from under $214 to more than $323 per patient per year and for second line from just over $500 to over $716 per patient per year. The cost of TB diagnosis, inclusive of all visits and laboratory testing ranged from $18.17 to $44.12 and the cost per diagnosed sputum smear positive patient ranged from $39.32 to $119.59.The Global Fund and the US Government provided the financing for about 16% to 68% of the costs depending on the type of facility; mostly paying for commodities and staffs salaries. Cost for ART was driven by drug costs, while staff was the largest cost category for most other services.

Conclusions: The relatively large ranges found in unit costs may indicate inefficiencies in the delivery of services and can make it harder to design accurate reimbursement rates. As funding for HIV/AIDS and TB is transitioning from donors to local government in Cambodia, additional financial and technical resources need to be secured to maintain commodities procurement as well as staff positions previously supported by donors.

TUPEE573

Determinants and aggregate estimates of HIV/AIDS domestic public spending in low-and-middle-income countries, 2006-2016

D. Mattur[1], J.A. Izazola-Licea[1], D. Tabasso[2]
[1]UNAIDS, Strategic Information, Geneve, Switzerland, [2]University of Essex, Department of Economics, Wivenhoe Park, United Kingdom

Background: Achieving fast-track results of ending HIV will need an increased participation from government's resources for HIV/AIDS. Domestic spending on HIV from public sources is reported by countries to UNAIDS during the annual reporting process. While more than 55 countries report on average, many countries have not been regularly reporting these data.

Other countries, even while not reporting regularly to UNAIDS perform in-depth HIV resource tracking, e.g. National AIDS Spending Assessments (NASA).

Understanding the predictors of domestic public spending on HIV helps in estimating aggregates by income level of countries or regions and serve as input to project it for sustainability and transition analyses.

Methods: Country reported domestic public AIDS spending data from Global AIDS progress reporting and existing published NASA reports were considered. A panel data from 2005-2016 from 112 low-and-middle-income countries were used for the analysis including 933 country/year data points. Estimates result from panel data random effects models.

Results: There are significant positive relations between the GDP per capita of a country (1.082), ART coverage (16.5) and HIV prevalence (0.063) with the domestic public spending on HIV on current US dollars.

The overall R-squared for the model was 0.68.
The domestic public spending by income level of countries has increased from $121 MN, $231 MN and $2415 MN for Low, Lower-Middle and Upper-Middle Income countries (LICs, LMICs and UMICs respectively) in 2006 to $256 MN, $980 MN and $6887 MN in 2016.
The domestic public spending has increased 60% between 2010 and 2016. Almost all regions increased their domestic resources. Asia Pacific region witnessed 132% increase in domestic resources between 2010 and 2016 while Eastern & Southern Africa increased by 57%. At 33%, Eastern Europe and Central Asia witnessed the lowest increase among regions.
Conclusions: Domestic resources currently constitute 57% of the global AIDS response, mainly public. With the flat lining or decrease of international resources, sustained increase in domestic public spending will be key in achieving fast-track targets to end AIDS as a global public health threat by 2030. Trends and projections of domestic public spending will be of significant use in projecting trends for transition and financial sustainability.

TUPEE574

Improving domestic funding for HIV/AIDS using a resource tracking methodology: Lagos State Experience

O. Fisher[1], U.H. Edumoh[2], O.K. Ogundapo[2]
[1]Lagos State AIDS Control Agency, Projects, Lagos, Nigeria, [2]Abt Associates, International Health Department, Lagos, Nigeria

Background: Lagos State with a population of over 23million people is ranked as one of the high HIV burden States in Nigeria with a prevalence rate of 2.2% among the general population. Due to low Government spending on HIV and AIDS services in the State coupled with the ongoing transition of donor supported services to the Government, the USAID funded Health Finance and Governance Project embarked to support the State to generate evidence to be used in making a case for more money for HIV/AIDS by conducting the State AIDS Spending Assessment (SASA) 2014-2015.
Description: The Lagos State AIDS spending assessment (SASA) 2013-2015 was conducted in 2016; this exercise utilized a resource tracking approach which tracked the magnitude of all funds allocated to HIV from all sources. The report was used as an advocacy tool by the Lagos State Agency for the Control of AIDS (LSACA) to mobilize more domestic funding from the Government for HIV/AIDS response in the State.
Lessons learned: The SASA study revealed a reliance on external funding for HIV/AIDS service delivery with 86% of total spending on HIV/AIDS coming from international sources in 2015 and public spending 9.3%, and the remainder from other sources.
The results was presented to the multi-sectoral Domestic Resource Mobilization Technical Working Group (TWG) on HIV/AIDS which brings together the central budget MDAs (Ministry of Budget, Finance etc.) and other stakeholders who have implications for budgetary allocations and releases. These results were then synthesized and presented alongside multidimensional benefits of spending more on HIV/AIDS. Leveraging on our understanding of the political economy landscape, these results were presented to targeted policy makers during the 2017 budget preparation process in the State. The outcome was that the HIV/AIDS budget for 2017 experienced a 450% year on year increase from 2016.
Conclusions/Next steps: There was a significant increase in budgetary allocation to the state HIV and AIDS response with about 82% of the funds released till date. This result accentuates the importance of the use of evidence, a multi-sectoral approach and an understanding of the political economy landscape to improve domestic resource mobilization for HIV/AIDS.

	Year 2015	Year 2016	Year 2017
State HIV/AIDS budget in Naira	81,850,000	114,850,000	630,000,000
Year on year percentage increase	-5.3%	40.3%	448.5%

[HIV/AIDS budget for Lagos State 2015-2017]

TUPEE575

Domestic government spending on HIV: Three scenarios assessing decreased donor support

J. Kates[1], A. Wexler[1], A. Haakenstad[2], M. Moses[3]
[1]Kaiser Family Foundation, Washington, United States, [2]Harvard, T.H. Chan School of Public Health, Boston, United States, [3]Institute for Health Metrics and Evaluation, Seattle, United States

Background: Recent reports of declining donor financing for HIV underscore the need to mobilize increased domestic government spending. At the same time, countries vary significantly in their ability to absorb such cuts, making it critical for donors to carefully assess the vulnerability of countries to declines and scale transitions accordingly.
However, to date, data needed to make such assessments have been quite limited. This study uses a new dataset to begin to answer these questions.
Methods: Using IHME's new global dataset on estimated 2015 HIV spending by country, we identified spending by domestic governments, relative to other financing sources. We ran three scenarios of decreased donor support (2%, 5%, and 10% cuts) to assess implications for domestic government spending. Finally, we developed a "country vulnerability" scale based on the share of financing provided by domestic governments.
Results: In 2015, of the estimated $33.3 billion spent on HIV in low- and middle-income countries, half ($16.7 billion) was provided by domestic governments. This varied significantly, ranging from 10% in low-income countries to 84% in upper middle-income countries. Conversely, donor financing comprised only 11% of financing in upper middle-income countries, but 86% in low- income countries. The three scenarios highlight the differential impact of donor cuts. For example, a 5% decline in donor financing in low-income countries represents $342 million, or almost half of what those governments are spending on HIV ($780 million). A 10% decline represents $684 million, or 88% of what they are spending. At the same time, many middle-income countries, particularly upper middle-income countries, could offset cuts more easily, though there may be other barriers to doing so (e.g., equity, human rights and political concerns).
Conclusions: The ability to identify and track domestic government resources for HIV is essential for understanding the full HIV financing envelope and carefully managing country transitions. As this analysis shows, for some countries, even modest declines in donor financing would create significant challenges for governments. For others, absorbing such declines would be more feasible. The findings here provide a new tool for donors and others to help make such assessments.

TUPEE576

A tale of two cities: A comparison of district level analysis of HIV budgets in Bandung and Semarang, Indonesia

Y. Nurhidayat[1], S. Putri[2], D. Solares[3], P. Loh[3], Seknas FITRA SHIFT
[1]Indonesia forum for Budget Transparency (Seknas FITRA), Jakarta, Indonesia, [2]Indonesia AIDS Coalition (IAC), Jakarta, Indonesia, [3]Asia Pacific Coalition on Male Sexual Health (APCOM), Bangkok, Thailand

Background: As the Government of Indonesia takes on increasing financial responsibility for its HIV response, the country will face several challenges, namely that budgetary analysis will become the responsibility of individual districts because of Indonesia's decentralised system of government. Meanwhile, district-level government processes are obscure and otherwise inaccessible to most local civil society organizations (CSOs).
Methods: From September - November 2017, as part of the Sustainable HIV Financing in Transition (SHIFT) program, the Indonesian AIDS Coalition (IAC) worked with the Indonesian Forum for Budget Transparency (Seknas FITRA) to analyze district level HIV budgets in Bandung and Semarang City. Under this collaboration, Seknas FITRA performed a structured review of key 2017 district-level government planning and budgeting documents to assess the extent in which each of the two districts include key population HIV interventions. Seknas FITRA then con-

ducted in-depth interviews and focus group discussions with government and civil society organizations to communicate and contextualize the findings.

Results: Districts exercise a high level of autonomy and determine, independently, where to rank HIV as a priority. Analysis of the 2017 Bandung and Semarang budgets show misalignment between investments and disease burdens across districts. Both Bandung and Semarang fall under the highest HIV prevalence category in Indonesia, and yet the budget allocation for HIV in Semarang is considerably larger. In Bandung, there was not a single programme specifically targeted on prevention for key populations. In Semarang, though there were resources budgeted for key population groups, many organizations either did not have the legal recognition to access these funds or did not have the capacity to apply for and manage district funds.

Conclusions: Budget transparency and analysis at the national and local district level will be essential to revealing situations where insufficient resources are allocated to fighting HIV or HIV resources are allocated inefficiently. In Indonesia, SHIFT is working to create new partnerships that assist HIV CSO and KP networks to navigate complex bureaucratic budgeting systems in order to carry out data-driven advocacy. Using these findings, IAC will support local CSOs to participate in District Financial Planning Cycle.

TUPEE577

Domestic financing for health: Are countries spending more on health?

A. Ithibu
Aidspan, Nairobi, Kenya

Background: The Global Fund to fight AIDS, Tuberculosis and malaria programs is a major financier of HIV programs in sub-Saharan Africa. More than half of its HIV investments are invested in Sub-Saharan Africa, where HIV programs are highly aid-dependent. In the face of dwindling donor aid and increasing donor fatigue, governments of these countries need to increase contributions to their national HIV responses.

Methods: The analysis targeted 13 African countries[1] classified as high impact countries by the Global Fund: Cote d´Ivoire, Congo (Democratic Republic), Ethiopia, Ghana, Kenya, Mozambique, Nigeria, Sudan, Tanzania, Uganda, South Africa, Zambia, and Zimbabwe. Investments in these High-impact countries account for nearly half of Global Fund investments. A trend analysis of the overall spending on health and proportion of government expenditure on health from 2011 to 2015 was performed.

Results: Of the 13 countries analysed, 6 were low income countries, 6 were lower middle income, while 1 was an upper middle income (South Africa). Current expenditure on health as a proportion of the GDP has remained stable for most of the countries between 2011 and 2015. The proportion of the CHE to the GDP was highest in Zimbabwe (10.32%) and lowest in Nigeria (3.56%).

In contrast, government spending on health has changed significantly for most of the countries over the five-year period. Government spending on health was highest in Sudan (18%) and lowest in Mozambique (1.22%). Of the 13 countries, 10 spent less than 8% of their government expenditures on health. Increases in government spending on health were highest in Sudan (8.09% in 2011 vs. 18.09% in 2015).

Conclusions: Domestic funding for health has increased significantly in recent years; it has actually doubled in between 2006 and 2011. However, there remains a huge gap in funding for health, and more specifically, HIV programs. It is important that countries continue increasing their contribution and involving other stakeholders such as the private sector.

Transitional financing

Late presenters drive the non-ART cost of HIV-care

S. Popping*[1], B.E. Nichols* (*equally contributing authors)[1], D.A.M.C. van de Vijver[1], P. Reiss[2,3], A. van Sighem[3], K. Brinkman[4], S. Geerlings[2], C.A.B. Boucher*[1], A. Verbon* (*equally contributing authors)[5], for the ATHENA HIV Observational Cohort
[1]*Erasmus Medical Center, Department of Viroscience, Rotterdam, Netherlands,* [2]*Amsterdam Infection and Immunity Institute, Academic Medical Center, Department of Internal Medicine, Division of Infectious Diseases, Amsterdam, Netherlands,* [3]*Stichting HIV Monitoring, Amsterdam, Netherlands,* [4]*OLVG, Department of Internal Medicine, Amsterdam, Netherlands,* [5]*Erasmus Medical Center, Department of Internal Medicine and Infectious Diseases, Rotterdam, Netherlands*

Background: In Europe, as many as 50% of HIV-infected individuals present late to care. Late presentation is associated with high morbidity from AIDS-defining malignancies and opportunistic infections which may substantially increase the cost of care. The cost associated with late presentation has not been comprehensively assessed in the treat-all era. Our aim was to assess the additional cost of late presentation and factors contributing to high non-ART costs in a treat-all era.

Methods: The ATHENA cohort prospectively captures data of >98% of patients in HIV-care in the 26 treatment centres in the Netherlands. For this analysis data is used from individuals who first initiated ART between 1 July 2012 and 1 July 2013. We assessed the cost of late presentation(CD4< 350 cells/μL and/or AIDS) and presentation with advanced HIV disease(CD4< 200 cells/μL and/or AIDS) in the first year on ART. Costs of ART, hospitalization, outpatient visits, co-medication and HIV-laboratory tests were calculated. Factors independently associated with non-ART costs, were determined by multivariable logistic regression, including parameters with *P*< 0.1 from the univariable analysis.

Results: A total of 1,149 individuals were included with a median age of 40 years (Interquartile range (IQR)30-47) and median CD4-nadir of 330 cells/μL(IQR 229-420). 652(56.7%) patients were late presenters and 226(19.7%) presented with advanced disease. Nearly half (42.5%) of patients with advanced disease were of non-Dutch origin, compared to 32% in the total cohort. The mean cost per patient was €13,919(Standard deviation(SD) €8,301) of which €11,208(SD €4,258) represented ART cost and €2,711(SD €7,186) non-ART costs. Higher non-ART cost were calculated in individuals with advanced disease, €6,403(SD €14,631), ascribed to more hospitalization and, to a lesser extent, comedication (figure1). Few patients drive the non-ART cost resulting in a high SD. The ART cost was similar regardless of infection stage at entry into care. Factors that contributed independently to higher non-ART cost include CD4-cell count, AIDS-defining illness, regimen switching, and malignancies (table1).

Conclusions: Late presentation is associated with high cost in the first year on ART. Efforts toward earlier diagnosis, linkage to care and start of ART will not only improve individuals' clinical prognosis and contribute to HIV prevention, but also reduce short-term costs.

[Figure 1 : Mean non-ART cost per patient on their first year on ART stratified by CD4 -nadir cell-count.]

Parameter		Lowest 90% of the non-ART cost (<€3,500) n=1034	Highest 10% of the non-ART cost (>€3,500) n=115	Multivariable analysis Odds Ratio (OR) (95% confidence-interval)
CD4 nadir (cells/µL)	<200	16.2%	51.3%	OR 2.56 (1.44 - 4.55)
	200-350	38.4%	20.9%	OR 0.87 (0.47 - 1.59)
	>350	45.5%	27.8%	ref
AIDS-defining illness	YES	2.2%	22.6%	OR 4.20 (1.91 - 9.27)
Regimen switching	≥1	23.4%*	44.3%	OR 2.55 (1.60 - 4.05)
Malignancies	YES	2.7%	20%	OR 2.66 (1.21 - 5.86)
Route of transmission	MSM	67%	44.3%	OR 0.42 (0.26 - 0.67)

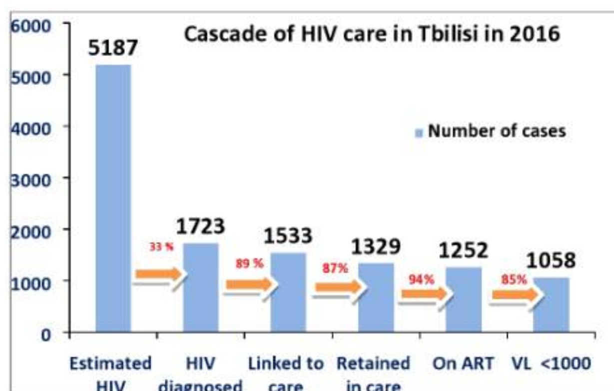
TUPEE579

Advocating for new forms of national funding of HIV and TB interventions as a response to mitigate the impact of donor retreat in Georgia

S. Chikhladze[1], N. Tsereteli[2], O. Chokoshvili[2], M. Chincharauli[3], M. Khmelidze[4]
[1]Center for Information and Counseling on Reproductive Health - Tanadgoma, Tbilisi, Georgia, [2]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia, [3]National Center for Tuberculosis and Lung Disease, Tbilisi, Georgia, [4]Georgian Harm Reduction Network, Tbilisi, Georgia

Background: The research implemented by the Georgian NGO "Tanadgoma" aimed at developing models of sustainable Tbilisi/Capital City response to HIV and TB in key affected populations (KAPs) and contributing to achieving 90-90-90 HIV/TB targets for key populations. Primary research objective was to elaborate lacking city-level data and treatment cascades for HIV and TB. This would allow identifying gaps and advocating for establishing funding mechanism for HIV/TB interventions from municipal level. The research was implemented under the project "Fast-track TB/HIV responses for key populations in EECA cities" funded by GFATM.

Methods: The research took place in September-December 2017. Overall research design and tools were developed by AFEW International and Alliance for Public Health. Methods used for developing Tbilisi HIV and TB treatment cascades involved analysis of key data sources available on national/city level at the National AIDS and TB Centers. Experts from AIDS Center and TB Center created city cascades using Spectrum based on the data collected.



[Tbilisi HIV Care Cascade 2016]

Results: As a result of the research for the first time in Georgia HIV/TB Tbilisi cascades were developed. Where possible the cascades address each key population for HIV/TB, including estimate of population size & estimated level of access, comparing levels of access with key targets from national level. The main findings indicate that on Tbilisi level the most significant gap is in diagnosing HIV, but once diagnosed, linkage and retention indicators are almost reaching the desired target. As for TB, treatment success rate among MDR TB cases including known HIV+ needs significant improvement as since 2012 it has never exceeded 45% and 30%, respectively. Tbilisi HIV cascade includes data on KAPs while these are missing in TB cascade.

Conclusions: Creation of city level HIV/TB data baseline and respective analyses is the first of its kind. Implications of such analysis include refining HIV/TB programming, improving diagnostics, service linkages and intersectional data management system, including data on KAPs. During transitional period in Georgia, the research data help identifying financial insufficiency, respectively plan and define city specific interventions/budgets, and provide evidence for advocacy to establish funding mechanism for HIV/TB interventions for KAPs in the city from municipal level.

TUPEE580

Musrenbang: An involvement the HIV community in the budget cycle process to strengthen the country role for HIV responses in Indonesia

B. Bariyah[1], S. Raharjo[2]
[1]Indonesia AIDS Coalition, Social and Mobilization, South Jakarta, Indonesia, [2]Indonesia AIDS Coalition, Advocacy, South Jakarta, Indonesia

Background: External funding for HIV prevention programs in Indonesia is coming to an end. Therefore, it takes effort to plan a funding transition from external funding into domestic. As part of the Sustainable HIV Financing in Transition (SHIFT) program run in four countries (Indonesia, Malaysia, Thailand, Philippines) funded by the Global Fund, Indonesia AIDS Coalition (IAC) is implementing a two year program in Indonesia focusing in transitioning HIV funding from external into domestic.

Description: A key activity under SHIFT is to strengthen the HIV community to be involved in the budget cycle process, called *Musrenbang*, in two districts where the program operates, Bandung and Semarang. Musrenbang includes the full budget cycle from district to national level and is held from January - December to determine the next year budget. It has become an important process to encourage and incorporate health issues, especially HIV / AIDS prevention, as priority issues in budgeting. The process of strengthening the HIV community in the two districts was achieved by improving basic advocacy skills and budget advocacy by studying the budget cycle and budgetary analysis.

Lessons learned: Musrenbang is a new area of engagement for the HIV community in Bandung and Semarang. Strengthening the HIV community to realize that this is an important opportunity for engagement takes a long time, they need ongoing technical assistance to beinvolved in this process. Moreover, the budget cycle process runs for a full year which requires an explicit commitment on the parts of . The space for negotiation and budget advocacy for HIV programs in district was actually opened after understand the mechanism and budget cycle process.

Conclusions/Next steps: Involvement of HIV Community in the Musrembang process is important and urgently needed to encourage and optimize the role of the country from the ground level through the budget that support the HIV responses in creating the sustainability. In addition, the presence and involvement HIV community emphasize that HIV response is a shared responsibility that need to be support and reinforced by the funding and government participation from the ground.

TUPEE581

Transitioning from international donor funded to government funded HIV/AIDS treatment and prevention programme in Nigeria

I.M. Ezekwe[1], O.C. Nwanyanwu[2], S. Aliyu[3]
[1]National Agency for the Control of AIDS (NACA), National Comprehensive AIDS Programme in States, Abuja, Nigeria, [2]Global Health Services Network, Michigan, United States, [3]National Agency for the Control of AIDS, Abuja, Nigeria

Background: The estimated population of Nigeria in 2016 was more than 190 million.[1] Despite the relatively low HIV prevalence of 2.9 percent, because of its large population, an estimated 3.2 million people were living with HIV in 2016.[1] Ninety percent of the one million persons on treatment in Nigeria receive treatment through donors - President's

Emergency Plan for AIDS Relief (PEPFAR) and Global Fund. International donors have been supporting the HIV response in Nigeria for many years and created systems for administration, program implementation, laboratory services, monitoring and evaluation, financial management, and reporting. With the donor envelope shrinking, the National Agency for AIDS Control (NACA) began the transition to a country-led, sustainable, and resource-appropriate model of HIV prevention and treatment.

Description: The transition process began in early 2014 with NACA requesting the transition of two states (Abia and Taraba) from the International Donor to the Government of Nigeria (GoN). Currently on treatment in these two states are **60,795** persons.

In both states, PEPFAR through the International Non-Governmental Organization (INGO) began its programs by jointly implementing HIV prevention and treatment activities with local transition in mind. Co-location offered the INGO and their respective State Implementation Planning Units (SPIUs) for HIV the opportunity to teach and learn from each other in planning, implementing, monitoring, and evaluating the programs. While INGO had a more robust complement of staff in all service areas, the few staff provided by the SPIUs were well trained and oriented, and engaged with INGO staff daily in conducting activities.

Lessons learned: Petroleum Subsidy Reinvestment and Empowerment Program Funds were made available to implement the President's Comprehensive Response Plan (PCRP). Transition from International donor funded HIV comprehensive treatment programme to Government ownership is seamless when recipients are involved in joint planning and implementation. With sufficient and regular funding, the transition proceeds smoothly.

Conclusions/Next steps: HIV prevention and treatment activities at the state level will be led by the existing State Management Teams (SMTs), with implementation carried out by the SPIUs. International donors should support Nigeria's effort to indigenize its operations and to get the best value for its money.

International assistance, frameworks, and funding mechanisms

TUPEE582

Innovation for an AIDS-free generation: Successes and challenges of a funds manager model to engage new partners for HIV prevention among adolescent girls and young women

F. Harris[1], C. Barbo[2], E. Easley[2], J. Mwangi[2], J. McCutcheon[2]

[1]JSI Research & Training Institute, Boston, United States, [2]JSI Research & Training Institute, Inc. (JSI), Boston, United States

Background: The DREAMS Innovation Challenge (DREAMS-IC) was established by the US Department of State (DOS)/PEPFAR in 2016 to aid in reducing HIV infections among adolescent girls and young women (AGYW). JSI Research & Training Institute, Inc. (JSI) supports 46 organizations' programs across 10 DREAMS African countries. These organizations differ in their level of institutional maturity, gender-responsive HIV programming, and knowledge of U.S. Government (USG) regulations.

Description: DREAMS-IC uses a Funds' Manager (FM) model to engage new organizations to implement innovative solutions for HIV prevention for an AIDS-free generation. As the DREAMS IC FM, JSI's responsibilities include: (1) management and monitoring of sub-awards for innovative HIV prevention programs, (2) capacity building to support sub-grantees' innovations targeting AGYW, (3) navigation of program alignment with donor priorities, national context, partner capacity, and beneficiaries' needs, and 4) technical assistance, contributing to sustainable local partners capable of leveraging international funding for the health and empowerment of girls.

Lessons learned:

1: Addressing the need to achieve evidence-based results and working with grantees to develop their organizational systems to facilitate better management of USG funds as well as strengthen the pool of local HIV implementers.

2: Some innovations require additional assistance in ensuring alignment with the UNAIDS/PEPFAR HIV prevention frameworks, given many sub-grantees have never received USG funding in the past. . The gap between technical requirements and sub-grantees' capabilities requires adequate time to bridge.

3: Adequate time should be planned for integration of USG regulations within organizations new to USG funding, particularly given various levels of management and coordinating structures.

Conclusions/Next steps: New, local organizations can offer innovative and culturally appropriate approaches to HIV prevention for AGYW. However, many require capacity strengthening over time to meet the rigorous expectations of international donors. This presentation will include an open discussion on how the international community can better empower local organizations and governments to effectively implement their public health agenda.

TUPEE583

Aid politics, developmental assistance for health and learned helplessness-narratives of evolving health systems in global south

M. Satpathy[1], J. Thomas[2], D.E. Lucero-Prisno III[3,4], B. Kanyemba[5,6], D. Haile Woldegebral[7]

[1]Utkal University, UGC Centre of Advanced Study in Psychology, Bhubaneswar, India, [2]Partners in Population and Development (PPD), Dhaka, Bangladesh, Dhaka, Bangladesh, [3]xi'an jiaotong-liverpool university (XJTLU), Suzhou, China, School of Public Health, Suzhou, China, [4]Global Health Focus, Suzhou, China, [5]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [6]Advocates for HIV Prevention-an Arm of AVAC, Cape Town, South Africa, [7]University of California Davis, School of Public Health, Davis, United States

Background: Globally, past three decades are marked by an increased and steady interest in global partnership, and collaboration by the developed world in furthering the welfare and wellbeing of resource-constrained societies and economies. Overseas investment in terms of Developmental Assistance steadily evolved with the passage of HIV/AIDS era in early 1980's, and a decline by 2015, as most developed nations retracted/reduced their commitment to invest in global health movement.

Methods: The paper builds on a reflexive thematic analysis using Global Burden of Disease Data focused around Developmental Assistance for Health and critiques its role in the posited health systems strengthening framework. With a focus on Global South (South Asia-India and Bangladesh), East Asia (China), Asia and Pacific (Philippines), and African continent, we analyzed the impact of Developmental Assistance for Health (DAH) in terms of 3 parameters: Improvement in Health and Wellbeing, Scale of Impact, and Changes in Health systems.

Results: The study converged on some paradoxical insights, built around the nexus of aid politics, and how it unwinds with passage of depleting aid-box. Consensus was on critical and instrumental role of DAH in reshaping, and revamping HIV/AIDS care, by significant investments in monetary, and in-kind contributions. DAH has contributed enormously by investing in global health, and thereby helped shape these economies improve their overall stature.

However, the study also indicated that, DAH and the aid politics has significantly weakened these nations by a process of systemic dependency, may be have induced a state of Learned Helplessness, unconsciously so. This systemic dependency, and increased expectation (and resultant disappointment post 2015), have shook the spine of the health systems.

Conclusions: This illusory entrapment in such a state, with lessened resilience calls for an increased engagement of the developed nations, and their re-orientation in terms of investments not just in capital commitment, but in altruistically engage to develop the health systems by infusing and enhancing knowledge economies. Similarly, it also indicates that Governments and policy makers of these nations need to recognize the need, and respond effectively with increased efforts at health systems strengthening, by adopting holistic strategies focused around social drivers of health and wellbeing.

TUPEE584

Where does the buck stop?: Analysis of HIV prevention research and development (R&D) direct and country focused investments in sub-Saharan Africa

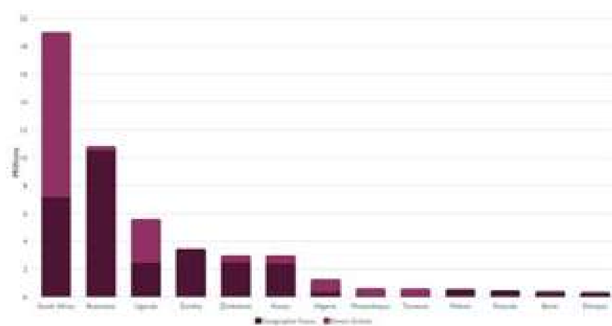
F. Riaz, K. Fisher, M. Warren
AVAC, New York, United States

Background: The Resource Tracking for HIV Prevention R&D Working Group report documented for 2016 the decade's lowest funding for HIV prevention research. This declining investment imperils the currently donor-dependent research landscape in sub-Saharan Africa - home to 81 percent of HIV prevention trial volunteers and two-thirds of people living with HIV globally. The magnitude of foreign investment in HIV prevention R&D for specific countries has remained unclear. Addressing this gap is central to understanding how HIV research supports African researchers.

Methods: To assess HIV prevention R&D investments in sub-Saharan Africa for the calendar year 2016, data was collected via annual surveys and direct disbursements by public, private and philanthropic funders. Grants were allocated to countries if they were either directly awarded to African researchers, or clinical or implementation science research geographically focused in sub-Saharan Africa. Where grants did not delineate between countries, the amounts were split equally. Investment trends were analyzed by country and prevention modality.

Results: Of the overall US$1.17 billion allotted to HIV prevention research in 2016, this analysis identified 98 grants totaling US$47 million awarded to researchers or trials in sub-Saharan Africa. Huge variance existed in investments, with four countries (South Africa, Botswana, Uganda and Zambia) receiving 81 percent of all funding. South African research institutions received the greatest amount of direct funding at US$11.6 million, while Botswana had the largest single grant (US$10.7 million) for a treatment as prevention (TasP) trial. Microbicides, TasP, preventive vaccines, voluntary medical male circumcision, pre-exposure prophylaxis and prevention of vertical transmission received 23 percent, 20 percent, 20 percent, 17 percent, 16 percent and 4 percent of total funding, respectively. Investment of US$3.7 million was made to strengthen existing HIV research infrastructure.

Conclusions: Direct funder investment in African researchers and institutions is critical to supporting national efforts to create a sustainable and robust HIV prevention research enterprise. Only 4 percent of biomedical HIV prevention research in 2016 was awarded directly to researchers or trials in sub-Saharan Africa. Yet, this investment in African researchers is critical to building sustainability and making the case for greater domestic investment in the region in the face of shifting donor priorities.



[Investment in Biomedical HIV Prevention R&D in Sub-Saharan Africa (USD)]

TUPEE585

Applying the Global fund allocation formula - are the data driving allocations?

A. Sharp, A. Jones, J. Sherwood, B. Honermann, G. Millett
amfAR, The Foundation for AIDS Research, Public Policy Office, Washington, United States

Background: Global Fund (GF) allocates funding to countries on the basis of a two-stage Formula: a quantitatively-measured raw allocation is qualitatively adjusted for contextual indicators, including HIV prevalence among key populations (KP). However, availability of KP data is limited, possibly diverting funds from concentrated epidemics. By modeling funding allocations, we identify the major drivers of allocations and qualitative adjustments and the impact of data availability.

Methods: We applied the Formula to available data across 101 recipient countries. HIV allocations (2017-2019) were linearly regressed on the raw allocation (per the Formula, number of people living with HIV and economic capacity, adjusted for minimum/ maximum shares and external funding sources) and data reportedly used in qualitative adjustments: domestic spending on HIV, past grant rating, ART coverage, World Bank income category, 'smoothing' of changes in 2014-2016 allocation to current raw allocation, and HIV prevalence data among KPs.

Results: Total allocations from the GF declined by 34% for 2017-2019 relative to 2014-2016. For individual countries, the strongest predictor of final allocation was raw allocation (adjusted R^2 = 0.713), with 88% of variation captured in a parsimonious model of raw allocation, domestic spending, income category, ART coverage, and smoothing in allocation differences relative to 2014-2016. Qualitative adjustments were primarily driven by smoothing to account for sharp declines in HIV allocations relative to 2014-2016; in addition, countries with higher domestic investments and lower ART coverage had greater proportional adjustments ($p < 0.05$). After controlling for other factors, KP prevalence data did not significantly predict allocation nor qualitative adjustments, although only 40% of countries had data for all KPs.

Conclusions: Country allocations were largely captured by public data, with remaining variation likely due to indicators described in the Formula but not publicly available. Qualitative adjustments to allocations were driven by the significant drop in HIV allocations relative to 2014-2016, possibly obscuring adjustments made for KP prevalence. Reducing year-to-year fluctuations in budget is needed to ensure Global Fund's ability to make epidemiologically appropriate allocations and ensure programmatic continuity. Greater transparency in methodology is needed to clarify how KP data are used in allocation decision-making.

TUPEE586

A quarter for prevention? Global fund investments in HIV prevention interventions in generalized African epidemics

G. Oberth[1,2], M.A. Torres[3], O. Mumba[4], M. O'Connor[5]
[1]International Council of AIDS Service Organizations (ICASO), Cape Town, South Africa, [2]Centre for Social Science Research, University of Cape Town, Cape Town, South Africa, [3]International Council of AIDS Service Organizations (ICASO), Toronto, Canada, [4]Eastern Africa National Networks of AIDS and Health Service Organizations (EANNASO), Arusha, Tanzania, United Republic of, [5]International Council of AIDS Service Organizations (ICASO), Ottawa, Canada

Background: In July 2016, the Joint United Nations Programme on HIV/AIDS (UNAIDS) announced that global efforts to reach fewer than 500,000 new HIV infections by 2020 are off track. UNAIDS estimates that ending AIDS by 2030 will cost $25 billion a year. About a quarter (26%) of this amount is required for prevention. The Global Fund to Fight AIDS, Tuberculosis and Malaria is a major financier of African HIV responses and a vital source of prevention investments.

Methods: A search was performed for Global Fund funding requests and signed grants from a sample of 25 African countries over the 2014-2016 funding cycle. Funding requests were accessed for 23 countries and signed grant agreements were accessed for 15 countries. Some documents were not publicly available. The budgets of the funding requests and grant agreements were examined to determine levels of HIV pre-

vention funding. Epidemiological and structural variables were explored to help explain the results.

Results: Of the funding requests examined, an average of 16% was dedicated to HIV prevention. Ten countries requested at least a quarter for prevention. Mauritius' request for prevention was the largest (67%) and Mozambique's was the smallest (3%). A significant correlation was found between the number of new HIV infections in a country and the amount of prevention funding requested (r=.747, p=< .01), suggesting that funding requests are aligned to disease burden. A significant correlation was also found between GDP/capita and the proportion of prevention funding requested (r=.676, p=< .01), likely because poorer countries are more dependent on the Global Fund for treatment. Of the grant agreements examined, an average of 15% was dedicated to HIV prevention. Only Botswana and Liberia had at least 26% of their grant budgets allocated to HIV prevention.

Conclusions: In order for the Global Fund to achieve its HIV prevention targets in its new strategy, there is a need to increase Global Fund investments in HIV prevention in Africa from current levels (15%) towards the UNAIDS benchmark (26%). Advocacy from civil society and communities is absolutely vital, particularly in urging countries to request greater HIV prevention funding for key populations and adolescent girls and young women.

TUPEE587

Review of strengthening integrated delivery of HIV/AIDS project (SIDHAS) accountability framework of HIV/AIDS financing with civil society organizations, government agencies and private institutions in Nigeria

O. Yemisi Bolanle, O. Agbaje, I. Utuk, C. Momah, N. Aliyu, C. Okhakumhe, C. Esuga, O. Olayemi, H. Khamofu, E. James, S. Raj Pandey
FHI 360, Program Management, Garki, Nigeria

Background: HIV care and treatment in Nigeria is largely managed by a combination of public and private health facilities. Although these institutions have experienced declines in funding from government/private owners over the years, they still account for the majority of patients in care. To bridge the funding gap, the USAID-funded SIDHAS project introduced different types of grants financing approaches and accountability frameworks to support scale up of HIV prevention, care and treatment services in 13 states in Nigeria. We share experiences from the various accountability frameworks applied on the project.

Description: From inception of SIDHAS project in 2011, FHI360 Nigeria conducted thorough pre-award assessments, after which 76 sub-awards were executed in 13 states between SIDHAS and State government for public health, faith-based, civil society organization, and private health facilities. Capacity building through trainings and mentoring was conducted. Accounting practices such as system enhancement, compliance audits, quarterly grant modification, expenditure analysis, scorecard audit, fund request review, documentation and reporting was mandated for each implementing agency (IA) routinely. A qualitative content analysis of the IAs' accounting practices, frameworks, reports and HIV prevention, care and treatment services delivered was conducted between October 2016 and September 2017.

Lessons learned: From the monthly expenditure analysis, sub-award monitoring reports and HIV program data reported across the 76 IAs showed that 100% of the IAs were compliant with submission of financial and program reports for the period of assessment. HIV testing, initiation of client on treatment and provision of care services were not interrupted at those sites within the period. An analysis of this result further shows that the combination of capacity building and use of accounting frameworks was instrumental to the results. About 82% Improvement in quality of program and financial reports received was recorded within the year demonstrating improved technical, institutional and financial domains of sustainability.

Conclusions/Next steps: A combination of accountability approaches resulted in improved ability of IAs to provide HIV services, manage, and account for donor resources. Providing a combination of accountability structures for IAs can expand their ability to better manage and sustain delivery of comprehensive HIV prevention, care and support services.

TUPEE588

Innovative Grant Fund: A lifeline for small community-based organizations

L. Mizuno, L. Wong
AIDS Healthcare Foundation, Global Advocacy, Los Angeles, United States

Background: In response to a lack of funding for smaller HIV/AIDS community service organizations around the world, in 2012 we created a Grant Fund which has funded 389 projects totaling $7.4 million over the past six years. The fund focuses on providing small, short-term grants to organizations whose activities advance HIV awareness, prevention, treatment and the elimination of stigma.

Description: Funding for the Grant Fund is generated through social enterprises in the United States, such as second-hand stores and pharmacies. The Grant Fund encourages innovation by funding pilot projects and programs that would not necessarily be eligible for traditional grants, such as advocacy campaigns and art exhibits. Additionally, the Grant Fund application is kept short with minimal jargon, as many small organizations may not have access to professional grant writers. Each month, the Grant Fund Committee reviews grants, funding organizations within 2-6 weeks of application on average. The structure of the Grant Fund has been developed to support organizations that may not normally get funded via traditional donors.

Lessons learned: The Grant Fund demonstrates the need for funding that creates opportunities for growth and innovation. The average operating budget for organizations applying for grant funding in 2017 was around $190,000. The average program budget was $50,000, of which, the average grant request was $19,900. This means that the average request was covering a little over half (53%) of the organization's total budget and 70% of the program budget. Approximately one fourth of applications were for pilot projects or independent programs with no other funding sources.

Conclusions/Next steps: From the growing interest in the Grant Fund, it is evident that there is a need for more innovative funding structures, especially those that don't always favor larger and more established organizations. Small community based organizations are the lifeblood of prevention many communities, and it is important for them to find sustainable paths for growth. As HIV service providers we strive to address the needs of clients "where they are." Unfortunately, the funding structures for HIV prevention services do not follow a similar philosophy to meet organizations where they are.

Financing HIV within UHC frameworks

TUPEE589

Financial feasibility of delivering HIV/AIDS services through health insurance schemes

F. Ilika, G. Alawode, S. Akande, E. Baruwa
Health Finance and Governance Project, Health Financing, Abuja, Nigeria

Background: HIV/AIDS is of a great burden in Nigeria with high reliance on donor funding. One of the ways to improve domestic funding for HIV/AIDS is its inclusion in health insurance benefit packages in order to ensure stable, predictable and sustainable financing. The National Health Insurance Scheme has decentralized health insurance to states and Lagos state is one of the early states to design their state health insurance scheme (SHIS). HIV/AIDS is often excluded in many health insurance packages and classified as a pre-existing condition. A primary concern for HIV inclusion in the SHIS is its potential negative impact on financial sustainability of the scheme.

Methods: This study was conducted in August 2017 to assess the financial impact and feasibility of providing HIV/AIDS services through the Lagos SHIS. An actuarial analysis was conducted and modular pricing for priority HIV services including HCT, PMTCT, and ART was done adopting historical data on population, HIV incidence, service utilization rates from routine health data, and projected costs from Global fund HIV

Quantification data. Additional risk premium for HIV/AIDS cover in the scheme was analyzed and a sensitivity analysis was done to compare input assumptions with probable situations.
Results: Additional risk premium of HIV/AIDS cover under the SHIS is N209.40 (68cents) per person per year, assuming 100% enrolment and a 30% contingency margin. Further sensitivity tests considering enrolment of 50%, 20% and 10% of the population produced variations with additional risk premium of N295.66, N694.81 and N1360.00 respectively. Varying incidence rate, service utilization, medical inflation and increase in exchange rates based on previous cycles; the additional risk premium is N302.81 ($1), values much lower than expected.
Conclusions: Findings showed that HIV service provision in the SHIS is financially feasible, but requires high insurance coverage levels to minimize costs. These findings will embolden HIV advocates to use similar financial evidence to make adequate cases to policy makers for HIV services inclusion in health insurance schemes; creating additional and sustainable financing for closing HIV treatment gaps. Donor efforts may be directed at strengthening systems for HIV service provision through systemic structures for reduced fragmentation, improved efficiency and sustainability.

Approaches to achieving sustainability

TUPEE590
Financing HIV/AIDS services through Health Insurance schemes - the Lagos state experience

U.H. Edumoh[1], O.K. Ogundapo[2], S. Akande[3]
[1]Abt Associates, International Health Division, Bethesda, United States, [2]Abt Associates, International Health Division, Lagos, Nigeria, [3]Abt Associates, International Health Division, Abuja, Nigeria

Background: Funding for HIV/AIDS remains a problem in most low and middle income countries, including Nigeria. In an effort to introduce a more sustainable means of financing for HIV in Lagos State, the Sustainable Financing Initiative executed by the Abt-Associates led USAID Health Finance and Governance (HFG) Project together with HIV stakeholders in the State sought to integrate HIV services within the newly introduced Health Insurance Scheme known as the Lagos State Health Scheme (LSHS).
Description: HFG supported HIV stakeholders in the Lagos State HIV Domestic Resource Mobilization Technical Working Group (DRM TWG), which comprises of both State, private, implementing partners, and CSOs to devise strategies for integrating vertical programmes providing HIV services within the Lagos State Health Scheme and include the full complement of HIV services (HTS, PMTCT, ARVs) on the benefit package of the scheme.
Lessons learned: Three main strategies were employed looking at the financial feasibility, technical feasibility and operational feasibility of integrating HIV services on the scheme. For the financial feasibility, an Actuarial analysis was conducted to determine the financial implication of having HIV and AIDS services on the LSHS benefit package. This amounted to an additional NGN209.40 per person per year on the premium at a point estimate of 100% coverage of the population. At lower levels of population coverage i.e 10% the cost could rise up to NGN1, 360.07. On the technical feasibility, a service availability mapping was conducted to identify the health facilities within the provider network with capacity to deliver HIV/AIDS services and address other technical aspects of integration. On the operational feasibility, an integration framework and implementation plan was developed on the key integration areas along the lines of service delivery arrangements, Human Resources for Health/capacity building, Logistics and supply chain management systems and monitoring and evaluation.
Conclusions/Next steps: Findings from the actuarial study and the technical and operational plans for service integration strengthened the inclusion of comprehensive HIV and AIDS services as part of the Lagos State Health Scheme benefit package. This will help ensure financial sustainability of HIV services in the State and improve access for HIV services for People living with HIV.

TUPEE591
Filling in the gaps: Extrapolating VMMC unit costs using aggregated primary data from several studies

S. Bautista-Arredondo[1], C. Pineda-Antunez[1], D. Cerecero-Garcia[1], S. Forsythe[2], M. Tchuenche[2], J. Kahn[3], A. Vassall[4], V. Mennon[5], L. Alexander[6], C. Chiwevu[5], K. Kripke[7], C. Levin[6], L. Bollinger[2]
[1]National Institute of Public Health in Mexico, Health Economics and Health Systems Innovation, Cuernavaca, Mexico, [2]Avenir Health, Glastonbury, United States, [3]University of California San Francisco, San Francisco, United States, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]HPI Costing Task Order, Washington, United States, [6]University of Washington, Seattle, United States, [7]Avenir Health, Washington, United States

Background: The policy-relevance of cost information hinges on it being provided in a timely fashion. But cost studies are expensive and slow to implement, meaning this type of evidence is not available at moments of critical decision-making. The objective of this work is to combine data on costs of VMMC services from several independent studies, to identify determinants of VMMC costs and extrapolate costs to areas where there is absence of information.
Methods: We identified high-quality VMMC cost studies through a literature review. Authors were contacted to share their data on costs and service delivery characteristics. We standardized the disparate datasets into an aggregated database which included 228 facilities in eight countries. We estimated VMMC unit costs (or average cost per circumcision). We conducted OLS regression models to estimate the effect of the determinants of unit cost variation across sites. Based on cluster analysis, we extrapolated unit cost to different implementing scenarios, including countries out of our sample and different levels of scale.
Results: The average unit cost was 73 USD (IQR: 28.3, 100.7). South Africa showed the highest within-country cost variation, as well as the highest mean unit cost (135 USD). Uganda and Namibia had minimal within-country cost variation, and Uganda had the lowest mean VMMC unit cost (22 USD). Our results showed evidence consistent with economies of scale. Private ownership and Hospitals were significant determinants of higher unit costs. By clustering countries with similar economic, epidemiologic and demographic indicators, and through multivariate extrapolations, we extrapolated unit cost to countries without available cost data.
Conclusions: Our results showed large variation in VMMC unit costs across and within countries. We identified several facility-level characteristics significantly associated with VMMC unit costs across implementation and country contexts. Our findings contribute to improving the availability of cost evidence, even for those countries with no previous studies, in order to increase the efficiency of service delivery.

TUPEE592
Integration of sexual reproductive health rights and sustainable development

J. Nyanjom, C. Ayoma
Family Health Options Kenya, Programs, Nairobi, Kenya

Background: Kenya like other countries in Africa is facing the risks of climate change and this is anticipated to affect the country's sustainable development efforts. Integration on the other hand links sectors and supports cross-sectoral collaboration and coordination. The world all over is working towards the sustainable development goals. SRHR and Sustainable development project, is a 3-year project being implemented by Family Health Options Kenya, an affiliate of IPPF together with two other partners in Kisumu and Siaya county. It focuses on improving resilience of the vulnerable communities through the integration of reproductive health and rights into sustainable development programs through promotion of adaptation practices that help community members improve their level of resilience, The objective of the project is to increase the capacity of vulnerable communities to apply an integrated approach to SRHR. The project works with structured community groups comprising of women, men and the youth.
Description: Capacity building: Awareness creation on the importance of integration and sustainable development, training on adaptation practices for sustainability

Service provision: Comprehensive sexual and reproductive health services through community outreach services, integration of SRHR services, especially HIV/AIDS and family planning with other practices such as kitchen gardening for nutritional foods
Reach out strategy: The structured groups reaching out to fellow community members and creating a ripple effect and a resilient community
Networking and linkages: Working closely with extension officers in the communities, the Community Health Volunteers and agricultural extension officers and this solely for continuity of service provision. The extension officers offer skills, information, such as importance of HIV testing and community-based trainings regularly to the community members
Advocacy: Advocacy on scale up and resource allocation for more communities to benefit from the integration.
Lessons learned: Cross sectoral collaboration is important in development and it maximizes on the resources available hence sustainability.
Results 16106 women of reproductive age reached with SRHR services among these 6719 women were tested and 102 linked to care.
Conclusions/Next steps: Scale up and resource allocation to reach more communities and advocacy for community members to continue getting quality SRHR services as they work towards sustainable development.

[Women's group dicussing HIV and nutrition]

TUPEE593

Twinning partnerships support training programs introducing new health worker cadres in South Africa to sustain the HIV response

J. Capati[1], I. Jurkevich[2], K. Utan[2]
[1]American International Health Alliance, Pretoria, South Africa, [2]American International Health Alliance, Washington, United States

Background: American International Health Alliance (AIHA) developed local capacity in South Africa to train healthcare workers with the targeted skills needed to provide quality HIV/AIDS-related services. AIHA supported training programs introducing two new health worker cadres in South Africa: clinical associates (physician assistants) and pharmacy technicians. AIHA capacity-building partnerships supported the training programs at partner institutions, which have graduated 909 clinical associates and 187 pharmacy technicians who are deployed throughout South Africa.
Description: Using a multi-pillar approach for strengthening human resources for health, AIHA's PEPFAR-funded and HRSA-supported HIV/AIDS Twinning Center Program established and/or strengthened curricula and faculty for the following training programs: the 3-year Clinical Associate Bachelor's programs at the University of Pretoria, Walter Sisulu University, and the University of the Witwatersrand; and the 2-year pharmacy technician diploma program at Nelson Mandela University. The clinical associate and pharmacy technician programs stress practical over didactic training with clinical rotations built into the programs.
Lessons learned: Clinical associates are helping to improve patient adherence, care and treatment through district hospital HIV services in rural, underserved and high prevalence district hospitals with a lack of doctors. They provide patient consultations, HIV testing, ARV initiation, adherence counselling, ART regimen change, opportunistic infection management and medical male circumcisions. Each clinical associate provides care for approximately 17 PLHIV in a typical day. At one NGO program, clinical associates perform 1,500 VMMCs per month at 16 sites in four provinces. Pharmacy technicians conduct ARV drug dispensing and support ART adherence in PHC settings. Clinical associate graduates recruited from underserved areas are returning to those areas to work: 80% work in public facilities and 64% work in rural areas.
Conclusions/Next steps: Twinning partnerships have demonstrated effectiveness in developing the local capacity to train the needed human resources for health for the HIV response. Instead of relying on seconded staff and foreign personnel; countries and donors should support investments to scale up local pre-service programs to train local health care workers to sustain the HIV response and achieve the 90-90-90 goals and ultimately sustain epidemic control throughout Sub-Saharan Africa.

TUPEE594

A novel approach to enhance the sustainability of national HIV/AIDS programs: PEPFAR's incorporation of sustainability tools within business processes

C. Hart, M. Ruffner, J. Timberlake, M. Wollmers
US Department of State/PEPFAR, Washington, United States

Background: Despite the enormous strides made towards controlling HIV/AIDS, there is still much work left to be done. Country-led efforts to accelerate viral suppression through "test and treat" must simultaneously lay the groundwork that sustains current and future achievements in controlling the epidemic.
Description: PEPFAR developed an HIV/AIDS Sustainability Index and Dashboard (SID) to sharpen the understanding of each country's sustainability landscape, and has mandated its use for investment planning and to inform and monitor progress. The SID process supports a common view of where efforts and investments must be focused.
Lessons learned: SID implementation has proven to be a successful model for transparent engagement of diverse stakeholders in strategic planning discussions. Sustainability at PEPFAR is now hardwired into its investment planning and monitoring processes. During COP development, SID results inform the identification of critical barriers to reaching 95-95-95 through the formulation of a "Table 6" for each country. The Table 6 completion process requires planners to identify systems investments and establish clear benchmarks and outcomes needed to address critical systems barriers. The aggregated table below demonstrates the level of systems investments in PEPFAR-supported countries in FY 2018:

TABLE 6 INVESTMENTS BY CATEGORY, FY 2018

[Table 6 Investments by Category, FY 2018]

A review of the relationship between targeted investments and interventions selected through the Table 6 completion process reveals clear evidence of improvements across health systems that support sustained epidemic control. An analysis of country-specific data that triangulates SID results, systems investments, and achievement of outcomes shows improvement across many SID elements in most PEPFAR partner countries—particularly in areas such as laboratory systems, policy and planning, domestic resource mobilization, and quality management.
Conclusions/Next steps: PEPFAR's establishment of a means to measure sustainability that is directly linked to its planning and monitoring processes is strongly influencing sustainability investments and

achievements. It allows program planners to invest in the most needed areas with clarity of expected outcomes, and supports them to define short-, mid- or long-term outcome views. Through the use of these unique tools, PEPFAR is spearheading efforts to remove critical barriers to reaching and sustaining epidemic control while building greater transparency and accountability for achieving those results.

TUPEE595

Supporting evidence-based planning for HIV counseling and testing and opioid substitution therapy services: Results from a cost study in 7 high-burden PEPFAR-supported regions in Ukraine

N. Kovalenko, M. Duda, N. Avaliani
USAID HIV Reform in Action Project, Objective 2. Health Finance and Budgeting, Kyiv, Ukraine

Background: As of today, HIV Counseling and Testing services (HCT) and Opioid Substitution Therapy (OST) services in Ukraine are provided without proper estimation of their real costs. As country strives to achieve 90-90-90 targets, understanding costs of key elements in HIV prevention and care continuum, such as HCT and OST, becomes critically important. This is further relevant as Ukraine aims to introduce pay-for-performance approach through the health financing reform. The USAID HIV Reform in Action project conducted analyzed costs per HCT and OST service using a costing model and identified facility-level cost drivers in a sample of facilities in 7 high-burden PEPFAR-supported regions.
Methods: We used a "bottom-up" method to estimate HCT and OST costs, using an electronic costing tool. Cost data, including direct, administrative, and overall unit costs, were collected from facility budgets, procurement records, and medical providers' self-assessments. For each cost item we specified quantity, technical specifications, purchasing price, and level of use. We also separately calculated costs of pre- and post-counselling and testing (rapid tests) in case of HCT services.
Results: We found variation in per person HCT and OST service costs across different types of facilities. The highest per person HCT cost was observed at a Primary Healthcare Center in Dnipropetrovsk oblast - 12.96 USD, the lowest - at the TB dispensary in Odesa oblast - 4.27 USD. In case of OST - the highest cost was observed at the hospital in Mykolayiv oblast - 2.44 USD; the lowest at TB dispensaries in Odesa Oblast - 1.16 USD. Factors affecting HCT and OST costs vary substantially and depend on a type of a facility, composition of personnel providing services (one or two nurses and doctor for HTC services; one doctor and one nurse for OST service); time spent for each service, procurement methods and utility costs.
Conclusions: Understanding the costs of providing HTC and OST services can optimize the allocation of resources and support effective decision-making at a facility level, thereby increasing efficiency. As the health reform seeks to decentralize planning and funding processes, local level data is instrumental for effective planning, service delivery, and attracting additional funding.

Are users willing to pay for condoms in sub-Saharan Africa? Surveys in five countries: Kenya, Nigeria, South Africa, Zambia, and Zimbabwe

R. Ganesan[1], J. Tuchman[2], L. Hartel[1], I. Thior[3], B. Deperthes[4], K. Kadirov[5], C. Broxton[5], C. Thompson[1], S. Hefter[1]
[1]Abt Associates, Rockville, United States, [2]USAID, Windhoek, Namibia, [3]AIDSFree Project, Arlington, United States, [4]UNFPA, New York City, United States, [5]USAID, Washington, United States

Background: The condom market in many sub-Saharan countries is dominated by subsidized condoms—free brands from the public sector and socially marketed (SM) brands from social marketing organizations (SMOs). The commercial sector share of the total market is often small. Freeing up resources devoted to subsidized condoms for use with other urgent priorities requires answering the following questions:
(1) are users of free condoms willing to pay for them?,
(2) are SM users willing to pay commercial prices? and
(3) if commercial brands were to reduce their prices, could they attract SM users?
Methods: Study countries were selected in consultation with government counterparts, condom manufacturers, SMOs, and donors, based on their potential for an increased role of commercial condom brands. The USAID-funded AIDSFree Project conducted cross-sectional household surveys with more than 6,500 adult male condom users in 2017 in Kenya, Nigeria, South Africa, Zambia, and Zimbabwe. Surveys used multiple price determination approaches—bidding game, discrete choice model, and van Westendorp price sensitivity measure—to estimate consumers' willingness to pay for condoms. Analyses included price sensitivity simulations and secondary source consultation (i.e., demographic health surveys and condom market assessments).
Results: Free condom supplies exceed demand in all countries except South Africa, where recent demand data were unavailable for comparison. In Kenya, Nigeria, and South Africa, free and SM users are willing to pay substantially more than what they currently do for condoms. Yet decreasing the price of commercial brands is unlikely to attract SM users. In Zambia and Zimbabwe, free and SM users are willing to pay marginally more than they currently do.
Conclusions: Our assessment calls for greater alignment between levels of supply and demand for free condoms. In Zambia and Zimbabwe, abrupt funding reductions for free and SM brands would likely prompt a substantial proportion of users to cease using condoms; a gradual, phased approach is recommended. In Kenya, Nigeria, and South Africa, the condom markets possess the right conditions for transition to more commercially sustainable models. However, this does not negate the need for targeted distribution of condoms to vulnerable populations or initiatives that promote condom use.

TUPEE597

Strengthening African civil society organizations for sustainable community-driven HIV programs: The blood:water model pairing grants and community system strengthening

N. Kist[1], C. Kuloba-Warria[2], B. Bruerd[3], A. Sands[4], S. Doerr[5]
[1]Blood:Water, Africa Partnerships, Nairobi, Kenya, [2]Warande Advisory Center, Principle, Nairobi, Kenya, [3]Blood:Water, Africa Partnerships, Nashville, United States, [4]Blood:Water, Systems, Nashville, United States, [5]Blood:Water, Nashville, United States

Background: Structural HIV-interventions are increasingly recognized as gatekeepers to accelerate and sustain progress towards the 90-90-90 goal. Local civil society organizations (CSOs) emerge as the critical link between community and facility contexts, ensuring a continuum of HIV-treatment, support and prevention. However, sector-wide funding constraints saw a decline in resourcing CSOs and their community-extension programs. Restrictions further inhibit CSOs' abilities to invest in operational health and longevity.
Description: In response, Blood:Water developed a framework complementing bilateral funding mechanisms by positioning flexible private philanthropy towards African CSOs responding to HIV/AIDS. Inextricably paired with programmatic grants is an Organizational Strengthening (OS) process that provides 10,000 USD of supplemental and restricted funding for organizational investments. A participatory self-assessment is applied using the Institutional Development Framework (IDF). CSOs are scored across 4 developmental stages: Beginning, Developing, Expanding, Sustaining (0.0-4.0). Quantitative and qualitative metrics are used to identify priorities for investment which are then executed, over two-year cycles for up to 8 years.
Lessons learned: 7 CSOs in 6 African countries have undergone the first cycle of the IDF process. Average scores place CSOs as Developing (2.3), considered vulnerable. Strengths across CSOs were technical resources (2.53) demonstrating mastery in programs and service delivery. Lowest scores were financial (2.25) and human resources (1.86). Factors attributing to this include limited diversity of funding sources and heavy restrictions on use. Lack of formal staff recruitment, compensation and development systems leaves CSOs vulnerable to high workforce at-

trition. CSOs invested their 1st funding cycle into solutions addressing policy, systems and skills gaps. Solutions were CSO-driven using local expertise exclusively. Results are monitored longitudinally with reassessments anticipated in 2019 to ascertain impact on overall stability and missional-efficacy.

Conclusions/Next steps: To date, this framework demonstrates the feasibility of strengthening African CSOs to sustain community HIV-interventions with limited resources. Strengthened organizations directly reinforce program quality and impact. When applied deliberately to complement the formal health sector, the anticipated outcome is a strengthened and resourced civil society organization implementing programs that create demand for and reinforce clinical models while championing their communities before government. These synergies will more efficiently resource comprehensive coverage of African-led and locally sustained HIV/AIDS responses.

TUPEE598

Community driven affordable and sustainable health service model for MSM and TG in Mumbai, India

U. Sharma, P. Bora, P. Naik, R. Thorat
Humsafar Trust, Mumbai, India

Background: HIV interventions in India have traditionally been government-funded. While the approach has always aimed to provide holistic services for key populations, the efforts often encounter barriers and challenges that limit these initiatives. Sustenance of a holistic approach was further impacted after 2014 due to down-scaling of HIV interventions. The Humsafar Trust (HST) a CBO in Mumbai, India, adopted a unique approach to continue providing HIV care and treatment services to MSM /TG communities.

Description: To ensure sustainability in and provision of health services, HST introduced a "Free-to -Fee" model in December 2015, by introducing Blue and Green health cards that would reduce reliance on funded interventions by introducing an annual fee of INR 1000 (USD 30) for clients earning over INR 15000/month (USD 250) entitling them to a Blue Health card. The card provided holders quarterly HIV/Syphilis tests as well as unlimited consultations with physicians, mental health professionals, nutritionists, and legal/crises support. These services would be offered at no cost to individuals (green card holders) earning less than INR 15000/month thus allowing free services being cross subsidized for those who can´t afford to pay. Self-reporting of income was adequate while assigning card to a client. Initially we faced challenges as the community had only received services for free till then, the approach received gradual acceptance in 2016-2017. Since its inception, HST has generated INR140000 ($11666) as a revenue along with providing services to free for an additional 1868 people.

Lessons learned: While efforts to improve HIV care and treatment services will remain, HIV interventions implemented by CBOs must focus on sustainability by introducing "Free to Fee" models as a way to cross-subsidize services. This would ensure that the most-at-need communities continue receiving services for free while those who can afford to pay can contribute toward sustainability. This model also ensures that `no one will be lost' as far as HIV prevention is concerned.

Conclusions/Next steps: Upscaling the "Free to Fee" model will be crucial along with including additional services to make the model as holistic as possible. Scaling and strengthening this model will further reduce reliance on external funding mechanisms for communities' health needs.

TUPEE599

Swa-Shakt - leveraging the power of communities: Member led local crowd funding model

T. Narendran
Vrutti, Livelihood Impact Finance & Resource Mobilization, Bangalore, India

Background: Community Organisations (COs) of marginalized populations infected and affected by HIV/AIDS in India are witnessing a substantial decrease in funding from Government and donor agencies.The uncertainty stems from various reasons, including change in priorities of the Government, shift in focus of donor agencies and growing competition between local NGOs and COs for limited funding opportunities. Long term sustainability of COs and the community's agenda is possible only if they are enabled to raise resources locally. The core of the Swa-shakt fundraising campaign lies in the direct involvement of the community to sustain their organizations while also empowering them, ensuring ownership and hugely reducing external dependencies. Swa-Shakt, derived from the Sanskrit word swashakti, blends two characters of `swa' meaning self and shakti meaning power. Swa-Shakt stands for being self sufficient.

Description: Between May 2016 and Sep 2017, Swa-shakt campaign was rolled out on a pilot basis in 25 Community Organizations across 5 states of India as part of the Avahan program funded by Gates Foundation and implemented by Swasti in partnership with Vrutti and CMS. Swa-shakt receives support from Swasti on strategic guidance, capacity building, communication materials, technology solutions, management of donations and overall coordination. A mobile cum web application called mCollect was used for data collection and monitoring during the process which tracked individual donations received and sends receipts to donors and receivers besides generating individual member and CO wise reports.

Lessons learned: USD 153,846 was raised involving 12000+ community members. Average collection per organisation is USD 2100 and average collection per member is USD 25. Through this campaign, COs raised 35-40% of total funds required yearly to run their organisation.

Conclusions/Next steps: Swa-shakt is a sheer example of grit and determination of the communities to realise their rights and stand on their own feet. Members are seen as beneficiaries and not as change agents. Swa Shakt shifts the center of the organisation from being dependent on external funding to being self sustained.

TUPEE600

Decentralized approach to achieving sustainable HIV financing: Experience from Kenya's transition into devolved government

S. Mairura, D.D. Mwai
Health Policy Plus - Palladium Group, Nairobi, Kenya

Background: In Kenya, HIV programming is heavily dependent on foreign aid. By 2015, HIV prevalence reduced to 5.9% from 14% in the 1990s. As a lower-middle income country, foreign aid will be less accessible; this calls for innovative local financing approaches. Fortunately, devolution of this responsibility to counties has increased local decision-making, creating an opportunity for more targeted responses and investments for HIV. Success is heavily dependent on counties' capacity to mobilize, accumulate, and allocate funds to health priorities. Through the USAID-funded Health Policy Plus (HP+) project, and with Ministry of Health support, counties employed better planning and budgeting strategies by focusing on ways to generate local revenue for sustainable financing for HIV.

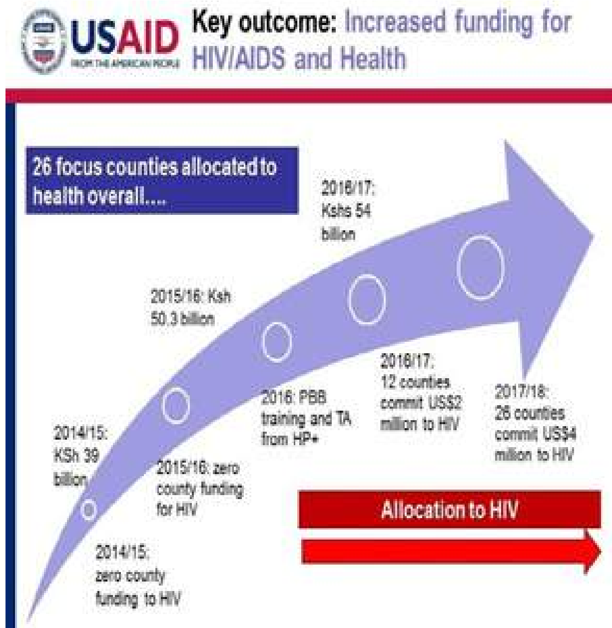
Description: To mobilize domestic resources, HP+ used a three-pronged approach: building capacity of 26 counties' planning and budgeting units through: training and mentorship on program-based-budgeting (PBB); assessing impact of PBB training by evaluating counties' strength in advocating for more resources for HIV and other health areas; and assessing impact of the training through evaluation of domestic resources mobilized for HIV, by analyzing resource allocation trends.

Lessons learned: PBB focused on identifying key programmes and sub-programmes necessary for achieving proposed health outcomes. While programmes were the same across all counties, counties were able to prioritize funding for key sub-programmes to include HIV. All 26 counties that received HP+ capacity building adopted the PBB approach and created a budget line item for HIV financing. Domestic resources mobilized amounted to US$7 million between fiscal years 2016/17 and 2017/18.

Conclusions/Next steps: This study points to the importance of domestic resource mobilization in greater sustainability for HIV financing within the uncertain context of donor funding. Enhanced capacity of county planning and budgeting units is critical in ensuring more domestic resources are mobilized and allocated to health, with devolved units

serving as a critical entry point for domestic resource mobilization activities, in addition to the national government.

Keywords: Devolution, Sustainability, HIV/AIDS Financing, Domestic Resource Mobilization, Capacity Building, Planning and Budgeting.



[Key outcome: Increased funding for HIV/AIDS and Health in Kenya]

TUPEE601

VIVE, much more than just a sustainable condoms socially-marketed brand

J. Rivas[1], S. Lungo[2], S. Barrios[2], O. Letouzé[3]
[1]Population Services International/PASMO, Marketing, Guatemala, Guatemala, [2]Population Services International/PASMO, Direction, Guatemala, Guatemala, [3]Population Services International, Marketing, Amsterdam, Netherlands

Background: In response to the HIV epidemic in Central America, Population Services International (PSI) created in Central America, its affiliate, the Pan American Social Marketing Organization (PASMO) in 1996. PASMO's inception project was to launch a regional socially-marketed condom brand, "VIVE," to improve availability of and access to high quality condoms. Sustainability of the brand and growth of the total market were core principles from the start of the project.

Description: To achieve brand sustainability, PASMO developed a tiered sustainability strategy, starting with cost recovery of commodities through product sales (achieved in 2000), cost recovery of commodities and marketing costs (achieved in 2010), and finally cost recovery of commodities, marketing and the bulk of operating costs (achieved in 2012).
PASMO´s strategy for growing the overall condom market was to implement a total market approach to ensure openness within the market for both public sector and fully commercial-sector brands to serve appropriate consumer segments. This strategy was coupled with highly targeted combination prevention programs to reach populations most affected by HIV and limiting drastic price increases.

Lessons learned: Today, PASMO's VIVE brand is the leading condom brand in Central America, both in terms of sales and brand image having 50.4% of regional market share. The use of marketing research tools has informed Vive's marketing strategies and ensured that the brand remained aligned with changing consumer preferences by applying multiple brand extensions, rebranding campaigns and new products. Through deliberate strategies to spark controversy and debate, VIVE mass media campaigns raised awareness about condoms and contributed to lower stigma associated with condom purchase and use. All these efforts have contributed to grow the Central American condom market from nearly 31 million in 2,000 to over 100 million in 2,016, and with behavioral data indicating that 48.4% FSW and 54.2% MSM are frequent users of the brand.

Conclusions/Next steps: Having a socially-marketed brand focused on sustainability, but combining marketing techniques and aiming to serve HIV target populations makes the condoms market wider, healthier, appealing and accessible for all.

TUPEE602

Community-led HIV prevention and care and harm reduction in Northern Myanmar

S. Nau
Metta Development Foundation, Community-Led Harm Reduction, Myitkyina, Myanmar

Background: Kachin state has been heavily affected by over 60 years of armed conflict between the Myanmar Army and the Kachin Independence Army (KIA). The situation in the region is characterised by insecurity, chronic under-spending in the health sector, and endemic corruption. Heroin is widely available and economic activity revolves mostly around the exploitation of natural resources. HIV prevalence is well above national average, with nearly 1 in every 2 People Who Inject Drugs (PWID). The provision of Harm Reduction services is largely insufficient and severely curtailed by a repressive legal framework, as well as strong opposition by a powerful anti-drug movement led by local Churches.

Description: From 2006 to 2012, *Metta Development Foundation* implemented a "Community-based HIV Intervention Project", which aimed at empowering People Living with HIV (PLH) and reducing stigma and discrimination in the wider community. A network of 68 Local AIDS committees (LAC's), composed of village administrators, elders, religious, women and youth leaders, and PLH were established to support HIV prevention and care activities. In 2014 and 2016, a similar approach was replicated to support the provision of Harm Reduction services in 7 locations, reviving LAC's and directly involving local community leaders, alongside PWID. The project main objective is to increase access to Harm Reduction services for PWID, while improving the acceptance of such services by local communities.

Lessons learned: Numerous Local AIDS committees created between 2006 and 2012 are fully autonomous and continue to be active, and stigma towards PLH has significantly reduced in concerned communities. Efforts to support Harm Reduction in 7 locations where communities were initially hostile to these services, have allowed the provision of 454,592 sterile Needles and Syringes, 623 HIV Tests and 244 referrals for OST in 2017. The project will be extended to a new location in 2018.

Conclusions/Next steps: The project shows that the involvement of community leaders in HIV and Harm Reduction programming in sensitive environments can contribute to the scale up of HIV and Harm Reduction services, improve community acceptance towards such services, and reduce stigma and discrimination.

[Enjoying playing game in peer group meeting supported by Local AIDS Committee.]

TUPEE603

Optimizing clients' retention on antiretroviral treatment using an "Out-of-facility health care worker group differentiated model" in Nigeria: Experiences and challenges

E. Nwabueze[1], A. Bukar[2], J. Ezekiel[3], M. Makumbi[4], N. Ndulue[5], P. Waibale[6,7]
[1]Management Sciences for Health, Country Office ART Team Lead and TB Team Lead, Abuja, Nigeria, [2]State Office Management Sciences for Health, State Team Lead, Minna, Nigeria, [3]USAID, Senior Care and Treatment Manager, Abuja, Nigeria, [4]MSH, Chief of Party, Abuja, Nigeria, [5]MSH, DPD, Abuja, Nigeria, [6]MSH, Technical Services, Abuja, Nigeria, [7]MSH, Senior Technical Director, Arinton, United States

Background: Monthly ARV drug refill is a known factor contributing to poor retention in care and treatment even for stable ART clients. In addition stigma and long distance from a treatment center deters clients from regularly accessing drug refills. Sustainable means are required in this donor fatigue era. This retrospective study was done to find out the impact of an out-of-facility ARV drug delivery program to community groups over a twelve-month period between March 2016 and February 2017.

Description: General Hospital (GH) New Bussa in Niger State in Nigeria had 3,678 on ART as at March 2016. The USAID-funded and MSH-led CaTSS project carried out a two-monthly ARV drug delivery to GH Babana, a spoke health facility serving hard-to-reach communities three hours' drive from the hub GH New Bussa.. There were 2 focal group discussions (6-8 persons) with HCWs and PLHIV. Optional choices for the spoke refills were given. Stable clients were clustered and mapped based on geographical location. We designed and deployed retention calendar, this simple M&E tool synchronizes individual PLHIV's refills, provides real time flagging of PLHIV expected for refills and who missed appointments. This ensured proper forecasting, immediate tracking and follow-up. Government staffs were involved throughout the implementation.

Lessons learned: There was an increased facility retention rate from 41% (March 2016) to 83% (February 2017). Retention rate in the cohort accessing out-of-facility drug delivery/refills was 92% (262/283). There were fewer missed appointments and LTFU at the spoke HF that were easily tracked and returned to treatment. HCWs appreciated the improved clients' satisfaction and quality of care. The clustered stable clients although fewer had improved health outcome and 100% suppression rate.

Conclusions/Next steps: This reduced clients' traffic, stigma and provided clinicians better opportunity and time to attend to the unstable clients at the hub creating clients satisfaction. This has strengthened collaboration with the government and sustainability of this implementation. The state government currently supports the transportation logistics for HCWs. This has also improved system performance, reduced workload and cost during tracking. Thus, recommended that it should be adopted across all facilities where sustainability is required if distance is a major barrier.

TUPEE604

Learning about the sustainability of pediatric and adolescent HIV programs in sub-Saharan Africa - how can qualitative methods help us get there?

A. Falconer[1], K. Morgan[1], F. Boldrini[2]
[1]Rabin Martin, New York, United States, [2]Rabin Martin, London, United Kingdom

Background: The joint Children's Investment Fund Foundation (CIFF) and U.S. President's Emergency Plan for AIDS Relief (PEPFAR) Accelerating Children's HIV/AIDS Treatment (ACT) Initiative aimed to double the number of children receiving antiretroviral treatment (ART) in nine sub-Saharan African countries over two years. CIFF invested in an independent evaluation of the sustainability of their investments in Kenya, Malawi, Tanzania, and Zimbabwe which asked:

· Are the essential domains of CIFF-funded pediatric and adolescent HIV programming sustainable once main program funding has concluded?

· What is needed to ensure the sustainability of CIFF-funded pediatric and adolescent HIV programming?

Methods: Sustainability can be complex to conceptualize and measure. This evaluation was rooted in a health systems approach and designed to provide a timely assessment of care cascade gains as well as pathways towards future sustainability. Building on examples from peer-reviewed sustainability literature, the PEPFAR Sustainability Index and Dashboard (SID) tool, ACT investment documents, CIFF and PEPFAR input, ACT grantee workplans, and field testing in Tanzania and Malawi, we developed a new pediatric and adolescent HIV sustainability heuristic. It aimed to assess inputs along three core domains:
(i) government, accountability, and leadership;
(ii) financing, and
(iii) program capacity, and outputs along the HIV care cascade.
Purposively sampled, semi-structured qualitative interviews (n=66) with government, donor, UN, NGO, and facility respondents in each country were used to evaluate inputs; NVivo 11 was used for analysis. Sustainability outputs were assessed using quantitative HIV care cascade data collected during and after the ACT initiative.

Results: Our approach enabled us to identify and comparatively assess sustainability pathways for ACT pediatric and adolescent HIV programming, despite the small-n nature of the study. These pathways are sufficiently nuanced to inform improvement of ACT sustainability within each country beyond the investment period.

Conclusions: This sustainability heuristic and its focus on qualitative methods can provide donors, advocates, and decision-makers focused on pediatric and adolescent HIV with a practical and nuanced assessment of program and investment sustainability. We believe this approach could be extended to develop sustainability pathways for other donor-funded programs in pediatric and adolescent HIV and beyond, delivering durable returns for donors and recipients alike.

TUPEE605

Bottom up or top down? Balancing the mix in annual HIV/AIDs operational planning and implementation for sustainability in HIV/AIDS service provision in Nigeria

S. Gombwer[1], O. Olayemi[1], I. Osaigbovo[1], S. Dada[1], E. Oladele[1], M. Opadotun[1], O. Adama[1], E. James[2], S. Raj Pandey[1]
[1]FHI360 Nigeria, Abuja, Nigeria, [2]USAID, Abuja, Nigeria

Background: Within the last 10 years, more resources have been deployed in the fight against HIV/AIDS than ever since the advent of the pandemic. However, weak capacities within governments and community based organizations (CBOs) at state level to plan, oversee, manage, and monitor programs to deliver quality services in a sustainable manner have posed challenges. This abstract describes the USAID-funded Strengthening Integrated Delivery of HIV/AIDS Services (SIDHAS) program's unique approach and experiences in supporting state governments and CBOs in planning, implementation, and monitoring of HIV/AIDS operational plans within the context of a PEPFAR supported project.

Description: Using the concept of "Co-location" as a program strategy SIDHAS built the capacity of 13 state governments and 26 CBOs to plan, implement, and monitor HIV/AIDS annual plans as part of operationalizing the national strategic heath development plan and the national strategic framework for HIV/AIDS. Co-location is a concept where government of Nigeria health providers are paired with a SIDHAS technical counterpart who works with them to provide technical assistance through supervision, coaching and mentoring.
A top to bottom approach is usually employed to kick start the processes of information sharing, joint planning, and building consensus to align with government and donor priorities. A bottom-up approach is then used in the development of specific state priorities. Through a participatory approach with stakeholders, the workplans are developed for state governments and CBOs. Approved, costed workplans guide implementation throughout. Early lessons from the field show positive signs that the mixed approach has resulted in increased ownership of the plans and integration of key elements into the state sustainability road map for 2016 -2018.

Lessons learned: A context specific, mixed approach to HIV and AIDS operational planning and an understanding of technical and operational challenges is needed to balance different priorities and build systems that promote sustainability of national and state governments HIV response.

Conclusions/Next steps: There is need to continue targeted policy advocacy and sustained engagements by civil society to the government of Nigeria to ensure implement the HIV sustainability road maps through funding of HIV response.

TUPEE606

Barriers to entering the African condom market

I. Thior[1], K. Kadirov[2], A. Berry[3], C. Jones[4], B. Deperthes[5], F. Roijmans[6], B. McKenna[7]
[1]AIDSFree, PATH, Arlington, United States, [2]United States Agency for International Development, Washington, United States, [3]United States Agency for International Development, Arlington, United States, [4]Global Insights, Sandpoint, United States, [5]United Nations Population Fund, New York, United States, [6]IplusSolutions, Washington, United States, [7]Reproductive Health Supplies Coalition, Brussels, Belgium

Background: Male and female condoms are the only devices that reduce the transmission of HIV and other sexually transmitted infections and prevent unintended pregnancy. Donor funding for condom procurement has been reduced in recent years. In 2013, about 10 condoms were made available to every man aged 15-64, and on average only one female condom per eight women in sub-Saharan Africa. To date very few condom manufacturers are present in the African market. In 2015, several condom manufacturers joined donor agencies to form a coalition whose main goal is to provide 20 billion condoms by 2020 in low- and middle-income countries. In furtherance of this goal, the authors conducted from August to October 2017 a survey to assess the barriers that prevent condom manufacturers from entering the African market.

Methods: A self-administered semi-structured questionnaire and in-depth interview were used to collect information on barriers to entering the African market among condom manufacturers.

Results: Nineteen manufacturers (out of 52 invited) from 12 countries, including the biggest male condom manufacturer in the world and all three female condom producing companies, completed the questionnaire. Biggest barriers to entering the African condom market were the high risk of insufficient return on investment (74%), inefficient distribution channels (74%), lack of purchasing power of targeted market segments (69%), lengthy and costly registration processes (68%), free and subsidized condoms (58%), and lack of partners and difficulty to vet financially strong local partners. Other barriers were macroeconomic and market-specific challenges related to government, currency stability, and trade policies.

Conclusions: The survey identified several critical barriers preventing entry to the African condom market. African governments could create an enabling environment for market entry by harmonizing regulatory standards, providing tax exemptions/incentives, reducing registration processing time and fees, facilitating adequate financing of local condom distributors, and establishing a public-private partnership for a healthy condom market. Donor agencies and governments should limit distribution of free and subsidized condoms to the right populations (key and poor populations) and dedicate funds for demand generation and promotion activities to grow the commercial condom market and make it more attractive.

TUPEE607

Active budget advocacy as a way to ensure sustainability of service provision to the communities and key populations on the regional level

D. Tyhach
Charitable Organization 'Charitable Society, All-Ukrainian Network of People living with HIV/AIDS, of Lviv City', Lviv, Ukraine

Background: There are around 4000 PLHIV in Lviv. Until 2016 social services for PLHIV were funded by donors without participation of the state, and only 2000 PLHIV could be provided with the services. According to Lviv regional `Strategy for ensuring a sustainable response to the TB epidemic, including chemoresistant TB and HIV / AIDS till 2020`, which was approved in September 2017, the total transition from the donors` funding to the local budgets should take place by 2020.

Description: At the beginning of 2015 the working group with representatives of AIDS Center, NGOs and regional authorities for justification of financial needs was formed. The group prepared a proposal for financing of social services for the funds of local budget in total amount of $ 5800. The proposal was introduced into the Integrative program of provision of medical care to the residents of Lviv region, however, it was removed by deputy corps. After this, an organized picket of the deputy meeting and media coverage of the event took place. As a result, funds for social support of the region residents in the amount of $ 5300 for provision of social services for HIV-positive children, was secured in the Program of provision of medical services to the region residents for the 2014-2017, amendments to which were approved on March 1 of 2016.

Lessons learned: In 2016 budget advocacy allowed to cover 70% of the needs for social services for HIV-positive children in the region. Due to further activities and strengthening of partnership with local authorities, in 2018 funding increased by 75% and reached $ 21,000. It will ensure 100% coverage of HIV-positive children by the needed social services and 30% coverage of HIV-positive adults, who are not reached by GF projects. The transparency of spending is ensured by the e-procurement system `ProZorro`.

Conclusions/Next steps:

1. Engagement of the HIV-positive community to the rights-protection actions is an effective tool in achieving positive changes.
2. Budget advocacy is a key for total transition to the funding of social services from the local state budgets.
3. Budget advocacy is more effective with the engagement of media for highlighting the process.

Economic evaluation and affordability assessments

TUPEE608

Costing of voluntary medical male circumcision in South Africa's private sector

M. Tchuenche[1], E. Njeuhmeli[2], C. Schütte[3], L. Ngubeni[4], I. Choge[5], E. Martin[6], D. Loykissoonlal[7], V. Kiggundu[2], A. Yansaneh[2], S. Forsythe[8]
[1]Avenir Health, Project SOAR (Supporting Operational AIDS Research), Glastonbury, United States, [2]USAID, Washington DC, United States, [3]Strategic Development Consultants, Hammarsdale, South Africa, [4]Avenir Health Consultant, Johannesburg, South Africa, [5]USAID, Pretoria, South Africa, [6]USAID, Pretoria, United States, [7]National Department of Health, Pretoria, South Africa, [8]Project SOAR (Supporting Operational AIDS Research), Avenir Health, Glastonbury, United States

Background: A previous study of the costs of providing a comprehensive set of services for surgical VMMC in South Africa at Government and PEPFAR-supported facilities noted that the lack of sufficient data from the private sector represented a gap in knowledge concerning the overall cost of scaling up VMMC services in South Africa.

Methods: VMMC Service delivery cost data were collected at 13 private for profit facilities in three provinces in South Africa: Gauteng, KwaZulu-Natal and Mpumalanga. Unit costs were calculated using a bottom-up

approach by cost components and disaggregated by the type and level of urbanization of the facility. Supply chain, VMMC demand creation, and higher-level management and program support costs were not collected and therefore not included.

Results: The unit cost (including the cost of training and continuous quality improvement) to provide VMMC at private facilities was $137, which was comparable to public and PEPFAR-supported nonprofit facilities. The largest cost components were consumables (40%), and direct labor (35%). Eleven out of the 13 surveyed facilities were fixed sites ($142), while the remaining were a fixed site with outreach services ($156) and a fixed site with outreach and mobile services ($123). The unit cost was not substantially different based on the level of urbanization: respectively $141, $129 and $143 at urban, peri-urban and rural facilities.

Conclusions: Private sector VMMC unit cost ($137) did not differ substantially from the costs at government and nonprofit, PEPFAR-supported facilities ($132). Consumables and direct labor accounted for 75% of total cost at for-profit facilities compared to 67% at public and nonprofit facilities. Results from this study complement unit cost data necessary to make informed decisions regarding the funding and scale-up of VMMC services in South Africa in both the private and public sectors.

TUPEE609

Out-of-pocket costs for patients receiving HIV care and treatment in Mozambique

A. Berruti[1], A. Krivelyova[2], F. Mbofana[3], D. Singer[4], A. Vergara[4]
[1]U.S. Centers for Disease Control and Prevention, Division of STD Prevention/NCHHSTP, Atlanta, United States, [2]ICF, Atlanta, United States, [3]Mozambique Ministry of Health, Maputo, Mozambique, [4]U.S. Centers for Disease Control and Prevention, DGHT, Atlanta, United States

Background: As of 2016, the Mozambique HIV prevalence among those aged 15-49 was estimated at 12.3%, with an estimated 1.6 million Mozambicans adults living with HIV/AIDS. In 2016 approximately 990,000 adults and 76,000 children were receiving antiretroviral therapy. Many HIV patients receive care and treatment funded by the government and donors, such as PEPFAR. Although services are largely free, HIV patients do incur costs to access treatment, potentially limiting uptake for some groups. This study quantified costs that different patient groups incurred while receiving publicly funded HIV treatment in Mozambique.

Methods: In -April 2017, a sample of 396 randomly selected adult patients (>18 years) receiving HIV care and treatment, with at least one prior appointment, was selected from 37 health facilities across 11 provinces in Mozambique). The survey assessed patients' costs associated with their access to HIV services.

Results: Results indicate that approximately 70% of respondents were female, and 21% lived in urban areas. The average age was 38 years (females, 37 years; males, 40 years). The findings indicated that 47% of respondents incurred some costs. Patients spent an average of US$19.57/year (2017) on costs to access treatment; more than 88% was for travel expenses (93% in Females and 75% in males). Patients living in rural and urban areas had average annual costs of US$17.81 and US$20.41, respectively. Males and females spent similar per year, US$18.24 and US$20.15, respectively. Patients' annual opportunity cost of the total time spent for treatment was $16.43 for male patients and $16.49 for female patients), approximately 4.3% of the per capita GDP in 2016.

Conclusions: Although HIV treatment was largely provided free, the study's findings suggest that (1) out-of-pocket costs to access this treatment are common and (2) patients spent a substantial amount of time at the HIV clinic. Results are similar to those found in similar studies in Tanzania, Kenya, and Swaziland.

TUPEE610

Cost evaluation of HIV-1 viral load testing: A comparative case study on open polyvalent platform versus integrated platform performed in CEDRES, Abidjan, Côte d'Ivoire (OPPera project)

N. Yakhelef[1], E. Guichet[2], F. Koné[3], G. Bado[4], H. Menan[5], A. Jousset[1], C. Rouzioux[6], B. Coriat[7]
[1]Solthis, Health Economics, Bagnolet, France, [2]Solthis, Virology, Bagnolet, France, [3]Laboratory of Cedres, Virology, Abidjan, Cote D'Ivoire, [4]Expertise France, Health Economics, Abidjan, Cote D'Ivoire, [5]CEDRES Laboratory, Virology, Abidjan, Cote D'Ivoire, [6]AP-HP Hôpital Necker-Enfants Malades; Université Paris Descartes, Virology, Paris, France, [7]Université Paris13, Sorbonne Paris Cité, Health Economics, Paris, France

Background: Monitoring of HIV patients receiving ARV through viral load (VL) testing is now recommended by WHO. Various technologies exist, however, cost evaluation data per VL test are scarce. We evaluated and compared the cost of VL performed on two different types of equipment: Open Polyvalent Platforms (OPP) vs. Integrated Platforms (IP) in CEDRES laboratory in Abidjan, Côte d'Ivoire.

Methods: Data collection covered the period from March 2013 to July 2016. Costs of VL performed on an OPP with Biocentric Generic HIV-1 VL reagents and on an IP with Roche *COBAS® AmpliPrep/COBAS®* TaqMan® HIV-1 *V2.0*) were evaluated. The costs were calculated using a "micro-costing" method, which includes the value of all resources consumed (time, goods and services) by the laboratory. Seven cost categories were identified: human resources costs, training costs, laboratory costs, VL reagent costs, small non-medical equipment costs, investment costs, overhead costs. The value of resources was estimated from the relevant quantities and corresponding unit price. All costs, both direct (i.e., resources used only by the VL laboratory) and joint, included both variable and fixed costs (depreciation of the equipment) and were expressed in euros and discount at 4%.

Results: A total of 12 771 VL tests were performed on OPP and 4 877 on IP. The overall cost of VL was €507 170 on OPP and €365 396 on IP. The unit cost was respectively €39.71 and €74.92. Overall, the main costs were reagents (respectively 68% and 55%), followed by single use and multiple use laboratory consumables (17% and 36%) and OPP equipment maintenance (5.3%). Human resources represented respectively 4.3% and 5.3%. Medical and non-medical equipment represented together 1.24% on OPP and 0.56% on IP.

Conclusions: This analysis showed that the unit cost of a VL test is much less expensive using OPP than IP in a West African country conditions. Further studies with other types of platforms would be important to draw a more complete picture of VL cost testing and allow decision-makers to optimize their choices in resource-limited countries.

TUPEE612

Evaluating HIV service expenditures in Ukraine: Results from a cost analysis study

M. Duda[1], A. Latypov[1], R. Dierst-Davies[2], J. Pearson[3], U. Kou Griffiths[4], I. Pykalo[5], I. Kuzin[6], N. Avaliani[7]
[1]Deloitte Consulting LLP, The USAID HIV Reform in Action Project, Kyiv, Ukraine, [2]Deloitte Consulting LLP, San Francisco, United States, [3]Deloitte Consulting LLP, Arlington, United States, [4]UNICEF, New York, United States, [5]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [6]Public Health Center of the Ministry of Health of Ukraine, Kyiv, Ukraine, [7]Deloitte Consluting LLP, The USAID HIV Reform in Action Project, Kyiv, Ukraine

Background: Ukraine has one of the most severe HIV epidemics in the region, with an estimated 238,000 people living with HIV in 2017. As funding for HIV services in Ukraine is provided from domestic and international sources, and with support from donors and international aid agencies decreasing significantly in the near future, a better understanding of how monies for HIV services are spent will help inform resource allocation and programming decisions.

Methods: A two-staged stratified sampling method was used to select study regions and facilities to evaluate funding spent by the government on HIV services. In total, three oblasts with high, medium and low prevalence rates (Mykolayiv, Poltava, and Zhytomyr), and 57 facilities (from

seven facility types) were sampled. Data collected included both direct (program staff, laboratory supplies, commodities, medications) and indirect (overhead) costs for nine separate HIV services provided. Both overall and per-patient costs for each service are presented.

Results: According to Ukrainian health authorities, $97,737,794 was spent on HIV services in 2015. Among sampled facilities, total expenditures were $7,642,333. A plurality of expenses were for medications (45%), with the least (1%) being spent on commodities (condoms and syringes). Per-patient costs were the greatest among those seeking TB treatment for PLHIV ($1,151.53) with the least expensive being condom distribution programs ($2.20). Among sampled facilities, 56% of expenditures ($4,249,901.64) were reported by AIDS Centers, with costs primarily driven by medication expenses. The most unstable per-patient costs across different facility types were program staff (range: $1.97-$424.54) and overhead (range: $3.53-$617.69) expenditures. Mykolayiv, a high prevalence region which included the greatest number of sampled facilities and patients, also incurred the greatest proportion of costs (55%). Overall, AIDS Centers and hospital-type facilities reported greater fixed costs (range: 73%-87%) compared to other facility types (range: 17%-30%).

Conclusions: Variations between costs of HIV services across different facility types indicate substantial savings that can improve the likelihood of achieving the 90-90-90 targets. Cost-saving strategies should focus on unique approaches for fixed and variable costs, including increasing patient volumes to improve patient to staff ratios, reducing unnecessary facility visits, reducing expenses on maintenance and utilities, and implementing integrated service delivery strategies.

TUPEE613

Systematic literature review of critical gaps in costs and cost-effectiveness analyses (CEA) of HIV testing services in sub-Saharan Africa

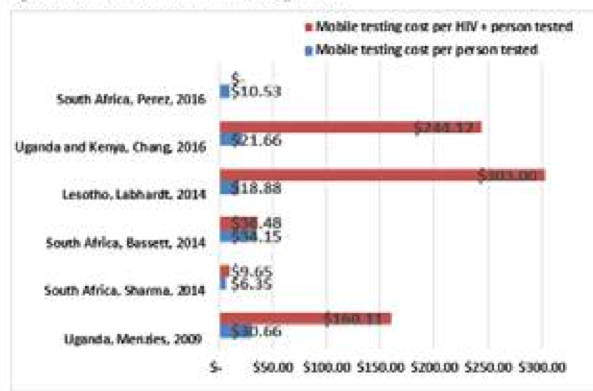
N. Ahmed[1], S. Rotolo[2], J. Ong[2], M. d'Elbée[2], L. Mwenge[3], K. Hatzold[4], G. Medley[2], H. Maheswaran[5], C. Johnson[6], L. Corbett[2], F. Terris-Prestholt[2]
[1]London School of Hygiene and Tropical Medicine., Global Health and Development, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Zambart, Lusaka, Zambia, [4]PSI, Harare, Zimbabwe, [5]Population Evidence and Technologies, Warwick Medical School, University of Warwick, Warwick, United Kingdom, [6]World Health Organisation, Geneva, Switzerland

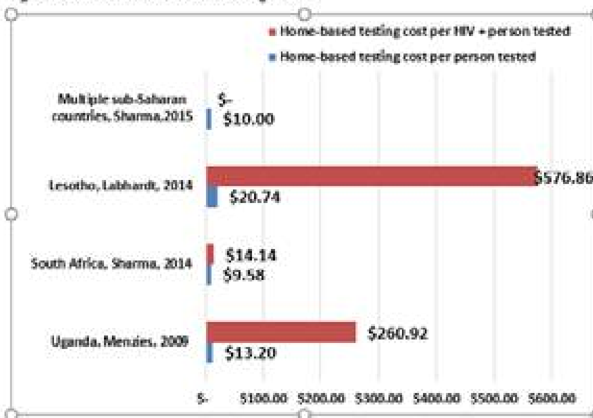
Background: HIV testing services (HTS) have undergone dramatic changes in recent years, and the most recent and the most innovative one is HIV self-testing. To date, there has been no systemic assessment of the evidence around the costs and cost-effectiveness of the broad HIV testing alternatives in sub-Saharan Africa.

Methods: We conducted a systematic literature review of costs and cost-effectiveness of HTS in sub-Saharan Africa between 2006 and 2017 following accepted guidelines (the CHEERS statement). We assessed study methodology, including primary or secondary costings, outcomes reporting as generic (QALYs, DALYs, HIV infection averted or life years gained or HTS specific). We analysed variations in unit costs per person tested ($pptested) and per positive case identified ($ppositive), cost-effectiveness, and identified cost drivers. All costs are presented in US$ 2016.

Results: Ninety-five studies met the eligibility criteria. Twenty-percent conducted primary costing exercises and applied it to perform CEA of alternative HTS. FBT, home-based and mobile-testing costs were presented in 73%, 12% and 7% of studies, respectively. Only 15% reported generic health outcomes. More than 50% assessed for uncertainty in parameters and reported cost drivers.

The reported unit costs for HTS varied widely. FBT $pptested ranged from $4.24 to $49.61 and $ppositive from $26.59 to $1,147. For mobile outreach, the $pptested was $6.35 to $34.15 and $ppositive was $9.65 to $303. Home-based HIV testing $pptested ranged from $9.58 to $20.74 and $ppositive ranged from $14.14 to $576.





[Costs of different HIV testing services in sub_Saharan Africa]

QALYs $pptested ranged from $522 to $1570. The main factors driving-up costs were: personnel, transportation, and HIV test kits commodity.

Conclusions: The observed unit costs and cost-effectiveness varied widely, attributable both to real differences in scale of implementation, uptake and HIV prevalence, and variation in study methodology. It is vital to understand costs as well as estimate ultimate CEA using generic health outcomes to allow optimisation across health budgets and scaling-up of HIV interventions to improve population health, even more so as the financing of HIV programs increasingly falls on national governments.

TUPEE614

The effect of universal test and treat on average cost per ART patient-year: Evidence from a health systems implementation trial in Swaziland

S. Khan[1], C. Wong[1], P. Geldsetzer[2], F. Walsh[3], C. Lejeune[1], T. Bärnighausen[2,4]
[1]Clinton Health Access Initiative (CHAI), Mbabane, Swaziland, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]Clinton Health Access Initiative (CHAI), Boston, United States, [4]Heidelberg Institute of Public Health, University of Heidelberg, Heidelberg, Germany

Background: As Swaziland and many other countries in sub-Saharan Africa are adopting 2015 World Health Organization (WHO) antiretroviral therapy (ART) guidelines and introducing universal test-and-treat (UTT) strategy, it is critical to understand the cost implications of this change to inform long-term financial planning. We present results from one of the first empirical costing studies of UTT under the "real world" conditions of scale-up in public-sector primary-care clinics.

Methods: From September 2014 through August 2017, we collected comprehensive data on facility-level ART costs from 14 facilities transitioning from standard of care (SOC) to UTT as part of a large-scale stepped-wedge health systems implementation trial. We take the perspective of the public-sector and use a "bottom-up costing" approach extracting data from facility budgets, expenditure reports, and patient

records. We use an activity-based allocation method for costs shared with non-ART patients. We include costs of medications, laboratory services, direct and indirect personnel, equipment and administrative services. The effect of UTT on average costs per ART patient-year was estimated using a multilevel generalized linear model. The model was adjusted for time fixed effects and clinic random effects.

Results: The **Table** shows detailed cost comparisons under UTT vs. SOC. The UTT effects were small and insignificant for overall costs and most cost categories. UTT effect estimates were $4 (95%CI -20 to 28) for average facility-level total cost per ART patient-year (p=0.75). The simple mean cost per patient-year across SOC was $215 (95% CI: 123-316) compared to $219 (95% CI: 138-293) in EAAA. There was marginal increase of 5 patient-years (95% CI: -1 - 9) due to EAAA (p=0.08).

Conclusions: Average public-sector costs per ART patient-year in Swaziland are essentially the same under the SOC and UTT. Differences in funding requirements for UTT will thus be largely driven by the number of patients receiving treatment, rather than by changes in the efficiency of service delivery.

	Universal Test and Treat (UTT) (mean cost ($) (95%CI)	Standard of Care (mean cost ($) (95%CI)	p-value
Total	**$219 (123-316)**	**$215 (138-293)**	**0.75**
ARVs	$95 (91 -99)	$95 (92-98)	0.76
Personnel	$100 (6-194)	$99 (28-170)	0.94
TB	$4 (0-8)	$1 (0-3)	0.04
Labs	$19 (10-28)	$20 (12-29)	0.70

[ART patient-year cost under universal test-and-treat (UTT) and standard-of-care (SOC)]

TUPEE615

Health care costs and deaths prevented by ACTA trial treatments for cryptococcal meningitis: A comparison between 5 induction strategies in sub Saharan Africa

T. Chen[1], L. Mwenge[2], S. Lakhi[3], D. Chanda[4], P. Mwaba[5], S.F. Molloy[6], A. Gheorghe[7], U. Griffiths[7], R.S. Heyderman[8,9], C. Kanyama[10], C. Kouanfack[11], S. Mfinanga[12], A.K. Chan[13], E. Temfack[14], S. Lesikari[12], M. Hosseinipour[10,15], O. Lortholary[16], A. Loyse[6], S. Jaffar[1], T.S. Harrison[6], L.W. Niessen[1], ACTA Trial Team
[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Zambart, Lusaka, Zambia, [3]University Teaching Hospital, Lusaka, Zambia, [4]Institute for Medical Research and Training, University Teaching Hospital, Lusaka, Zambia, [5]Lusaka Apex Medical University, Lusaka, Zambia, [6]St George's University of London, London, United Kingdom, [7]London School of Hygiene and Tropical Medicine, London, United Kingdom, [8]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [9]College of Medicine, University of Malawi, Blantyre, Malawi, [10]UNC Project, Kamuzu Central Hospital, Lilongwe, Malawi, [11]Hôpital Central Yaoundé/Site ANRS Cameroun, Yaoundé, Cameroon, [12]National Institute Medical Research, Muhimbili Medical Research Centre, Dar es Salaam, Tanzania, United Republic of, [13]Dignitas International, Zomba Central Hospital, Zomba, Malawi, [14]Douala General Hospital, Douala, Cameroon, [15]University of North Carolina, Chapel Hill, United States, [16]Institut Pasteur, Paris, France

Background: Mortality from cryptoccocal meningitis remains high. The ACTA trial demonstrated that 1 week of amphotericin B (AmB) plus flucytosine (5FC) was associated with lower mortality, and 2 weeks of oral fluconazole (FLU) plus 5FC combination was non-inferior compared with 2 weeks of AmB+5FC (gold standard), 2 weeks of AmB+FLU, or 1 week of AmB+FLU. We assess health service resource use and related costs in relation to health outcomes for the 4 alternative treatments compared with 2 weeks AmB+5FC.

Methods: Participants were randomised in a ratio of 2:1:1:1:1 to oral 5FC+FLU, 1 week AmB+FLU, 1 week AmB+5FC, 2 weeks AmB+FLU or 2 weeks AmB+5FC between 2013 and November 2016 in Malawi, Zambia, Cameroon and Tanzania. Data on individual resource use and health outcomes were collected from everyone. A costing study from the provider's perspective was done in Zambia.

Total health service costs for each treatment were estimated using the ingredient approach. The primary health outcome was health care cost per deaths prevented per 100 patients. Non-parametric bootstrapping was used with 1000 samples of 678 participants and 95% CI calculated using the 2.5th and 97.5th percentiles of the bootstrap samples.

Results: 678 participants were enrolled. Mean total costs per patient were US$1654 for oral FLU+5FC, $1936 for 1 week AmB+FLU, $2070 for 1 week AmB+5FC, $2321 for 2 weeks AmB+FLU, and $2481 for 2 weeks AmB+5FC. Hospitalization cost was the major component of total service costs. Differences between arms were driven by costs related to the component drugs and related complications, in particular AmB.

One week AmB+5FC was less costly as well as more effective than (dominated) 2 weeks AmB+5FC; Oral FLU+5FC was less costly than 2 weeks AmB+5FC and at least as effective as 2 weeks AmB+5FC. If the mortality for 1 week AmB+5FC was varied to the upper 95% CI, 1 week AmB+5FC still dominated 2 weeks AmB+5FC. The incremental cost effectiveness ratio for 1 week AmB+5FC versus oral FLU+5FC was US $53 (95% CI: 16-151) per death averted.

Conclusions: 1-week AmB+5FC and 2-weeks oral FLU+5FC are suitable for implementation in resource-limited settings. 5FC needs to be made available widely.

TUPEE616

Financial mobilization for antiretroviral therapy program: Multi-level predictors of willingness to pay among patients with HIV/AIDS in Vietnam

C. Nguyen
Duy Tan University, Institute for Global Health Innovations, Hanoi, Vietnam

Background: In Vietnam, significant progress has been made in increasing the number of patients receiving anti-retroviral therapy (ART) in the last number of years. As this number increases and international aid and funding for HIV services declines, a greater proportion of ART funding will need to be provided by the government budget, health insurance or by the patients themselves. This study aims to assess the willingness of HIV patients to pay for ART.

Methods: A cross-sectional study which included 1,133 HIVpositive patients was conducted across 8 outpatient centres in Hanoi and Nam Binh in Northern Vietnam in 2013. Participants were asked if they were willing to pay for ART to treat HIV using contingent valuation method.

Results: Over 90% of the patients were willing to pay for ART for an average amount of 19.7 USD per month. Regression models showed that the willingness of patients to pay for ART was influenced by factors such as employment, income, quality of life and social factors. The amount patients were willing to pay was also associated with gender, living place and level of HIV service administration.

Conclusions: By establishing these factors which influence the amount of willingness to pay for ART, plans for the future can be effectively designed and patient groups at risk can be appropriately managed.

Supporting sustainable financing for civil society

TUPEE617

How to build consortium of different key communities for effective advocacy to insure sustainable funding of HIV response

I. Gordon[1], G. Dovbakh[1], E. German[2], P. Sabelashvili[2]
[1]Eurasian Harm Reduction Association, Vilnius, Lithuania, [2]Eurasian Coalition on Male Health, Tallinn, Estonia

Background: Highly stigmatised and criminalised key populations/communities in EECA excluded from the continuum of HIV care due to legal, institutional, social and other barriers being key drivers of the epidemic. In last year's funding of services for key populations more depends on national governmental officials who stigmatising key populations and are not ready to invest into services. Having the same advocacy targets on

national and regional level it is important to coordinate advocacy for sustainability by different communities in coordinated consortium.
The Eurasian Regional Consortium (the consortium) brings together 3 regional networks: Eurasian Harm Reduction Association, Eurasian Coalition on Men's Health, Eastern European and Central Asian Union of PLWH to jointly build capacity of PWUD, MSM and PLWH communities in Armenia, Estonia and Kyrgyzstan to advocate governments to invest in services along the continuum of HIV care that those communities prioritize themselves in EECA.
Description: The consortium builds the capacity of key population CBOs via learning by doing approach to assess and prioritize HIV services and to conduct community-led quality access and quality assessment for the HIV response by provision of grants and technical assistance to all 3 countries and start budget advocacy.
Lessons learned: As a direct result, community-based testing was introduced in Armenia, and the Kyrgyzstan State HIV Program 2017-2021 included additional commodities for prevention as requested by MSM community. Assessment of access to services done by three different communities together build cooperation and strengthen join advocacy effort in budget advocacy and promotion of priority services for communities on national and local level.
Conclusions/Next steps: The Consortium developed budget advocacy models and processes for use across EECA and built relevant capacities of different communities. This bottom-up approach has been critical in generating community interest in budget issues, which have to date been seen as an issue that is not important for key populations. With the technical support from the regional Consortium it became possible for key populations to engage in direct dialogue with national decision-makers on budgeting issues together by three communities and several national partners.

Financing HIV drug access: the economics of generics and differential pricing structures

TUPEE618

Estimated cost-based generic prices for treatments of opportunistic infections

M. Barber[1], D. Gotham[2], A. Hill[3]
[1]*Harvard University, Harvard T.H. Chan School of Public Health, Boston, United States,* [2]*Independent, Boston, United States,* [3]*University of Liverpool, Liverpool, United Kingdom*

Background: Medicines used to treat opportunistic diseases are mostly off-patent, but there have nevertheless been concerns with price changes and unaffordability. For example, the fluconazole market is dominated by an originator-run donation programme, which excludes countries with large HIV burden such as Ukraine, Russia, India, Brazil, China, and Thailand. Pyrimethamine has recently been the subject of a 55-fold price hike in the US, and is not publicly procured in South Africa.
Methods: Current unit prices in the UK, South Africa (SA), and India were collected for medicines used in major opportunistic diseases from publicly available databases. Data on per-kilogram cost of exported active pharmaceutical ingredient (API) were retrieved from an online database of Indian export-import logs. Per-dose API costs were calculated, to which $0.01 per tablet or $0.70 per vial, as applicable, were added to estimate the cost of production. A 27% margin was then added to account for tax, and a 10% margin for profit. For liposomal amphotericin B, as API data were unavailable, we give the cost-based estimated price as the range of observed prices for formulated vials exported in bulk from India.
Results: Prices were highly variable between countries compared. In all cases for the UK, and all but one for SA, prices were substantially higher than estimated cost-based prices. In most cases, Indian prices were below estimated cost-based prices (likely reflecting conservative assumptions in estimation). Comparison of estimated cost-based price to current prices identified two cases worthy of further investigation: treatment for CMV retinitis, for which SA price was >12x and Indian price ≥2x the estimated cost-based price, and treatment for disseminated mycobacterium avium complex, for which SA price was more than two times estimated cost-based price. The price of liposomal amphotericin B was 14 times lower than in SA.

Disease	Treatment (regimen assumed for comparison)	Cost-based estimated generic price	UK price	India price	South Africa price
Pneumocystis pneumonia	Trimethoprim-sulphamethoxazole 160 mg/800 mg 6 tablets daily for 3 weeks	$5.43	$29.17	$1.21	$0.36
Toxoplasma encephalitis	Pyrimethamine 200 mg 1 tablet + 6 weeks of daily: 75mg pyrimethamine, 6000mg sulfadiazine, 15mg leucovorin	$94	$640	N	N
Cryptococcal meningitis	Liposomal amphotericin B 240mg daily for 2 weeks + fluconazole 400mg daily for 8 weeks + fluconazole 200mg daily for 12 months*	$2,352-9,274	$7,557	$988	$13,983
Disseminated mycobacterium avium complex	Daily: 1000mg clarithromycin 500 + 900mg ethambutol	$146	$322	$35	$322
Esophageal candidiasis	Fluconazole 200mg daily for 21 days	$1.65	$3.55	$0.81	$3.97
CMV retinitis	Valganciclovir 900mg twice daily for 3 weeks, then 900mg daily for 6 months	$481	$7,734	$987	$5,973
Tuberculosis	RHZE 600/300/1600/1100mg daily for 2 months, then RH 600/300mg daily for 4 months	$28	$302	$22	$41
Data in US dollars. N - insufficient data. *Flucytosine not included as data unavailable.					

[Estimated cost-based generic prices and current lowest prices.]

Conclusions: The current prices of valganciclovir in the SA, the UK, and India, are substantially higher than estimated cost-based generic price. In addition, the price of liposomal amphotericin B is higher in SA and the UK than in Inida Estimation of cost-based generic prices can identify cases in which there may be suboptimal market competition.

TUPEE619

Reigniting the fight for access to medicines: Outcomes and recommendations from the 2018 global summit on intellectual property and access to medicines (GSIPA2M2018)

O. Mellouk[1], S. Baptiste Simon[2], W. Mosime[3]
[1]*ITPC, Marrakech, Morocco,* [2]*ITPC, Johannesburg, South Africa,* [3]*ITPC, Gaborone, Botswana*

Background: It has been 24 years since the adoption of the TRIPS agreement by all WTO members in Marrakech. The agreement required countries to amend their national laws and grant 20-year product patents on pharmaceuticals. Since 2005, the true scope and negative impact of this Agreement on access to medicines have become evident.
The extent of work and expertise of CSOs and the critical role they play in balancing WTO mandated IP rules with public interest and public health while also resisting the onslaught of TRIPS-plus measures is under-recognised and under-resourced.
Description: In January 2018, 134 experts, treatment advocates and community advocates from 34 countries gathered in Marrakech at the initiative of ITPC for the first Global Summit on IP and Access to medicines planned as a return to Marrakesh to reflect, discuss and strategize on over two decades of the implementation of the TRIPS Agreement, its impact on health and access to medicines and to both imagine and re-imagine what the next two decades of TRIPS implementation will (or could) bring.
Lessons learned: The Summit highlighted the critical role played by PLHIV, patient groups, NGOs in the implementation of TRIPS flexibilities since 1995 and identified key factors in enabling environment to sustain the work of CSOs in this area. Participants collectively brainstormed on a more radical agenda for the interpretation and implementation of TRIPS flexibilities and identify key opportunities for this agenda and expand access to medicines. The summit provided a platform to discuss success-

es and setbacks in resisting trade, lobbying and litigation threats that undermine the use of TRIPS flexibilities, push the enforcement agenda and force the adoption of TRIPS-plus measures. Finally, the summit enabled discussions and conceptualisations of alternative frameworks for IP and Health that ensure the primacy of the right to health over trade rules.
Conclusions/Next steps: This presentation aims to share with the broader HIV and access to medicines movement outcomes and conclusions of this unique summit.

TUPEE620

The impact of dolutegravir in first-line adult ART on HIV transmission and cost of HIV in South Africa

G. Meyer-Rath[1], L. Jamieson[2], S. Masuku[2], F. Venter[3], L. Johnson[4]
[1]Boston University, Center for Global Health and Development, Johannesburg, South Africa, [2]Health Economics and Epidemiology Research Office (HE2RO), University of the Witwatersrand, Johannesburg, South Africa, [3]Wits Reproductive Health and HIV Institute, University of the Witwatersrand, Johannesburg, South Africa, [4]Centre for Infectious Disease Epidemiology and Research (CIDER), University of Cape Town, Cape Town, South Africa

Background: South Africa will switch all adults currently on first-line antiretroviral treatment (ART) regimens containing efavirenz (tenofovir (TDF) +emtricitabine(FTC)+efavirenz (EFV)) to regimens containing dolutegravir (DTG). We examined the impact on HIV transmission and mortality and the cost of the country's HIV programme over the next 20 years (2017/18 to 2036/37) compared to a baseline of the current HIV programme, as well as a scenario where universal testing and treatment (UTT) was fully implemented by 2022.
Methods: We used a previously developed model of the cost of ART in South Africa to calculate the average cost of fixed-dose combination regimens containing either TDF+FTC+EFV or TDF+lamivudine (3TC)+DTG, with TDF+3TC+DTG drug prices based on recent negotiations ($75 per adult patient year, 39% lower than TDF+FTC+EFV). We assumed full roll-out of the new regimen by April 2019. We used this cost as an input into a separate HIV transmission model updated with assumptions about the impact of DTG on viral suppression and treatment failure.
Results: Switching to a DTG-containing first-line regimen by 2019 reduces new HIV infections and AIDS deaths by 18% and 7% by 2036/37, respectively, averting 570,000 HIV infections and 48,000 AIDS deaths over 20 years and increasing progress towards the third UNAIDS 90-90-90 target from 80% to 88% by 2020/21. Fully implementing UTT reduces infections by 20% and deaths by 14% over baseline; combining full UTT with DTG reduces infections by 37% and deaths by 20%. The annual cost of the HIV programme is decreased by 18% in the first year of full DTG roll-out, and by 34% by 2036/37. Full UTT first increases annual cost, then decreases it by 1% over baseline, with the first cost savings seen in 2036/37. Adding DTG to full UTT decreases total cost by 36% by 2036/37, with immediate cost savings.
Conclusions: Switching adults from EFV to DTG and fully implementing UTT reduces new HIV infections and AIDS deaths by similar amounts over 20 years in South Africa, but DTG dramatically reduces the cost of world's largest ART programme from the first year of introduction onwards even when fully implementing universal testing and treatment.

HIV and universal health coverage

TUPEE621

Out-of-pocket spending by the pregnant women attending antenatal care/ prevention of mother-to-child HIV transmission services in Ethiopia, and its implication for universal health coverage: Applying econometric model

E.A. Zegeye[1], J. Mbonigaba[2], C. Kabiru[3]
[1]Federal Ministry of Health, Health Economics and Financing Analysis Team, Addis Ababa, Ethiopia, [2]University of KwaZulu Natal, Economics Department, Durban, South Africa, [3]African Population and Health Research Center (APHRC), Nairobi, Kenya

Background: Universal health coverage (UHC) aims to provide health care access for those in need, including pregnant women attending antenatal care (ANC)/ prevention of mother-to-child HIV transmission (PMTCT) service, without any financial barriers. However, out-of-pocket fees affect ANC/PMTCT service access, coverage and utilization among pregnant women. This paper aims to assess possible explanatory factors for direct medical out-of-pocket spending and their effect on UHC.
Methods: A random sample of 484 pregnant women attending twelve health facilities was interviewed across six regions in Ethiopia. Six health facilities from urban and six health facilities from rural settings were selected from the latest 2012 ANC sentinel HIV prevalence report (EPHI, 2014). Ordinary least square econometric model was employed. The dependent variable was the total direct medical out-of-pocket spending by the pregnant women. Direct medical costs consisted of consultation fees, laboratory tests and drug purchase. Normality distribution, linearity and homoscedasticity were tested.
Results: A pregnant woman incurred direct medical costs of Ethiopian birr/ ETB 119 (United States dollar/ USD 6) and ETB 6 (USD < 0.5) in urban and rural settings, respectively ($p< 0.001$). ANC/PMTCT visits and locations were the statistically significant factors related to the dependent variable ($p < 0.05$). Holding other factors constant, a unit increase in ANC visit is related to 33% increase in the direct medical expense (for the care fees, laboratory tests and drug costs) at the public health facilities. A pregnant woman from an urban setting incurred five times higher out-of-pocket spending when compared to her rural counterpart, ceteris paribus.
Conclusions: A pregnant woman from an urban setting experienced higher out-of-pocket spending when compared to a pregnant woman in a rural setting. An increase in ANC/PMTCT visits is directly related to an increase in medical expense, which may have a negative spillover effect on the path towards UHC.

TUPEE622

Do people living with HIV in Thailand with different health schemes have equitable access and receive equal quality services on their HIV treatment?

R. Jommaroeng[1,2]
[1]National Institute of Development Administration (NIDA), Graduate School of Public Administration, Bangkok, Thailand, [2]Ramkhamhaeng University, Dual Master's Degree in Public and Business Administration, Bangkok, Thailand

Background: Thailand is currently categorized as an upper-middle income country by the World Bank since 2011 and has geared towards universal health coverage since 2002 as steered by the World Health Organization. The country is implementing four health policies, including the National Health Security Scheme (NHSS), Social Security Scheme (SSS), Civil Servant Medical Benefit Scheme (CSMBS) and Migrant Security Fund (MSF) with an attempt to provide access to quality healthcare services for all, which include HIV treatment. However, the country is struggling in policy implementation, raising concerns whether people are actually receiving equitable HIV services due to different schemes.
Methods: This study is a document research with key informant interviews, specializing HIV from the international development, civil society and community sectors. The four policies are different in nodality, au-

thority, treasure and organization, hence are analyzed using a comparative public policy method.
Results: Of all Thai nationals, the CSMBS started in 1980, covering 7.7% and all are civil servants. It provides the greatest benefits but with the highest spending in healthcare. The SSS started in 1990, covering 7.7% among those in the private sector. It is the only trilateral co-payment but has less benefits than CMBS and NHSS. The NHSS started in 2007, covering 75.3% among those besides CMBS and SSS but clients are experiencing stigma and discrimination due to perceived low socioeconomic beings from healthcare providers, resulted in low service quality. The MSF started in 2014, covering approximately 107,000 migrants with lowest benefits but is experiencing great loss and low policy implementation. HIV treatment is provided in the first three health scheme but the MSF only provides HIV treatment if it is only for the prevention of mother-to-child transmission.

	Civil Servant Medical Benefit Scheme (CSMBS)	Social Security Scheme (SSS)	National Health Security Scheme (NHSS)	Migrant Security Fund (MSF)
Year of commencement	1980	1990	2007	2014
Coverage	7.7% of Thai nationals (Approx. 5 million persons)	16.0% of Thai nationals and work-permitted non-Thai nationals (Approx. 10.5 million persons)	75.3% of Thai nationals (Approx.48.0 million persons)	Approx. 107,000 migrants (Targets: 1.34 million persons)
Beneficiaries	Government civil servants and families with less than 3 children under 20 years of age	Employees in private sector	All citizens besides CSMBS and SSS coverage	Documented and undocumented international migrants
Approximate annual budget	US$1,818.9M	US$713.1M	US$2,972.3M	N/A
Source of budgets	Government	Trilateral co-payment (government, employers and employees)	Government	Beneficiaries US$61.8/year/ person US$41.2/ six months/person US$10.7/three months/person
Cost per person	US$415.4	US$60.3	US$89.1	US$28.4
HIV and other Service coverage and exception	All covered	All diseases except medical checkups	All diseases except medical checkups	Except terminal kidney disease, mental illness, HIV (only cover the prevention of mother-to-child transmission)
Authority	Ministry of Finance Department of Comptrollers' General	Ministry of Labor Social Security Office	National Health Security Office	Ministry of Public Health Office of the Permanent Secretary-general
Laws	Judicial Royal Servant in Ministry of Royal Treasury Act 1890; Specific Budgetary Reimbursement Determination Act 1975; Royal Decree on Welfare and Medical Benefits 1980 and its amendments (2nd Amendment); Provision of Ministry of Finance on Financial Reimbursement on Medical Benefits 2010; Bangkok Metropolitan Administration Ordinance on Medical Benefits 1987; Provisions of Ministry of Interior on Medical Benefits for Local Administration Staff 1998	Compensation Act 1994; Social Security Act 1990; Social Security Act (4th Amendment) 2015	National Health Security Act 2002	Public Health Ministerial Ordinance on Healthcare and Health Security dated 30 March 2015

[Comparisons of the four government-implemented healthcare schemes]

Conclusions: Thailand is still striving to achieve equitable healthcare provision. The country should now integrate different health care schemes under the condition of not diminishing high benefit schemes and increasing standards of underprivileged health schemes.

TUPEE623

The financial feasibility of inclusion of HIV/AIDS in the benefit package of Lagos State Health Scheme

O.K. Ogundapo[1], S. Akande[2], U.H. Edumoh[1], A. Dagadu[3], O. Fisher[4]
[1]Abt Associates, International Health Division, Lagos, Nigeria, [2]Abt Associates, International Health Department, Abuja, Nigeria, [3]HR Actuaries, Lagos, Nigeria, [4]Lagos State AIDS Control Agency, Lagos, Nigeria

Background: An actuarial analysis was conducted for Lagos State in order to ascertain the financial implication on the premium cost of adding comprehensive HIV and AIDS services (PMTCT, HTC & ART) to the benefit package of the Lagos State Health Scheme (LSHS). A previous benefit package had been costed that included only the testing component of PMTCT as part of services to be offered on the scheme. This was due to the fact that many stakeholders were concerned about the affordability and sustainability of a benefit package with comprehensive HIV/AIDS services.
To support the state in taking a decision, the USAID funded Health Finance and Governance (HFG) Project supported the Lagos State Government to answer the financial feasibility question using an evidence based approach of actuarial analysis.
Description: An actuarial study was undertaken to estimate the modular costing of HIV services using State validated data as encounter data, weighting of different ARV regimen and costing data from the State (CHAI references). Sensitivity analysis using the incidence rates, medical inflation and coverage estimates were included in the analysis.
Lessons learned: The additional risk premium for adding comprehensive HIV services on the benefit package is estimated to be NGN209.40 ($0.68) per enrollee per year. This pricing includes the cost of a viral load test done once a year) assuming a 100% coverage of all Lagos residents. Further stress tests at 10% and 20% coverage puts the cost at NGN1360 and NGN694.81respectively. The modular break down is shown in the table below. From the sensitivity analysis conducted, the most important risk factor affecting this cost was the utilization of HIV services within the health scheme.
Conclusions/Next steps: The additional cost on the premium of integrating HIV and AIDS services on the Lagos State Health scheme benefit package is at an affordable range of 209.40 - 1360.07 NGN per enrollee per year. The delivery of HIV and AIDS services on the scheme will however require additional technical and operational feasibility studies which has been carried out but outside the scope of this study. Other considerations are the provider payment methods for the HIV/AIDS services.

Additional risk premium for HIV/AIDS cost of cover	Amount in Naira
HTC	13.60
ART	133.05
PMTCT	15.96
contingency margin	46.78
Total cost for additional HIV/AIDS cover	209.40

[Modular costing of HIV Services]

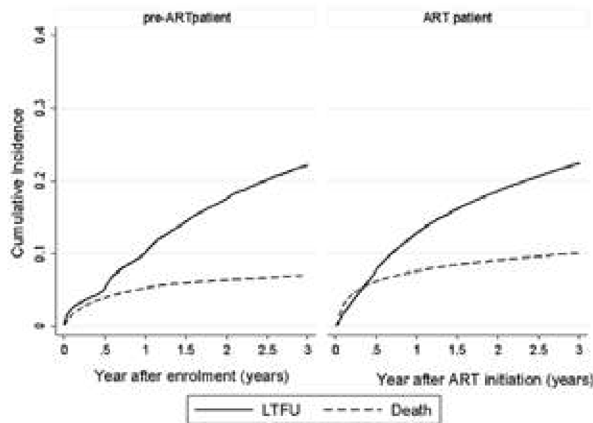
Loss to follow-up and associated factors of patients through the National AIDS Program in Thailand

S. Teeraananchai[1], K. Ruxrungtham[1,2], M.G. Law[3], A. Avihingsanon[1,2], S. Chaivooth[4], A. Teeraratkul[5], S. Bhakeecheep[4], S. Ongwandee[6], S. Thanprasertsuk[6], S.J. Kerr[1,3]
[1]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Chulalongkorn University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, [3]Kirby Institute, University of New South Wales, Sydney, Australia, [4]The HIV/AIDS, Tuberculosis and Infectious Diseases Program, National Health Security Office (NHSO), Bangkok, Thailand, [5]Thailand MOPH - U.S. CDC Collaboration, Nonthaburi, Thailand, [6]Ministry of Public Health, Nonthaburi, Thailand

Background: Loss to follow-up (LTFU) before (pre-ART) and after starting ART (ART-patients) are factors that prevent countries from meeting the UNAIDS 90:90:90 targets.

Methods: We studied LTFU in Thai HIV patients aged ≥15 years enrolled in the National AIDS Program (NAP) from 2008 to 2014, a period when linkage with the death registry was complete. LTFU was defined as not attending clinic within 12 months (pre-ART), or within 6 months (ART-patients), irrespective of whether they later returned to the program. Follow-up was based on CD4 count or ART prescription visits. Competing risk models were used to calculate the adjusted sub-distribution hazards (aSHR) for LTFU, with death as a competing risk.
Results: 137,431 pre-ART patients registered to the program, with median age 36 (Interquartile range (IQR) 30-43) years and median CD4 count of 115 (IQR 34-299) cells/mm3. In pre-ART patients, 8,697 (6%) were LTFU over 78,165 person-years (pys): a crude LTFU rate of 11.1 per 100 pys (95% Confidence interval (CI) 10.9-11.4). In 141,117 ART patients, median age at ART initiation was 37 (IQR 31-43) years with median baseline CD4 count of 93 (IQR 30-220) cells/mm3. Over 353,480 pys, 30,762 (22%) were lost: a crude LTFU rate of 8.7 per 100 pys (95%CI 8.6-8.8). Cumulative LTFU incidence in pre-ART patients was 5.3% at 6 months and 10.2% at 1 year, whereas in ART-patients it was 4.0% and 12.8% respectively (Figure 1). Among pre-ART patients, younger age (< 30 vs age ≥45, aSHR 1.60, 95%CI 1.49-1.72), higher CD4 count (≥350 vs < 100; aSHR 6.31, 95%CI 5.74-6.95) and CDC Category A (vs C) disease (aSHR 1.29, 95%CI 1.21-1.37) were associated with a higher chance of LTFU. In ART-patients, higher baseline CD4 count (CD4 ≥350 vs CD4 < 50; aSHR 2.06, 95%CI 1.97-2.15) and CDC Category A/B (vs C) disease were associated with an increased risk of LTFU.
Conclusions: High LTFU rates occur in both pre-ART and ART patients in the Thai NAP and hinder progression towards reaching 90:90:90 targets. Strategies need to address improving retention in all patients, especially those with higher CD4 counts, now that Thai guidelines recommend commencing ART at any CD4 count.



[Figure 1. Cumulative incidence of LTFU and death between pre-ART patients and ART patients.]

TUPEE625

A community perspective of Indonesian universal health care (Jaminan Kesehatan Nasional)

S. Putri, I. Widjaja, A. Sentosa
Indonesia AIDS Coalition, Advocacy, Jakarta Selatan, Indonesia

Background: Jaminan Kesehatan Nasional (JKN) is the national insurance scheme under the auspices of the Indonesian government providing Universal Health Coverage (UHC), it has been implemented since 2014. JKN is touted by the government as being available for all levels of Indonesian society and it is the only insurance that covers HIV-related treatment.
A study was conducted by Indonesian AIDS Coalition (IAC) to evaluate the level of understanding of key populations (KPs) in relation to health insurance and JKN assessing the level of coverage by key population groups and their utilization of the scheme.
Methods: The qualitative case study was carried out through focus group discussions (FGDs) with the KPs (MSM, PWUD, sex workers and women living with HIV) in Jakarta in 2015. An additional FGD was conducted with people living with HIV (PLHIV) in November 2017 with representatives from 10 provinces in Indonesia carried out under the Sustainable HIV Financing in Transition (SHIFT) program.
Results: There are variations in the knowledge of JKN among providers related to HIV services and hierarchical referral system. The MSM participants feel that preponderance of perceived lower quality of JKN in coverage, ease of access on a cover, and in the variety of medications or treatments prescribed rather than previous one. The PWUD participants mentioned that they don't face any barriers to access the JKN services, however, there was an impression that decision to cover the services hinge largely on the discretionary power of the health care providers, and favorable initial diagnosis that stated no drug services is a key aspect to successful claims. Sex worker participants raised domicile issue as a barrier to access the JKN, thereby reducing its universality. Those barriers impact to the low uptake of the JKN coverage and utilization by PLHIV and KP.
Conclusions: It is agreed that JKN offers benefits for KP and PLHIV but at the same time it should coincide with strengthening the health services. In the future, capacity building and improved information relating to JKN are important to better sensitize the community. Recommendations include the development of additional educational materials and resources intended for peer educators and clients.

Crossing the country boundary; ART service linkages between two countries-India and Nepal contributed to uninterrupted supply

P. Pandeya[1], N. Bohidar[2], N. Sharma[3], N. Kaur[4]
[1]CARE Nepal, Program, Tansen, Nepal, [2]CARE India, Program Monitoring and Evaluation, Delhi, India, [3]Fairmed Foundation, Program, Kathmandu, Nepal, [4]CARE India, Program, Delhi, India

Background: Nepal has identified the labor migration to India is a common and increasing phenomenon. HIV infection in major cities in India (Delhi, Mumbai & Calcutta) and transmission to their families in Western Nepal. Nepal spelled out one major HIV/AIDS strategy to work with India to prevent HIV infection and to work together to provide treatment. A 5 years´ project (2012-2016) implemented in Nepal and India explored many possibilities to work together.
Description: A 5 years´ research project (EMPHASIS) implemented in Nepal and India engaging local partners, PLHIV organizations and government organizations. Local partners and PLHIV organizations (6 NGOs and 70 staff, 5 PLHIV organizations, 300 volunteers, 16 health facilities) worked with Nepalese people in India and Nepal worked with Indian citizens in Nepal. In both countries similar strategies were adopted to reach, test and treat. The communication, experience sharing and developing interventions were made by two country teams together. This has provided to reach both country´s Apex body of HIV/AIDS, facilitated to hold bilateral meeting and the efforts could make an understanding to provide ART services (treatment) to Nepalese in India and Indians in Nepal. The same was communicated to all the sites by India and Nepal both. The effort supported 6500 PLHIV from Nepal to get ART in India and 700 Indians to get ART from Nepal. ART adherence, follow up and ultimately uninterrupted ART supply is possible in two countries.
Lessons learned: Evidences created through the program implementation can influence the local government and health facility. Sharing progress and impact with the concern stakeholders can have greater impact that can influence the governments. Tireless advocacy with the documentation, voice of people and impact showing clips can influence the governments. Engaging government staff at all level of program implementation can be a good strategy to influence the governments.
Conclusions/Next steps: Uninterrupted ART treatment to the people will contribute to reduce the risk of drug resistance as well as the cost to get treatment. Providing ART to the people irrespective of the country will contribute to the overall health goal to make the world healthy.

Evidence from integration of health services

TUPEE628

The relationship between efficiency and quality in health facilities providing HIV testing and counseling and prevention of mother-to-child transmission: Evidence from Kenya, Nigeria, Rwanda, South Africa and Zambia

C. Chivardi[1], S. Sosa Rubi[1], D. Contreras Loya[1], G. De la Hera Fuentes[1], M. Opuni[2]
[1]National Institute of Public Health, Center for Research for Health System, Cuernavaca, Mexico, [2]Independent Consultant, Geneva, Switzerland

Background: Given constrained funding for HIV programs across Sub-Saharan Africa, delivering services efficiently is vital. It has not yet been studied, however, what managerial factors may contribute to the efficient and high-quality execution of HIV prevention programs. The objectives of this study are to describe the levels of efficiency and quality of health facilities providing HIV testing and counseling (HTC); to analyze the trade-off between efficiency and quality in these facilities; to examine the management characteristics associated with efficiency and quality.
Methods: We used data from 338 facilities in Kenya, Nigeria, Rwanda, South Africa, and Zambia covering 2011, 2012, or 2013. We estimated and adjusted efficiency scores using Data Envelopment Analysis (DEA) and estimated quality scores using factor analysis. We mapped the relationship between the efficiency and quality of care. Finally, we used seemly-unrelated regression analysis (SUR) to examine the relationship between quality and efficiency scores and management characteristics at facility level.
Results: Facilities in South Africa and Rwanda were quite efficient while facilities in Nigeria and Zambia were relatively inefficient. Quality of services were rather poor across countries and between 24% and 27% of facilities had either high efficiency/low quality or low efficiency/high quality indicating some trade-off between efficiency and quality. Number of managerial meetings, frequency of HIV-related supervisions, and provision of HIV staff rewards for performance were all associated with better performance. Existence of a community advisory council monitoring facility performance and funding subject to management of inputs also improved quality. Most incentives for good performance contributed to high quality at the expense of efficiency. This was true of rewards for good performance provided to the HIV unit, funding based on facility management, and the provision of staff training as a result of good performance.
Conclusions: In all countries, substantial efficiency and quality gains could be made in delivering HTC services and our study suggested a number of management practices that could improve efficiency and quality. Additional exploration of the relationship between quality and efficiency in HIV service delivery is needed and further investigation of management practices associated with efficiency and quality of care is required.

TUPEE629

Integrating HIV testing services (HTS) into household vulnerability assessments (HHVAs): A window to meeting the first 90 among children and adolescents in Nigeria

T.A. Idaboh[1], E. Oladele[1], S. Cartier[1], N. Ike[1], S. Momoh[2], C. Agbakwuru[2], S. Raj-Pandey[3], E. James[4], D. Magaji[5], H. Khamofu[6]
[1]FHI 360 Nigeria, HIV Prevention Care and Treatment, Abuja, Nigeria, [2]FHI 360 Nigeria, Monitoring and Evaluation, Abuja, Nigeria, [3]FHi 360 Nigeria, Party Sidhas Project, Abuja, Nigeria, [4]USAID Nigeria, TB/HIV, Abuja, Nigeria, [5]USAID Nigeria, HIV/TB, OVC, Abuja, Nigeria, [6]FHI 360 Nigeria, Party Technical Sidhas, Abuja, Nigeria

Background: Undiagnosed HIV-infection is more common among children and adolescents, who are harder to reach than adults, hence a high priority target for HIV testing services (HTS). HTS is the critical first step to accessing HIV services, therefore an integral part of the HIV/AIDS response to prevent spread and improve health outcomes for those already infected. Orphans and Vulnerable Children (OVC) programs reach large numbers of children and adolescents in the community, so we decided to take advantage of this to reach them with HTS. This paper describes HTS uptake when offered as part of household vulnerability assessments (HHVAs) for OVC/households reached on a PEPFAR/USAID-funded project - Strengthening Integrated Delivery of HIV/AIDS Services (SIDHAS) implemented in 13 Nigerian states. We also examined HIV-positivity prevalence by vulnerability categorization of assessed households.
Methods: Trained case-managers, supervised by project-supported community based organizations were engaged to provide community-based HTS to children and adolescents (0-19 years) enrolled in the SIDHAS OVC Program. Caregiver permission was obtained before testing for children ages < 18 years, except emancipated minors ages 15-17 years who provided consent for themselves. HTS and linkages of positive beneficiaries were integrated into HHVAs between January and March 2016, in 124 local government areas in Nigeria. Using the National 'HHVA Tool', households were assessed, scored and categorized into 3-levels - "Most-Vulnerable", "More-Vulnerable" and "Vulnerable" - based on the following criteria: household headship, health, education level of the household head, shelter/housing, food security/nutrition, means of livelihood and household income.
Results: A total of 31,510 households with 71,442 children (36,596 males, 34,956 females) were assessed. Forty percent of children (n=28,577) were tested for HIV. Among those tested, 3.9% (n=1,127) tested positive. 7.9% (n=89) of HIV+ children were from "Vulnerable" households, 73.3% (n=826) were from "More-vulnerable" households and 18.8% (n=212) were from "Most-vulnerable" households. HIV-prevalence was similar across vulnerability levels (range 3.6% to 4.2%), but increased slightly with increased vulnerability.
Conclusions: Offering HTS during community-based HHVA affords care-providers the opportunity to reach the most-vulnerable children and adolescents who may not otherwise be reached, thus reducing the numbers who remain undiagnosed and increasing linkages to critical services for those who test HIV-positive.

TUPEE630

Does integration of HIV and sexual and reproductive health (SRH) services improve the patient's experience? Results from a cluster randomized trial in Zimbabwe

C. Dell'Aira[1], M. Gorgens[1], F. Mhuriro[2], K. Takarinda[2], I. Taramusi[2], J. Friedman[1], C.N. Sisimayi[3], S. Zizhou[4]
[1]World Bank, Washington DC, United States, [2]Ministry of Health, Harare, Zimbabwe, [3]World Bank, Harare, Zimbabwe, [4]Ministry of Health and Child Welfare, Harare, Zimbabwe

Background: It is assumed that integrating Human Immunodeficiency Virus (HIV) services with sexual and reproductive health (SRH) services improves programmatic efficiency. Yet, it is unclear how integration may affect patient satisfaction and patient's burden to access care. We therefore aim to assess impact of the Government of Zimbabwe's 2016 HIV-SRH integration program on patient satisfaction and on the patient's burden to access care.
Description: 15 districts were randomly allocated to treatment and 13 to control group. The sample of facilities included all 31 district hospitals (DHs), within which 34 out-patient departments (OPDs), and 149 randomly selected primary health centers (PHCs). The study used linear models on facility-level endline data separately for the PHC, DHs and OPDs.
Lessons learned: Patient satisfaction was not affected by the intervention in PHCs. In DHs, however, satisfaction was found to be significantly higher in patients receiving care from treated facilities compared to controls, according to both an arithmetically-derived Satisfaction Score and a Principal Component Analysis-computed Satisfaction Component ($ps< 0.05$). This higher satisfaction was mostly found in the subgroup of patients receiving SRH compared to controls ($p< 0.05$). In treated OPDs, overall satisfaction was higher ($p< 0.05$) than in controls. In particular, satisfaction scores reveal that patients receiving both HIV and SRH care

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

experienced higher satisfaction (p< 0.0001), while SRH patients were found to be less satisfied than controls (p< 0.05). Regarding patient burdens, patients receiving care from treated PHCs experienced lower loss of income and childcare costs due to visiting the facility (p< 0.05). Patient burden was unchanged in DHs. In contrast, treated OPD patients benefitted from receiving a higher number of services, while spending less in care costs (p< 0.05). The increase in number of services mainly affected patients receiving both SRH/HIV services (p< 0.0001), who also experienced lower waiting time than control (p< 0.0001); care costs, instead, were found to particularly decrease in the subset of SRH patients when compared to controls (p< 0.05).
Conclusions/Next steps: Overall, the integration of HIV and SRH can yield improvements in patient experience, but with some limitations. Further research will explore possible mechanisms that can account for difference between the intervention groups.

Evidence from cross-sectoral programming

TUPEE631

HIV prevention and SRH education on the football pitch: Results from a mixed-methods evaluation of an HIV prevention programme delivered to adolescent boys by football coaches

M. Malotana[1], N. Advani[2], S. Zwele[1], T. Gubesa[1], D. Lee[3], C. Barkley[1]
[1]Grassroot Soccer South Africa, Maboneng, South Africa, [2]Self-employed, Cape Town, South Africa, [3]Grassroot Soccer, Inc., Norwich, United States

Background: Little is known about effective approaches to address the unique HIV and SRH needs of **adolescent boys.** In 2016 Grassroot Soccer (GRS) conducted a mixed methods evaluation of an HIV prevention and life skills programme (SKILLZ) delivered to adolescent boys by coaches from local football associations (LFAs) within the South African Football Association (SAFA). The objective was to assess the effectiveness of SKILLZ at improving knowledge of HIV risk factors and prevention; gender equitable beliefs; and positive self-image among participants.
Methods: LFA coaches conducted the SKILLZ intervention (seven 1.5-hour sessions) in the peri-urban communities of Alexandra and Soweto in Johannesburg, and Khayelitsha in Cape Town. Participants (mean age = 13.8) completed a 17-item questionnaire at baseline (September-December 2016, n=974) and immediately after the intervention (March-May 2017, n=974). Focus group discussions (FGDs) were conducted with participants (n=1) and coaches (n=1) and in-depth interviews (IDIs) were conducted with GRS staff (n=2) and LFA administrators (n=1). Quantitative data was analysed in R and significance was assessed via Wilcoxon Signed Rank Test. Qualitative data was analysed using an inductive coding approach to identify emergent process and outcome themes.
Results: All 17 questionnaire items showed significant improvements pre- to post-intervention as shown in Table 1. The largest changes were seen in items about communication about HIV with friends, gender equitable decision-making responsibility in relationships, and drinking alcohol increasing HIV risk. Larger changes were seen in older participants (ages 14-17) in items pertaining to decision-making responsibility in relationships and attitude toward people living with HIV. Qualitative data found demand for more support and training among LFA coaches and unanticipated improvements to communication and discipline on the football pitch.
Conclusions: These findings suggest that local football structures may be under-utilised in reaching adolescent boys, showing that SKILLZ is an effective intervention for short-term improvements to HIV knowledge and attitudes toward gender equality and health. Greater positive change was seen among older youth in several items, indicating that the intervention could be more effective for older adolescents. Both the intervention (SKILLZ) and delivery channel (LFAs) present opportunities for scale and merit more rigorous, longer-term evaluation.

Q	Statement	Pre	Post	Change	p-value*
1	I have talked about HIV with an adult in the past two months (outside SKILLZ).	43%	61%	41%	<0.01
2	I have talked about HIV with a friend in the past two months (outside SKILLZ).	44%	67%	53%	<0.01
3	I can tell if someone has HIV by looking at him or her.	59%	84%	41%	<0.01
4	I would say no to playing sport with someone who has HIV.	64%	84%	32%	<0.01
7	Unequal power in relationships can contribute to the spread of HIV.	57%	83%	45%	<0.01
9	It is the male´s responsibility to make decisions in a relationship.	50%	80%	61%	<0.01
12	Drinking alcohol can increase my risk of getting HIV.	57%	89%	57%	<0.01
13	Drinking alcohol is a choice.	68%	90%	33%	<0.01
14	Male circumcision reduces a male´s risk of getting HIV.	60%	86%	43%	<0.01

Approaches to financing across sectors

TUPEE632

Alignment in HIV programming and funding by key donors is critical for achieving epidemic control - an example from Kenya

D. Koros, T. Daniel
PEPFAR Kenya, PEPFAR Country Coordination Office, Nairobi, Kenya

Background: In most developing countries, HIV programs are heavily donor funded. Donors have different priorities and requirements, and most host country governments do not have full understanding or control of those requirements. As a result, duplication and funding overlaps are commonplace. With proper coordination and alignment, epidemic control could be achieved at a much faster rate.
Description: An example is the PEPFAR and Global Fund (GF) collaboration in Kenya. Before 2015, PEPFAR and GF were working almost independently with little or no information moving across the two key donors. Though efforts were made to share information for planning, funding applications, and program implementation, there were no structured ways of engagement or proper guidelines. In 2015, deliberate efforts were made both at headquarters and in-country for PEPFAR to engage with GF in all its processes. This included engagement with GF on the Country Operational Plan (COP) guidance, in-country dialogue and approval meetings; recruitment of PEPFAR-Global Fund Liaison Officers; and commitment to host countries through Geneva-based leadership consultations to eliminate duplicative programming.
Lessons learned: As a result, the PEPFAR Kenya COP 2016-2017 as well as the GF New Concept Note 2015-2017 and GF New Funding Request 2017-2019 demonstrated better alignment in funding allocation, geographic prioritization, commodity procurement, human resource support, target setting, program monitoring strategies, and oversight. Key achievements include: 1) GF's allocation to care and treatment reduced from 78% to 61% of its total funding given PEPFAR's investments and priorities; 2) funding and target allocations to key populations substantially increased, more than twofold for men who have sex with men (19,000 to 52,000 for GF and PEPFAR combined); 3) adolescent girls and young women (AGYW) support were well coordinated; and 4) HIV and TB commodities procurement, including joint procurement and supply planning, quantification, forecasting and monitoring ensured fewer stock-outs and expires. These are critical factors in attainment of 90/90/90 UNAIDS targets.
Conclusions/Next steps: When donors work in a well-coordinated manner, there will be increased program coverage for critical interventions with a resultant faster attainment of epidemic control.

Combination programming on social drivers of HIV (including education; violence; & workplaces)

TUPEE633

Building synergies between health and health sector: Labour inspectors can play a key role

S. Mabhele
ILO, Workquality, Pretoria, South Africa

Background: Labour inspectors advise workplaces as well as ensure compliance. In both of these functions, they can play a key role in ensuring non-discrimination, enhancing access to HIV information and services for workers.
The ILO has developed a *'Handbook on HIV and AIDS for Labour Inspectors.'* The purpose of the handbook is to strengthen the capacity of Labour Inspectors to effectively address HIV-related issues in the workplace. Labour Inspectors were trained by the ILO in four selected countries, including Botswana, Lesotho, South Africa and Zambia.
Description: Trainings of Labour Inspectors were conducted at national level. The methodology focused on five sequential steps: A pre-and post-assessment on the knowledge of Labour Inspectors regarding HIV and AIDS; development of a customized Labour Inspection Checklist/Form on HIV and AIDS by inspectors; conducting HIV and AIDS focussed labour Inspections using the Labour Inspection Checklist/Form; a one-day Feedback session to allow the labour Inspectors to report on their findings; and analysing the data/reports submitted by labour inspectors in collaboration with Ministries of Health and Labour; National AIDS Councils/Commissions; Employers and Workers' Organizations. The ILO trained more than **130 Labour Inspectors**, majority of whom were women.
Lessons learned: The Labour Inspectors reached more than 300 workplaces employing more than 10,000 working women and men in different sectors. Labour Inspectors are a critical resource in facilitating access to the world of work in order to revolutionize prevention to HIV and AIDS. The workplaces where Labour Inspections were conducted employ a significant number of populations that are regarded to be left behind, including young people and men.
Conclusions/Next steps: Majority of the workplaces reached did not have workplace policies on HIV and AIDS even though located in areas with high HIV prevalence. Some of the workers have never been exposed to HIV related services, and therefore would welcome workplace programmes that include HIV and AIDS. Collaboration with the National AIDS Authorities to agree on a plan of action will be considered. The workplace remains part of the communities that could reach men in order to facilitate increased access to HIV/AIDS and other health services.

TUPEE634

Scaling up HIV services for workers in the agriculture sector through an integrated approach

D. Muhika[1], H. Amakobe[2], S. Mabhele[3]
[1]*Central Organization of Trade Unions in Kenya, Nairobi, Kenya,* [2]*International Labour Organization, Nairobi, Kenya,* [3]*International Labour Organization, Pretoria, South Africa*

Background: According to the Economic Survey 2017, there are 336,700 people on wage employment within the agricultural sector in Kenya. The mobile nature of agricultural sector workers, many of whom are seasonal workers, increases their vulnerability to HIV. They are often excluded from community-based initiatives and support systems, isolated in large plantations and farms with limited access to health and HIV services. The Central Organization of Trade Unions in Kenya (COTU-K) through its affiliate the Kenya Plantation and Agricultural Workers' Union (KPAWU) has up-scaled its efforts to improve working conditions for workers in the sector in partnership with the International Labour Organization (ILO) through a HIV, Tuberculosis, social protection, Sexual and Gender Based Violence (SGBV) integrated services approach.
Description: The ILO/COTU(K)/KPAWU partnership collaborated with AIDS Healthcare Foundation, Stop TB Partnership, National Hospital Insurance Fund and the county governments to reach workers in tea, sisal and flower plantations (some subscribed to Fair Trade Certification) in Baringo, Nairobi, Kajiado, Kilifi, and Nakuru. This partnership managed to enhance knowledge on HIV, non-discrimination and promote an enabling work environment, reaching 3831 male and 2349 female workers who were also sensitized on SGBV and importance of enrolling with social protection schemes.
The six months initiative resulted in 1415 male and 1287 female workers knowing their HIV status with 14 male and 11 female who tested positive linked to treatment. TB screening was conducted with 918 chest X-rays done for suggestive cases, 4 male and 2 female workers were diagnosed with TB with one male case being Multi Drug Resistant TB. All were linked to treatment.
Lessons learned:
- Plantations adhering to Fair Trade Certification provide a good entry point to promote HIV related non-discriminatory practices due to compliance auditing
- In the absence of discrimination and harmonious industrial relations between workers and the employers, people living with HIV are more likely to disclose their status and become champions against stigma with creation of support groups at the workplace.

Conclusions/Next steps: Considering persisting myths and misconceptions about HIV, future interventions will focus on addressing high levels of stigma in the sector, while building linkages with county health services for HIV prevention and care.

TUPEE635

How are economic factors and HIV risk related? A social-ecological exploration of the relationship between economic factors and HIV risk among adolescents in KZN, South Africa

A. O'Regan, S. Zissette, C. Godwin, G. Guest, L. Lorenzetti
FHI 360, Behavioral, Epidemiological & Clinical Sciences, Durham, United States

Background: While South Africa has made significant progress in improving HIV prevention and treatment services, there are still high rates of new HIV infections, particularly among young people ages 15-24. The USAID-funded Accelerating Strategies for Practical Innovation and Research in Economic Strengthening (ASPIRES) project helps young people prevent HIV infection through integrated economic strengthening and HIV education programs.
We present qualitative findings from this project with the aim of examining the synergistic effects of combining HIV and economic strengthening educational programming on participants' attitudes, behaviors, and inter-personal relationships.
Methods: From October 2016 to April 2017, 60 adolescents (ages 14-17, 55% girls) participated in the ASPIRES program in rural KwaZulu Natal, South Africa. Through this mixed-methods cohort study, in-depth interviews were conducted at two time points during program implementation and once more six months after the program ended. We used thematic analysis to identify and explore consistent themes across the transcripts and data collection periods. Inter-coder agreement checks were carried out by two analysts on 10% of all transcripts in order maintain consistency in definition and application of codes.
Results: Overall, the study found that participants gained knowledge on financial literacy and how to prevent HIV, as well as knowledge on how maintaining financial security can help protect against HIV. In addition, participants felt an improved sense of self and new hope for the future following participation in the program. Participants described having a positive outlook on their future with clear goals and the confidence to achieve them. Many described changing their relationships with others as a result of program participation.
Examples of this included an increase in respect for elders and ending friendships with peers who were not supportive of their new life vision or who participated in sexually or financially risky activities. Participants described sharing these lessons with others in their family and young people in the community.

Conclusions: Combining HIV prevention and economic strengthening education programs for young adults can improve their understanding of sexual health and financial literacy. These programs seem to have a synergistic effect on participants perception of self-worth that transcends the program through diffusion of ideas to others.

TUPEE636

Capacity Building of sex workers community: Sex Worker Academy Africa

M. Braden Njukia[1], P. Abdalla[2]
[1]African Sex Workers Alliance, Capacity Building, Research, Advocacy and Human Rights, Nairobi, Kenya, [2]Kenya Sex Workers Alliance, Nairobi, Kenya

Background: The Sex Worker Academy Africa is a ground-breaking learning programme for community empowerment and capacity building, led by and for sex workers. It delivers an effective blend of knowledge and experience. The Academy is presented over the course of a week, and includes workshops, site visits and art advocacy sessions.
Description: The Academy brings together national teams of sex workers from across Africa to develop organising skills, learn best practices, stimulate national sex worker movements, and strengthen the regional network. The Academy is an African Sex Workers Alliance (ASWA) initiative implemented by Kenya Sex Workers Alliance (KESWA) in Nairobi, Kenya. The Global Network of Sex Work Projects (NSWP) supported the concept of South-South learning and capacity building.
Lessons learned: The Sex workers implementation tool (SWIT) is the foundation and the backbone of the sex workers academy Africa. The Academy provides sex workers with tools to advocate for and ensure that HIV and sex work-related policies, and HIV and STI prevention, treatment, care and support programming are rights-based, and designed and implemented with the meaningful participation of sex workers. At the Academy, participants acquire the skills and knowledge to influence both policy and service delivery.
Conclusions/Next steps: the SWIT recommendations require meaningful sex worker participation in all aspects of planning, implementation and monitoring and evaluation. It is informed by sex worker experiences and preferences, research, and evidence, and represents consensus between sex worker networks, UN agencies, civil society and donors.

TUPEE637

Improving HIV testing for HIV-exposed infants (HEIs) through community participation

P. Chibanda[1], M. Sichamba[2], G. Sikazwe[3], K. Banda[4], C. Thompson[5], HEI
[1]USAID's Systems for Better Health, International Health Division, Lusaka, Zambia, [2]USAID's Systems for Better Health, International Health Division, Kabwe, Zambia, [3]Ministry of Health, Health, Kabwe, Zambia, [4]Ministry of Health, Health, Chipata, Zambia, [5]Abt Associates Inc., Rockville, United States

Background: HIV testing for HEIs is critical for early infant diagnosis, and subsequent access to care and treatment. The Zambian HIV guidelines state that children born to HIV positive mothers are tested at 6 weeks, then 6, 12 and 18 months. Three of the Systems for Better Health-supported health facilities showed particularly low levels of HEI testing: Ngungu Centre tested 22% of HEIs at 18 months; Chikando Zonal Centre tested 33% of HEIs at 12 months, and Kayanga Health Post tested 40% of HEIs at 12 months.
Description: SBH helped these health facilities develop and implement quality improvement (QI) initiatives using the Ministry of Health's performance improvement approach (PIA): context analysis, stakeholder analysis and engagement, defining desired performance, measuring performance, identifying and analyzing the causes of performance gaps, designing and implementing interventions, and monitoring and evaluating results. Depending on the facilities' needs, interventions included:
· Orienting staff and community volunteers on EMTCT
· Assigning a community volunteer to each HEI to conduct follow up
· Establishing monthly appointment lists of HEIs due for testing
· Integrating HIV testing for HEIs with other activities
· Improving data management systems for tracking HEIs
· Sensitizing communities on HIV testing for HEIs through quarterly committee meetings
· Supporting consistent and accurate reporting of HIV commodities to ensure availability of test kits
Interventions were implemented over 12 months and monitored monthly using the "Exposed Infant Monthly Appointment Tool."
Lessons learned: The facilities demonstrated remarkable improvements in testing HEIs. Ngungu Centre and Chikando Zonal Centre increased testing of HEIs at 18 months and 12 months to 100%, whereas the Kayanga Health Post reached 73.8% of HEIs tested at 12 months. These results suggest that a PIA and corresponding interventions that improve outreach, tracking, and commodity logistics help in increasing HIV testing for HEIs. The use of community volunteers to conduct follow ups on HEIs proved to be effective.
Conclusions/Next steps: The PIA can be effective in significantly improving HIV testing of HEIs, using simple and low-cost interventions. The Zambian government and cooperating partners should invest in supporting similar QI initiatives in health facilities to improve key HIV and other health indicators.

TUPEE638

Vulnerability reduction minimizes risk of STI in FSW

P. Khandelwal
Catalyst Management Services Pvt ltd, Research, Bangalore, India

Background: A study was conducted among the FSW groups in the high HIV prevalence states of India in the phase-III of Avahan India AIDS initiative, funded by Bill and Melinda Gates Foundation, implemented by Swasti, to find out the instances of STI in FSW in the last six months and the possible reasons exposing an FSW to the threat of STI. The primary imperative of phase-III has been vulnerability reduction and sustainability of the Community Organizations.
Methods: The study was conducted in five states in India with high HIV prevalence, the study included primary data collection among FSW, MSM and TG groups in these states. The outcome monitoring survey of Avahan phase III was conducted in August 2017 with a sample of 10891 FSW across these five states. The results were then analysed keeping the instances of STI in last six months as outcome variable, and taking profile characteristics, age, education, clients, income as independent variable.
Results: The scores for different variables like social protection, financial security, safety, security and justice was calculated and independently regressed against STI status. It was observed that FSW with high CVRICI (Comprehensive Vulnerability Reduction Intervention Coverage Index) score had less probability of having STI (AOR 0.812, CI (0.416-1.587)). The profile variables like education and typology were negatively related to STI status. The FSW with better access to better security and justice options had 60% less chances of having STI. The FSW with lesser vulnerability score had less likelihood of having STI (AOR 3.003 CI (2.248-4.011)).
Conclusions: Most interventions in the field of STI are clinical in nature and focuses largely on diagnosis and treatment but not prevention. This study attempts to prove that non-clinical vulnerability reduction interventions with focus on empowerment, vulnerability reduction, social and financial security can lead to STI reduction. The results of the study reflect that given the FSW are provided with institutions like access to social safety, social protection, financial security, it makes them more empowered to adopt safe sex behaviour and hence less vulnerable to STI. Collective action also plays a key role in inducting safe sex behaviour in the FSW.

TUPEE639

Can we make comprehensive sexuality education more effective? A review of 23 school-based comprehensive sexuality education programmes in sub-Saharan Africa

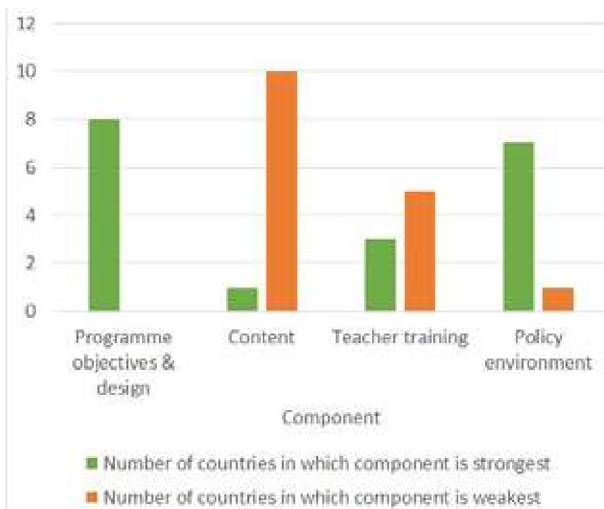
X. Hospital[1], J. Herat[2], P. Machawira[3], W. Ngué[1], C. Castle[2]
[1]UNESCO, Section Education, Dakar, Senegal, [2]UNESCO, Paris, France, [3]UNESCO, Harare, Zimbabwe

Background: Good quality comprehensive sexuality education (CSE) equips young people with knowledge, attitudes and skills to engage in positive social and sexual relationships. Combined with sexual and reproductive health (SRH) services and commodities, school-based CSE is a key element of HIV prevention. As part of a long-term UNESCO endeavour to support CSE in Africa, we reviewed school-based programmes across 23 sub-Saharan countries to assess the status and inform further interventions.

Description: : Using the Sexuality Education Review and Assessment Tool, we analysed data collected in collaboration with ministries of education between February 2011 and January 2016. Analysis of field interviews and teaching, learning, and training materials provided raw data to assess components such as curriculum content, teacher training, programme objectives and design, and policy environment. The tool provided a grid to rate the components against international standards and identify two per country: the weakest and the strongest. This review reported the frequency of strongest and weakest components across the 23 countries.

Lessons learned: CSE programme design is the strongest component in 8 countries, above policy environment (7 countries, Figure 1). Curriculum content is the most frequent weakest component (10 countries), with important variations among countries. As regards content sub-components, the strongest themes were human development and youth empowerment, while relationships and SRH were most frequently the weakest component. There was a much stronger focus on life skills (8 countries), but limited attention to gender or social norms (weakest in 4 and 5 countries, respectively). Nine countries had the strongest curriculum in the 5-8 age range, but conversely 7 countries had the weakest curriculum in the same range. Curricula for the 15-18 age range were the least developed overall.

Conclusions/Next steps: Strong programme objectives and design shows that many ministries of education address the elements that make CSE effective. There is an important gap in curriculum content for the 15-18 age range, and wide variations between countries in the 5-8 range. Finally, there is a need to pay more attention to content on relationships and SRH, and on social norms and gender, in order to make life skills more relevant and effective.



[Figure 1. Number of countries per type and strrenght of component]

TUPEE640

Effectiveness of integrated approaches to reduce HIV/AIDS among young people - a case of an integrated area based approach (IABA) concept in rural areas of Chikwawa District in Malawi

C.F. Mbukwa
Centre for Youth Empowerment and Civic Education, Programs Department, Chikwawa, Malawi

Background: Centre for Youth Empowerment and Civic Education (CYECE) is implementing an SRHR project called; GET UP! SPEAK OUT! Which focuses on addressing harmful, cultural and religious beliefs which affect young people from accessing quality SRHR and HIV/AIDS services within their communities. This project is implemented in a consortium with 5 organsations: CAVWOC, COLWHA, CHRR, YONECO and FPAM. The 5 year project is being funded by the Dutch Government. Under the main goal of ensuring that all young people, especially girls and young women are empowered to realize their SRHR without fear of stigma and discrimination. The Integrated Area Based Approach (IABA) concept is a model which focuses on demarcating a particular area in a community where you would like to see change and create Zero Tolerance to New HIV/AIDS infections specifically among young people.

Description:
1. Social Mapping: analysing the working environment in Traditional Authority Lundu in Chikhwawa district
- identifying the existing structures and institutions for collaboration.
2. capacity building of young people, community, Police VSU & CBOs for them to continuously support project activities.
- administered a Community Score Card process to identify existing gaps (ie distance to facilities, attitude of service providers, lack of YYFHS etc.)
3. conducted community interface forums with community stakeholders and young & young people.

Lessons learned:
- need to follow up on by laws against Stigma and Discrimination against PLWHA
- IABA process helped CYECE to establish critical partners for which to work with in the fight against HIV/AIDS but also promoting access to SRHR services among young people in line with the UNAIDS targets of 90-90-90 to end HIV/AIDS.

Conclusions/Next steps: CYECE is very much convinced that the community scorecard helped in bringing out the issues as to why young especially the girls and young women do not access services from health centres in their communities & also to see the gap and how to bridge it. This will also help us to contribute towards achieving Malawi National HIV strategic Plan which highlights the need to align the national response to the UNAIDS 90-90-90 strategy for adolescent girls and young women especially those living with and affected by AIDS.

TUPEE641

'Money was the motivator': An evaluation of the integration of a matched-savings program into a HIV prevention program for street-connected young people in Eldoret, Kenya

L. Embleton[1], D. Ayuku[2], P. Braitstein[3,4,5]
[1]University of Toronto, Institute of Medicine, Faculty of Medicine, Toronto, Canada, [2]Moi University, Department of Behavioural Science, College of Health Sciences, Eldoret, Kenya, [3]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [4]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [5]Moi University, College of Health Sciences, School of Medicine, Eldoret, Kenya

Background: We integrated a matched-savings program (MSP) conditional on attendance into an adapted HIV prevention intervention for street-connected young people (SCY) in Eldoret, Kenya. The integration of the MSP aimed to increase attendance at the program sessions, give SCY an economic boost to start an income generating activity (IGA), and secure livelihoods to reduce structural drivers of SCY's HIV-risk. We sought to evaluate the feasibility, acceptability, and explore outcomes of the savings program.

Description: We rigorously adapted the Stepping Stones and Creating Futures intervention for a new context with SCY in Eldoret, Kenya. A MSP conditional on attendance was added to the program to supplement the livelihood curriculum and assist participants in relation to setting an achievable goal and developing an IGA. Participants contributed 25-200 Kenyan Shillings (KES) per week and savings were matched based on individual attendance at twice weekly sessions over 14 weeks.
From August to December 2017 we piloted the program at the Academic Model Providing Access to Healthcare using a pre- and post-test study design. In total 80 SCY were enrolled into the program with 20 participants per age and sex stratified group (16-19 and 20-24 years). Through participant observation, savings account records, and focus group discussions (FGDs), we evaluated the program.
Lessons learned: Participants saved 1302 USD, with females saving 615 USD, and males 687 USD. FGDs revealed that the MSP was the primary motivator for attending the sessions, and that SCY would not have attended without this component.
Participants reported that in combination with the livelihood program, the MSP had positively impacted their lives by allowing them to start an IGA, move from the streets into rental houses, and taught them the value of saving.
Participants reported challenges around trust with their finances, and many with low attendance were unsure about the program returning their money.
Conclusions/Next steps: In our setting, the MSP was the key to engaging SCY in an HIV prevention program that impacted their health and well-being. Our results demonstrate combination HIV prevention programs for SCY are not only feasible, but essential to address structural drivers of HIV-risk for this population.

TUPEE642

Feasibility and acceptability of integrating intimate partner violence screening and counselling into community HIV testing and counselling services in Kenya

L. Digolo[1], E. Sakwa[2], G. Zulaika[3], D. Njeru[1], J. Thiomi[1], R. Karuga[1]
[1]LVCT Health, Nairobi, Kenya, [2]Root Capital, Nairobi, Kenya, [3]Liverpool School of Tropical Medicine, London, United Kingdom

Background: HIV and intimate partner violence (IPV) are commonly co-occurring epidemics affecting the health of women globally and especially in sub-Saharan Africa.
This study aimed to assess the feasibility and acceptability of integrating IPV screening and counselling into community based HIV testing services (CHTS) in Kenya.
Methods: This study employed a mixed qualitative and qualitative design and was implemented between August and December 2013 in three community testing facilities. A total of 332 women aged 18 years and older and 12 HIV testing counselors who gave consent were enrolled. The intervention involved IPV screening using a WHO adapted tool and brief counselling for women who report experience of IPV by counsellors who had undergone a three day training. A subset of 37 women were purposively selected for In-depth interviews to assess acceptability of the IPV screening and counselling; and with 12 counselors to assess feasibility of integration of the services into HTS. A focus group discussion was conducted with the counselors to identify gaps in the IPV training curriculum. Frequencies were used to describe the characteristics of the study participants and to measure acceptability. Thematic analysis was conducted with the aid of NVIVO 10 software.
Results: Majority of the women 332(92%) accepted to undergo IPV screening. Most, 315(94.6%) rated screening and counselling services as good and were willing to discuss their experiences with the HIV counsellors. Majority, 282(85%) said the time taken to screen and counsel was adequate (15 to 30 minutes). The providers found the additional time take to screen and counsel reasonable. However, some found the screening questions difficult to explain and translate into local language and noted that a single counselling session was not sufficient. With regards to knowledge and skills, most providers felt that the IPV training equipped them to provide effective screening and counseling services.

Conclusions: This study provides evidence that supports the integration of IPV and HIV services particularly in Sub-Saharan Africa where the two public health problems are still highly prevalent. For successful integration facilities require: a simple screening tool and well trained HIV service providers on IPV identification and IPV counselling services.

TUPEE643

Community-wide implementation of positive parenting: A prevention strategy for HIV/AIDS

C. Winkelman[1], K. Mashego[2]
[1]Families Foundation, Hilversum, Netherlands, [2]City of Tshwane, Department of Health/Multisectoral Mangement Aids Unit, Tshwane, South Africa

Background: The Director of the Multisectoral AIDS Management Unit (MSAMU) at the City of Tshwane, South Africa, initiated consideration of a wide-reach positive parenting programme as an HIV/AIDS prevention strategy.
By strengthening parents' capacity to deal with risky behaviour through enhancing parenting skills, improving family communication and relationships, (proven outcomes of positive parenting) and supporting better decision-making by adolescents increases parents' ability for discussions about sexuality and prepares teenagers to make decisions that would keep them safe and could delay engagement in sexual activity.
Description: A pilot was initiated in townships and informal settlements of the City of Tshwane. 18 SWs and managers of the City and SOS Children Villages Mamelodi were trained in the 8-week Triple P - Positive Parenting Program Teen Group and delivered the programme to 300 parents between August 2015 and October 2016. The programme was delivered at six communities.
Local "community health workers" were engaged in the programme as peer educators to recruit and support parents. The project was supported by a partnership between City of Tshwane, Ubuntu Parenting Family and Youth Institute South Africa and Triple P International, with University of Queensland providing evaluation support.
Lessons learned: The programme had significant positive outcomes on the behaviour of parents and teenagers and high satisfaction with the programme as illustrated by the evaluation results.
Families typically included children of broader age range than teens, suggesting the programme should address 0 -16.
Practitioners evaluated the program as effective and useful, however a limited number delivered the programme. This speaks to the importance of supervisory and organisation support in implementing a new programme.
Conclusions/Next steps: The evaluation suggests that the Triple P teen group program has the potential to significantly strengthen family relationships and communication, parent's confidence and competence and teenagers dealing with risky behaviour. This will strengthen the capacity of the family to deal with risky situations and prevent early sexual activity.
Next steps:
- Follow-up evaluation to determine if positive outcomes are sustained over time.
- Additional training to extend the target population to parents of children 0-16.
- Increased support to practitioners to deliver the programme.

TUPEE644

Integrating HIV prevention services in residential and support services for women in crisis: What works for women in Ukraine?

H. Skipalska[1], T. Castillo[2], N. Pustilnik[1]
[1]Ukrainian Foundation for Public Health, Kyiv, Ukraine, [2]HealthRight International, New York, United States

Background: Many women in crisis due to violence, homelessness, displacement, or sex work need residential, legal and socio-psychological support. Research has demonstrated that many of crisis's drivers are linked with increased risk of HIV infection (i.e. violence against women).

Street-involved women and sex workers often lack information about HIV risks. Integration of HIV prevention services in comprehensive support for women in crisis is essential for improving their health outcomes.
Description: We developed a continuum model of care encompassing three elements: outreach work, drop-in centers (DIC), and shelters. The model presents an opportunity for synergy in violence response, HIV prevention, and social protection. Outreach work is directed at identification, first psychological aid and rapid HIV testing. Then clients are referred to the DIC, where they receive case management support, HIV/STI/HCV and reproductive health education, testing and treatment. For women in need of transitional housing, shelters provide a comprehensive support program for building basic life skills, supporting economic empowerment and securing long-term housing.
Lessons learned: Addressing the social drivers of HIV, such as violence, homelessness and socio-economic status through the continuum of care model for women in crisis has been integral for improving women's health. At DICs and shelters women are offered health education and violence prevention programs that incorporate HIV topics. As a result, women have adapted positive health behaviors and become more assertive and independent (i.e., ask partner about their HIV status or condom negotiation). Women at the DIC were supported in finding employment, resorting documents, claiming social welfare payments thus reducing their risks of returning to risky behavior or problematic environment.
Conclusions/Next steps: Incorporating HIV prevention services in the system of support services is an effective way of improving health outcomes for women. The continuum model of care is a good example of development synergy. It can be replicated in national AIDS responses in context of reaching the Sustainable Development Goals. Having been successfully piloted in Kyiv, the model was extended to other cities (Berdiansk, Zaporizhia and Kharkiv).

Delivering gender transformative programmes and tackling violence against women and girls: programmatic lessons

TUPEE645

Child marriage, HIV and young people: An appeal for a strong alliance

A.H. van der Kwaak[1], N. Tromp[2], P. Baatsen[3], M. Deminent[4]
[1]*Royal Tropical Institute, Amsterdam, Health, Amsterdam, Netherlands,* [2]*KIT Royal Tropical Institute, Health, Amsterdam, Netherlands,* [3]*Royal Tropical Institute, Amsterdam, Netherlands,* [4]*Plan NL, Amsterdam, Netherlands*

Background: At present (2016-2020) we are engaged in an alliance combatting child marriage, teenage pregnancy and female genital mutilations/cutting (Yes I Do) in 7 countries among which some with high a HIV prevalence among girls and boys. We also collaborate with other child marriage alliances and till now HIV seems to be hardly prioritized in the discourse of preventing girls from becoming young brides and mothers. This is an omission in the Theory of Change, pathways of change and interventions. Here we make a plea for integrating and building alliances between HIV and child marriage interventions.
Description: Yes I Do interventions include community mobilization, meaning full participation of young people, increased access to social and health services, economic and educational empowerment and legal advocacy. Young girls and boys are the main target group as well as their social environment in all layers of the community. Gender transformative approaches and engagement of men are crosscutting; boys and men are not seen as part of the problem but as part of the solution.
Lessons learned: Working with 5 pathways is effective. Young people are both victims as well as agents of change, eager to be informed to give better shape to their lives. Child marriage and divorce after child marriage make them vulnerable, teenage pregnancy is a silenced problem, no attention seems given to the risk of HIV or STI infections. Child marriage interventions and health programs are operating in parallel atmospheres.
Conclusions/Next steps: In child marriage programs attention needs to be given to HIV prevention, treatment and care while in HIV programs providers need to become aware of extra vulnerabilities such as child marriage and consequences. Only then both programs become more effective. Support clubs for girls and boys, combined comprehensive sexuality education information in and out of school and training health service providers facilitate the strong link between child marriage and HIV interventions. This will be essential for realizing SDG 3 and 5.3.

TUPEE646

Mbereko+Men: Innovative model for male engagement in PMTCT and family health in rural Zimbabwe

K. Webb[1], L. Comrie-Thomson[2,3,4], Z. Kapamurandu[1], P. Wata[1], B. Madzima[5], L. Davis[2,3], M.-A. Nicholas[2], S. Luchters[2,3,6], D. Patel[1]
[1]*Organisation for Public Health Interventions and Development, Harare, Zimbabwe,* [2]*Burnet Institute, Melborne, Australia,* [3]*Monash University, Department of Epidemiology and Preventive Medicine, Melborne, Australia,* [4]*Ghent University, Department of Obstetrics and Gynecology, Ghent, Belgium,* [5]*Ministry of Health and Child Care, Harare, Zimbabwe,* [6]*International Centre for Reproductive Health (ICRH), Department of Obstetrics and Gynecology, Ghent University, Belgium*

Background: Zimbabwe has an adult HIV prevalence of 14.6%. Male partner involvement is associated with improved PMTCT and maternal/child health service uptake and outcomes. Little is known about the most effective approaches for engaging men in gender transformative programs for PMTCT and family health in high prevalence settings, including men's needs and priorities for family health. We present implementation evidence and key lessons from engagement of rural men in men's dialogue sessions and development of men's Family Health Charters in the Mbereko+Men Program in Zimbabwe.
Description: The Mbereko Model is a multi-component community-based strategy for engaging women in empowerment support groups for PMTCT/MNCH. Since 2010, over 863 Mbereko women's empowerment groups have been formed in geographical catchment of 46 clinics in 3 provinces of Zimbabwe with over 14,000 members. Based on community and Mbereko mother feedback, the model evolved to Mbereko+Men in 2016 to include men's facilitated dialogues in the geographical catchment of 4 rural health facilities, in Mutasa District, Manicaland Province.
Lessons learned: Since September 2016, the Mbereko+Men project has created 30 men's dialogue forums with 781 participating men. Dialogue forums explore men's needs and preferences around 10 key topics, mirrored to information provided to women in Mbereko groups. Each men's meeting results in development of a consensus-based commitment or 'resolution' of men to support family health in a community-held Men's Family Health Charter. Routine facility data demonstrates male partner participation in antenatal care and male partner testing in ANC are significantly higher in Mbereko+Men project areas above national targets (47% and 33% respectively).

Broad Theme	Men's Family Health Charter Resolutions *key themes from 30 Charters
Men's role in family health	- Men to accompany their pregnant wives for ANC booking before 12weeks of pregnancy - To plan, discuss and share ideas on how money and other resources are used in the family.
HIV prevention for mother, father and baby	- Couples to have HIV testing together. - Responsible fathers disclose HIV status to partners. - Open discussion of condom use and sex during pregnancy and postnatal
Health of mother and baby during pre-and-postnatal	- Share household chores and give partner time to rest - Share childcare and participate and play with young children
Birth & importance of birth preparation	- Support partners with developing a birth plan and preparations - Accompany wife to facility and be present during delivery
Postnatal HIV care and family planning	- To ensure that the whole family is tested for HIV even if they are well, not only parents. (Family HIV testing). - Demystify condom use in married couples and use it as dual method of family planning - Support exclusive breastfeeding - Promote open discussion of reproductive health including sex in married couples - Share responsibility for family planning - Help bring child to clinic for routine check-ups/illness
Family violence	- Promote a free and warm family environment - Zero tolerance for violence in the home, neighbourhood or community

[Men's Family Health Charter Resolutions]

Conclusions/Next steps: Mbereko+Men has been an effective model for engaging men in a conservative, rural population in Zimbabwe in transformative dialogues regarding family health, roles, and support. The Zimbabwean Ministry of Health and Child Care have adopted and costed the Mbereko+Men model as part of "community outreach events" in the "The Plan for Elimination of Mother to Child Transmission (eMTCT) of HIV & Syphilis in Zimbabwe 2018-2022". Future research seeks to establish family health outcomes including MTCT, in Zimbabwe's drive to eMTCT.

TUPEE647

Creating a continuum of care for survivors of gender-based violence: Evaluation of a mobile phone-based referral system in Botswana

A. Cannon[1], S. Treves-Kagan[2], M. Cutherall[3], J. Fehringer[1], H. Apps[4], P. Ramaphane[4], J. Curran[1], K. Scurria[1], S.S. Bloom[3]
[1]University of North Carolina at Chapel Hill, MEASURE Evaluation, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Health Behavior; MEASURE Evaluation, Chapel Hill, United States, [3]University of North Carolina at Chapel Hill, Maternal and Child Health; MEASURE Evaluation, Chapel Hill, United States, [4]WoMen Against Rape, Maun, Botswana

Background: Gender-based violence (GBV) is a critical risk factor for HIV infection. Reducing GBV and HIV is an urgent priority in Botswana. MEASURE Evaluation collaborated with the Government of Botswana Gender Affairs Department and USAID Botswana to implement a pilot of a GBV Referral System (GBVRS). The GBVRS included a Referral Information System (RIS) which uses simple mobile technology to facilitate referrals and track GBV cases through multiple sectors; provider training to ensure high-quality GBV care; relationship strengthening between providers; and community mobilization to reduce GBV acceptability and increase awareness of services.
Methods: We implemented a 12-month pilot of the GBVRS. To evaluate the pilot, service provider interviews (n=117) and community member focus groups (n=65) were conducted in intervention and control communities at two time points. Data from 12 months of RIS usage, key informant interviews (n=7), and monitoring reports from implementing partners were also analyzed. Dedoose was used for qualitative analysis.
Results: At endline, providers in intervention areas reported greater trust in fellow service providers, confidence in identifying GBV cases, and understanding appropriate protocols compared to those in control communities. Between August 2016-July 2017, 401 GBV cases were entered in the RIS. Of the cases logged, 33% (n=134) were provided with a referral and 30% (n=41) of referrals were completed. RIS uptake was uneven between sites and provider type. Challenges noted were adopting new processes, technical difficulties with the phones, and high staff turnover. Community FGDs found that inequitable gender norms undermined understanding of GBV and service utilization; modest improvements regarding GBV acceptability were seen among male focus group participants in intervention sites compared to comparison sites.
Conclusions: This is the first use of a formal GBV referral system in Botswana and one of few in low or middle income countries. This evaluation provides promising results and insights to enhance comprehensive GBV service delivery through an innovative data system and surrounding support. Given the strong connection between HIV and GBV, investing in systems to improve the standard of care for GBV survivors is critical to ending both epidemics.

TUPEE648

Improved services, health seeking behavior, and outcomes for gender-based violence survivors, including post-exposure prophylaxis (PEP) in rural Zambézia province, Mozambique

C. Audet[1], S. Van Rompaey[2], W. Gong[3], E. Graves[3], M. Bravo[2], F. Melo[4], J.E. Malinha[4], E. Chele[5], C. De Schacht[2]
[1]Vanderbilt University Medical Center, Health Policy, Nashville, United States, [2]Friends in Global Health, Maputo, Mozambique, [3]Vanderbilt University Medical Center, Nashville, United States, [4]Friends in Global Health, Quelimane, Mozambique, [5]Zambézia Provincial Health Directorate, Quelimane, Mozambique

Background: Gender-based violence (GBV), including physical, psychological, and sexual assault (SA), represent a significant public health issue. In Zambézia, Mozambique, "one-stop" care models were established at nine district health facilities (HF) by late 2015, creating a single entry point for GBV-related services, but low numbers of people seeking care have limited the impact on health for survivors.
Methods: In January 2017 we initiated a campaign to improve the number of GBV survivors who seek care at the health facility. We conducted theater presentations and lectures to educate community members about the importance of seeking immediate care for GBV and provided a 4-day training to service providers (followed by regular clinical mentoring) to reinforce GBV treatment protocols. We also introduced a home-based care system to follow up patients who did not return for repeat HIV testing. We compared pre- (July 2016 - January 2017) vs. post-intervention (February - September 2017) patient characteristics using Pearson and Student's t-tests. We employed a negative binomial model to assess change in rate of care-seeking.
Results: From July 2016 to September 2017 we compiled data on 473 GBV events at nine HF. Patients were primarily female (90.5%), married (42.7%), and with a mean age of 23 years (SD 12.4). Physical violence was reported in the majority of cases (383, 81%), SA in 89 cases (18.8%), and psychological violence in 1 case (0.2%). Daily rate of care seeking increased from 0.10 to 0.13 events per day with a rate ratio of 1.33 (CI: 1.11, 1.61; p=0.002). During the post-intervention period, 73% of SA survivors sought care within 72 hours (vs. 51% pre-intervention; p=< 0.001); 100% of eligible survivors initiated PEP (vs. 86% pre-intervention; p=0.07); 71% completed (28 days) PEP (vs. 21% pre-intervention; p=0.004); and 57% completed an HIV test at one-month (vs. 21% pre-intervention; p=0.036). No improvement was found in survivors' three- or six-month HIV testing.
Conclusions: GBV campaign activities contributed to significant improvement in the rate and promptness (within 72 hours) of care seeking, as well as completion of PEP medication. Our findings highlight the impact of awareness-raising campaigns and need for further clinical support to ensure patient follow-up.

Social protection: new evidence and programmatic lessons

TUPEE649

Human rights documentation and advocacy program in Myanmar: Ending discrimination against PLHIV and key populations through scaling up their capacity to advocate for themselves

J. Shrestha[1], K. Su Win[2]
[1]Asia Catalyst, Capacity Building and Community Initiatives, Bangkok, Thailand, [2]Asia Catalyst, Capacity Building and Community Initiatives, Yangon, Myanmar

Background: Asia Catalyst (AC) programs and activities through 2011-2016 in Myanmar revealed few community-based organisations(CBOs) have sound organizational management and skills to effectively advocate, thereby limiting communities' ability to achieve advocacy goals. AC's baseline data showed limited understanding among CBOs of in-

ternational rights frameworks, documentation skills, or evidence-based advocacy. Equipping and upscaling skills of local through a long-term sustained approach was vital. Development partners in the country concurred.

Description: 10community leaders from 4CBOs representing WLHIV, sex workers, LGBT and PUD participated in series of workshops. The workshops, designed through participatory peer-to-peer learning approach, centered on community-lived experiences and local contexts. Participants developed qualitative tools for powerful evidence collection. CBOs received sub-grants to conduct rights documentation and advocacy on: access to discrimination free SRHR services for WLHIV and sex workers, access to drop-in-centers for PUD and end of arbitrary arrests of LGBT persons.

Lessons learned: Grassroot CBOs while having limited skills in organizational planning and advocacy plays instrumental role in service delivery. There is limited ability to identify and use the opportunity presented by service delivery work to advance advocacy goals they are seeking. CBOs need support to identify opportunity within their existing workplans to integrate sustained knowledge sharing exercise and advocacy skills enhancement of the community. However, CBOs also have limited human and other resources posing challenges in prioritizing sustained knowledge building and policy advocacy roles. Despite this, communities recognize the importance in engaging in dialogues for structural reforms where their issues are highlighted. Creating a safer space for communities to freely share, learn and strategize is important.

Conclusions/Next steps: During this democratic transition in Myanmar, as the country is reviewing archaic laws or drafting new ones that will have long-term impact, community engagement is critical. There are opportunities for this engagement for the CBOs. There are ever increasing civil society movements, including experienced advocates who were in exile during the previous government, and continued donor interests in capacity building, advocacy and services delivery. For a truly community-led advocacy engagement to ending discrimination, stigmatization and criminalization of marginalized communities requires sustained long-term support, including investment in creating enabling environment for effective advocacy for their rights.

TUPEE650

Tracking HIV-sensitive social protection strategy implementation: Policy implications

D. Chipanta
UNAIDS, Community Support Social Justice and Inclusion, Geneva, Switzerland

Background: The 2016 Political Declaration on Ending AIDS encourages Member States to strengthen national social and child protection systems to ensure that by 2020, 75% of people living with, at risk of or affected by HIV benefit from HIV-sensitive social protection *(1)*. UNAIDS is mandated to support countries in monitoring and reporting on progress towards global AIDS commitments adopted through the 2016 Political Declaration on Ending AIDS (and previously the 2001 Declaration of Commitment on HIV/AIDS, the 2006 Political Declaration on HIV/AIDS, and the 2011 Political Declaration on HIV and AIDS), with the objective of identifying progress, challenges and constraints in the AIDS response.

Methods: Data on social protection policies and mechanisms are reported by national authorities and civil society through the UNAIDS Country Offices using the National Composite Policy Instrument (NCPI).

Results: Of the 114 reporting countries that submitted the social protection data, 91 countries (80%) have a social protection strategy that is being implemented, 9 countries (8%) have a social protection strategy that is not being implemented, and 14 countries (12%) do not have an approved social protection strategy. Analysis of the elements of HIV sensitivity indicate that 12 countries (11%) report having a social protection strategy implemented that includes all 6 of an HIV-sensitive social protection strategy.

71 countries (62%) reported having social protection strategies that refer to HIV, 68 (60%) countries´ strategies recognize people living with HIV as key beneficiaries, 32 (28%) recognize key population and 31 countries (28%) recognize unpaid work in the context of HIV. 28 of the 108 reporting countries implement cash transfer programmes aimed at young women in this age group.

Conclusions: Countries are failing short of meeting their commitments on social protection. Key populations and unpaid work in the context of HIV remain key areas of focus in increase the HIV sensitivity of social protection. More research is needed to understand the design features that will lead to more HIV sensitive social protection programmes.

TUPEE651

Caregiver participation in savings and internal lending communities improves the vulnerable household wellbeing and increases HIV testing

U. Ossai[1], A. Efuntoye[2], C. Anoje[2], S. Amadiegwu[2], C. Ujuju[2], P. Gado[3], D. Magaji[4], C. Miller[5], J. Hembling[5]
[1]Catholic Relief Services Nigeria, Health, Abuja, Nigeria, [2]Catholic Relief Services, Health, Abuja, Nigeria, [3]United States Agency for International Development, F.C.T, Nigeria, [4]United States Agency for International Development, Abuja, Nigeria, [5]Catholic Relief Services, Baltimore, United States

Background: Nigeria has a high HIV burden with 2.9 million people living with the virus. Caregiver's inability to meet the basic needs of orphans and vulnerable children (OVC) negatively affects their wellbeing and increases their vulnerability to HIV. To ensure vulnerable caregivers (VC) had reliable income to meet the needs of OVC, Catholic Relief Services-led Sustainable Mechanism for Improving Livelihoods and Household Empowerment (SMILE) project used a savings group methodology called savings and internal lending communities (SILC) to strengthen the household economy and build resilience of VC. Between 2015 and 2017, 1,148 SILC groups were formed comprising of 24,794 members (17,985 women and 6,809 men) including SMILE participants and other community members. By 2017, the groups accrued total assets worth over N146 million (approximately USD 406,000). The purpose of this study was to determine if OVC caregivers participating in SILC had better outcomes than non-participating caregivers.

Methods: The study administered a structured questionnaire to a random sample of 2,105 caregivers and 3,038 children who received project services across five states in Nigeria. Dependent variables of interest include HIV testing and progression in school. Multivariate logistic regression was used to assess associations between participation in SILC and wellbeing outcomes while controlling for potential confounders.

Results: The result showed the adjusted odds of female children 10-17 years progressing in school were 3.77 times greater if their caregivers were SILC participants compared to female children whose caregivers who were not SILC participants ($p< 0.01$). There were no differences in school progression for male children by SILC participation. Similarly, the odds of caregivers knowing the HIV status of their female children (0-17 years) was 1.89 times greater compared to caregivers who were not SILC participants ($p< 0.05$). There was no association between caregiver knowledge of their male children's HIV status and SILC participation.

Conclusions: SILC intervention strengthened the economy of caregivers with a positive effect on caregivers' ability to meet their children's needs. Integrated activities have reinforcing effect notably on the uptake of HIV testing among caregivers who participated in SILC.

TUPEE652

Economic empowerment for key populations; potential for HIV prevention

E. Mwangi
Partners for Health and Development in Africa, Capacity Building and Mentorship, Nairobi, Kenya

Background: The burden of HIV is highest among low income countries, sub-Saharan Africa (SSA) contributes 71% of new HIV infections (UNAIDS, 2014), which has previously been agued to have a close correlation with the poverty levels in SSA. Kenya's HIV Prevalence is 6.0% with 29.3% HIV prevalence among sex workers. Nairobi has the highest number of SWs, with a population estimated at 45000 SW. Sex workers are also among groups who are economically underprivileged, with majority living in low socio-economic areas and at the fridges of the society.

This situation is largely worsened by lack of education, skills, resources and poor exposure to the available entrepreneurship opportunities. Consequently, majority cannot improve their livelihoods and hence engage in risky behaviors, such as drug abuse and condomless sex.
Description: In October 2016, an entrepreneurship, financial literacy and life skills training was conducted for 30 sex workers in Nairobi. Out of the thirty, five who had the best business proposals were selected to form a self help group. In December 2016, these sex workers were provided with financial support through a negotiated line of credit to establish businesses. They also accessed a peer mentorship program and a quarterly performance review on progress was done. At the end of Dec 2017, a semi-structured interview was conducted to examine their current lifestyle, business performance and risk taking behaviors. Data was then analyzed thematically.
Lessons learned: All participants had improved their livelihood within the first year, three out of the five startups were generating 20% increase in profits by the second quarter. Two out of the three had also managed to start developing their rural homes and one was paying university fees for her child. All the participants were repaying their loans and venturing into various investments. The data analysis also revealed a reduction of risky sexual behavior as they could now select clients confidently negotiate for condom use.
Conclusions/Next steps: Economic empowerment through self help groups has proved to be a much needed structural intervention for HIV/STI risk reduction. Sex workers when offered alternative livelihoods adopt safer sex, develop confidence and make independent decisions.

TUPEE653

Social protection schemes for people living with HIV (PLHIV) through single window model: Case study from India

A. Verma, N. Goel, R. Rana, R. Bhushan, N. Pandey, N. Rawat
National AIDS Control Organization, Ministry of Health & Family Welfare, New Delhi, India

Background: India has an estimated 2.1 million People living with HIV in which 1.16 million on ART. Poor awareness, low demand, social apathy, systematic flaws, procedural delay and stigma and discrimination is big hindrance in enrollment and access of social protection benefits. Women and Children (< 15 years), which constituted 39% and 7% of estimated 2.1 million PLHIVs, are more vulnerable and standing far behind in availing social protection benefits.
Methods: National AIDS Control Organization (NACO) along with State and district administration particularly District AIDS Prevention Control Units (DAPCU) adapted community centric approaches to coordinate with government, autonomous institutions, civil society for enabling HIV sensitive policies and schemes.
Following NACP IV mandates of ensuring social protection for PLHIVs; 'DAPCU led single window model on social protection' was piloted and scaled up in 186 high prevalent districts with support of UNDP.
Joint advocacy have taken place for HIV sensitive social protection. 142 directives were issued by Government. Compendium of government orders, social protection web portal, demand generation toolkit are made available and have used for demand generation, demand aggregation, quality assurance and grievance redressal.
Results: Uptake of social protection schemes by community increased. Priorities given to widow, orphan children for nutritional support, free transport, financial assistance, shelter, insurance, legal aid etc. Access of social protection impacted positively in improving qualities of lives of PLHIVs particularly women and children, prevent further indulgence in risky behavior, support to realize one's rights.
450 government officials from 21 states are trained in 10 regional workshops. 2083 help desk are established in various facilities to aware communities on social protection, generate demand and enroll them in various schemes. 39 directories on HIV sensitive social protection by State Government made available.
More than 1.05 million benefits are accessed by PLHIVs that include 28733 widow pensions, 125857 nutritional benefits, 20002 guardian schemes , 19957 insurance, 7159 legal aid, 285208, free transport benefits etc.
Conclusions: Single window model is economically and programmatically viable option that enabled environments for sensitive policies, social protection schemes, reduces stigma & discrimination, secured human rights and paved way to lead lives of PLHIV with dignity.

TUPEE654

What is different? Lessons learned from the National Strategic Framework (NSF) 2017-2021 development process in Nigeria

F. Agbo[1], A. Ogundipe[2]
[1]*National Agency for the Control of AIDS, Strategic Knowledge Management, Abuja, Nigeria,* [2]*National Agency for the Control of AIDS, Policy and Strategy, Abuja, Nigeria*

Background: Traditionally the development of HIV/AIDS strategic plans in Nigeria has followed a top down approach due to the Federal nature of governance and perceived capacity gaps at sub-national levels. The federal level coordination agency leads the reviews of the HIV response and develops the National Strategic Framework (NSF) that guides the development of the National Strategic Plan (NSP). State level coordination agencies then derive state strategic plans (SSPs) from the NSP.
Over the last two cycles of the strategic planning process, it has been observed that this approach has led to products that were non-responsive to the state epidemic status, capacity and available resources. Thus, most SSPs were inadequately implemented due to poor ownership and resourcing and never seemed to guide implementation.
Description: This informed the adoption of a different methodology in developing the NSP 2017-2021. A team of consultants, staff from the National Agency for the Control of AIDS (NACA) and the Federal Ministry of Health (FMOH) worked to develop and finalize the NSF 2017-2021. The team developed comprehensive guidance notes to guide development of sub-national plans by states. The guidance notes identified priority thematic areas, suggestive list of interventions and a Microsoft Excel based costing tool with standard unit cost. State coordinating agencies constituted technical teams to lead the development of SSPs. State teams were trained on the guidance notes and NACA staff drafted to the states to provide hands-on support to states to develop their SSPs. Sub-national plans developed were then consolidated into the NSP 2017-2021.
Lessons learned: The new approach ensured that SSPs were responsive to the state epidemic and set targets were reflective of the resources and capacity in the states. It allowed states to prioritize interventions and activities appropriate to local context, epidemiological data and evidence of what works as a sub-set of overall country priorities. It enhanced the capacity of NACA staff to support the strategic planning process thus reducing cost of hiring consultants. Also states capacities were developed, and ownership of the state plans assured.
Conclusions/Next steps: Implement SSPs at state level and the NSP at national level and put in place tools to track their implementation.

TUPEE655

Impact of drought on HIV response and interventions in arid and semi-arid regions of Kenya

M. Josephine Muthoni[1], O. Cyprian[2], M. Mumma[2]
[1]*UN World Food Programme, VAM, Nairobi, Kenya,* [2]*UNWFP, Nairobi, Kenya*

Background: Tremendous progress has been made in controlling and reversing the HIV trend in Kenya. However, despite the significant progress, there remains a high new HIV infection rate among young people and key populations. Further, the HIV response in arid and semi-arid areas which experience cyclical drought and accompanied high levels of food insecurity and malnutrition remain a concern. With the well-established links between malnutrition, food insecurity and HIV, a good number of PLHIV and their households are classified as food insecure with high levels of negative coping mechanisms.
Further, gaps are experienced in service delivery with nutrition and HIV services often offered separately and gaps persist in prevention of

mother to child transmission, antiretroviral treatment coverage, and in the coverage and distribution of health facilities and personnel.
Methods: A mixed methods research approach was used in data collection in kilifi, Turkana and Kitui counties. Three comprehensive care clinics (CCCs) from each county were selected as the entry point. 1272 children aged 2 to 14 years, adult men and women were sampled. Household Dietary Diversity Score (HDDS) was assessed using one 24-hour recall period. Household Food Insecurity Access Scale (HFIAS), Coping strategies, Coping Strategy Index (CSI) and levels of malnutrition were assessed using BMI and Z scores. data was stripped and analyzed thematically using SPSS v24.
Results: Drought affected access to HIV care, treatment and adherence. PLHIV prioritized finding food over accessing medicine; food scarcity also forced PLHIV to skip or discontinue medication. Ignorance was noted on PEP, PrEP, female condoms use. There was increased risk of HIV transmission through transactional and commercial sex, gender-based violence and disruption of social networks. PLHIV adopted strategies to cope with the effects of drought including controlled food consumption, reduced portion sizes, reduced number of meals, and relied on less preferred foods.
Conclusions: Strengthened inter-sectoral linkages between nutrition, HIV, WASH and communicable diseases in coordinating drought responses that are cost-effective are needed. Consideration of mixed livelihoods when designing drought response and resilience programmes can be used as a strategy to build resilience into communities to reduce outlays on emergency responses.

TUPEE656

Facilitating outreach services for PLHIV: Experience from the Global Fund-supported Vihaan programme in Hyderabad, India

S. Ramasamy Murugesan[1], V. Arumugam[1], H. Rosenara[2], V. R. Nair[3], R. Chauhan[1], G. Pandey[1], S. Chakraborty[1], B.B. Ubarhande[1], P.K. Shetty[2], V. Joseph[2], M. Balani[2], S. Mehta[4]
[1]India HIV/AIDS Alliance, Strategic Information, New Delhi, India, [2]India HIV/AIDS Alliance, Care & Support, New Delhi, India, [3]India HIV/AIDS Alliance, Care & Support, Hyderabad, India, [4]India HIV/AIDS Alliance, New Delhi, India

Background: India HIV/AIDS Alliance implements the Global Fund supported Vihaan programme to deliver care and support services for people living with HIV (PLHIV) through its 350 community-based Care & Support Centres (CSC) across India. Care and support helps increase treatment adherence, improves quality of life and ensures access to social entitlement services for PLHIV. Promoting linkages to social protection schemes helps in the socio- economic empowerment of PLHIV, as it increases their access to pension schemes, nutritional programmes and income generation activities.
Methods: A cohort of 34,528 PLHIVs were recruited for the programme and followed for four years (at least once in 6 months) with Vihaan intervention. Client data were collected using Client registration form for baseline and the follow up service data were collected and documented over the period of 4 years. For analysis, the clients who had been followed-up in the last one year and received services including social protection has been considered. Descriptive and regression analyses were carried out using the SPSS 20.0. A linear regression was performed to ascertain the effects of Vihaan services (Social protection) on health indicator.
Results: In last one year (2017) 31% of the clients has received outreach services from the CSCs which includes 67% health referral, 21% linked with social protection services and 12% received counselling. The characteristics of the clients received outreach services and not received are similar with average age 34 years, 50% male, 43% illiteracy, 65% married and 15% widowed. However, when there latest CD4 cell count is analysed there is good increase and through linear modelling with R^2=22%, a client who had received CSC services has a chance of gaining 75 CD4 cell count.
Conclusions: Care and support services support in physical quality of life of PLHIV and thus Vihaan care and support model (peer led linkages with social protection) can be replicated with further testing of significance.

TUPEE657

The role of oral-HIV self-testing in enrolment of female sex workers into comprehensive HIV programmes in Kenya

T. Achia[1], K. Chesang[1], P. Gichangi[2], G. Mgomella[1], J. Kimani[3], C.T. Ruto[1], P. Young[1], S. Ohaga[4], J. Ambia[4], P. Matti[4], K. Agot[4]
[1]Division of Global HIV and TB, US Centers for Disease Control and Prevention, Nairobi, Kenya, [2]International Centre for Reproductive Health, University of Nairobi, Ghent University, Belgium., Mombasa, Kenya, [3]University of Manitoba / Partners for Health and Development in Africa, Nairobi, Kenya, [4]Impact Research and Development Organization, Kisumu, Kenya

Background: Female sex workers (FSW) enrol to receive comprehensive HIV, STI and reproductive health services at Drop-in Centres (DiCEs) - FSW dedicated clinics/safe spaces. Enrolment entails registering and HIV testing service, and is the entry point to DiCE services. However, enrolment and subsequent utilization of services at the DiCEs are known to be sub-optimal.
Methods: Using quasi-experimental design, we sought to find out if peer educators (PEs) distributing HIV oral-self testing (HIVOST) increased FSW enrolling into DiCEs versus routine programming. We conducted the study from February 2016 - May 2017 in eight sites spread in four regions, all with high HIV burden and attributing to 88% of Kenya's FSW population. Two DiCEs in each region were randomly selected. The intervention phase involved PEs distributing HIVOST at hot-spots, linked to the selected DiCE, to FSW who had never sought HTS or last tested over six-months, and subsequently confirming their HIV status at the selected DiCE after using HIVOST. In the control phase, PE referred an equivalent FSW population from the same hot-spots to the selected DiCE for routine HTS. In each region, one site started with the 6-months intervention phase, 3-months wash-out period to wane-off the effects of HIVOST, and 6-months control phase (Group-1), while the other site started with the control, wash-out, and intervention (Group-2). The choice of the different starting times was to spread the distribution of HIVOST to cover different months as the intensity of sex work is known to vary throughout the year. We used Stata for analysis and accounted for the study design.
Results: Overall, 1,415 FSW were enrolled. During the intervention phase, 900 FSW were enrolled, and 515 during the control phase. The proportion of Intervention phase enrolment was significantly higher compared to the control phase (48% vs18%; p< 0.001). Similar independent results were observed for group-1 and group-2. Adjusting for DiCE characteristics (urban/rural and work load) and study phases, enrolment likelihood was significantly greater in the intervention phase compared to the control phase [adjusted odds ratio=8.44, 95% confidence interval=5.04-14.1].
Conclusions: This study suggests that HIVOST improves FSW enrolment to DiCEs and uptake of HIV, STI and RH services.

Innovations in behavioural data collection and use

TUPEE658

Innovative, technology-driven methodologies to collect qualitative data among youth

L. Hightow-Weidman[1], S. Legrand[2], K. Muessig[3], K. Soni[1], K. Knudtson[1], R. Stephenson[4]
[1]University of North Carolina-Chapel Hill, Medicine/Infectious Diseases, Chapel Hill, United States, [2]Duke University, Duke Global Health Institute, Durham, United States, [3]University of North Carolina-Chapel Hill, Health Behavior, Chapel Hill, United States, [4]University of Michigan, School of Nursing, Ann Arbor, United States

Background: In-person methods for collecting qualitative data from youth to inform intervention development traditionally involve focus groups, in-depth interviews and advisory boards (YABs). While these proven methodologies have strengths, youth engagement can be limited by structural barriers (e.g. lack of transportation, inconvenient tim-

ing) and reluctance to participate due to stigma or discomfort with group settings. As an increasing number of HIV prevention and care interventions are successfully delivered online, innovative approaches to youth engagement in virtual spaces can also be applied across the intervention lifespan to increase the quality and validity of formative data.

Description: We present unique technology-based methods employed to elicit participant feedback during the development of four HIV prevention and care interventions. In *Tough Talks*, an avatar-based intervention that utilizes natural language processing to increase HIV disclosure among young men who have sex with men (YMSM), an online comic book caption contest was launched to gather real-world HIV disclosure discussions. Winning entries were awarded prizes and participant dialogues are used to program avatar responses (Figure 1). In *Test Rehearsal,* an interactive mHealth intervention that uses virtual reality scenarios to educate YMSM about HIV self-testing, asynchronous online focus groups enumerated barriers and facilitators to HIV testing among youth. In *iTech*, a Youth Advisory Council, composed of YAB members from 6 diverse sites across the US, convenes monthly videoconferencing meetings to foster continuous youth engagement. Finally, in *Love Lab* and *We Prevent*, qualitative relationship histories were collected from youth via video-chat. Youth could create, annotate and change online relationship diaries under the guidance of an interviewer, to explore periods of risk and facilitate the development and targeting of couples-based interventions.

Lessons learned: Beyond facilitating intervention delivery, technology can serve as a platform for formative data collection, mitigating the limitations of in-person methods and increasing access to diverse and "hard-to-reach" youth. It is critical to ensure that platforms used to engage and communicate with youth are secure, easy to use, and function even in low-bandwidth settings.

Conclusions/Next steps: Innovations in communication technologies offer researchers viable and valuable means to collect formative data. Utilization of these methodological innovations may better position interventions to impact behavior among youth.

[Tough Talks Comic Book Disclosure Dialgogue Submission]

TUPEE659

Estimating over-reporting in condom use among Senegalese sex workers

A. Lepine[1], C. Treibich[2], K. Gueye[3], C.T. Ndour[3], P. Vickerman[4]
[1]LSHTM, London, United Kingdom, [2]University of Grenoble, Grenoble, France, [3]Ministry of Health of Senegal, Dakar, Senegal, [4]University of Bristol, Bristol, United Kingdom

Background: Social desirability bias, that is the tendency to under-report socially undesirable health behaviours, significantly distort information on sensitive behaviours gained from self-reports. As a result, self-reported condom use among high-risk populations is systematically over-reported. The main objective of the paper is to test whether the list randomization is an effective method to estimate misreporting in condom use among female sex workers and to identify factors associated with condom use.

Methods: We used a list randomization and a secret vote to indirectly elicit condom use among 805 female sex workers surveyed in 2015 and 2017 in Senegal, a country where sex workers face high social stigma and a high risk of HIV/AIDS infection.

Results: Based on the list randomization, we find that the condom use rate in their last sexual intercourse with a client is 80% (79%) in 2015 (2017), which is significantly lower than the 97% obtained when self-reported. The secret vote method estimates a condom use of 88%. When estimating condom use among sub-groups, we find that condom use among HIV positive female sex workers is only 31%, which is 46 points lower than the condom use in HIV negative FSWs. However, we did not find any significant difference in condom use among sex workers who were enrolled in the PrEP demonstration project.

Conclusions: Our study confirms that, unlike the secret vote method, a well-designed list randomization is an inexpensive and an easy method to implement in order to elicit condom use among high-risk groups in low-income countries.

TUPEE660

69% of respondents in Eastern Europe and Central Asia (EECA) know their HIV status: Results of the largest ever online survey in social network Odnoklassniki (OK)

E. Kiryushina[1], V. Saldanha[1], S. Kolomiiets[1], L. Zohrabyan[1], T. Yepoyan[2], Y. Plakhutina[2], A. Ilieva[2], E. Sergeeva[3]
[1]UNAIDS, Regional Office for Eastern Europe and Central Asia, Moscow, Russian Federation, [2]UNESCO, HIV and Health Education Programme for Eastern Europe and Central Asia, Moscow, Russian Federation, [3]OK Social Network, Moscow, Russian Federation

Background: On WAD 2017, a survey with 13 HIV-related questions was launched in Odnoklassniki, the largest Russian language social-media platform (71 mln users monthly).

Methods: An invitation link to an anonymous survey was promoted via banner at the ok.ru home page, in a thematic HIV group at ok.ru/test, and via a promo video and social media posts by UNAIDS Goodwill Ambassador Vera Brezhena (9 mln followers). The questions used UNAIDS Global AIDS Monitoring indicators.

Results: This is the largest online HIV survey ever conducted in EECA, with 169,314 respondents in 4 days. 80% of respondents were women. 98% were from EECA and 84% from Russia. Age groups distribution was: 10-19: 4,4%, 20-25: 7%, 26-39: 33,6%, 40-59: 42,9% and 60+: 11,65%.
97072 (57%) respondents completed the full survey with further results. 63% accurately answered all questions about HIV. 95% identified condom use every time person has sex as an effective HIV prevention measure. When asked about the age to educate an adolescent on condom use, 65% answered „Before the start of sexual activity" and 28% - "age of 14". 90% indicated tolerant attitudes towards people living with HIV. 63% reported to be ready to share food with a person living with HIV.
63% reported that they had an HIV test within a year. 84% of respondents knew where to get tested for HIV.

Conclusions: The survey demonstrated high level of awareness and knowledge about HIV prevention and a relatively low level of discrimination towards PLWHIV in EECA. However, 80% of respondents are women, but most new HIV infections in EECA are among men. So, it remains a challenge to reach men with HIV testing services, especially those most likely to be living with HIV. The survey showed that a large population can be reached online, and social media can serve as an effective tool to promote HIV prevention and access to HIV testing. Greater advocacy is needed to improve HIV testing coverage and close the gaps in areas where inaccurate knowledge and unsafe behaviours are reported.

Big data: an untapped opportunity?

TUPEE661

Rapid population size estimation of online men who have sex with men using Facebook marketing data in India

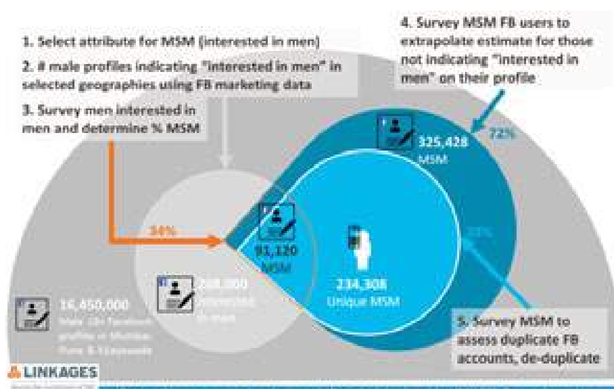
B. Eveslage[1], T. Saidel[2], P. Shah[3], J. Baishya[4]
[1]FHI 360, Global Health Population and Nutrition, Washington, United States, [2]Partnership for Epidemic Analysis (PEMA), New Delhi, India, [3]FHI 360, New Delhi, India, [4]USAID, New Delhi, India

Background: Population size estimates (PSE) are used by key population (KP) HIV programs to plan implementation and measure progress toward targets. However, it's challenging to estimate sizes of KPs not linked to known networks or physical venues. Programs need a way to quantify the reachable/accessible population, including those not present in physical venues.

Methods: Between September and October 2017, the USAID- and PEPFAR-supported LINKAGES project in India used a new method to rapidly enumerate online men who have sex with men (MSM) leveraging publicly available marketing data on Facebook and short online surveys on Survey Monkey to refine estimates useful for programming.

Results: Using Facebook's ad manager, there are 16.5 million adult male profiles in the program's catchment areas of Mumbai, Thane, Pune, and Vijayawada and 268,000 profiles if restricted to profiles indicating "interested in" men. A survey advertised to those profiles acquired 29 respondents, 34% reporting MSM behavior. A similar survey more widely distributed to MSM through ads and social media postings acquired 318 MSM respondents and found 72% do not specify "interested in" men on their Facebook profile. These data were used to estimate 325,428 Facebook profiles used by MSM in the 4 geographies, representing 234,308 individual MSM (after de-duplicating for 28% of MSM reporting two or more profiles on the survey). This estimate represents 1.42% of the adult male population on Facebook in the same geographies. Sixty-one percent of these MSM reported exclusively meeting partners for dating or sex online and not at physical locations where existing PSE and outreach efforts focus.

Conclusions: Leveraging Facebook's marketing data is a promising approach for assessing the size of online markets for KP HIV services - a new way to complement existing PSE approaches quickly and affordably. The approach can be adapted for other settings/populations by identifying the attributes on people's social media profiles which predict whether they are KP members and then refine based on the accuracy of that attribute and its expression among the target audience. The method is still being developed and needs to be tested rigorously with better quality surveys to establish proof of concept.



[Figure 1: Estimating the population of online MSM in areas of India using Facebook marketing data]

TUPEE662

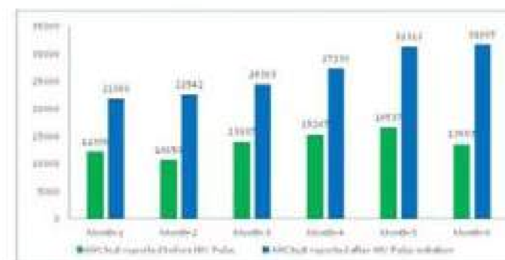
Technology based solution improves HIV testing reported by private facilities in the States of Tamil Nadu and Kerala, India

M.S. Rao[1], D.A. Hedge[2], S. K S[2], J. Niranjan[1], J. Rappai[3], C. S[1], S. Ramaswamy[1], M. Nair[4], M.K. Suryadevara[5], S. Kumar[1], S.S. Raghavan[6], R. L[1], D.M. Bhowmik[5]
[1]SAATHII, Programs, Chennai, India, [2]NACO, Programs, New Delhi, India, [3]SAATHII, Programs, Trivandrum, India, [4]SAATHII, M&E, Trivandrum, India, [5]SAATHII, Programs, Hyderabad, India, [6]SAATHII, Programs, New Delhi, India

Background: Reporting of HIV testing by private health sector is a challenge due to lack of policy for mandatory reporting in India. A large proportion of pregnant women deliver in private facilities in Tamil Nadu (41%) and Kerala (75%). Svetana, a GFATM funded program, was implemented to engage with 4177 private maternity facilities in the two states to increase PMTCT coverage. Collecting monthly HIV testing reports from these facilities was challenging as a limited number could be visited and report collection over phone was time consuming and unreliable. A technology based solution was introduced in both states to facilitate correct and consistent reporting of HIV testing directly by the private facilities.

Description: HIV Pulse a simple application for online, SMS or mobile based reporting system was developed, tested and rolled out by SAATHII in 2016-2017. Private facilities that agreed to share reports of monthly HIV testing were registered in HIV Pulse. Indicators for reporting were: number of pregnant women and general clients tested and found reactive for HIV and Syphilis. Between April 2016 and December 2017, 2332 private facilities were registered in HIV Pulse and 56% started reporting regularly.

Lessons learned: HIV Pulse contributed to 93% (82300 to 1,58,988) increase in reporting of HIV testing over a six month period. The number of HIV testing reported through HIV Pulse was significantly (75% to 100%) higher compared with testing data collected over phone. SMS reminders and in some cases phone based follow up with facilities helped to improve regularity and consistency of reporting. Facility staff found reporting in HIV Pulse to be simple and less time consuming for sharing of monthly reports. Reporting in HIV Pulse required involvement of the facility in charge which was considered more authentic.



[ANC Testing Trend Before and After roll out of HIV Pulse]

Conclusions/Next steps: Simple technology based solutions such as HIV Pulse can significantly increase private health sector reporting of HIV testing in India. This solution is being scaled up across 22 states of India in partnership with the Government PMTCT program.

Innovative approaches to track individuals

TUPEE663

Constructing a treatment cascade from routine laboratory data for HIV PCR positive children in two districts in South Africa

F. Moyo[1,2,3], A. Haeri Mazanderani[4,5], U. Feucht[6], S. Bhardwarj[7], O. Mhlongo[8], M. Goosen[4], D. Greyling[4], K. Ngoma[9], G. Sherman[2,4,10]
[1]National Institute for Communicable Diseases, Centre for HIV and STIs, Sandringham, Johannesburg, South Africa, [2]Wits Health Consortium, Paediatric HIV Diagnostics, Johannesburg, South Africa, [3]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [4]National Institute for Communicable Diseases, Centre for HIV and STIs, Johannesburg, South Africa, [5]University of Pretoria, Medical Virology, Pretoria, South Africa, [6]University of Pretoria, Department of Paediatrics, Pretoria, South Africa, [7]UNICEF Nigeria, Garki, Nigeria, [8]Department of Health, Maternal Child and Women's Health, Pietermritzburg, South Africa, [9]UNICEF South Africa, Pretoria, South Africa, [10]University of the Witwatersrand, Department of Peadiatrics and Child Health, Johannesburg, South Africa

Background: Retention-in-care is associated with improved virological control and survival amongst HIV-infected children. Using routine laboratory HIV test data, we followed the retention-in-care and virological outcomes of HIV-PCR positive children aged < 18-months in one urban and one rural district in South Africa.

Methods: HIV-PCR positive results of children tested between April 2015-May 2016 from Tshwane (urban) and uMkhanyakude (rural) districts, were extracted from the National Health Laboratory Service's Corporate Data Warehouse (CDW). HIV test data (PCR, viral load (VL), CD4) are routinely collected into the CDW to facilitate near real-time monitoring. For each child, HIV test data were collected for ≥13-months after the initial PCR positive result using both an automated patient-linking algorithm and manually searching demographics within the CDW. Test-sets were linked if ≥2 demographics (surname, name, date of birth, folder number) matched exactly. Programmatic indicators evaluated included age at HIV diagnosis, result return-rate and retention-in-care at 6 and 12-months.

Results: 304 and 94 children tested HIV-PCR positive in Tshwane and uMkhanyakude, respectively. Median age at HIV diagnosis was 2.3-months (IQR: 0.1-6.7) for Tshwane and 3.6-months (IQR: 1.4-7.1) for uMkhanyakude. In Tshwane, 218 (72%) children with an initial HIV-PCR positive result returned for their result; 192 (63%) had a confirmatory HIV test; 58 (19%) were retained in care at 6-months; 50 (16%) had a VL test and 24 (8%) were virologically suppressed. 40 (13%) children retained in care at 6-months had subsequent follow-up. In uMkhanyakude, 73 (78%) children returned for their result after testing HIV-PCR positive; 59 (63%) had a confirmatory HIV test; 30 (32%) were retained in care at 6-months; 25 (27%) had a VL and 15 (16%) were virologically suppressed. 21 (13%) children retained-in-care at 6-months had subsequent follow-up.

Conclusions: We demonstrate the value of routine laboratory data for constructing a treatment cascade of HIV-infected children. Data demonstrates high drop-off rates immediately following first HIV-PCR positive result, with loss-to-follow up of 70-80% by 6-months. However, once children present at 6-months, subsequent drop-offs of only 6-10% were seen at 12-months. Strengthening systems for tracking HIV-infected children in the first 6-months of treatment must be prioritzed for enhanced monitoring and improved retention-in-care.

TUPEE664

Replicating the success: Using an HIV model of Peer Driven Intervention (PDI+) to increase TB new case detection in Cambodia

S. Tuot[1], C. Ly[2], S. Ong[2], S. Ly[2], S.C. Choub[2], S. Yi[1]
[1]KHANA, Center for Population Health Research, Phnom Penh, Cambodia, [2]KHANA, Phnom Penh, Cambodia

Background: Cambodia has made great strides in tuberculosis (TB) control and achieved the Millennium Development Goals (MDG) target to halve TB deaths and prevalence by 2015. However, new case detection and treatment coverage remain a challenge. To increase new case detection rates, KHANA, under support of the national TB program, has implemented an innovative approach that was adapted from HIV model of peer driven intervention (PDI+) that was successfully employed in HIV new case detection.

Description: In 2017, KHANA was awarded a grant from TB Reach Wave 5 to implement the Community-based Innovations for Revitalized TB Active Case Finding (ACF) for Improved Detection and Linkage to Treatment. The existing KHANA's community HIV infrastructure and networks, allowed us to integrate, mainstream and build synergy among keystakeholders at grassroots levels. The project has been implemented in four Operational Districts from August 2017. Three approaches were used for the intervention:

1) snowball active case finding (ACF);
2) integrated active case management (IACM); and
3) community mobilization for sustainability.

Lessons learned: Working with community lay counselors, seeds and recruits have been identified. These included former people with TB and familiy contacts. They were given a coupn if ageed to be a seed and another five coupons to refer their peers. The eligibility screening tools and TB risk evaluation using a multi-TB symtopm questionniare were used to screen the participants. A TB pre-counseling and consent form were completed for TB screening. As the result, by January 2018, 2,732 of people coming with a coupon were verbally screened and met TB risk criteria, and all of them were tested for TB. In total, 644 people were diagnosed of TB (all form of TB), yielding a positivity rate of 23 %. The majority of the positive cases (97%) received TB treatment.

Conclusions/Next steps: Findings from this intervention indicate that the PDI+ could be effectivly adapted to increase TB new case detection in Cambodia. This innovative strategy should be scaled up as part of the National TB Program. Further studies are needed to more comprehensively evaluate the impacts and cos-effectiveness of the model in Cambodia as well as in other resource-limitted settings.

TUPEE665

Time to HIV test uptake and associated factors among partners of newly diagnosed HIV infected persons in Rakai district, Uganda

S. Kigongo[1], D. Nabukalu[1], S. Kasasa[2], M. Sakor[3], K. Namatovu[3], P. Ssebbowa[1], J. Kagaayi[1]
[1]Rakai Health Sciences Program, Rakai, Uganda, [2]Makerere University School of Public Health, Kampala, Uganda, [3]Rakai District Local Government, Rakai, Uganda

Background: A substantial number of persons living with HIV are unaware of their status but literature on targeted HIV testing among exposed persons are limited. We aimed to determine the median time to HIV testing from date of partner elicitation, and factors associated with HIV test uptake in exposed persons in a low resource setting.

Methods: We reviewed service records at 6 facilities for 349 HIV exposed persons confidentially identified by their newly-diagnosed HIV infected partners (the index). Entry into the risk set was from the date of partner elicitation, and censoring was either at the endpoint (HIV test uptake) or administrative at the study end date of March 31st, 2017. The Kaplan-Meier method was used to estimate median time to HIV testing, and a Cox proportional hazards model was used to determine factors associated with HIV testing. Selection of covariates was based on plausibility and these included age, sex, marital status, notification options, phone access, location, prior partner violence, relationship to index, and key population status of index.

Results: The median time to HIV testing was 366 days (IQR 37-372). Exposed persons with phone access and those with an active relationship with the index partner had higher likelihood of testing for HIV (adj. HR=1.60, 95% CI 1.07, 2.38; and adj.HR=1.92, 95% CI 1.06, 3.50 respectively), while exposed persons residing outside Rakai district had lower likelihood of testing for HIV (adj.HR=0.14, 95% CI 0.04, 0.46).

Conclusions: A very long median time to HIV testing in exposed persons (366 days) reflects need for creative interventions for active partner tracking especially for those in temporary relationships, those who do not live with sexual partners, and those without phone access.

Innovative uses of data to strengthen systems and programmes

TUPEE666

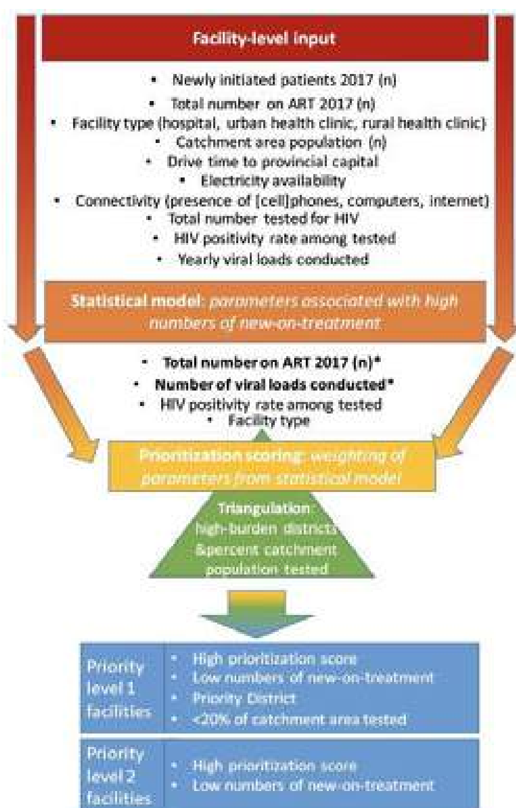
Prioritizing healthcare facilities for on-site mentorship to increase HIV treatment uptake: Results from EQUIP

B.E. Nichols[1,2], C. Hendrickson[2], N. Sigwebela[3], C. Moyo[4], M.P. Fox[1,2], S. Rosen[1,2], on behalf of EQUIP

[1]Boston University, Global Health, Boston, United States, [2]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]EQUIP, Centurion, South Africa, [4]EQUIP Zambia, Lusaka, Zambia

Background: Throughout Africa, resources are being invested in healthcare facilities to increase the number of new patients initiating ART, with the goal of achieving the "second 90." A practical methodology for determining which facilities should be prioritized to maximize uptake has not been developed. As part of a PEPFAR program to expand and improve service delivery in two provinces in Zambia, we developed a methodology to rank individual health facilities for on-site mentorship based on their potential to contribute to total numbers of patients initiating treatment ("new-on-ART").

Description: Using PEPFAR data, we ranked facilities in the selected provinces by number of patients initiated on ART in 2017. Using multivariable regression, we identified facility-level parameters associated with being in the top quartile of new-on-ART in 2017. Those parameters were then assigned weights, and the weights summed, at the facility level to calculate the prioritization score.



[Identification of priority facilities to target for on-site mentorship to maximize new-on-treatment: methodology flowchart]

Facilities that received a high prioritization score but did not rank highly on treatment initiation numbers (i.e. facilities that did not initiate as many new patients as their prioritization score suggested they should) were prioritized to receive intensive day-long on-site mentorship (target setting, stock monitoring, clinician mentoring on routine HIV testing, ART initiation, and record keeping).

Lessons learned: Thirteen of 76 facilities were identified as high priority for on-site mentorship. Eight of these were provided mentorship by EQUIP, as were two non-priority facilities. Prioritized facilities that received mentorship achieved 78% of their new-on-ART targets in the month prior to the intervention and 104% of their targets in the month after the intervention. In the two priority facilities not offered mentorship, 53% and 64% of the target was achieved in pre- and post-intervention months, respectively. In non-priority facilities that received mentorship, 63% and 72% of targets were achieved in pre- and post-intervention months.

Conclusions/Next steps: Early data suggest that prioritizing facilities for mentorship on the basis of unrealized potential can increase numbers of new-on-ART more efficiently than giving all facilities equal support. A practical, easily-applied methodology for prioritizing which specific healthcare facilities should be supported first thus offers a promising way to reallocate resources more efficiently to achieve national and global targets.

TUPEE667

Barriers to reaching the first 90: A simultaneous, multicountry online survey to identify barriers in HIV rapid test kit service delivery and commodity availability in low- and middle-income countries

A. George[1], J. Heavner[2], M.L. Field-Nguer[3], C. Ndongmo[4], M. Wattleworth[5]

[1]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Health Systems Strengthening - Forecasting and Supply Planning, Atlanta, United States, [2]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Arlington, United States, [3]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Task Order 1 HIV/AIDS, Arlington, United States, [4]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Health Systems Strengthening - Lab and VMMC, Arlington, United States, [5]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Systems Strengthening - Lab and VMMC, Arlington, United States

Background: In 2017, anecdotal reports indicated site-level stockouts of HIV rapid test kits (RTKs) in several countries. Two projects under the USAID Global Health Program-Procurement and Supply Management (GHSC-PSM) project and Rapid Test Kit (GHSC-RTK) investigated stockout causes, service delivery barriers, and supply chain management challenges in more than 20 countries.

Methods: October 24-November 15, 2017, the two projects simultaneously conducted a qualitative survey in 22 countries. The 47-question survey, which included multiple-choice and open-answer questions, was sent to GHSC-PSM field offices for data collection and response through SurveyMonkey, a cloud-based online survey development service. Answers extracted from SurveyMonkey were cleaned, aggregated, and analyzed by headquarters staff of GHSC-PSM and GHSC-RTK.

Results: Survey analysis highlighted: a) major issues that currently hinder countries' ability to provide testing services, including poor planning practices (of the 23 percent of countries without established min/max levels, 80 percent have reported stockouts at one or multiple levels in the last two years) and inefficient distribution systems (25 percent of countries use a push model; 14 percent of countries do not have emergency distribution procedures; both systems could help prevent stockouts) and b) correlation between service delivery practice/planning and availability of RTKs at all supply chain levels (58 percent of countries test through unplanned campaigns, of which 43 percent reported stockouts at all levels in the last two years).

Conclusions: This survey was a first in the number of participating countries and the types of data collected, helping identify countries with considerable barriers to reaching the goal of having 90 percent of people with HIV know their status. Results highlighted correlation — if not causality — in how service delivery decisions can affect product availability, and ultimately a program's ability to reach its testing objectives. Finally, the survey is helping partners prioritize countries and systems strengthening interventions, and showed opportunities for service delivery planning and improved communication to help ensure availability of RTKs at testing sites.

Task-shifting and sharing practices during implementation of differentiated care for HIV service delivery: Experiences from Uganda

S. Kironde[1,2], R. Berger[2,3], A. Hurst[4]
[1]University Research Co., LLC, Chevy Chase, United States, [2]Human Resources for Health in 2030 (HRH2030) Program, Arlington, United States, [3]Chemonics International Ltd., Arlington, United States, [4]United States Agency for International Development (USAID), Arlington, United States

Background: The adoption of 'Test and Start' to accelerate the achievement of the 90-90-90 goals has increased the number of ART clients. In many countries, this requires the adoption of streamlined service delivery approaches to combat potential health systems constraints - notably the lack of adequate human resources for health (HRH). Differentiated service delivery (DSD) models are one such innovative approach. Under these models, drug refills are separated from clinical consultations, and stable ART clients have less frequent clinical consultations; receive their refills faster and less frequently; and can be managed outside health facilities by health workers or ART clients themselves.
Implementing DSD models in high HIV burden, resource limited settings often requires optimization of the limited HRH resources to include task-shifting and sharing. In 2017, the HRH2030 program, funded by USAID, through PEPFAR, explored such practices at 20 health facilities offering DSD models in Uganda to better understand staffing requirements.
Methods: 1,720 client flow observations were undertaken across eight 'critical tasks' along the ART service delivery continuum for DSD and the standard models of care. For each observation, service providers performing specific tasks were identified and their frequency of task performance tallied. For analysis, these service providers were grouped into professional and lay health workers as shown in the table.
Results: It was found that the proportion of critical tasks carried out by both professional and lay health service providers (51% vs 49%, p=0.2408) was similar. Nurses performed 66% of observed tasks in the professional group while facility-based auxiliaries - a type of trained, facility-based but non-professionally certified lay provider performed 48% of all tasks in the second group. Additionally, lay providers were found to be more involved in enrollment and triage (p< 0.0001) while the professional group were more involved in clinical consultations, laboratory/blood work and drug dispensing (p< 0.0001).

Critical Task	Differentiated Service Delivery Model - No. of observations of who performed critical task												
	Standard Care		Facility Individual Fast Track		Facility Group		Community Group Client Led		Community - Individual		Totals		p Value
	Health care workings performing task (Prof. = Professional, Lay = Lay)												
	Prof.	Lay	Prof.	Lay	Prof.	Lay	Prof.	Lay	Prof.	Lay	Prof.	Lay	
Enrolment/Registration	24	82	0	84	9	22	18	79	0	40	51	307	p<0.0001
Triage	53	48	3	80	17	5	18	45	2	48	93	226	p<0.0001
Health Education	27	23	8	29	14	9	61	21	34	20	144	102	p=0.017
Consultation/Clinical Assessment	86	5	20	8	27	1	59	11	5	1	197	26	p<0.0001
Laboratory Work/Blood Draw	18	1	4	2	2	0	28	2	3	0	55	5	p<0.0001
Adherence Counseling	15	5	6	4	6	0	1	0	2	10	28	19	p=0.185
Drug Dispensing	72	31	74	8	26	6	54	51	24	30	249	126	p<0.0001
Updating Records	4	10	27	5	2	2	17	12	9	4	59	33	p=0.0065
											876 (51%)	844 (49%)	p=0.2408

Legend:
- (Prof.) Professional health workers include the following categories of service providers: Medical Doctors, Non-Physician Clinicians, Nurses, Pharmacy Technicians or Attendants, Laboratory Technicians and Social Service Workers
- (Lay) Lay health workers include the following categories of service providers: Community Health Workers, Facility-based Auxiliaries, Peers and Counsellors

[Table. Frequency of various service providers observed performing critical tasks across 5 models of ART service delivery in Uganda]

Conclusions: Appropriate task-shifting and sharing can reduce overburdening and optimize client flows hence improving health worker utilization during the implementation of DSD models. Our data suggest that if countries allowed greater use of task shifting/sharing and lay workers through DSD, limited clinical staff could be prioritized for ART initiation or complex cases.

Evidence synthesis to populate a dynamic HIV transmission model for 6 US cities

E. Krebs[1], D. Panagiotoglou[1], L. Wang[1], B. Enns[1], X. Zang[1], C. Del Rio[2], J. Dombrowski[3], D.J. Feaster[4], M. Golden[3], R. Granich[5], B. Marshall[6], S.H. Mehta[7], L. Metsch[8], B.R. Schackman[9], S.A. Strathdee[10], B. Nosyk[1], on behalf of the Localized HIV Modeling Study Group
[1]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]Emory Center for AIDS Research, Rollins School of Public Health of Emory University, Hubert Department of Global Health, Atlanta, United States, [3]Division of Allergy & Infectious Disease, Adjunct in Epidemiology, University of Washington, Department of Medicine, Seattle, United States, [4]Center for Family Studies, Department of Epidemiology and Public Health, Leonard M. Miller School of Medicine, University of Miami, Miami, United States, [5]International Association of Providers of AIDS Care, Washington, DC, United States, [6]Brown School of Public Health, Department of Epidemiology, Providence, United States, [7]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, United States, [8]Mailman School of Public Health, Columbia University, Department of Sociomedical Sciences, New York, United States, [9]Weill Cornell Medical College, Department of Healthcare Policy and Research, New York, United States, [10]School of Medicine, University of California, Department of Medicine, San Diego, United States

Background: Dynamic HIV transmission models can provide evidence-based guidance on optimal combination implementation strategies to treat and prevent HIV/AIDS. However, these models can be extremely data intensive, and the availability of good quality data characterizing regional microepidemics varies substantially within and across countries. We aim to provide a comprehensive description of a novel evidence synthesis process to populate and calibrate a dynamic, compartmental HIV transmission model for six US cities.
Methods: We executed a mixed-method evidence synthesis strategy to compile model parameters in six categories:
(i) Initial HIV-negative and HIV-infected population;
(ii) parameters used to calculate the probability of HIV transmission;
(iii) screening, diagnosis, treatment and HIV disease progression;
(iv) HIV prevention programs;
(v) the costs of medical care; and
(vi) quality-adjusted life year weights for each stage of HIV disease progression.
We defined parameters that required city-specific data and stratification by gender, risk group and race/ethnicity a priori, and sought out databases for primary analysis to augment our evidence synthesis. We ranked the quality of each parameter using a context- and category-specific rubric and verified data sources and assumptions with a scientific advisory committee using a web-based survey.
Results: We synthesized evidence from 74 peer-reviewed publications, 102 public health and surveillance reports, and executed primary analyses using 11 data sets to identify the 1,731 parameters needed to populate our model (1,093 (63%), 218 (13%), and 330 (19%) parameters in categories (i), (ii) and(iii), respectively, with 1,562 (90%) parameters being unique to each city). Parameters ranked as best- to moderate-quality evidence comprised 47% of the 169 common parameters and ranged from 61% to 63% across cities for the city-specific parameters. In addition to variation in parameter values across cities, we also found extensive variation in key parameters within cities across risk and race/ethnic groups (Figure 1).
Conclusions: Systematic reporting of the evidence synthesis process used to populate models and explicit quality assessment of data inputs can promote better integration of modelling in decision-making. Effectively communicating this process can help prioritize data collection to reduce decision uncertainty and strengthen model conclusions.

TUPEE670

Risk assessment scale for differentiated preventive care for key populations in Mumbai, India

S. Acharya[1], S. Katkar[2], J. Patil[3], M.S. Setia[4], P. Keskar[2]
[1]Mumbai Districts AIDS Control Society, City AIDS Control, Mumbai, India, [2]Mumbai Districts AIDS Control Society, Mumbai, India, [3]Mumbai Districts AIDS Control Society, TSU, Mumbai, India, [4]Consultant, Mumbai, India

Background: The National AIDS Control Programme has implemented targeted interventions (TIs) for key populations (KPs): female sex workers (FSWs), men who have sex with men (MSM) and male-to-female transgendered people/Hijras (TGH). The individual tracking system (ITS) uses indicators of risk assessment - sexual behavior, alcohol use, and violence - to classify KP as low, medium, or high risk. The assessment is uniform across these three KP groups.
Methods: We changed the risk assessment scale to incorporate number of sexual acts, condom use with different types of partners, anal sex, and substance use according to the specific KP typology; and reclassified them as low, medium, and high risk. We assessed the change in risk assessment between the original and the new scale in 3818 KPs (FSWs=1333, MSM=1649, TGH=836). We compared HIV and STI incidence among KPs according to old and new classifications.

	Original Scale	Low risk	Medium risk	High risk	p value
New Scale	Low risk	243 (18)	417 (31)	17 (1)	<0.001
FSWs (n=1333)	Medium risk	13 (1)	477 (36)	166 (12)	
	High risk	0 (0)	0 (0)	0 (0)	
MSM (n=1649)	Low risk	0 (0)	1352 (82)	37 (3)	<0.001
	Medium risk	0 (0)	44 (3)	206 (12)	
	High risk	0 (0)	0 (0)	0 (0)	
TGH (n=836)	Low risk	134 (16)	552 (66)	1 (0.1)	<0.001
	Medium risk	0 (0)	120 (14)	27 (3)	
	High risk	0 (0)	0 (0)	2 (0.2)	

[Comparison of original and revised risk assessment scale in key populations]

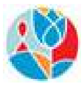
Results: The results of the old classification were: 72% low, 28% medium, and 0.1% high; and with the new classification were: 10% low, 78% medium, and 12% high. Only 27% of KPs were classified similarly in both scales. In 73% of KPs, the risk was upgraded in the new scale; the proportion was 45% in FSWs, 97% in MSM, and 69% in TGH ($p< 0.001$). About 69% (95% CI: 68%, 71%, $p< 0.001$) change from low to medium or high in all KPs could be attributed to the new scale; this proportion was high in MSM (84%, 95% CI: 83%, 86%, $p< 0.001$) and TGH (79%, 95% CI: 75%, 82%, $p< 0.001$) and low in FSWs (39%, 95% CI: 35%, 43%, $p< 0.001$). The incidence of HIV (0.55% vs. 0.28%, $p=0.27$) and VDRL positivity (0.44% vs. 0.28%, $p=0.49$) was higher among high/medium risk KPs according to new classification.
Conclusions: The revised risk assessment scale was able to classify a significantly higher proportion of KPs as medium or high risk, particularly MSM and TGH. These KPs also had a higher incidence of HIV and syphilis. Thus, using type-specific scale may be useful to identify high risk KPs for intensive follow-up and strengthen the existing intervention programmes for differentiated and focused preventive care.

TUPEE671

Social media platforms- a tool for increasing access to medicines in low income countries

C. Nwuba[1], L. Odoemene[2], D. Fatoke[3], D. Lapoutre[4], L. Matowe[5], E. Ehijie[6], R. Atteh[2]
[1]Iplus Solutions, Nigeria Supply Chain Integration Project, Abuja, Nigeria, [2]Federal Ministry of Health, Nigeria Supply Chain Integration Project, Abuja, Nigeria, [3]Sustainable HealthCare International, Nigeria Supply Chain Integration Project, Abuja, Nigeria, [4]Iplus Solutions, Nigeria Supply Chain Integration Project, Woerden, Netherlands, [5]Pharmaceutical Systems Africa, Nigeria Supply Chain Integration Project, Harare, Zimbabwe, [6]University of Benin, Nigeria Supply Chain Integration Project, Benin, Nigeria

Background: Generating health commodities supply chain data occurs routinely in most countries at different levels. A major challenge however, is the incomplete and fragmented nature of the data generated, with gaps in data and issue visibility making it extremely difficult for program managers and logistics officers to detect and resolve supply chain related issues at service delivery points (SDPs), build better awareness of stock issues as they arise and support affected SDPs to improve their performance on an ongoing basis.
This paper describes the outcome of interventions to enhance data quality and issue visibility for increased access to HIV, TB & Malaria drugs in 1,412 health facilities across 44 local government areas in Nigeria.
Description: To improve data quality and issue visibility at SDPs, the Nigeria Supply Chain Integration Project in conjunction with i+ Consortium, developed simplified data capture and quality verification tools for use by government instituted logistics management units across 14 States. Data officers within these units were trained on the use of these tools and a "WhatsApp" group was formed as a "real time" alert system to enable them report issues detected for timely action. In addition, monitoring/supervisory visits to health facilities were conducted to provide capacity building and support to health facilities that require on-site interventions.
Lessons learned: The "WhatsApp" group served as a medium for presenting health facilities' stock performance, alerting and enabling state/national level managers, partners and donors to see and address issues as they arise. This resulted in the re-distribution of 1,134,851 packs of malaria and HIV drugs & products worth about $17,281,758 USD thus averting expiries and stock outs at SDPs. The data verification tools helped to analyze logistics data and review issues detected at SDPs for corrective follow up actions.
Conclusions/Next steps: In resource limited countries, lack of data and stock issue visibility at SDPs and ability to react appropriately in a timely way has led to stock-outs, overstocks, expiries, and other losses throughout the health system. It is therefore vital to introduce simple and efficient communication channels to ensure regular contact with SDPs, improve issue visibility and enable "real time' resolution of issues as they arise.

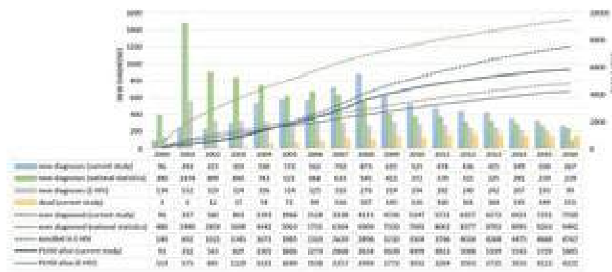


TUPEE672

How to ascertain an accurate number of people living with diagnosed HIV and fill data gaps from the past - lessons learned from a high prevalence setting in Europe

L. Lemsalu[1,2], B. Rice[3], A. Uusküla[2], M. Raag[2], I. Lutsar[4], K. Rüütel[1]
[1]National Institute for Health Development, Tallinn, Estonia, [2]University of Tartu, Institute of Family Medicine and Public Health, Tartu, Estonia, [3]London School of Hygiene and Tropical Medicine, Department of Social and Environmental Health Research, London, United Kingdom, [4]Estonian Society for Infectious Diseases, Estonian HIV Database, Tartu, Estonia

Background: In 2013, HIV prevalence was estimated to be 1.3% in Estonia. Unique identifier based HIV surveillance became available in Estonia in 2009 and until then included anonymous reporting of up to 30%. Only AIDS related mortality is monitored. Ascertaining the number of people currently living with diagnosed HIV has remained a challenge.
Methods: All healthcare services are recorded electronically since early 2000s in Estonia. For this study, all electronic healthcare records which included an HIV diagnosis (ICD-10 codes B20-B24, Z21, F02.4, O98.7, R75) and a national identification-code were extracted from the following national databases: Estonian Health Insurance Fund, 2000-2016, covering >94% of the population; Health Board, 2010-2016, passive HIV surveillance; Prisons healthcare, 2008-2016. Data was linked with the national Death Registry. We compare our results with other HIV data sources including E-HIV, a prospective clinical cohort study in Estonia that started recruitment in 2009.
Results: By end 2016, 9492 HIV diagnoses had ever been recorded through national statistics (Figure). Our analyses found a 21% lower figure of 7518 unique HIV diagnosed individuals. Of these 7518 people, 22% had died (n=1673). Of the remaining 5845 people alive, 72% were enrolled and alive in E-HIV.



[Figure. Number of people diagnosed with HIV (PLHIV) in all electronic databases available in Estonia]

Conclusions: For the first time, we present a de-duplicated number of people diagnosed with HIV in Estonia who remain alive. The higher cumulative figure reported through national statistics includes people who have died as well as people reported anonymously. Our data show a time lag in linking to HIV care, as recently more people newly appear in our data set than are reported as new diagnoses to national statistics each year. E-HIV has a good coverage of HIV diagnosed people and could become a national HIV treatment registry. Linking data from different registries helps to improve data quality and provides vital information for prevention and treatment activities.

TUPEE673

A mobile electronic system to monitor mode, content and duration of health navigation services for people living with HIV in Guatemala

J.P. Alvis Estrada[1], R. Santa Luce[1], D.A. Davis[2], K.M. Guzmán Guevara[1], M. Meekins[2], M.I. Loya-Montiel[1], S. Northbrook[3], C. Barrington[2]
[1]Universidad del Valle de Guatemala, Center for Health Studies, Guatemala City, Guatemala, [2]University of North Carolina, Department of Health Behavior, Gillings School of Global Public Health, Chapel Hill, United States, [3]US Centers for Disease Control and Prevention, HIV Program, Guatemala City, Guatemala

Background: Health navigators provide instrumental and emotional support for people living with HIV to stay in care and adhere to treatment. Timely monitoring of navigation services is challenging due to the burden of reporting a high volume of diverse activities and outcomes. We developed a mobile electronic monitoring system for navigators as part of a multi-level intervention to decentralize HIV care and treatment and offer holistic care for men who have sex with men (MSM) living with HIV in Guatemala City.
Methods: We designed a mobile application using free and open-source tools for navigators to report details about interactions with patients. The app prompts navigators to enter data in three areas: 1) mode of support provided - in person (accompaniment to appointments, meeting with families/partners, support visit) or distance (phone call, text messages, social networks); 2) content of interaction (appointment reminder, HIV education, emotional support, clinic procedures, employment issues); and 3) duration of interaction.
Results: From July 2017 to December 2017, 96.5% (385/399) of MSM enrolled in the intervention received the support of a health navigator. A total of 2037 reports were recorded by 11 navigators. Navigators took from 1-5 minutes per interaction to enter data. The median number of interactions per participant was 5 (IQR: 3-8). Most frequently covered topics during interactions were: appointment reminders 35.8%, employment issues 19.7%, family concerns 14.3%, partner relations 14.1%, HIV education 11.5%, and clinic procedures 9.4%. The majority of interactions occurred remotely (75.9%) with a median duration of 5 min (IQR: 5-10) for telephone interventions and 3 hours for in-person interventions (IQR: 1-4). Information from the app was used to identify areas for follow-up training regarding navigator functions as well as content areas, such as PrEP/PEP.
Conclusions: The mobile monitoring app is a user-friendly and low-cost tool that allows navigators to quickly and efficiently record details about each interaction with participants. Access to up-to-date navigator data allowed the intervention team to more effectively monitor and provide timely feedback and follow-up training. These data can also facilitate analysis of the required intensity and content of support for different types of patients to tailor and streamline navigator interventions.

TUPEE674

Clinical monitoring system for people living with HIV (SIMC) and continuum care improvement in Brazil

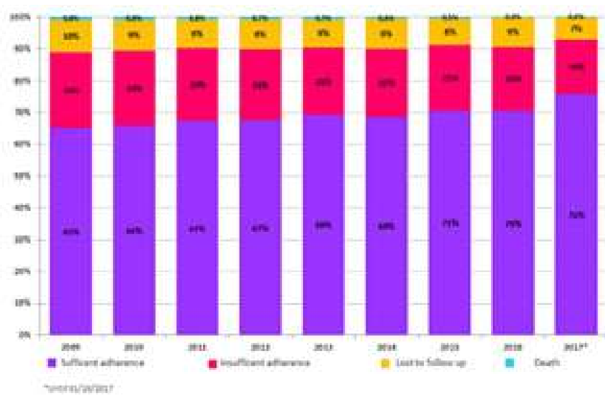
M. Camelo de Moura Vasconcelos[1], R. Vianna Brizolara[1], A.F. Kolling[2], J.G. Silva Netto[1], F. Barros Perini[1], A.R. Pati Pascom[1], A. Schwartz Benzaken[1]
[1]Brazilian Ministry of Health, STI AIDS and Viral Hepatitis Department, Brasilia, Brazil, [2]Brazilian Ministry of Health; PhD student on Collective Health of University of Brasilia;, STI AIDS and Viral Hepatitis Department, Brasilia, Brazil

Background: The HIV care cascade assessment enables measurement, understanding and monitoring of ART delivery policy and guide the development of interventions to improve people living with HIV (PLHIV) care. A tool to easily monitor PLHIV viral load (VL) suppression allows health care providers (HCP) to identify care gaps (low adherence, lost to follow up and treatment failure), as well as readily indicates treatment success, and potentially contributes to reduce transmissibility and morbidity-mortality of PLHIV.
Description: Brazilian´s Ministry of Health developed in 2013 a clinical monitoring system (SIMC) that link data from national ART delivery and laboratory (CD4 and VL) control systems to help HCP to develop better

interventions in the process of continuum care of PLHIV. Besides showing treatment GAP - PLHIV that are not on ART - since 2016 is possible to monitor patients with lost to follow up and/or detectable VL.

Lessons learned: After SIMC´s development and its use encouraged, analyzes of PLHIV (≥ 18 years old) between 2013 and 2017, demonstrate that there was an increase of PLHIV on ART with sufficient adherence (SA) and reduction with insufficient adherence (IA), as well lost to follow up (LTFU) - SA and IA considered right time ART delivery above or below 80%, respectively, and LTFU as more than 100 days without ART delivery. In 2013, of the approximately 355,000 PLHIV with at least one ART delivery, 69% had SA, 21% had IA and 9% had LTFU. In contrast, of the 431,000 PLHIV who delivered ART in 2017, 76% had SA, 18% had IA and 7% had LTFU. Data from PLHIV (≥ 12 years old) on ART, between 2013 and 2016, also showed that there was an increase in VL suppression (40% in 2013 and 53% in 2016).

Conclusions/Next steps: The SIMC development, with crucial information to HCP about PLHIV in treatment GAP, detectable VL or lost to follow up, helped to improve PLHIV care in Brazil. However, it is necessary to encourage its use and systematic monitoring, contributing to the establishment of strategies that will have a long-term impact on SA to ART, reduction of LTFU, as well as the increasingof people with VL suppression.



[Distribution of PLHIV (18+) on ART in the year, according ART status, per year of delivery. Brazil, 2009-2017]*

TUPEE675

Review of home and community-based care (HCBC) for orphans and vulnerable communities programme implementation in KwaZulu-Natal, South Africa: Towards re-engineering the HCBCs programme

N.G. Khanyile[1], N.C. Dlamini[2]
[1]Government, Department of Social Development, Executive Section, Pietermaritzburg, South Africa, [2]Department of Social Development, Population & Demographic Trends, Pietermaritzburg, South Africa

Background: South Africa remains one of the high-burden HIV/AIDS country globally with an estimated 5, 7 million individuals infected. One of the greatest HIV/AIDS consequences that face South Africa's children and their future, particularly in KwaZulu-Natal (KZN), is orphan-hood and child-headed families that render them unable to reach/attain their full developmental potential.

Description: To mitigate the ravaging effects of the HIV/AIDS pandemic on children, youth and other vulnerable communities, the Department of Social Development (DSD) through the community and home based care (CHBC) programme provide funding and support to organizations that offer a range of services to individuals and families infected and affected by HIV/AIDS with particular focus on orphans and vulnerable children (OVCs). Essentially HCBC's provide two broad categories of interventions

(i) Care and Support,

(ii) Prevention Programmes.

Lessons learned: Of the eleven HCBC centres reviewed, all had some form of governance structure and business plan and none provided training. In terms of prevention services, two reported home visits, two had awareness campaigns, two had socio-behavioural change programmes, and two had youth programmes. Regarding psychosocial support four conducted counselling, five had food security programme, three provided educational support, none monitored treatment adherence. Referrals were reported in only three centres where two made referrals to SASSA and one to home affairs. Only three had some form of monitoring documentation. These results suggest that there are major programmatic challenges, poor quality of services and implicit inadequate reach of the vulnerable and needy individuals and children.

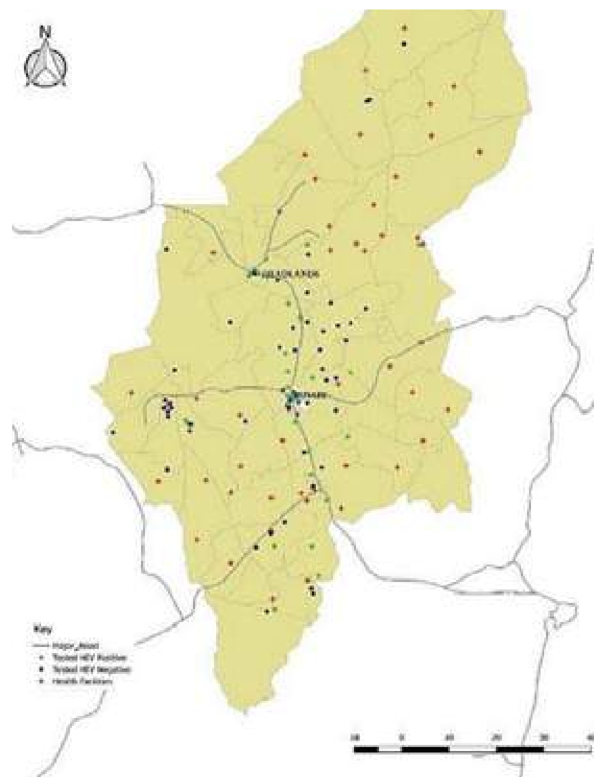
Conclusions/Next steps: The results suggest a need for a more in-depth assessment of the programme, its quality, impact, reach of the deserving communities particularly orphans and a need for programme restructuring plus establishment of an effective monitoring and evaluation programme. The evaluation should include interviews and focus group discussions with staff, beneficiaries and community members on programme activities. Indicators for effective monitoring and evaluation will also be developed.

TUPEE676

Reaching the first 90 through community HIV testing services requires use of digital systems to understand geo-coverage. A case of implementing DHIS2 Mobile tracker during HIV testing

T.W. Zulu
FHI 360, Harare, Zimbabwe

Background: Zimbabwe Population Based HIV Impact assessment (2017) have shown that considerable progress towards the 90-90-90 UNIADS targets have been made. However, there are some sub-geographies with significant gaps especially on HIV case detection. FHI360 was awarded a five-year USAID-funded Zimbabwe HIV Care and Treatment (ZHCT) mechanism to provide homebased index case HIV testing (HIHT) as the main activity to close the gap on reaching the first 90 UNAIDS target. Reported here is the coverage of HIV testing in one of the 10 districts under FHI360 where an electronic HIV testing register was introduced.



[HIV Testing coverage in one of the districts (Makoni)]

Description: In the first 18 months, the project has been using a paper based system to collect patient data on HIV testing. However, program managers were not sure if all areas were covered with HIHT. The project

assumed that services were being provided to only easy to reach areas. As a result, DHIS2 Mobile Tracker Capture was customized to include capturing of geo-coordinates when providing HIV testing which will allow pinpointing geographical location of HIV testing. The application works offline and synchronize with central server when there is connectivity. Makoni district was selected for the pilot and nurse testers were trained. QGIS was used to analyze and present spatial data collected between October to December 2017.

Lessons learned: A total of 146 people were tested, 32% (47/146) were positive and 98% (46/47) were linked into care during this period. Majority of the clients tested were those living within four kilometers of the major roads as shown in Figure 1.

Furthermore, HIV testing services were provided to clients living in peri-urban area (65% of tested). The North-East and South-East part of the of the urban area with more than 40km and 29Km respectively was poorly covered during this period. The major reason stated is that of inaccessibility.

Conclusions/Next steps: Reaching the first 90 of UNAIDS targets will be difficult if HTS services are only limited to easy to reach areas. Use of electronic systems with geo-coordinates in the provision of HIV services will help to improve service coverage and identification of hotspots when feedback is provided to field teams in a timely manner.

TUPEE677

Evaluation of "Getting to 90," a data-driven health department - service agency initiative to improve viral suppression rates among HIV-positive housing consumers in New York City

E. Wiewel[1], C. Beattie[1], Y. Zhong[1], R. Silverio[1], E. Jimenez-Levi[1], X.P. Farquhar[1], P. Brown[1], J. Thomas[2], J. Rojas[1]
[1]New York City Department of Health and Mental Hygiene, Long Island City, United States, [2]RDE Systems, Little Falls, United States

Background: The World Health Organization recommends that 90% of persons diagnosed with HIV be engaged in care and 90% of those achieve viral suppression ("suppression") in order to control the epidemic. The US National HIV/AIDS Strategy and Centers for Disease Control and New York State's Ending the Epidemic initiative prioritize increasing care and suppression among low-income and racial/ethnic minority persons. More than one-third of New York City's (NYC) persons with HIV receive subsidized housing assistance, but many remain unsuppressed. The "Getting to 90" initiative was developed to help HIV housing agencies reduce barriers to suppression. We evaluated the impact of this initiative.

Description: In August 2016, the NYC Department of Health and Mental Hygiene (DOHMH), a grantee for the US Housing and Urban Development's Housing Opportunities for Persons with HIV/AIDS (HOPWA) program, launched "Getting to 90" for 14 HOPWA-funded agencies, which serve low-income and predominantly racial/ethnic-minority persons with HIV (Table). DOHMH and technical staff established a 90% suppression goal; streamlined collection of consumer care and suppression information in the NYC HOPWA data system (eCOMPAS); matched eCOMPAS with NYC HIV surveillance data; analyzed factors associated with non-suppression among HOPWA consumers; and provided agencies with analysis results, customized care- and suppression-rate dashboards, and monitoring and technical assistance.

Lessons learned: At baseline, 88% of NYC HOPWA consumers were documented in eCOMPAS as being in care and 73% suppressed (Figure). During the initiative, agencies participated in eCOMPAS training and received six quarterly dashboards, five quarterly technical assistance calls, and lists and epidemiologic profiles of their unsuppressed consumers. Non-clinical professionals successfully incorporated suppression into routine work, supervision, team meetings, and in-house trainings, and had timely awareness of their housing consumers' suppression status. Agency-reported care engagement rates from baseline to 15 months increased to 95%. Suppression rates increased at 10 of 14 agencies and to 82% overall (Figure).

Conclusions/Next steps: Local health departments can play an important role in providing data and technical assistance to agencies responsible for providing services and increasing suppression among persons with HIV. "Getting to 90" advanced innovative use of program and jurisdictional surveillance data to strengthen suppression efforts among HOPWA agencies.

	N	%
Total	*950*	*100%*
Age at end of 2017		
<30 years	83	9%
30-44 years	313	33%

TUPEE678

Digital innovation to improve access to health services: Online platform with geo-referenced information

B. Caceres[1], M. Romero[2], M. Gutiérrez[3], L. Malajovich[4], L. Cahn[5]
[1]Fundación Huésped, Digital Innovation Lab, Buenos Aires, Argentina, [2]Centro de Estudios de Estado y Sociedad (CEDES), Buenos Aires, Argentina, [3]International Planned Parenthood Federation. Western Hemisphere Region (IPPF/WHR), New York, United States, [4]International Planned Parenthood Federation. Western Hemisphere Region (IPPF/WHR), Buenos Aires, Argentina, [5]Fundación Huésped, Buenos Aires, Argentina

Background: Increasing access to supplies and services for prevention, diagnosis and care of HIV/AIDS is a key aspect to reach 90-90-90 targets. Massive increases in the use of internet devices and availability of public data allow innovation on digital solutions offering useful data to citizens.

The purpose of the program is to create a platform with geo-referenced information about condom delivery points, HIV testing, infectology centers among other health services and allows the collection of user feedback to improve quality of care.

Description: A responsive website was developed, specially focused on young people, originally for Argentina (#Dónde) and then also to 40 countries in Latin America and the Caribbean (VAMOS). In addition to localizing health services, the platform encourages citizen participation to assess services' quality. Users can add information and evaluate each service in order to identify opportunities for improvement.

The information gathered is used to advocate in order to improve services and delivery. Through user involvement, collaboration with social organizations and the public sector, the tool is continuously updated and improved.

Lessons learned: The national platform had 15045 visits during the last year; regional platform had 2256 visits during the first three months; young people represent 61% of the users. 12 youth organizations are committed to its use and dissemination. User involvement is reflected in 177 reviews and comments received. This initiative contributes to achieving an Open Government Partnership goal. 11 requests for access to public information were made in order to obtain or update more than 15000 records in the database.
Conclusions/Next steps: Success in the use of technologies and data to improve access to rights is evidenced through platform creation and proper operation. This project is the result of collaboration between social organizations and the public sector. Plans for the future include updating the database and increasing the number of user reviews, thus becoming a reference and a means to identify and solve issues within health service settings. Additionally, developing a pilot project to measure service attendance after location within the platform. VAMOS regional platform is going to develop an online counseling tool to provide information in a comprehensive approach.

TUPEE679

Using data to optimize provision of DREAMS social asset building services in safe spaces across two counties in Western Kenya

W. Olando[1], S. Goldfrank[2], I. Jurkevich[2]
[1]American International Health Alliance, Nairobi, Kenya, [2]American International Health Alliance, Washington, United States

Background: Nearly 1,000 adolescent girls and young women (AGYW) are infected with HIV every day. This group accounts for over 70% of new HIV infections among adolescents in sub-Saharan Africa. DREAMS is an initiative of the President's Emergency Plan for AIDS Relief (PEPFAR) that supports AGYW through a multi-layered, evidence-based package of interventions, including social asset building (SAB) focused on strengthening social, health, economic, educational, and other factors to create a strong, positive safety net for AGYW at risk.
Description: With PEPFAR support, American International Health Alliance (AIHA) implements a DREAMS project for girls aged 10-14 in high HIV burden counties in Western Kenya where the HIV prevalence rate is over 25%. SAB takes place in Safe Spaces; it is one aspect of the project that provides a platform from which other interventions are offered and monitored to ensure each girl receives comprehensive, individualized services. Optimally, AGYW should receive a minimum of 3 primary interventions, 3 secondary interventions, and 2 contextual interventions.
Lessons learned: AIHA conducted a survey in early 2017 revealing that 17,509 AGYW were enrolled in SAB: 1,937 (11%) received 4+ services; 6,809 (39%) received 2-3 services; 2,879 (16%) received 1 service; and 5,884 (34%) had received no services. AIHA developed a structured tracker to monitor service layering at its 200 project Safe Spaces in Bondo and Siaya counties. AIHA conducted a follow-up assessment in January 2018, revealing that out of the 24,661 AGYW enrolled: 7,329 (30%) received 4+ services; 12,900 (52%) received 2-3 services; 3,954 (16%) received 1 service; and only 478 (2%) had not received any service.
Conclusions/Next steps: As revealed by the second survey, the service provision tracker allows for continuous monitoring of each girl at the lowest level of implementation, helps identify gaps in service, and facilitates more effective prioritization of girls for intervention. Use of the tracker helped reduce the number of girls receiving no services from 5,884 to 478 within a year's time, thus ensuring girls receive the required package of interventions to support them as they grow into determined, resilient, empowered, AIDS-free, safe women.

TUPEE680

Using low cost performance tracer systems for data collection and performance monitoring of large HIV programs in resource limited settings

D. Damba[1], A. Maganda[1], P. Amuge[2], P. Nahirya Ntege[2]
[1]Baylor College of Medicine Children's Foundation Uganda, Monitoring and Evaluation, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation Uganda, Research, Kampala, Uganda

Background: In the era of scaling up of HIV/AIDS programs to meet the UNAIDS 909090 goal, strong low cost M&E tools that provide real time quality data for tracking program performance are inevitable. This paper presents a new innovation (Performance Tracer system) used to collect data and monitor performance of a large HIV/AIDS program in Uganda.
Description: Baylor Uganda is implementing a large PEPFAR funded HIV/AIDS project in Western Uganda, at 361 health facilities since 2012. The project scope has over 182 performance indicators being monitored. Of them, 10 performance tracer indicators were objectively selected for weekly tracking in 2017. Program components tracked include HIV testing, HIV Treatment, Viral load, TB-HIV, PMTCT and Logistic stock status. Trained health workers submit weekly reports for these tracers through an-affordable mobile SMS platform. The platform has a user friendly dashboard with weekly analytics shared with management and district health teams for review and action planning. Comparison was done to assess impact of tracer system for program performance before (FY2016 Quarter 4) and after (FY2017 Quarter 4).
Lessons learned:
- Monitoring performance using tracers motivated implementers to refocus on key interventions and identifying areas which require quick actions. Consequently, there was a general improvement in the program performance as per set targets. A comparison before and after showed an improvement of 18% in positives identified, 25% in HTS yield, 22% in new ART initiation, 3% in viral load suppression, 11% in new TB case identification, 26% in HIV exposed infants identified and 14% in ARV stock availability.
- The weekly Tracer platform promoted program ownership, data use and increased timely responsiveness to actions among implementers.
- The system is scale-able and effective in enabling staff to fast track actions to gaps
- Mobile SMS is an affordable and efficient platform to monitor performance while engaging implementers
- Transfer of trained staff and mobile network interruptions affected the functionality of the system.

Conclusions/Next steps: Objectively selected tracer indicators can be used to monitor performance of large programs through a reliable and efficient electronic system. Such low cost tracer systems should be scale-up to monitor progress in line with UN909090 goal.

TUPEE681

HIV prevention cascades: Progress towards a single unifying framework that can replicate the success of treatment and care cascades

R. Schaefer[1], E. Fearon[2], S. Gregson[1,3], J.R. Hargreaves[2,4]

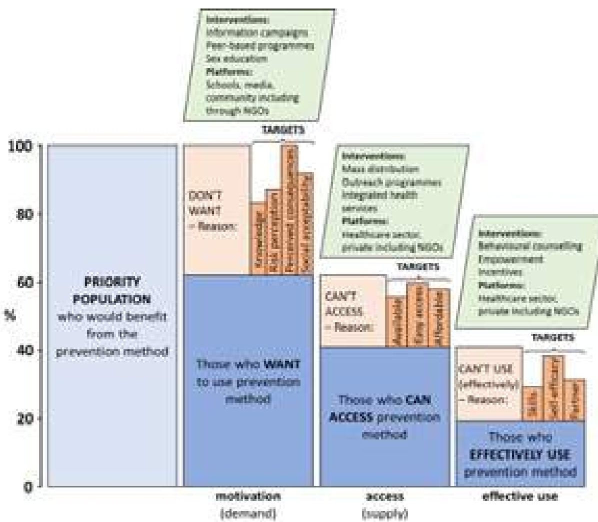
and improved targeting of HIV prevention programmes, similar to HIV treatment cascades. However, different prevention cascade formulations exist, reflecting their different purposes. This project aimed at developing a unifying HIV prevention cascade framework on which different applications with different requirements could be based.

Description: A series of meetings and seminars was conducted to establish goals of HIV prevention cascades, review prevention cascade models, and develop new models of cascades. Prevention cascade frameworks were applied to existing datasets to understand gaps in data currently collected. A stakeholders meeting and workshop were held in Harare, Zimbabwe, with policy-makers, non-governmental organisations, programme planners, and international and local researchers to consult on the utility and functions of HIV prevention cascades and develop models for prevention cascades.

Lessons learned: Previously proposed HIV prevention cascade models (Lancet HIV issue July 2016) were considered too complex for many intended uses of prevention cascades, especially routine monitoring and advocacy for HIV prevention. Particularly, estimating the impact of HIV prevention (infections averted) (proposed by Garnett et al., 2016) should be seen as a useful but separate modelling exercise.

Instead, a generic HIV prevention cascade model is proposed that consists of three core steps of motivation for using a prevention method, access to this, and effective use of it in a priority population (Figure blue). This cascade is part of a framework that incorporates the explanatory factors underlying gaps in cascade steps and indicates types of interventions to address these (Figure orange/green). The simple core cascade and wider framework reconcile contrasting needs for simple and complex cascade models.

Conclusions/Next steps: The HIV treatment cascade has shown how a framework can become a driving force for treatment programmes and policy. While applications of the proposed HIV prevention cascade framework need piloting and methods for measuring the framework need to be developed and validated, the HIV prevention cascade has similar potential for boosting our HIV prevention efforts to bring about substantial declines in HIV incidence.



[A generic and unifying HIV prevention cascade framework. Blue: Core cascade. Orange: Reasons underlying gaps in cascade. Green: Interventions.]

TUPEE682

Age-specific national HIV care continua in sub-Saharan Africa

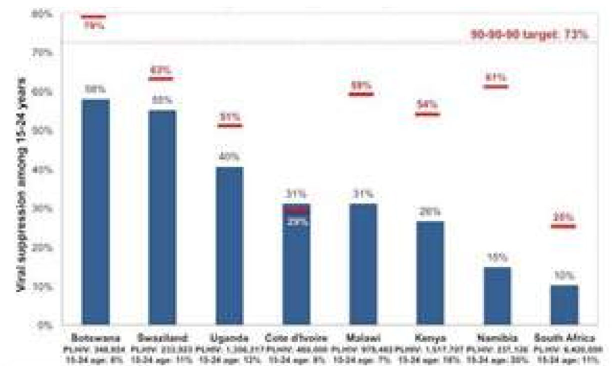
S. Gupta[1], R. Granich[2]
[1]Independent Consultant, Delhi, India, [2]Independent Consultant, San Francisco, United States

Background: In Sub-Saharan Africa (SSA), epidemic control requires increased coverage of HIV testing and treatment for adolescents and young adults (15-24 years). Adolescents and young adults account for nearly 11% of all people living with HIV (PLHIV) yet nearly one-third of new HIV infections occur in this age category.

Methods: For 21 highest burden countries in SSA (95% regional HIV burden), we searched PubMed, US President's Emergency Plan for AIDS Relief (PEPFAR) operational plans, country progress reports and conference abstracts for the age-specific continua published between 2012-2017. We reviewed published national HIV care continua with age-specific data and compared the progress towards 90-90-90 across age groups.

Results: Of the 21 countries, 10 countries published age-specific continua between 2012 and 2017 (53% regional burden). The age distributions were < 15,15-24 and >25 years. Only three countries published the complete 90-90-90 data. All countries reported data on second 90 (on ART), three countries reported on first 90 (diagnosed), and eight countries on the third 90 (viral suppression).

ART coverage among 15-24 year olds living with HIV varied from 17%-72% and was significantly lower than the ART coverage for < 15 and >25 year olds in all but three countries (Uganda, Cote d'Ivoire and Cameroon). Similarly, viral suppression rates among 15-24 year olds varied from 10%-58% and were lower than the national average in all countries except Cote d'Ivoire.



[Figure. Viral suppression among adolescents and young adults (15-24 years) in 8 countries]

Only Botswana has achieved 90-90-90 for all age groups except 15-24 year olds. In Namibia 15-24 year olds account for 20% of all PLHIV, however, ART coverage and viral suppression was 49 and 46 percentage points lower than that among all PLHIV above 24 years of age, respectively.

Conclusions: Publicaly available comprehensive HIV care continua for adolescents and young adults are limited and are compromised by inconsistent methods and data availability. Although the available data is limited, it is consistent with the PEPFAR Population-based HIV Impact Assessment results and shows the need for improved HIV efforts for the bulging youth population in SSA while sustaining the progress made towards 90-90-90 for paediatrics and adults.

TUPEE683

Impact of electronic logistics information system on HIV service delivery in Zambia

W. Nicodemus, C. Opit, J. Sikazwe, W. Bomett
John Snow, Inc., Lusaka, Zambia

Background: The Zambian Ministry of Health faced many challenges in managing procurement and distribution of medical products and supplies. Long lead times, stockouts, and general lack of efficiency characterized the in-country supply chain.

Description: In 2014, USAID implementing partners began working with the Zambian Government to pilot and scale up an electronic Logistics Management Information System (eLMIS). This open-source software facilitates data collection in low-infrastructure environments for review, aggregation, analysis, and forecasting by incorporating a wide range of systems (medical records, laboratory data) and enabling data visibility from point of origin to point of delivery. The eLMIS has been deployed to seven countries.

Lessons learned: Through eLMIS, Zambia has achieved measurable improvements in logistics management, according to the eLMIS mid-line evaluation, including:

- Increased visibility of supply chain operations resulting in broader involvement of user groups for supply chain decision making: User sessions in eLMIS increased by 149% between May 2015 and January 2018
- Increased throughput of health commodities to support WHO universal test-and-treat strategy (UNAIDS 90-90-90 goals): Increased use of HIV test kits by 141% and ARVs by 254% between the start of 2015 and end of 2016
- Improved health care service delivery resulting in reduced missed treatments and better patient adherence to treatments: Expired products at sites reduced by 80% between March 2016 and February 2017; ARV availability at sites increased by 20% since 2015
- Potential reduction in supply chain supervision costs: Targeted supervision visits conducted to easily identifiable problem sites based on insights from data; Fostering of a cohesive experience among implementing partners, leading to improved quality and lower costs of intervention.

Conclusions/Next steps: Electronic information systems require allocation of resources and time to achieve sustainability and attain the full change management maturity model. Some challenges persist in Zambia; there is a need to continue cultivating reliance on data for decision-making. Data are widely used to guide procurement and routine operational decisions, but not yet for supervision and policy development. The technology and implementation experience from Zambia will benefit neighboring countries grappling with similar challenges.

TUPEE684

Maximizing data use to respond to healthcare landscape changes: Lessons learned from a national survey on the state of community-based organizations

S. Linov, M. Stanley, B. Hujdich
HealthHIV, Washington, United States

Background: Implementation of healthcare reform, advancement of national public health strategies, and biomedical prevention developments are some of the fundamental shifts impacting HIV non-profit organizations in the United States. Reduction and re-direction of HIV funding and increased focus on accountability and outcomes requires these organizations to remain responsive and proactive.

Description: HealthHIV conducted a first-of-its-kind national survey of over 600 AIDS Service Organizations and Community-Based Organizations (ASO/CBOs) to evaluate the sustainability and availability of services, and the capacity and structure of the organizations providing them. With the survey, HealthHIV developed a National Directory of ASO/CBOs to document the availability, scope, location, and type of services available to healthcare consumers. The *State of ASOs/CBOs in the US* survey assessed how ASO/CBOs are responding to the healthcare landscape changes, particularly its impact on workforce development; program coordination; fiscal sustainability; strategic partnership development; leadership advancement; and strategic planning.

Findings provided a qualitative perspective on the challenges ASO/CBOs face in responding to environmental, political, and economic changes in the healthcare landscape. Participation, content, and categories make it a unique analysis of the overall health of ASOs and a valuable tool for responding to collective challenges.

Lessons learned: ASO/CBOs are the point of medical care for many people living with HIV and face barriers in responding to the changing healthcare landscape. Services commonly provided by ASO/CBOs (condom distribution, HIV counseling/testing), do not reflect the social, environmental, and economic developments impacting people living with or at risk for HIV. Responses indicated an inability to innovate based on client need and a lack of diversity in funding streams across ASO/CBOs in the US.

Conclusions/Next steps: While ASO/CBOs are expanding to incorporate clinical services and updating billing infrastructure to bill third party payers, organizations are not able to sustain services and maintain purposeful data to improve health outcomes. Better understanding the infrastructure and sustainability challenges of ASO/CBOs allows stakeholders to inform creation of educational resources and capacity building programs, establish training blueprints for policymakers, and prepare strategies to respond to healthcare landscape changes. The State of ASO/CBOs Survey will facilitate decision-making on funding pursuits, service expansion, and capacity building assistance in the US.

TUPEE685

Harmonization processes on HIV data for key population clinical cascades in and it's impact on HIV programing in Tanzania

N.E. Makyao, NACP Prevention and Management Study Group
Ministry of Health, National AIDS Control Program, Prevention, Dar es Salaam, Tanzania, United Republic of

Background: In an efforts to attain the 90,90 90 Global targets, Tanzania developed HIV data for key and vulnerable populations reporting system through harmonization of all data recording and reporting tools and indicators from all partners and donars. The process was consultative with all key stakeholders. The aim of this data is also improvement of data quality for better programing among KVPs.

Methods: Four Technical consultative meetings with LGAs, CSOs, KP community and all partners to review tools used, indicators and reporting modalities was conducted. Consensus was reached through the use of one National reporting system for all implementing partners and KP organisations. Tools which report from community to facility level (identified HF) at a catchment area were developed with 15 indicators and reporting timeline was agreed. Quarterly reports agreed for all KPs as per the National Guidelines which was disaggregated by KP type, age, geographical location and implementing partners. Data collected include behavioural data, services accessed and visit type. Each client is provided by unique identification code.

Results: Five main implementing partners are supporting the Ministry who are ICAP, Jhpiego, HJF AMREF and MUHAS TAPP. Data reported from all the implementing partners from January to December 2017 show HIV clinical cascade performance for KPs in Tanzania. Total KPs reached were **82,746,** Tested **80,180,** identified positive **7,146,** initiated ART **5441,** and the linkage is at 70% of all identified KPs. Strategies used to reach the performance included engagement of identified KP friendly facilities and attached peers to the friendly facilities. Also provided facility led ART outreach services targeting general and KP.

Conclusions: Harmonisation of all KP reporting system to one National reporting tool has enabled to track KP HIV programing through the clinical cascade. All partners are using one National system through DHIS2 system. This has improved HIV programing among this group and informs the country on KP cascade.

TUPEE686

Implementation of HIV testing status of TB cases and ART coverage: A descriptive analysis of PEPFAR and national data in 15 countries in East and Southern Africa

E. Noykhovich[1], C. Nichols[2], J.S. Cavanaugh[3]
[1]*Peace Corps, Office of Global Health and HIV, Washington, United States,* [2]*USAID, Office of HIV/AIDS, Washington, United States,* [3]*The U.S. Department of State, The Office of the U.S. Global AIDS Coordinator and Health Diplomacy, Washington, United States*

Background: HIV testing should be offered to presumptive and diagnosed TB patients because it is a critical entry point for HIV-positive TB cases to be linked to a continuum of health services and initiated on lifelong antiretroviral therapy (ART). Such clinical services can reduce morbidity and mortality associated with TB/HIV co-infection.

We analyzed data from 15 countries in East and Southern Africa supported by the U.S. President's Emergency Plan for AIDS Relief (PEPFAR) and from national estimates to evaluate the state of implementation of these services.

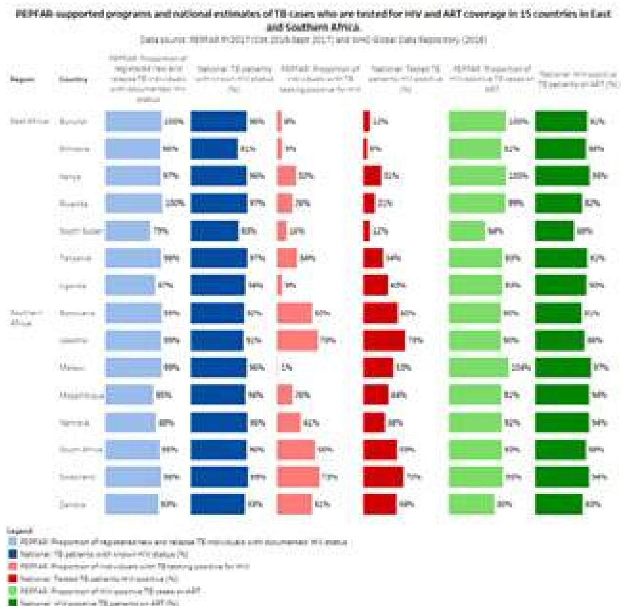
Methods: We analyzed documented client interactions for new and relapsed TB cases, inclusive of adults and children, at PEPFAR-supported TB clinics in 15 countries from October 2016 - September 2017 as they related to:
1) the proportion of TB cases who had a known HIV status
2) the proportion of TB cases who were HIV-positive
3) and the proportion of HIV-positive TB cases who were on ART.
We analyzed comparable national-level estimates from the 2017 World Health Organization (WHO) Global TB Report.
Results: As reported by both sources across 15 countries, a majority of TB cases knew their HIV status and a majority of HIV-positive TB cases were on ART. For nine out of 15 countries (Burundi, Ethiopia, Kenya, Rwanda, Tanzania, Botswana, Lesotho, Malawi), the PEPFAR-supported programs reported a higher proportion of registered new and relapsed TB patients who knew their HIV status when compared to same metrics reported by national estimates in these countries. The PEPFAR range was 85% in Mozambique to 100% in Burundi and Rwanda. For 11 out of the 15 countries (Burundi, Ethiopia, Kenya, Rwanda, Tanzania, Uganda, Botswana, Lesotho, Malawi, South Africa and Swaziland), the PEPFAR-supported programs reported a higher proportion of HIV-positive TB cases who were on ART when compared to the same metrics reported at the national level in these countries.
Conclusions: Although PEPFAR-supported programs and national estimates may not serve directly comparable underlying populations, it is prudent to consider the state of implementation of these services as reported by these sources to identify gaps in the delivery of these services and inform strategies to meet 100% coverage.



[PEPFAR-supported programs and national estimates of TB cases who are tested for HIV and ART coverage in 15 countries in East and Southern Africa.]

TUPEE687

Identifying optimal definition of rapid molecular cluster growth for public health intervention in Illinois, USA

N. Benbow[1], M. Ragonnet-Cronin[2], J. Wertheim[2], R. D'Aquila[1], C. Ward[3], F. Ma[3], C. Hayford[4]
[1]Northwestern University, Chicago, United States, [2]University of California San Diego, San Diego, United States, [3]Illinois Department of Public Health, Chicago, United States, [4]Northwestern University, Chicao, United States

Background: HIV sequence data from routine genotype testing are reported to health departments across the US and efforts are underway to use the data to target prevention and care interventions. The Centers for Disease Control and Prevention (CDC) recommends targeting interventions to recent, and rapidly growing, molecular clusters which they define as: clusters of HIV sequences from diagnoses in the last 3 years using a genetic distance threshold of 0.5% and in which ≥5 sequences are from persons diagnosed within the prior year. We used retrospective data to compare how well different schemes to describe rapid growth of a cluster predicted future growth, or yield, defined as the percent increase in the number of persons in that cluster in the following year.
Methods: We used HIV-1 *pol* sequences from persons diagnosed with HIV between 2013 through 2016 reported to the Illinois health department through June 2017. We examined 8 different schemes: the CDC definition and 3 variations which relaxed the minimum number of new diagnoses in the last year, and four which involved clustering and relative cluster growth (i.e. $\Delta N \div \sqrt{N}$) at 0.5% and 1.5% each. For each scheme, we calculated the number of clusters, and used logistic regression to identify factors associated with clustering.
Results: The 0.5% relative cluster growth scheme had greatest yield (73%) from a relatively small number of clusters (N=15). The CDC definition had a 50% yield from only 5 clusters, compared with a less-stringent definition (at least 3 recent diagnoses) with a higher yield (59%) resulting from many more clusters (N=23). Schemes using 1.5% genetic distance to determine clustering or relative growth had the lowest yield (11% and 18%). In the three schemes that better predicted growth, clustered individuals were more likely to be young (AOR=2.1,p< .05). Other demographic characteristics associated with clustering varied depending on the scheme.
Conclusions: Schemes that considered recent cluster growth were more likely to grow the following year. Variations in criteria defining rapid growth produced different number of clusters, growth rates, and demographic composition. Health departments could benefit from using this comparison approach to identify priority clusters that best fit their epidemic and available resources.

Approaches to using data to improve programming

TUPEE688

Using simple electronic systems to enhance data quality and use for HIV/AIDS programming

D. Damba[1], A. Maganda[1], P. Nahirya Ntege[2]
[1]Baylor College of Medicine Children's Foundation Uganda, Monitoring and Evaluation, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation Uganda, Research, Kampala, Uganda

Background: Use of electronic medical records systems to enhance data quality and use in HIV/AIDS programming has been emphasized and well documented, however adopting such systems has been on small scale. This study presents findings and experiences from a large HIV/AIDS program implementing simple and easy to use electronic system(OPENMRS) in Uganda.
Methods: Baylor Uganda is implementing a large HIV/AIDS program in Western Uganda serving over 70,000 HIV positive patients on treatment, 5,000 HIV exposed infants, 6300 sex workers and 1800 TB patients annually. The organization is implementing OPENMRS computer system in 80 health facilities. Training of staff, computers provided and supportive supervision done. Mentor coaches were identified to provide onsite technical assistance. Forty eight health facilities implementing OPENMRS and fifteen non-OPENMRS(un-computerized) were selected to assess impact of the system on data quality and use. The period of review was January 2017 and September 2017. Data quality components assessed were data accuracy, completeness, reporting rates, timeliness and staff capacity to use data. Data sources were Patient registers, OPENMRS, staff interviews. Descriptive statistics and odds ratios (OR) were generated using SAS 9.2 software for comparison.
Results: Results showed significant differences between OPENMRS and non-OPENMRS sites with respect data quality and use. Adherence to reporting timeliness was higher in OPENMRS sites (87%) compared to non EMR sites (73%). OPENMRS sites were 3.1 times (95%CI, 2.13-4.07) more likely to report accurate data than non-OPENMRS sites. Completeness was 1.7 times (OR=1.7, 95%CI=1.22-3.18) better in OPENMRS than non-

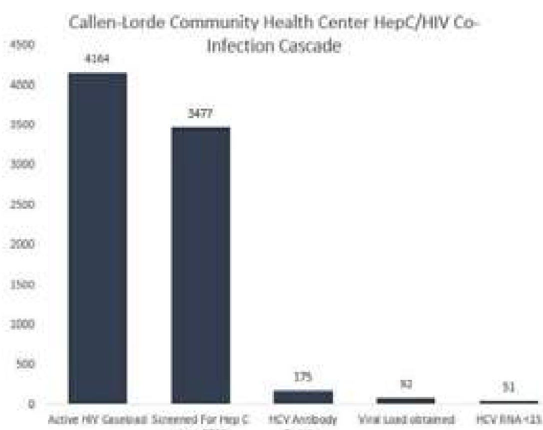
OPENMRS sites. 89% of staff at OPENMRS sites had used their data for planning compared to 65% in non-OPENMRS sites. 81% of OPENMRS sites had initiated quality improvement projects based on gaps in their data compared 52% non-OPENMRS sites. The average time of generating a report and reviewing it was half-a day for OPENMRS sites compared to 5 days in non-OPENMRS sites. All sites had submitted reports within 7 working days.
Conclusions: There was a strong association between computerization, data quality and use to improve HIV programming, with better results observed in computerized sites. There is need to design and implement low cost electronic systems to enhance data quality and use.

TUPEE689

Creation of a hepatitis C care cascade to identify gaps in diagnosis and treatment - experiences from an urban community health center

A. Stivala, P. Carneiro, R. Vail, P. Meacher, J. Bosco, A. Radix
Callen-Lorde Community Health Center, New York, United States

Background: Hepatitis C (HCV) is a major cause of chronic liver disease, cirrhosis, and hepatocellular cancer. Over the last decade there has been an increase in reported HCV infections among HIV-infected MSM, with incidence of 6.3 /1000 person-years (95% CI 5.0-7.5), 19-fold higher compared to HIV-negative MSM. The NYS guidelines recommends HCV screening annually for HIV-infected MSM. HCV sero-status awareness remains low in this community, and many never receive treatment. The new direct acting antiviral regimens are highly effective and provide a pathway to cure, however access remain limited. Barriers to treatment include requiring HCV-experienced medical providers, medication costs, complex preauthorization requirements, drug-drug interactions, concurrent medical conditions and psychosocial factors. Callen-Lorde Community Health Center predominantly cares for the LGBT communities and people living with HIV. As part of a quality improvement program we developed a Hepatitis C Care Continuum to determine adherence to screening guidelines and subsequent treatment of those found to be HCV-infected.
Description: To develop the HCV care cascade we used the electronic health record and laboratory results to assess the proportion of PLWH who had been screened for HCV in the past 2 years. For patients with positive HCV antibody we investigated the number who known HCV RNA in accordance with guidelines. Chart reviews were conducted for patients with viremia to assess whether referrals were made for treatment and subsequent sustained virologic suppression.
Lessons learned: Of 4164 PLWH (88% MSM, 10% transgender women), 3477 (84%) received HCV screening within 2 years. 175 (4%) had HCV antibodies. Only 92 (53%) had a viral load obtained, and 51 (55%) of these were virally suppressed (< 15 IU/mL mL).
Conclusions/Next steps: Creation of a HCV Care Cascade allowed us to identify gaps in HCV diagnosis and treatment. Subsequent interventions have focused on improving HCV screening, provider and patient education, follow-up of individuals needing further HCV viral load testing and referrals for HCV treatment.



[Callen-Lorde Community Health Center HIV/HCV Co-infection Cascade]

TUPEE690

Improving continuum of HIV care: Experience from Ukraine

A. Chuykov[1,2], Y. Lopatina[3], G. Tyapkin[3], A. Zakowicz[1]
[1]AIDS Healthcare Foundation, Europe Bureau, Amsterdam, Netherlands, [2]Ural State Medical University, Yekaterinburg, Russian Federation, [3]AHF Ukraine, Kyiv, Ukraine

Background: Until now there have been a few publications on HIV continuum of Care from Eastern European Countries. First evaluation of HIV continuum of Care from AHF-supported Clinical Sites in Europe was published in 2017. Having strategic information on continuum of care is a key for effective monitoring of patient retention and treatment success.
Description: We analyzed electronic medical records of 29,693 patients from 29 AHF supported clinical sites in Ukraine. All data have been taken from databases created and maintained by AHF. We conducted evaluations of HIV treatment coverage and viral load suppression rates in January 2017 and January 2018. After first evaluation, we developed and implemented a comprehensive package of interventions, consisting of decentralization of services, integration of TB component into HIV care, outreach medical care for temporarily and permanently disabled patients, retention in care interventions including comprehensive psychosocial support, active case finding, and restoration of documents.
Lessons learned: As a result of implementation of the intervention package, the number of clients on ART in AHF supported programs increased from 19,392 in 2016 to 24,699 in 2017 while proportion of clients on ART therapy remained stable (83%). Additionally, the programs noted an increase of patients with viral load suppression from 9,681 (42%) in 2016 to 20,340 (69%) in 2017. Viral load suppression rates increased significantly in Mykolaiv Region (from 42% to 75%), Odessa Region (from 43% to 66%), Dnepropetrovsk region (from 38% to 58%), Kiev Region (from 41% to71%) and Donetsk Region (47% to 65%). There was no significant difference between genders. The lowest proportion of patients on ART and viral load suppression rate were identified in in the age group 25-34 (75% and 61% respectively). Additionally, it was found that VL suppression rates among patients with TB was 54% in Ukraine.
Conclusions/Next steps: Continuum of care is an effective tool to monitor patient retention in care and success of antiretroviral therapy at the country and program level. We suggest implementing it further in the region. Decentralization, integration of services, and targeted psychosocial activities has been found to be effective instruments to improve continuum of care in AHF supported clinical programs in Ukraine.

TUPEE691

Assessing the needs of the beneficiaries, measuring the impact of our programs: Preliminary results of a community study among the beneficiaries of the CBO Alternatives Cameroon in Douala

J. Ntetmen, J. Mandeng Mbem, F. Mananga
Alternatives-Cameroon, Management Staff, Douala, Cameroon

Background: Measuring the impact of CBO programs on their beneficiaries is often difficult. This is the case for Alternatives Cameroun, CBO working for LGBTI rights, including their access to comprehensive HIV care. Studies are often out of reach for CBOs and do not always provide program-specific information from the CBO. We decided to conduct a study with our beneficiaries, almost without costs, managed by the community actors themselves and which could provide a basis on which to measure the impact of our programs.
Methods: We administered a questionnaire to 105 MSM and 104 WSW during encounters with our beneficiaries. The questionnaire included 3 psychological tests and about 30 questions on sexuality and HIV, human rights, violence and mental health.
Results: The results revealed that 78% of MSM and 84% of WSW had no knowledge of LGBTI rights; 58% of MSM and 55% of WSW had a good knowledge of HIV; 85% of MSM and 78% of WSW wanted to have children, and among them, respectively 68% and 78% wanted to have them through a heterosexual relationship. The WSWs were 58% to consume tobacco and 18% to consume drugs, against 8% of MSM for tobacco

Author Index

and 3% for drugs. Severe depression was diagnosed in 32% of MSM and 30% of FSF. Also, 26% of passive MSM (role of dominated in the couple) against 14% of assets (dominant role), have already been paid for sex, while 30% of active FSF and 15% of passive have already been paid for sex. The condom is widely used in MSM couples (71%), and almost not between FSF (7%).
Conclusions: The study provided new insights for action, especially in mental health and human rights, with a baseline from which to measure changes to our beneficiaries attributable to our programs. This information has made more „SMART" description of the project objectives that we have written since then. By replicating the study at least every two years, we will be able to measure the achievement of these objectives.

Diagnose one, link one1 (D1L1): Strategy increases new HIV diagnoses and improves testing yield among key and vulnerable populations in Tanzania

C. Casalini[1], G. Mbita[2], N. Rutabanzibwa[1], D. Mjungu[1], M. Ndolichimpa[1], M. Katabalila[1], E. Mlanga[3], G. J.Lija[4], A. Komba[1], K. Curran[5]
[1]Jhpiego, Program, Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego, Research, Dar es Salaam, Tanzania, United Republic of, [3]USAID, Dar es Salaam, Tanzania, United Republic of, [4]NACP, Dar es Salaam, Tanzania, United Republic of, [5]Jhpiego, Baltimore, United States

Background: The 2016-17 Population HIV Impact Assessment suggests that Tanzania is not on track to reach the first 90 of UNAIDS' 90-90-90 goals. Sauti is a PEPFAR/USAID funded project which provides combination HIV prevention services including HIV testing and linkage to care to key and vulnerable populations (KVP) in 14 regions of Tanzania. HIV testing services (HTS) are provided on an outreach basis in hotspots such as bars, brothels, mines and truck stops, or in homes in the case of HIV-exposed partners and children of index cases. In fiscal year (FY) 2017 (Oct 2016-Sept 2017) Sauti aimed to test 541,682 and diagnose 37,450 individuals, but halfway through the year had reached 43% of the testing target and 23% of the new diagnosis target, respectively.
Methods: Due to mid-year achievement concerns, in May 2017 project leadership communicated a new strategy, "Diagnose One, Link One" (D1L1), to Sauti's 290 frontline HTS providers. The strategy consisted of: 1) Daily providers' target allocation; 2) Daily providers' performance monitoring and guidance using WhatsApp groups; 3) Effective use of GIS and data dashboards to guide HTS delivery; 4) Efficient leveraging of services and resources across partners and project-platforms. We conducted a two-population proportions z-test to compare the increase of HIV yield between Q4 and Q1.
Results: By year-end FY 2017, Sauti project had tested 505,274 and diagnosed 35,920 HIV infected KVP, 93% and 95% of the annual target. In Q1 and Q2, the project identified 1,524 and 7,614 new HIV positive KVP, respectively, compared to 10,862 in Q3 and 15,920 in Q4. These findings represent an increase in HIV yield as well as total clients diagnosed, from 4-5% in Q1 and Q2, to 8% in Q3 and 11% in Q4, a trend observed among all sub-populations (See Fig 1). The 7% increase in yield between Q1 and Q4 was statistically significant ($p < 0.001$, $z = 8.5562$).
Conclusions: A rapid increase in both new HIV diagnoses and HIV testing yield among KVP was observed following the introduction of the Diagnose One, Link One performance monitoring strategy. Similar approaches could help community based HTS programs achieve the first 90 of the UNAIDS' 90-90-90 goals.

TUPEE693

Measuring continued use of oral PrEP: A review of indicator definitions and programmatic implications

S.Y. Jenkins[1], A. Hainze[1], H. Subedar[2], Y. Pillay[2]
[1]Clinton Health Access Initiative, Pretoria, South Africa, [2]National Department of Health, Pretoria, South Africa

Background: Oral pre-exposure prophylaxis (PrEP) was launched in South Africa in 2016 in a phased approach to support reduction of new HIV infections. Routine programme data supports continual programme evaluation and adjustment. Contextualisation of continued use of PrEP is critical to this. This paper reviews definitions, data, and programmatic implications of measure of continued use of PrEP.
Methods: It is programmatically important to separate the concepts of retention in antiretroviral therapy (ART) and effective continued-use of PrEP. PrEP users may start, stop, and re-start PrEP over time, which does not necessarily indicate inappropriate usage. Based on current programme outcomes, many individuals who initiate PrEP stop use between initiation and one month. In order to better understand programmatic implications of varying approaches to defining continued use of PrEP, NDoH and CHAI undertook an assessment of two potential continued use definitions and resulting insights. Calculations are shown in Figure 1.
Results: Continued use outcomes are shown in Table 1 based on original and updated calculations, by site type. Both calculations demonstrate overall trends in PrEP stoppage, with slower rates of stoppage in later months and a slight increase in usage at 16 months. Further, sites that work primarily with men who have sex with men (MSM) demonstrated higher levels of continued use than sites that work primarily with sex workers (SW) for months where data is available. Utilising both calculations allows for clearer differentiation of drop-off point and for stakeholders to further reflect on how programmatic differences between sites - such as PrEP targets or differing practices on offering PrEP - affect drop-off in the first month of use.
Conclusions: The updated calculation enables clearer programmatic differentiation between individuals who may have been prematurely initiated or not managed appropriately during the critical first month of use rather than those who may face challenges in later stages or may be appropriately cycling. Operations research is currently evaluating discontinuation justifications at varying durations of PrEP use, though side effects appear to be a driver across durations. NDoH and partners are also developing options for targeted interventions to address site-level challenges and share opportunities for programmatic improvement.

Continued use of oral PrEP	At 1 month	At 4 months	At 7 months	At 10 months	At 13 months	At 16 months
Original calculation, all sites	53%	30%	21%	18%	14%	17%
Updated calculation, all sites	n/a	54%	38%	33%	25%	26%
Original calculation, sex worker sites	37%	20%	19%	18%	14%	17%
Updated calculation, sex worker sites	n/a	46%	37%	33%	25%	26%
Original calculation, MSM sites	84%	65%	49%	n/a	n/a	n/a
Updated calculation, MSM sites	n/a	79%	58%	n/a	n/a	n/a

[Table 1 Continued oral PrEP use outcomes, by site type and original and updated definitions]

$$\textbf{PrEP continued use}_{original} = (\text{Continuing PrEP}_{current\ month} + \text{Restart PrEP}_{current\ month})/\text{Initiated on PrEP}$$

$$\textbf{PrEP continued use}_{updated} = (\text{Continuing PrEP}_{current\ month} + \text{Restart PrEP}_{current\ month})/\text{Continuing PrEP}_{1\ month}$$

TUPEE694

A descriptive analysis of TB screening of ART patients and linkage to critical health services among PEPFAR-supported programs in Kenya, Tanzania, Uganda and Rwanda at semiannual time points, 2017

C. Nichols
USAID, Office of HIV/AIDS, Arlington, United States

Background: Tuberculosis (TB) is the leading cause of death for people living with HIV (PLHIV) and routine TB screening of antiretroviral (ART) patients is a critical health service in countries with dual epidemics. Linking ART patients who have been screened for TB into receiving TB preventive therapy (TPT) if clinically indicated or TB treatment if diagnosed, can reduce morbidity and mortality. The U.S. President's Emergency Plan for AIDS Relief (PEPFAR) tracks the number of ART patients who have been screened for TB and related indicators that have helped to monitor program success and offer insight into implementation.
Methods: We conducted a descriptive analysis and assessed percent completeness and additional proportions as measures of data quality on documented client interactions collected at PEPFAR-supported ART sites from Kenya, Tanzania, Uganda and Rwanda between October 2016-March 2017 and April-September 2017 to investigate the state of implementation of these critical health services.
Results: The proportion of ART patients who were screened for TB increased across the two time periods for Kenya (92.54% to 95.6%), Tanzania (89.54% to 95.90%) and Rwanda (91.93% to 98.00%). The completeness of reporting for TB screening results improved across the two time periods for Tanzania (99.00% to 100%) and Rwanda (94.66% to 100%), and was low for Uganda (8.36%) for the time period April - September 2017. The proportion of ART patients who screened positive for TB ranged from 0.50% in Rwanda from October 2016 - March 2107 and to 6.22% in Kenya from October 2016 - March 2017.
Conclusions: The majority of PEPFAR-supported programs in East Africa are routinely screening ART patients for TB and these proportions increased over time, meeting an important global health benchmark. The proportion of patients who screened positive for TB remains low compared to the mean annual risk of HIV-infected individuals developing TB, which is approximately 10%. Our findings suggest that additional clinical training on symptom-based screening for TB might be needed to better identify positives and that data collection challenges, such as incomplete reporting of disaggregated data and proper documentation regarding the number of specimens sent for a diagnostic test, should be addressed.

Country	Patients on ART (N)	Patients on ART who were screened for TB (N)	Proportion of patients on ART who were screened for TB (%)	Completeness of reporting for TB screening results (%)	Patients who screened positive for TB (N)	Proportion of patients who screened positive for TB (%)	Specimens sent for diagnostic test (N)	Patients started on TB treatment (N)	Patients who screened negative for TB (N)
Kenya, Oct 2016-Mar 2017	1,011,712	936,270	92.54%	99.48%	57,961	6.22%	45,689	6,104	873,456
Kenya, Apr 2017-Sept 2017	1,041,326	995,264	95.60%	98.00%	59,738	6.12%	59,901	8,557	915,577

TUPEE695

Using client tracking to improve access to counseling and testing services for adolescent girls and young women in Western Kenya

N. Migowa[1], S. Goldfrank[2], I. Jurkevich[2]
[1]American International Health Alliance, Nyanza, Kenya, [2]American International Health Alliance, Washington, United States

Background: DREAMS, funded by President's Emergency Plan for AIDS Relief (PEFPAR), is an evidence-informed initiative that arms adolescent girls and young women (AGYW) with knowledge, life skills, and support they need to stay healthy and HIV-free. DREAMS relies on functioning community health systems to ensure HIV testing services (HTS) support the needs of AGYW to more effectively address HIV/AIDS and reach global 90-90-90 targets.
Description: American International Health Alliance (AIHA) implements a DREAMS intervention targeting girls aged 10-14 to ensure they receive a core package of services to help reduce new HIV incidence by 40% in high-burden counties in Western Kenya. HTS is a core service AGYW receive through referrals and linkages, so girls know their HIV status and can make informed decisions to mitigate risky behavior. Caregivers were often unwilling to take girls for testing by themselves, however, so project mentors would accompany them, adding another layer of complexity to the HTS process. AIHA worked closely with Kenya's Ministry of Health (MOH) and County AIDS and STI Coordinators (CASCOs) to arrange for counsellors to provide HTS services at project Safe Spaces. Enrolled AGYW, accompanied by a parent or caregiver for consent, can get tested there. AIHA implemented a detailed process to track girls, HTS referrals, and status, ensuring girls who test positive are put on treatment, while those who test negative are scheduled for annual retesting. After the referral form is completed, it is filed and updated in DREAMS Database.
Lessons learned: Of the 24,620 AGYW presently enrolled by year 2 of the project, 19,353 (79%) were tested and aware of their HIV status; 27 girls tested positive and were referred to healthcare facilities for treatment and follow up care is support of Kenya's efforts to attain the global 90-90-90 targets.
Conclusions/Next steps: Implementers must continually evaluate projects and adjust operations to better meet local challenges and context. Working with stakeholders to find solutions that meet the needs of project beneficiaries can result in increased success and, in this case, resulted in a 90% success rate of AGYW enrolled in AIHA's DREAMS project knowing their HIV status.

TUPEE696

Is the whole greater than the sum of it's parts? Using narrow age bands in routine adult HIV surveillance for enhanced programme targeting and planning

M. Deda, K. Webb, P. Nesara
Organisation for Public Health Interventions and Development, Strategic Information and Evaluation, Harare, Zimbabwe

Background: Zimbabwe has an adult HIV prevalence of 14.6%. Since 2011 the National HIV & AIDS surveillance system has been tracking HIV prevention and control activities amongst older adults receiving services at public health facilities using a single broad age band (25-49 years). However, results from the 2016 Zimbabwe Population-Based HIV Impact Assessment showed noteworthy disparities of HIV prevalence by age and sex amongst persons between the age of 25 and 49 years. These results prompted the FACE-HIV programme to pilot a surveillance system collecting routine public health facility data on HIV prevention and control activities using narrower age bands (25-29, 30-34, 35-39, 40-49) amongst adults to solicit for enhanced HIV prevention and treatment program decision-making.
Description: A passive facility-based HIV surveillance system was implemented among 368 health facilities in 12 Districts from Oct-Dec 2017. Routine age and sex dis-aggregated service uptake and outcome data amongst adults (25-49) receiving HIV services at public health facilities were collected within narrow age bands.

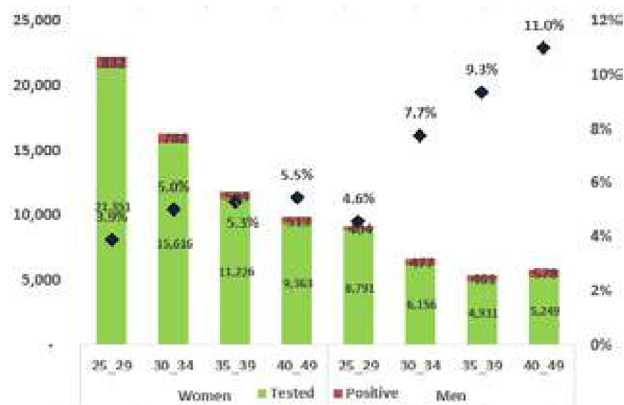
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

Lessons learned: A total of 82,683 clients within the 25-49 year age group were tested for HIV, 4,641 were newly identified HIV positive giving a yield of 5.6%. Amongst women and men the HIV testing yield was 4.7% (2,721/57,556) and 7.6% (1,920/25,127) respectively. When the same data were analysed using narrower age bands, noteworthy disparities by volume of tested clients and yield were observed (fig 1).
Across all age groups, absolute numbers of women tested for HIV was greater than men. For both women and men, as age increased, the volume of clients tested for HIV decreased, but the yield increased. The increase in yield was more marked in men, with the group with the highest yield being men aged 40-49(11%; 578/5249).



[Figure 1_HIV testing yield by narrow age bands and sex]

Conclusions/Next steps: The observed findings confirm the urgent need to collect and analyse increasingly granular routine facility HIV surveillance data for better understanding of HIV program performance and targeting of programme interventions as the programme reorients towards meeting the UNAIDS 90-90-90 2020 targets.

TUPEE697

Trends in one-year retention among clients on antiretroviral therapy in PEPFAR-supported sites from 2015-2017

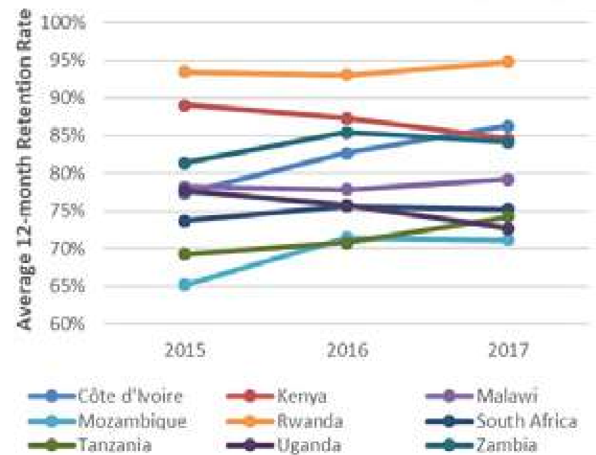
K. Clark, A. Radin, I. Zaidi
Office of the U.S. Global AIDS Coordinator and Health Diplomacy, Washington D.C., United States

Background: Recent PHIA results document high levels of viral suppression among people on ART, yet retention measured through routine program data suggest that retention among HIV+ clients newly initiating on antiretroviral therapy continues to be a significant barrier. In 2014, PEPFAR began prioritizing the highest burden geographic areas for accelerated epidemic control to increase diagnosis, linkage, and retention.
Methods: We conducted a retrospective analysis using facility-level 12-month retention data reported at 7,042 PEPFAR-supported facilities from 2015 to 2017 in the following countries: Côte d'Ivoire, Kenya, Malawi, Mozambique, Rwanda, South Africa, Uganda, Tanzania, and Zambia. Sites were selected for inclusion in the analysis if data were reported on the PEPFAR 12-month retention indicator during all three years under review. 5,707 (81%%) sites in the sample were in PEPFAR areas of geographic scale-up. We reviewed trends in overall 12-month retention rates and assessed if there was a relationship between PEPFAR geographic prioritization and changes in 12-month retention rates from 2015-2017.
Results: The overall mean rate of 12-month retention in was 78.4% (*SD*=17.3) in 2015 and 78.7% (*SD*=14.8) in 2017. 29.6% of the sites reporting in 2015 had a 12-month retention rate >90% compared to 29.2% in 2016 and 25.2% in 2017. 2,781 (48.7%) sites in PEPFAR scale-up areas observed an increase in 12-month retention compared to 631 (47.3%) in non-PEPFAR scale-up areas. There was no statistically significant difference in proportions (p = .085) between retention in scale-up and non-scale-up areas. Decreases in 12-month retention were observed in over half of sites in both PEPFAR scale-up (47.6%) and non-scale-up (50.0%) areas.

	Increase in 12-Month Retention	Retention Maintained at 100%	Decrease in 12-Month Retention	Total Sites
Sites in PEPFAR Scale-Up Areas	2,781 (48.7%)	211 (3.7%)	2,715 (47.6%)	5,707 (100%)
Sites not in PEPFAR Scale-Up Areas	631 (47.3%)	36 (2.7%)	668 (50.0%)	1,335 (100%)

[Retention in PEPFAR-Supported Sites]

Conclusions: Results reported for the PEPFAR 12-month retention indicator are likely an underestimation of actual 12-month retention as facilities often struggle to account for "silent transfers," particularly as efforts have been made to decentralize ART service delivery. Data from the PHIA demonstrate high levels of retention and viral suppression of clients on ART. Further investigation of both the data quality for retention indicators and programmatic strategies to improve tracing of clients between sites is needed to understand the observed decreases.



[Trends in Average 12-Month Retention by Country]

TUPEE698

Accelerating data use for Indonesia's Fast-Track response

S. Sulami[1], S. Rizal[1], V. Indrawati[2], C. Francis[3], J. Macom[4], A. Human[5]
[1]*FHI360, M&E and Strategic Information, Jakarta, Indonesia,* [2]*Ministry of Health, M&E and Surveilance, Jakarta, Indonesia,* [3]*FHI360, Chief of Party LINKAGES/USAID Project, Jakarta, Indonesia,* [4]*FHI360, Technical Advisor, Jakarta, Indonesia,* [5]*FHI 360 Indonesia, Jakarta, Indonesia*

Background: Each month, more than 4,000 health facilities across Indonesia collect and report HIV service-delivery data into the national HIV information reporting system (SIHA). Data are presented in tabular form across hundreds of indicators. This information is difficult to track, review, and analyze, and visual graphs are complicated to make. Not surprisingly, evidence has not been systematically used at all levels for accelerating HIV programming towards HIV epidemic control.
Description: The LINKAGES Indonesia Project - with support from USAID, under PEPFAR - partnered with Indonesia's Ministry of Health (MoH) to create the *Cascade Generator,* using Microsoft Excel and a MySQL application that is integrated directly into SIHA. For the first time, visual HIV testing and treatment cascade dashboards can be generated at facility, district, province, and national levels with just a few clicks. Data can be isolated for various time periods, key population groups, and HIV service modalities. The Cascade Generator enables users to focus on data that directly corresponds to national epidemic control objectives, making data more manageable and supporting more comprehensive data utilization efforts.
Lessons learned: The *Cascade Generator* has been introduced in two PEPFAR-targeted provinces, Jakarta and Papua. One hundred-fifty facilities, eight district health offices, two provincial health offices, and the MoH have initiated its use during Fast-Track planning and analysis consultations. In mid-2017, PEPFAR assessed its use and determined

that approximately half of Jakarta-based stakeholders had utilized the Cascade Generator at least once to review Fast-Track coverage or to identify quality improvement priorities. In the area of HIV testing, data generated through the Cascade Generator led to the amplification of mobile testing across Jakarta, increasing testing coverage by 53% over 2017.

Conclusions/Next steps: The Cascade Generator will be introduced by the MoH into 34 other provinces and 96 districts as Fast-Track implementation intensifies across the country. At the request of Jakarta's Public Health Office, additional Cascade Generator templates to support further data analysis efforts, including dashboards that track 95-95-95 performance against targets, are currently being added. The project will continue to place increased emphasis on data analysis assistance, and the systematic use of this data for quality improvement.

TUPEE699

Measuring advocacy and capacity building: Experience of major MSM/LGBTI-focused project in EECA

R. Stuikyte[1], S. Chikhladze[2], D. Kamaldinov[3], K. Kepuladze[2], M. Kasianczuk[4], V. Djuma[4]
[1]Consultant, Vilnius, Lithuania, [2]NGO Tanagdoma, Tbilisi, Georgia, [3]Humanitarian Project, Novosibirsk, Russian Federation, [4]Eurasian Coalition on Male Health (ECOM), Tallinn, Estonia

Background: Eurasian Coalition on Male Health (ECOM) initiated a project in 5 countries aimed at improving responses to increasing HIV epidemics among MSM/LGBTI in Eastern Europe and Central Asia (EECA) through advocacy and empowered community engagement in policies and services. To assess the work, in 2017, it conducted a baseline assessment (BA) covering: development of LGBT community; levels of epidemics and services available; recognition of MSM/LGBTI in national HIV policy documents; involvement of LGBTI leadership and MSM services in national HIV and other governance; domestic investments in HIV among MSM/LGBTI.

Methods: The BA protocol with qualitative and quantitative (scoring) tools was developed. Data were collected through literature review and semi-structured interviews with LGBT groups/MSM services and national stakeholders.

Results: Involvement of MSM and transgender people in HIV decisions varies from third to half of the maximum possible scores, with higher levels in Georgia and Kyrgyzstan, where investment in HIV prevention among MSM is highest. While all the countries indicate MSM as a key population in HIV policy documents, funding for services has come exclusively from the Global Fund. Transgender people is recognized as a key population only in Kyrgyzstan; there is a complete lack of data on them across the countries. LGBTI leadership is being renewed across the countries but without focused leadership building. Valuable experiences have been identified: special seats allocated for community representatives and first transgender person elected to HIV coordination mechanism in Belarus, PrEP initiation in Georgia, strong cross-fertilization among LGBTI groups and HIV-MSM services in Kyrgyzstan, first-time allocation of national funding for HIV prevention among MSM in Macedonia. Regional and country-specific recommendations were produced.

Conclusions: The BA might serve as an example for monitoring progress of advocacy and capacity building and producing comparative indexes on stronger and weaker sides of each country. Similar assessments should combine self-assessment of LGBTI/MSM stakeholders and confidential feedback from external partners (major differences seen in BA). The assessment will be repeated in 2019 to measure ECOM project's impact. ECOM considers extending BA to other EECA countries to map EECA situation and compare of changes in its project countries with non-project countries.

TUPEE700

HIV rapid test procurement forecast at a regional level: Improving operational planning to achieve the HIV screening and detection targets

L. Khomych, M. Duda
Deloitte Consulting Overseas Projects, LLC, USAID Project, Kyiv, Ukraine

Background: Ukraine has one of the highest HIV burdens in Eastern Europe with an estimated 243,000 people living with HIV/AIDS (PLWH). As of early 2018, 58.6% of PLWH have learned of their status. Scale-up of HIV testing is needed to reach the first 90 of the global targets. In the context of Ukraine's health financing reform and HIV services' decentralization, USAID HIV Reform in Action Project developed and tested an electronic tool for forecasting program and financial needs for rapid HIV tests supply at the regional level. The tool enables evidence-based supporting of HIV strategies and policies in programmatic scale-up and HIV testing provision.

Description: Our analysis reflected allocative and technical efficiencies as a key strategic pillar for HIV rapid test kit needs forecasting, with a particular focus on the first 90 target. The projections use regional 90-90-90 targets. Input data include area-specific demographic, epidemiological, service utilization, and costing data. The tool allows forecasting of three alternative scenarios based on procurement practices used at the targeted area.

We tested the tool in seven PEPFAR-supported high-burden regions. The routine application of the tool permitted calculation of rapid HIV testing financial and programmatic needs for annual procurement plans.

Lessons learned: The tool supported local-level authorities in projecting financial needs to purchase rapid HIV tests based on their regional epidemiologic situation. Our experience demonstrated the difference in financial forecast needs based on rapid HIV test procurement practice: centralized, or pooled procurement vs. local procurement of small amounts of test kits.

Conclusions/Next steps: A multipronged approach to forecasting the programmatic and financial needs for rapid HIV testing could be introduced countrywide into the routine operational planning process at regional and local levels. Using such a tool will allow governmental policy-makers to make informed decisions to achieve 90-90-90 targets in a cost-effective manner and enhance transparency and accountability in decision-making and programmatic planning at the regional level. Programmatic planning should select the more suitable procurement option (pooled vs. local procurement).

TUPEE701

All for the Africans but nothing by the Africans? Analysis of the contribution of African HIV research institutions in the IAS 2017 conference

J. Gonzalez Perez[1], A. Zakowicz[2], K. Ssamula[3], L. Buzaalirwa[3], A. Kayongo[3]
[1]AIDS Healthcare Foundation, Kigali, Rwanda, [2]AIDS Healthcare Foundation, Amsterdam, Netherlands, [3]AIDS Healthcare Foundation, Kampala, Uganda

Background: Research conducted in Africa has changed the way that HIV is prevented and managed globally. When the epidemic started expanding in Africa in the early 1990´s, foreign support (also in research) was critical to confront that threat. Today, is Africa still depending on foreign institutions and researchers to end HIV? We present here data on institutions that presented HIV research from Africa in the most recent International AIDS Society Conference on HIV Science (IAS 2017).

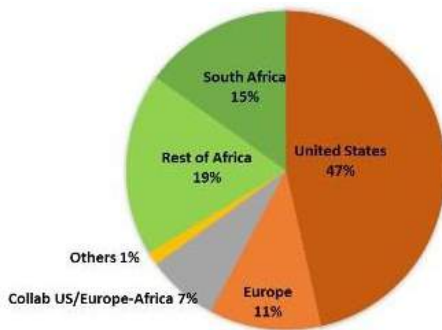
Methods: All abstracts accepted for IAS 2017 for Oral sessions and Poster discussions presenting research conducted in Africa were included in the study. Affiliations of the first four authors in each abstract were classified in seven categories: Research institutions [RI] - based in the United States (US-RI), Europe (UE-RI) or Africa (Afri-RI), Long term collaboration programs between RI in US or Europe and RI in Africa (Colab-RI), Non for profit with headquarters [HQ] out of Africa (Intl-NGOs), Non for profit with HQ in Africa (Afri-NGOs) and Ministries of Health [MoH] of African countries (Afri-MoH). Weighted scores based on author order were given

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

to each affiliation, keeping the total score for each abstract equal. After categorization, percentages were calculated of the contribution of each category to the total.

Results: 83 abstracts met the inclusion criteria. 46% of them focused on Implementation Science (Track D), none of them on Basic Science (Track A). Countries where HIV research was more frequently conducted were South Africa (22 abstracts), Malawi (13) and Uganda (9). By institutions, US-RI were responsible for 30% of the HIV research conducted in Africa presented in IAS 2017, Afri-RI for 22% (almost two thirds of these from South Africa), Intl-NGOs for 21%, Afri-NGOs for 8%, UE-RI and Colab-RI for 7% each and Afri-MoH for 5%.

Conclusions: Foreign research institutions and international NGOs are still responsible for almost 60% of the research conducted in Africa presented in IAS 2017. South African universities are the main actor in HIV research within the African continent. The role of long term collaboration programs between African and US or European universities in HIV research is lower than expected.



[Contribution of institutions conducting research in Africa to IAS 2017 by location]

TUPEE702

Mapping population sizes and hotspot locations for female sex workers improved targeting for HIV prevention interventions in Ethiopia

W. Girma, E. Workalemahu, T. Negatu
Population Services International/Ethiopia, Addis Ababa, Ethiopia

Background: HIV prevalence among female sex workers (FSWs) in Ethiopia is approximately 23%. To address risk of HIV in this population, the MULU/MARPs combination HIV prevention project was launched in 2012 across 168 Ethiopian towns/cities. Implementation was challenged by insufficient data on FSW locations and sizes. A rapid size estimation approach was developed to aid program implementation.

Description: FSWs were enumerated from 100 cities/towns through interviews with key informant (KI), who included FSWs, venue managers/owners, cashiers, and guards at FSWs workplaces. KIs were asked about the number of FSWs who negotiated sex for money in the last month. The number of venue-based FSWs reported by KIs were summed to estimate population size in a given town.

The number of street-based FSWs was estimated using a capture/recapture approach. Street vendors/guards of FSWs helped to identify street-based FSWs. Further, service facilities were also mapped from 79 towns, including facilities that provide HIV testing, family planning, and sexually transmitted infection diagnosis and treatment. KIs provided informed consent and data collection was conducted June-October, 2013 (44 cities/towns), February-March 2014 (35 cities/towns), and March-May, 2017 (21 cities/towns).

Lessons learned: The FSW population in the 100 study towns was estimated to be 84,801 (41,768 in 2013, 31,932 in 2014, and 11,101 in 2017) and were found to operate in 34,732 locations (57.9% establishment /bars, hotels, cafes, groceries & coffee house, 41.5% homes and 0.6% streets). A total of 3,544 private, public, public/private, and NGO facilities were mapped and about 550 (11%) provided comprehensive HIV services including HIV counselling and testing, STI screening, and FP services. The results of this rapid size estimation approach have been used for project target-setting, allocation of resources, and developing coverage standards specific to each project town. It also helped to establish private network service facilities in hot-spots to provide standard services and evidence for national planning processes. One limitation is dependence of interviewers on KIs who can over/under estimate the size for various reasons.

Conclusions/Next steps: Rapid size estimation approaches may be less precise than other estimation approaches, but can be a useful exercise for programs seeking to better target services for hidden populations.

TUPEE703

Reaching universal coverage, through low cost integration with health system model: Madhya Pradesh, India

P.K. Malaiya[1], P. Gupta[2], A. Hegde[3]
[1]Madhya Pradesh State AIDS Control Society, Health & Family Welfare Madhya Pradesh, Bhopal, India, [2]UNICEF, Madhya Pradesh State AIDS Control Society, Bhopal, India, [3]National AIDS Control Organization, Health and Family Welfare, New Delhi, India

Background: Madhya Pradesh, low prevalent, central state in India, reports 2.2 million estimated annual pregnancies. 95% of the estimated pregnant women are registered for antenatal services and 75% are tested for HIV in 2017. These services are delivered through 680 facilities located in Community centers and Primary health centers. This paper describes the improvement in PPTCT in terms of screening and treatment services.

Description: The major barrier in reporting of Prevention of Mother to child transmission services of HIV/AIDS program was the need for hardware and internet connectivity and data monitoring of these facilities. Although pregnant women were accessing services for PMTCT, it was not being reflected in the health system. The reporting from the facilities was 8% in 2014, which increased to 80% in 2017. These improvement in reporting was due to the integration with the maternal health system. Nodal officers from maternal health were identified at State, district, block and facility level: were trained on their responsibility to ensure reporting pf the PMTCT services in the health system. These trainings were conducted during their regular monthly review meeting. These trained officers during their regular supportive supervision visits to the facilities and during their review of the facilities ensured reporting of PMTCT services in the health system.

Lessons learned: Despite many constraints on the need of hardware and internet connectivity, the facilities delivering services ensured that they report in the health system, through utilisation of the health system hardware and internet facilities. Total number of ANC registration in the year of 2014-15, 2015-16 & 2016-17 were 1.90,1.84,1.84 million and out of which pregnant women screened for HIV were 36%,54% 61% respectively, i.e. **97% increment** over 3 years. The treatment initiation to the HIV positive pregnant women and ARV prophylaxis to HIV exposed babies increased to 94.9% in 2016-17 from 58.8% in 2014-15. Integration with maternal health systems and strengthening of data monitoring and reporting from the facilities providing testing & counselling services led to this upscale.

Conclusions/Next steps: Monitoring of Health facilities and strengthening reporting through the maternal health system has contributed to documenting the increase uptake of HIV services and improvement in treatment services.

TUPEE704

Focused HIV programming: A visual analysis of routine HIV data from 51 sub-districts in KwaZulu-Natal province, South Africa

I. Maina[1], T. Ngwenya[2], E. Mungai[3], F. Ndlovu[2]
[1]UNAIDS, Pretoria, South Africa, [2]KwaZulu-Natal Office of The Premier, Priority Programmes, Pietermaritzburg, South Africa, [3]KwaZulu-Natal Treasury, Pietermaritzburg, South Africa

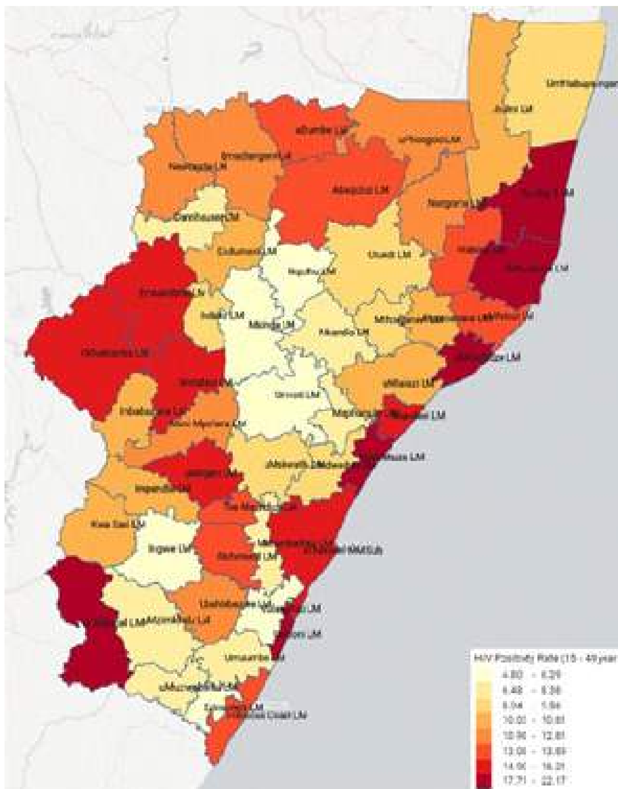
Background: KwaZulu-Natal (KZN) province remains the epicenter of the global HIV epidemic and despite massive investment in HIV programmes, infection rates remain unacceptably high. In 2016, the Provin-

cial Council on AIDS (PCA) embarked on the process to develop the KZN HIV, TB and STI strategic plan for 2017 - 2022. The purpose was to use routine HIV data for focussed programme planning on where, how and what for each of its 11 districts and 51 sub-districts.

Description: The first step in developing the plan was to better understand the epidemic in all districts and sub-districts. To achieve this, incidence, prevalence and behavior trends from survey data, modeling and programme performance from routine data was analysed. This paper focusses on the latter and specifically facility data on HIV positivity aligned to government financial year 2015/16.

Routine health data for selected indicators was analysed using a geo-spatial tool disaggregated by age and location. Each facility was mapped to understand its catchment population and assigned to a sub-district. HIV positivity rates for the following age categories was used for analysis: 18 months, 1 - 4 years, 5 - 14 years and 15 - 49 years. For improved targeting, the actual number of people diagnosed HIV positive in that year was also reviewed.

Lessons learned: The epidemic is not homogeneous in the province both at district and sub-district level. Across all age-groups, Ethekwini Metro has a high positivity rate and carries 40% of the total provincial burden. Sub-district analysis indicate major variances with cities and coastal areas having higher rates. For example, figure 1 shows that 12 of the 19 sub-districts with positivity rates over 10% among 15 - 49 age group were along major routes or towns.



[2015/16, KZN HIV Positivity Rates Among 15 - 49 Year Old]

Based on analysis, the province was able to prioritize specific high burden districts and sub-districts for intensification of high impact interventions. In 2017, the results informed Global Fund resource allocation for HIV prevention to five identified high burden districts and 10 sub-districts.

Conclusions/Next steps: Visual analysis of rountine data collected at sub-district can easily be used for focussed HIV programmming at different levels. Further disaggregation by sex and ward level is recommended.

TUPEE705

Effective use of LabEQIP tool for VL laboratory network optimization in Rwanda: Data-driven decision making to building laboratory capacity to meet the 3rd 90

A. Bingi Tusiime[1], F. Gasaza[2], E.I. Mwikarago[3], E. Ntagwabira[3], E. Karangwa[3], I. Buki[2], H. Steppe[4], S. Were[5], M.C. Wattleworth[5], C.B. Ndongmo[5], M.L. Field-Nguer[6]

[1]USAID Global Health Supply Chain Program - Procurement and Supply Management (GHSC-PSM) Project, Arlington, United States, [2]USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) Project, Kigali, Rwanda, [3]Rwanda Biomedical Center, Kigali, Rwanda, [4]Llamasoft, Inc, Alexandria, United States, [5]USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) Project, Arlington, United States, [6]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Task Order 1 HIV/AIDS, Arlington, United States

Background: To reach the 3rd global 90-90-90 goal of having 90% of those on treatment virally suppressed, countries require thorough analysis and understanding of their national laboratories and referral sites networks. These networks should be optimized to strategically plan for future testing capacity needs. To that end, a comprehensive laboratory network optimization exercise in Rwanda supported viral load (VL) scale-up while scaling down CD4 testing.

Methods: Using the Laboratory Efficiency and Quality Improvement Planning (LabEQIP) software, a mapping and network optimization tool, partners in Rwanda collected data on patient numbers, facilities, and equipment utilization rates. The existing testing network and respective referral sites contained nine conventional VL and 92 CD4 instruments. Using LabEQIP, partners ran various scenarios to determine the optimal testing capacity, equipment placement and utilization rates, sample transportation, and referral linkages.

Results: A key finding from the exercise was that the National Reference Laboratory (NRL) was overburdened by participating referral sites while the Rwanda Military Hospital Laboratory (RMHL) was underutilized. Reassignment of some ART sites from NRL to RMHL resulted in a 6% reduced workload at NRL that RMHL was able to absorb; this also led to a 15% decrease in travel distances to support the network. Moreover, a scenario assuming the projected 8% increase in VL patients found the national equipment capacity to be adequate, as the labs were found to have only 23% utilization rate at baseline. Another scenario analysis showed that the existing POC CD4 network could meet projected overall 85% decrease in testing demand through reallocation of existing POC CD4 machines, leading to cancellation of a planned order of 22 new ones, saving at least $240,000 in equipment and installation.

Conclusions: The experience in Rwanda is illustrative of how national VL programs can benefit from the use of the LabEQIP tool. By providing rich, data driven scenario planning for VL network optimization, the tool informs policy and programmatic decisions that produce greater network efficiency, better clinical outcomes, and significant cost savings. The tool can also be used for long-term monitoring and revisions to VL networks.

TUPEE706

Using surveillance and other data systems to improve linkage to HIV care for racial and ethnic minorities in the United States: Lessons from the CAPUS demonstration project (2012-2016)

M.S. Mulatu, P. Sweeney, T. Hoyte, K. Williams

Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States

Background: In the United States, blacks/African Americans and Hispanics / Latinos are disproportionately affected by HIV. Increasing access to care for people living with HIV (PLWH) and reducing HIV-related disparities are key national objectives. Data-to-Care (D2C) is a public health strategy that uses HIV surveillance and other data to improve linkage, retention, and health outcomes for PLWH who are not linked to medical care.

Description: The Care and Prevention in the United States (CAPUS) project implemented in 2012-2016 by eight state health departments included a combination of interventions to reduce HIV-related morbidity,

mortality, and disparities among racial/ethnic minorities. A key component of CAPUS required grantees to develop capacity to use HIV surveillance and other data to:
a) identify and help PLWH link to or re-engage with care,
b) monitor their clinical outcomes, and
c) improve the quality of care and prevention services provided to them.
We synthesized qualitative and quantitative data reported by grantees to describe their D2C implementation and outcomes.
Lessons learned: Grantees enhanced their capacity to implement D2C by improving their data systems; integrating surveillance, care and prevention data; and enacting policies and procedures for using surveillance information for program follow-up. Using multiple data systems, grantees identified and contacted 4,952 PLWH presumed to be not-in-care (64.0% blacks/African Americans, 29.2% whites, 4.1% Hispanic/Latino). Of those, only 36.6% were confirmed as not-in-care (41.6% of blacks/African Americans, 30.9% of Hispanic/Latinos, 25.2% of whites). Linkage services were provided to 57% of those confirmed as not-in-care (60.5% of blacks/African Americans, 58.7% of Hispanics/Latinos, 42.5% of whites). Overall, 82.4% of those provided linkage services were linked to or re-engaged with medical care (84.4% of blacks/African Americans, 78.4% of Hispanics/Latinos, 69.7% of whites).
Conclusions/Next steps: CAPUS grantees enhanced their capacity to use surveillance and other data to identify PLWH who were not-in-care and link to or re-engage them with medical care. Better outcomes for blacks/African Americans and Hispanics/Latinos, compared to whites, suggest that D2C programs that prioritize racial/ethnic minorities may help address disparities in access to HIV medical care. Further improvements in data systems and outreach services are essential for the success and scale-up of D2C programs.

TUPEE707

Strengthening data management and utilization to improve the quality of HIV/AIDS services provided by the Zambia Defence Force health facilities

S. Jere[1], D. Kaoma[1], L. Nonde[1], I. Jurkevich[2], F. Malasha[3], E. Lifuka[4]
[1]American International Health Alliance, Lusaka, Zambia, [2]American International Health Alliance, Washington, United States, [3]Zambia Defence Force, HIV Secretariat, Lusaka, Zambia, [4]DAO PEPFAR, Lusaka, Zambia

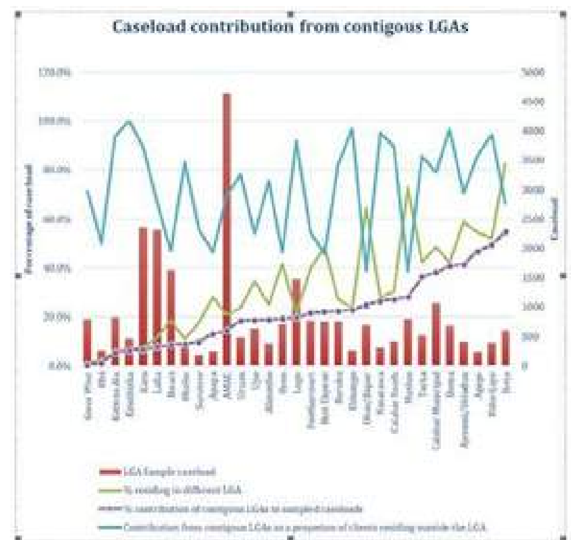
Background: The Zambia Defence Forces (ZDF) Military Medical Service plays a substantial role in the country's HIV/AIDS response. ZDF's 54 military bases provide health services, including HIV testing, counselling, care, and treatment, to over 400,000 military personnel and civilians across Zambia.
According to a study conducted by the University of Zambia's Department of Population Studies (UZDPS), data management and utilization to inform facility-level decisions at ZDF health centers is low due to a range of factors, including inadequate integration of monitoring and evaluation (M&E) systems, poor record documentation of records, and lack of standardized training resources.
Description: With support from the President's Emergency Plan for AIDS Relief (PEPFAR) and the U.S. Department of Defense (DOD), the American International Health Alliance (AIHA) is working with ZDF to promote data use for quality improvement (QI) in 19 (ZDF) health facilities by establishing M&E Hubs at 19 ZDF health facilities. In collaboration with the Ministry of Health and UZDPS, AIHA trained 3 health personnel (1 in data management and 2 in QI) from each of the 19 facilities in data management and QI. Post-training follow ups were conducted to ensure facilities were adhering to QI plans developed during training and onsite mentorship was done to support facilities that did not initiate QI processes.
Lessons learned: Site Improvement Monitoring visits conducted by DOD at three sites selected among the 19 facilities in 2016 scored 59% in QI; in 2017, two of the facilities selected scored 100%, demonstrating improved quality of HIV-related services. Staff at all 19 facilities discuss performance data in review meetings and revise action plans accordingly. Challenges such as staff attrition, inadequate support from District Health Offices (DHOs), and resource limitation still exist as impediments to further progress.
Conclusions/Next steps: Bridging identified gaps in effective collection and utilization of data to improve the quality of health services and outcomes requires, among other things, additional training, strong engagement of DHOs in the provision of onsite mentoring, and support for harmonization of data collection tools.

TUPEE708

Should health-facility service data alone be used to locate the HIV epidemic? Experience from a Health Facility Catchment Area Mapping study in Nigeria

O.J. Ibitoye[1], M. Langley[2], D. Oliver[2], T. Murove[3]
[1]Catholic Relief Services, Monitoring, Evaluation, Accountability & Learning, Abuja, Nigeria, [2]Cathoilic Relief Services, Programme Impact and Quality Assurance, Baltimore, United States, [3]Catholic Relief Services, Abuja, Nigeria

Background: Locating the epidemic is critical to any disease control effort. In Nigeria, PEPFAR utilized patient-level data to prioritize scale-up interventions in 32 of the 774 Local Government Areas (LGA) towards controlling the HIV epidemic. While PEPFAR relied on health-facility service data to determine its focus, failure to take patients' residence into consideration challenged the accuracy of the prioritization. A Health Facility Catchment Area Mapping (HFCAM) was conducted to inform program and policy decisions regarding epidemic control activities performed by PEPFAR Implementing Agencies and their partners in Nigeria.
Description: The HFCAM collected demographic, geo-location of patient residence (LGA) and health facility data along with HIV treatment records from 26,365 (7,163 Male; 19,202 Female) beneficiaries between June and August 2016 in 176 PEPFAR supported facilities across 31 priority LGAs. The data collected was used to develop catchment maps. The maps show the spatial distribution of clients who reside in PEPFAR prioritized LGAs overlaid with that of clients who cross LGA boundaries to access care in the prioritized LGAs. The HFCAM concluded that 27.5% of clients access services outside their LGA of residence and 70% of clients who cross LGA boundaries did so from contiguous LGAs to a PEPFAR prioritized LGAs.



[Figure: Caseload contribution to Scale up LGAs by contiguous LGAs]

Lessons learned: In response to the HFCAM findings, PEPFAR created a new category of support in Nigeria - 'Sustain Support Plus' - which joins the other categories of support ('Scale-Up' and 'Sustained Support'). The 13 'Sustain Support Plus' LGAs are contiguous to scale-up LGAs and have started to benefit from an expanded range of PEPFAR priority interventions to address the identified challenges in accessing core community-based interventions. PEPFAR has described this as "cluster-based targeting" which considers LGA catchments in planning coverage of interventions. Through the granular analysis of client records and spatial visualization, the HFCAM supported greater precision in targeting services for PLHIV.

Conclusions/Next steps: Combining facility-based coverage data with patient-level geographic data leads to improved evidence on the location of the HIV epidemic, improving program decisions towards epidemic control. Future research will explore the characteristics of individuals who seek care in their LGA versus those who do not. This will allow further refinement in effective targeting.

Evaluating large scale programmes: approaches to rigorous evaluation

TUPEE709

Implementation of "Getting 2 Zero" in Miami: A progress report

T. Brown, Z. Blair, M. Brown, T.Y. Cooke, W. Darrow, E. Dormevil, D.M. Felder, J. Garcia, M. Guzman
Florida International University, Stempel College of Public Health & Social Work, Miami, United States

Background: Miami-Dade County is currently ranked number one in the United States for new HIV infections per 100,000 residents. To reduce HIV incidence and improve other outcomes, the Mayor's Office appointed a "Getting 2 Zero (G2Z) Task Force" of 29 stakeholders to review HIV prevention, treatment, and control policies, programs, and practices in the county. The Task Force began to meet in September 2016 and concluded its work in February 2017 by proposing 16 recommendations for implementation. We followed up on the implementation of G2Z recommendations by tracking the progress of the Florida Department of Health (FDOH)-Miami and their partners.

Description: Eight members of a master's of public health class on "Health Promotion Program Planning and Intervention Design" formed a research team and divided the 16 recommendations into eight pairs. Each team member then followed up on two of the recommendations by contacting a representative of the health department or another person designated in the action plan as taking the lead. Information obtained from personal communication, meeting attendance and minutes, and other sources was used to create a timeline displaying monthly progress from June 2017 through January 2018.

Lessons learned: As of February 1, 2018, progress was reported on 13 recommendations and no progress on three. Those being implemented had achieved varying degrees of completion (Table on the next page). For example, significant strides had been made with respect to:
(1) improving access to PrEP and nPEP,
(2) routine HIV/STI testing, and
(3) providing rapid access to ARV treatment and retention in care.
Major obstacles still remained with:
(1) implementing comprehensive sex education in public schools,
(2) bridging gaps when clients move or lose eligibility, and
(3) expanding the network of housing available for PLWHA.

Conclusions/Next steps: Significant progress had occurred on implementing recommendations under the control of FDOH. Recommendations that required legislation, policy changes, and multi-agency collaboration or additional resources had made less progress. No additional resources had been allocated by FDOH, the Mayor's Office, or other agencies to assure complete implementation of Task Force recommendations in Miami-Dade County.

Recommendation	Community Partner	January 1-December 31, 2017	February 1, 2018 Update
Updates provided by Y.T. Cooke			
1. Provide comprehensive sex education throughout the Miami-Dade County Public School system (M-DCPS), recommending modifications in the M-DCPS comprehensive sex education curriculum as age appropriate. 2. Expand PrEP (Pre-Exposure Prophylaxis) and nPEP (non-occupational Post-Exposure Prophylaxis) capacity throughout Miami-Dade County, and increase utilization by all potential risk groups	Miami-Dade County Public Schools Florida Department of Health in Miami-Dade County and Gilead Sciences, Inc.	Not implemented--Why? ~Parents want control over sex education of their children. ~M-DCPS adopted an abstinence only curriculum. ~Abstinence only rule is now under review. ~Comprehensive sex education in M-DCPS is possible. Non-profit CBO could partner with Planned Parenthood. Number of PrEP locations: 25 Number of nPEP locations: 16 Number of PrEP prescriptions: • June 2017 - 907 patients (676 continuing, 119, new patients) • August 2017 - 984 patients • September 2017 - 832 patients (Hurricane Irma disruptions) October 2017 - 1044 patients	Quarterly meetings between community representatives and the Superintendent of M-DCPS have been scheduled to discuss health-related issues. Bullying is at the top of the list. Comprehensive sex education is lower down on the list of priorities The number of people using PrEP in Miami-Dade County almost doubled from 663 at the end of 2016 to an estimated 1031 people at the end of November 2017. Adherence is believed to be as good for PrEP as it is for ARV treatment, but providers are concerned about discontinuance by patients after 6 months of use.
Updates provided by Z. Blair			
3. Implement routine HIV/STI testing in healthcare settings (hospitals, urgent care centers, medical practices). 16. Identify barriers and improve access to existing HIV/AIDS services for HIV positive undocumented immigrants	Florida Department of Health in Miami-Dade County, Gilead FOCUS Project Miami-Dade County Ryan White Part A/MAI Program	Baptist Hospital Homestead, Borinquen Clinic, and Jackson Health System have implemented routine testing in ERs. Want to expand to Baptist West Kendall and Jackson Health System Adolescent Emergency Rooms. Clinic hours and weekend availability created. Increased number of participating providers and mobile units .	The number of people using PrEP in Miami-Dade County almost doubled from 663 at the end of 2016 to an estimated 1031 people at the end of November 2017. Adherence is believed to be as good for PrEP as it is for ARV treatment, but providers are concerned about discontinuance by patients after 6 months of use. Established relationship with a local immigration service provider to provide monthly HIV testing and services to clients attending immigration clinics.
Updates provided by M. Brown			
4. Create a comprehensive HIV/AIDS communications toolbox 11. Expand the network of housing available for PLWHA, with particular attention to pregnant women, released ex-offenders, youth and other high-risk HIV-positive groups.	Florida Department of Health -- Central Office in Tallahassee Miami-Dade County - Homeless Trust, City of Miami HOPWA Program, Miami-Dade County Ryan White Part A/MAI Program	Created a comprehensive HIV/AIDS communications toolbox. Plans being made for a "Getting to Zero" campaign No progress reported	Creating a marketing campaign to educate providers on Florida Statute 381.004. The Statute mandates routine HIV testing in healthcare settings unless a patient chooses to opt-out. No progress reported
Updates provided by J. Garcia			
5. Convene a multi-agency consortium of public health/academic institutions/service providers to share data/collaborate on research identifying the driving forces of the HIV/AIDS epidemic in Miami-Dade County. 6. Decrease the lag time from diagnosis to linkage to HIV/AIDS care to within 30 days or less for: (1) clients newly diagnosed, (2) clients returning to care and (3) clients post-partum with HIV/AIDS, irrespective of where clients were diagnosed and where clients seek treatment. This action recommendation includes expanding the Department of Health´s „test and treat" program and other forms of fast-track post-diagnosis clinical engagement.	Florida Department of Health in Miami-Dade County Florida Department of Health in Miami-Dade County	No progress reported In 2016, the Test and Treat Rapid Access Program was launched to help newly diagnosed clients start ARV treatment as early as possible. Early treatment slows disease progression, decreases transmission, and provides access to medical care, support services, and other benefits.	Partnering with Florida International University's Stempel College of Public Health and Social Work to identify research needs and opportunities for collaboration. A 5-year strategic plan will be developed. Partnering with Ryan White Part A to expand the Test and Treat model to sub recipients Modified all 2018 testing site contracts mandating linkage to be completed within 30 days. Creating Linkage to Care Coordinator position to oversee linkage specialists Working with Ryan White Outreach committee to address linkage areas of opportunity
Updates provided by M. Guzman			
7. Increasing system capacity to bridge the gaps in provision of treatment and medication (and maintain PLWHA in care) when changes in income and/or residence create eligibility problems. 12. Create/expand a network of internal (in-jail) and post-release HIV/AIDS service provision to inmates in the Miami-Dade County jail system, to address viral suppression while incarcerated and effective linkage to medical / mental health / substance abuse /housing care upon release, including providing sufficient medication to effectuate continual viral load suppression during post-release linkage to care.	Florida Department of Health- Central Office Florida Department of Health in Miami-Dade County and Jackson Health System Correctional Services	Correctional Health Services is modifying their process to provide inmates upon release with a 30-day supply of medication. Hiring a linkage to care specialist for post-release HIV services. Jackson Health System Correctional Services in partnership with FDOH-Miami and South Florida AIDS Network will work on a plan to extend ARV medication supplies for 30 days post-release.	Hired a Linkage to Care Coordinator. No progress reported
Updates provided by D.M. Felder			
8. Enlist commercial pharmacies as HIV/AIDS treatment partners, from making PrEP and nPEP more available (see Recommendation #2) to having pharmacists alert HIV/AIDS care clinicians and/or case managers when antiretroviral (ARV) medications are not picked up on time 15. Build a county-wide system of HIV/AIDS program effectiveness evaluation, basing it on a common set of outcome measures across all providers.	Florida Department of Health - Central Office (Beal) Miami-Dade County Ryan White Part A/MAI Program Florida Department of Health in Miami-Dade County, Government of Miami-Dade County	In August 2017, Miami- Dade County RW Partnership created a Pharmacy Workgroup to explore barriers to accessing medications through ADAPT. Walgreens Minute Clinic will be starting a PrEP/nPEP pilot program at two locations with future plans to expand to all 17 locations. The program is scheduled to start in November 2017. No progress reported	RW Partnership created a commercial pharmacy with in-house clinical services to provide PrEP and nPEP. Trying to establish an nPEP standing order at a commercial pharmacy Urging revision of Florida Statute 348.3 to allow youth to access PrEP without parental consent. No progress reported
Updates provided by E. Dormevil			
9. Partnership with Managed Care Organizations (MCOs) and Medicaid for the purpose of data-matching and to allow Florida Department of Health (FDOH) to follow HIV-positive clients in managed care plans (public and private). 10. Develop a county-wide integrated system of HIV/AIDS care, including a county-wide treatment consent form and develop county-wide data-sharing system addressing various social service needs (transportation, legal services)	Florida Department of Health - Central Office FDOH-Miami Miami-Dade County Ryan White Part A/MAI Program Miami-Dade County Miami-Dade County RW Part A/MAI Program, Florida Department of Health in Miami-Dade South Florida Behavioral Health Network	No progress reported No progress reported	Data sharing agreement initiated with the Agency for Healthcare Administration (ACHA) to obtain health outcomes for Medicaid clients. Exploring the creation of a statewide Ryan White consent form. Meeting with County official to create a county-wide consent form.
Updates provided by T. Brown			
13. Identify root causes of HIV/AIDS stigma and reduce the stigma through education and communication programs directed toward Miami-Dade County´s multicultural and multiethnic communities and providers. 14. Reform and modernize Florida's current statutes criminalizing HIV non-disclosure.	Florida Department of Health in Miami-Dade County, Miami-Dade County Ryan White Part A Florida Department of Health - Central Office, State Legislative	Educational and communication campaigns to address stigma have been created. Plans are being made to develop a measure of stigma. Senate Bill 628 was proposed in the 2017 Florida Legislative sessions, but it failed to pass.	Ryan White support agency will be launching a plan to address stigma in January 2018 and will develop an indicator to measure stigma RW Partnership signed on as a community partner for the "Untransmittable=Undetectable" (U=U) campaign A "Dear Colleague" letter will be sent to Ryan White sub recipients and community agencies educating on the significance of the U=U campaign. The bill has been filed for consideration in the 2018 Florida Legislative

[Implementing G2Z Task Force Recommendations in Miami]

The impact of an interpersonal communication intervention on knowledge and uptake of the new Woman's Condom among young adults (18-24 years) in urban Zambia: A randomized evaluation

J. Pinchoff[1], C. Boyer[2], N. Taruberekera[3], N. Mutombo[4], R.N. Chowdhuri[5], T.D. Ngo[1]
[1]*Population Council, Population Gender and Youth, New York, United States,* [2]*Innovations for Poverty Action, New York, United States,* [3]*PSI, Evaluation, Johannesburg, South Africa,* [4]*Society for Family Health, Lusaka, Zambia,* [5]*Consultant, Lusaka, Zambia*

Background: There is a need to diversify contraceptive choices, particularly in settings such as Zambia which experience high rates of HIV (13.3%) and unmet need for family planning (27.1%). A new Female Condom (FC), the *Maximum Diva* Woman's Condom (WC), was introduced combined with social marketing in urban Zambia.
Methods: A cluster randomized controlled trial was implemented to determine the impact of an interpersonal communication (IPC) intervention on FC knowledge, perceptions, and use. A baseline survey (n=2,392) was conducted in March 2016. The WC was distributed throughout 40 urban wards comprising Lusaka, Zambia coupled with a mass media campaign. Twenty wards were randomly assigned the IPC intervention. After one year, an endline survey (n=2,430) was conducted. Models were fit to determine the impact of IPC on outcomes of interest including FC knowledge, male condom use, interest in trying a FC, a condom perceptions index and knowledge of modern contraception.
Results: Using an intention-to-treat approach, no change in outcomes between intervention and control wards was detected. While IPC agents were assigned to intervention wards, IPC attendees could be from any ward. Therefore, an average treatment effect on the treated approach was also explored. Using this approach to compare participants who attended IPC events to those that did not, an increase in FC knowledge (OR=2.47, 95% confidence intervals (1.36, 4.46)) and 79% improvement in perceptions of condoms index score (OR=0.21, 95% confidence interval (-0.04, 0.47)) was measured. Both models controlled for various demographic and sexual behavior characteristics. However, only 66 endline participants attended IPC events (3%). Process evaluation findings suggest low availability of the product (only 5% of randomly sampled outlets had it in stock), high variation in the intensity of the IPC, but high interest in using the product.
Conclusions: Overall, IPC resulted in a slight increase in FC knowledge among those who attended. There were several challenges to implementing an IPC intervention targeting such a general population of young adults in a large urban area, which may have resulted in insufficient saturation and intensity to see an impact comparing treatment to control areas.

TUPEE711

Trust but verify: Is there a role for active surveillance in monitoring adverse events in large-scale voluntary medical male circumcision programs?

P. Marongwe[1], C. Feldacker[2], P. Gonouya[3], T. Madoda[4], S. Balachandra[5], M. Tshimanga[4], J. Mandisarisa[5], V. Chitimbire[3], X. Sino[6], B. Makunike-Chikwinya[1], V. Murenje[1], S. Barnhart[2]
[1]*ITECH Zimbabwe, VMMC, Harare, Zimbabwe,* [2]*University of Washington, Global Health, Seattle, United States,* [3]*Zimbabwe Association of Church Hospitals (ZACH), VMMC, Harare, Zimbabwe,* [4]*ZICHIRE, VMMC, Harare, Zimbabwe,* [5]*Center for Disease Control Zimbabwe, VMMC, Harare, Zimbabwe,* [6]*Ministry of Health and Child Care, VMMC, Harare, Zimbabwe*

Background: Ensuring quality service provision is fundamental to ZAZIC's voluntary medical male circumcision (VMMC) program in Zimbabwe. ZAZIC (a name created by merging partners´ names) aims to create safe space to identify and manage adverse events (AEs); acknowledge surveillance weaknesses; and introduce quality improvement strategies. From October, 2014 -September, 2017, ZAZIC conducted 205,847 MCs. Passive surveillance recorded a moderate and severe AE rate of 0.2% and 95% follow-up visit adherence, suggesting program safety.
Description: To increase confidence in AE identification and improve reporting, ZAZIC implemented focused quality assurance (QA) at 6 conveniently-selected, high volume VMMC sites. ZAZIC Gold-Standard (GS) clinicians prospectively observed 100 post-VMMC follow-ups per site in tandem with facility-based providers to confirm and characterize AEs. Mentoring in AE recognition, reporting and management was conducted. GS clinicians also reviewed site-based routine VMMC data between Oct-Dec 2016, comparing recorded to reported AEs. Site leadership interviews noted strengths and weaknesses in AE-related issues.
Lessons learned: First, AEs identified using active prospective surveillance are considerably higher than passive surveillance: observations suggest AE rates from 1-5%. Most observed AEs were infections among clients under age 15. Second, facilities noted significant challenges in conducting VMMC follow-ups due to human resource and transport constraints. Although post-operative self-care appears to produce generally good results for adults, younger clients and guardians need additional attention to ensure quality care. Lastly, retrospective record review suggests discrepancies in AE documentation and reporting. Increased training in AE identification, management, and documentation matched with additional nurses and vehicles is needed. Evidence of missed severe AEs resulting in permanent impairment or morbidity was not found. This intensive QA activity required additional financial, transport, and human resources over routine program monitoring.
Conclusions/Next steps: Although results cannot be generalized, active surveillance suggests that AEs may be more frequent and follow-up lower than reported. Root causes for poor follow-up, poor documentation and/or poor reporting remain unclear and require further investigation. ZAZIC is responding with expanded active surveillance, accelerated refresher/retraining for clinical and data teams, improved post-operative counseling for younger clients, and creation of a Quality Assurance Task Force. ZAZIC will expand implementation of this QA effort.

Site	Reported Passive Surveillance: Oct 2014-Sept 2017			Observed Active Surveillance AE rate: Oct 2016-Dec 2016 (b)	AEs Expected** Oct 2014-Sept 2017 (ab)
	AEs*	MCs (a)	AE Rate		
1	10	14707	0.1%	5%	735
2	22	13892	0.2%	4%	556
3	30	8174	0.4%	4%	327
4	31	17908	0.2%	5%	895
5	25	11242	0.2%	5%	562
6	39	6727	0.6%	1%	67

*Moderate and severe AEs; **AEs expected (ab) was calculated by multiplying the number of MCa reported over the passive surveillance period (a) by the observed active surveillance AE rate (b) to estimate the AEs that may have actually occurred over the past reporting period.

[Table 1: Comparison of retrospective AE data to AEs observed through routine QA]

Implementation science: lessons from researcher / programme partnerships

focused on large cohorts of persons living with HIV to document and improve long-term treatment outcomes. Structural and contextual factors continue to pose challenges to the quality of data collected. We describe implementation challenges and opportunities in three hospitals in Cameroon, part of the Central Africa International Epidemiology Databases to Evaluate AIDS (CA-IeDEA).

Description: Using a mixed methods approach, including data source review, source data verification, data collection and management systems, and interviews with data collection staff and HIV care providers, we identified structural, contextual, and individual factors that impede quality data collection in the three IeDEA clinics in Cameroon. Thereafter, processes and mechanisms were implemented to address the challenges. Existing problems with data collection tools were also identified and addressed.

Lessons learned: Over 12000 patients have been consented and enrolled in the three Cameroon CA-IeDEA clinics. Patient treatment data are collected on paper forms and archived in a central location and entered in an electronic (REDCap) database. In 2017, we implemented measures to address existing challenges. These included retraining of data staff on good clinical practices and ethical conduct of research, providing standard operating procedures for data collection and management processes, implementing a rigorous monitoring and evaluation plan, and revising the staffing systems. Structural and contextual constraints to effective data collection included lack of coordination between caregivers and data collectors in various units, insufficient number of trained data processing staff, weak data tracking mechanisms, and inadequate infrastructure and equipment for collecting clinical information.

Conclusions/Next steps: Identifying and addressing structural, contextual, and personnel factors that impede the collection of quality data is essential in large cohort studies. Researchers and policy makers should be aware of and address these challenges prior to implementing cohort studies in resource limited settings.

TUPEE713

Research protocol considerations when working with male couples: Lessons learned from the field

A. Solomons, Together Tomorrow Study Team
Positive Vibes Trust, Windhoek, Namibia

Background: Two-thirds of new HIV infections among men who have sex with men (MSM) occur from primary partners. However, there is limited understanding of the unique behaviours, needs and challenges of male partnerships in African contexts. The Together Tomorrow study was the first study to our knowledge to explore the HIV risk taking behavior and prevention and treatment needs of male-male partnerships in Namibia and South Africa.

Description: This mixed methods study comprised of three phases:
1) formative work with community stakeholders;
2) focus group discussions and in-depth interviews with gay, bisexual and other MSM, and;
3) a quantitative survey, with optional HIV testing and counselling, with male couples. Recruitment and data collection was done by local implementing partners.

Lessons learned: Implementing research protocols is an iterative process that requires adaptability to various contextual (social, cultural, legal, political) considerations. In contexts where homosexuality is criminalised or highly stigmatised, community engagement and mobilisation becomes a scientific and ethical imperative. This was achieved through extensive community mobilisation with LGBT community-based organisations and gender sensitization of tribal authorities.

While the protocol initially prescribed gender-matching of researchers and participants, in practice, gender matching was not the preferred option for the male-couples who largely felt more comfortable speaking to female interviewers, mentioning that in general, men did not talk to other men about personal matters. Initial formative research also indicated that the eligibility criterion of a relationship of at least one month in duration would be too short a time to assess relationship dynamics, resulting in an amendment to 3 months for the survey phase. The uptake of optional HIV testing at both sites was considerably low. Participants' reasons for declining included concerns about pressure to disclose their status to their partner and inadvertent disclosure of an HIV positive status (a positive test takes a longer time with counsellor or emotional reactions to results).

Conclusions/Next steps: The development and application of research protocol is in itself a research activity, and should be adaptive to varying contextual factors. With LGBT+ in general, the contextual factors influencing the expression of sexual orientation and gender identity, should remain top of mind.

TUPEE714

Challenges in recruiting prisoners with opioid use disorder into HIV prevention using methadone: Lessons learned from program implementation in Kyrgyzstan

A. Kurmanalieva[1], N. Shumskaia[2], J. Rozanova[3], L. Azbel[4], K. LaMonaca[3], R. Marcus[3], J. Miceli[3], C. Bachireddy[5], F. Altice[3]
[1]AIDS Foundation East-West (AFEW) in the Kyrgyz Republic, Research Department, Bishkek, Kyrgyzstan, [2]AIDS Foundation East-West (AFEW) in the Kyrgyz Republic, Bishkek, Kyrgyzstan, [3]Yale School of Medicine, New Haven, United States, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]National Clinician Scholar, Veterans Affairs Medical Center, University of Pennsylvania, Philadelphia, United States

Background: Methadone is the most cost-effective HIV prevention strategy in Eastern Europe & Central Asia (EECA), where the HIV epidemic is volatile and driven primarily by injection drug use. As criminalization of drug use results in high incarceration rates, we conducted a longitudinal MATLINK study employing SBIRT (screening, brief intervention to expand coverage of methadone maintenance therapy (MMT), and linkage to treatment) to improve primary and secondary HIV prevention among prisoners with opioid use disorders in Kyrgyzstan. Here, we critically reflect on experiences of recruiting prisoners into MATLINK in Kyrgyzstan where prison-based MMT is available.

Description: Recruitment for MATLINK in Kyrgyzstan began in March 2017 in six (including one women's) prisons. Eligibility criteria were ≤1-year pre-release, plans for release near the capital city (Bishkek) and opioid dependence based on the Rapid Opioid Dependence Screen (RODS). While target enrollment was 100 participants, only 86 out of 894 screened prisoners were eligible for study recruitment based on the RODS, time to release, and region of release criteria (and 83 consented).

Lessons learned: Among 894 screened prisoners, only 128 (14.3%) reported using an opioid within one year pre-incarceration, and 106 (11.9%) met RODS criteria for pre-incarceration opioid dependence. In comparison, according to a nationally representative biobehavioral survey of Kyrgyz prisoners, 35% reported pre-incarceration opioid use (PUHLSE, 2014). MATLINK recruitment revealed that prisoners may be reluctant to disclose pre-incarceration opioid use during screenings for a health intervention study. This may reflect a social desirability bias, with prisoners mistaking abstinence during incarceration for long-term recovery, and believing they don't need addiction treatment. Prisoners, however, may report HIV risk behaviors like injection drug use in a confidential health survey not followed by linkage to care.

Conclusions/Next steps: Prisoners may underreport pre-incarceration opioid use at screening for HIV prevention interventions circumventing opioid dependence diagnosis tools. This has implications for design and implementation of HIV prevention programs using Methadone among prisoners who have injected drugs. Future studies may compare screening via a short biobehavioral survey with using the RODS. Qualitative interviews should also explore how prisoners may perceive recruitment into HIV prevention studies and what reservations they experience.

TUPEE715

HIV case finding and linkage to care in eleme local government area, Rivers State: *a comparative analysis of facility HIV services optimization and community based HIV intervention*

A.P. Emenike[1], O.D. Ekele[2], T. Badru[2], C. Agbakwuru[3], E. Oladele[4], O. Adedokun[3], G. Owhonda[5], H. Khamofu[6]
[1]Family Health International [FHI 360], Port Harcourt, Nigeria, [2]Family Health International [FHI 360], Monitoring and Evaluation, Port Harcourt, Nigeria, [3]Family Health International [FHI 360], Monitoring and Evaluation, Abuja, Nigeria, [4]Family Health International [FHI 360], Prevention Care and Treatment, Abuja, Nigeria, [5]Rivers State Ministry of Health, Public Health, Port Harcourt, Nigeria, [6]Family Health International [FHI 360], DCOP Technical, Abuja, Nigeria

Background: A combination of effective and efficient approaches are necessary for scaling up of HIV case-identification, particularly in resource-limited settings. To increase access and coverage, communities need to be linked to facilities via community-based interventions that seek to promote health seeking behavior. This study compares the effect of community based HIV testing services (HTS) to HTS optimization at the facility level.

Description: This is a pre-and post-intervention study conducted in Eleme, one of the priority LGA supported by the USAID funded Strengthening Integrated Delivery of HIV/AIDS Services (SIDHAS) in Rivers State. The pre-intervention phase (PIP1) covers the period November 2015 - October 2016 while the post intervention phase is from November 2016 - Oct 2017. PIP1 involved community entry/mobilization, HIV screening in general population, referrals and linkage to care and treatment services from the community to the facility, while the PIP2 focused on optimization of HIV testing services within the facilities through multipoint/Provider Initiated Testing and Counselling[PITC], targeted testing in the communities, Sexual Network and Genealogy Testing and referrals by escort to Service Delivery Points. We reviewed HTS and ART commencement data to compare differences in positivity yield and linkage between both phases.

Lessons learned: The PIP1 had 107,813 individuals counselled, tested and received result, 1,406 tested HIV Positive and 964 linked to ART while the PIP2 had 24,078 individuals tested, 614 HIV positive and 610 linked to ART. Findings show increase in positivity yield from 1% to 3% and linkage from 87% to 99% in PIP1 and PIP2 respectively.

Conclusions/Next steps: Although community outreaches create awareness, a targeted approach to HTS including sexual network/genealogy testing may be a more efficient approach. In addition, PITC in health facilities yields a higher positivity and linkage rates, maximizes use of testing resources by focusing on higher risk populations.

TUPEE716

Implementing proactive HIV testing in General Practice in Amsterdam within a fast-track city initiative (H-TEAM)

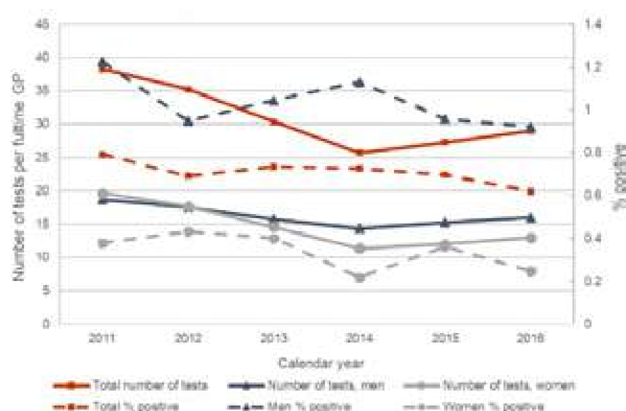
K. Groen[1], M.L. Groot Bruinderink[1], M.M. Kroone[2], G.J. de Bree[1,3], J.E.A.M. van Bergen[4,5], on behalf of the HIV Transmission Elimination AMsterdam (H-TEAM) Initiative
[1]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, [2]Public Health Service Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, [3]Academic Medical Centre of the University of Amsterdam, Department of Global Health and Division of Infectious Diseases, Amsterdam, Netherlands, [4]Academic Medical Centre of the University of Amsterdam, Department of General Practice, Division Clinical Methods and Public Health, Amsterdam, Netherlands, [5]STI AIDS Netherlands (Soa Aids Nederland), Amsterdam, Netherlands

Background: An estimated 300-400 individuals in Amsterdam live with undiagnosed HIV and 33% are diagnosed late. A recent study by our group showed that in the 5 years prior to HIV diagnosis, 60% consulted the GP with one or more HIV indicator conditions. To promote targeted and proactive testing by GPs we designed, implemented and evaluated several interventions, including multifaceted interactive training sessions for Amsterdam GPs using laboratory feedback.

Description: Since 2015, 171 of 545 Amsterdam GPs participated in these training sessions on HIV/STI testing behaviour, which included personal feedback and the development of practice-improvement plans. Additionally, all Amsterdam GPs receive a quarterly newsletter on HIV and can participate in an annual free HIV testing week. A unique dataset was generated by retrieving HIV and STI test request data (2011-2016) for each individual GP from all diagnostic laboratories they use (90% estimated coverage). Test request data were converted into an annual average per fulltime GP and HIV positivity rate, separated by gender.

Lessons learned: The training sessions were well-received (rating 8.5/10) and facilitated the development of quality improvement plans by GPs. Close collaboration between GPs, local GP-representing organisations and laboratories was key in developing and implementing the training sessions and database. Amsterdam GPs together request 10,000 HIV tests annually, with large inter-GP and inter-practice variation. We found a decreasing trend prior to 2015 from 38 HIV tests per GP in 2011 to 26 in 2014, followed by a slight increase to 29 in 2016 (figure, preliminary). Since 2014 more men than women are being tested. Over 30,000 tests for chlamydia and gonorrhoea are requested annually. Interestingly, anal testing for chlamydia and gonorrhoea, which GPs often neglect, doubled between 2014 and 2016.

Conclusions/Next steps: The decreasing trend in HIV/STI testing by Amsterdam GPs has reversed since 2014, coinciding with the start of the H-TEAM initiative. We are currently performing a subanalysis comparing GPs participating in training sessions to non-participating GPs. Upon receiving 2017 data we will conduct additional analysis on this unique dataset, including geospatial mapping. Detailed insight into testing behaviour by GPs will be essential for designing interventions that further curb the HIV epidemic in Amsterdam.



[Figure: Average number of HIV tests requested per fulltime GP and positivity rate in Amsterdam (total and separated by patient gender, preliminary)]

TUPEE717

Strengthening HIV and tuberculosis surveillance through intensified case finding in a prison in North-East India, 2017

T. Bhatnagar[1], M. Ralte[2], L. Ralte[3], Chawnglungmuana[4], L. Sundaramoorthy[1], L. Chhakchhuak[3]
[1]ICMR-National Institute of Epidemiology, ICMR School of Public Health, Chennai, India, [2]Mizoram State AIDS Control Society, Ministry of Health, Mizoram, Aizawl, India, [3]Govt of Mizoram, Department of Health and Family Welfare, Aizawl, India, [4]SHALOM, Aizawl, India

Background: Structural and individual level factors in prisons increase the risk of HIV/tuberculosis and create challenges towards detection and management. WHO and India's HIV/tuberculosis control programs recommend intensified case finding in prisons. The northeastern state of Mizoram in India is reported to have the highest HIV prevalence, driven by people who inject drugs. Currently low detection rates of HIV and tuberculosis points towards apparently poor infrastructure and ineffective implementation of existing surveillance strategies within the prison healthcare system in Mizoram's capital city of Aizawl. Our objectives

were to identify the barriers for routine case detection activities and assess the operational feasibility of implementing the intensified case finding strategy in Aizawl prison.

Methods: We conducted in-depth interviews and focus group discussions (FGD) with prison authorities/inmates, and state/district officials of HIV and tuberculosis control programs. Subsequently, we implemented the intensified screening through entry screening of new inmates, mass screening of resident inmates and exit screening at release for four months. We setup chest x-ray, sputum smear microscopy and HIV testing facilities within the prison and referral to external facility for Cartridge Based Nucleic Acid Amplification Test (CBNAAT). We did content analysis of transcribed text from in-depth interviews/FGDs using coding and themes and estimated proportions for key variables.

Results: We identified poor tuberculosis-related awareness among inmates, low risk perception during incarceration, negative attitude of healthcare providers, poor testing and referral infrastructure, lack of trained technicians, and absence of inmate tracking mechanism as key barriers. We screened 738 inmates (Male:626/Female:112). Of 391 (53%) having presumptive tuberculosis symptoms 145 (37%) underwent sputum microscopy. We detected 14 new tuberculosis cases; overall tuberculosis positivity 1.9%. We tested 431 (65%) of 657 inmates for HIV, of which 41 (9.5%) new cases were detected; overall HIV positivity 16.5%. Three males were HIV-tuberculosis co-infected.

Conclusions: It is feasible to implement intensified case detection in the prison setting albeit with challenges in sputum microscopy/CBNAAT and linkages with treatment facility outside the prison. Inter-departmental coordination along with upgradation of the prison health infrastructure are vital to overcome logistic, linkage & security barriers and establish a sustainable intensified surveillance system.

TUPEE718

The people living with HIV Stigma Index 2.0: Community-driven strategic information for change

B. Friedland[1], C. Mallouris[2], J. Hows[3], F. Anam[4], L. Sprague[3], L. Nyblade[5], S. Baral[6], A. Gottert[7], J. Pulerwitz[7], S. Geibel[7]
[1]Population Council, NY, United States, [2]UNAIDS, Geneva, Switzerland, [3]GNP+, Amsterdam, Netherlands, [4]ICW, Nairobi, Kenya, [5]RTI, Washington, DC, United States, [6]Johns Hopkins University, Baltimore, United States, [7]Population Council, Washington, DC, United States

Background: The People Living with HIV (PLHIV) Stigma Index is the most widely used global survey measuring stigma and discrimination among PLHIV. Launched in 2008, and administered by PLHIV to their peers, the Stigma Index has generated evidence that has been used to identify the extent of stigma and its effects, and to influence policy. Shifts in the HIV response, including an increased focus on HIV treatment and care, prompted the original developers (GNP+, ICW, and UNAIDS) to work with Population Council/Project SOAR and partners to update the tool.

Description: A small working group (SWG) was established to guide an iterative update process with representatives from GNP+, ICW, UNAIDS, USAID and researchers from the Population Council, Johns Hopkins University and RTI. The SWG outlined a process for evaluating, updating, pre-testing, and pilot-testing the revised Index.

Lessons learned: Based on a desk review of 13 country reports and 4 regional reports; input from 15 key informants; and a 2-day stakeholder consultation (April 2016), both topical and methodological aspects of the Stigma Index were identified for updating. In addition to restructuring and streamlining the original instrument, the healthcare section was expanded, with an emphasis on the impact of stigma and discrimination on access to HIV care and treatment. Modules were added to assess stigma and discrimination among sex workers, men who have sex with men, lesbians, transgender individuals and people who inject drugs. Validated scales that assess internal stigma and mental health were incorporated and a new scale to measure resilience was added. Feedback from 60 PLHIV who pre-tested a draft of the updated questionnaire was incorporated before the formal pilot study was conducted in Cameroon, Senegal and Uganda among 1207 respondents. Results of the pilots indicated good variability in responses for most questions; a few minor adjustments to the questionnaire were made and the Stigma Index 2.0 was shared in November 2017.

Conclusions/Next steps: Results from pilot testing the Stigma Index indicate the updated questionnaire performs well in sub-Saharan Africa. Other countries are encouraged to implement the Stigma Index 2.0 to expand the body of evidence from a range of experiences and settings

Effective approaches to linking population and programme data, to inform HIV programming

TUPEE719

Measuring behavioural and health seeking outcomes among people who inject drugs using the Polling Booth Survey (PBS) in Kenya

J. Musimbi[1], S.J. Malaba[1], J. Kioko[2], S. Kaosa[2], P. Bhattacharjee[3], H. Musyoki[4]
[1]Partners for Health and Development in Africa (PHDA), Key Populations, Nairobi, Kenya, [2]Partners for Health and Development in Africa, Technical Support Unit-Key Populations, Nairobi, Kenya, [3]University of Manitoba, Community Health Sciences, Nairobi, Kenya, [4]National AIDS and STI Control Programme, Key Populations, Nairobi, Kenya

Background: People who Inject Drugs (PWIDs) in Kenya are characterized by high levels of risk in terms of their injecting practices through sharing of needles and 8.8% of PWIDs are women of age 15-49 years. PWIDs have a HIV prevalence rates at 18.3% (NASCOP 2013). Kenya conducted three rounds of nationwide polling booth survey (PBS) in 2014, 2015 and 2017 to measure changes in behavior of PWIDs as a result of program interventions and understand if the PWIDs programs are achieving their intended effects.

Description: PBS is a group interview method, where individuals give their responses through a ballot box. Individual responses are anonymous and unlinked. Anonymity of the respondent improves reporting on sensitive and personal behaviors. Participants were selected using probability sampling and organized into small homogenous groups of 10-12 people. During the third PBS, we included groups for the young PWIDs. A total of 87 polling booth sessions were conducted involving 1131 PWID (both men and women), representing 97% of the sample size. The age distribution among the PWID was 25% 24 years and below and 75% 25 years and above.

Lessons learned: A new needle and syringe were used by 88% of PWID the last time they injected and there was no difference between the old and young PWIDs, but 13% of PWID shared their needle when they last injected compared to 16% who shared during the previous PBS. When asked about condom use at last sex with a non-regular partner, 76% responded that they used a condom. Condom burst when last a condom was used was at 17% for the old PWID and 26% for the young PWID. Out of those who took part in the PBS, 20% were positive, with 78% and 68% on care and ART respectively. The percentage of PWID who experienced sexual violence increased from 8% to 12%.

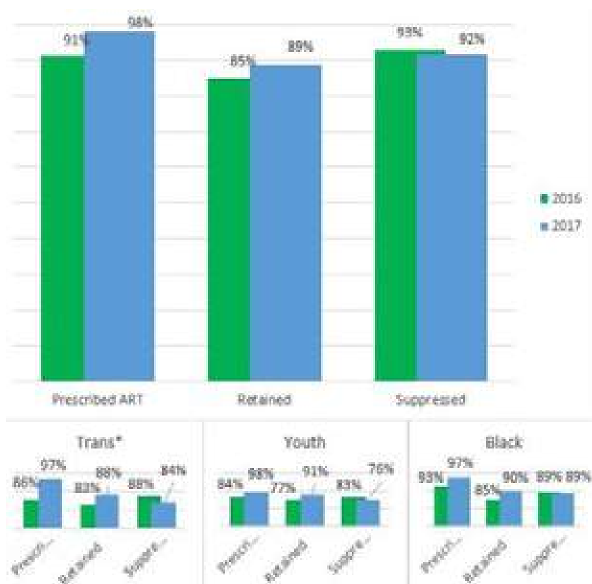
Conclusions/Next steps: Responding to HIV programming needs of PWIDs at scale is key ingredient in national HIV response. As programs with key populations scale up in Kenya, it is important to measure KP programs effectiveness. Behavioural surveys like PBS that can measure sensitive behaviours should be part routine National monitoring.

TUPEE720

HIV treatment cascades: A community health framework for addressing HIV quality improvement

P. Carneiro[1], M. Domingo[1], P. Hawley[1], S. Mosher[1], A. Fortenberry[2], P. Meacher[2], A. Radix[2]
[1]*Callen-Lorde Community Health Center, Population Health, New York, United States,* [2]*Callen-Lorde Community Health Center, New York, United States*

Background: HIV Treatment Cascades (HTCs) have tracked worldwide achievement on 90-90-90 UNAIDS goals. While HTCs are excellent visualizations to assess the impact of HIV quality improvement, little is known about their application in community health practice. In 2017, Callen-Lorde - the largest LGBTQ Community Health Center in NYC - created a strategy to improve the quality of our HIV care in 2017 based on HTCs. We discuss here the implementation, impact and outcomes of our approach.
Description: We obtained four nested indicators for 2016: Active Caseload- patients receiving HIV primary care; Prescription of Antiretroviral Therapy (ART); Retention- patients receiving a primary care visit in the 6 months prior to the end of the year; and Viral Load Suppression (VLS)- patients with viral load of < 200 copies/ml. We also investigated several subgroup categories: transgender identity, Black race, and youth (=< 25) to assess their unique outcomes. Overall, our population achieved 91-85-93. The achievement in subgroups was: Transgender (86-83-88), Black (93-85-89), Youth (84-77-83). Based on these outcomes, our HIV program team set forth a set of 2017 quality improvement initiatives including: A Rapid ART initiation program, a redesigned multidisciplinary HIV intake linking all newly diagnosed (NDs) to social support and navigation, sharing quarterly cascade data on internal systems and social media, installing an open-access program to eliminate challenges in appointment adherence and implementation of a VLS cash-incentive program for women, youth & transgender folks.
Lessons learned: HTCs can be successfully used in community health settings to assess gaps in care, guide quality improvement and organize multidisciplinary teams maximizing impact. Reducing barriers to care through open-access programs and service navigation has been key to patient retention, and Rapid ART initiation has been essential for VLS. Data sharing has contributed greatly to patient education and collective goal setting. Our cash incentive program has proven impactful in its nascent phase. Our 2017 HTC shows overall achievement of 98-89-92 (Figure 1).
Conclusions/Next steps: HTCs should be used in community health settings to develop and implement HIV quality initiatives. HTCs can support data-sharing, community education, and cooperative multidisciplinary interventions. In this, subgroup analyses are indispensable to ensuring impact on key populations.



[Figure 1. Depicting the 2016 and 2017 HIV Treatment Cascade. Selected Subgroup Analysis shown below]

TUPEE721

Virtually found: A differential approach of community mobilization for MSM and TGs on social media platform for HIV screening

S. Kandaswamy[1], U. Chawla[2], R. Sarkar[2], V. Arumugam[1], S. Mehta[3]
[1]*India HIV/AIDS Alliance, Strategic Information, New Delhi, India,* [2]*India HIV/AIDS Alliance, Program & Policy, New Delhi, India,* [3]*India HIV/AIDS Alliance, Chief Executive, New Delhi, India*

Background: The HIV epidemic in India remains concentrated to key population groups. HIV prevention among FSWs, MSM and TGH is changing rapidly. The National HIV/AIDS programme is investing heavily on focused prevention via physical outreach through targeted interventions (TIs) spread across the country for the key population. However, in the current context especially among FSW, MSM and to some extent TGH, soliciting clients and potential sexual partners is increasingly becoming virtual due to increased access to technology such as internet and mobile applications via the use of smart phones and computers.
Methods: India HIV/AIDS Alliance conducted a rapid assessment of most frequented sites on the internet used for finding potential sexual partners by MSM and TGs. We also identified potential social platforms such as Grinder, BlueD, Planet Romeo, Facebook, Instagram and Tinder to reach out MSM and TGH community. Communication materials were posted on those platforms to identify and contact individuals, offering them HIV prevention messages as well as free, confidential and community friendly HIV screening services via the Samarth programme sites for one month period. Data were collected and analysed on the output. Comparative analyses was carried out between physical contact and social media contacts.
Results: Total MSM and TGs that came to Samarth clinic via social media exclusively was 1,229 (MSM 829, TG 13 and not specified 387). This has resulted in an increase in reaching Samarth via social media exclusively from 6% to 45% (after). Majority of the respondents were between 25-34yrs (60%), graduates (50%) and salaried/employed (60%). Proportion of individuals reached by via social media strategy as compared to physical outreach under the programme and is willing to take an HIV test is 4:1.
Conclusions: India is now struggling to develop its next generation HIV prevention programming. There is a clear realisation of the fact that internet, smart phone applications etc. have to be addressed.

TUPEE722

Developing a standardized tool for data use and decision-making to estimate the human resources for health (HRH) requirements for implementing differentiated care for HIV in high burden settings

S. Kironde[1,2], R. Berger[2,3], A. Hurst[4], E. Kleinau[1,2]
[1]*University Research Co., LLC, Chevy Chase, United States,* [2]*Human Resources for Health in 2030 (HRH2030) Program, Arlington, United States,* [3]*Chemonics International Ltd., Arlington, United States,* [4]*United States Agency for International Development (USAID), Arlington, United States*

Background: The adoption of the 'Test and Start' strategy to accelerate the achievement of the 90-90-90 goals has increased the number of PLHIV receiving ART. Stable ART clients often do not require the same level of clinical oversight and could receive services through alternative models, allowing limited HRH to see those clients who require regular monitoring.
Service providers have identified differentiated service delivery (DSD) models of care for clinically stable ART clients as a way to provide services more efficiently. Estimating and optimizing available or required human resources becomes the next requirement. To aid in decision-making for implementation and resource allocation, the HRH2030 program, funded by USAID, through PEPFAR, developed a simple, client-focused tool that guides users for standardizing estimation of HRH needs.
Methods: From August to December 2017, data were collected from 20 experienced ART clinics and community-based service points in Uganda (see table) that manage about 62,000 clients. The information obtained was used to benchmark client-service provider contact time

for critical tasks performed along the HIV service delivery continuum under different DSD models. Key data collected included: annual ART client caseloads (new and current); client classifications (stable, unstable) as well as by sub-population; DSD models implemented; service provider types, numbers, task distribution and level of effort.
Client flows for 395 ART recipients were observed for a total of 1,720 critical task observations over a period of over 64,000 minutes. Using these data, a prototype tool that estimates HRH need based on the users' client load and workforce was developed and piloted in Cameroon and Uganda. Expert stakeholder interviews were also utilized to fine-tune the tool.
Results: The tool contains algorithms that enable users to estimate HRH needs from the annual ART client caseload and allows the building of scenarios for workforce mix and task- sharing/shifting for optimizing resource allocations. Results from a pilot in Cameroon suggest it helps facility staff make more informed HRH decisions.
Conclusions: Use of DSD models globally is rapidly expanding. Two country pilots have shown promising value for this tool. Implementation in additional settings will gauge further utility, accuracy, areas for additional refinement, and options for country-specific contextualization.

TUPEE723

Fast Track VCT@Work for workers in informal sector to achieve 90:90:90 in India

R. Bhushan, A. Verma, N. Goel, R. Rana, N. Rawat, N. Pandey
National AIDS Control Organization, Ministry of Health & Family Welfare, Govt. of India, New Delhi, India

Background: An emerging trend of HIV positivity among workers engaged in informal sector is a major concern. In India, the HIV positivity among workers in different occupations is much higher than national adult HIV prevalence (0.25%). Due to non-availability of adequate evidences the workers in informal sector are not reached. Early detection and linking them with preventive services is challenge.
Methods: National AIDS Control Organisation (NACO) collected data from 16000 ICTC on testing done across the country for the period of 2013-2016. The data was analysed to understand source of referrals & occupation sectors; trends across gender, age and occupation sectors across districts, and State-specific trends among various occupational groups. During the said period, around 32.45 million of HIV tested were conducted and analyzed. Out of which 20.69 million (65%) had worker representation.
Results: The analysed data showed that the overall HIV sero-reactivity among workers is 1.39% with sero-reactivity 1.61% reported during 2014-15 and 1.77% during 2013-14. Sero-reactivity is four times higher than HIV prevalence among general population. HIV positivity among truckers is 2.30% which is continue to be significantly high as compared to other groups like transport workers (1.69%), petty business (1.38%), agriculture (1.37%), hotel staffs (1.28%), domestic workers (1.06%) etc. Analysis also indicated the demarcation of specific occupations sector in geographical distribution that need focus intervention. The analysis was shared with key stakeholders at national and state levels for developing specific strategies to reaching out to these categories. As a result, partnership formalised with 16 Ministries for sustainable engagement, 315 Industries are mobilized and 55000 workers trained. Directives from national level for fast track VCT@Work with expansion of services like ICTC, STI Clinic, ART Centre are issued.
Conclusions: The analysis of HIV testing data is proven strategy to strengthen HIV/AIDS intervention targeted to workers in various occupations. Analysis and evidence helped to engage Ministries, industries and other stakeholders for worker education, prevention, reduce stigma & discrimination, early detection and link them with services as well impact mitigation through social protection.

TUPEE724

Reaching the uncircumcised through community HIV testing services (HTS): Are mobile men creating regional circumcision prevalence discrepancies?

A. Christensen[1], C. Casalini[1], D. Boyee[2], A. Mwanamsangu[3], E. Nesso[1], R. Bandio[1], I. Sanga[1], S. Mmbando[4], G. J.I.Lija[4], E. Mlanga[5], J. Zoungrana[3], A. Komba[1], J. Reed[6], K. Curran[6]
[1]Jhpiego, Program, Dar es Salaam, Tanzania, United Republic of, [2]FHI360, Dar es Salaam, Tanzania, United Republic of, [3]Jhpiego, Research, Dar es Salaam, Tanzania, United Republic of, [4]NACP, Dar es Salaam, Tanzania, United Republic of, [5]USAID, Dar es Salaam, Tanzania, United Republic of, [6]Jhpiego, Baltimore, United States

Background: Tanzania's voluntary medical male circumcision (VMMC) program reached over 2.5 million males in regions with low male circumcision coverage and high HIV prevalence. Modeling, using the Decision Makers' Program Planning Toolkit 2, indicates many scale up districts are approaching 80% male circumcision coverage. Sauti, a PEPFAR/USAID-funded project in Tanzania, offers community-based combination prevention services, including HTS, to key and vulnerable populations (KVP), including mobile men and partners of female sex workers, and refers HIV negative, uncircumcised men to VMMC services.
Methods: We reviewed program data across ten Sauti regions between August 2015 and September 2017 to determine circumcision prevalence for men served by HTS. We reviewed HIV negative male clients and their self-reported circumcision status. Further analysis was conducted determining their resident or non-resident status of region where they received HTS (as a proxy for mobility). A two-population proportions z-test was used to compare the region prevalence of circumcision between 2015 Tanzania Demographic Health Survey and Sauti.
Results: Among 578,126 men reached through HTS, 533,371 (92.3%) responded to the question about past circumcision, and 55.6% reported being circumcised. HIV negative men reached by Sauti's program self-reported circumcision at much lower rate compared to the 2015 TDHS circumcision prevalence in 9 of the 10 regions Differences were statistically significant ($p < 0.001$). The three regions with the largest differences between Sauti and TDHS estimates (Dodoma 51% vs 100%, Morogoro 41% vs. 99%, Dar es Salaam 60% vs. 93%, respectively) are all considered 'traditionally circumcising' regions; they do not have VMMC programming. Further analyses of uncircumcised men receiving HTS in these three regions indicated that 35% on average were non-resident, indicating that they had recently moved.

Region	# Males reporting to be circumcised (Sauti project 2015-17)	# Males reporting to be Uncircumcised (Sauti project 2015-17)	Total Males responding to circumcision question (Sauti project 2015-17)	% Males reporting to be circumcised (Sauti project 2015-17)	Male circumcision prevalence (TDHS 2015)	% Difference in circumcision estimates between TDHS and Sauti	P-value
Dodoma	358	340	698	51	100	49	<0.001
Arusha	5,307	5,010	10,317	51	91	40	<0.001
Kilimanjaro	28,410	24,171	52,581	54	100	46	<0.001
Morogoro	930	1,331	2,261	41	99	58	<0.001
Dar Es Salaam	73,955	48,366	122,321	60	93	33	<0.001
Iringa	12,445	9,410	21,855	57	80	23	<0.001
Mbeya	34,901	53,983	88,884	39	55	16	<0.001
Tabora	32,851	47,274	80,125	41	62	21	<0.001
Shinyanga	34,676	71,553	106,229	33	54	21	<0.001
Njombe	20,804	27,296	48,100	43	67	24	<0.001
Total	244637	288734	533371	46	-	33.7	<0.001

[Table 1. Circumcised versus uncircumcised men by region, Sauti project versus TDHS]

Conclusions: Given discrepancies in circumcision prevalence, further investigation is warranted to determine why a substantial proportion of uncircumcised males are presenting for HTS in regions where circumcision is considered nearly universal according to TDHS, and whether this is due to the mobility of these men. Community-based HTS are reaching large numbers of uncircumcised HIV negative men, suggesting a potential role for direct provision of adult circumcision services in combination prevention package in regions not typically served by VMMC programs.

TUPEE725

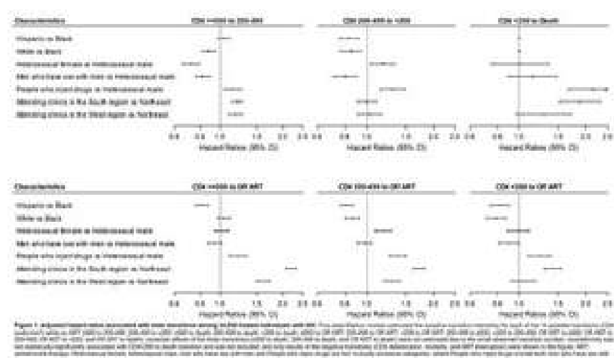
Combined estimation of disease progression and antiretroviral therapy retention among treated individuals with HIV in the United States

L. Wang[1], J. Eun Min[1], A. Nijhawan[2], C. Somboonwit[3], J. Aberg[4], R.D. Moore[5], K. Gebo[5], B. Nosyk[1,6]
[1]BC Centre for Excellence in HIV/AIDS, Health Economic Research Unit, Vancouver, Canada, [2]University of Texas Southwestern Medical Center, Department of Internal Medicine, Dallas, United States, [3]University of South Florida Morsani College of Medicine, Department of Internal Medicine, Tampa, United States, [4]School of Medicine at Mount Sinai New York, Department of Medicine, New York, United States, [5]John Hopkins University School of Medicine, Department of Internal Medicine, Baltimore, United States, [6]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada

Background: Accurate estimates of rates of disease progression and antiretroviral therapy (ART) retention are critical to mathematical HIV models designed to inform resource allocation decisions. We aim to jointly estimate on-ART CD4 progression, mortality, and ART interruption rates, and to examine variations in these rates by geographic region and individual characteristics, using a continuous time multi-state Markov model.

Methods: Data were obtained from the HIV Research Network cohort, a consortium of adult and pediatric clinics in the United States. Individuals aged 15 years or older who were in care (having at least one CD4 test and one HIV primary care visits) and had at least one ART prescription between 2010 and 2015 were included in the analysis. Study entry was defined as the date of their first CD4 test while on ART between 2010 and 2015. Continuous-time multi-state Markov models were used to estimate the transitions among five states (on ART CD4 cells/µL: ≥500; 200-499; < 200; off ART; and death), operationalized by a matrix with 14 possible instantaneous transitions. Covariates were included to examine and adjust for differences in the transition rates by region, race/ethnicity, gender, HIV risk group, and clinical status.

Results: The median age at study entry of the 34,656 individuals included in this analysis was 44.5 years [IQR: 35.0, 51.3]. Over a median of 4.5 years of follow-up [2.8, 6.0], 44.8% of individuals interrupted ART, and 3.8% of individuals died. In the multivariable analysis, black race, people who inject drugs, and attending clinics in the south or west regions, were independently associated with increased rates of ART interruption, and faster disease progression (CD4 decline or death) (Figure1). The differences remained statistically significant after additionally adjusting for age, time since diagnosis and CD4 counts at ART initiation among a subset of study sample with known ART initiation dates.



[Adjusted hazard ratios associated with state transitions among 34,656 treated individuals with HIV]

Conclusions: This study reveals heterogeneities in disease progression on ART and ART retention rates across racial and ethnic groups, HIV risk groups and regions. These differences represent potential targets for intervention and otherwise should be incorporated in mathematical models of regional HIV micro-epidemics in the United States.

TUPEE726

Geospatial linkage of community and secondary data to focus HIV programmes for impact: The tale of two provinces

C.P. Rousseau[1], N. Slingers[2]
[1]SANAC, Edenvale, South Africa, [2]SANAC, Pretoria, South Africa

Background: Focus for Impact is the key principle described in the National Strategic Plan for HIV, TB and STIs (NSP) 2017-2022, that describes South Africa's strategy to deal with these epidemics. Focus for Impact is an innovative approach to reduce the morbidity and mortality associated with HIV by designing and packaging appropriate interventions that target the areas with the highest disease burden and populations disproportionately at risk of new infection, geospatially linking community and secondary data. The concept was piloted and refined in two provinces in South Africa.

Description: The Focus for Impact approach sets out to systematically answer four key questions:

1 - **Where** are the HIV high burden areas *(spatial location using geospatial data)*?

2 - **Why** are these high burden areas *(associated risk profile using secondary data)*?

3 - **Who** is at increased risk of new infection is these high burden areas *(population specific data)*?

4 - **What** are the multi-level multi-sectoral high impact interventions *(tailored interventions)* that should be put in place to reduce the HIV burden in this area?

Lessons learned: Differences in success of implementation of the Focus for Impact approach in the two provinces is due to differences in levels of maturity of information systems, community engagements structures and district coordination structures. One of the most important lessons learnt was that "perfect" data may not exist, yet sufficient geospatial, community and secondary data exist to lay the foundation for HIV programming decisions. For Focus for Impact to reach its potential, deliberate steps need to be taken to ensure that it receives the buy-in and support from political and administrative layers within society - from national, through provincial, district and ward layers.

Conclusions/Next steps: At its core, Focus for Impact is a useful decision-making tool that can be updated and reviewed regularly and allows decision-makers to adjust interventions and areas of focus within a specific geographical area, for timely and high impact interventions. The Focus for Impact approach has been refined, incorporating lessons learnt, and is now being implemented across all 9 provinces in South Africa where it is included in the Provincial Implementation Plans for the NSP.

TUPEE727

Facility level cascades: Uniting public health and clinical data through a government-led initiative to improve programming

B.D. Agins[1,2], D.J. Ikeda[1,2], L. Hollander[2], S. Weigl[2], S. Sawicki[2], D. Belanger[2], C. Wells[2], N.B. Magnani[2], C. Steinbock[2], N. West[2], L. O'Shea[2], J. Morne[3]
[1]UCSF, HEALTHQUAL, Institute for Global Health Sciences, San Francisco, United States, [2]New York State Dept of Health AIDS Institute, Office of the Medical Director, New York, United States, [3]New York State Department of Health, AIDS Institute, Albany, United States

Background: National and local HIV public health programs have used the HIV treatment cascade to shape implementation of strategies for epidemic control however they have not engaged clinical care facilities in this public health initiative. To address this gap, the New York State

Tuesday 24 July

Author Index

(NYS) Department of Health AIDS Institute developed a model of facility-level cascades that drives improvements in healthcare organizations to focus on gaps identified through measurement of indicators defined by the cascade.

Description: Quality measures were embedded in a cascade framework that included identification of PLWH accessing any service in a health-care facility, whether or not provided in an HIV program. Care status was ascertained for all patients who were subdivided into "open" (unlinked) and "active" (enrolled) groups. New and established patient cascades were required that included measures of linkage, ART and viral suppression (VS), together with formal reports on methodology and improvement plans. Quality coaches were available to provide technical support. Sites were targeted for assistance based on need.

Lessons learned: Cascades were designed and submitted from 268 sites representing 82 healthcare organizations. Among 23887 PLWH receiving non-HIV services, the care status of 17236 was not ascertained or documented to ensure engagement in care. Mean VS was 79% for active patients (range 0-100%; 75th percentile = 89%). Providers identified novel ways to combine data sources to mine information leading to identification of PLWH touching their institutions but not engaged in HIV care. When seen in emergency, acute care or non-HIV ambulatory care settings, HIV care status of "open" patients was often not ascertained to determine if they were linked to care, on ART or suppressed. Gaps were noted for established patients when results were disaggregated by key population groups. Improvement plans were refined to address all gaps identified in the cascade analysis.

Conclusions/Next steps: Facility-level cascades were successfully implemented as a NYS government-led strategy to End the Epidemic. Visual display of data facilitated engagement of healthcare providers in epidemic control activities. Engagement in care of open patients is prioritized for statewide program improvement. The facility-level cascade methodology for quality measurement offers an innovative and important tool for integrating QI into public health initiatives.

TUPEE728

Nutrition and food security status of PLHIV and gap analysis in comprehensive care clinics in Kenya

M. Josephine Muthoni[1], C. Ouma[2], M. Mumma[2]
[1]UN World Food Programme, VAM, Nairobi, Kenya, [2]UN WFP, Nairobi, Kenya

Background: Kenya is one of the UNAIDS fast track countries and global plan PMTCT countries. High levels of malnutrition and food insecurity exist in the arid and semi-arid areas in turn affecting PLHIV and their households. In 2017, Kenya experienced a serious drought leaving 3.1 million people food insecure. However, there was no clear data on the impact of the drought on PLHIV and the country's HIV response. Nutrition and food security status of PLHIV accessing treatment was assessed to guide decision making on appropriate nutrition and food support interventions for comprehensive treatment packages.

Methods: Descriptive cross-sectional national survey that sampled 3690 respondents, (2790 adults and 900 children) from 31 Comprehensive Care Clinics (CCCs) in 10 national AIDS and STI Control Programmed (NASCOP) operating regions. Target population were clients aged from 6 months onwards enrolled at CCCs. Three categories of clients considered; clients on prophylaxis not on ART; on ART < six months and on ART > six months. SPSS v.18 and WHO Anthro softwares were used.

Results: Thinness was more prevalent in males: Pre- ART 26.1%, Early ART 22.5% and Late ART (22.0 percent) than in the females (12.6 %) among Pre- ART, (14.9%) among Early ART and (13.7 %) among Late ART. Overweight/obesity was (23 %, 15.7 % and 20.4 %) in Pre- ART, Early and Late ART respectively. Late ART females presented with the highest prevalence of overweight/obesity 28.0 % and Early ART male clients had the lowest prevalence (5.8 percent). More boys (53.3%)than girls 36.9% were stunted among children 24-59 months(p=0.04). Severe thinness was higher in boys (14.3 %) compared to girls (11.3 % (*P=0.773*).

In adults, Food Consumption Score(FCS) was acceptable (>35). (88 %, 85 %, and 83 %) of Early ART, Pre- ART and Late ART respectively, had acceptable FCS (FCS>35). 10 to 13 %had borderline FCS (21.5-35), while 5 % had poor FCS (0-21).

Conclusions: Men and women are presenting different forms of malnutrition. Underweight in children and men, and overweight in females depicts the challenge of managing the double burden of malnutrition in PLHIV and calls for interventions that take into cognizance the emerging trend.

TUPEE729

Next generation HIV programming for sub to middle income countries for MSM

U. Chawla[1], R. Sarkar[1], V. Arumugam[2], S. Kandaswamy[2], S. Mehta[3]
[1]India HIV/AIDS Alliance, Programme and Policy, Delhi, India, [2]India HIV/AIDS Alliance, Strategic Information, Delhi, India, [3]India HIV/AIDS Allliance, Delhi, India

Background: The context of HIV prevention among women in sex work, men who have sex with men and transgender is changing rapidly. In urban settings, key population groups who traditionally were available to HIV services and outreach at identified "hot spots", are diminishing and away from HIV programming. In the current context, especially among women in sex work, MSM and transgenders, soliciting clients and potential sexual partners is increasingly becoming virtual due to increased access to technology such as internet and mobile applications.

Methods: Dedicated and differential approach of community mobilization on social media platform such as Grinder, BlueD, Planet Romeo, Facebook, Instagram and Tinder - via the co-investment grant to venture into virtual space with an existing campaign "Pata Lagao" - meaning "Find out" that literally translates to "Find out your HIV status" to experiment and assess, if virtual outreach has any impact on increasing uptake of services including testing for HIV.

Results: Source of information for visiting clinic being social media increased from 6% to 45% in two months. 1,229 (*MSM-828, TG-13 and not specified - 387)* new individuals were contacted and provided information on HIV prevention and the project services. Of the 1,229 reached, 44% showed interest or agreed to visit Samarth Clinics. 132 (MSM 119 and TG 13) individuals reached the clinics and were tested for HIV and provided prevention services or linked to treatment, care and support services as the case may be. The monthly average of outreach has also significantly increased from 521 (Before) to 763 (after). HIV testing as one of the most important result, the success rate is 90% for physical outreach as compared to 11% for virtual outreach.

Conclusions: Experience from an initiative in five urban sites in India provides evidence that with right messaging, focused virtual outreach and accessible community friendly HIV services - key population groups such men who have sex with men and transgender can be reached and they are willing to come forward to access services. Investing in newer approaches to HIV prevention programming is the need of hour if we need to stay ahead in fight against HIV and AIDS.

TUPEE730

Strengthening strategic information to enhance geographic prioritization of harm reduction services in Kenya

S. Ayon[1], O. Mlewa[1], J. Ndimbii[1], G. Mburu[2], B. Wang[3], A. Ragi[1], F. Muturi[4], S. Ikonya[5]
[1]KANCO, Nairobi, Kenya, [2]Lancaster University, Lancaster, United Kingdom, [3]International HIV/AIDS Alliance, Brighton, United Kingdom, [4]KANCO, Kajiado, Kenya, [5]KANCO, Nakuru, Kenya

Background: Since 2012, KANCO has been implementing HIV and Harm reduction services through a blended service provision approach which brings together county government, law enforcement and community organizations to enhance access to these services for People who use drugs (PWID) and mitigate stigma and discrimination. However, scarcity of data regarding the size and locations of drug users has limited implementation of harm reduction services. To date, harm reduction services in Kenya have been concentrated in Nairobi and Coastal towns where relatively good data exists. However anecdotal evidence indicates increasing drug use in-other parts of the country.

Methods: As part of the Alliance Integrated Harm Reduction Project (AIHRP) funded by the International HIV/AIDS Alliance, KANCO conducted a number of size estimation exercises to enhance availability of strategic information to inform harm reduction and HIV programming. A size estimation exercise was conducted in Nakuru and Kajiado Counties in 2017 using a combination of peer driven snowballing methods, focused group discussions and Key informants interviews.
Results: In Nakuru and Kajiado Counties, there are an estimated 575 and 163 People Who Use Drugs (PWUDs) respectively. Out of these, People Who Inject Drugs (PWIDs) comprised 43% (n= 249 and 70) respectively. Results also suggested that majority of these people who use drugs were unreached with HIV prevention, treatment and care services. Majority of them also reported, multiple incidences of stigma and discrimination, and difficulty accessing harm reduction services, such as clean needle and syringes, Methadone, SRHR and TB services.
Conclusions: These results show that drug use and injecting is prevalent in smaller towns in Kenya, and is not just confirmed to Nairobi and the Coast. To ensure scale-up and universal access to harm reduction interventions, enhanced capacity and coverage of harm reduction is essential even in smaller towns. In addition, continued advocacy for community involvement, collaboration with local governments to fund/implement comprehensive harm reduction services, collaboration with law enforcement agencies, and use of blended outreach are all required to facilitate ease of access to services and mitigate stigma and discrimination directed at drug users.

TUPEE731

The importance of establishing baseline data for viral load testing scale up - laboratory assessments Zambia experience

B. Gorogodo[1,2], F. Marange[1,3], L. Stewart-Isherwood[1,4,5], T. Taleng[1,5], K. Chigudu[1,6], C. Moyo[3], S. Chisala[3], W. Stevens[1,5,7]
[1]University of the Witwatersrand, Department of Molecular Medicine & Haematology, Johannesburg, South Africa, [2]Right to Care - EQUIP, Monitoring & Evaluation, Johannesburg, South Africa, [3]Right to Care - EQUIP, Programs, Pretoria, South Africa, [4]National Health Laboratory Services, Programs, Johannesburg, South Africa, [5]Right to Care - EQUIP, Programs, Johannesburg, South Africa, [6]Right to Care - EQUIP, Information Technology, Johannesburg, South Africa, [7]National Health Laboratory Services, Department of Molecular Medicine & Haematology, Johannesburg, South Africa

Background: Zambia has a population of 15 473 905 with 1.2 million adults living with HIV among whom 65% are accessing Anti-Retroviral Therapy (ART). Scaling-Up of HIV Viral Load (VL) testing in Zambia is imminent to achieve the third 90 goal as set by UNAIDS. To ensure there is baseline data for comparison of impact of intervention with regards to VL scale-up for the country; the Zambia Ministry of Health (MoH) engaged EQUIP to conduct assessments of laboratories.
Methods: An electronic Rapid Assessment Tool, hosted on ArcGIS, was used for data collection. The primary focus was to assess the role of laboratories and facilities in the VL value chain. Questions covered in the assessment varied from pre-analytic, analytic to post analytic processes including quality management and health and safety. Data illustrations into graphs and interpretation was done using excel pivot tables.
Results: A total of 653 facilities were assessed and 50% of these facilities have functional laboratories, 21% have mini labs and the remaining 29% have no laboratories. The results showed that, 73% of the facilities collected VL specimens and referred the specimens for testing; 5% of the facilities acted as hubs. The remaining 20% facilities did not offer any VL support i.e. they did not collect any VL specimens whilst only 2% laboratories offered VL testing. Overall, only 32% of the assessed facilities responded to having storage space for Consumables and Reagents. Health and safety adherence was generally a challenge with 52% of facilities having a safety manual available whilst 48% did not having one.
Conclusions: Given that at least 65% of HIV infected population are on ART; there is an urgent need for special focus on increasing the demand for VL testing in Zambia. Therefore, recommendations on how to improve pre-analytic, analytic and post analytic will inform MoH's decision making on the scaling up of VL testing to reach the third 90 UNAIDS target for Zambia.

TUPEE732

Utilizing innovative modern data collection methods to identify most-at-risk HIV positive children and adolescents in 11 districts of Zimbabwe

T. Zvirawa[1], N. Willis[2], M. Mawodzeke[1], T. Chimbidzikai[1]
[1]Africaid, Program, Harare, Zimbabwe, [2]Africaid, Management, Harare, Zimbabwe

Background: Tremendous progress has been made towards identifying children and adolescents living with HIV (CALHIV). Limited resources has necessitated the shift in HIV testing strategies from generalized testing to targeted testing. Using targeted testing enables HIV burdened countries to direct resources towards most at risk population. Africaid uses an innovative data collection tool utilizing its database to refer and link siblings and partners of children and adolescents living with HIV to HIV Testing Services (HTS).
Description: Africaid is implementing a project aimed at improving children and adolescents´ experience of HTS, diagnosis and linkage to care and treatment support across Zimbabwe. Africaid is piloting the use of innovative data collection in 11 districts to evaluate the acceptability of using index case finding in identifying CALHIV. Community Adolescent Treatment Supporters (CATS) who identify CALHIV in their communities using a network of already registered beneficiaries in the Zvandiri database as index cases.CATS enrol CALHIV in the Zvandiri program using mobile and web-based database for easy and routine tracking, follow ups and documentation of conditions upon enrolment into the program. This enables CATS to provide differentiated services to clients.
Lessons learned: The database which captures CALHIV proved to be a cost-effective mechanism of tracking most at risk adolescents. As a result of the follow ups conducted through using contacts in the database a total of 3, 033 (1, 788 females and 1, 245 males) siblings and partners were identified and linked to for HTS. This resulted in 2, 827 (1, 643 females and 1, 184 males) being tested and 860 (520 females and 340 males) tested positive and were linked onto care and treatment. The pilot also revealed that most at risk adolescent are reluctant and afraid to visit clinics for testing and hence using the database enabled their peers the CATS to sensitize, mobilize and encourage them to get tested for HIV.
Conclusions/Next steps: Pilot results demonstrated that using modern data collection methods for tracking and tracing HIV positive clients assists in identifying CALHIV in need of HTS through working with their peers. This will be scaled up through the utilization of HIV self-testing kits in the intervention districts.

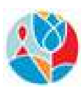
Data and accountability and transparency

TUPEE733

Using community-led participatory action research for accountability on the Global Fund´s Country Coordinating Mechanisms: CCM Scorecard and CCM Community & Civil Society Shadow Reports in Africa

P.D. Tucker[1], O. Mumba[2]
[1]AIDS Accountability International, Research, Bruxelles, Belgium, [2]East African Network of AIDS Service Organisations (EANNASO), Urusha, Tanzania, United Republic of

Background: Effective Country Coordinating Mechanisms (CCMs) are a vital part of the Global Fund architecture at country level. CCMs are responsible for submitting requests for funding and for providing oversight during implementation. CCMs are assessed using external assessors or a self-assessment and are overly concerned with box-ticking and not with impact.
Methods: The CCM Scorecard and Country CCM Shadow Reports is a nine country study that saw twenty-two community and civil society watchdogs evaluate the CCMs against the Global Fund´s own Eligibility Performance Assessment, and research for themselves how their CCMs



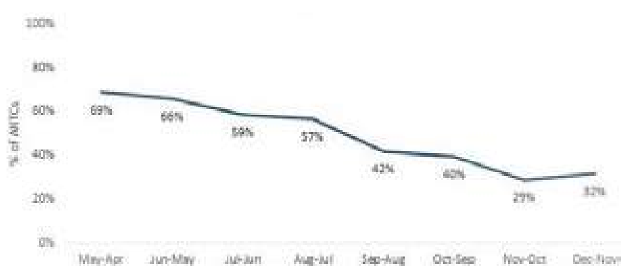
are performing, as a means to improve accountability. GFATM CCM Hub was brought in from the beginning as an advocacy target.
Results: Overall the CSO ratings of CCMs differ from Geneva ratings 36% of the time, reasonably equally distributed as both better ratings and lower ratings.
Oversight (ER4) was the area in which CCMs were most over-rated by the Geneva EPAs. The country CSOs rated CCM performance on oversight lower 26% of the time.
A close second was Conflict of Interest (ER6) where the CSO Shadow Report process graded the CCMs lower than the Geneva process did 21% of the time.
With regard to ER5, CCM membership composition, we see agreement between Geneva EPAs and CSO Shadow EPAS 59% of the time, and 26% of the time a higher rating than Geneva gave the CCM.
ER6, Adequate CSO representation and accountability to their constituency showed 75% agreement between CSO EPA and Geneva EPA. The higher rating 15% of the time, and only lower rating of 9% of the time suggests that they are satisfied with the Geneva EPA assessment in this area.
Conclusions: The research shows that there is little accuracy and reflection of circumstances experienced by stakeholders in country in the Geneva assessments of CCMs, and that the way assessments are done needs to be changed to ensure accountability. The findings hugely affected the GFATM CCM Evolve process and this demonstrates that innovative methods of including advocacy targets and community research can be powerful.

TUPEE734

Systematic data quality improvement by innovative and simple technique at large scale - an experience from world's second largest ART program

M. Bamrotiya[1], R. Gupta[1], M. Shah[2]
[1]National AIDS Control Organization-India, Department of Health and Family Welfare-Government of India, New Delhi, India, [2]UW I TECH, New Delhi, India

Background: India is a home of almost more than 2.1 million HIV positive people, of which approximately 1.2 million are on treatment from 538 government run ARTCs (Anti Retro Viral Center) across India. Improvement in data quality at ARTC level is meant to provide accurate input for program functioning and planning. An offline system of reporting from ARTC to state and national level had data quality issues which hindered its reliability for planning.
Description: To improve the data quality, a monthly feedback mechanism from national level to State officials was developed by using a simple Microsoft excel sheet that finds out errors and discrepancies between two successive monthly reports from each ARTC. State officials studied the errors and got them rectified from ARTCs gradually. At least one error was found out in 69% of ARTCs at the beginning while comparing the report of May 2017 with that of April 2017. With monthly feedback and constant technical support to the states by senior officials at national level, these errors were reported by 66%, 59%, 57%, 42%, 40%, 29% and 32% of ARTC for June, July, August, September, October, November and December respectively.
Lessons learned: Data quality improvement usually requires rigorous and resource intensive efforts especially when data system is not online or automated. It was believed that constant positive supervision and feedback has a motivating effect and usage of simple tools are more effective at large scale.



[Figure. % of ARTCs with at least one error in reporting]

Conclusions/Next steps: It is planned to share the same tool to state officials and later to ARTC with a simple guidance video for usage which should reduce these errors further. It is also envisaged to include another set of indicators in current tool for making it more comprehensive. Such efforts should bring more ownership about data among program managers and motivate them to use data for local purposes. It would also make forecasting and planning based on such data more reliable and realistic which would benefit the program and nation.

TUPEE735

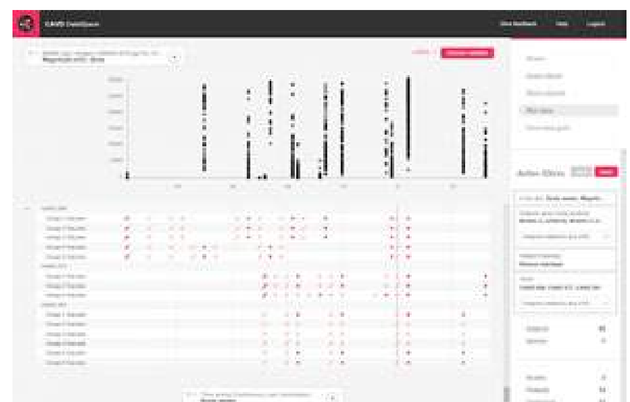
The CAVD DataSpace data sharing and discovery tool facilitates exploration of HIV immunological data from pre-clinical and clinical HIV vaccine studies

B.T. Mayer, D. Holman, W.J. Fulp, J.Y. Kim, E. Henrich, R. Gottardo
Fred Hutchinson Cancer Research Center, Vaccine and Infectious Disease Division, Seattle, United States

Background: The Collaboration for AIDS Vaccine Discovery (CAVD) is an international network whose primary mission is to accelerate the development of a safe and effective HIV vaccine through a combined effort across research institutions. The DataSpace (dataspace.cavd.org) is an integral part of the CAVD's Global Access policy which requires public access to data and information from CAVD studies.
DataSpace is a web-based, data sharing and discovery tool developed to empower researchers by increasing awareness of the breadth of HIV vaccine studies and facilitating self-guided data exploration (Table).
Description: Currently, binding antibody, neutralization antibody, and cellular immunoassay results from over 186 vaccine products tested in 61 studies conducted in the CAVD have been harmonized and are available for exploration and download. Data are included from both clinical trials and studies of non-human primates and other animals. An application programming interface (API) for the R programming language is also available through the DataSpaceR package (https://github.com/FredHutch/DataSpaceR).

Value to researchers	Core functionality
Provides quick reference for detailed information about studies, products, and assays.	Learn context - Find information about studies and assays to inform which data to analyze and how to interpret the results. Study information includes: treatment regimens, assays performed, product and assay descriptions, study objectives and findings, and publications.
Helps researchers find cohorts and data of interest.	Reference what study populations and data exist - Find which assays were performed on subjects with common attributes and what data are available for exploration. Data identified through the DataSpace application can be easily exported from DataSpace in CSV or Excel formats or by using the API in the DataSpaceR package.
Facilitates data exploration.	Standardized data facilitates comparisons across studies -Integration of harmonized data across studies provides consistent data (fields, terminology, and response call calculations), making it easier to: (1) perform meta-analyses, (2) compare assay performance over time, (3) correlate assays, (4) reproduce published results and figures, and (5) estimate sample size using historical data to inform design of future studies.

[Core functionality and value of the DataSpace]



[A screen capture of the DataSpace visualization tool illustrating study data aligned by final vaccination.]

Lessons learned: We present three case studies establishing DataSpace functionality (Table). First, we recreate published figures using the DataSpaceR API to illustrate DataSpace as a tool for study reproducibility. Second, we perform an adjuvant study power calculation to demonstrate how DataSpace can be utilized for study design. Lastly, we perform a meta-analysis of vaccine durability to highlight how to align metadata across studies, a very powerful feature of DataSpace (Figure).
Conclusions/Next steps: By publishing, collating, and annotating the immunological data from these studies, DataSpace is an invaluable resource for investigators and scientists to build upon HIV vaccine science. Cross-assay or cross-study comparisons are streamlined by ensuring that all study data are quality controlled and follow a standardized format. As we demonstrated, access to metadata is made easy, and studies with complex schemas can be easily aligned by final vaccination time points to analyze vaccine durability (Figure). The API allows seamless access to the data, facilitating more advanced statistical analysis that may require sophisticated methods from statistical programming languages. DataSpace is continually adding new studies and data, with 110 studies expected to be available by the end of 2018.

Monitoring and reporting in the SDG era

TUPEE736

Roll out and scale up of WHO-endorsed TB diagnostic technologies to diagnose TB and MDR-TB in African: From Stop TB to End TB Strategy era

J.D.D. Iragena, F. Jallow, M. Gasana, H. Lago
WHO Regional Office for Africa, CDS/HTH, Brazzaville, Congo, Republic of the

Background: To roll out and scale up diagnostic tests for TB and MDR-TB in 47 African countries requires coordinated efforts at all levels of stakeholders. The End TB Strategy aims at early diagnosis with universal DST and quality-assured laboratory network. The use of the rapid test Xpert MTB/RIF® has expanded since 2010 and it is now recommended as the initial diagnostic test in all persons with signs and symptoms of TB. More than 100 countries are now already using the test and as of 31 of December 2017, a total of 9,449 GeneXpert instruments and 34,422,850 Xpert MTB/RIF cartridges had been cumulatively procured in the public sector in 130 of the 145 countries eligible for concessional pricing.
Description: Laboratory data analysis was carried out in 47 members States. The implementation of diagnostic tests and scale-up through the laboratory network have been assessed using excel sheet and checklist. Laboratory indicators before 2015 and after 2015 were considered using data collected from countries for 2016 and 2017 WHO Global TB Reports.
Lessons learned: DOTS and Stop TB Strategies resulted in 28 member states achieving benchmark of one microscopy center per 100,000 populations, while 15 achieved 1 culture and 1 DST laboratory to 5 million populations. By the end 2015, the coverage with diagnostic technologies was still sub-optimal. Out of 42 countries, 35 (83%) had dedicated National TB Reference Laboratories with 60% of them having quality management systems in place towards accreditation. In 2017, the uptake of WHO-endorsed diagnostic tests for TB showed slower progress in some countries against 2015 as a baseline. All 47 member states in Africa have been procured with GeneXpert instruments. Beside all, fifteen countries lack capacity to diagnose and confirm XDR-TB.
Conclusions/Next steps: New diagnostic tests should be accompanied by the "know how to" implement. Political commitment to rapidly scale up tests and improve the quality of laboratory services is a key. The laboratory indicators within the End TB Strategy should be kept in mind to better monitor progress against the targets.Three phases need to be considered as important to achieve implementation and rapid uptake: laboratory preparedness, technology transfer and routine testing.

TUPEE737

Completeness rates of HIV indicator data reporting through District Health Information Software (DHIS2): Experience from military sites in Uganda

B. Lutimba Mutebi[1], J.B. Ddamulira[1], D. Bwayo[1], C. Wamundu[2], J. Akao[3], F. Young[4], M. Chen[4], R. Flueckiger[4]
[1]Research Triangle Institute International, Kampala, Uganda, [2]Uganda People's Defense Forces, Kampala, Uganda, [3]Department of Defense-US Mission, Kampala, Uganda, [4]RTI International, Research Triangle Park, United States

Background: Health facility-generated data reported through routine health information systems are the source for programmatic monitoring and evaluation in Uganda. Since 2013, the Uganda People's Defence Force (UPDF) has adopted the District Health Information Software (DHIS2), contributing to improved availability of routine health facility data at 26 military health centers. Funded by the United States President's Emergency Plan for AIDS Relief (PEPFAR), RTI International supported the UPDF to assess completeness reporting on 13 PEPFAR core HIV indicators by 26 military health centers during the past two years of implementation of DHIS2, (January 2016 to December 2017).
Methods: Data on the 13 HIV indicators reported quarterly, by 26 antiretroviral treatment (ART) military health facilities (seven military hospitals and 19 lower level health centers) were extracted from the Ugandan DHIS2 database. Completeness of reporting was analyzed for each indicator (as shown by respective cells in the database) and expressed as the percentage of data values reported over those expected. All ART-accredited health facilities are expected to report data for each indicator for each quarter. Completeness rates were calculated quarterly, and trends were measured over time. Data were extracted from DHIS2 and analyzed in MS Excel 2016.
Results: On average, completeness of reporting increased significantly by 16.8% for all HIV indicators (75-95%, p>0.0001 for TX_NEW and TX_CURR; 45-55%, p>0.0001 for TX_RET; 65-100%, p>0.0001 for TX_PVLS; 65-85%, p>0.0001 for TB_STAT, TB_SCREEN, TB_ART and PMTCT_EID, 90-100%, p>0.001 for HTS_TST, HTS_TST_POS and PMTCT_STAT). (See PEPFAR Monitoring, Evaluation and Reporting Indicator Reference Guide [Version 2.0, 2017] for definitions of the above indicators). Data on voluntary medical male circumcision completeness increased significantly from 85-98%, p>0.0001. Completeness during the period at lower-volume units was higher than that at high-volume units (95% and 85% respectively).
Conclusions: Completeness of data reporting for most key HIV indicators improved after the adoption of DHIS2, notwithstanding that other support from RTI (e.g.staff training, coaching) also contributed to improvements. However, major data gaps were identified for the treatment retention, TB, and EID indicators. Periodic orientation and on-site mentorship of all health workers on key indicator definitions need strengthening.

Chidamide reactivates and diminishes latent HIV-1 DNA in patients on suppressive antiretroviral therapy

Y. Sun[1], J. Li[1], J. Ma[2], C. Wang[1], F. Bai[1,3], K. Zhao[1,4], Z. Yu[1,5], W. Kang[6], Y. Zhuang[1], N. Yao[1], Q. Liu[1], B. Dang[1], B. Wang[1], Q. Wei[1], Z. Liu[1], L. Wang[1], W. Kang[1], L. Wang[1], J. Xia[1], T. Wang[7], T. Zhu[8]
[1]Fourth Military Medical University, Xi'an, China, [2]Xi'an Jiaotong University, Xi'an, China, [3]323th Hospital of PLA, Xi'an, China, [4]Xi'an Communication Institute, Xi'an, China, [5]Political Work Department of People's Republic of China Central Military Commission, Beijing, China, [6]Fourth Military Medical University, Department of Infectious Diseases, Tangdu Hospital, Xi'an, China, [7]Jinan University, Institute of Life and Health Engineering, College of Life Science and Technology, Guangzhou, China, [8]University of Washington, Department of Laboratory Medicine, Seattle, United States

Background: A proposed strategy to purge HIV reservoir is to reactivate provirus transcription with latency-reversing agents (LRAs), inducing viral antigen expression and allowing immune-mediated clearance of reservoir cells in the presence of combination antiretroviral therapy (cART). Here we evaluated the safety and efficacy of chidamide, a benzamide histone deacetylase inhibitor, in patients on suppressive cART.
Methods: Seven aviremic HIV-1-infected patients received eight oral doses of 10 mg chidamide twice a week (Tuesday/Friday) for 4 weeks while maintaining baseline cART. Safety was evaluated at each visit and plasma concentrations of chidamide was measured by liquid chromatography-mass spectrometry. Histone acetylation levels in $CD4^+$ T cells were analyzed by flow cytometry. Plasma HIV RNA was determined using Cobas Taqman HIV-1 Test, v2.0. Cell-associated HIV RNA (CA-HIV RNA) and total HIV DNA (CA-tHIV DNA) were quantified by the SupBio PCR test in PBMCs. Thirteen plasma biomarkers of inflammation were evaluated by luminex multiplex assays and ELISA. Changes from baseline to specific time points were compared using Wilcoxon matched-pairs signed-rank tests, and a two-sided p-value of less than 0.05 was considered significant.
Results: All participants (6 male, 1 female) completed full chidamide dosing, and showed acceptable drug tolerance with only grade 1 adverse events presented. No drug accumulation effects were detected per chidamide dosing. In addition, the cyclic increase of histone acetylation in $CD4^+$ T cells was observed. All participants showed robust and cyclic viremia (peak viremia range 147-3850 copies/mL) as well as increased CA-HIV RNA (median peak increase 9.4-fold vs. baseline, range 2.0-fold to 34.9-fold) during chidamide treatment. At day 56, plasma HIV RNA of all participants recovered to undetectable level. Furthermore, we discerned the significant reduction of CA-tHIV DNA (day 27 vs. baseline, p = 0.018, and day 56 vs. baseline, p = 0.028). Equally important was that chidamide exhibited an anti-inflammatory property as evidenced by inhibition of pro-inflammatory cytokines: MCP-1, MMP-9, IP-10, LBP, P-selectin, and CD40 ligand.
Conclusions: Chidamide can safely disrupt the latency of HIV DNA resulting in the clearance of reactivated reservoirs, which makes it a promising candidate toward the eradication of HIV reservoir.

The antiretroviral CCR5-inhibitor maraviroc effectively reverses HIV latency by phosphorylation of Nf-B

J. Symons[1], S.F.L. van Lelyveld[2], W. de Spiegelaere[3], A.M.J. Wensing[4], J.M. Zerbato[1], P.M. van Ham[4], J. Drylewicz[5], A. Middel[2], A.I.M. Hoepelman[2], P.U. Cameron[1,6], H.K. Lu[1], A.I. Dantanarayana[1], J.A.M. Borghans[5], L. Vandekerckhove[3], S.R. Lewin[1,6], K. Tesselaar[5], M. Nijhuis[4]
[1]The Peter Doherty Institute for Infection and Immunity, The University of Melbourne, Melbourne, Australia, [2]University Medical Centre Utrecht, Department of Internal Medicine and Infectious Diseases, Utrecht, Netherlands, [3]Ghent University, Department of Internal Medicine, Ghent, Belgium, [4]University Medical Centre Utrecht, Department of Medical Microbiology, Virology, Utrecht, Netherlands, [5]University Medical Centre Utrecht, Department of Immunology, Utrecht, Netherlands, [6]Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia

Background: One strategy to eliminate latently infected cells in HIV-infected individuals on antiretroviral therapy (ART) is to induce HIV transcription with latency reversing agents (LRAs). Potent non-toxic LRAs are urgently warranted. The clinically approved CCR5-inhibitor maraviroc (MVC) demonstrated an increase in HIV transcription *in vitro* and may therefore act as an LRA. We investigated the effect of MVC on HIV transcription and its mechanism of action *in vitro*, *ex vivo* and *in vivo* during a MVC-intensification trial.
Methods: Activated PBMCs were infected with HXB2 (MOI 0.01) and cultured with MVC. Seven days post-infection p24 was measured in supernatant by ELISA (n=9). Changes in NF-B phosphorylation were assessed by densitometry Western-Blot (n=2). 5 million resting CD4 T-cells were isolated from HIV infected individuals on ART, treated with MVC or vorinostat and unspliced (US) and multiply spliced (MS) HIV-RNA were quantified by qPCR (n=6). In a double-blind, placebo-controlled trial, MVC or placebo was added to suppressive ART in immune non-responders (MVC=10, Placebo=5). Changes in cell-associated (CA)-US HIV-RNA and NF-B regulated gene mRNA were quantified by droplet-digital-PCR (ddPCR). Mann-Whitney-U-test and paired T-test were performed using GrapPad-Prism.
Results: *In vitro,* a significant increase in HIV production was observed when MVC (1pM-1µM (p< 0.02) to infected PBMC. A 2.5-fold increase in phosphorylated NF-B was observed in uninfected MVC treated CD4+ T-cells. Additionally, *in vivo,* a significant difference, between MVC and placebo, in NF-kB regulated gene expression, including IFN-g, IL6 and TNF-a, was observed (p=0.02, 0.03, 0.05 respectively). Patients baseline characteristics did not differ between the MVC-intensification and placebo-group. A significant difference in CA-US HIV-RNA expression was detected between baseline and week eight (MVC 1.8-fold increase; placebo 2.5-fold decrease; p=0.0121). *Ex vivo,* MVC induced a 3.5 and 1.7-fold increase in US HIV-RNA compared to DMSO (p=0.0004) and vorinostat (p=0.0496) respectively. Additionally, MVC induced a 2-fold increase in transcription of MS HIV-RNA compared to DMSO (p=0.0245).
Conclusions: MVC activates phosphorylation of NF-B and increases HIV-RNA transcription in resting CD4 T-cells. Potency for latency reversal *ex vivo* was more effective than vorinostat. Given the excellent safety profile of MVC, further studies of MVC as an LRA are warranted *in vivo.*

WEAA0103

Activation of latent HIV and SIV RNA transcription *in vitro* and *in vivo* in ART suppressed SIV-infected rhesus macaques by the Ingenol-based protein kinase C agonist, GSK445A

A. Okoye[1,2], R. Fromentin[3,4], J. Brehm[5,6], A. Maxwell[1,2], M. Vaidya[1,2], M. Pardons[3,4], V. Tai[5], J. Tang[5], J. Smedly[2], M. Axthelm[1,2], J. Lifson[7], L. Picker[1,2], L. Trautmann[8,9], D. Favre[5,6], N. Chomont[3,4]
[1]*Oregon Health and Science University, Vaccine & Gene Therapy Institute, Beaverton, United States,* [2]*Oregon National Primate Research Center, Beaverton, United States,* [3]*Centre de Recherche du CHUM, Montreal, Canada,* [4]*Université de Montréal, Microbiology, Infectiology and Immunology, Montreal, Canada,* [5]*GlaxoSmithKline, HIV Discovery Unit, Durham, United States,* [6]*University of North Carolina, HIV Cure Center, Chapel Hill, United States,* [7]*Frederick National Laboratory, Leidos Biomedical Research Inc., AIDS and Cancer Virus Program, Frederick, United States,* [8]*Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States,* [9]*Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Silver Spring, United States*

Background: Induction of HIV gene expression in latently-infected CD4+ T cells is an essential step for the clearance of proviral reservoirs in virally suppressed individuals. Activation of NF-kB signaling pathway by Protein kinase C agonists (PKCa) is a potent mechanism for HIV latency disruption *in vitro*. However, significant toxicity risks and the lack of evidence supporting their activity *in vivo* have prevented further evaluation of PKCa. Extending prior results, we sort to confirm that GSK445A, a stabilized Ingenol-B PKCa derivative, can induce HIV/SIV transcription *in vitro*, and demonstrate pharmacological activity *in vivo* in ART suppressed SIV-infected RM.
Methods: CD4+ T cells from 3 virally suppressed humans were exposed to increasing concentrations of GSK445A for 30 min to measure cell-associated multiply spliced (tat/rev) RNA after 18 hours. Next, CD4+ T cells from virally suppressed humans (n=5) and RM (n=3), were exposed for 30 min at an optimal dose of 25nM GSK445A to quantify cell-associated RNA and cell free RNA in the supernatant at 18 hours. Pharmacological activity and tolerability of GSK445A IV was assessed in 5 healthy RM at doses from 10 to 20mg/kg. Finally, 4 adult RM were IV inoculated with SIVmac239, and placed on ART (tenofovir/emtricitabine/dolutegravir) starting 56 days post-infection. After 34 weeks, RM received 3 biweekly doses of GSK445A, IV at 15mg/kg. SIV DNA and RNA in cells and plasma were quantified by qPCR/qRT-PCR.
Results: CD4+ T cells exposed to GSK445A produced unspliced HIV and SIV RNA (gag) and viral particles, indicating that GSK445A efficiently reverses HIV/SIV latency *in vitro*. In vivo, GSK445A tolerability was established around 10-15mg/kg and pharmacological activity demonstrated by CD69 upregulation in CD4+ T cells in blood. In suppressed RM, 3 of 4 individuals showed blips in plasma viral loads ~0.5-1 log above threshold (15 RNA copies/ml). All but 1 RM showed increases in unspliced SIV RNA in PBMC and increases in SIV RNA/DNA ratio (average transcription per infected cell) following each dose of GSK445A.
Conclusions: These results indicate that GSK445A is a potent latency-reversing agent *in vitro* and is amenable to testing latency disruption strategies *in vivo* in RM models of HIV cure/remission.

The RNA-binding proteins, SRP14 and HMGB3 play a crucial role in controlling HIV replication and latency

G. Khoury[1], M.Y. Lee[1], S. Ramarathinam[2], S. Sonza[1], A.W. Purcell[2], D.F.J. Purcell[1]
[1]*Peter Doherty Institute, Microbiology & Immunology, Melbourne, Australia,* [2]*Biomedicine Discovery Institute, Monash University, Biochemistry and Molecular Biology, Clayton, Australia*

Background: HIV latency is known to be reinforced by many impediments to RNA transcription, however translational blocks to HIV replication are less well characterised. The transactivator of transcription Tat protein is essential for progeny virion production in natural infection of HIV. RNA-binding proteins that facilitate translation of Tat may be absent or downregulated in resting CD4+ T cells, the main reservoir of latent HIV. In this study, we examined the role of Tat RNA-binding factors in expression of Tat and control of latent and productive infection.
Methods: Affinity purification-mass spectrometry analysis (nanoLC-MS/MS) was used to detect binding partners of MS2-tagged *tat* mRNA in a T cell-line model of HIV latency (J-Lat6.3). 243 interactions were identified with high confidence using the MiST three parameter scoring system at a threshold cutoff of 0.7. 13 proteins were chosen for follow-up. The effect of knockdown and overexpression of the proteins of interest on Tat transactivation and translation was assessed by luciferase-based reporter assays, and infections with a dual colour HIV reporter virus allowed investigation of the dynamics of latent (BFP+/mCherry+) and productive (EGFP+BFP+/EGFP+mCherry+) infection. Changes over time in the levels of mRNA and protein in activated CD4+ and resting CD4+ T cells after NL4.3-eGFP infection were determined.
Results: After preliminary studies, two candidate proteins, SRp14 and HMGB3 were selected for detailed investigation. Knockdown of SRP14 negatively affected translation of Tat and Tat-mediated transactivation, which led to an increase in latent infection (BFP+ expression), while the knockdown of HMGB3 resulted in an increase in Tat transactivation and translation as well as an increase in productive infection (EGFP+BFP+/mCherry+ expression). Interestingly, these effects correlated with the levels of the proteins in rCD4+ T cells following HIV-1 infection as we observed a decrease in SRp14 levels while HMGB3 peaked very quickly after infection in rCD4+.
Conclusions: Our study revealed that SRp14 is a positive regulator of Tat expression and negative regulator of latent infection, whereas HMGB3 is a negative regulator of Tat expression and positive regulator of latent infection. The role of these proteins in controlling HIV-gene expression during latency will be further assessed as potential drug targets.

WEAA0105

Using the PPARg antagonism to block/lock HIV reactivation in Th17 cells

Y. Zhang[1], D. Planas[1], H. Chen[1], A. Gosselin[1], J.-P. Routy[2], P. Ancuta[3]
[1]*Universite de Montreal and CHUM Research Centre, Microbiology, Infectiology and Immunology, Montreal, Canada,* [2]*McGill University Health Centre, Montreal, Canada,* [3]*Universite de Montreal and CHUM Research Centre, Montreal, Canada*

Background: The Th17-polarized cells represent a subset of CD4+ T-cells that orchestrate mucosal immunity against pathogens. The transcriptional profile of Th17 cells is compatible with optimal HIV replication. Th17 are strategically located at mucosal barrier surfaces and represent the first HIV infection targets during sexual transmission. Finally, Th17 cells are long lived and support HIV reservoir persistence during antiretroviral therapy (ART). Of note, the nuclear receptor PPAR is a negative regulator of HIV replication and a transcriptional repressor of the Th17 master regulator RORt. In an effort to identify novel Th17-targeted therapies, we investigated the potential use of PPAR antagonism for viral latency reversal and/or boosting Th17 functions.
Methods: Memory CD4+ T cells were isolated from peripheral blood by negative selection. Cells of HIV-uninfected individuals were stimulated via CD3/CD28 during 3 days, exposed to replication-competent or single round VSVG-pseudotyped HIV, and cultivated in presence/absence of PPAR antagonist T0070907 for 12 days. HIV reactivation from CD4+ T-cells of ART-treated individuals was measured using a viral outgrowth assay. HIV replication was monitored by HIV-DNA real-time PCR and ELISA/FACS. CCR5 expression was measured by FACS. Genome-wide tanscriptional profiling was performed using the Illumina RNA-Seq technology followed by RT-PCR validations.
Results: The PPAR antagonist T0070907 increased IL-17A production, but unexpectedly inhibited HIV replication by acting at multiple levels including CCR5-mediated entry; HIV transcription; and lipid metabolism. Transcriptional profiling and RT-PCR validations revealed that T0070907-mediated effects coincided with the induction of cholesterol-25-hydroxylase (CH25H), an enzyme converting cholesterol into 25-hydroxycholesterol (25HC), a broad inhibitor of viral replication and also an intrinsic ligand of RORt. Finally, T0070907 inhibited HIV reactivation and increased IL-17A production in CD4+ T cells from ART-treated HIV+ individuals.
Conclusions: Together, our results identify PPAR as a new therapeu-

tic target to reduce HIV replication/reactivation in CD4+ T-cells, while boosting the Th17 effector functions. These effects are explained by the capacity of T0070907 to induce the synthesis of 25HC, while preventing PPAR-mediated RORt repression. These findings demonstrate the possibility to disconnect HIV replication from effector functions in Th17 cells and open the path for new therapeutic interventions to restore Th17-mediated mucosal immunity in HIV-infected individuals receiving ART.

WEAA02 Killers or helpers: The double life of T cells

WEAA0201

Increase in restriction factor expression in response to viral rebound after analytical treatment interruption in HIV-infected patients

M.-A. De Scheerder[1,2], C. Van Hecke[1,2], N. De Langhe[1], M. Sips[1,2], L. Vandekerckhove[1,2]
[1]UZ Gent, Algemene Inwendige Ziekten, Gent, Belgium, [2]UGent, HCRC, Gent, Belgium

Background: Restriction factors are host proteins interfering at different steps of HIV replication cycle in an attempt to limit viral production and spreading. We conducted a longitudinal analysis of the expression profile of antiviral restriction factors and cofactors in a cohort of eleven HIV-1 infected, long-term treated patients who underwent analytical treatment interruption (ATI), the HIV-STAR study(NCT02641756). The expression of known HIV-1 restriction factors (APOBEC3G, SAMHD1, MX2, PAF1, SLFN11, TRIM5 and BST2/tetherin), cofactors (NLRX1 and PSIP1) and interferon stimulated genes (ISGs) IFIT1 and MX1 were evaluated at four well-defined time points: on cART (T1), after ATI (VL< 20copies/ml, T2), at rebound (VL>1000copies/ml, T3) and after treatment restart (VL< 20copies/ml, T4).
Methods: Peripheral blood mononuclear cells were isolated from all patients at the four time points. Quantitative real-time PCR was performed to determine the expression of these HIV-1 restriction factors, cofactors and ISGs. Statistical Friedman's and post hoc Dunn's analysis were performed and Spearman correlation was employed to identify associations between restriction factor/cofactor, ISG expression levels and patient clinical characteristics.
Results: For two restriction factors a significant increase in expression between T1 and T2 (APOBEC3G, SLFN11) was observed. Furthermore, upregulation of MX2 and both ISGs were observed between T1 and T3 ($p< 0.05$). Significant positive correlations between ISG and restriction factor/cofactor expression were identified at T1, T3 and T4. In addition, a correlation between high HIV DNA load and IFIT1 at T2 and high viral load zenith and SLFN11 at T4 was found, suggesting that these virological characteristics drive a more robust restriction factor response. Furthermore, a low CD4 nadir was correlated with a higher expression of the viral co-factor PSIP1 at T2. No associations were found between the expression of restriction- or co- factors and time to viral rebound.
Conclusions: A significant difference in restriction factor expression between at least two time points was identified for SLFN11, APOBEC3G and MX2 and a trend towards difference in expression levels for most of the other restriction factors studied. In contrast to the ISGs, our data indicate that restriction factors increase earlier after ATI before time of viral rebound, potentially implicating them as markers/predictors of rebound.

WEAA0202

RhCMV-induced, SIV-specific MHC-E-restricted T cells recognize SIV through the T cell receptor

S. Abdulhaqq[1], B. Bimber[2], H. Wu[1], A. Ventura[1], K. Wisskirchen[3], A. Legasse[2], M. Axthelm[2], U. Protzer[3], S. Hansen[1], D. Douek[4], L. Picker[1], J. Sacha[1]
[1]Oregon Health and Science University, Vaccine and Gene Therapy Institute, Beaverton, United States, [2]Oregon Health and Science University, Oregon National Primate Research Center, Beaverton, United States, [3]Technical University of Munich, Munich, Germany, [4]National Institutes of Health, Vaccine Research Center, Bethesda, United States

Background: RhCMV68-1 vaccine vectors expressing SIV antigens demonstrate a profound ability to control post-challenge viremia with subsequent SIV clearance in over half of all vaccinated rhesus macaques (RM). The T cells induced by these vectors are effector-memory T cells unconventionally MHC restricted by MHC-II or MHC-E molecules. To effectively deploy these responses against HIV/SIV it is essential to garner a better understanding of how these cells function. However, the unique nature of these terminally differentiated cells complicates conventional analytical methods, e.g. antigen-specific T cell lines. Here, we employ bulk and single-cell sorting with downstream mRNA sequencing of SIV-specific MHC-E-restricted CD8+ T cells to derive full length, paired / T cell receptor (TCR) sequences and to characterize their transcriptional phenotype.
Methods: We stimulated PBMC from strain 68-1 RhCMV/Gag vaccinated RM with optimal peptide epitopes from previously identified T cell responses in the presence of TAPI-0. Antigen-specific T cells dually expressing CD69 and membrane-bound TNF- were sorted using a FACS Aria. Whole transcriptome sequencing was used to identify the CDR3 amino acid sequence and V(D)J usage. Paired TCR chains were exogenously expressed in allogeneic CD8+ T-Cells from RhCMV/Gag-naïve RM.
Results: Using our system we were able to identify, sequence, and subsequently express paired / TCRs from MHC-E-restricted, SIV-specific CD8+ T cells. We confirmed that allogeneic CD8+ T cells transduced with these exogenous TCRs secreted effector cytokines upon encountering antigen in the context of MHC-E. MHC-E TCR transductants also recognized SIV infected CD4+ T cells derived from autologous or allogeneic sources, demonstrating the presence of MHC-E-bound minimal optimal epitopes on the surface of infected cells. Total transcriptome analysis revealed distinct populations within the MHC-E restricted cells, and expression of canonical Th1 markers, consistent with conventional MHC-Ia-restricted SIV-specific CD8+ T cells.
Conclusions: Our data demonstrate that Mamu-E-restricted T cell specificity is derived from its cognate TCR, and that the mRNA profiles of these cells resemble conventionally MHC-restricted T cells. This new system facilitates downstream transcriptomic analysis of antigen-specific T cells independent of knowledge of the restricting allele and tetramers, and will shed light on the phenotype and function of unconventionally MHC-restricted CD8+ T cells induced by RhCMV vaccination.

WEAA0203

Genetic factors leading to loss of viral control in HIV elite controller patients

J.M. Benito[1,2], M. Garcia[1,2], V. de Santisteban[1,2], R. Ramos[3], C. Restrepo[1,2], M.A. Navarrete-Muñoz[1,2], A. León[4], E. Ruiz-Mateos[5], A. Cabello[6], J. Alcamí[7], M. Górgolas[6], N. Rallón[1,2], On behalf of ECRIS integrated in the Spanish AIDS Research Network
[1]Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Universidad Autónoma de Madrid (IIS-FJD, UAM), Madrid, Spain, [2]Hospital Universitario Rey Juan Carlos, Móstoles, Spain, [3]Unidad de Genómica Parque Científico de Madrid, Madrid, Spain, [4]Hospital Clinic-IDIBAPS, HIVACAT, Universidad de Barcelona, Barcelona, Spain, [5]Hospital Virgen del Rocío, Sevilla, Spain, [6]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [7]Unidad de Inmunopatología del SIDA, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain

Background: Despite the ability of HIV elite controller patients (EC) to spontaneously maintain undetectable HIV plasma viral load (pVL), some of them lose this ability over time. The mechanisms underlying this phe-

nomenon are not completely understood. We investigated the association of genes related to HIV pathogenesis, with the loss of spontaneous virological control in EC.

Methods: A retrospective longitudinal study was performed in 13 EC: Six experienced loss of virological control (at least two consecutive measurements of VL above 50 copies/mL over 12 months of follow-up), named transient-controllers (TC), and 7 maintained virological control during follow-up (named persistent-controllers, PC). Cell samples were obtained at two timepoints: 1-2 years before (T1) and 1-2 years after (T2) loss of virological control for TC, and separated 1-2 years for PC. We assessed the expression of 43 genes related to HIV pathogenesis by real-time qPCR. Differential gene expression between TC and PC at the two timepoints and between timepoints was analyzed using StatMiner software (Applied Biosystems) applying a false discovery rate (FDR)< 0.05. Principal component analysis (PCA) was employed to discriminate between TC and PC at different timepoints.

Results: PCA was able to discriminate between TC and PC at T1 when both groups presented undetectable pVL. However, the discrimination was not so clear at T2 when TC already had detectable levels of pVL. On the other hand, PCA discriminated T1 and T2 samples from TC but it was not for T1 and T2 samples from PC. Interestingly, several genes involved in HIV control such as CDKN1A (p=0.024), CTR9 (p=0.006) and IFI16 (p=0.046) were down-regulated in TC compared to PC at T1, whereas there were no significant differences at T2. Moreover, gene expression did not change between T1 and T2 in PC, whereas several genes (ABCA1, IL10, IL21, PAF1,TRIM26) significantly increased its expression at T2 compared to T1 in TC.

Conclusions: Our results demonstrate a down-modulation of different genes with anti-HIV activity in EC patients that precede the loss of natural HIV replication control. These genes could be considered potential biomarkers of loss of natural control and could provide new insights for the clinical management of these exceptional patients.

Background: Understanding the T cell parameters supporting the generation of broadly neutralizing antibodies (bnAbs) against HIV-1 will help to optimize and target future vaccine strategies. Unlike HIV infected adults, who rarely make bnABS, most vertically infected children generate broad and potent neutralizing antibodies, suggesting the immune environment in these infants supports their generation.

Methods: Using blood and lymph node samples from infants and adults, we performed flow cytometry, confocal imaging and analysis of plasma markers by ELISA/ multiplex assays.

Results: As in the rare adults that make bnABs, circulating T follicular helper cells (T_{FH}) correlate with neutralization breadth in infected infants, but are much more frequent than in their adults counterparts. This is reflected in lymph nodes (LN), were germinal center T_{FH} are double the frequency in infants, irrespective of HIV status. Moreover, HIV infected infants have a clear Th2 bias in their LN T_{FH} response, with a high frequency of HIV-specific IL-21 producing T_{FH}, compared to adults, whose low frequency HIV-specific T_{FH} make IFN-gamma. Unlike in adults, T_{FH} in HIV infected infants are subject to increased regulation in LN, where the ratio of regulatory T_{FH} to T_{FH} is double that of infected adults and HIV-specific CXCR5+ CD8 T cells are frequently detected. Finally, breadth in infants correlates with plasma levels of IL-5, a cytokine that supports the induction of regulatory T and B cells.

Conclusions: The existence of differences in the immune response to natural infection of infants and adults is important, as it argues that vaccination strategy should be tailored to the group being targeted. For example, a vaccine that sought to break tolerance controls in adults might not be appropriate in infants. Furthermore, the general observation that infants make better anti-HIV antibodies should raise the question of whether infants are potentially a better target for HIV vaccination. Understanding the role of T-cell help and regulation in the process of bNab generation in infants can inform the development of vaccines targeted at this age group.

WEAA0205

Initiation of antiretroviral therapy during hyperacute HIV infection preserves germinal center T follicular (GCTfh) helper cell function

O. Baiyegunhi[1], F. Laher[1], K. Dong[2], B. Walker[2], T. Ndungu[1,3], Z. Ndhlovu[1,2,3]

[1]University of KwaZulu Natal, Nelson Mandela School of Medicine, Durban, South Africa, [2]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [3]Africa Health Research Institute, Durban, South Africa

Background: T follicular helper (Tfh) cells are important for the development of antibody responses against HIV infection. Paradoxically, the pathologic expansion of Tfh is associated with hypergammaglobulinemia and B cell dysfunction. Many HIV induced immune dysfunctions are reversed or attenuated by antiretroviral therapy (ART) but it is unclear if early treatment restores germinal center (GC) Tfh delivery of help to B cells leading to the establishment of GC reactions and effective antibody responses.

Methods: Excisional lymph node and paired blood samples were collected from 20 treated persons at the onset of plasma viremia, in many when viral loads are less than 1000 RNA copies/ml plasma. 10 HIV negative and 8 untreated individuals were included as controls. GCTfh and B cell phenotype and *in-situ* microscopy was performed on all study subjects. MHC class II tetramer staining, digital droplet PCR and intracellular cytokine staining were used to quantify and phenotype HIV-specific GCTfh responses is a subset of donors based on MHC class II haplotype expression and sample availability.

Results: Despite prompt plasma virus suppression there was significant expansion of GCTfh frequencies in lymph nodes from early treated persons compared to HIV negative donors. Class II tetramer staining and intracellular flowcytometry analysis revealed 1% to 9% of expanded GCTfh cells was HIV-specific. Expansion of plasmablasts (p=0.0336) and GC B cells (p=0.0571) correlated with GCTfh cell frequencies (p=0.0003, r=0.9321). GCTfh/B cell cultures induced higher IgG production in early treated compared to untreated donors. HIV Gag p24 antigen was detected in CXCR3+ GC Tfh and follicular dendritic cells, almost exclusively within GCs.

Conclusions: These results demonstrate that GCTfh responses induced during treated hyperacute are qualitatively superior compared to responses untreated hyperacute HIV infection. Our results also provide hints of persistent low-level viral replication in the lymph nodes of early treated individuals despite sustained plasma viral suppression. These results have implications for HIV cure and for vaccine strategies aimed at inducing long lasting anti-HIV antibody responses.

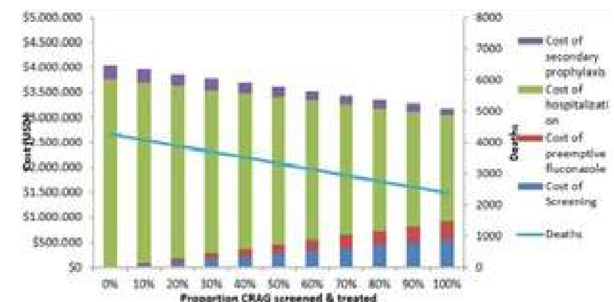
Evaluation of a national cryptococcal antigen screening program for HIV-infected patients in Uganda: A cost-effectiveness modeling analysis

R. Rajasingham[1], D. Meya[2], G. Greene[3], A. Jordan[3], T. Chiller[3], D. Boulware[1], B. Larson[4]
[1]University of Minnesota, Minneapolis, United States, [2]Infectious Diseases Institute, Kampala, Uganda, [3]CDC, Atlanta, United States, [4]Boston University, Boston, United States

Background: Cryptococcal meningitis accounts for 15% of AIDS-related mortality. Cryptococcal antigen (CrAg) is detected in blood weeks before onset of meningitis, and CrAg positivity is an independent predictor of meningitis and death. CrAg screening for patients with advanced HIV is recommended by the World Health Organization, though implementation remains limited. Our objective was to evaluate costs and mortality reduction (lives saved) from a national CrAg screening program across Uganda.
Methods: We created a decision analytic model to evaluate CrAg screening. CrAg screening was considered for those with a CD4< 100 cells/µL per international guidelines, and in the context of a national HIV test and treatment program where CD4 testing may not be available. Costs (2016 USD) were estimated for screening, preemptive therapy, hospitalization, and maintenance therapy. Parameter assumptions are based on large prospective CrAg screening studies in Uganda, and clinical trials from sub Saharan Africa.

Population screened		Prevalence	Source
CD4 count ≤100 cells/µL		0.16	(1, 2)
CD4<100 cells/µL CrAg screened		0.8	Assumption
Return to clinic for CrAg results		0.8	Assumption
Asymptomatic CrAg+ receives preemptive treatment		1.0	
CrAg prevalence			
CrAg negative		0.9675	(3)
Prior CCM		0.0019	(3)
Incident CrAg +		0.0306	(3)
Symptomatic CrAg+		0.0102	(3)
Asymptomatic CrAg+		0.0204	(3)
Of incident asymptomatic CrAg+			
High titer		0.39	(3)
Low titer		0.61	(3)
CrAg+ outcomes			
CrAg+ high titer, no preemptive fluconazole or ART, develops CM		1.0	[illegible]
CrAg+ low titer, no preemptive fluconazole or ART, subsequently develops CM		0.50	(4, 5)
CrAg+ high titer, receives preemptive fluconazole, subsequently survives		0.64	(3)
CrAg+ low titer, receives preemptive fluconazole, survives		0.86	(3)
CrAg+ symptomatic presents to hospital		0.73	(6)
CrAg+ fails fluconazole, presents to hospital		0.80	Assumption
Symptomatic Meningitis outcomes			
CM who present to hospital		0.30	Assumption
Unmasking CM on ART, survives hospitalization with treatment		0.50	(7)
Input Costs		USD	
CrAg test cost		$3.41	
	CrAg LFA	$2.00	Source - Immy (personal communication)
	Import cost	$0.80	Source - Immy (personal communication)
	Shipping	$0.03	0.03 per test to ship 20,000 tests
	Labor	$0.58	Lab worker salary for 10 minutes to perform test
Fluconazole	200mg tablet	$0.14	(3)
Preemptive fluconazole course		$39.06	Including 8 months maintenance on 200mg daily
Hospitalization			
Hospital stay	$9.94 per day x 14 days	$139.13	
Lab testing		$89.18	1 CBC, 3 Cr, 3 K, 3Na, CSF analysis, CSF culture, CrAg
Supplies	$3.41 per day x 14 days	$47.68	
LPs	$9.29 per LP x 3	$27.88	
Personnel	$6.64 per day x 14 days	$93.03	Nurse, Doctor, HIV counselor, Phlebotomist, Lab tech
Amphotericin	50mg per day x 14 days	$165.94	(8)
Hospitalization total		$562.99	
Post hospitalization consolidation and maintenance with fluconazole		$56.78	1 year

[Table 1. Input parameters for base case model]



[Figure 1: Cost of CrAg screening and preemptive treatment with differential levels of implementation. With 100% CrAg screening and treatment, 1900 lives are saved (44%) and $860,000 dollars, compared to no screening.]

Results: In the base case for 1 million persons with a CD4 test annually, 128,000 with a CD4< 100 cells/µL were screened, and 8,233 were asymptomatic CrAg+ and received preemptive therapy. Compared to no screening, CrAg screening and treatment in the base case costs $3,356,724, and saves 7,320 lives, for a cost of $459 per life saved.
Within a national HIV test and treat program, of 1 million HIV-infected persons, 5,920 were incident CrAg positive (CrAg prevalence 1.5%). The total costs of a CrAg screening and treatment program was $4.12 million dollars, with 2,229 known deaths. Conversely without CrAg screening, the cost of treating meningitis was $5.45 million dollars with 6,712 deaths. Thus, despite the very low CrAg prevalence at about 1.5% in the general HIV-infected population, CrAg screening saved over $1.32 million (i.e. 13% of total costs) and averted 67% of deaths, saving $295 per death averted.
Conclusions: CrAg screening and treatment programs are cost saving and lifesaving and could be adopted and implemented by ministries of health to reduce mortality in those with advanced HIV disease. Even within HIV test and treat programs where CD4 testing is not performed, and CrAg prevalence is only 1.5%, CrAg screening is a worthy investment.

WEAB0102

HIV-associated central nervous system infections in Indonesia: A cohort study examining etiology, presentation and outcome

D. Imran[1], R. Estiasari[1], K. Maharani[1], S. Sucipto[1], D.C. Lestari[2], R. Eddy[3], E. Yunihastuti[4], T. Harjono[4], D. Oei[1], I.S. Timan[5], D. Wulandari[5], R. Wahyuningsih[6], A. Lastri[1], K.S.A. Myint[7], R. van Crevel[8,9]
[1]Cipto Mangunkusumo Hospital - Faculty of Medicine Universitas Indonesia, Department of Neurology, Jakarta, Indonesia, [2]Cipto Mangunkusumo Hospital - Faculty of Medicine Universitas Indonesia, Department of Microbiology, Jakarta, Indonesia, [3]Cipto Mangunkusumo Hospital - Faculty of Medicine Universitas Indonesia, Department of Radiology, Jakarta, Indonesia, [4]Cipto Mangunkusumo Hospital - Faculty of Medicine Universitas Indonesia, Department of Internal Medicine, Jakarta, Indonesia, [5]Cipto Mangunkusumo Hospital - Faculty of Medicine Universitas Indonesia, Department of Clinical Pathology, Jakarta, Indonesia, [6]Cipto Mangunkusumo Hospital - Faculty of Medicine Universitas Indonesia, Department of Parasitology, Jakarta, Indonesia, [7]Eijkman Institute for Molecular Biology, Jakarta, Indonesia, [8]Eijkman-Oxford Clinical Research Unit, Jakarta, Indonesia, [9]Radboud Center for Infectious Diseases, Radboud University Medical Center, Department of Internal Medicine, Nijmegen, Netherlands, [10]Faculty of Medicine Universitas Padjadjaran, TB/HIV Research Center, Bandung, Indonesia

Background: HIV infection leads to increased susceptibility and worse outcome of central nervous system (CNS) infections. We examined etiology and outcome of CNS infections and the effect of HIV in Indonesia, which is witnessing the second fastest growing HIV epidemic in Asia.
Methods: We prospectively included adults with suspected CNS infections during 15 months in a referral hospital in Jakarta. Systematic screening included HIV testing, routine cerebrospinal fluid (CSF) examination, neuroimaging, and paired HIV-RNA measurement in blood and CSF.
Results: 274 patients with suspected CNS infection (median age 26) presented with headache (77%), fever (78%), seizures (27%), loss of consciousness (71%) and focal neurological signs (40%). HIV infection was found in 147 (54%) patients with 56% newly diagnosed. Those with previously diagnosed HIV infection, 50% had a history of prior or current ART use and 18% reported cotrimoxazole PCP-prophylaxis. Lumbar puncture in HIV-positive subject was done in 80 patients (54%), and brain CT scan in 116 patients (79%). Among HIV-infected patients, we diagnosed cerebral toxoplasmosis (33%), tuberculous meningitis (22%), cryptococcal meningitis (9%), viral encephalitis (5%), brain abscess (2%), neurosyphilis (0.5%) and cerebral lymphoma (0.5%) while no diagnosis could be made in 28% of patients. HIV-RNA was done in blood and CSF of 65/147 patients (44%). Six patients have undetected HIV-RNA in their blood and CSF. Blood HIV-RNA range was 80 - $7.26.10^6$ and in CSF was 138-$1.69.10^6$ Follow-up was 97% complete. Mortality was strongly associated with HIV-infection; 37% of those with and 26% of those without HIV died dur-

ing hospitalisation, and 67% respectively 45% had died after six months follow-up (p< 0.01). Compared to patients with previously diagnosed HIV infection, those with newly diagnosed HIV had a similar CD4 cell count (median 29/ml versus 30/ml), but a higher mortality (log-rank test 0.03).
Conclusions: In this setting, patients with CNS infections came very late and with severe disease. HIV infection was very common, very advanced and associated with very poor outcome. Although 50% have ART history, only 6 patients have undetected HIV-RNA in their blood and CSF. These data underline the need to step up efforts to improve testing, ART and opportunistic infection management.

WEAB0103

Burden of sexually transmitted infections and prevalence of HIV among key population individuals presenting with STIs in Nepal

D.P. Bhandari, K.P. KC, H. Subhani, R.K. Shrestha, B.M. Shrestha, P.K. Thakur, I. Adhikary, B. Shrestha
FHI 360, Nepal, Kathmandu, Nepal

Background: Under the current global vision to control the HIV epidemic the through expanded provision of antiretroviral medications, relatively little attention has been devoted to sexually transmitted infections (STIs). Unfortunately, STIs remain a major cause of morbidity among people living with HIV, and STIs are associated with increased risk for HIV infection. This analysis assessed the burden of STIs among key populations (KPs), as well as prevalence of HIV among STI patients attending LINKAGES/Nepal-supported clinics.
Description: LINKAGES/Nepal — led by FHI 360 with support from the U.S. Agency for International Development and the U.S. President's Emergency Plan for AIDS Relief — provides HIV and STI diagnostic and case-management services to female sex workers (FSWs), clients of FSWs, men who have sex with men (MSM), male sex workers (MSWs), and transgender people in 16 districts of Nepal. The STI case-management services include counseling and syndromic management, syphilis screening using the rapid plasma reagin (RPR) test and treatment with benzathine penicillin, condom distribution to all KP members, and presumptive treatment of cervicitis for FSWs.
Lessons learned: From October 2016 to September 2017, 23,454 individuals (49 percent males, 50 percent females, and 1 percent trans people) were screened for STIs, of whom 5,475 (23 percent) were diagnosed with any STI. The most common diagnoses were vaginal discharge syndrome (69 percent) followed by syphilis (14 percent), urethral discharge syndrome (9 percent), and genital warts (4 percent). HIV prevalence among STI patients was 0.8 percent. HIV prevalence was highest among patients with syphilis at 3 percent; followed by patients with genital warts, at 2 percent; and vaginal discharge syndrome, at 0.4 percent. Out of 42 HIV-positive cases among STI patients, 21 (50 percent) had syphilis, 16 (38 percent) had vaginal discharge syndrome, 4 (10 percent) had genital warts, and one (2 percent) had urethral discharge syndrome.
Conclusions/Next steps: The STI burden among KP program beneficiaries is high, and many HIV-positive KP members are co-infected with an STI. Providing integrated services helps to link a large number of KP individuals to needed STI services in this resource-limited setting.

WEAB0104

Natural history of anogenital HPV infection and related disease among HIV-positive men: Findings from a Cohort Study in South Africa

A. Chikandiwa[1], P.T. Pisa[1], C. Tamalet[2], E.E. Muller[3], R. Kularatne[3], P. Michelow[4], M.F. Chersich[1], P. Mayaud[1,5], S. Delany-Moretlwe[1]
[1]University of the Witwatersrand, Wits Reproductive and HIV Institute, Johannesburg, South Africa, [2]Timone University, Clinical Microbiology IHU and CNRS-URMITE, Marseille, France, [3]National Health Laboratory Service, National Institute for Communicable Diseases, Johannesburg, South Africa, [4]University of the Witwatersrand, Anatomical Pathology, Johannesburg, South Africa, [5]London School of Hygiene and Tropical Medicine, Clinical Research, London, United Kingdom

Background: Persistent anogenital HPV infection causes anogenital warts (AGW), penile and anal cancers. We determined persistence of anogenital HPV infection, squamous intraepithelial lesions (SIL) and AGW among men living with HIV (MLHIV).
Methods: We enrolled 304 sexually-active MLHIV ≥18 years from Johannesburg. We collected socio-behavioral data, blood (CD4+ counts and HIV-1 plasma viral load [PVL]), anal, genital swabs (HPV DNA genotyping with Roche Linear Array and HPV16/18 viral load [VL] with RT-PCR on 22 swabs), and anal smears and examined for AGW at enrolment and 6-monthly follow-up visits for 18 months. Time to AGW incidence or clearance was estimated by Kaplan-Meier method. Correlates of persistent HPV infection, SIL and AGW clearance were evaluated with generalized estimating equations, logistic and ox regressions respectively. ROC analysis evaluated performance of HPV16/18 VL in predicting persistent SIL.
Results: A total of 260 (86%) and 259 (85%) MLHIV had anal and genital HPV results at both enrolment and final visits respectively. The median age was 38 [IQR: 22-59] years, 25% reported ≥1 sexual partners in the past 3 months and 5% reported ever having sex with other men. Most participants (65%) were on ART, with median CD4+ count 445 cells/μL (IQR: 328-567). Prevalence of anal and genital HPV infection was 39% (88/227) and 79% (224/283) respectively. The prevalence of anal SILs and AGW were 49% (120/244) and 12% (36/304) respectively. Persistence for anal and genital HPV infection were 26.2% (21/80) and 35.4% (68/192) respectively. HPV persistence was strongly associated with low enrolment CD4+ count (< 200 vs. >500 cells/μL, aOR=6.58; 95%CI: 2.41-17.94). Anal SIL incidence and persistence were 27.4% (34/124) and 30% (36/120) respectively. Prevalent anal HPV infection (aOR=5.08; 95%CI: 2.04-12.66) was associated with persistent SILs. AGW incidence was 1.4 per 100 person-years. Median time to AGW clearance was 0.7 (IQR, 0.5-1.1) years. AGW clearance was strongly associated with CD4+ count (< 350 vs.≥350 cells/μL, aOR=3.69; 95%CI: 1.44-9.47). Enrolment HPV16/18 VL performed poorly in predicting persistent SILs.
Conclusions: MLHIV have high persistence of anogenital HPV infection and related disease. HPV vaccination among boys and effective use of ART with immunological reconstitution could reduce this burden.

WEAB0105

Kaposi disease in HIV-infected patients with suppressed HIV viremia: The experience of the French national multidisciplinary committee ONCOVIH

R. Palich[1], M. Veyri[2], M.-A. Valantin[1], A.-G. Marcelin[3], F. Boué[4], A. Guihot[5], C. Solas[6], H. Ait-Mohand[1], V. Martinez[1], I. Poizot-Martin[7], D. Costagliola[8], J.-P. Spano[2], C. Katlama[1], ONCOVIH Study Group
[1]Pitié-Salpêtrière Hospital, AP-HP, Infectious Diseases, Paris, France, [2]Pitié-Salpêtrière Hospital, AP-HP, Oncology, Paris, France, [3]Pitié-Salpêtrière Hospital, AP-HP, Virology, Paris, France, [4]Antoine-Béclère Hospital, AP-HP, Clinical Immunology, Clamart, France, [5]Pitié-Salpêtrière Hospital, AP-HP, Immunology, Paris, France, [6]La Timone Hospital, AP-HM, Pharmacology, Marseille, France, [7]Saint-Marguerite Hospital, AP-HM, Clinical Immunology, Marseille, France, [8]Pierre Louis Institute of Epidemiology and Public Health (IPLESP, UMRS 1136), Paris, France

Background: Kaposi disease (KD) is among the most frequent HIV associated cancers, classically occurring in HIV-replicating individuals. Since 2014, the ONCOVIH national multidisciplinary committee (MDC) registers

cancers in HIV infected patients. We report our experience of KD occurring in patients despite sustained virological suppression.
Methods: This observational and national study enrolled all cases of individuals with a first episode or a relapse of KD, on ART for at least 12 months, with a plasma viral load (pVL) < 50cp/ml at the time of KD diagnosis.
Results: The French ONCOVIH MDC registered a total of 72 KD cases between 05/2014 and 11/2017. We included for analysis the 22/ 72 (31%) who fulfilled inclusion criteria, whereas 38/72 (53%) had pVL >50 cp/ml at the time of KD diagnostic, and 12 had missing data. They were 18 male and 4 female, born in France for 10 of them and in Africa for 12, with a median age of 51 years (IQR 34-61). HIV infection was diagnosed 12 years earlier (IQR 5-14). CD4 nadir was 200/mm^3 (IQR 73-290), and median duration of virological suppression 4 years (IQR 2-5). KD was a relapse in 59% of cases, and a first episode in 41%. KD localisations involved skin (100% of cases), lymph nodes (27%), bronchi (18%), oesophagus/stomach (14%), bone (14%), and/or palate (5%). Median CD4 count was 478/mm^3 (IQR 269-630) with a CD4/CD8 ratio of 0.58 (IQR 0.34-0.75). At time of MDC, KD therapy had included anthracyclines in 36% of cases and/or taxanes in 27% of cases. In November 2017, from the follow up of 16/22 patients, all were alive, with a KD in partial remission in 31% of cases, stability in 38% and progression in 31%.
Conclusions: Kaposi disease is observed in aging patients with suppressed viremia either as relapse or new case. HHV-8 as main cause for KD need to be further investigated. Follow up should bring information towards treatment response. Anti PD1 may deserve a pilot investigation in patients failing standard anti-KD chemotherapies.

WEAB0106

Kaposi sarcoma incidence remains unchanged among African American males in the Southern United States: U.S. Cancer Statistic Data, 2000-2014

E. Chiao, T. Aaron, Y. Dong, R. Kathryn, J. Kramer, W. Donna
Baylor College of Medicine, Houston, United States

Background: Kaposi sarcoma (KS) is the most common neoplasm of people living with HIV today. Although the overall incidence of KS has been reported to be declining in the US, KS has strong racial/ethnic, age, and regional diversity in incidence trends.
Methods: We analyzed KS incidence data from the US Cancer Statistics (USCS) registry for the years 2000-2014. The USCS registry is the official data source for federal government-reported cancer incidence statistics and covers 97% of the US population. Women were excluded because of the low numbers of KS cases in certain geographic regions, and our analyses only included 20 to 54 year-old age-group as prior validation studies indicated that ~94% of KS cases in this age-range are HIV-related. We calculated adjusted incidence rates and assessed annual trends among sociodemographic and geographic subgroups using joinpoint regression analysis.
Results: During the study period, 12,549 men were diagnosed with KS. The overall incidence of KS among men decreased from 1.42/100,000 in 2000 to 0.95/100,000 in 2014, decreasing by 3.60% (95% confidence interval [CI], -4.00% to -3.13%) annually. The overall annual percent change (APC) for men significant decreased (-6.27%, p<0.05) from 2007-2010 and again (-2.13%, p<0.05) from 2010-2014. Among African American, non-Hispanic Caucasian, and Hispanic men, the incidences in 2014 were 2.37/100,000, 0.49/100,000, and 1.22/100,000, respectively. Although there was a decrease in the APC among African American men from 2000-2014 (-3.31%, p<0.05), there were differences in the rate of change among African American men by region. In the Northeast, the APC was noted to have 3 joinpoints, with non-significant decreases in incidence in years 2009-2012 (APC=-0.23%, p< 0.05), followed by a significant decrease in years 2012-2014 (APC=-26.17%, p<0.05). In the Midwest and West there were significant decreases throughout years 2000-2014 (APC=-3.4%, p<0.05, and APC=-5.59%, p<0.05, respectively). However, in the South, there has been no significant change in incidence (APC=-0.86%, p>0.05) of KS among African American men.
Conclusions: Geographic disparities in KS incidence remain for African American men in the U.S. Between the years 2000-2014, unlike other regions, the incidence of KS has remained unchanged in the southern U.S.

WEAB02 ART in infants and children

Developmental and cognitive effects of type of antepartum and postpartum ARV exposure for Ugandan and Malawian IMPAACT PROMISE HIV-exposed versus unexposed children at age 12, 24 and 48 months

M. Boivin[1,2], L. Maliwichi-Senganimalunje[3,4], L. Wambuzi Ogwang[5], R. Kawalazira[3], A. Sikorskii[6], I. Familiar-Lopez[7], A. Kuteesa[5], M. Nyakato[5], A. Mutebe[5,8], M. Makitende[5], M. Mallewa[3], H. Ruisenor-Escudero[7], J. Aizire[9], T. Taha[9], M.G. Fowler[10]
[1]Michigan State University, Psychiatry and Neurology & Ophthalmology, East Lansing, United States, [2]University of Michigan, Psychiatry, An Arbor, United States, [3]Malawi College of Medicine - Johns Hopkins University, Blantyre, Malawi, [4]University of Malawi, Chancellor College, Zomba, Malawi, [5]Makerere University - Johns Hopkins University, Kampala, Uganda, [6]Michigan State University, Psychiatry and Statistics & Probability, East Lansing, United States, [7]Michigan State University, Psychiatry, East Lansing, United States, [8]Global Health Uganda, Kampala, Uganda, [9]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [10]Johns Hopkins University, Pathology and Infectious Diseases, Baltimore, United States

Background: Triple ARVs during pregnancy and breastfeeding dramatically decrease the risk of HIV transmission from mothers to infants. However, prolonged antepartum and postpartum exposure to Triple-ARV prophylaxis may disrupt infant neurodevelopment. The present study evaluates developmental outcomes for HIV-exposed uninfected (HEU) and unexposed uninfected (HUU) Ugandan and Malawian children enrolled in the IMPAACT PROMISE RCT study.
Methods: Pregnant HIV-infected mothers were randomized to Triple-ARV prophylaxis (3TC-ZDV/LPV-RTV or FTC-TDF/LPV-RTV), versus Zidovudine (ZDV). Postpartum, the mother/newborn dyads were randomized to maternal Triple-ARV or infant Nevirapine (NVP) during breastfeeding. 942 children were enrolled between 9 and 12 months of age: 465 were unexposed/uninfected (HUU) (49%) and 454 (48%) were girls. HEU and age-matched HUU children were enrolled at the two IMPAACT PROMISE study sites: 465 (49%) in Blantyre, Malawi, and 477 (51%) in Kampala, Uganda. Mullen Scales of Early Learning (MSEL) was used for developmental assessment at 12, 24, and 48 months of age, and the Kaufman Assessment Battery for Children (KABC) for cognitive assessment at 48 months only.
Results: Controlling for sex, study site, and age at assessment, there were no significant MSEL differences among PMTCT ante- and postpartum treatment arms at 12 and 24 months (Table 1). There were significant differences among the treatment arms at 48 months for the MSEL composite cognitive score (p=0.04) and Fine Motor scale (p=0.001). For the KABC at 48 months, there were significant differences among the study groups for all the global scales except the nonverbal index. However, the maternal Triple-ARV (antepartum and postpartum) children were not at a significant disadvantage to the HUU group on any of the pairwise comparisons. Among all significant p values in Table 1, only MSEL fine motor remained significant after a Bonferroni adjustment for multiple comparisons. Again, the maternal Triple-ARV exposed children were not at a significant disadvantage.
Conclusions: Both ante- and postpartum maternal triple-ARV exposure did not result in greater developmental or cognitive risk for their HEU children through 48 months of age compared to HUU children. Overall, HUU and HEU children were developmentally comparable. These findings are reassuring as PMTCT programs using maternal ART are widely rolled out in resource-constrained settings.

Table 1. The standardized cognitive composite and the scale least square (LS) means and standard errors (SE) for the Mullen Scales of Early Learning (MSEL) are presented at 12, 24, and 48 months by row; along with the Kaufman Assessment Battery for Children, 2nd edition (KABC) global domains LS means for the 48-month assessment. Probability (P) values for the analysis of covariance (ANCOVA) controlling for age at assessment, gender, and study site (Uganda, Malawi) are presented for the between-group comparison among the four antepartum & postpartum ARV treatment arm combinations (3rd column from right) and for the between-group differences when adding the HUU group.

Outcome	Time point, in months	Triple ARV, infant NVP, LS mean (SE)	Triple ARV, maternal triple ARV, LS mean (SE)	Zidovudine, infant NVP, LS mean (SE)	Zidovudine, maternal triple ARV, LS mean (SE)	P-value for comparison by exposure	HIV-unexposed uninfected (HUU), LS mean (SE)	P-value for comparison of all groups

Central nervous system toxicity of efavirenz in HIV-infected children in Tanzania

L. Van de Wijer[1], D.N. Mchaile[2], A.F.A. Schellekens[3,4], N.N.J. Lambregts-Rommelse[3], Q. de Mast[1], B.T. Mmbaga[5], A.J.A.M. van der Ven[1], G.D. Kinabo[2]
[1]Radboud University Medical Center, Department of General Internal Medicine, Nijmegen, Netherlands, [2]Kilimanjaro Christian Medical Centre, Department of Pediatrics, Moshi, Tanzania, United Republic of, [3]Radboud University Medical Center, Department of Psychiatry, Nijmegen, Netherlands, [4]Nijmegen Institute for Scientist Practitioners in Addiction, Nijmegen, Netherlands, [5]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, United Republic of

Background: The World Health Organization recommends efavirenz as part of the first-line combination antiretroviral therapy (cART) for HIV-infected children. Awareness of central nervous system (CNS) side effects in adults is increasing. Reliable data on CNS toxicity in children, however, remain sparse. We compared neuropsychological symptoms, cognitive performance as well as adherence between long-term treated HIV-infected Tanzanian children on efavirenz vs. control regimens.

Methods: Cross-sectional observational study among HIV-infected children (6-12 years) on cART for ≥6 months and with viral loads ≤ 1000 copies/ml in Kilimanjaro, Tanzania. We used the Child Behavior Checklist (CBCL6-18) to evaluate behavioral and emotional problems. Cognitive performance was assessed using the Raven's Colored Progressive Matrices and the Digit Span test. Non-adherence was defined as any reported missed doses over the previous 3 days or < 100% adherence since the last clinical visit. Our study was powered to show a group difference of 0.5 SD in CBCL6-18 total problem scores. MANCOVA and logistic regression were used to assess differences between groups. Analyses were adjusted for age, sex, being treatment naïve, duration of cART, history of TB treatment, parental loss, and HIV disclosure.

Results: One-hundred-forty-one children were enrolled of whom 72 (51%) used efavirenz. Groups did not differ in age, sex, nadir CD4+ or general demographics. We found no differences in the CBCL6-18 behavioral and emotional problem scores (total/internalizing/externalizing), cognitive performance tests or adherence. Efavirenz-treated children had lower CBCL 6-18 competence scores (P=0.025), which was mainly due to lower scores on school performance with mean (SD) 4.1 (1.4) and 4.7 (0.9) (P=0.001) for efavirenz and controls respectively.

Conclusions: Overall, we did not see differences in emotional and behavioral problems, cognitive performance scores or adherence between efavirenz-treated children and controls, which is in contrast to earlier studies in adults. The lower school performance scores in efavirenz-treated children, however, warrant further study.

Background: There are limited data describing characteristics at second-line ART initiation and subsequent outcomes among children, particularly in resource-limited settings.

Methods: Data through 2015 on HIV-infected children aged < 18 years initiating ART from 11 cohort networks were pooled. Characteristics at second-line ART initiation and immunological and clinical outcomes measured at one and two years after initiation were summarized by region: North America, Latin America (Caribbean, Central & South America), Europe, Asia, Southern Africa (South Africa & Botswana) and the rest of sub-Saharan Africa (SSA). Results were not adjusted for censoring due to loss to- or end of- follow-up.

Results: Of 85,389 children who started first-line ART, 3,555 (4%) switched to second-line, primarily with protease inhibitors (92%). Median [interquartile range (IQR)] age at second-line ART initiation varied from 4.1 [1.9, 7.5] years in North America to 10.3 [6.7, 13.8] years in Latin America (Table). The lowest CD4 counts at second-line initiation were in SSA and Latin America (235 [81, 561] and 239 [63, 661] cells/mm³, respectively). Overall, the median [IQR] follow-up after second-line ART initiation was 29 [12, 51] months, with the shortest follow-up in SSA (21 [8, 39] months) and the longest in North America (63 [32, 101] months). In the first year after initiation of second-line ART, observed mortality was higher in Latin America (4.9% [1.8, 10.6]) and SSA (2.8% [2.0, 4.0]) compared to Southern Africa (0.7% [0.3, 1.4]); progression to AIDS was highest in SSA (12.1% [9.4, 15.4]) followed by Asia (4.6% [2.2, 8.4]). Median CD4 counts one year after second-line initiation improved and were >500 cells/mm³ in all regions.
No deaths were observed between one and two years of follow-up after second-line ART initiation in North or Latin America, while there were increases in cumulative mortality through two years in the other regions. There were continued improvements in CD4 counts in most regions at two years of follow-up.

Conclusions: We found wide regional variations in age and CD4 count at second-line ART initation among children. Immunological restoration was observed in all regions after switch to second-line. However, deaths continued to be observed in some regions through two years of follow-up.

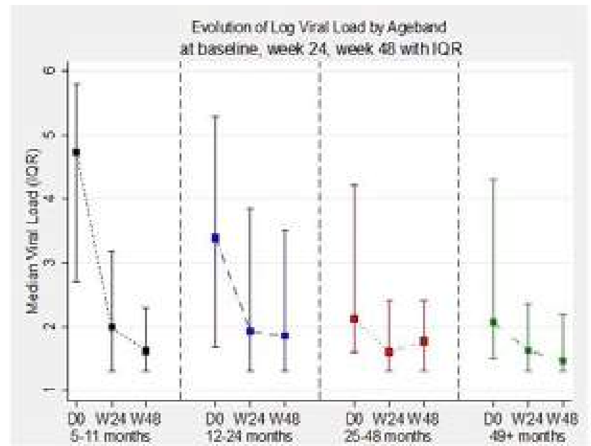
WEAB0204

Pellets' formulation of Lopinavir/ritonavir in children: 48-week evolution of viral suppression across age categories in the LIVING study

I. Andrieux-Meyer[1], O. Salami[2], R. Omollo[3], T. Egondi[3], M. Waweru[3], S. Odiambo[3], M. Wasunna[3], V. Musiime[4], E. Obimbo[5], E. Bukusi[6], P. Oyaro[6], J. Mwanga-Amumpaire[7], J. Mbuthia[8], J. Lee[1], F. Kyhomuhendo[3], F. Simon[1], W. Nyandiko[9], A. Kekitiinwa[10], M. Lallemant[1], D. Wamalwa[5], LIVING Study Group
[1]Drugs for Neglected Diseases Initiative, Geneva, Switzerland, [2]Drugs for Neglected Diseases Initiative, Paediatric HIV, Nairobi, Kenya, [3]Drugs for Neglected Diseases Initiative, Nairobi, Kenya, [4]Joint Clinical Research Centre, Kampala, Uganda, [5]University of Nairobi, Nairobi, Kenya, [6]Kenya Medical Research Institute, Nairobi, Kenya, [7]EPICENTRE, Mbarara, Uganda, [8]Gertrude's Children's Hospital, Nairobi, Kenya, [9]AMPATH, Moi University, Eldoret, Kenya, [10]Baylor Centre of Excellence in Pediatric HIV, Kampala, Uganda

Background: The pellets' formulation of LPV/r which is palatable, heat-stable and easy-to-administer has received tentative USFDA approval for use in infants and young children. However, there is a paucity of clinical data on its effectiveness and safety in routine care. The LIVING study is evaluating the effectiveness, safety, PK and acceptability of LPV/r pellets + ABC/3TC (or AZT/3TC) dispersible tablets, in HIV+ children unable to swallow tablets in Kenya and Uganda.
Methods: An open-label, single-arm, prospective, multi-centre, phase-3b implementation study. Inclusion criteria: ARV naïve, on liquid LPV/r-based or failing NNRTI based ART; Weight ≥3 and < 25kg. ART dosing based on WHO weight bands. Children assessed at baseline, 1 month then 3-monthly. AEs were graded using DAIDS tables. We evaluated viral suppression across 4 age categories (months): 5-11, 12-24, 25-48 and ≥49.
Results: As of 31/10/2017, 723 patients had been enrolled, of whom 459 and 303 had reached WK24 and WK48 respectively, with a cohort retention of 88.6% (follow-up on going, 7 deaths,). Baseline and WK 48 VL available in 266 children (136 (51.0%)females, median age 43 months (95% CI 25-62), 5 (9.4%) ART naïve, 229 (86.1%) switched from LPV/r syrup, and 12 (4.5%) from NVP based ART.
At baseline, Viral load parameters were as follows: median (IQR) (log10 cp/ml) and proportion with VL< 50 and < 400 cp/ml across age categories were 4.7(2.7-5.8), 14.0% and 28.5% in the 5-11months, 3.4(1.7-5.3) , 25.0% and 45.0% in the12-24 months, 2.1(1.6-4.2) 27.0% and 57.0% in the 25-48 months and 2.1(1.5-4.3), 36.0% and 57.0% in the≥ 49 months.
At WK48, VL parameters were 1.6 log (1.3-2.3), 52.0% and 76.0% in the 5-11months, 1.9(1.3-3.5)52.5% and 62.5% in the12-24 months, 1.8(1.3-2.4), 49.0% and 80.0% in the 25-48 months and 1.5(1.3-2.2) 60.0% and 81.0% in the ≥ 49 months. 36 children had 103 AEs grade 3/4, 2 leading to treatment stoppage.
Conclusions: LPV/r Pellets-based ART in children is associated with very levels of HIV viral suppression regardless of age at initiation.



[Viral suppression stratified by age at enrolment]

WEAB0205

Pharmacokinetics, safety, and efficacy of bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) single-tablet regimen in HIV-1-infected children (6 to < 12 years)

M. Cotton[1], A. Liberty[2], C.A. Rodriguez[3], K. Chokephaibulkit[4], P. Kosalaraksa[5], E. Hellstrom[6], E. Natukunda[7], P. Wong[8], S.R. Majeed[8], E. Quirk[8], H. Graham[8], C. Pikora[8]
[1]Stellenbosch University, Tygerberg Hospital, Cape Town, South Africa, [2]Chris Hani Baragwanath Academic Hospital, Soweto, South Africa, [3]University of South Florida, Morsani College of Medicine, Tampa, United States, [4]Siriraj Hospital, Mahidol University, Bangkok, Thailand, [5]Khon Kaen University, Khon Kaen, Thailand, [6]Be Part Yoluntu Centre, Western Cape, South Africa, [7]Joint Clinical Research Centre, Kampala, Uganda, [8]Gilead Sciences Inc., Foster City, United States

Background: Bictegravir (BIC, B), a novel, unboosted integrase strand transfer inhibitor (INSTI) with a high barrier to resistance and low potential for drug interactions, has been coformulated with the recommended NRTI backbone of emtricitabine (F, FTC) and tenofovir alafenamide (TAF) (B/F/TAF) into a once-daily (QD), single-tablet regimen (STR). We report pharmacokinetics (PK), safety and efficacy in children who switched from a stable antiretroviral regimen to B/F/TAF.
Methods: We conducted a prospective, single-arm, open-label, 2-part, 48-week (W) clinical trial to evaluate switching to the adult formulation of B/F/TAF (50/200/25 mg) QD in virologically suppressed children (6 to < 12 years) weighing ≥25 kg. Intensive PK was evaluated at W2 or W4. PK parameters were compared to B/F/TAF-treated adults to confirm BIC dose. Adverse events (AE), laboratory tests, HIV-1 RNA, were assessed. We report follow up data through W12.
Results: 25 children enrolled; median (range) age 10 (6-11) yrs, median (range) weight 28.4 (25.0-39.0) kg, 52% female, 64% Black, median CD4 count 928 cells/μL. BIC AUC_{tau} was similar, C_{max} 77% higher, and C_{tau} 22% lower in children ≥25 kg than adults. BIC C_{tau} was well above protein-adjusted effective concentration for wild-type virus (162 ng/mL) in all children. FTC and TAF exposures were within safe and efficacious ranges of adults (table). Through median (Q1, Q3) exposure to study drug of 16.1 (15.9, 17.7) weeks, most common AEs were grade 1 diarrhea and upper respiratory tract infection (each 16%, 4/25); no other AE occurred in >2 participants. No participant discontinued for an AE. All (100%) had HIV-1 RNA < 50 c/mL at W12; none met criteria for resistance testing.
Conclusions: B/F/TAF maintained virologic suppression and was well tolerated in children through at least 12 weeks. Similar to adults, therapeutic plasma concentrations of all B/F/TAF components of B/F/TAF were achieved. Efficacy and safety in children are consistent with phase 3 B/F/TAF results in adults and adolescents, showing high proportions with viral suppression, excellent tolerability, and no resistance. B/F/TAF may be an important unboosted INSTI, STR option for HIV-infected children due to its small tablet size, high barrier to resistance and lack of food requirement.

	Parameter	Children[a]	Adult[b]	%GLSM Ratio (90% CI)
BIC	AUC_{tau}, ng*h/mL	121034 (36.4)	102001 (26.9)	116 (104, 130)
	C_{max}, ng/mL	10989 (28.3)	6146 (22.9)	177 (162, 194)
	C_{tau}, ng/mL	2367 (78.8)	2610 (35.2)	78.3 (63.4, 96.7)

WEAC01 The new high risk populations: Who are they?

WEAC0101

Reaching out to hidden population in Malaysia: MSMs, transgender and sex workers in Muslims majority setting where sex is a crime

Y. Md Yusralhakim
Malaysian AIDS Council, Global Fund, Kuala Lumpur, Malaysia

Background: Malaysia has 31 million populations with 61.3 % Muslims, Homosexuality and sex out of marriage are illegal and criminalised under both civil and Shariah Laws. Because of this criminalisation, MSM, Sex Workers and Transgender go hidden. In 2016, Malaysia estimated number of MSM is 170 000 and number of transgender remains unknown, however a Delphi-exercise in 2014 determined that there were 24,000 transgender sex workers and 21 000 female sex workers. MSM saw HIV prevalence rise from 3.9 to 8.9% between 2009 and 2014. Sexual transmission of HIV in general, has recorded a 2.5 fold increase, accounting for 84% of new HIV infection in 2016 compared to 32% in 2006.
Description: Reaching out to MSMs,Transgender, PWID and sex workers is one of the biggest challenges. In response to this, The Malaysian AIDS Council (MAC) implemented the Case Management Program for Key Populations funded by The Global Fund that aims to reach out to these hard-to-reach populations and refer them to services at government clinics by using a peer-to-peer approach. 85 peer caseworkers were trained to link KP clients to 52 government clinics which been branded as Community Friendly Clinics. The programme involves series of empowerment trainingfor caseworkers, desensitisation workshops for healthcare providers and removing legal barriers advocacy.
Lessons learned: Through this programme, from January to December 2017, 10,656 KP clients were reached either through online or venue based approaches, of this number, 5461 went for HIV screening, and 467 were diagnosed positive and 131 has initiated HIV treatment. 56% were from sexual transmission groups (MSM, SW and TG) and of those, 57% Malays (Islam), 18%, Chinese, 11% Indian and 12% others, this never been captured before since sexual transmission took over IDU as the main driver for HIV infection.
Conclusions/Next steps: In ensuring the sustainability of HIV response, a continuous creation of enabling environment in every angles for KPs should be in place, peer-to-peer and personalised care for KPs should come hand in hand with removing legal barriers and community friendly services that is stigma and discrimination free.

WEAC0102

Geosocial networking app use among men who have sex with men in China: Findings from the T2T study

H. Zou[1,2,3], X. Meng[4], Y. Lu[2], Z. Wang[2], T. Jia[4], H. Yin[4], Z. Luo[5], Y. Ding[5], W. Chen[5], S. Huang[6], H. Zheng[6], B. Yang[6], A. Grulich[3], The T2T Study
[1]Sun Yat-sen University, School of Public Health (Shenzhen), Shenzhen, China, [2]Sun Yat-sen University, School of Public Health, Guangzhou, China, [3]University of New South Wales, Kirby Institute, Sydney, Australia, [4]Wuxi Municipal Centre for Disease Control and Prevention, Wuxi, China, [5]Shenzhen Nanshan Center for Chronic Disease Control, Shenzhen, China, [6]Dermatology Hospital, Southern Medical University, Guangzhou, China

Background: Men who have sex with men (MSM) are increasingly using geosocial networking (GSN) mobile applications (app) to socialize in the community. Our study aimed to describe app use among MSM in China to provide reference for app-based HIV interventions.
Methods: MSM aged ≥18 years old who had ≥2 male sex partners were recruited between January and August, 2017 in 3 metropolitan cities: Guangzhou, Shenzhen and Wuxi. A self-completed tablet-based questionnaire was collected about socio-demographic characteristics, sexual behavior characteristics and app use. A blood sample was collected to test for HIV and syphilis, and an rectal swab and urine sample were collected to test for gonorrhea and chlamydia. Anogential warts were checked by a clinician.
Results: A total of 603 subjects were enrolled (mean age=27.9 years, SD=7.8). Some 80% of MSM had ever used an app, 76.7% of whom had been using an app for more than 12 months, and 41.6% spent >30 minutes per day on apps. The proportion of app use increased significantly with increasing age, longer time of stay in the study city, higher educational level and more frequent alcohol use (P< 0.05 for all). MSM engaging in receptive anal intercourse were more likely to use an app over the past 6 months (P< 0.001). There was no difference in the proportion of patients with or without regular partner who used an app (P=0.348). App users had more sex partners (P< 0.001), higher usage of Rush (P=0.006) and marijuana (P=0.046), and more HIV tests (P< 0.001) in the past 6 months, compared to non app users. Prevalence of HIV (10.7% vs 7.1%), syphilis (9.9% vs 5.8%), urethral chlamydia (5.2% vs 8.3%), rectal gonorrhea (3.5% vs 2.4%), urethral gonorrhoeae (3.1% vs 4.1%) and anogenital warts (5.0% vs 3.3%) were similar in the two groups (P>0.1 for all). App users had significantly more rectal chlamydia (15.6% vs 6.6%, P=0.035).
Conclusions: The majority of MSM had frequent and long-term use of GSN app. Partnered status did not affect men's app use behaviors. GSN app should be used as a platform to carry out interventions aimed at reducing HIV and rectal sexually transmitted infections.

WEAC0103

Extended risk network testing to find HIV cases among key populations in Ukraine: Predicting recruitment of HIV-positive clients with machine learning

P. Smyrnov[1], Y. Sereda[2], I. Sazonova[1], K. Boiko[1], Y. Kuznetsova[1], K. Slobodianiuk[1], O. Denisiuk[1], S.R. Friedman[3]
[1]Alliance for Public Health, Kyiv, Ukraine, [2]Independent Consultant, Kyiv, Ukraine, [3]National Development and Research Institutes, New York, United States

Background: Alliance for Public Health implements extended risk network testing during community-based outreach to improve HIV case-finding among key populations. We aimed to develop a prediction model for finding HIV-positives in the recruitment network using machine learning.
Methods: Since 2016, 51,069 people who inject drugs and their extended risk network peers were recruited in 12 regions of Ukraine. Initial recruitment started from HIV positive cases found in harm reduction program. Enrollment criteria for seeds were 14+ years, people who inject drugs, HIV positive rapid test. Participants got coupons to invite their peers defined as an injecting partner, sexual partner, sexual or injecting partner of somebody from the social network who can be also at risk of HIV. Recruitment was stopped if there were two HIV-negative cases next to

each other in a chain. Data on recruitment chains and participants' characteristics were collected in real-time using Syrexcloud mobile application. Random Forest machine learning algorithm was used for predicting presence of HIV-positives within two waves of recruitment among the subset of participants who received coupons (N=22,236).

Results: Among participants who received coupons, 80% of them (n=17,872) recruited at least one peer and 35% of them (n=7,678) recruited at least one HIV-positive participant within two waves of recruitment network. The full random forest model with 17 predictors yielded an accuracy of 84.9% for classification of HIV-positives and negatives (sensitivity of 83.2% and specificity of 85.8%). The most informative predictors of recruitment of HIV-positives included size of recruited network for each participant (mean minimal depth (MMD) = 1.33), result of HIV rapid test at screening (MMD=2.00), region (MMD=2.12), experience of HIV testing before screening (MMD=2.78), and age (MMD=2.95). Sex (MMD=4.37), group of key population (MMD=3.97) and marital status (MMD=3.56) had the lowest contribution to prediction.

Conclusions: High level of prediction model accuracy suggests that application of Random Forest machine learning algorithm during recruitment could improve HIV-positive yield among recruited participants. Further validation of Random Forest prediction algorithm includes its implementation as a decision-making tool for improving recruitment strategy, such as distributing more coupons to participants with high probability of recruitment of HIV-positives.

WEAC0104

When and why? Timing and determinants of post-migration HIV acquisition among sub-Saharan immigrants in France

A. Gosselin[1,2], A. Ravalihasy[1,2], J. Pannetier[1], F. Lert[1],
A. Desgrées du Loû[1,2], Parcours Study Group
[1]CEPED (Université Paris Descartes, IRD, Inserm), Paris, France, [2]Institut de Recherche pour le Développement, Marseille, France

Background: Mounting evidence has recently highlighted the fact that many HIV-positive immigrants in Europe acquired their infections post migration, in relation to experiences of social hardship that entail at-risk sexuality (e.g. transactional). However, the timing of these infections is not known. This study aims to estimate the timing of post-migration HIV infection among Sub-Saharan immigrants in France, who are particularly affected by HIV, and to understand the correlates of post-migration infection.

Methods: Life-event and clinical information were collected in 2012-2013 from a random sample of 277 HIV-infected outpatients infected after arrival in France and 431 patients not diagnosed with HIV, born in Sub-Saharan Africa and living in the Paris area. The 6th year in France was chosen as the settlement delay based on previous analysis. We assumed HIV infection after six years (i.e. after the settlement period) in France if at least one of the following criteria was fulfilled: (i) HIV diagnosis at least 11 years after the six years in France, (ii) at least one negative HIV test in the 6 first years in France, (iii) sexual debut after 6 years in France. Otherwise, time of HIV infection was based on statistical modeling of first CD4 T-cell count. We assessed the determinants of HIV acquisition after six years in France using multinomial logistic regression models.

Results: Overall, 58% of Sub-Saharan immigrants who acquired HIV in France had been infected during the first six years in the country (55% of men and 61% of women). Conversely, about 42% of immigrants had contracted HIV after settlement. Factors associated with post-settlement infection were arrival in France at a younger age (between 18 and 27 years old versus later (OR=2.40[1.08-5.31]) and arriving with a long-term permit versus being undocumented (OR=2.23[1.12-4.43]). Bivariate models showed that post-settlement infection was associated with occasional and transactional relationships (OR=1.98[1.04-3.79]) and concurrent partnerships (OR=1.91[1.01-3.60]).

Conclusions: The majority of post-migration HIV acquisition occurs during the settlement period. Therefore, HIV prevention efforts should target newly arrived immigrants. However, long-time immigrants are also at risk for HIV, and specific prevention tools and interventions should be directed at this population.

	Bivariate models		Multivariate models	
	RRR [IC 95%]	p	RRR [IC 95%]	p
Legal permit at arrival in France				
Undocumented	ref		ref	
Short term permit	1.21 [0.63-2.34]	0.557	1.11 [0.62-2.00]	0.724
Long term permit or French nationality	2.60 [1.43-4.74]	0.002	2.23 [1.12-4.43]	0.023
Had at least one casual or transactional partnership after 6 years in France (ref. No)				
Yes	1.98 [1.04-3.79]	0.039	1.49 [0.64-3.51]	0.348
Had at least one concurrent partnership after 6 years in France (ref. No)				
Yes	1.91 [1.01-3.60]	0.047	1.31 [0.67-2.56]	0.416

[Factors associated with the probability to be infected after settlement (in reference to the non infected group)]

WEAC0105

Patterns of substance use among young men who have sex with men and their associations with HIV risk behavior and sexually transmitted infections

M. Newcomb, G. Swann, B. Mustanski
Northwestern University, Medical Social Sciences, Chicago, United States

Background: Young men who have sex with men (YMSM) carry a heavy burden of HIV in the United States. Substance use predicts condomless anal sex (CAS) and HIV incidence, but little is known about patterns of polysubstance use and individual differences in patterns of use, particularly among YMSM under age 21. The current study used longitudinal data to describe patterns of polysubstance use, examine demographic differences in patterns of use, and predict HIV risk across groups of substance users.

Methods: We utilized an analytic sample of 601 YMSM aged 16-20 from the RADAR cohort study of YMSM in Chicago (N=1,125, age range 16-29). Participants completed study visits every 6 months between 2015 and 2017, at which time we assessed past 6-month substance use and sexual behavior. STI testing was conducted annually. We used latent class analysis (LCA) to empirically derive groups of individuals who tend to use similar substances. We included the most frequently endorsed substances as latent class indicators (binge-drinking, chronic marijuana use, stimulants, ecstasy, prescription drugs). We then conducted one-way ANOVA and chi-square analyses to examine demographic differences in class membership and negative binomial and logistic regression models to predict HIV risk.

Results: LCA revealed 4 latent classes of substance users. Binge-Drinkers (N=166) were more likely to be White and gay-identified; Binge-Drinkers and Prescription Drug Users (N=144) were more likely to be White; Polysubstance Users (N=70) were more likely to be gay-identified and the least likely to be Black; and Low Substance Users (N=221) were the most likely to be Black, younger and bisexual. Polysubstance Users had the highest rates of CAS and STIs concurrently and longitudinally, followed by Binge-Drinkers and Polysubstance Users, Binge-Drinkers, and Low Substance Users (all comparisons p< .05).

Conclusions: The YMSM groups reporting use of multiple substances had the highest HIV risk. Polysubstance use has consistently been linked to HIV, but these analyses point to prescription drug use as another important target for HIV prevention among YMSM. Importantly, low substance use and CAS among Black YMSM contrast with their high HIV incidence in Chicago. Patterns of substance use cannot fully explain racial disparities in HIV.

WEAD01 Justice on the margins: Legal strategies to address barriers to HIV services

WEAD0101

Innovative paralegal and advocacy program enhancing access to justice and harm reduction services in Mombasa county

H. Tayab[1], A. Badhrus[1], F. Jeneby[1], M. Fahmy[1], F. Abdulrahman[1], M. Handulle[2]
[1]Muslim Education and Welfare Association (MEWA), Health and Harm Reduction, Mombasa, Kenya, [2]Mainline, Harm Reduction, Amsterdam, Netherlands

Background: Criminalization of drug use, denial of health services, gross human right violations by law enforcers and community increases PWUD risk of premature death and morbidity.
Kenya has an estimated 18,327 People Who Inject Drugs (PWIDs), of whom 8500 are in Coast region. Their HIV prevalence is 18.6% compared to 5.6% for general population.
In 2015, growing threat of terrorism in Kenya triggered Presidential directive to control drugs menace in Mombasa. This led to massive indiscriminate arrests of PWUDs and also threating the safety and security of Outreach workers, thereby triggering disruption in service delivery.
Scarcity of drugs led to shift in to injecting while shortage of HIV preventive commodities resulted it to sharing and unprotected sex.
Over 300 PWUDs incarcerated in three days, some of whom were under HIV, TB, treatment and care and on OST/MAT Program.
Description: MEWA initiated Paralegal and Advocacy Program, whereby its staff, Judiciary and law enforcers were trained on provision of harm reduction services, health and human rights of PWUDs in accordance to Kenya Constitution.
MEWA also provided hygiene kits and legal aid, set up support groups and lobbied for alternative sentencing for PWUDs in prison, with assistance to secure national identity cards.
MEWA with Judiciary and Kenyan Prison Services established a framework for improved PWUDs access to justice, fair trials, alternative sentencing and access to MAT.
Lessons learned: The Climax of our achievement is the issuance of court order obliging the Prison service, the MAT Clinic and MEWA to ensure accused PWUDs are enrolled on MAT and access all other relevant Harm Reduction services.
A total of 2493 (F:365M:2128) PWUDs reached with biomedical and harm reduction services, 305(F:53M:252) with legal aid and 194(F:14M:180) economic empowerment and 99(F:15M:84) supported to receive identity cards and 5 male children with birth certificates.
Hundreds of PWUDs understand their constitutional rights, can now vote, access revolving funds and freely move without police harassment.
Conclusions/Next steps: However, rogue law enforcers and routine public servants transfer undermines effective service delivery.
There is need to scale up Paralegal training to enforce respect of health and human rights of PWUD in Mombasa County.

WEAD0102

Paralegal community in the epidemic of injustice: The role of paralegals from drug users communities in the fulfillment of drug users rights

A. Qisthi
Persaudaraan Korban Napza Indonesia, Legal Advocacy, Jakarta, Indonesia

Background: In the beginning 2015, President Joko Widodo declared the "War on Drugs" as respond to "Drugs Emergency Situation" in Indonesia. This declaration further enhances repressive actions and punitive policies for drug users. the lack of access to justice (access to legal aid) resulted in the increasing number of drug users ending up in prison. This resulted in overloading in prisons, which in turn resulted in further larger impacts. The lack of access to health toward drug users with special needs, for example, the lack of Anti Retroviral Therapy (ART) for drug users living with HIV/AIDS, lack of Opiate Substitution Therapy (OST), and sterile needles has resulted in the deteriorating health of drug users and resulting in deaths from other infectious diseases.
Description: In 2017, Persaudaraan Korban Napza Indonesia (PKNI) as a national network of 26 drug user communities spread across the country implement community paralegal program in 10 cities. as an effort in breaking the barriers, community paralegals are giving legal assistance to drug users when they are dealing with the law to promote the access to justice. In addition to legal assistance, paralegals are also trying to meet access to health services for drug users with special needs such as with HIV / AIDS and Hepatitis C, and drug users who require OST. From 145 drug users assisted, there are 133 men and 12 women, and the age average of drug user was 18-35 years old. Paralegals have a role to minimize the use of a criminal approach. During the program execution of 53 completed paralegal cases succeeded in stopping criminal proceedings in 37 cases with details of 19 cases declared free in the absence of evidence and 13 cases successfully stopped by encouraging the authority of the investigator to place the client into the rehabilitation site.
Lessons learned: The existence of paralegals contributes significantly to the fulfillment of the right to justice and the right to health of drug users.
Conclusions/Next steps: Community paralegal must remain sustainable, surely with the increasing role and number of paralegals in the region in Indonesia as the front guard of primary justice.

WEAD0103

Street lawyers from the harm reduction project at the ARF and their contribution to the fight for the right to health of PWUD and people living with HIV

M. Malyshev[1,2]
[1]Andrey Rylkov Foundation for Health and Social Justice, Harm Reduction, Street Social Work, Moscow, Russian Federation, [2]Tver Government University, Tver, Russian Federation

Background: The street lawyers program offers social support and rights protection to PWUD and people living with HIV - based on the only harm reduction project in Moscow, a city of 12 million.
Description: Several years after the launch of the Harm Reduction Moscow project, the problem of stigmatization of drug users and people living with HIV in various spheres of public life in Russia has become more pressing. As a result, rights violations, denial of medical care and criminal prosecution became widespread. To counteract that, a project was launched in 2013 to provide legal assistance and support.
Street lawyers are social workers engaged in outreach work and social support who also motivate representatives of vulnerable groups to protect their rights and dignity.
The work of street lawyers includes several consecutive stages:
- Informing
- Mediation
- Official appeals to the authorities
- Judicial protection.
In 2017, 651 clients received legal advice, 149 violations of rights were documented, a total of 58 appeals to the authorities were filed and 44 clients achieved the desired result.
Lessons learned: Four years of work have shown that social workers play a key role in protecting the rights of vulnerable groups. They motivate, offer support and provide a link between lawyers, legal knowledge in general and stigmatized groups. During the course of the project, an algorithm was developed to protect the rights of clients, which proved an effective model of interaction between representatives of vulnerable groups, social workers and lawyers. Important and successful cases are those where the client feels motivated to resist stigmatization and stand up for their rights when making decisions and acting on them.
Conclusions/Next steps: The project showed that the most effective way to provide legal assistance to vulnerable groups is to link clients with social workers and lawyers, where the main role for the protection of rights lies with the client and the social worker. This approach helps achieve positive results in rights protection at the same time empower-

ing clients and the community. That's why we recommend this approach for use in other projects aimed at protecting the rights of of PWUD and PLHIV.

WEAD0104

A novel method of working with judges to build their capacity on HIV and human rights in Africa

D. Patel[1], P. Patel[2], A. Saha[1], C. Grant[3], D. Owolabi[1]
[1]UNDP, Istanbul, Turkey, [2]Consultant, Istanbul, Turkey, [3]Consultant, Johannesburg, South Africa

Background: In 2014, judges in Africa with the United Nations Development Programme (UNDP) created the Regional Judges' Forum for Africa. The goal of the Forum, led by a small number of senior judges from African countries, was to develop the HIV/TB and related human rights expertise of a core group of judges, who would then sensitise fellow judges nationally and regionally, and support institutionalizing this expertise.
Description: The Forum has met annually since 2014, created a database to provide judges with relevant reference materials, and developed an online space for the judges to communicate and share information. Annual meetings cover many topics, including the rights of key populations. Each topic includes discussion of the relevant scientific information; personal experiences from members of the affected population, and latest judicial rulings. The sessions consist of presentations, with time allotted for discussion among the judges. Resource people include HIV/TB clinicians and scientists, PLHIV, members of key populations, lawyers, and judges.
The number of judges in the Forum and the countries represented in the Forum increased from 11 to 33 and from 8 to 19, respectively.
Lessons learned: Such Forums should be convened and run by judges with the support of non-judicial organisations. Judges were most interested in learning about the developments in HIV-related jurisprudence; the science related to HIV and TB and their treatments; and hearing directly from key and vulnerable populations about their lived realities.
The Forum resulted in numerous, rights-respecting judicial decisions; training of judicial officers by members of the Forum; increased personal awareness and development on key HIV legal issues; greater judicial access to reference materials; a stronger relationship between judges and civil society; and the organisation of judicial oversight of prisons to address overcrowding.
Conclusions/Next steps: To ensure sustainability, UNDP and the South African Judicial Education Institute (SAJEI) are working to institutionalise the HIV-related judicial capacity building within the SAJEI and other national judicial training institutions.
This model is a low-cost method for effectively building the capacity of judges, and it can and should be replicated in other regions.

WEAD0105

Assessing HIV key populations' participation in seeking justice to test the effectiveness of human rights redress mechanism in Indonesia

A. Wirya, F. Aotari
LBH Masyarakat (Community Legal Aid Institute), Jakarta, Indonesia

Background: Indonesia has established several redress mechanisms to address human rights violations; many of which are relevant to the problems faced by HIV key populations. However, the effectiveness of these systems is still in questions.
This research documented human rights violations withstood by HIV key populations (people living with HIV, drug users, sex worker, and men who have sex with men) and their efforts to seek justice in order to understand the potentials and weaknesses of utilizing Indonesian redress mechanism.
Methods: This research used quantitative data collected by thirty enumerators in seventeen districts in Indonesia. They were selected from HIV key population groups who had received training on human rights, redress mechanism, and documentation method. They were tasked to document human rights violations in their districts which took place between January 2016 and October 2017 using structured interview. In total, this research documented 151 human rights violations.
Results: Only 46 out of 151 victims seek remedy after violations occurred (30.46%). Thirty of them (65.22%) reported their cases to non-governmental organizations (NGO), where twenty eight reports were then followed up to the relevant state agencies by asking clarification, condemning the abuse, reprimanding the perpetrators, or demanding compensation. Seven victims directly complained to the institution whose employees violated their rights. The rest sought help to independent governmental bodies, such as Provincial Health Department, Provincial AIDS Commission, and police. Around 39.13% of victims felt satisfied, 39.13% felt unsatisfied, and 21.74% felt neutral toward the result. Victims are disappointed because their cases which were not followed up seriously, the perpetrator were not caught, or they were unable to gain remedy. Victims are satisfied when they got information about the follow-up, they could access antiretrovirals which they were unable to obtain before, and discriminations ceased.
Conclusions: Key populations who experienced human rights abuses mostly did not pursue remedy or protection. They believed that redress would be useless and even harmful - a belief that is proven true by more than one third of victims who sought justice. However, many victims were satisfied with NGOs which did not hesitate to reprimand the government and demand compensation.

WEAD02 Time for a youthquake in HIV prevention and treatment

WEAD0201

The association between incarceration and transactional sex among HIV-positive young men who have sex with men (YMSM) in the United States

M. Philbin[1], E. Kinnard[1], A. Tanner[2], S. Ware[2], B. Chambers[3], A. Ma[4], J.D. Fortenberry[5]
[1]Columbia University Mailman School of Public Health, Sociomedical Sciences, New York, United States, [2]University of North Carolina Greensboro, Greensboro, United States, [3]University of California, San Francisco, United States, [4]Southern Illinois University, Edwardsville, United States, [5]Indiana University School of Medicine, Indianapolis, United States

Background: Criminal justice practices in the United States disproportionately affect sexual and racial/ethnic minority men, who are at higher risk of incarceration. Previous research demonstrates associations between incarceration and sexual risk behaviors for men who have sex with men (MSM). However, little of this work focuses on young MSM (YMSM), particularly HIV-positive YMSM, even though one-third report having ever engaged in sexual risk behaviors such as transactional sex. We therefore explored the association between incarceration and transactional sex among HIV-positive YMSM.
Methods: As part of the CATCH study, we recruited 97 HIV-positive YMSM across 14 Adolescent Trials Network clinical sites from August 2015 to February 2016. Following consent, youth completed an ACASI survey on psychosocial characteristics and medical/behavioral history. We used multivariate logistic regression to examine the association between incarceration (i.e., ever been in jail/prison) and transactional sex (i.e., ever exchanged sex for money or drugs) among YMSM; the Minority Stress Model informed control variable selection.
Results: The majority of YMSM were 24 years old (78%), identified as racial/ethnic minority (95%), not in school (54%), single (74%), and earned < $12,000/year (67%); nearly half had ever been homeless (41%). Additionally, 42% had been incarcerated and 28% had engaged in transactional sex. In the multivariate model, having ever been incarcerated remained independently associated with having engaged in transactional sex (aOR=3.20; 95% CI: 1.07-9.63). Being 24 years old versus younger (aOR=9.68; 95% CI: 1.42-65.78) and having ever been homeless (aOR=3.71; 95% CI: 1.18-11.65) also remained independently associated with having engaged in transactional sex.

Conclusions: Incarceration may represent a particularly severe stressor for young men with multiple marginalized identities—HIV-positive, MSM, and racial/ethnic minority—and put them at higher risk for engaging in transactional sex. Tracing the relationship between incarceration and transactional sex highlights a potential key source of health disparities among HIV-positive YMSM; it also identifies important targets for subsequent intervention studies—e.g., housing, mental health, employment—that place this population at risk of incarceration and transactional sex. Facilitating HIV-positive YMSM's engagement with community-level and HIV clinic-specific services may serve as a key strategy to promote health and mitigate harms related to incarceration and transactional sex.

WEAD0202

Gendered powerlessness in at-risk adolescent and young adult women: An examination of condom use behavior

D. Chiaramonte[1], R.L. Miller[1], C.B. Boyer[2], K.S. Lee[3], O.J. Santiago-Rivera[4], Adolescent Medicine Trials Network for HIV/AIDS Interventions

[1]Michigan State University, Psychology Department, East Lansing, United States, [2]University of California, Department of Pedatrics, San Francisco, United States, [3]Michigan State University, University Outreach and Engagement, East Lansing, United States, [4]Michigan State University, East Lansing, United States

Background: The burden of HIV among adolescent women remains unacceptably high. Although researchers have established that adult women's social powerlessness influences their ability to negotiate the use of condoms effectively, researchers have seldom examined this effect using multidimensional higher-order models or among adolescents. Informed by Connell's Theory of Gendered Powerlessness, we derived a developmentally appropriate model of gendered powerlessness for adolescents. Connell proposes three components of powerlessness: cathexis (e.g., gendered social norms and expectations), sexual division of power (e.g., gendered subordination in sexual situations), and division of labor (e.g., gendered economic subordination).

Methods: Anonymous ACASI surveys were administered in community venues in 14 U.S. cities to at-risk adolescent women aged 12-24 years (N=1,101). The young women in this sample were primarily Black (82%) and heterosexual (87%). We used exploratory and confirmatory factor analyses to determine the dimensionality of gendered powerlessness and structural equation models to examine its association to condom use.

Results: Three latent factors (financial independence, sexual division of power, structure of cathexis) provided an optimal fit to the data (ppp=0.118 with 95% CI [-25.06, 107.63]). Controlling for age, sexual division of power and structure of cathexis were negatively associated with using condoms with main partners (ppp=0.135 with 95% CI [-32.84, 113.75]); as powerlessness increased, as indicated by the sexual division of power and structure of cathexis, condom use declined.

Conclusions: We find general support for Connell's theory of gendered powerlessness among adolescents. Our results provide convincing evidence for a three-component model of gendered powerlessness for adolescent women and that two of these components are highly relevant to predicting their condom use with their primary sexual partner. Prevention efforts targeting at-risk adolescent women would benefit from overturning sexual divisions of power and countering the structure of cathexis that undermines young women's sexual agency.

WEAD0203

Ethnographic study for HIV prevention reveals a typology consisting of five distinct types among South African adolescents and young women

K. Crowley[1], J. Piper[2], J. Cummins[2], G. Gao Guodong[3], L. Burn[4], K. Igumbor[5], R. Agarwal[6], F. Veronese[7]

[1]University of Maryland Robert H. Smith School of Business, Center for health Information and Decision Systems, College Park, United States, [2]National Institute of Allergy and Infectious Diseases, Division of AIDS, Prevention Science Program, Rockville, United States, [3]University of Maryland Robert H Smith School of Business, Center for Health Information and Decision Systems, College Park, United States, [4]KantarTNS, Cape Town, South Africa, [5]Kantar TNS, Cape Town, South Africa, [6]University of Maryland Robert H. Smith School of Business, Center for Health Information and Decision Systems, College Park, United States, [7]National institute of Allergy and Infectious Diseases, Division of AIDS, Prevention Science Program, Rockville, United States

Background: The uptake of HIV prevention products among adolescents and young women in Sub-Saharan Africa has been problematic. Suboptimal product use in recent prevention trials highlights the challenges for conferring protection to targeted users. It has become clear that current methods of assessing acceptability are not useful at predicting actual use by this population. New approaches are needed to better understand the sociocultural context of young women in Sub-Saharan Africa.

Methods: We conducted a detailed ethnographic study among low income South African girls and women between the ages of 14 and 25 in three urban and peri-urban locations (Living Standards Measure 4-7). Data were collected for each participant through a qualitative study consisting of interviews with 11 industry experts, 32 depthnographic interviews and observations with low income females across both in-home and out of home contexts, 8 auto-ethnographic interactions (including digital and social media autobiographies), 12 hostess focus groups and influencer in depth interviews, and finally 6 partner in-depth interviews. Data were analyzed using qualitative methods including discursive and thematic analysis.

Results: Our data revealed a psychographic typology derived out of the complex dynamic between female vulnerability and socio-economic privilege:"The Good Girl," "Responsible Mother," "Material Girl," "Protection Savvy," and "Gender Prisoner." Each type carries a distinctive psychographic profile, home life, critical events related to sexual activity and family life, and relationship statuses. Together, the unique attributes that define a type are associated with different forms and levels of vulnerabilities to sexually transmitted infections. The data also suggest that each type may require differentiated and targeted education reflecting the variability across the typology with regards to sexual education, partners, products, and influences.

Conclusions: Current HIV prevention product promotion strategies have generally adopted a "one-size-fits-all" approach that does not include a nuanced understanding of the context, needs, and motivations underlying the behavior of different user types. Development of typologies for target populations may allow a more targeted approach for designing, marketing, and promoting HIV prevention products to adolescents and young women, and their partners.

WEAD0204

Should I take PrEP? A mental models assessment of young African women's motivations for and barriers to PrEP initiation and adherence

N. Argo[1], T. Krishnamurti[2], B. Fischhoff[1], L.-G. Bekker[3], S. Delany-Moretlwe[4], E. Bukusi[5], L. Myers[3], J. Imrie[6], J. Odoyo[7]
[1]*Carnegie Mellon University, Engineering and Public Policy, Pittsburgh, United States,* [2]*University of Pittsburgh, Pittsburgh, United States,* [3]*Desmond Tutu HIV Foundation, Cape Town, South Africa,* [4]*3Wits Reproductive Health and HIV Institute, Johannesburg, South Africa,* [5]*Kenya Medical Research Institute, Nairobi, Kenya,* [6]*Wits Reproductive Health and HIV Institute, Johannesburg, South Africa,* [7]*Kenya Medical Research Institute, Nairobi, South Africa*

Background: Young women in sub-Saharan Africa have among the highest HIV incidence rates globally, yet in previous trials they have exhibited some of the lowest PrEP uptake and adherence. What are the motivations for and barriers to PrEP usage for young African women? How can such knowledge be used to effectively design scalable PrEP demonstration projects?
Methods: Employing the mental models methodology, our team conducted surveys with 15 experts to characterize young women's decision making about initiation and adherence to PrEP, followed by in-depth interviews with 48 young women (age 16-25) and 45 men (age ≥18 p) in Kisumu, Kenya and Cape Town and Johannesburg, South Africa. Interviews were coded, theme frequencies were calculated, and linked themes were diagrammed into "mental models." Expert and women's models were compared. Lastly, a follow-up survey (n=444; 243 F, 201 M) was conducted at each field site to establish prevalence of beliefs and attitudes identified in the interviews and identify demographic correlates to those beliefs.
Results: While the expert mental models focused on more rational decision themes such as PrEP's role in health outcomes, the young women's mental models were driven by present bias (valuing the costs and benefits of now), particularly pertaining to relationships and influenced by affect or feelings. Overall, women rated the benefits of taking PrEP (e.g., feelings of safety, individual and community empowerment, health) as more influential on their decision to try PrEP than potential costs (side effects, clinic visits, relationship uncertainties, and daily pill-taking). Factors predictive of women's interest in PrEP included: living in Cape Town, previous knowledge of PrEP, the woman's perceived risk of HIV in the next year, PrEP efficacy beliefs, and the expectation that she would use a condom less if she takes PrEP.
Conclusions: PrEP messaging should highlight the immediate and positive emotional benefits of PrEP usage. Findings support the creation of a decision tool that would provide women with personalized recommendations based on risk and preferences, allowing them to answer the question of whether PrEP would be good for them before introducing questions about how it will work in their life.

WEAD0205

Experiences and outcomes of group psychotherapy as an antiretroviral adherence support intervention among young people failing on ART at Newlands Clinic, Harare, Zimbabwe

B.M. Kasimonje[1], T. Shamu[2], C. Chimbetete[2]
[1]*Newlands Clinic, Mental & Social Health, Harare, Zimbabwe,* [2]*Newlands Clinic, Harare, Zimbabwe*

Background: Adherence to antiretroviral therapy (ART) is a major challenge faced by young people living with HIV (YPLHIV). We examined the experiences and outcomes of an Enhanced Adherence Counselling Group Intervention (EACGI) prior to regimen switch among adolescents failing first line ART.
Description: We analysed records for (YPLHIV) aged between 13 and 25 years with confirmed virological failure (VF) who were invited to EACGI. This intervention was a 12-week curriculum of weekly 1.5-hour sessions which accommodated 8-15 people per group. The aim of the intervention was to facilitate readiness to switch treatment to second line ART, and improve adherence through Phenomenological, Motivational Interviewing and Cognitive Behavioural Therapy principles. Each participant had an HIV viral load (VL) test pre and post EACGI and at 3, 6, 9 and 12 months post switch to assess virological outcomes.
Lessons learned: Fifty-nine patients (57.6% female, n=34) were followed up for 46.8 person-years. Median duration of first line ART was 6 years (IQR: 4 - 8) at time of invitation to EACGI. Twenty-two patients (37.3%) did not attend a session, 8 were female and 14 were male. The most common reasons for not attending were lack of interest and school or work schedules. The main reasons for poor adherence among the 37 attendees were hopelessness, family dysfunction, lack of illness, an aversion to a daily routine attached to stigma, and medication side effects. Among patients who attended >75% of sessions, 76%, 94%, 94% and 100% achieved viral suppression (VL< 50 copies/ml) at 3, 6, 9 and 12 months, respectively, compared to 50%, 55%, 55% and 50% among those who attended at least one but ≤75%. Those who did not attend any session had suppression rates of 32%, 41%, 41% and 39%, respectively.
Conclusions/Next steps: Patients who attended >75% EACGI had better second-line virological outcomes compared to those who attended less or none in this small cohort. EACGI is a promising tool for preparing patients within this key population for second line treatment, increasing the likelihood for improved adherence and improved treatment outcomes for second line therapy.

WEAD0301

A political economy of HIV treatment policy: Drivers of health policy diffusion

M. Kavanagh[1], S. Gupta[2], K. Parish[3]
[1]*Georgetown University, O'Neill Institute for National & Global Health Law, Washington, United States,* [2]*International Association of Providers in AIDS Care, Delhi, India,* [3]*University of Pennsylvania, Political Science, Philadelphia, United States*

Background: Why do some countries rapidly adopt policies suggested by scientific consensus while others are slow to do so? HIV treatment is a particularly salient case in point. Scientists, physicians, and the World Health Organization (WHO) spend significant effort identifying the optimal standards of medical care—yet the guideline policies that govern public health and medical practice often lag far behind evidence. Efforts to address differences in adoption of "evidence-based" policy focuses on variation in the capacities for adoption and interpretation of scientific evidence. We challenge this view, hypothesizing that socio-political institutions are often decisive in how quickly countries will adapt science into policy.
Methods: We used a mixed methods strategy. First, we constructed a database of national HIV treatment guidelines, collecting 290 published national ART guidelines for adults and adolescents from 122 countries (98% of global HIV burden). Using this database, we built a model to reflect the epidemiologic, economic, and political context and used a Cox-Proportional Hazards Model to test our hypothesis. Second we conducted interviews with 24 key informants with direct knowledge of guidelines processes to establish causality in our study.
Results: Neither HIV prevalence nor national wealth is a significant driver of policy change in our quantitative or qualitative results. Qualitative analysis shows neither interpretation of medical evidence nor formal cost-benefit analysis explain differences. Instead, the formal structures of government and the degree of ethnic cleavages predict the speed with which new medical science is translated into policy. More veto points in government is strongly associated with faster policy adoption—with a full swing in the data associated with a 275% increase in adoption speed. HIV policy change is slower in contexts with complex racial/ethnic divisions—as much as 60%, *ceteris paribus*.
Conclusions: Our findings challenge expectations in scholarship and practice that policy divergence and inequities are primarily addressed through greater evidence and dissemination channels. That political

factors are systematic, rather than random, suggests a new approach is needed by agencies such as the WHO and UNAIDS. Building diffusion strategies, messages, and policy networks that are tailored to national political context is possible when systematic socio-political factors are identified.

WEAD0302

Using TRIPS-flexibilities as a leverage to improve access to HIV and hepatitis C medicines in Ukraine

S. Kondratyuk
All-Ukrainian Network of People Living with HIV/AIDS, Advocacy Team, Kiev, Ukraine

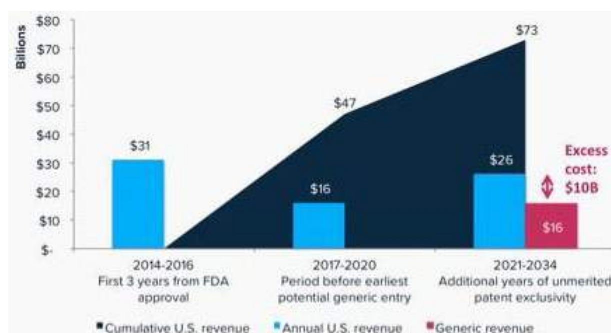
Background: Significant treatment gaps persist for HIV (63%) and hepatitis C (>99%) in Ukraine. High prices for patented ARVs and DAAs contribute to inefficiency of country HIV and hepatitis C response.
Description: To ensure better affordability of HIV and hepatitis C medicines, the All-Ukrainian Network PLWHA (the 'Network') used patent oppositions and compulsory licensing (CL) request as leverage in negotiations with patent holders. The national HIV program experienced a funding gap in HIV medicine procurement in 2016.
In February 2016, in response to potential drug shortages the Network organized a meeting with the Ministry of Health and originators (Abbvie, GlaxoSmithKline, MSD, and Janssen). Network shared information about treatment gap, called the companies to lower the prices and called government consider using CL. As the response to this action, ViiV included Ukraine in the MPP DTG license (April 2016). In addition, the Network requested GSK/ViiV to include Ukraine in the license for ABC for adults in May 2016. The negotiations with GSK were conducted simultaneously with preparation of a patent opposition on ABC.
The Network repeatedly emphasized to MSD and GSK representatives that the patent monopolies on TDF/FTC/EFV, ABC and ABC/3TC are unjustified, as the patents do not comply with patentability requirements and were already opposed in other countries. All these efforts may have encouraged MSD and GSK to provide the Network with a patent rights non-enforcement letters in May-July 2016 and procurement of generic products began in 2017. This has reduced the price by 83%, 59% and 56% on TDF/FTC/EFV, ABC and ABC/3TC respectively, generating annual savings up to 13,9 mln USD.
Successful pre-grant patent oppositions in relation to SOF filed by the Network and consequent temporary generic competition for SOF may have encouraged originator to add Ukraine to the VL and caused price decrease for 77%.
Lessons learned: When patent holders provide non-enforcement letters or include country in VL, it causes significant price reduction as it creates an opportunity for generic competition.
Conclusions/Next steps: Patients´ organizations work on patent oppositions and compulsory licensing is a powerful leverage in efforts to improve access to HIV and hepatitis C treatment.

WEAD0303

America's $10 billion overspend on sofosubvir-based hepatitis C treatment resulting from unmerited patents

A. Pattillo, J. Fortunak, D. Ravicher, M.H. Hughey, T. Amin, P. Radha Krishtel
Initiative for Medicines, Access and Knowledge, New York, United States

Background: About one quarter of the estimated 1.2 million HIV-infected persons in the United States are also infected with Hepatitis C virus (HCV). Co-infection of HCV is especially common (50%-90%) among HIV-infected injection drug users. With the introduction of direct-acting antiviral sofosbuvir (Sovaldi™, SOF) in 2013 and additional SOF-based combination therapies since, the cure for HCV became reality. To date, SOF-based therapies have accounted for approximately three out of four of all DAA prescriptions written for HCV patients in the U.S.
However the high price of the SOF-based therapies has resulted in payer rationing and limited access to the medicines, particularly among HCV patients on Medicaid and those in the correctional systems.
Methods: Our team of patent lawyers, scientists and health market experts
a) Examined the patent portfolio of sofosbuvir,
b) Analyzed the commercial market dynamics for sofosubivr-based products,
c) Assessed the current landscape of patient access to HCV medicines in the U.S., and
d) Modeled the projected overspend on SOF-based products in the U.S.
Results:
1) Nearly all (26 of the 29) of the patents on Sovaldi™ are secondary patents that relate to various prodrugs, processes, and crystalline forms that are distinct from the base compound sofosubvir. These along with the three patents on the base compound were analyzed by technical experts and found to be likely unmerited given obviousness and prior art in the field.
2) The average net price paid in the U.S. across all SOF-based products by public and private payers from Q316 to Q317 was $40,200. Our analysis suggests that net prices will continue a downward trend toward $30,000 for 2018.
3) 85% of patients in the U.S. that have been diagnosed with HCV will not get access to treatment in the coming year.
4) U.S. payers are projected to spend an excess of $10 billion for branded SOF-based products in 2021-34 as compared to treatment costs with generic sofosbuvir.
Conclusions: Unmerited patents have been identified on Sovaldi™ resulting in prolonged exclusivity periods that prevent generic product entry, burden payers with billions in overspend, and generate significant access problems for HCV patients in the U.S.



[Summary of U.S. revenue from Sovaldi®-based combination drugs and estimated excess costs for branded versus generic products]

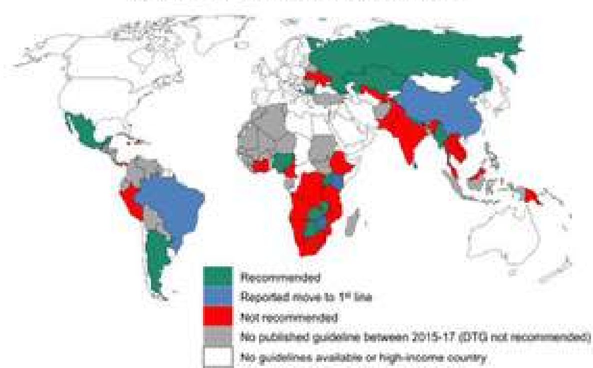
WEAD0304

Dolutegravir and the universal antiretroviral regimen: Good may be the enemy of perfect

R. Granich[1], S. Gupta[2], L. Kosicki[3], B. Williams[4], M. Ruffner[5]
[1]Senior Public Health Consultant, San Francisco, United States, [2]Independent Consultant, Delhi, India, [3]SGAC/PEPFAR, Washington DC, United States, [4]SACEMA, Stellenbosch, South Africa, [5]SGAC/PEPFAR, Washington, United States

Background: Tenofovir, Lamivudine and Dolutegravir (TLD) is the best potential global universal treatment regimen. Dolutegravir's tolerability, durability, effectiveness, simplicity, cost-savings and high resistance barrier could accelerate progress towards 90-90-90.
Methods: We searched Internet, PubMed, national surveillance reports, UNAIDS/WHO reports, President´s Emergency Plan for AIDS Relief (PEPFAR) 2017 operational plans, and conference abstracts for nationally representative information regarding DTG. We describe policy/implementation status for the 94 low- and middle-income countries (LMICs) with published national guidelines (92% global HIV burden). We compare PEPFAR 2019 and 2018-2019 cost savings for Tenofovir-Lamivudine-Efavirenz (TLE) 600 vs. TLD for people living with HIV on ART for 16 PEPFAR supported countries in sub-Saharan Africa. A similar comparison was done assuming achievement of 90-90-90.

Results: DTG is already widely used in the higher income settings and increasingly a first-line drug in LMICs (Table 1). DTG is recommended in all of the high-income countries as part of an optimal first line regimen, as an alternate option in WHO 2015 guidelines, and in 17 LMICs including Botswana, Lesotho, Nigeria, Uganda and Zambia. Despite not having formal published recommendations, DTG is already being procured in Kenya, Zimbabwe and other LMICs. Although 2018 transition to TLD will likely be incomplete, transitioning all patients supported by PEPFAR in 16 countries in sub-Saharan Africa to TLD ($75 pppy) when compared with current TLE costs ($79 pppy), could save $63,107,532 and $175,925,064 for 2020 and 2018-2020, respectively. Assuming achievement of the 90-90-90 target, cost-savings for 2020 for the 16 countries would be $42,411,600. DTG and alternative service delivery models (e.g., reduced clinic visits, laboratory testing and viral load costs), could reduce overall treatment costs to well below $200 per person per year in Sub-Saharan Africa. Cost savings that would accompany the decrease in the development and transmission of resistant virus are likely to be even greater.
Conclusions: Rapidly transitioning from current 1st line treatment to the DTG universal regimen represents an opportunity to make a major impact on the epidemic of HIV if done swiftly. Other disease control efforts have made concerted efforts across multiple regions and countries when faced with the need for rapid action, why not HIV?



[Global Dolutegravir 1st Line Recommendations for 94 Countries]

WEAD0305

Review of national guidelines in 16 sub-Saharan African countries for inclusion of the adolescent HIV care continuum

J. Kottutt[1], E. Rivadeneira[2], S. Hrapcak[2]
[1]Emory University, Rollins School of Public Health, Hubert Department of Global Health, Atlanta, United States, [2]Centers of Diseases, Control and Prevention, Division of Global HIV and TB, Center for Global Health, Atlanta, United States

Background: Adolescents living with HIV (ALHIV) have poorer HIV-related outcomes than adults due to unique developmental, psychosocial, and clinical needs that are often not addressed. The 2016 WHO consolidated HIV guidelines recommend provision of adolescent-friendly HIV services to improve these poor outcomes. The purpose of this review was to assess national HIV/ART guidelines from sub-Saharan African countries for inclusion of recommendations targeting services for ALHIV along the HIV cascade.
Methods: National ART/HIV guidelines from PEPFAR-supported countries in sub-Saharan Africa that have pediatric/adolescent HIV programs were reviewed. All documents were publically available and in English. Pertinent information on five areas (Table 1) were abstracted by two authors (JK and SH) and inconsistencies resolved.
Results: Data were available and abstracted for 16 countries (Table 1). Kenya was the only country whose guidelines included all five recommendations. Recommendations on frequency of HIV testing in sexually active adolescents were included in 50% of countries (n=8); however, the recommended frequency was not consistent (annual testing n=6, every 6-12 months n=1, every 3-6 months n=1). Although 14 countries (88%) included a section on disclosure to children/adolescents, only 8 (50%) included recommended age of full disclosure. The age varied across countries: 8-10 years (n= 1), ≥10 years (n=3), 10-12 years (n=1), 10-14 years (n=1), 11-14 years (n=1), and 13 years (n=1). Age of consent for treatment initiation was clearly defined in only 3 countries (19%), all recommending 12 years old. The majority (n=15; 94%) included recommendations on frequency of viral load (VL) testing, with 9 (56%) following WHO recommendations for testing at 6 and 12 months after ART initiation, then annually; however, 5 (31%) recommended more frequent VL testing every 6 months in ALHIV due to higher rates of virologic failure. 44% (n=7) included guidance on transition to adult services, although only 25% (n= 4) included recommended age of transition which varied from 15 to 20 years.
Conclusions: There is currently a lack of consistency in national HIV/ART guidelines to address the unique needs of ALHIV. More specific guidance should be included in national guidelines for healthcare workers to provide appropriate adolescent-friendly HIV services to improve clinical outcomes in ALHIV.

Recommendation	Countries including recommendation in national HIV/ART guidelines
Frequency of HIV testing in sexually active adolescents	Lesotho, Kenya, South Africa, Tanzania, Rwanda, Swaziland, Uganda, Zambia
Recommended age of full disclosure	Lesotho, Cameroon, Ethiopia, Kenya, Namibia, Tanzania, Rwanda, Zambia
Age of consent for treatment initiation	Kenya, Rwanda, Swaziland
Frequency of routine viral load (VL) in adolescents	Malawi, Lesotho, Cameroon, Kenya, Namibia, Nigeria, South Africa, South Sudan, Tanzania, Rwanda, Zimbabwe, Swaziland, Botswana, Uganda, Zambia
Recommended age for transition from adolescent to adult services	Kenya, Namibia, Uganda, Zambia

[Inclusion of the Adolescent HIV Care Continuum in National HIV/ART Guidelines in 16 countries in sub-Saharan Africa]

WEAE01 Reaching men: Yes we can!

WEAE0101

Multiple disease screening to destigmatize HIV testing and increase identification of persons living with HIV in Kisumu, Kenya

K. Ndede[1], D. Naitore[2], F. Lugalia[1], C. Wells[3], B. Senyana[3], J. Otieno[4], R. Fayorsey[3], M. Hawken[2], E. Abrams[3]
[1]ICAP at Columbia University, Kisumu, Kenya, [2]ICAP at Columbia University, Nairobi, Kenya, [3]ICAP at Columbia University, New York, United States, [4]Jaramogi Oginga Odinga Teaching and Referral Hospital, Kisumu, Kenya

Background: There are approximately 1.5 million people living with HIV in Kenya, and approximately
1 million are on ART. Attainment of the 90:90:90 goals depends on identifying the remaining HIV-infected population, the majority of which are asymptomatic and do not access health services routinely. Adult HIV Testing Services (HTS) at Jaramogi Oginga Odinja Teaching and Referral Hospital (JOOTRH) in Kenya, have predominately been offered via universal opt-out provider-initiated testing and counseling (PITC) of out-patients. This has resulted in testing a predominance of women and a yield of < 1%. To de-stigmatize HIV testing and reach more men, ICAP initiated a strategy of providing HTS as part of screening for multiple diseases.
Description: In March 2017, a multiple disease screening program was established at JOOTRH, offering a package of wellness services including screening for obesity (weight, height), hypertension (blood pressure), and symptomatic TB and HIV testing. The service was advertised by radio and billboard as a free health check. Located at the entrance to

JOOTRH, clients and visitors (>15 years old) were eligible to access the service which was available from 8am to 9pm daily including weekends.
Lessons learned: From July to December 2017, 5645 adults were screened. The mean age was 32.9 years (SD 11.7, range 15-78). Of those screened 100% were eligible for an HIV test (never tested or tested >3 months ago) and 2% (113/5645) tested HIV-positive. Of those tested, 46% (n=2604) were female and 54% (n=3041) were male (p< 0.01), with a positivity yield of 2.2% (58/2604) in women and 1.8% (55/3041) in men. The extended hours were utilized, with 15.4% (n=867) being tested after 5pm on weekdays and 15.4% (n=868) being tested on weekends. Amongst those tested on the weekends, 54% (465/868) were men and 46% (403/868) were women (p< 0.01).
Conclusions/Next steps: Providing HTS within a multiple disease screening package is an innovative approach that successfully tested a high number of men, a group that does not routinely access health services. Proportionally, more HIV-positive individuals were identified with this strategy than out-patient PITC. A higher testing yield may be possible if the project targets high-risk populations and first time testers.

WEAE0102

Cracking the code to increase men's uptake of HIV testing: Providing convenient and confidential outreach HIV testing services through mobile clinics

E. Geoffroy[1], N. Khozomba[2], J. Jere[2], E. Schell[3,4], T. Schafer[3], J. Goldman[5], K. Kabwere[6]
[1]Global AIDS Interfaith Alliance (GAIA), Programs, Marblehead, United States, [2]Global AIDS Interfaith Alliance, Blantyre, Malawi, [3]Global AIDS Interfaith Alliance, San Rafael, United States, [4]University of California, San Francisco, United States, [5]Elizabeth Taylor AIDS Foundation, Beverly Hills, United States, [6]Mulanje District Hospital, Mulanje District Health Office, Mulanje, Malawi

Background: In Malawi only 66% of men age 15-64 have been tested for HIV compared with 76% of women. With funding from the Elizabeth Taylor AIDS Foundation, in July 2014, Global AIDS Interfaith Alliance (GAIA) introduced a program to increase rates of male testing by reaching out to men with weekend HIV testing services (HTS) at convenient times and locations.
Description: Working in partnership with the District Health Offices, sites in need of HTS are identified. The mobile clinic is staffed by a driver and three trained health providers who travel to where men (and their partners) gather, including markets, tea estates, and churches/mosques, to provide HIV testing. Program data is collected using Magpi, a mobile app on a secured phone. Encrypted data is uploaded in real time using wi-fi or cell connection.
Lessons learned: Through December 2017, there have been 106 male targeted testing events, testing 6,166 people, of which 71% were male, compared to 26% males tested at weekday mobile clinics over the same period. Notably, 38% of males tested were aged 15-24 and of these, 42% had not previously been tested. Across all ages, 30% of males had not been previously tested. Three percent of men were found positive, with 5% of men over 25 testing positive, and all were referred to the nearest clinic providing antiretroviral therapy. The percentage of men attending these events has increased over time from 69% in 2014 to 78% in 2017. Convenience of location (38%), publicity surrounding the event (35%) and convenience of time (23%) were cited as primary reasons for attending.
Conclusions/Next steps: Men can effectively be reached for HIV testing in order to achieve the first UNAIDS "90" target by making testing convenient, providing a gender-segregated space, and providing male counselors. Using a secure mobile data collection app allows for real time data analysis to improve program performance and target geographical areas where incidence is high and enables rapid in home follow up visits for those who consent. The next phase of the project will link treatment initiation and adherence data with testing data to assess time from diagnosis to treatment to adherence.

WEAE0103

Engaging young men in health care and HIV testing: The SHAZ! HUB youth drop-in-centre

M.S. Dunbar[1], G. Chapwanya[1], G. Kumalo-Sakutukwa[2], I. Mahaka[1], A. Mpakati[1], M. Lightfoot[2]
[1]Pangaea Zimbabwe AIDS Trust, Harare, Zimbabwe, [2]Center for AIDS Prevention Studies, UCSF, San Francisco, United States

Background: HIV testing efforts in sub-Saharan Africa have focused on young women. However, studies show that young men face challenges in accessing preventative health care, including HIV testing, tending to be diagnosed late and presenting for HIV treatment with advanced disease. At the SHAZ! HUB, a youth drop-in center and clinic in urban Zimbabwe, the majority of the clients are male.
We explored factors contributing to this high uptake of services among young men.
Methods: We summarized information from clinical intake forms and conducted four focus group discussions, two with males aged 16-19 years and two with males aged 20-24, on topics related to health seeking behavior, facilitators and barriers to accessing services, and favorable and facilitative aspects of service delivery.
Results: From July 2016, the SHAZ! HUB provided sexual health and HIV services to 2,243 clients, 1,332 (60%) of whom were male. Seventy percent were between the ages of 16-19 years, and the majority of clients sought HIV testing. The main barriers mentioned to seeking services generally were lack of confidentiality, fears of being embarrassed or made to feel uncomfortable, and the notion that clinics are "for women and babies".
When asked about favorable aspects of the SHAZ! HUB, participants cited factors focusing on environment, health care workers, and additional recreational services/benefits offered. For example, participants highlighted the privacy afforded by the HUB, and that services were "male friendly" - meaning the young men were not judged and given factual information and support on how to reduce risk that focused on the male perspective (e.g., no judgement when disclosing multiple sex partners).
Participants also appreciated that they were allowed to be "loud," and that they were not chastised for "misbehaving." Other appealing aspects of the HUB included being able to access wi-fi, relax with friends and watch satellite TV, and access workshops on life skills and financial literacy.
Conclusions: These lessons learned suggest that programs seeking to engage young men could consider combining health services with recreational opportunities, non-judgmental information and support within a private, youth friendly environment. Such factors create openings for young men to engage in prevention and care.

WEAE0104

Home-based testing identifies more previously undiagnosed older men than mobile testing in Botswana

M. Roland[1], L. Block[2], P. Bachanas[2], M.G. Alwano[1], W. Abrams[1], K. Wirth[3], T. Gaolathe[4], J. Makhema[4], M. Mmalane[4], S. Lockman[3], S. El-Halabi[5], J. Moore[2]
[1]Centers for Disease Control & Prevention, Gaborone, Botswana, [2]Centers for Disease Control & Prevention, Division of Global HIV/AIDS & TB, Atlanta, United States, [3]Harvard T.H. Chan School of Public Health, Boston, United States, [4]Botswana Harvard Partnership, Gaborone, Botswana, [5]World Health Organization, Geneva, Switzerland

Background: UNAIDS estimates that 85% of HIV-positive individuals in Botswana know their status. As countries approach UNAIDS 95-95-95 targets, it is important to employ the most effective HIV testing strategies to reach the remaining undiagnosed people of all ages and sexes.
Methods: The Botswana Combination Prevention Project (BCPP) is a randomized controlled trial in 30 matched rural or semi-urban communities. We describe newly identified HIV-positive community residents by age, sex and testing strategy in the 15 intervention communities where mobile and home testing strategies were employed between October 2013 and September 2017. Chi-square tests account for possible community-level intra-cluster correlations.

Results: 49,693 participants did not know or have documentation of their negative HIV status in the prior 3 months and were tested for HIV with home (19,349; 39%) or mobile (30,344; 61%) testing. Among these, 1,870 (3.8%) were newly diagnosed. Similar absolute numbers of women and men, 956 and 916 respectively, were diagnosed (Table 1). The proportion of new diagnoses was higher in the oldest age categories as compared to the 16-24 year olds (p< .0001). Older males yielded the highest proportion of new diagnoses among all categories (p< .0001). When examining testing by venue, home testing represented 39% of the total tests conducted and yielded 46% of the new positives identified. The testing yield for new HIV diagnoses in the home (4.5%) was significantly higher than the 3.3% yield with mobile testing (p< .0001). Similar absolute numbers of males and females were newly diagnosed with the 2 testing modalities. However, home testing yielded more new diagnoses among older persons compared to mobile (p< .0001).

Conclusions: In this rural and semi-urban population, home testing yields were greater than mobile testing yields particularly among older males, suggesting that this strategy remains important for identifying HIV-infected individuals in a country with high HIV identification coverage. While a similar absolute number of males and females overall were identified with each strategy, absolute numbers and proportionate yield varied across age-sex categories and testing approach. Similar granular data may be used to select testing strategies specific to the first 95 gap across age-sex categories within local geographic areas.

	Total Females	Total Males	Females 16-24	Females 25-34	Females 35-64	Males 16-24	Males 25-34	Males 35-64

WEAE0105

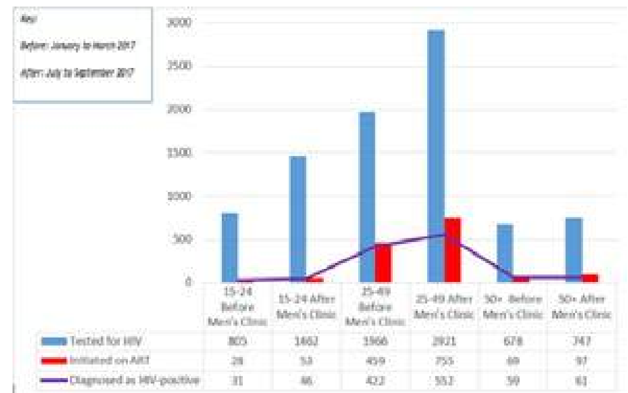
Male engagement works to improve HIV services uptake among men

T.A. Lekhotsa[1], B. Oguntoyinbo[2], M. Mputsoe[3], M.G. Mefane[4], V. Tukei[5], E. Tumbare[1]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Programs, Maseru, Lesotho, [2]Elizabeth Galser Peddiatric AIDS Foundation, Research, Maseru, Lesotho, [3]Elizabeth Glaser Pediatric AIDS Foundation, Strategic Information and Evaluation, Maseru, Lesotho, [4]Ministry of Health, Sexual and Reproductive Health Ministry of Health Lesotho, Maseru, Lesotho, [5]Elizabeth Galser Pediatric AIDS Foundation, Research, Maseru, Lesotho

Background: HIV testing services (HTS) are a critical entry point to HIV care and treatment. However, in Lesotho uptake of HTS is lower among men than women (36% of men were tested compared to 58% of women: DATIM, October 2015-September 2016) because cultural and social barriers can prevent or delay men from getting an HIV test. Elizabeth Glaser Pediatric AIDS Foundation (EGPAF) established Men's Clinics in June 2017 for the provision of comprehensive health services for men in health facilities as part of the DREAMS initiative to increase uptake of HIV services among men.

Methods: Routine program data were analyzed to examine changes in HIV testing and antiretroviral treatment (ART) uptake among men before (January to March 2017) compared to after (July to September 2017) implementation of the men's health services in seven selected health facilities (two hospitals and five clinics) in Lesotho. Data on HIV testing and ART initiation were abstracted from routine aggregate program data and downloaded into Stata for review and analysis. The Men's Clinics intervention consisted of dedicated clinic space for male clients only to receive services by male nurses and counsellors to help men feel more comfortable accessing services. Comprehensive clinical services (STI Screening and treatment, HTS, care and treatment, Pre-P and PEP, TB Services, treatment for other co-infections, Condom distribution, and counselling for HIV prevention, Education on PMTCT and Index family testing, and Referral Male Medical Circumcision) were offered at unconventional hours of service (morning, evening, and weekend hours), and through innovative appointment scheduling to reduce waiting times and improve client satisfaction.

Results: The results indicate that since Men's Clinics were introduced in June 2017 there was a 49% increase in the number of men tested for HIV; a 29% increase in the number of men diagnosed as HIV-positive; and a 63% increase in the number of men initiated on ART by the end of September 2017.



[Figure 1: Number of men tested for HIV, diagnosed as HIV-positive, and initiated on ART before and after introduction of the Men's Clinic, by age]

Conclusions: Providing male-only comprehensive clinical services is a promising strategy for increasing men's access to HIV testing and linkages to care. Future scale-up of Men's Clinics could help in identifying large numbers of men who are living with HIV.

WEAE02 Tough choices, smart decisions, maturing responses

WEAE0201

Impact of the PEPFAR geographic pivot on HIV & non-HIV health services in Uganda

J. Wilhelm[1], L. Paina[1], M. Qiu[1], M. Makuru[2], F. Ssengooba[2], S. Bennett[1]
[1]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [2]Makerere University School of Public Health, Health Policy & Management, Kampala, Uganda

Background: In Uganda, PEPFAR implemented a geographic prioritization (GP), which discontinued support for outreach, training, supervision, and staff incentives to roughly 730 health facilities, shifting them to government central support (CS). CS facilities are located in low HIV-prevalence districts or did not provide high-volume HIV care.

Methods: In order to assess the impacts of the GP, we fielded a survey at 262 health facilities across Uganda in mid-2017. The survey collected information on PEPFAR support, service delivery, commodities, laboratory, time-allocation, motivation, and human resources. We also obtained DHIS2 records on select HIV and non-HIV services (2013-2017) and HRHIS staffing data (2015-2017). We conducted difference-in-difference analysis comparing CS facilities to those maintained on PEPFAR before and after GP using random intercept regression models.

Results: Relative to maintained facilities, CS facilities are significantly more likely to report termination of workers, declining frequency of supervision, and worsening financial status. CS facilities are also signifi-

cantly more likely to report discontinuing HIV outreach (52% vs. 4%, p< 0.001), worsening quality of HIV care (42% vs. 0%, p< 0.001), less improvement in the quality of maternal neonatal and child health care (34% vs. 70%, p< 0.001), and increased disruption of viral load (23% vs. 5%, p=0.002) and sputum (22% vs. 6%, p=0.026) testing. More workers at CS facilities report less time on HIV care (32% vs. 11%, p=0.004) and declines in satisfaction (27% vs. 1%, p< 0.001) since transition.
However, the HRHIS data shows that adjusted difference-in-difference in staffing ratios for CS facilities relative to maintained facilities was small and not statistically significant. According to DHIS2 data, there were no significant differential trends in volume of HIV tests, current on ART, OPD visits, ANC visits, Facility-based deliveries, or DPT/Pentavalent-3rd dose.
Conclusions: Early results suggest that the PEPFAR GP in Uganda has had limited immediate impacts on service delivery and staffing levels at CS facilities, despite the impacts reported in our survey. However, discontinuation of outreach, reduced access to supervision, weakened links to lab hubs, and declining time-allocation for HIV care may ultimately hinder the ability to identify and retain HIV patients and jeopardize Uganda's progress towards the 90-90-90 goals.

WEAE0202

From 90-90-90 towards HIV elimination with boosted-integrated active HIV case management (B-IACM) in Cambodia

P.S. Ly[1], V. Ouk[1], C. Kaoeun[2], S. Samreth[3], B. Ngauv[3], S. Seng[4], D. Nhim[5], S. Wignall[5]
[1]NCHADS, NCHADS, Phnom Penh, Cambodia, [2]NCHADS, AIDS Care Unit, Phnom Penh, Cambodia, [3]NCHADS, Technical Bureau, Phnom Penh, Cambodia, [4]FHI 360, LINKAGES Project, Phnom Penh, Cambodia, [5]FHI 360, LINKAGES, Phnom Penh, Cambodia

Background: The National HIV Program in Cambodia has been successful in reducing HIV prevalence in the general adult population from 1.7% in 1998 to 0.6% in 2016 with strong prevention programs, expansion of HIV testing, and optimization of the continuum of care with ART coverage reaching more than 80% PLHIV. In 2016 AEM modeling, 70,498 individuals were estimated to be HIV infected; 58,338 (83%) knew their status; and, 56,754 (97%) of these on ART1 but 12,000 PLHIV do not yet know their HIV status and new approaches are needed to find them. Cambodia's HIV program, having achieved UNAIDS 90-90-90 targets, is focused on elimination of HIV transmission by 2025 and B-IACM is central to that plan.
1. Spectrum/AEM modelling 2016
Description: The BIACM strategy, implemented at the Operational District (OD) level, involves an HIV Case Management Coordinator (CMC) assisted by a Case Management Assistant (CMA) work daily with HIV Case Management Service Providers (CMPs) who coordinate, communicate, and share information concerning HIV cases. Their efforts ensure timely enrollment in care and initiation of ART and support adherence and achievement of viral load suppression. Pregnant women, HIV-exposed infants, and PLHIV partners are targeted for testing, enrollment in HIV care and treatment if HIV+. Coordination meetings between CMC and CMPs and broader stakeholders review site performance and identify solutions to improve care and retention. Direct data reporting to the National Center for HIV/AIDS, Dermatology and Sexually Transmitted Infections (NCHADS) is used to generate a dashboard that allows offsite monitoring and intervention as necessary.
Lessons learned: B-IACM has doubled previous yield, increasing new HIV case detection from 444 (pre-B-IACM from February 2014 - September 2015) to 753 (B-IACM from October 2015 to May 2017) in Battambang and Siem Reap. The B-IACM strategy has: improved targeting for HIV testing and the achievement of the first 90%[2]; improved ART initiation rates to 96% (1,577/1,647), the second 90; and, increased adherence achieving viral load suppression to undetectable levels in 97% of cases, the third 90.
2. http://www.unaids.org/en/resources/presscentre/pressreleaseandstatementarchive/2017/july/20170720_PR_Global_AIDS_Update_2017
Conclusions/Next steps: NCHADS will scale up B-IACM implementation to all provinces in Cambodia as it moves toward achieving 95-95-95 by 2025.

WEAE0203

Reaching the first "90": Decentralizing and strengthening provider initiated testing services at primary health care facilities in Ukraine

M. Makovetska, A. Vasylkova, N. Davydenko, O. Yaremenko, N. Avaliani
Deloitte Consulting, LLP, USAID HIV Reform in Action Project, Kiev, Ukraine

Background: As of October 2017, an estimated 98,600 people living with HIV (PLWH) in Ukraine are not aware of their diagnosis. To achieve the first "90" of the UNAIDS targets, it is necessary to diagnose 74,806 PLWH. However, the current HIV detection system in Ukraine has several gaps and limitations, including a limited number of "entry points" into the cascade of HIV prevention and care. The USAID HIV Reform in Action project sought to decentralize HCT services to increase HIV service entry points and accelerate progress towards the first "90" target.
Description: Decentralizing HTC services from regional level AIDS centers and local hospitals to the expanded network of primary health care centers (PHC) sites was implemented in 14 cities across 7 regions of Ukraine between March 2016 and December 2017. The decentralization strategies included allocation of funds for rapid HIV tests from local budgets; training for PHC personnel in HIV testing services; and removing local procedural barriers for the provision and scale-up of HCT services through the introduction of policies to use two rapid tests for HIV diagnosis.
Lessons learned: By the end of the pilot, all sites allocated funds for procurement of rapid test kits resulting in a 6-time increase in rapid test supply compared to the previous year. The number of PHCs providing HCT increased from 25 PHCs across 14 cities in 2015 to 225 PHCs in 2017. The comprehensive strategy, including workforce training, funding allocations and decentralization of patient's entry points, was critical to achieving successful outcomes.
Conclusions/Next steps: Increasing the number of HTC service delivery and patient entry points to the health care system will expand testing services beyond traditional entry points and help detect HIV patients coming to HCF for regular primary health care services. Plans are underway to disseminate pilot results to all 7 study regions, including districts and cities, to share lessons learned. To sustain the outcomes, local authorities need to invest in training of human resources, infrastructure, and other health-system-strengthening components, as well as increase local budget allocations for HIV services.

WEAE0204

Monitoring viral load for the last mile: What will it cost?

B.E. Nichols[1,2], S.J. Girdwood[2], T. Crompton[3], L. Stewart-Isherwood[4,5], L. Berrie[4,5], D. Chimhamhiwa[3], C. Moyo[6], J. Kuenhle[7], S. Rosen[1,2], on behalf of EQUIP
[1]Boston University, Global Health, Boston, United States, [2]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]Right to Care, GIS Mapping Department, Johannesburg, South Africa, [4]National Health Laboratory Service, Johannesburg, South Africa, [5]Wits Health Consortium, Johannesburg, South Africa, [6]EQUIP Zambia, Lusaka, Zambia, [7]United States Agency for International Development, Lusaka, Zambia

Background: Routine viral load testing is the WHO-recommended method for monitoring HIV-infected patients on ART, and many countries are rapidly scaling up testing capacity. Providing testing access to the most remote populations (the "last mile") is especially challenging. Using a geospatial optimization model, we estimated the incremental costs of reaching the hardest-to-reach 20% of patients in Zambia by expanding the transportation network required to bring blood samples from ART clinics to centralized laboratories and return results to clinics.
Methods: The model first optimized a sample transportation network (STN) that can transport 80% of anticipated sample volumes to centralized viral load testing labs on a daily or weekly basis, in line with the Zambia 2020 viral load targets. Data incorporated into the model included the location and infrastructure of all 2,500 Zambian health facilities and laboratories, measured distances and drive times, expected future

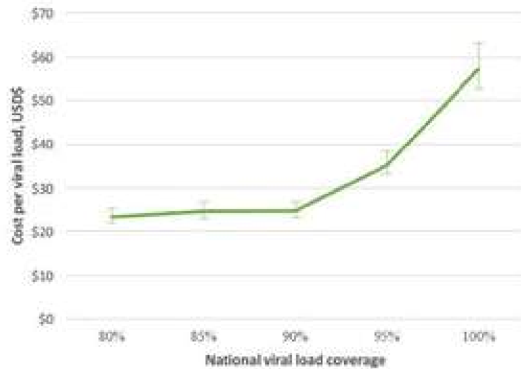
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

viral load demand by health facility, and local cost estimates. We then continued to expand the modeled STN in 5% increments until 100% of sample volumes were met.

Results: The cost per viral load test when reaching 80% patient volumes using centralized viral load testing was a median of $23.43 (IQR $21.92-$25.42). With an expanded STN, the incremental cost per test rose to $24.72 ($23.08-$26.90) for 80-85% and $24.82 ($23.28-$26.94) for 85-90%. Above 90% coverage, the incremental cost per test increased substantially to $35.17 ($33.17-$38.35) for 90-95% and $57.23 ($52.67-$63.16) for 95-100%. The high numbers of kilometers driven per sample transported increases the costs dramatically for reaching the clinics that serve the last 5% of patients.



[Median incremental cost per viral load (and interquartile range) in Zambia when increasing coverage in 5% increments ($US)]

Conclusions: Providing sample transport services to the most remote clinics in low- and middle-income countries is likely to be cost-prohibitive. Other strategies are needed to reduce the cost and increase the feasibility of making viral load monitoring available to the last 10% of patients. The cost of alternative methods for reaching the last patients, such as optimal point-of-care viral load equipment placement and usage, dried blood spot specimen utilization, or use of drones in geographically remote facilities, should be evaluated.

WEAE0205

The impact of PEPFAR PMTCT funding on reduced infant mortality and improved ANC care in Kenya: A quasi-experimental evaluation

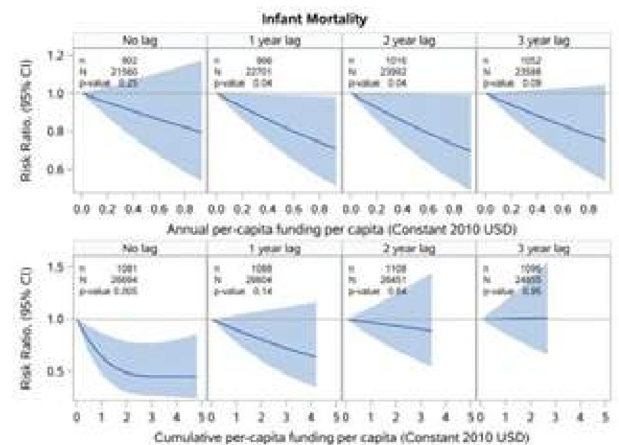
D.A. Barnhart[1], I. Tsikhutsu[2,3], F. Sawe[2,3], J. Muli[2,3], D. Kirui[2,3], W. Sugut[2,3], N. Abboud[4], T. Hamm[5,6], P. Coakley[5,6], P.W. Hickey[5], V. Wolfman[5,6], E. Lee[5,6], D. Spiegelman[7]
[1]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States, [2]Walter Reed Program-Kenya, Kericho, Kenya, [3]U.S. Military HIV Research Program, Silver Spring, United States, [4]Office of the U.S. Global AIDS Coordinator and Health Diplomacy, Washington, United States, [5]U.S. Military Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [6]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [7]Harvard T.H. Chan School of Public Health, Departments of Epidemiology, Biostatistics, Nutrition, and Global Health, Boston, United States

Background: From 2004-2014, the President's Emergency Plan for AIDS Relief (PEPFAR) invested over $240 million in Prevention of Mother to Child Transmission of HIV (PMTCT) in Kenya. During this same time, child mortality in Kenya decreased by half. The extent to which this decrease is attributable to PEPFAR is unknown.

Methods: We mapped annual PEPFAR funding for PMTCT to Kenyan provinces using 2004-2014 Country Operational Reports and linked funding to Demographic and Health (DHS) and AIDS Indicator Surveys (AIS). We used a quasi-experimental dose-response analysis to evaluate the impact of annual (ANN-PC) and cumulative (CUM-PC) per capita PEPFAR funding for PMTCT on infant mortality, neonatal mortality, and HIV counseling, testing, and receipt of test results during antenatal care (HIV testing at ANC). Risk ratios were estimated using generalized estimating equations, and regression models were adjusted for year, province, and respondent characteristics.

Results: Our secondary analysis included 30,424 infants and 21,048 mothers. We found that a $0.33 increase in ANN-PCF, or the difference between the 75th and 25th (IQR) percentiles of annual funding levels, was significantly associated with an 11% (95% CI: 1-21%) reduction in infant mortality after a 1-year lag. This reduction was sustained after a 2-year lag. An $0.83 increase in CUM-PCF, or the IQR of cumulative funding levels, was significantly associated with a 31% decrease in infant mortality (95% CI: 11-46%), with the estimated associations attenuating with successive lags. A $0.33 increase in ANN-PCF was also associated with a 6% increase in HIV testing at ANC after a 3-year lag (95% CI: 2-10%), with similar findings for CUM-PCF. As expected, funding was not associated with neonatal mortality.

Conclusions: We found evidence that PEPFAR funding for PMTCT may be causally associated with reduced infant mortality and increased HIV testing at ANC in Kenya. The full impact of PMTCT funding may not be felt for several years after it is allocated. Our methods, paired with routine, publicly available data sets like DHS and AIS, can be extended to other countries and health challenges to demonstrate the impact of large-scale donor programs like PEPFAR and to inform resource allocation by policymakers.



[Infant mortality and per capita PEPFAR funding for PMTCT in Kenya]

WEAE03 Money, money, money: Dynamic financing solutions

WEAE0301

Global optimization of the response to HIV

J. Stover, Y. Teng
Avenir Health, Center for Modeling and Analysis, Glastonbury, United States

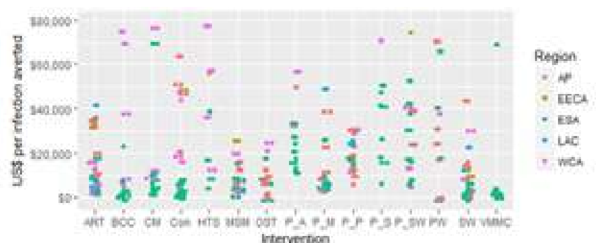
Background: Over $20 billion is spent annually on HIV programs in low- and middle-income countries. The allocation of resources by country and intervention depends on a mixture of need, funding sources, capacity, effectiveness, policy, politics and social factors. We investigated how well the current allocation is optimized for cost-effectiveness.

Methods: We applied an HIV simulation model, Goals, to 55 countries accounting for about 90% of all new infections to determine the cost per infection, death and DALY averted for each of 13 interventions. Units costs were based on Investment Cases for each country. The models were fit to surveillance and survey data and UNAIDS official estimates. Cost-effectiveness ratios were calculated by country and intervention by scaling up each intervention, one-at-a-time, over five years and recording the incremental costs, infections, deaths and DALYs compared to a counterfactual of no scale up of any interventions. The results comprise a database of total cost and cost-effectiveness measures for 716 country/intervention pairs.

Results: Cost-effectiveness varies widely across countries and interventions as shown in Figure 1 for cost per infection averted. Six percent of these combinations are cost savings because the total cost of the

intervention is less than the savings generated due to treatment costs averted. ART dominates cost per death and DALY averted and also ranks high in cost-effectiveness for infections averted. The most cost-effective prevention interventions are generally VMMC, PMTCT, outreach to sex workers and condom promotion. These programs currently receive about 14% of direct intervention funding, which is about two-thirds of the need. The most cost-effective programs are in East and Southern Africa where incidence is high and costs are generally low. Currently almost 60% of all resources and 70% of donor resources are focused on ESA. About 15% of donor resources go to West and Central Africa where cost-effectiveness can be considerably worse.

Conclusions: Resources for HIV prevention and treatment are generally targeted appropriately but more focused allocation of resources could improve cost-effectiveness by about a quarter. Resource allocations should be continually assessed because cost-effectiveness can change significantly as incidence patterns change.



Regions: AP=Asia/Pacific, EECA=Eastern Europe and Central Asia, ESA=East and Southern Africa, LAC=Latin America and Caribbean, WCA=West and Central Africa

Interventions: ART=Antiretroviral therapy, BCC=behavior change communications, CM=community mobilization, Condom=condom promotion, HTS=HIV testing services, MSM=outreach to MSM, OST=opioid substitution therapy, P_A=PrEP for adolescents, P_M=PrEP for MSM, P_P=PrEP for people who inject drugs, P_S=PrEP for sero-discordant couples, P_SW=PrEP for sex workers, PW=outreach to people who inject drugs, SW=outreach to sex workers, VMMC=voluntary medical male circumcision

WEAE0302

How does domestic HIV/AIDS financing respond to declines in development assistance for HIV/AIDS?

A. Haakenstad[1], M. Moses[2], T. Tao[2], A. Chapin[2], J. Dieleman[2]
[1]Harvard T.H. Chan School of Public Health, Boston, United States, [2]Institute for Health Metrics and Evaluation, University of Washington, Seattle, United States

Background: Development assistance for HIV/AIDS aims to complement and enhance domestic spending. However, prior analyses have shown that development assistance displaces government financing: as aid grows, increases in government spending are not as large as they would be in the absence of aid. Furthermore, when aid retracts, government funds do not necessarily fill the gap in financing. While this dynamic has been studied for the health sector overall, we know little about whether it extends to the HIV/AIDS sector. We analyze this relationship using newly available HIV/AIDS financing data.

Methods: Our data consist of estimates of HIV/AIDS financing by source and treatment generated by IHME. The number of people living with HIV/AIDS and ten-year lag-distributed income data are sourced from the Global Burden of Disease Study 2016. General government expenditure estimates are drawn from the World Bank's World Development Indicators. We use fixed effects and system generalized methods of moments regression to analyze the relationship between external and government financing for HIV/AIDS overall, broken down by treatment, and with an interaction capturing the distinct effect of declines of aid.

Results: Unlike the broader health sector, the development assistance disbursed to fight HIV/AIDS is associated with increases in the rate of change of government spending on HIV/AIDS - for each additional dollar of development assistance for HIV/AIDS, an estimated 9 (95% UI: 2-16) additional cents are spent by governments on HIV/AIDS. This effect is even stronger for spending on HIV/AIDS treatment. However, when external assistance declines, so does domestic financing. And declines in domestic expenditure transpire at approximately the same rate - or even faster - than increases.

Conclusions: Our analysis suggests that the declines in HIV/AIDS aid over the past five years are associated with decreases in the domestic financing available for HIV/AIDS. Domestic sources of HIV/AIDS funding are not filling the financing gaps created. If the decreases in development assistance continue, and are accompanied by sustained declines in government financing, treatment and prevention efforts and the major reductions in incidence and mortality achieved over nearly two decades may be at risk.

WEAE0303

Forecasting the cost of financing ART in sub-Saharan Africa under differential funding scenarios

T. Frank, A. Carter
Institute for Health Metrics and Evaluation, Seattle, United States

Background: Amid stagnated international funding for HIV and longer lifespans for people living with HIV (PLHIV), quantifying future antiretroviral therapy (ART) needs is vital for HIV program design and financing. With the present study we summarize the expected cost of financing ART for each country through 2040 by predicting the price of ART, projecting funding under different scenarios, and modeling the HIV epidemic for each scenario.

Methods: We estimated ART prices using a frontier analysis based on Global Price Reporting Mechanism data. We projected current levels of government health expenditure and development assistance for health for HIV treatment based on 15th (pessimistic), 50th (reference), and 85th (optimistic) percentile rates of change across 46 countries, which then informed ART coverage projections by translating predicted funding into expected treatment using our cost projections. We used each scenario as inputs into Spectrum, a cohort component model that applies disease progression parameters to an age- and sex-specific population over time. Spectrum results provided a full time series of HIV prevalence by country through 2040.

Results: Estimated median annual ART price per patient was projected to decrease from $82.51 USD in 2016 to $26.74 in 2040. Country-specific ART cost varied considerably, from $21.03 to $41.64, with the highest prices predominantly in western sub-Saharan Africa (SSA). In the reference scenario, the number of PLHIV in SSA increased from 14.3 million in 2016 to 40.5 million in 2040, a trend primarily fueled by population growth and extended survival of PLHIV. Conversely, incidence was projected to decrease from 1.4 per 1,000 population in 2016 to 0.75 per 1,000 in 2040. Compared with the reference scenario, by 2040, the optimistic scenario estimated 29.4 million PLHIV in SSA whereas the pessimistic scenario projected 81.5 million. Cumulatively, the estimated cost of purchasing ART for SSA exceeded $30 billion for the 2016-2040 reference scenario.

Conclusions: The large disparity in the number of PLHIV in 2040 between the optimistic and pessimistic scenarios underscores the vital impact of HIV funding. Despite declines in projected HIV incidence, demographic factors and greater survival stresses the importance of sustained - if not heightened - HIV funding in the future.

Location	Male PLHIV (thousands)	Female PLHIV (thousands)	Price of ART (USD)
South Africa	3602.1	5326.4	21
Nigeria	2342.4	3437.3	28.6
Tanzania	1358.6	1886.8	26.6
Uganda	1291	1858.8	27.3
Kenya	1170.8	1743.1	23.8
Mozambique	1130.8	1731.3	29.3
Zimbabwe	1039.7	1456.3	22.4

WEAE0304

Achieving sustainable Workplace HIV/AIDS Programmes through a phased out catalytic financing model: Case of Swedish Workplace HIV/AIDS Programme in sub-Saharan Africa

D.M. Mwaura
International Council of Swedish Industries (NIR), Swedish Workplace HIV/AIDS Programme, Nairobi, Kenya

Background: The Swedish Workplace HIV and AIDS Programme (SWHAP) is a joint initiative by the International Council of Swedish Industry (NIR) and the Swedish Industrial and Metalworkers' Union (IF Metall). It is a strategy to contribute to the establishment and/or support of HIV workplaces programmes in sub-Saharan Africa; an example of how management and employees can contribute to a successful intervention that saves lives and secures future markets. The programme helps companies invest in workplace programmes that reverse the negative impact of HIV and AIDS making the programmes sustainable and best practice. It is a case of how transitional funds can establish sustainable programmes and catalyse further investments from private sector into HIV/AIDS and wellness programmes.
Description: The funding model entails a three phase formula where after the start-up engagement, the activity budgets are funded 60% during the first phase, 50% in the second phase and 40% during the third and final phase of the co-funding. This scaled-down approach ensures commitment to continuation of the programme through mainstreaming into the company sustainability plan. The funding is also on reimbursable claims based on actual implementation and expenditure thus a result based financing.
Lessons learned: During 2016, 361 workplaces in 116 companies benefited from the transitional financing. A total of 29,705 employees got information and awareness with HIV testing at 52% average. 9,793 family members were educated on HIV/AIDS and tested. 8,704 key populations reached while 367,830 condoms distributed. On transition, 99% of the companies funded have sustained the programmes becoming best practice examples in contribution to the National frameworks of HIV/AIDS responses and winning various awards; Examples of workplaces that uphold rights of infected employees and non-discrimination practices. The steering committees in the various workplaces have promoted social dialogue even in addressing matters pertaining to management/workers relationship leading to harmonious working environment.
Conclusions/Next steps: This transitional financing model exemplifies how to start sustainable programmes past the partnership,speaks to the business benefits, leading to increased funding from the companies and into sustainability plans.
Next is is to share the model widely with development partners in Public-Private Partnerships. The model infrastructure is applicable for other programmes for sustainability.

WEAE0305

Optimizing resource allocation for HIV prevention programs: Proof of concept of an analytical framework using data from Mexico

A. Salas-Ortiz[1], G. La Hera-Fuentes[1], S.A. Bautista-Arredondo[1,2]
[1]*National Institute of Public Health, Centre for Health Systems Research, Cuernavaca, Mexico,* [2]*UC Berkeley, School of Public Health, Berkley, United States*

Background: Annually, the National Centre for the Prevention and Control of HIV/AIDS of Mexico (CENSIDA) invites Civil Society Organizations (CSOs) to apply for funding to implement HIV prevention projects. Given Mexico's concentrated epidemic in key populations, CSOs play a fundamental role in delivering prevention services to these communities. Even though this program has been implemented for a long time, there is no evidence regarding its performance.
The present analysis shows how decision-makers can use monitoring data to improve the allocation of domestic resources to HIV prevention interventions.
Methods: The conceptual framework proposed by Bautista-Arredondo et al., (2008) was used to evaluate the program's efficiency. The approach assesses the level of efficiency considering three dimensions: cost-effectiveness, targeting and technical efficiency. The approach consists of comparing an observed indicator to a normative one (benchmark). Data from 142 funded projects in 2016 were analysed from the CENSIDA's monitoring tool. Data abstracted from the records included: input costs by category, number of outputs by key populations and interventions delivered by each project. These facets were identified through content analysis and used to calculate unit costs. Benchmarks for the cost-effectiveness and targeting dimensions were constructed based on prior literature and HIV prevalence data; minimum unit costs were considered the benchmark for the technical efficiency dimension. Observed indicators were compared with each respective benchmark.
Results: Current literature suggests that interventions to diagnose HIV are the most cost-effective in contexts of concentrated epidemics; yet, only 24% of interventions implemented in the sample focused on testing. Regarding targeting, men who have sex with men and male sex workers received less funds proportional to their HIV prevalence and size. There was considerable heterogeneity in unit costs within interventions, suggesting significant inefficiencies in service delivery.
Conclusions: These findings allowed stakeholders to re-design the 2017 call to incentivize CSOs to: propose a higher number of the required interventions, intervene in difficult-to-reach key populations, and carry out cost-effective prevention services. This study highlights how monitoring data has the potential to better inform the decision-making process. Moreover, it is an example for middle-income countries in which a financial transition from international donors to domestic funding is occurring.

WEAE04 PrEP: Work in progress

WEAE0401

Factors influencing initiation, continuation & discontinuation of oral PrEP at selected facilities in South Africa

D. Pillay[1], S. Jenkins[2], M. Murire[1], K. Stankevitz[3], H. Subedar[4], S. Mullick[1]
[1]*Wits Reproductive Health and HIV Institute, Johannesburg, South Africa,* [2]*Clinton Health Access Initiative, Pretoria, South Africa,* [3]*FHI 360, Durham, United States,* [4]*South Africa National Department of Health, Pretoria, South Africa*

Background: Sex workers (SW) and men who have sex with men (MSM) in South Africa are at substantial risk of HIV. Hence oral pre-exposure prophylaxis (PrEP) was launched for SW in 2016 and MSM in 2017. Programmatic data shows variability in initiation and continuation between these populations. This study examines factors related to PrEP initiation, continuation, and discontinuation during the national PrEP rollout.
Methods: A cross-sectional survey was administered September 2017-January 2018 among clients (ages 18-62) and providers at 9 facilities implementing oral PrEP in South Africa. The client survey captured PrEP initiation, continuation and discontinuation. The provider survey captured knowledge, attitudes and practiced behaviors towards PrEP. Descriptive analyses were performed on survey data. Continuation and discontinuation questions allowed for multiple responses.
Results: 288 clients (152 SW, 68 MSM, 68 other) and 30 providers (3 clinicians, 13 nurses, 6 counselors, 8 peer-educators) participated. Of 152 SW, 57 (37.5%) self-identified as current PrEP users and 46 (30.2%) as past users. Of 68 MSM, 25 (36.8%) self-identified as current PrEP users and 34 (50%) as past users. Primary reasons current and past users initiated PrEP included: being sexually active (SW 33%; MSM 18.6%), having multiple sexual partners (SW 26.2%; MSM 8.5%), and perceiving HIV risk (SW 22.3%; MSM 8.5%). Reasons current users continued PrEP were similar to initiation reasons: being sexually active (SW 50.9%; MSM 76.0%), having multiple sexual partners (SW 35.1%; MSM 24%), and perceiving HIV risk (SW 40.4%; MSM 40%). The primary reason for past users discontinuing PrEP was that side effects were too great (SW 71.7%; MSM 79.4%). The

majority of providers (n=29; 96.7%) said that participants experienced minimal side effects on PrEP and only 8 (26.7%) identified side effects as a barrier.

Conclusions: SW and MSM in South Africa identify their sexual behavior and perception of HIV risk as reasons to initiate oral PrEP. However, side effects appear to be a challenge among users for oral PrEP continuation, and appear underestimated by providers. This highlights the need to better sensitize providers on user perceptions about side effects in order to inform their counseling messages and side effect management.

WEAE0402

PrEP uptake among pregnant and postpartum women: Results from a large implementation program within routine maternal child health (MCH) clinics in Kenya

J. Kinuthia[1,2], J. Pintye[2], F. Abuna[3], H. Lagat[3], K. Mugwanya[2], J. Dettinger[2], M. Serede[3], J. Sila[3], J.M. Baeten[4], G. John-Stewart[4], PrEP Implementation for Young Women and Adolescents (PrIYA) Program
[1]Kenyatta National Hospital, Nairobi, Kenya, [2]University of Washington, Department of Global Health, Seattle, United States, [3]University of Washington-Kenya, Nairobi, Kenya, [4]University of Washington, Departments of Global Health, Epidemiology and Medicine, Seattle, United States

Background: Very few examples of PrEP delivery to pregnant and postpartum women have been reported. The PrEP Implementation for Young Women and Adolescents (PrIYA) Program provides real-world evidence on delivering PrEP to pregnant and postpartum women in Kenya.

Methods: PrIYA is part of the DREAMS Innovation Challenge funded by PEPFAR managed by JSI Research & Training Institute, Inc. We approached HIV-uninfected pregnant women seeking routine antenatal (ANC) and postnatal (PNC) services at 16 maternal and child health clinics in Kisumu, Kenya from June to December 2017. At each patient encounter, screening for behavioral risk factors and willingness to consider PrEP was conducted per national PrEP guidelines. Those who were willing to consider PrEP were assessed for medical eligibility and those eligible were offered PrEP at the same visit. Logistic regression models determined correlates of PrEP initiation.

Results: In total, we conducted 9,704 assessments among pregnant/postpartum clients for behavioral risk factors and willingness to consider PrEP. The median age was 24 years (IQR 21-28); 31% did not know their male partner's HIV status and 84% were married. Overall, 1,856 (19%) of encounters led to PrEP initiation; only 6 women (< 0.01%) were medically ineligible (creatinine clearance < 50 min/mL). Frequency of PrEP initiation differed by male partner HIV status (HIV-negative 7%, unknown 43%, HIV-positive 79%, p< 0.001). PrEP initiation was more common in the postpartum period than during pregnancy (23% vs 16%, p< 0.001). Women younger than 24 years of age were more likely than older women to initiate PrEP (OR=1.18, 95% CI 1.08-1.28, p=< 0.001). Initiating PrEP was also associated with having an STI (OR=2.66, 95% CI 1.48-4.77, p=0.001) and being forced to have sex in the last 6 months (OR=3.69, 95% CI 1.69-8.06, p=0.001). The most frequently reported reasons for declining PrEP were the perception that HIV risk was low (46%) and the partner was HIV-negative (43%); few women accepting PrEP feared intimate partner violence as a result (2%).

Conclusions: In this pregnant and postpartum population, a substantial number of women desired and started PrEP. PrEP initiators were younger and more likely to have HIV risk factors than those who declined PrEP.

WEAE0403

How long will they take it? Oral pre-exposure prophylaxis (PrEP) retention for female sex workers, men who have sex with men and young women in a demonstration project in Kenya

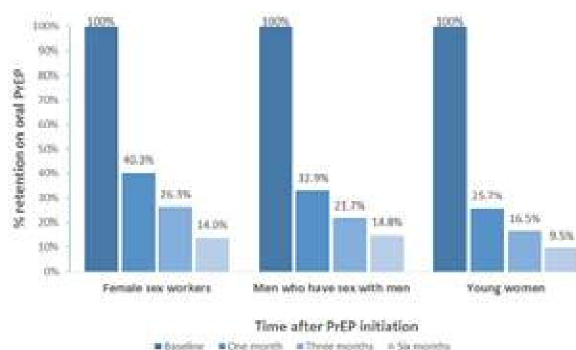
J.K. Kyongo[1], M. Kiragu[2], R. Karuga[1], C. Ochieng[1], A. Ngunjiri[1], C. Wachihi[3], H. Musyoki[4], L. Digolo[1], L. Otiso[2], L. Gelmon[3], N. Kilonzo[5], W. Mukoma[6]
[1]LVCT Health, Research & Strategic Information, Nairobi, Kenya, [2]LVCT Health, HIV Services, Nairobi, Kenya, [3]Partners for Health and Development in Africa, Nairobi, Kenya, [4]National AIDS and STIs Control Program (NASCOP), Nairobi, Kenya, [5]National AIDS Control Council (NACC), Nairobi, Kenya, [6]LVCT Health, Directorate, Nairobi, Kenya

Background: Female sex workers (FSW), men who have sex with men (MSM) and young women (YW) account for majority of new infections in Kenya. Oral PrEP effectively protects against HIV infection but data on PrEP retention and influencing factors in real-world settings is limited. We present data on retention on PrEP in a prospective oral PrEP demonstration project in Kenya.

Methods: Between August 2015 and October 2016, we enrolled 1585 participants; 528(33%) FSW, 438(28%) MSM and 619(39%) YW; on oral PrEP. Two public and four private health facilities were used as points of care, with monthly PrEP refill and adherence/risk behavior counselling visits. Follow up duration was one year and participants did not receive reimbursements. Retention was defined as returning for PrEP refill as scheduled and assumed to imply PrEP use. Reasons for drop-out and continuous use were documented through facility registers and in-depth interviews and focus group discussions with PrEP users and health care workers (HCWs). Data was analysed using STATA (quantitative) and NVivo (qualitative).

Results: Retention at one, three and six months was 40.3%, 26.3% and 14% for FSW; 32.9%, 21.7% and 14.8% for MSM and; 25.7%, 16.5% and 9.5% for YW. For all populations, the instantaneous hazard rate of terminating PrEP use was lowest at twenty weeks. FSW < 23 years were more likely to drop out compared to older FSW (HR 0.76 (95% CI: 0.60 to 0.97) p < 0.029). No age variations were observed among MSM and YW. Reasons for choosing to stop using PrEP included reduced self-perception of risk, sexual partner on successful antiretroviral therapy, community stigma, PrEP myths and misconceptions, risk of social harm, negative attitude from HCWs, challenges accessing study site and tedious procedures at health facilities. Motivators for continuous PrEP use include peer/guardian/partner support, access to combination HIV prevention services and social responsibility.

Conclusions: In our context, we observed high attrition from oral PrEP use by all populations but especially by young women. There are individual, community and health system barriers and enablers of continuous PrEP use. Most of these are modifiable and need to be considered by countries and programs scaling up oral PrEP.



[Retention on oral pre-exposure prophylaxis (PrEP)]

WEAE0404
Cost and impact of PrEP implementation in Haiti to adopt WHO recommendations: Results from EQUIP

R. Kolesar[1], K. Rebe[2], D. Lauture[3], S.N. Magwaza[4,5], W.J. Domercant[3], E. Emmanuel[3], M. Leonard[3], M.-L. Excellent[6], F.J. Louis[3], EQUIP PrEP Technical Working Group
[1]University of Boston (Affiliation), Public Health (Health Economics), El Malecón, Dominican Republic, [2]ANOVA Health Institute, Health4Men, Cape Town, South Africa, [3]Maternal Adolescent and Child Health Systems, EQUIP Innovation for Health, Port au Prince, Haiti, [4]Maternal Adolescent and Child Health Systems, EQUIP Innovation for Health, Durban, South Africa, [5]University of Witswaterand, School of Public Health, Johannesburg, South Africa, [6]Maternal Adolescent and Child Health Systems, EQUIP Innovations for Health, Port au Prince, Haiti

Background: The World Health Organization expanded its recommendation on the provision of Pre-Exposure Prophylaxis (PrEP) to include all people at substantial risk of HIV exposure to achieve the UNAIDS' "Fast-Track" strategy . The Haitian National AIDS Control Program included PrEP for key populations (KP) in the HIV/AIDS national strategic plan (2018-2023). Hence, EQUIP-Haiti, conducted PrEP impact and cost modeling studies to measure effects of PrEP implementation to inform policy decision in Haiti.

Methods: *Goals* module of *Spectrum*, the UNAIDS analytical software, was used for estimating the effects of interventions on HIV infections and resource requirements. Key parameters included, unit cost, population size estimates, epidemiological and behavioral data, intervention coverage by sex, risk group, year, and effectiveness. The Haiti *Integrated Biological and Behavioral Surveillance* survey for KPs was used. . Comparison made of 3 scenarios for annual direct service costs between 2019 - 2023; proportion of KP-initiated on PrEP and HIV infections averted by 2023. A 3-step process estimated potential costs and impact of PrEP implementation:

· A cost component-based approach identifying the specific cost elements to estimate an annual unit cost per person on PrEP;

· Simulations with different adherence rate measures and HIV treatment coverage assumptions with increments from 2018-2023;

· Estimating the impact and cost of scaling up condom use in the general population, and comparing result against the current status.

Results: The estimated first year PrEP unit cost per client is $228.87 that declines to $173.85 annually thereafter. Of the 3 scenarios, the 2nd was feasible for Haiti assuming 80% adherence and 5% coverage in 2017 with a 10% increase from 2018-2023. The total direct cost was estimated at $2.9-$3.1 million annually for direct service provision to 10% of KPs initiated within 2 years between the 2018-2023 period. This translates to 16,263 people on PrEP with a projected HIV aversion of 2, 528 cumulative infections by 2023.

Conclusions: The study results informed policy decision for PrEP implementation in Haiti. In the future, the proposed scenarios must consider integrated services and health system issues affecting implementation.

WEAE0405
The cost-effectiveness of multi-purpose HIV and pregnancy prevention technologies in South Africa

M. Quaife[1,2], F. Terris-Prestholt[1], R. Eakle[2], M. A Cabrera Escobar[2], M. Kilbourne-Brook[3], M. Mvundura[3], G. Meyer-Rath[4,5], S. Delany-Moretlwe[2], P. Vickerman[6]
[1]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom, [2]University of the Witwatersrand, Wits RHI, Johannesburg, South Africa, [3]PATH, Seattle, United States, [4]Boston University, Center for Global Health and Development, Boston, United States, [5]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [6]University of Bristol, Bristol, United Kingdom

Background: A number of antiretroviral HIV prevention products are efficacious in preventing HIV infection. However, the sexual and reproductive health needs of many women extend beyond HIV prevention and research is ongoing to develop multi-purpose prevention technologies (MPTs) that offer dual HIV and pregnancy protection. We do not know if these products will be an efficient use of constrained health resources. In this paper we estimate the cost-effectiveness of combinations of candidate multi-purpose prevention technologies (MPTs), in South Africa among general population women and female sex workers (FSWs).

Methods: We combined a cost model with a static model of product impact based on incidence data in South Africa to estimate the cost-effectiveness of five candidate co-formulated or co-provided MPTs: oral PrEP, intravaginal ring, injectable ARV, microbicide gel, and SILCS diaphragm used in concert with gel. We accounted for the preferences of end-users by predicting uptake using a discrete choice experiment (DCE). Product availability and protection were systematically varied in five potential rollout scenarios. The comparator for each scenario was current levels of male condom use, while a health system perspective was used to estimate discounted lifetime treatment costs averted per HIV infection. Product benefit was estimated in disability-adjusted life years (DALYs) averted. Benefits from contraception were incorporated through adjusting the uptake of these products based on the DCE and through estimating the costs averted from avoiding unwanted pregnancies.

Results: At central incidence rates, all single- and multi-purpose scenarios modelled were cost-effective among FSWs and women aged 16-24, at a governmental willingness-to-pay threshold of $1,175/DALY averted (range: $214 to $810/DALY averted among non-dominant scenarios), however none were cost-effective among women aged 25-49 (minimum $1,706/DALY averted). The cost-effectiveness of products improved with additional protection from pregnancy. Estimates were sensitive to variation in incidence assumptions, but robust to other parameters.

Conclusions: To our knowledge, this is the first study to estimate the cost-effectiveness of a range of potential MPTs; suggesting that MPTs will be cost-effectives amongst higher incidence FSWs or young women but not lower incidence older women. More work is needed to make attractive MPTs available to potential users who could use them effectively.

WEAE05 I want you back: Improving retention on HIV programmes

WEAE0501
10 years of Community ART Groups (CAG): Retention and viral load uptake in Tete, Mozambique

L. Haldna, A. W. Torrens
Medecins Sans Frontieres, Operational Center Brussels, Brussels, Belgium

Background: Community ART groups (CAG), peer support groups involved in community ART distribution and mutual psychosocial support, were piloted by MSF in 2008 to respond staggering ART attrition in Tete, Mozambique. 10 years later, outcomes of CAG were analyzed - whether community-based care in rural setting has increased retention and improved clinical outcomes.

Methods: Retrospective cohort design was used with data from HIV electronic register and CAG group register. A total of 2167 patients from 2008 to 2017 ever registered in CAG in Changara and Marara districts were included in the analysis. Kaplan-Meier techniques were used for estimating mortality and lost to follow-up (LTFU) rates per 100 person-years. Individual level predictors of attrition were assessed using logistic regression and chi-square tests.

Results: Mortality, LTFU and returning to individual care rates among 2167 CAG members were, respectively, 2.3, 1.6 and 1.6 per 100 person-years. Long-term retention in HIV care was found high: 93.1% at 2 years, 90.2% at 4 years and 87.5% at 9 years. Retention did not decrease significantly after 4th year (p=0.4006) in care. Patients who never had viral load (VL) monitored (*a*OR 4.266, 95%CI 3.34-5.46) or had unsuppressed VL (*a*OR 3.954, 95%CI 2.58-6.07) were at higher risk of LTFU or death. 53.9% of patients with VL >=1000 cp/ml were part of CAG, while unsuppressed VL is CAG exclusion criteria. 15.32% of patients had joined CAG with advanced HIV (CD4 < 200 cells/µl), these patients were at higher risk of attrition (*a*OR 1.861, 95%CI 1.36-2.54).

Conclusions: Long-term retention was exceptionally high, especially for a rural population, confirming positive results from previous studies. Nevertheless, finding about outcomes indicate that to reduce attrition, efforts are needed to strengthen the detection of PLWHA on earlier stage and to ensure clinical follow-up and VL routine monitoring. Risk factors associated with attrition demonstrate crucial added value of CAG model as peer-to-peer support and not only as community provision of ART. Results of this study have potential benefit to the global HIV response to provide out-of-clinic treatment to increasing number of patients, moreover it is a comprehensive insight how community-based care has functioned over a long period of time.

WEAE0502

Increasing retention in care through community systems strengthening: Lessons learned from 15 districts in South Africa

M.R. Manganye[1], S. Berrada[1], A. Wagner[1], S. Gombarume[2], C. Wylie[1], A. Make[1]
[1]Hospice Palliative Care Association of South Africa, CaSIPO - Care and Support for Improved Patient Outcomes, Cape Town, South Africa, [2]USAID/Southern Africa, Care and Treatment, Pretoria, South Africa

Background: The United States Agency for International Development-funded Care and Support to Improve Patients Outcomes Project (CaSIPO) aims to maximize the quality of life for patients on antiretroviral treatment (ART) through provision of comprehensive care and support services in the community. As the South African Government vows to provide access to treatment to all people living with HIV and AIDS, adherence to treatment and retention in care are critical to the sustainability of the ART program.
Description: CaSIPO works with 15 high burden Districts to strengthen community systems to promote patients' retention in care. Community adherence clubs (CACs) offer a much-needed adherence support structure to stable patients on ART along convenient access to their medications. CaSIPO uses innovative approaches to adapt to local context and establish CACs in rural, semi-rural and urban settings. Working closely with community based organizations (CBOs), ward based outreach teams and clinics, CaSIPO developed their skills and knowledge to provide adherence support, health promotion, nutrition assessment counselling and support, screening for tuberculosis and sexually transmitted infections, family planning education and active referral.
Lessons learned: CaSIPO undertook various capacity development strategies to strengthen the CBOs' systems and structures and empower them with the necessary tools to provide patients-centred sustainable adherence support. Between June 2016 and December 2017, CaSIPO empowered 194 CBOs across 15 Districts to provide quality comprehensive care and support services to 110,994 HIV stable patients attending 4,526 CACs. Quality is a key driver of retention in care. Through training, mentorship and intensified technical assistance program, CaSIPO established a quality assurance system for community based services resulting in 96% retention in CACs (n=106,781; d= 110,994; December 2017). Over 18-month period, 4,213 of 110,994 CACs patients had exited the clubs, with 69% (2,907) transferred to other decanting modalities and only 7% (295) lost to follow up.
Conclusions/Next steps: South Africa unique and complex public health dynamic led CaSIPO to adopt a mixed approach to provide sustainable and scalable community adherence support structure to ART patients. Strengthening the community system and facilitating linkages between community and health facilities has proven to be critical in promoting retention in care.

WEAE0503

Same day ART initiation does not reduce 12-month retention among HIV-infected children in Uganda

A. Kekitiinwa[1], P. Elyanu[2], E. Nazziwa[3], G.P. Kisitu[2], R.N. Ssebunya[2], C. Katureebe[4], G. Namayanja[5], I. Lukabwe[4], E.N. Magongo[4], A. Namale[3], P.N. Ntege[2], M.R. Adler[3]
[1]Baylor College of Medicine Children's Foundation, Pediatrics and Child Health, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Kampala, Uganda, [3]Centre for Disease Control, Entebbe, Uganda, [4]Ministry of Health, Kampala, Uganda, [5]Centre for Disease Control, Kampala, Uganda

Background: Countries have adapted the WHO Test and START guidelines for antiretroviral therapy (ART) initiation, but there is limited evidence on how soon to start ART in children without jeopardizing retention. Uganda has implemented Test and START guidelines for children which included same day initiation since 2014. We compared 12-month probability of retention in HIV-infected children aged < 15yrs initiated on ART on the same day of diagnosis versus 2-14 days or >14 days from diagnosis during HIV Test and START policy implementation in Uganda.
Methods: We retrospectively reviewed clinic charts for HIV-infected children diagnosed and initiated on ART from June 2014 to March 2015 in 42 health facilities in Uganda. Retention was defined as being alive and on ART during the 12th month on ART. Kaplan-Meier estimates were used to calculate the 12-month probability of retention (overall and stratified by health facility level and age at diagnosis) and the log-rank test to compare groups.
Results: Of 899 HIV infected children, 115(12.8%) were excluded for missing diagnosis date and 784(87.2%) were included in the analysis. Of these 784 children, 56% were girls, median ages (IQR) at diagnosis and ART initiation was 3(1, 7) years and 4(1, 7) years respectively. Three hundred and seventeen (40.4%) children started ART on the same day they were diagnosed, 155(19.8%) started within 2 to 14 days and 312(39.8%) started after 14 days. The overall probability of one-year retention was 89.9%; Retention was similar among children who initiated ART on the same day (89.7%) compared to those initiated 2-14 day's (94.0 %) and >14 days (90.2 %), p=0.3. Retention was highest in those diagnosed at age 5-14yrs (93.5%) and at health centres (96.0%); and lowest in children under 2 years of age (85.9%) and regional referral hospitals (89.7%). Retention in each age and health facility stratum did not differ by time from diagnosis to initiation (table 1).
Conclusions: Starting ART in children on the same day of diagnosis does not jeopardize retention on treatment.

Characteristic		All		Same Day N=317	2-14 Days N=312	>14 days N=312	P-Value*
		# Retained/ Total	Incidence (95%CI)	Incidence (95% CI)	Incidence (95%CI)	Incidence (95%CI)	
Overall	Crude	713/784	89.9% (87.5%, 91.8%)	89.7% (85.8%, 92.6%)	94.0% (88.8%, 96.9%)	90.2% (86.3%, 93%)	0.3
Health Facility	Regional referral hospital	395/435	89.7% (86.6%, 92.1%)	90.6% (85.3%, 94.1%)	92.6% (85.2%, 96.4%)	89.1% (82.8%, 93.2%)	0.6
	General Hospital	192/208	90.3% (85.8%, 93.4%)	90.7% (81.4%, 95.4%)	97.0% (81.0%, 99.0%)	91.8% (84.2%, 95.8%)	0.5

Community patient tracking by Lay Community Health Workers (CHWs) is an effective strategy towards the 2nd & 3rd 90

B.M. Morapedi, G. Morineau, C. Lesedi, J.M. Irige, B. Mantu, O. Sokwe, C. Pheko, K. Poloko
FHI 360, APC Botswana Project, Gaborone, Botswana

Background: In June 2017, Botswana introduced 'Treat all' to facilitate universal coverage of antiretroviral treatment (ART) towards the 90-90-90 targets. Treat all provides access to ART to Botswana citizens irrespective of CD4 count. FHI 360, Advancing Partners and communities (APC) project, funded by PEPFAR through USAID in Botswana built the capacity of communities towards epidemic control by introducing community health workers (CHWs) to support health facilities trace patients with known sero-positive status who never started ART and defaulters, in eight districts. Health facility staff traditionally trace defaulters through phone calls.

Description: Working in collaboration with the Ministry of Health & Wellness (MoHW) District Health Management Teams (DHMTs), CHWs were trained on community HIV care including patient tracking strategies and provided standard operating procedures (SOPs) for guidance. Senior Community Health Workers (SCHWs) were posted in health facilities and together with nurses in the infectious Disease Control Centres (IDCC) identified patients that were in the registers but never started ART or defaulted.

A team of CHWs was assigned a caseload of patients to track in the community. Successfully traced patients were linked to facilities through unaccompanied and accompanied referrals. They were also provided information on "Treat All" to support them to opt for ART initiation.

Lessons learned: During the period October 2016 to September 2017, out of 1,277 clients referred to APC CHWs for tracing, 584 (46%) included sufficient information in their clinical file for tracing. From those traced, 317 (54%) linked back to health facilities and initiated on ART, 146 (25%) were found already on ART, 46 (8%) were referred but did not link, 40 (7%) had changed physical address, 27 (5%) declined to be linked back to care, and eight were reported deceased.

Conclusions/Next steps: Implementation of community patient tracking contributed to linkage of PLHIV to ART and updating patient facility records. Home visits by CHWs increases uptake of ART services. CHWs are critical to fill the human resource constraints within the health system and their knowledge of their community ensures successful tracing of those lost by the health system. Tracking patients that have defaulted from ART is resource intensive but worth it.

'My best friends and my worst enemies': Understanding the roles of families in retaining South African adolescents living with HIV in care

T.D. Ritchwood[1], N. Ntlapo[2], M. Atujuna[2], S. Letoao[3], A. Oduro[2], L.G. Bekker[2]
[1]*Medical University of South Carolina, Public Health Sciences, North Charleston, United States,* [2]*University of Cape Town, Desmond Tutu HIV Centre, Observatory, South Africa,* [3]*Information Health Measurement, Mbabane, Swaziland*

Background: Adolescents living with HIV (ALWH) are less likely than their child or adult peers to be retained in HIV care and adhere to their medication regimens. While familial involvement is critical to the treatment success of ALWH, most of interventions for this group focus only on individual-level factors and do not include family members. This current study investigated the role of families in ALWHs' treatment retention and adherence and solicited strategies from ALWH, their caregivers, and local stakeholders to better integrate families in intervention efforts.

Methods: Fifty-nine semi-structured, in-depth interviews were conducted to qualitatively determine how the families of ALWH support or hinder their treatment retention and adherence and to determine how best to include them in intervention efforts. Participants were ALWH (n=20; 13-19 years of age), their caregivers (n=19), and local stakeholders (n=20) from Cape Town, South Africa. Data were coded and analyzed using inductive content analyses. We then grouped codes into perceived positive and negative familial roles, and suggestions on how families could help to improve ALWH treatment retention and adherence.

Results: Findings revealed several positive roles that family members served in supporting ALWH, including: reminding them to take their pills; reinforcing notions of personal accountability; providing informational, instrumental, and emotional support; assisting youth when their primary caregiver was unavailable; and normalizing pill taking. While most participants identified their families as sources of support, a number of participants expressed negative familial roles, including being sources of discrimination, ridicule, and discord; and lacking a role entirely. Moreover, participants reported that HIV disclosure within families is often challenging, leaving many ALWH with no one with whom they can confide within their social networks, limiting their family's ability to provide critical support. ALWH suggested that their families assist with retrieving medications from pharmacies and commit to unconditional acceptance, regardless of whether they adhere to their treatment regimens.

Conclusions: Families play an important role in the adolescent HIV treatment cascade and could both facilitate and derail treatment retention and adherence. This study highlights the need for systematic, intergenerational approaches that incorporate socio-structural factors in efforts to retain ALWH in HIV care.

Antiretroviral treatment did not restore functionality of cervical mucosal cells for Th17-related cytokines altered after HIV infection

M.P. Caruso[1], M.P. Holgado[1], J. Falivene[1], J. Salido[1], D.H. Zurita[2], A. Nico[2], V. Fink[2,3], N. Laufer[1,2], H.M. Perez[2], P. Cahn[2,3], O. Sued[3], G. Turk[1], M.M. Gherardi[1]
[1]Universidad de Buenos Aires, Consejo Nacional de Investigaciones Científicas y Técnicas, Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Facultad de Medicina, Buenos Aires, Argentina, [2]Hospital General de Agudos 'Dr. JA Fernández', Buenos Aires, Argentina, [3]Fundación Huésped, Buenos Aires, Argentina

Background: Th17 and Treg cells play a key role in HIV infection and mucosal defenses. A reduction of Th17 cells in the female genital mucosa(FGM) of HIV+ women has been previously described.
Aim: To analyze the effects of antiretroviral treatment(ART) in these T-cell subsets in FGM in different groups of individuals.
Methods: Cervical mononuclear cells(CMCs) and exocervical swabs from FGM were obtained from the following groups: HIV- (n=21), HIV+ART+(n=32) and HIV+ART- (n=12). Cytokines(CKs) secreted by CMCs after stimulation with PMA+Ionomycin and chemokines in exocervical swabs were quantified by Cytometric Bead Array.
Results: CMCs production of Th17-related-CKs (IL17A, IL17F, IL21 and IL22) and Treg-related-CKs (IL10 and TGF-1) were evaluated. HIV+ART- group showed diminished proportions of positive responses for Th17-related-CKs compared to HIV- (IL17A, IL17F and IL21:p< 0.01). Minor proportions were still found in HIV+ART+ group (IL17A and IL17F:p< 0.05). In Treg-related-CKs, reduction was only found for IL10 in both HIV+ groups (p< 0.05).
Analysis of global pattern of secretion of Th17-related-cks, indicated that in HIV+ART- the secretion pattern was severely modified (p=0.0297). In HIV+ART+ the Th17-related-cks pattern tend to be restored, but a significant lower percentage of samples secreted 4CKs (HIV-:62.5% vs HIV+ART+:16.67%; p=0.0281). By contrast, when Treg-related-CKs pattern was compared none significant differences were found.
Thirteen different chemokines were evaluated in exocervical swabs. Differences in both HIV+ groups vs HIV- were detected: minor levels of CXCL5 and CXCL1 (neutrophil recruitment); major levels of CCL17 (homing of Treg-cells).
To inquire if CMCs function deterioration could be related with minor chemokine levels observed, HIV+ART+ group was divided in two according to the number of Th17-related-CKs secreted: "at least 3CKs" and "1 or less CKs".
Interestingly, for CXCL5 and CXCL1, significant lower levels were found in the "1 or less" group (compared to HIV- and to "at least 3", all p< 0.05). Also in HIV+ART+, positive correlations were found between logCXCL5 vs logIL17A(r=0.5666, p=0.0241), logCXCL1 and logIL17A(r=0.7273, p=0.0006) and logCCL17 vs logIL10(r=0.5700, p=0.0186).
Conclusions: These results suggest that HIV infection severely affects the functionality of cervical mucosal cells, and ART was not able to totally restore it. Earlier ART start might mitigate this HIV infection effect.

Effect of ART on reducing fungal translocation in HIV-infected patients

J.P. Routy[1,2], V. Mehraj[1,2], R. Ramendra[3], C. Costiniuk[1], B. Lebouché[1], . Chen[1,4], R. Ponte[2], R. Thomas[5], B. Trottier[6], J. Szabo[5], P. Coté[6], R. LeBlanc[7], J.-G. Baril[6], N. Bernard[2], D. Sheppard[2,3], C. Chartrand-Lefebvre[8], M. El-Far[8], M. Durand[8], H. Lu[4], C. Tremblay[8,9], Montreal Primary HIV-infection Study and Canadian HIV and Aging Cohort Study Groups
[1]Chronic Viral Illness Service, McGill University Health Centre, Montréal, Canada, [2]Research Institute of McGill University Health Centre, Montréal, Canada, [3]McGill University, Department of Microbiology and Immunology, Montréal, Canada, [4]Shanghai Public Health Clinical Center, Infectious Diseases, Shanghai, China, [5]Clinique Médicale l'Actuel, Montréal, Canada, [6]Clinique Médicale Quartier Latin, Montréal, Canada, [7]Clinique Médicale OPUS, Montréal, Canada, [8]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montréal, Canada, [9]Université de Montréal, Département de Microbiologie, Infectiologie et Immunologie, Montréal, Canada

Background: LPS, LBP, and sCD14 are validated markers of microbial translocation in HIV-infected persons. (1-3)--d-glucan (DG) is a major component of most fungal cell walls that binds to the extracellular domain of myeloid cells, Dectin-1. We and others have shown that DG plasma levels may be considered as a marker of gut fungal translocation in HIV-infected persons. However, the contribution of ART in improving gut fungal translocation remains to be defined. Herein, we look to assess the role of ART on normalization of DG levels when initiated during acute (AHI) and chronic HIV infection (CHI).
Methods: 177 participants (42 AHI, 93 CHI, and 42 controls) without suspicion of fungal/bacterial infection nor colitis were assessed in a cross-sectional analysis. 32 AHI patients were longitudinally assessed. Plasma levels of DG were quantified using Fungitell® assay and were compared with age, sex, viral load, CD4, CD4/CD8 ratio, marker of gut damage (I-FABP), microbial translocation (LPS, LBP and sCD14), and inflammation (IL1-, IL-6, IL-8 and TNF-).
Results: The mean age of participants was 47.9±12.6 years with 86.4% being male. Plasma DG levels were elevated during AHI (59.4±33.6 pg/mL, p=0.002) and further increased in CHI (135.6±48.6 pg/mL, p< 0.001) vs. seronegative controls (26.7±9.7 pg/mL). We observed a positive correlation of DG with age (r=0.351; p< 0.001) and with viral load (r=0.429; p< 0.001) as well as a negative trend for CD4 counts (r=-0.135; p=0.125). DG levels correlated with sCD14 (r=0.404; p=0.002), IL-6 (r=0.404; p=0.001), and IL-8 (r=0.640; p< 0.001) among HIV-infected persons. DG levels increased over 2-years in the untreated AHI (111.2±96.4 pg/mL p< 0.001) and remained stable in the early treated group. Similarly, CHI persons on 13.5±7.0 years of ART did not show a decrease in their DG levels (135.2±47.3 pg/mL, p< 0.001). Multivariate analysis showed DG elevation was independent of age, sex, CD4 and CD8 counts.
Conclusions: The elevation of plasma DG levels observed during acute and chronic infection did not decrease with early ART initiation nor long-term ART usage. Elevated DG levels, which correlated with markers of immune activation, may be directly involved in HIV pathogenesis via Dectin-1 mediated protein kinase C pathway in myeloid cells.

WEPDA0103

Persistence of myeloid cell-associated inflammation in HIV-infected children after 8 years on early initiated therapy - the key role players in HIV persistence?

S. Naidoo[1], K. Veldsman[1], M.F. Cotton[2], R.H. Glashoff[3]
[1]Stellenbosch University, Medical Virology, Cape Town, South Africa, [2]Stellenbosch University, Tygerberg Children's Hospital, Cape Town, South Africa, [3]Stellenbosch University, Division of Medical Microbiology, Cape Town, South Africa

Background: Combination antiretroviral therapy (ART) does not completely eradicate HIV latently infected cells. Resting CD4+ T cells remain the most studied source of residual viremia. Research evaluating the role of myeloid lineage cells, such as monocytes and macrophages, in HIV persistence is limited. These long-lived cell types provide optimal hide-

outs for the virus and are less susceptible to HIV-induced cytopathic effects and death. Evaluating the interplay of the immune mechanisms of myeloid cells and HIV persistence within a pediatric population may provide valuable insight into therapeutic targets for eradicating latent reservoirs.

Methods: Plasma samples originating from the Children with HIV-Early Antiretroviral Therapy (CHER) trial were evaluated. ART was initiated at < 1 year of age and children sustained viral suppression at 7-8 years. Cytokines (IL-1b, IL-6, IL-8, IL-10, INF-, TNF-a, TGFb1,2,3, sCD14, sCD163, GCSF, CMCSF, VEGF) and chemokines (MCP-1, MIP-1a, MIP-1b, LBP) involved in monocyte/macrophage activation and trafficking were measured using Luminex® Multiplex assays. Age-matched controls were measured for the same biomarkers. A subset of HIV-infected participants was tested for total HIV-1 DNA using qPCR targeting a conserved region in HIV integrase. Statistical analysis employed a Wilcoxon matched paired test for nonparametric data.

Results: 163 samples (88 HIV-infected and 75 HIV-uninfected controls) were evaluated. The median baseline viral load at ART initiation was 738,500.5 copies/ml. Median CD4-percentage at baseline was 36.9% (range: 23.1-57.1%). At 7-8 years of age, there were no significant differences between the CD4-percentage of the HIV-infected (38.3%) and control groups (40.0%) (p=0.261). HIV-infected children showed highly significant (p< 0.001) levels of IL-1, IL-6, TGF3, sCD14, sCD163, MCP-1, MIP-1a, MIP-1b, GCSF, CMCSF, LBP, and VEGF when compared to controls. Significant increase in IL-8 (p=0.0450), TNFa (p=0.0033), TGFb1 (p=0.0140) and TGF2 (p=0.0042) were also observed. Among 32 children assessed for HIV-1 DNA at follow-up, a median of 32.5 copies/million cells (range: 0-562.6) was observed at 7-8 years of age.

Conclusions: Despite early therapy initiation, long-term viral suppression, low cell-associated HIV-1 DNA detection and normalized CD4 counts, HIV-infected children display persistent myeloid-cell associated inflammation which may drive ongoing low-level replication. The increase in sCD14 and LBP levels implicate bacterial gut translocation.

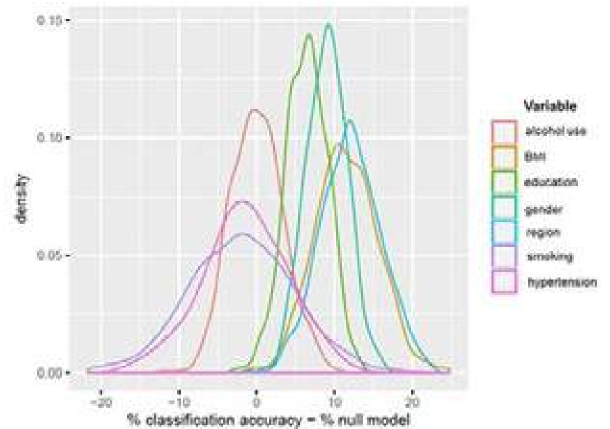
Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [5]Institute for Transfusion Medicine, University Hospital, University Duisburg-Essen, Essen, Germany, [6]Mbeya Medical Research Centre, Mbeya, Tanzania, United Republic of, [7]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Abuja, Nigeria, [8]Makerere University-Walter Reed Project, Kampala, Uganda, [9]Henry M. Jackson Foundation Medical Research International, Kericho, Kenya, [10]Kenya Medical Research Institute, Nairobi, Kenya, [11]Henry M. Jackson Foundation Medical Research International, Kisumu, Kenya

Background: Immune activation is a significant contributor to HIV pathogenesis and disease progression. In ART virally-suppressed individuals, low-level immune activation has been linked to several non-infectious comorbid diseases (NCDs). However, such studies have not been systematically performed in sub-Saharan Africa and thus the impact of demographics, cART and regional endemic co-infections on immune activation is not known. We therefore comprehensively evaluated in a large multinational African cohort markers for immune activation and its distribution in various settings.

Methods: In total, 2747 specimens from 2240 HIV-positive (1492 on cART, 748 without cART) and 477 HIV-negative individuals from the observational African Cohort Study (AFRICOS) were analyzed for 13 immune parameters. Samples were collected together with medical history, sociodemographic and comorbidity data at 11 HIV clinics across 5 programs in Uganda, Kenya, Tanzania and Nigeria. Data were analyzed with univariate and multivariate methods such as random forests and principal component analysis.

Results: Immune activation was markedly different between HIV-positive with detectable viral load and HIV- individuals across sites (p< 0.001), but only differed in some markers between HIV+ cART+ (< 50 copies/ml) and HIV- individuals. Random Forest analysis revealed that immune activation parameters could successfully predict the country origin of the specimens (P< 0.001) as well as to lesser degree the level of education. In particular, CCL2 and IL2RA were significantly diametrically expressed in the five regions (P< 0.001). This was the case across HIV-positive and HIV-negative individuals and was not due to other infections such as hepatitis B, C, tuberculosis or co-trimoxazole prophylaxis. Within the 2240 HIV-positive individuals, our study revealed significant gender specific immune activation expression patterns that were not present in HIV-negative individuals. Moreover, when we compare HIV-negative individuals and HIV-positive individuals with fully suppressed viremia, the latter group has a significantly larger number of NCDs, an effect that increases with age(p=0.0069). These two groups can be distinguished based on diverging immune parameters such as CXCR10 and IL2RA .

Conclusions: We demonstrate region-specific, gender-specific and education-specific differences in immune activation expression. Furthermore, several immune activation markers are differentially expressed in individuals with NCDs an effect that significantly increases with age.



[Random Forrest Analysis of Immune Parameters Predicting Region, Gender and Education in HIV+ individuals]

Anticoagulant therapies alleviate SIV-associated hypercoagulation as well as immune activation and inflammation

T. He[1,2], G. Haret-Richter[2], B. Andrade[3], C. Xu[2], B. Policicchio[2], P. Sette[2], K. Raehtz[2,4], E. Falwell[2], T. Dunsmore[2], K. Martin[2], G. Padovani[2], I. Francischetti[5], C. Apetrei[2,4], I. Sereti[6], I. Pandrea[1,2]
[1]University of Pittsburgh School of Medicine, Pathology, PITTSBURGH, United States, [2]University of Pittsburgh, Center for Vaccine Research, Pittsburgh, United States, [3]Instituto Brasileiro para a Investigação da Tuberculose, Multinational Organization Network Sponsoring Translational and Epidemiological Research (MONSTER) Initiative, Salvador, Brazil, [4]University of Pittsburgh School of Medicine, Department of Microbiology and Molecular Genetics, Pittsburgh, United States, [5]National Institute of Allergy and Infectious Diseases, Laboratory of Malaria and Vector Research, Bethesda, United States, [6]National Institute of Allergy and Infectious Diseases, HIV Pathogenesis Section, Laboratory of Immunoregulation, Bethesda, United States

Background: Cardiovascular disease remains one of the leading non-AIDS causes of death among chronically HIV-infected subjects, fueled by a hypercoagulable state along with persistent immune activation and inflammation (IA/INFL). Tissue factor (TF) and its downstream thrombin

production may bridge IA/INFL and hypercoagulation via protease-activated receptor (PAR) signaling. We hypothesize that anticoagulant therapies targeting these coagulation pathways can break the vicious cycle of hypercoagulation and IA/INFL and reduce the risk of cardiovascular comorbidity in HIV infection.
Methods: We experimentally administered a thrombin inhibitor (Dabigatran) and a PAR-1 inhibitor (Vorapaxar) in five SIV-infected pigtail macaques (PTMs) each, and compared with a TF inhibitor (Ixolaris) treatment in PTMs reported before. Five untreated SIV-infected PTMs were used as controls. Treatments were initiated at the time of infection for at least 80 days. Coagulation markers (D-dimer, sTF), endothelial and platelet activation markers (sICAM-1, sP-selectin), as well as immune activation (CD38/HLA-DR, Ki-67, CD80, CD86) and inflammation markers [C reactive protein (CRP), proinflammatory and anti-inflammatory cytokines] were measured throughout and after treatment.
Results: All three anticoagulant therapies resulted in a different extent of reduction in hypercoagulation, marked by lower levels of D-dimer, sTF, sICAM-1 and sP-selectin compared with controls after SIV infection. Treated PTMs also showed lower CRP, lower proinflammatory cytokines and chemokines (IL-1, IL-17, Eotaxin, MIP-1, VEGF) and higher protective cytokine IL-12.
Meanwhile, treated PTMs had lower activated monocytes marked by CD80 and CD86. Among the anticoagulant therapies, Ixolaris had the best effect in reducing D-dimer levels and IA/INFL markers. Additionally, besides reduced monocyte activation, Ixolaris also lowered T cell activation ($CD38^+$ HLA-DR^+ coexpression). Ixolaris-treated PTMs also had a better survival, with no progression to AIDS within 100 days post infection.
Conclusions: Our results reinforced the close causative relationship between hypercoagulation and IA/INFL in SIV pathogenesis. Anticoagulant therapies may thus represent effective strategies not only for reducing hypercoagulation but also to alleviate IA/INFL. Targeting TF directly, exerted a better effect compared with anticoagulant therapies targeting downstream players of the coagulation pathway, indicating that interventions prior to the establishment of coagulation-inflammation vicious cycle may be more successful. Future studies to the effect of anticoagulants in viral-suppressed setting are warranted.

Validation of Alere ™ q HIV-1/2 detect for detection of acute HIV infection at Anonymous Clinic, The Thai Red Cross AIDS Research Centre

I. Srila-Or[1], T. Pankam[1], S. Pattanachaiwit[1], S. Barisri[1], P. Raprasert[1], J. Jantarapakde[1], S. Areeyowattana[1], S. Sirivichayakul[2], P. Phiayura[1], R. Ramautarsing[1], N. Phanuphak[1,3], P. Phanuphak[1,2]
[1]The Thai Red Cross AIDS Research Centre, Laboratory, Bangkok, Thailand, [2]Chulalongkorn University, Faculty of Medicine, Bangkok, Thailand, [3]SEARCH, Bangkok, Thailand

Background: Diagnosis of acute HIV (AHI) is important to facilitate early linkage to treatment, to reduce onward HIV transmission and to reduce the risk of developing drug resistance in people taking pre-exposure prophylaxis (PrEP). Qualitative detection of HIV type-1 and type-2 by nucleic acid amplification test (NAAT) for the diagnosis of AHI is labor intensive and is limited to facility-based testing. The Alere™q HIV-1/2 Detect (Alere™q) is a point-of-care, qualitative, cartridge-based NAAT which allows its use in community-based settings. We assessed the performance of Alere™q in AHI detection.
Methods: Ten HIV-uninfected and 90 AHI (30 4th generation immunoassay (G)+/3rdG+/2ndG-, 30 4thG+/3rdG-/2ndG-, and 30 4thG-/NAAT+) stored plasma samples (at -80°C for up to 5 years prior to use) were selected. All samples were tested by Alere™q. Sensitivity, specificity, NPV, and PPV were calculated. NAAT was performed using APTIMA HIV-1 Qualitative Assay. Quantitative HIV-RNA (Roche Molecular Systems, Inc., Mannheim, Germany) measured from all 90 AHI samples on the day of diagnosis were retrieved from database.

Results: Alere™q was detectable in 80/90 (88.9%) AHI samples: 29/30 (96.7%) 4thG+/3rdG+/2ndG-, 30/30 (100%) 4thG+/3rdG-/2ndG-, and 21/30 (70%) 4thG-/NAAT+ samples. Sensitivity, specificity, PPV, and NPV for AHI detection were 88.9%, 100%, 100% and 50%, respectively. Median (IQR) HIV RNA level of 10 AHI samples with undetectable Alere™q was 282 (29-40,311 copies/ml) which mainly (9/10) had HIV-RNA < $\log_{10}$ 3.40 and the other one had HIV RNA 40,311 copies/mL ($\log_{10}$ 4.61). Median (IQR) HIV RNA of 80 AHI samples with detectable Alere™q was 630,276 (165-17,515,700 copies/ml which mainly (75/80) had HIV-RNA > $\log_{10}$ 3.40).
Conclusions: Alere™q demonstrated high specificity and PPV to detect AHI from stored samples. The low sensitivity was 88.9% in our study, although could not completely exclude potential HIV RNA degradation due to storage, could be a concern if Alere™q will be used to screen for AHI. Alere™q missed one AHI cases who had HIV RNA above 2,500 copies/mL ($\log_{10}$ 3.40). More data on the sensitivity of Alere™q on real-time samples from HIV testing or PrEP facilities is needed to inform its potential role in community-based testing.

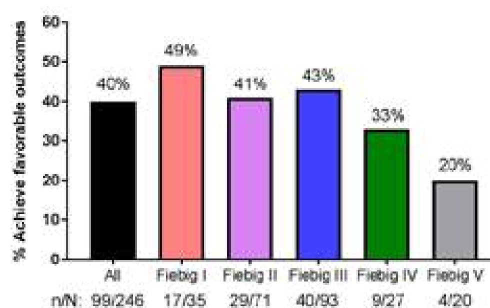
[1]The Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [2]United States Military HIV Research Program; Walter Reed Army Institute of Research, Silver Spring, United States, [3]Department of Global Health, University of Amsterdam, Amsterdam, Netherlands, [4]HIV-NAT, The Thai Red Cross AIDS Research Center, Bangkok, Thailand, [5]SEARCH, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [6]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Background: Antiretroviral therapy (ART) in acute HIV infection (AHI) improves immune recovery. Viral load (VL) suppression, CD4 T cell count (CD4) and CD4/CD8 ratio are clinical markers for HIV-associated morbidity and mortality. There are limited data on the proportion of treated AHI individuals who attain a favorable clinical phenotype (FCP).
Methods: Analysis included data from participants in the RV254/SEARCH 010 AHI cohort in Thailand who were enrolled between 04/2009 to 06/2017 and were ART naïve at enrollment and on ART for ≥ 24 weeks. FCP was defined as fulfilling all 3 criteria:
1) VL < 20 copies/ml at all visits from week 24 onwards,
2) Last CD4 > 500 cells/mm³,
3) Last CD4/CD8 ratio > 1.
CD4, CD8 and VL were performed every 3 months. Mann-Whitney U and Fisher's exact tests were used to compare continuous and binary outcomes, respectively, between groups. Logistic regression determined factors associated with favorable outcomes.
Results: 246 AHI participants in Fiebig stages I to V were included of whom 96% were male. Baseline median (IQR) values were age of 27 (23-32) years, CD4 of 376 (267-505) cells/mm³, CD4/CD8 ratio of 0.8 (0.4-1.1), and VL of 5.8 (5.3-6.8) $\log_{10}$ copies/mL. The majority (99%) initiated efavirenz-based regimens. The median (IQR) ART duration was 3.2 (2.6-4.4) years. FCP was achieved in 40% with differences between Fiebig I and Fiebig V (p=0.046) (Figure).



[Proportions with favorable clinical phenotype after treatment]

Proportions achieving each outcome were 76% for VL suppression, 81% for CD4 > 500 cells/mm³and 59% for CD4/CD8 ratio > 1. FCP was associated with pre-ART CD4 (OR 1.27, 95% CI 1.11-1.46, p=0.001) and CD4/CD8 ratio (OR 4.31, 95% CI 2.42-7.67, p< 0.001) but not VL, age or sex. In comparison, FCP was less likely in a chronic HIV Thai cohort (25%, p =0.002) of 271 males who were older (31 years [25-37]) but had longer duration of ART (5.3 years [4.0-6.3]).
Conclusions: Despite initiating ART as early as Fiebig I/II AHI, less than half achieved favorable clinical markers of persistent viral suppression, normalized CD4 and CD4/CD8 ratio. Understanding the pathogenesis that distinguishes these clinical phenotypes may be important in improving therapy and developing remission strategies.

Increasing contribution of integrated forms to total HIV1-DNA in blood, in primary infection during natural history - ANRS PRIMO and SEROCO cohorts

P. Tremeaux[1], T. Lenfant[1], F. Boufassa[2], A. Essat[3], A. Melard[4], M. Gousset[4], O. Delelis[5], J.-P. Viard[1], M. Bary[6], C. Goujard[7], C. Rouzioux[4], L. Meyer[8], V. Avettand-Fenoel[4,9], SEROCO and PRIMO ANRS Cohorts
[1]Paris Descartes University, Paris, France, [2]Université Paris Sud, Bicetre, France, [3]Inserm CESP U1018, Bicetre, France, [4]Université Paris Descartes, Paris, France, [5]Centre National de la Recherche Scientifique UMR8113, Cachan, France, [6]AP-HP, Hôpital Bicêtre, Kremlin Bicetre, France, [7]AP-HP, Hôpital Bicêtre, Bicetre, France, [8]INSERM CESP U1018, Bicetre, France, [9]Necker Hospital, APHP, Paris, France

Background: HIV1-DNA persistence in infected cells is the main hurdle preventing eradication. Markers estimating HIV reservoir size have been mostly studied in treated patients but less in natural history. Total cell-associated HIV-DNA includes integrated forms and more labile unintegrated forms, while integrated HIV-DNA represents the most stable and productive form in infected cells. This study aimed to describe the blood dynamics over years of total HIV-DNA and integrated HIV-DNA during primary infection (PHI) and in recent to chronic infections and to AIDS, in untreated patients.
Methods: Both markers were quantified from frozen PBMC of 74 PHI patients from the ANRS-PRIMO cohort and 97 recent seroconverters (< 12 months since contamination) from the ANRS-SEROCO cohort for whom at least two cell samples were available. Total HIV-DNA and integrated HIV-DNA evolutions were modeled (mixed-effect linear models) and their predictive values were studied (Cox models).
Results: High levels of total HIV-DNA (median 3.59 $\log_{10}$ copies/10^6 PBMCs [IQR: 3.29-4.03]) were observed at PHI with low levels of integrated forms among total HIV-DNA for most patients (2.15 $\log_{10}$ copies/10^6 PBMCs [IQR: 0.95-3.16]), suggesting a major proportion of unintegrated forms in PHI. Among recent seroconverters, those who progressed towards AIDS during the study (Rapid Progressors, n=34) had higher total HIV-DNA and integrated HIV-DNA levels at inclusion compared to others (Progressors, n=63), and higher integrated/total HIV-DNA ratio (100% *vs* 44%, respectively). In multivariate analysis, integrated HIV-DNA load was strongly associated with the risk of developing AIDS (aRR=2.6, p=0.002). A total of 340 sequential samples were available. Parallel rates of increase were observed for both markers over six years follow up in Rapid Progressors and Progressors, with the highest levels observed in patients with AIDS (ratio at 100%).
Conclusions: The low contribution of integrated forms at PHI indicates that the stable reservoir is not completely established. These results may partly explain the high benefice of early treatment on total HIV-DNA, preventing its progressive increase and controlling formation of unintegrated HIV-DNA. The risk of "rapid" or "slow" progression seemed to be determined early in the course of infection, enhancing the crucial need for early diagnosis and treatment implementation.

WEPDB0104

Intermittent viremia after treatment interruption increased risk of ART resumption in post-treatment HIV-1 controllers. ANRS VISCONTI study

L. Hocqueloux[1], V. Monceaux[2], V. Avettand-Fènoël[3,4], S. Orr[5], F. Boufassa[5], O. Lambotte[6], T. Prazuck[1], P. Miailhes[7], D. Salmon[8], C. Lascoux-Combes[9], A. Lafeuillade[10], L. Meyer[5], M. Müller-Trutwin[2], C. Rouzioux[3,4], A. Saez-Cirion[2], ANRS VISCONTI Study
[1]CHR d'Orléans - La Source, Infectious and Tropical Diseases, Orléans, France, [2]Institut Pasteur, HIV Inflammation and Persistance, Paris, France, [3]CHU Necker - Enfants Malades, APHP, Virology, Paris, France, [4]Université Paris Descartes, Paris, France, [5]INSERM CESP U 1018, University Paris Sud, APHP Bicetre Hospital, Le Kremlin-Bicetre, France, [6]ImVA UMR 1184, Le Kremlin-Bicetre, France, [7]CHU de la Croix-Rousse, Service des Maladies Infectieuses, Lyon, France, [8]CHU Cochin, APHP, Service des Maladies Infectieuses, Paris, France, [9]CHU Saint-Louis, APHP, Service des Maladies Infectieuses, Paris, France, [10]Hôpital Général, Service des Maladies Infectieuses, Toulon, France

Background: Some HIV-1-infected individuals achieve durable virological remission after discontinuation of antiretroviral therapy (ART). Because remission is a major objective in the global strategy towards an HIV cure, a better characterization of this phenomenon is necessary. We report here the long-term outcome of 23 post-treatment controllers (PTC) since their enrollment in a French study.
Methods: PTC were defined as HIV-1-infected individuals who achieved viral suppression (plasma viral load [pVL] < 400 copies/ml) for at least 12 months after treatment interruption. These cases have been prospectively followed in the ANRS VISCONTI study since 2008. Intermittent viremia was defined after treatment interruption as a transient pVL >400 copies/ml, and virologic failure (VF) as 2 consecutive pVL >400 copies/ml. Inflammation markers (IL-18, sCD14, CRP, IP-10, I-FABP and sCD163) were analyzed in plasma from 11 PTC at enrollment in the VISCONTI study.
Results: Twenty-three PTC (one case of mother-to-child transmission) were included, all of whom had started ART at the time of primary-infection (PHI). Main characteristics (median or %) at PHI were: age = 34 years, sex male = 65%, Caucasian = 70%, MSM = 48%, symptomatic PHI = 87%, pVL = 5.2 log copies/ml. ART was stopped after a median 3.7 years. Thereafter, PTC were followed-up for a median 11.9 years (until last visit or ART resumption). Overall, CD4 count and CD4/CD8 ratio were stable over time. Median total HIV-DNA was 1.85 log copies/10^6 PBMC at enrollment. Intermittent viremia was noted in 7 PTC (30%). Five patients (22%) resumed ART after a median 8.6 years off-ART: four because of VF, one for a non-AIDS defining cancer. Patients who had intermittent viremia were more likely to resume ART than those without: 5/7 versus 0/16, respectively (p=0.0006). PTC without intermittent viremia presented low levels of inflammation when compared to HIV controllers or HIV-infected individuals on ART (p< 0.05 for IL-18, sCD163 and sCD14).
Conclusions: Among PTC, one third presented an intermittent viremia after treatment interruption and were at increased risk of ART resumption. By contrast, the other PTC who had tighter control of viral replication maintained their status during follow up and had close to normal inflammation levels.

WEPDB0105

Auranofin plus nicotinamide impact HIV reservoir among ART suppressed HIV individuals

L.B. Giron[1,2], J. Hunter[2], J. Galinskas[2], D. Dias[2], P.R.A. Ferreira[2], S. Tenore[2], G. Gosuen[2], S. Samer[2,3], M.S. Arif[2,4], E.D. Libera[2], A. Savarino[5], L.M.R. Janini[2], M.C.A. Sucupira[2], R.S. Diaz[2]
[1]The Wistar Institute, Philadelphia, United States, [2]Federal University of Sao Paulo, Sao Paulo, Brazil, [3]Emory University, Atlanta, United States, [4]North Western University, Chicago, United States, [5]Istituto Superiore di Sanità, Rome, Italy

Background: Multiple interventional strategies may be fundamental to decrease the size of HIV-1 reservoir along with antiretroviral therapy (ART). To measure the impact of isolated and combined strategies in decreasing total HIV-1 DNA, we investigated the effect of treatment in-

tensification with Dolutegravir (DTG) with and without Maraviroc (MVC), Nicotinamide (NA), and Auranofin. NA is a class III HDAC inhibitor with anti-lymphoproliferative effect, and Auranofin induced decay in viral DNA of ART treated SIVmac251-infected macaques.
Methods: Data from six arms of NCT02961829 with 5 patients each followed every 4 weeks for a total of 48 weeks were analyzed. Selected patients were ART suppressed for >2 years, with CD4 nadir >350. Groups were: 1) continuation of ART, 2) intensified ART (ART+DTG and MVC), 3) intensified ART and HDACi (ART+DTG+MVC+NA), 4) intensified ART and Auranofin (ART+DTG+MVC+Auranofin), 5) partially intensified ART (ART+DTG), 6) partially intensified ART (DTG)+NA+Auranofin. Auranofin was used for the first 24 weeks of the study in G4 and G6. After week 48, Total viral DNA was measured by qPCR in PBMCs and rectal biopsy tissues, this latter performed at baseline.
Results: Treatment intervention was well tolerated, and main adverse events (AE) were anxiety and sleep disorders, attributable to efavirenz/dolutegravir interaction. There were transient non-statistic significant decreases in CD4 counts at weeks 8 and 12 from baseline in auranofin groups, (week 8: -119.3 ±194.7; week 12: -187 ±210.7 cells/mL). A decrease in viral DNA was observed in G6 as compared to all other groups. (p= 0.022; Odds ratio: 9.75, 95%CL: 1.1-72.39). Intensified ART with DTG+MVC presented higher decrease in the total DNA as compared to intensified ART with DTG only (G2 vs G5, p=0014). All individuals presented undetectable viral loads throughout the study, but G1 showed a significant linear trend towards an increase of the viral reservoir (p< 0.05). There was no correlation between proviral DNA from PBMCs and rectal biopsy tissues at baseline.
Conclusions: The interim analysis of this phase II trial suggests that NA+auranofin administration in combination with intensified ART is well tolerated, and an impact on the proviral reservoir size is possible.

TB/HIV co-treatment with super-boosted lopinavir and anti-tuberculosis treatment lowers abacavir concentration in children

H. Rabie[1], T. Tikiso[2], H. McIlleron[2], J. Lee[3], I. Andrieux-Meyer[3], M. Cotton[1], M. Lallemant[3], P. Denti[2]
[1]University of Stellenbosch,Tygerberg Hospital and Family Clinical Research Unit, Department of Pediatrics and Child Health, Cape Town, South Africa, [2]University of Cape Town, Division of Clinical Pharmacology, Cape Town, South Africa, [3]Drugs for Neglected Diseases Initiative (DNDi), Geneva, Switzerland

Background: The available data describing the pharmacokinetics and efficacy of abacavir given with super-boosted lopinavir (LPV/r plus additional ritonavir), rifampicin, and other anti-TB drugs is limited. Our objective was to compare pharmacokinetics of abacavir during treatment with standard doses of LPV/r vs. anti-TB treatment and super-boosted lopinavir.
Methods: 87 TB/HIV-infected South African children (median, range age: 2.8, 0.25-6 years; weight: 9.4, 4-16 kg) were sampled on 3 separate visits: after at least 2 weeks on TB treatment and super-boosted lopinavir during the intensive phase and end of TB treatment; and one month after TB treatment completion on standard doses of LPV/r dose without additional ritonavir. Abacavir twice-daily was co-administered throughout. All drugs were dosed according to the South African weight-band dosing recommendations. At each visit, blood samples were collected immediately before dosing and 1, 2, 4, 6, 8, and 10 hours after. NONMEM 7.3 was used to develop a population pharmacokinetic model.
Results: Abacavir pharmacokinetics was best described by a two-compartment model with first-order elimination and transit compartment absorption. Allometric scaling was used to adjust for the effect of body size, after which maturation could be identified: clearance was predicted to reach half its mature value at around 2 months after birth and to be fully mature by around 2 years of age. The typical clearance in a 9 kg child co-treated with normal dose LPV/r is estimated at 8.8 L/h. During co-administration of TB treatment with lopinavir super-boosting, a 38% decrease in bioavailability (and AUC) was found. Finally, the trough concentrations observed just before the morning dose were higher than the extrapolated values predicted 12 h after a morning dose, best explained by a 24% reduction in clearance overnight.
Conclusions: The proposed model successfully characterised the PK of abacavir, including the effect of body weight and age. Abacavir exposure was decreased by concomitant administration of rifampicin and super-boosted lopinavir. Larger trough concentrations were observed in the morning, possibly indicating circadian variation in the pharmacokinetics. Although 67 (82%) children were virologically suppressed at the end of TB treatment compared to 6 (6%) at study entry, further investigation should address whether dosing adjustments are necessary.

Chan School of Public Health, Global Health and Population, Boston, United States, [7]Muhimbili University of Health and Allied Sciences, Internal Medicine, Dar es Salaam, Tanzania, United Republic of, [8]University of Heidelberg, Clinical Pharmacology and Pharmacoepidemiology, Heidelberg, Germany, [9]Karolinska Institutet, Division of Clinical Pharmacology, Department of Laboratory Medicine, Stockholm, Sweden

Background: Efavirenz (EFV) containing antiretroviral therapy (ART) is the regimen of choice for tuberculosis (TB)-HIV co-infected patients on anti-TB therapy. Efavirenz is primarily metabolised via hepatic cytochrome P450 and has considerable interpatient variability. We investigated the role of ethnicity and pharmacogenetic variations in EFV plasma exposure.
Methods: We conducted a multi-centred prospective cohort study of TB-HIV co-infected adults with a CD4 count of < 200cells/mL in Ethiopia and Tanzania. Patients were initiated on rifampicin-based anti-TB therapy, and 4 weeks later EFV-based ART was also initiated and there patients were followed for 1 year. Efavirenz plasma concentrations were measured at 4 and 16 weeks post ART initiation. Genotyping for functional *CYP2B6, CYP3A5, ABCB1, UGT2B7* and *SLCO1B1* variant alleles was conducted.
Results: A total of 427 TB-HIV co-infected patients were included in the analysis (231 Tanzanians and 196 Ethiopians). In the sample 44% of the patients had smear positive TB and 54% of patients had a CD4 count of < 100cells/mL. Genotypic distribution of *CYP2B6* was similar between the two countries with 50% having the *CYP2B6*1/*1* genotype; however, there was a significantly larger proportion of *CYP3A5*0/*0* among the Ethiopians compared to Tanzanians (61% vs 28%).
In the sample 28% and 35% of patients had EFV levels < 1000ng/mL at weeks 4 and 16 respectively. In multivariate regression analysis, participants with *CYP2B6*1/*6* and **6*6* allele had 0.50 (95% CI:0.29-0.87) and 0.23 (95% CI:0.05-1.03) times the risk of EFV concentrations < 1000ng/mL at 4 or 16 weeks as compared to those with **1/*1* respectively. In addition, 44% of patients with both *CYP2B6*1/*1* and *CYP3A5*0/*0* had EFV < 1000ng/mL which is a 2.2 higher risk compared to those who did not have both alleles.
Conclusions: *CYP2B6* and *CYP3A5* appear to be the primary determinants of plasma EFV concentrations among TB-HIV patients. After adjustment for these alleles there was no difference in EFV concentration by country, suggesting other genetic differences may not significantly

contribute to EFV metabolism. Individual-level genotyping of *CYP* alleles is cost prohibitive in most treatment programs in Africa; however, provider knowledge of the population distribution of *CYP* alleles can help guide TB-HIV treatment in low-resourced African settings.

WEPDB0203

A randomized, open-label, balanced, two-treatment, single-dose, crossover oral bioequivalence study of Lopinavir/Ritonavir Granules 40mg/10mg with KALETRA® (Lopinavir/Ritonavir) Oral Solution 80 mg/20mg per mL in normal healthy adults under fed conditions

D. Abhijit[1], C. Santanu[1], D. Akhilesh[1], K. Umakant[1], R. Bangaru[2], A.K. Datla[2], P. Deshpande[3], A. Kanda[3], E. Patras[3]

[1]*Mylan Laboratories Limited, R&D, Hyderabad, India,* [2]*Mylan Laboratories Limited, Clinical Research Center, Hyderabad, India,* [3]*Mylan Laboratiories Limited, Business Development, Hyderabad, India*

Background: The development of pediatric fixed-dose combinations (FDCs) for all lines of therapy has become a priority to simplify dosing, increase adherence and thus improve pediatric care. The use of LPV/r oral solution is limited by taste aversion and requires special storage conditions -refrigeration. Alternative palatable oral solid formulations as granules/pellets for small children are wanted. The objective of this study was to evaluate the relative oral bioavailability and safety profiles of Lopinavir/Ritonavir Granules 40 mg/10mg (2 Sachets with 40/10mg, Mylan Laboratories Limited, India) with KALETRA® (Lopinavir/Ritonavir, AbbVie Inc.) Oral Solution 80mg/20mg/mL.

Methods: In this open label, 1:1 randomized, two-period, two-treatment, cross-over, single dose evaluation, the relative oral bioequivalence was tested in 68 healthy adult subjects under fed conditions. In each study period, a single oral dose of either test product (T) or reference product (R) was administered orally under fed conditions. Subjects were monitored for safety and tolerability until completion of the study. Serial blood samples from pre-dose 0.00 hour up to post-dose 36.00 hours were collected in each period.

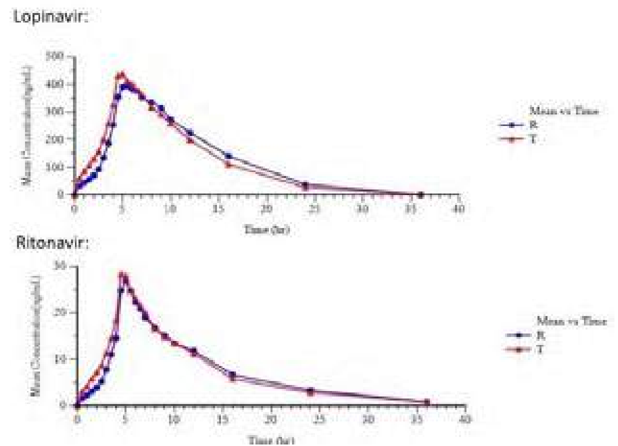
Geometric least squares mean, ratio of test product (T) and reference product (R), (T /R) , 90% confidence intervals, Intra Subject Variability (CV in %) and power (in %) for the Intransformed pharmacokinetic parameters Cmax, AUC0-t and AUC0-inf for Lopinavir and Ritonavir

Parameters (units)	Geometric Least Squares Means Test product (T)	N	Geometric Least Squares Means Reference product (R)	N	T vs. R (90% CI)	T/R (%)	Intra Subject CV %	Power (%)
	Lopinavir							
Cmax (ng/mL)	389.809	68	369.967	68	94.15-117.91	105.36	40.9	94.7
AUC0-t (ng. hr/mL)	3144.695	68	2955.001	68	94.48-119.86	106.42	43.4	92.6
AUC0-inf (ng. hr/mL)	3215.917	67	3076.989	63	92.58-117.99	104.52	43.2	91.7
	Ritonavir							
Cmax (ng/mL)	27.859	68	25.242	68	100.91-120.72	110.37	32.1	99.2
AUC0-t (ng. hr/mL)	219.562	68	201.972	68	98.53-119.94	108.71	35.4	98.1
AUC0-inf (ng. hr/mL)	226.160	68	208.668	68	98.36-119.42	108.38	34.9	98.3

[Table 1: Mean and SD of pharmacokinetic parameters estimated for test product and reference product]

Drug concentrations in plasma were quantified by using a validated method for test product (T) and reference product (R). Pharmacokinetic parameters (Cmax, AUC0-t, AUC0-inf, Tmax, Kel, t½ and AUC_%Extrap_obs) were computed using the non-compartmental model of Phoenix® WinNonlin® software version 6.3 (Pharsight Corporation, USA) for T and R. Statistical comparison of the pharmacokinetic parameters of both formulations were carried out by using PROC GLM from SAS® statistical software version 9.2 to assess the bioequivalence of T and R.

Results: The 90% confidence interval for the ratio of the test and reference product averages pharmacokinetic parameters Cmax, AUC0-t and AUC0-inf were between 80% and 125% for the ln-transformed data with respect to Lopinavir and Ritonavir.



[Linear plots of mean plasma concentration versus time curves of Lopinavir - Ritonavir after administration of test product (T) and reference product (]

Both the test and reference products were well tolerated, when administered as single dose under fed conditions.

Conclusions: Under fed conditions, the test product Lopinavir/Ritonavir Granules 40 mg/10 mg of Mylan Laboratories Limited, India was bioequivalent to the Reference product KALETRA® (Lopinavir/Ritonavir) Oral Solution 80 mg/20mg/mL of AbbVie Inc., USA, with regard to rate and extent of absorption. This new pediatric FDC could provide an easy-to-use treatment for small children.

WEPDB0204

Single-dose fed bioequivalence study of Lamivudine, TenofovirDisoproxilFumarate and Dolutegravir tablets (300mg/300mg/50mg) versus EPIVIR® tablets (300mg; ViiV-Healthcare), VIREAD® tablets (300mg; Gilead Sciences) and TIVICAY® tablets (50mg; ViiV-Healthcare) in healthy adult volunteers

D. Abhijit[1], C. Santanu[1], R. Chetan[1], G. Sachin[1], R. Bangaru[2], A.K. Datla[2], P. Deshpande[3], A. Kanda[3], E. Patras[3]

[1]*Mylan Laboratories Limited, R&D, Hyderabad, India,* [2]*Mylan Laboratories Limited, Clinical Research Center, Hyderabad, India,* [3]*Mylan Laboratiories Limited, Business Development, Hyderabad, India*

Background: Dolutegravir (DTG) is one of the most frequently used recommended antiretrovirals for the treatment of HIV in high-income countries. WHO and several national guidelines recommend DTG/3TC/TDF as an alternative first- and third-line in low-and middle-income countries. The objective of this study was to compare the relative bioequivalence and safety profile of Mylan's lamivudine, tenofovirdisoproxilfumarate and dolutegravir tablets, 300 mg/300 mg/50 mg FDC tablets (T) with the reference combination (R) of EPIVIR® (300 mg), VIREAD® (300 mg) and TIVICAY® (50mg).

Methods: In this open label, randomized, two-period, two-treatment, cross-over, single dose evaluation, the relative oral bioequivalence was tested in 33 healthy adult human subjects under fed conditions. In each period, each subject received a single, oral dose of T (Mylan's 3TC/TDF/DTG tablets) or R. Serial blood samples were collected pre-dose and at 21 timepoints until 72 hours post dose. Subjects were monitored for safety and tolerability. Single-dose pharmacokinetic parameters for FTC/TAF/DTG were calculated using non-compartmental techniques.

Results: All statistical analyses of these data reveal that the 90% confidence intervals are within the acceptable bioequivalent range of 80.00% and 125.00% for the natural log transformed parameters LNAUCL, LNAUCINF, and LNCPEAK for lamivudine, tenofovir and dolutegravir. (Table 1).

Product	Parameter	Arithmetic Mean (%CV) T= Mylan	Arithmetic Mean (%CV) R = Reference	LSMEANS Ratio (T/R)	90% Confidence Interval
3TC	AUCL (ng•hr/mL)	11648 (18.64)	11911 (18.84)	0.98	96.41% - 100.29%
3TC	AUCINF (ng•hr/mL)	12062 (19.04)	12206 (18.26)	0.99	96.94% - 101.15%
3TC	CPEAK (ng/mL)	1960 (27.94)	2064 (24.37)	0.94	88.17% - 100.59%
TNF	AUCL (ng•hr/mL)	3124 (19.55)	3107 (19.45)	1.01	98.10% - 103.80%
TNF	AUCINF (ng•hr/mL)	3311 (19.74)	3269 (19.85)	1.01	98.69% - 104.32%
TNF	CPEAK (ng/mL)	318.7 (24.99)	278.9 (20.60)	1.11	104.08% - 119.12%
DTG	AUCL (ng•hr/mL)	71099 (24.79)	70780 (26.25)	1.00	95.64% - 104.78%
DTG	AUCINF (ng•hr/mL)	74636 (25.55)	73486 (26.72)	1.01	96.51% - 105.45%
DTG	CPEAK (ng/mL)	4025 (18.75	3840 (18.14)	1.03	99.05% - 107.71%

[Table 1: Pharmacokinetic Results 3TC, TNF and DTG]

The AEs were mild in severity. Overall both R and T were well tolerated administered as a single, oral dose under fed conditions.
Conclusions: This study demonstrates that Mylan's 3TC/TDF/DTG 300 mg/300 mg/50 mg tablets are bioequivalent to a combination of EPIVIR® (300 mg), VIREAD® (300 mg) and TIVICAY® (50 mg) as separate tablets following administration of a single, oral dose administered under fed conditions.

WEPDB0205

Population pharmacokinetics of cabotegravir in adult healthy subjects and HIV-1 infected patients following administration of oral tablet and long acting intramuscular injection

K. Han[1], P. Patel[2], M. Baker[3], D. Margolis[2], W. Spreen[2], S. Ford[4]
[1]ViiV Healthcare, Upper Merion, United States, [2]ViiV Healthcare, Research Triangle Park, United States, [3]ViiV Healthcare, Münchenbuchsee, Switzerland, [4]GlaxoSmithKline, Research Triangle Park, United States

Background: Cabotegravir is an integrase inhibitor currently in Phase 3 development as an oral tablet and an intramuscular long-acting injection (LAI_{IM}) for HIV treatment and prevention. The aim was to characterize cabotegravir population pharmacokinetics (PopPK) using data from Phase 1 and 2 studies, evaluate the association of intrinsic and extrinsic factors with the variability of cabotegravir PopPK, and perform simulations to inform dosing strategies.
Methods: All analyses were implemented in NONMEM 7.3 and R. Covariate relationships were evaluated using a forward addition (p< 0.01) and backward elimination (p< 0.001) approach. Model adequacy and predictive performance was assessed using bootstrapping and visual predictive check. Clinical relevance of covariates was assessed using tornado plots. Simulations were performed using parameter estimates from the final model.
Results: A total of 12,294 cabotegravir plasma concentrations were collected from 881 healthy (44%) and HIV infected (56%) adults in 11 studies at 9 dose levels (5mg to 60mg for oral tablet; 100mg to 800mg for LAI_{IM}). LAI_{IM} was administered in 64% of the subjects. A two-compartment model with first-order oral and intramuscular absorption and elimination including inter-occasion variability adequately described the data. Clearances and volumes were scaled to body size. Relative bioavailability of the oral to LAI_{IM} formulation was >70%. Residual variability was higher following LAI_{IM} administration. Race and age were not significant covariates. LAI_{IM} absorption rate constant was lower in females, in subjects with higher BMI and if the LAI_{IM} dose was given as one single injection instead of two "split" injections. However, gender, BMI or split dose alone was associated with less than 15% of change in exposure at steady-state following oral or LAI_{IM} administration. Simulations supported dosing strategies for ongoing Phase 3 studies.
Conclusions: A robust PopPK model for cabotegravir was developed and used for simulations to support dosing recommendations for HIV treatment. Gender, BMI, and split LAI_{IM} dosing were statistically significant covariates on cabotegravir LAI_{IM} absorption, but the magnitude of their impact on cabotegravir exposures was not clinically relevant. No dose adjustment of cabotegravir is recommended based on gender, BMI or body size, split LAI_{IM} dosing, race, or adult age group.

Implementation and impact of a technology-based HIV risk-reduction intervention among Thai men who have sex with men using 'Vialogues': A randomized controlled trial

T. Anand[1], C. Nitpolprasert[1], J. Jantarapakde[2], R. Meksena[2], S. Phomthong[2], P. Phoseeta[2], P. Phanuphak[2], N. Phanuphak[2]
[1]Adam's Love, Bangkok, Thailand, [2]PREVENTION, The Thai Red Cross AIDS Research Centre, Bangkok, Thailand

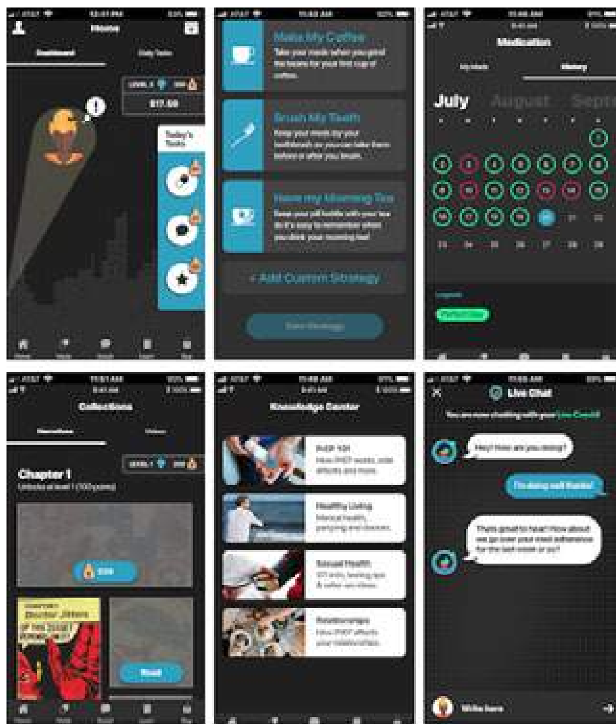
Background: To conduct a randomized control trial to evaluate the impact of a novel technology-based intervention on HIV/AIDS knowledge, self-perceived risk, condom use attitudes, self-efficacy intentions, sexual risks and condom use behaviors among Thai MSM.
Methods: The technology-based HIV risk reduction intervention was piloted by Adam's Love (www.adamslove.org). Participants aged 18 years or above, and having engaged in unprotected sex in the past six months were enrolled and randomly assigned to control or intervention arm, and received private clinic-based HIV counseling and testing at baseline, month 6 and month 12. Intervention arm participants engaged in 12 monthly HIV/STI prevention and educational sessions delivered via Vialogues.com (using online time-based videos followed by time-stamped discussions around the video content with a health educator, focusing on applying knowledge and skills learned during the session in setting long-term goals to reduce sexual risks). The differences in behavioral outcomes between the arms over the 12-month period were assessed.
Results: Of 76 MSM enrolled, 37 were randomized to intervention and 39 to control arm. Median age was 28 (IQR 24-32) years. Of 37 intervention arm participants, 33 (89.2%) completed all 12 monthly Vialogues sessions. Mean session duration was 37.45 minutes. Retention rates at month 12 among intervention and control arms were 97.3% and 79.5%, respectively. At month 12, median percentage of condom use for anal intercourse was higher in the intervention versus control arm (100% vs. 93.3%, p=0.023). Over the 12-month period, intervention arm reported significant reduction in self-perceived risk for HIV (3.08 on 5-point LIKERT scale to 2.6, p=0.001), popper usage (29.7% to 13.9%, p=0.002), seeking sex online (59.5% to 44.4%, p=0.01), median number of sexual partners in the past three months (2 to 1, p=0.003), and increased median percentage of condom use (88.9% to 100%, p=0.006). Process measures yielded high participant satisfaction of Vialogues (mean 4.67 on a 5-point scale, SD 0.48).
Conclusions: Our study provides clear evidence that 'Vialogues' intervention significantly reduced number of sexual partners and increased condom use rates among MSM. HIV program implementers are encouraged to harness the potential of free, online learning technologies used in this study.

WEPDC0103

P3 (Prepared, Protected, emPowered): Feasibility and acceptability of a PrEP adherence app featuring peer-to-peer sharing, game-based elements and in-app adherence counseling

S. Legrand[1], K. Knudtson[2], K. Muessig[3], M. Dixon[4], A. Mcgee[2], J. Dormitzer[5], R. Jackson[6], E. Adam[7], L. Hightow-Weidman[2]
[1]Duke University, Duke Global Health Institute, Durham, United States, [2]University of North Carolina-Chapel Hill, Medicine/Infectious Diseases, Chapel Hill, United States, [3]University of North Carolina-Chapel Hill, Health Behavior, Chapel Hill, United States, [4]Ayogo, Vancouver, Canada, [5]Fenway Health, Boston, United States, [6]Cook County Hospital, Chicago, United States, [7]Emory University, Atlanta, United States

Background: To date, efficacious interventions to promote and sustain pre-exposure prophylaxis (PrEP) adherence among youth are limited. Smartphone apps provide a platform to address adherence barriers by delivering tailored strategies and culturally-relevant content in an engaging format. App-based interventions that also allow for intensified interactions through direct communication with adherence counselors may improve outcomes among nonresponsive youth.
We describe the development and initial testing of a PrEP adherence app for young men who have sex with men (YMSM) and young transgender women who have sex with men (YTWSM) that includes provision of adherence counseling delivered within the app through a provider texting interface.
Methods: P3 (Prepared, Protected, emPowered) is an app built upon an established theory-based, health platform, optimized through our teams' prior work with HIV+ YMSM and with youth advisory board (YAB) members at 7 Adolescent Trials Network for HIV Interventions (ATN) sites. P3 includes interactive components to encourage peer-to-peer sharing and the development of daily medication self-monitoring behaviors. Game-based elements, including virtual and real-world rewards, based on established behavioral economics principles, incentivize engagement. Strengths-based adherence counseling delivered by a centrally-located adherence counselor via two-way text messaging through the app addresses individuals' unique barriers to PrEP adherence.
Results: Usability testing was conducted with 12 YMSM/YTWSM (mean age 20.9, 10 male), either PrEP experienced or considering, at 2 ATN sites using a clickable app prototype (screenshots presented in Figure 1).



[Figure 1. Screen Shots of the P3 app]

Most (92%) found the app highly acceptable, particularly the tailored medication reminders, the daily medication tracking with corresponding medication history calendar, and the accessibility, comprehensiveness and tone of the information provided. Youth were enthusiastic about connecting directly with an adherence counselor and provided concrete recommendations for rapport building, session duration and explicitly defining the counselors' role.
Conclusions: P3 represents, to our knowledge, the first theoretically-based PrEP adherence app for YMSM/YTWSM that includes features to increase intervention engagement (e.g. gamification, financial incentives, social connectivity) and provides in-app adherence counseling. Interventions that capitalize on technology-based platforms have great potential to encourage health promotion behaviors. A technical pilot of P3 will be conducted in Summer 2018 followed by an efficacy trial if feasibility/acceptability is achieved.

WEPDC0104

Effectiveness of community-led sex-positive campaign on HIV testing for young men who have sex with men (YMSM) in Metro Manila (MM), Philippines: TestMNL

L.-A.F.M. Lomarda[1,2], R.G. Pagtakhan[1], P.J. Tanpoco[1]
[1]LoveYourself Inc., Mandaluyong City, Philippines, [2]APCOM, Bangkok City, Thailand

Background: In a predominantly Catholic country like the Philippines, HIV prevention campaigns use stigma and fear to educate the public about HIV. There is an absence of sex-positive HIV prevention efforts in the Philippines that use internet and social media to engage YMSM. This campaign is an attempt to leverage on online platforms to drive sex-positive HIV prevention efforts while engaging YMSM. Due to the concentration of HIV infections in MM, this campaign is focused on young gay men (18-24 years old) who regularly seek out male sexual partners online.
Description: In 2015, TestBKK has been a successful campaign in Thailand to encourage YMSM to get tested for HIV. LoveYourself, a community-based LGBT organization, partnered with APCOM to test the effectiveness of this sex-positive HIV prevention model in the Philippines. After a series of focus group discussions, LoveYourself and APCOM adapted TestBKK's simple, clear, and easy-to-remember slogan to encourage YMSM to get tested for HIV: "SUCK. F*#K. TEST. REPEAT". The campaign is promoted in campaign websites, social media, gay networking apps, and offline events.
The campaign reached 46,910 individuals to learn about HIV testing in MM via www.TestMNL.org; 18,369 individuals were tested for HIV (38.25% are YMSM); and 1,343 turned positive (7.31%). On social media, TestMNL created 79,934+ views on campaign videos on Facebook and YouTube, 7,642 Facebook likes, and 3,155 Twitter followers.
Lessons learned: Partner clinics of TestMNL reported an average increase in HIV testing of 62.05% compared to previous months the year before. Meetings with community groups, clinical partners, private partners and YMSM also reported the effectiveness of the campaign in their engagements on the importance of sexual health promotion, creating a shift to a more sex-positive environment in the gay community in MM. Formative assessment is essential to determine the type, tone, theme, and approach of campaign that will work.
Conclusions/Next steps: The campaign concludes the need for more community-led sex-positive campaigns that will educate YMSM about their sexual health, and encourage them to get tested for HIV. Scale up of the program is needed to provide more opportunity to develop new campaign messages that address key barriers to HIV continuum of care.

WEPDC0105

Internet-based self-testing model - "Easy Test": A cross-sectional survey targeting MSM who never tested before in 14 provinces of China

X. Jin[1], D. Xiao[2], X. Xiu[1], Z. Ding[1], Y. Zhang[1], Y. Jie[1], Y. Liao[1], H. Wu[3], N. Cao[4], B. Shepherd[5], J. Vandenhombergh[5], Y. Bao[1]
[1]AIDS Healthcare Foundation (AHF), AHF China Office, Beijing, China, [2]Tongzhi Welfare, Beijing, China, [3]Beijing Youan Hospital, Beijing, China, [4]Hospital of Dermatology, Chinese Academy of Medical Sciences & Peking Union Medical College, Nanjing, China, [5]AIDS Healthcare Foundation (AHF), Los Angeles, United States

Background: HIV prevalence among men who have sex with men (MSM) increased rapidly from 2006 to 2016 in China. While about half of MSM have never been tested HIV, even though facility-based HIV testing sites had been greatly scaled up by public health services. With the country's explosive internet growth, MSM often socialize and search for casual sexual partners through online activity, cellular phone applications and social media. To reach an MSM community whose members rarely access traditional, offline testing facilities, innovative and convenient HIV testing models are urgently required.
Methods: An Internet-based Self-testing Model ('Easy Test') was developed by AIDS Healthcare Foundation (AHF) to provide free online applications with instructed testing from October to December 2017 in 14 Chinese Provinces. Clients were required to complete a questionnaire and pay a $5 deposit when applying for a blood-based HIV test. Upon uploading an image of the client's test result to the online applications, the deposit would be refunded. For clients with an HIV-positive result, a one-on-one accompanied referral was provided for further status confirmation and medical services.
Results: A total of 879 MSM applied a self-testing test kit and completed the questionnaire. Of the total tested, 78% (683/879) of clients provided feedback of their test results, of which 52% (352/683) had never before been tested for HIV. HIV prevalence was 14% (98/683) with 72% (71/98) of those found positive linked and enrolled in treatment. For all testers, the median age was 28 years (IQR, 24-34 years); Han ethnicity (92%); single (74%); college-educated and above (69%); monthly income between $450-$750 US dollars (51%). Of those never tested before, 37% (108/295) reported seldom or never using condoms during anal sex in the past three months. Reported condom use during most recent anal intercourse was 76% (266/352), and of those, 48% (128/266) failed to consistently use condoms during the entire process of anal intercourse.
Conclusions: The online 'Easy Test' model is an innovative, effective remedial measure for high-risk MSM who are reluctant to be HIV tested at stationary facilities. It effectively increases access to HIV treatment services for HIV-positive MSM in China.

WEPDC0106

From online reach to offline services: Using social media strategies to increase uptake of and access to HIV testing among MSM in Vietnam

T.T. Tran[1], K. Green[1], V.D. Nguyen[2], N.B. Vu[1], T.T. Nguyen[3], T.T. Doan[4], M.T. Le[5], M.T. Ngo[6]
[1]PATH, Ha Noi, Vietnam, [2]PATH, Ho Chi Minh City, Vietnam, [3]KOL, Ho Chi Minh City, Vietnam, [4]Lighthouse, Ha Noi, Vietnam, [5]G-Link, Ho Chi Minh City, Vietnam, [6]USAID, Ha Noi, Vietnam

Background: Rates of HIV are increasing among the estimated 330,000 men who have sex with men (MSM) in Vietnam. Face-to-face outreach only reaches a fraction of at-risk MSM. A 2015 USAID/PATH Healthy Markets (HM) study found that 98% of MSM surveyed across four provinces regularly used Facebook, and preferred social media as a source of HIV and health information. HM and MSM leaders co-created a fun, sex-positive HIV prevention and service awareness, trust, and uptake campaign—"My Future, My Choice"—that utilized a Facebook community (Rainbow Village), online influencers trained as HIV lay testers, and an HIV service booking application (I Reserve), to allow for a measurable online-to-offline HIV testing-treatment cascade.
Methods: Three techniques were applied to characterize the online-to-offline cascade in Ho Chi Minh City (HCMC) and Hanoi from 2016-2017 (18 months):
1) an online Facebook user survey;
2) a rapid survey assessing MSM self-reported motivation for HIV testing when they presented for an HIV test;
3) results from online peer influencers and I Reserve app, applying an HIV testing-treatment cascade analysis.
Results: By December 2017, Rainbow Village had over 232,000 members; 88% were aged 25 or over and 70% were HCMC/Hanoi residents. The Facebook user study (n=424) found 50% of respondents visited Rainbow Village at least once a week, 75% were not in contact with HIV outreach workers/peers, and 38% self-assessed at substantial HIV risk. The rapid survey on primary HIV testing motivators (n=3,989) found that 35% stated online content as the reason for testing, 8% of whom tested HIV-positive—compared to 5% of those motivated by face-to-face peer interactions/referrals. Among 2,454 people reached by online peer influencers or the I Reserve app, 73% tested, 11% of whom were HIV-diagnosed and enrolled in treatment (100%). This compares to an overall 6% HIV positivity yield among MSM seeking HIV lay or self-testing.
Conclusions: Online interventions effectively reach MSM who may never be contacted through conventional face-to-face peer outreach, and are more effective in reaching higher risk MSM. Online strategies should be further scaled and adapted alongside face-to-face interventions to reach more diverse segments of at-risk MSM.

WEPDC0107

Online supervised HIV self-testing identified high HIV yield among Thai men who have sex with men and transgender women

J. Jantarapakde[1], K. Himmad[1], T. Sungsing[1], S. Promthong[1], W. Waiwinya[1], P. Meekrua[2], S. Sukthongsa[2], S. Hongwiangchan[3], N. Upanun[4], D. Trachunthong[1], S. Barisi[1], S. Jirajariyavej[5], S. Charoenying[6], S. Mills[6], R. Vannakit[7], M. Cowing[8], S. Buchbinder[8], N. Phanuphak[1]
[1]The Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]Service Workers in Group Foundation, Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]Sisters Foundation, Chonburi, Thailand, [5]Taksin Hospital, Bangkok, Thailand, [6]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [7]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand, [8]The Foundation for AIDS Research (amfAR), New York, United States

Background: Online technology has high potential to enhance access to HIV counseling and testing among members of key populations whose HIV status is undiagnosed. We evaluated HIV-positive/reactive rates and confirmed successful linkage to antiretroviral treatment (ART) among MSM and TGW in an implementation research study ('Online Supervised HIV Self-Testing') in Thailand.
Methods: During December 2015-June 2017, MSM and TGW self-selected to enroll into 1 of 3 groups:
1) clinic-based HIV testing and counseling (Offline group);
2) online pre-test counseling and clinic-based HIV testing (Mixed group); and
3) online pre-test counseling and supervised HIV self-testing (Online group).
Linkage to ART was provided immediately after HIV-positive/reactive test results were known. Online retention and support were provided to the Mixed and Online groups only. Sociodemographic data, beliefs and experiences around stigma and discrimination related to HIV and/or being MSM or TGW, sexual and drug use behaviors, perceived barriers and facilitators for access to HIV testing were collected by self-administered questionnaires. Factors associated with unsuccessful linkage to ART were identified using binary logistic regression method.
Results: Of 564 participants (465 MSM and 99 TGW), 200 selected the Offline group, 156 selected the Mixed group, and 208 chose the Online group. Mean (±SD) age was 27.9 (7.2) years. Baseline HIV-positive/reactive result was higher in the Offline (13.0%) and Online (14.4%) groups, compared to the Mixed group (3.2%), p=0.001. Linkage to ART, however, was least successful in the Online group (52.8%), compared to the Offline (83.9%) and Mixed (75.0%) groups, p=0.02. Being in the Online

group (aOR=8.54, 95%CI 1.08-67.59, p=0.04), aged < 17 years at first sex (aOR=13.16, 95%CI 1.62-107.08, p=0.02), and having single partner (aOR 12.61, 95%CI 1.52-104.9, p=0.02) increased risk for unsuccessful linkage to ART. Stigma and discrimination experiences did not reduce the chance of successful ART linkage.
Conclusions: Offering online supervised HIV self-testing successfully engaged MSM and TGW with high HIV-reactive yield into HIV testing service. Linking clients tested HIV-reactive online to come out for offline HIV confirmation and ART initiation proved to be a real challenge. Innovative methods to support transition of these clients from online to offline services are urgently needed.

WEPDC02 Sex and drugs: Ongoing syndemics in the PrEP and treatment era

WEPDC0201

Syndemics predict bio-behavioral HIV sexual transmission risk (TRB) longitudinally in US HIV clinics

S. Satyanarayana[1], S.A. Safren[1], B.G. Rogers[1], S.A. Bainter[1], K.A. Christopoulos[2], R.J. Fredericksen[3], W.C. Mathews[4], R.D. Moore[5], M.J. Mugavero[6], S. Napravnik[7], M.J. Mimiaga[8], K.H. Mayer[9], H.M. Crane[3]
[1]*University of Miami, Psychology, Coral Gables, United States,* [2]*University of California, San Francisco, United States,* [3]*University of Washington, Seattle, United States,* [4]*University of California, San Diego, United States,* [5]*Johns Hopkins University, Baltimore, United States,* [6]*University of Alabama at Birmingham, Birmingham, United States,* [7]*University of North Carolina at Chapel Hill, Chapel Hill, United States,* [8]*Brown University, Providence, United States,* [9]*Harvard University, Boston, United States*

Background: Syndemic conditions are co-occurring psychosocial conditions that interact synergistically to exacerbate the risk for HIV transmission. Little is known about the role syndemics play in HIV transmission risk in resource-rich clinic settings. While antiretroviral therapy (ART) is key to treatment-as-prevention, to attain the 90-90-90 goals for HIV control, HIV care clinics will likely need to identify individuals most in need of psychosocial interventions. Syndemics could potentially aid providers in identifying these individuals.
Methods: Data were obtained from 15,739 HIV-positive individuals receiving care through the Centers for AIDS Research Network of Integrated Clinical Systems (CNICS) at seven US sites between July 2000 and April 2017. Syndemic conditions (substance abuse, at-risk drinking, depression, anxiety) and sexual risk behaviors were collected using validated instruments through patient-reported outcomes completed at clinical visits at least 6 months apart. Because sexual orientation data were only available for some of the sample, sexual risk groups were classified iteratively by examining self-identified sexual orientation and then sexual behaviors depending on sex of partner(s) and sex acts. Using multilevel modeling, we modeled time, number of syndemic conditions, and HIV risk group as predictors of bio-behavioral transmission-risk behavior (TRB; condomless anal or vaginal sex while virally detectable [HIV RNA>400]) with a partner of negative or unknown status.
Results: Between-person and within-person effects of syndemics on TRB emerged. Patients who, on average, had more syndemics had greater odds of engaging in TRB, such that each syndemic condition endorsed increased the odds by 1.61 (OR=1.61; 95%CI=1.51, 1.72). Additionally, within individuals, each additional syndemic condition endorsed at any given time point resulted in 1.75 odds greater of engaging in TRB (OR=1.75; 95% CI = 1.52, 2.02). Compared to females (referent), heterosexual males had 41% lower odds of engaging in TRB (OR=0.59; 95%CI=0.43,0.80). There were no other risk-group differences.
Conclusions: Across risk groups, identifying syndemics via patient-report-outcome measures in HIV clinics is feasible. Integrating the treatment of syndemic conditions with approaches to promote sexual and behavioral health in HIV clinic settings carries potential for reducing the number of new infections via TRB.

Correlates of benzodiazepine and opioid co-prescription among people living with HIV in British Columbia, Canada

S. Parent[1], S. Nolan[2,3], N. Fairbairn[2,3], M. Ye[1], A. Wu[4], J. Montaner[1,3], R. Barrios[1,5], L. Ti[1,3], STOP HIV/AIDS Study Group
[1]*British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada,* [2]*British Columbia Centre for Substance Use, Vancouver, Canada,* [3]*University of British Columbia, Department of Medicine, Vancouver, Canada,* [4]*British Columbia Centre for Excellence in HIV/AIDS, Canada, Canada,* [5]*Vancouver Coastal Health, Vancouver, Canada*

Background: The co-prescription of opioids and benzodiazepines is relatively contraindicated due to possible overdose risk. However, people living with HIV (PLWH) may have concurrent psychiatric or chronic pain diagnoses that require the use of either opioids or benzodiazepines for symptomatic treatment. Consequently, some PLWH may be at-risk for the health harms associated with the co-prescribing of these medications. Given this, the objective of this study was to characterize patient factors associated with the co-prescribing of opioids and benzodiazepines among PLWH in British Columbia (BC), Canada.
Methods: Using data derived from the Seek and Treat for Optimal Prevention HIV/AIDS in BC cohort, we used bivariable and multivariable generalized estimating equation models to establish the prevalence of a concurrent opioid and benzodiazepine co-prescription and determine factors associated with this practice.
Results: Between April 1996 and February 2015, a total of 14 484 PLWH were included in the study. A total of 3835 (26.5%) participants were prescribed both medications at least once during the study period. At baseline, 45.5% were prescribed opioids only, 19.9% were prescribed benzodiazepines only, and 30.8% were prescribed neither medication. A concurrent opioid and benzodiazepine prescription was independently and positively associated with depression/mood disorder (adjusted odds ratio [AOR]=1.32, 95% confidence interval [CI]: 1.22-1.43) and anxiety disorder (AOR= 1.45, 95%CI: 1.27-1.66), whereas female sex (AOR=0.76, 95%CI: 0.64-0.91) and substance use disorder (SUD) (AOR=0.82, 95%CI: 0.74-0.90) were negatively associated with the outcome.

Characteristic	Unadjusted Odds Ratio (95% Confidence Interval)	Adjusted Odds Ratio (95% Confidence Interval)
Sex (male vs female)	0.78 (0.67-0.90)	0.76 (0.64-0.91)
Age at baseline (10 years)	1.16 (1.11-1.22)	1.11 (1.04-1.18)
Calendar year (10 years)	0.73 (0.68-0.79)	0.65 (0.59-0.72)
Depression/mood disorder (no vs yes)	1.47 (1.37-1.57)	1.32 (1.22-1.43)
Anxiety (no vs yes)	1.48 (1.33-1.66)	1.45 (1.27-1.66)
Substance use disorder (no vs yes)	0.95 (0.88-1.03)	0.82 (0.74-0.90)
Charlson comorbidity index	1.08 (1.06-1.10)	1.09 (1.07-1.11)
CD4 cell count (100 cells/mm3)	1.00 (0.98-1.03)	1.02 (1.00-1.05)
Viral load (log10 copies/ml)	1.04 (1.02-1.07)	1.03 (1.00-1.07)

[Bivariable and multivariable generalized estimating equation analyses of factors associated with opioids and benzodiazepiness co-prescription]

Conclusions: Our findings indicate that co-prescription of opioids and benzodiazepines was seen in a high proportion of patients. Concurrent prescription was positively associated with anxiety and depression/mood disorder, but negatively associated with being female and presence of a SUD. These findings hint towards groups to target for prevention of harms stemming from co-prescription. However, given the risks associated with co-prescribing and the common comorbidities among PLHIV where these medications may be indicated, careful consideration should be taken prior to co-prescribing. Future research should seek to further explore co-prescription practices in order to determine their appropriateness in these circumstances.

WEPDC0203

When sex, drugs and violence overlap: Assessing the syndemic and synergistic effects of intimate partner violence, crystal methamphetamine, and depression on HIV sexual risk among women who inject drugs

C. Stoicescu[1], L.D. Cluver[1], R. Ameilia[2]
[1]University of Oxford, Social Policy & Intervention, Oxford, United Kingdom, [2]University of Indonesia, Department of Criminology, Depok, Indonesia

Background: Women who inject drugs are disproportionately affected by concomitant intimate partner violence (IPV), depression and substance use. Little is known about the synergistic effects of these conditions on women's HIV risk in low- and middle-income countries. The Perempuan Bersuara study assessed additive and interactive effects of syndemic health conditions on HIV risk in Indonesia's largest sample of drug-using women.

Methods: 731 women aged ≥18 years and injecting drugs in the preceding year were recruited from Jakarta and Bandung using respondent-driven sampling. Logistic regressions and marginal effects models tested associations and predicted probabilities of exposure to depression, IPV and crystal meth on 3 sexual risk outcomes. Additive interaction was assessed using relative excess risk due to interaction (RERI), attributable proportion due to interaction (AP) and synergy index (S).

Results: Prevalence of concurrent exposure to IPV, crystal meth and depression was 26%. Relative to the absence of these conditions, simultaneous exposure to all 3 increased rates of HIV risk: STI symptomatology (from 12% to 60%), inconsistent condom use (from 3% to 22%), and survival sex (from 6% to 25%). Additive interaction was detected between: (a) IPV x crystal meth on inconsistent condom use (AP=0.38,p< 0.05), such that 38% of inconsistent condom use among women reporting IPV and crystal meth was attributable to the interaction between these exposures; (b) depression x crystal meth on STI symptomatology (RERI=2.04,p< 0.001; AP=0.61,p< 0.001) and survival sex (RERI=1.20,p< 0.01; AP=0.53,p< 0.01), meaning that 61% of STI symptoms and 53% of survival sex participation among women reporting depression and crystal meth use was attributable to interaction between those exposures; and IPV x depression on STI symptomatology (RERI=3.01,p< 0.01; AP=0.52,p< 0.001; S=2.70,p< 0.01) and survival sex (RERI=1.21,p< 0.05; AP=0.40,p< 0.05), suggesting the joint effect of IPV and depression resulted in a 3-fold increase in STI symptoms and 1.2x increase in survival sex compared to each exposure's main effect.

Conclusions: This study provides new empirical evidence showing the syndemics of IPV, depression and crystal meth interact synergistically to heighten HIV risk among women who inject drugs. Interventions that consider the full scope of syndemic vulnerabilities, rather than addressing individual afflictions separately, are essential.

WEPDC0204

Combination prevention for women who use alcohol in South Africa: Outcomes from the Women's Health CoOp Plus Study in Pretoria, South Africa

W. Wechsberg[1], W. Zule[1], C. van der Horst[2], C. Peasant Bonner[1], J. Ndirangu[3], F. Browne[1], T. Kline[4], B. Howard[1], N. Rodman[5]
[1]RTI International, Substance Use, Gender & Applied Research, Durham, United States, [2]UNC School of Medicine, Chapel Hill, United States, [3]RTI International, Substance Use, Gender & Applied Research, Washington, United States, [4]RTI International, Statistics and Epidemiology, Durham, United States, [5]RTI International, Research Computing Division, Durham, United States

Background: Women who use substances, are at heightened risk for HIV but have been largely ignored by HIV primary and secondary prevention efforts. They are also more likely to experience gender-based violence (GBV) and sexual risk, with many reporting sex work - increasing their HIV risk and decreasing their access to HIV care and antiretroviral (ARV) adherence. The purpose of this study was to determine the efficacy of voluntary HIV counseling and testing (HCT) compared to the Women's Health CoOp (WHC+; 2 sessions) a gender focused prevention package to reduce substance use, GBV, sexual risk, and increase linkage to HIV care and adherence for women; hypothesizing that the WHC+ will report less substance use, GBV, sexual risk and more ARV adherence.

Methods: This NIH cluster randomized trial recruited 641 Black African women (Mean age = 29.9 SD = 0.31 from 2013-2016) across the 14 geographic zones in Pretoria. Women completed interviews, drug, alcohol, pregnancy and HIV screening at baseline, 6- and 12-months in both arms with over 90% follow-up. CD4 tests were added to assist clinical staging in linkage to local clinics. Dried blood spots were obtained for viral load (VL) testing from a subset of women who were HIV positive.

Results: Over 90% of women completed the study. Multiple and logistic regression using robust standard errors to account for clustering at the zone level and controlling for sex work and HIV status revealed that women in the WHC+ arm were less likely to report frequent heavy drinking (p< .001); physical beating by boyfriend (p< .001); and reported more protected condom use (p< .03) with main partner at 6-month follow-up compared to those in the HCT arm. Of those linked to HIV treatment, 81% of participants in the WHC+ arm reported adhering to their ARVs compared to 65% of participants in the HCT arm (p=.07). There was a relationship between reduced heaving drinking and ARV adherence.

Conclusions: The WHC+ combination prevention was found efficacious reducing intersecting risks, linking women who tested HIV+ to care and helping with adherence. It could have further impact with booster sessions after 6 months with larger implementation.

WEPDC0205

Behavioral activation integrated with sexual risk reduction counseling for high-risk MSM with crystal methamphetamine dependence: An initial randomized controlled trial

M. Mimiaga[1,2,3], D. Pantalone[3,4], K. Biello[3,5], J. White Hughto[3,6], J. Frank[2,5,7], C. O'Cleirigh[3,8], S. Reisner[9,10,11], A. Restar[5,7], C. Santostefano[7], K. Mayer[3,12], S. Safren[3,13]

Chan School of Public Health, Department of Epidemiology, Boston, United States, [12]Harvard Medical School/Beth Israel Deaconess Medical Center, Department of Infectious Diseases, Boston, United States, [13]University of Miami, Department of Psychology, Coral Gables, United States

Background: Men who have sex with men (MSM) continue to be the largest risk group for HIV infections in the U.S., where crystal methamphetamine abuse heightens risk for HIV infection through greater engagement in condomless anal sex (CAS). One potential contributor to the intractability of existing crystal methamphetamine treatments may be a lack of attention to replacement activities or the role of depressed mood. Behavioral activation (BA) is an evidence-based approach for depression that involves identifying and participating in pleasurable, goal-directed activities. The hypothesis was that, for MSM abusing crystal methamphetamine, re-learning how to engage in non-drug-using aspects of life would facilitate their ability to benefit from sexual risk reduction (SRR) counseling.

Methods: Project IMPACT was a pilot randomized controlled trial. Forty-six MSM at sexual risk of acquiring HIV who met DSM-IV criteria for crystal methamphetamine dependence were enrolled. Of those MSM, 41 were randomized: 21 were assigned to the intervention, consisting of two sessions of SRR, ten sessions of BA with SRR, and one session of relapse prevention (13 sessions total); 20 participants were assigned to a control condition (two sessions of SRR).

Results: At the acute post-intervention visit, intervention participants reported an average of 3.2 CAS acts with men who were HIV-infected or whose status they did not know, compared to 4.5 among control participants (=-0.36;95%CI:-0.69,-0.02;p=0.035). At the 6-month post-intervention visit, intervention participants reported 1.1 CAS acts with men who were HIV-infected or whose status they did not know compared to 2.8 among control participants (=-0.95;95%CI:-1.44,-0.46;p< 0.0001). Similarly, intervention participants reported 1.0 CAS acts under the influence of crystal methamphetamine with men who were HIV-infected or whose status they did not know compared to 2.5 among control participants (=-0.87;95%CI:-1.38,-0.36;p=0.0005). Lastly, intervention participants reported more continuous days abstaining from crystal methamphetamine compared to control (50.1 vs. 39.0, respectively) (=0.25;95%CI:0.16,0.34;p< 0.0001).

Conclusions: Findings are encouraging, provide evidence of feasibility (98% retention at 6 months) and acceptability (93% of counseling sessions attended; all participants rated the intervention as "acceptable" or "very acceptable"), and demonstrate initial efficacy for reducing sexual risk for HIV and crystal methamphetamine use. Future testing in a fully-powered efficacy trial is warranted.

WEPDC0206

Association between syndemics (of alcohol and drug use, and violence) and HIV-related sexual risk among men who have sex with men in India: Findings from a large-scale national bio-behavioural survey

V. Chakrapani[1], P.V.M. Lakshmi[1], P. Kumar[2], V. Srinivas[2]

[1]Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India, [2]National AIDS Control Organisation (NACO), New Delhi, India

Background: Despite more than a decade of HIV prevention interventions among men who have sex with men (MSM) in India, consistent condom use is suboptimal (about 50%). Syndemics theory states that multiple co-occurring psychosocial health problems could synergistically increase negative outcomes (e.g., HIV risk). We examined whether syndemic conditions such as alcohol use, drug use (including injecting drug use), and violence victimisation contribute to HIV-related sexual risk among MSM.

Methods: We used data from a national Integrated Bio-Behavioural Surveillance (IBBS), a cross-sectional survey among 23,081 MSM recruited through probability-based sampling from 24 states in India. We used three syndemic indicators:

1) alcohol use (at least once in the past week);
2) drug use (including injectable drugs in the past year); and
3) violence victimisation (physical and/or sexual violence in the past year).

Inconsistent condom use in anal sex ('sexual risk') was assessed by how frequently condoms were used in the past month ('every time' coded as consistent; the rest as inconsistent). Logistic regression was used predict to predict inconsistent condom use with three syndemic indicators and their interaction terms (alcohol use x drug use x violence victimisation).

Results: Participants' mean age was 27.6 years (SD 7.4). Most had completed secondary school, and 37% had paying partners. Prevalences of alcohol use, drug use, and violence victimisation were 48.8%, 11.1% and 24.7%, respectively. With the interaction terms of 3 syndemic conditions in the model (Table 1), alcohol use (aOR = 1.09,
p< .01), drug use (aOR = 1.26, p< .001), and violence victimisation (aOR = 1.46, p< .001) were found to significantly predict inconsistent condom use. Further, the interaction terms of the three syndemic indicators were also significant and positive in sign, indicating the synergistic effect of co-occurring syndemic conditions in heightening the sexual risk.

Conclusions: Syndemic conditions are highly prevalent and synergistically increase sexual risk among MSM. While HIV prevention interventions that address one or two of these syndemic conditions (alcohol and drug use, and violence victimisation) could reduce sexual risk, integrating interventions that jointly screen for and address syndemics, in addition to routine condom promotion interventions, could substantially reduce sexual risk among MSM.

Variables	Syndemic variables + Interaction terms	
	B (S.E.)	aOR (95% CI)
Syndemic indicators		
Syndemic indicator 1: Alcohol use - **A**	.08 (.03)	1.09* (1.01, 1.17)
Syndemic indicator 2: Drug use - **D**	.36 (.13)	1.43** (1.09, 1.88)
Syndemic indicator 3: Violence victimisation - **V** (sexual and/or physical)	.38 (.05)	1.46*** (1.30, 1.64)
Interactions terms of 3 syndemic indicators		
A x D x V	.48 (.23)	1.62*** (1.02, 2.57)
A x V	.01 (.08)	1.01 (.86, 1.19)
A x D	-.13 (.15)	.87 (.64, 1.19)
D x V	-.24 (.20)	.78 (.52, 1.16)
Constant	-.04 (.06)	.95
Note. Adjusted for age, education, marital status and sexual identity (kothi, panthi, double-decker and bisexual). Age, education, and sexual identity were statistically significant. *p <.05, **p <.01, ***p<.001		

[Table 1. Multivariable logistic regressions: Sexual risk regressed on syndemic indicator variables and their interaction terms (N = 23,801 MSM) *inconsistent condomm use in the past month with any type of male partners]*

Examining the socioeconomic gradient in viral suppression in Malawi

L. Sithole[1], A. Palma[2], D. Payne[3], E. Kim[3], C. West[3], M. Nzima[4], G. Bello[5], MPHIA Study Team

[1]National AIDS Commission, Planning, M&E and Research, Lilongwe, Malawi, [2]Columbia University, ICAP, New York City, United States, [3]Center for Diseases Control, Lilongwe, Malawi, [4]UNAIDS, Lilongwe, Malawi, [5]Ministry of Health, Lilongwe, Malawi

Background: Achieving viral suppression is associated with better health outcomes for people living with HIV. Studies in some countries have revealed socioeconomic disparities in viral suppression. Due to lack of valid measures of socioeconomic status, most studies construct wealth indices based on household asset variables often collected in population-based surveys. There are, however, multiple techniques for constructing a wealth index and there is lack of consensus regarding which technique is superior. This study examined the socioeconomic gradient in viral suppression in Malawi, checking robustness of results to choice of method for constructing the wealth index.

Methods: The Malawi Population-based HIV Impact Assessment (MPHIA) was a nationally representative survey conducted in Malawi in 2015-2016. Among 17,187 adults aged 15-64 who were interviewed and tested for HIV using the national algorithm, 2227 (13%) tested HIV positive, and 2220 (99.7%) of these had a viral load test performed. The Erreygers Index (EI) for income-related health inequality was computed for viral suppression under three scenarios based on statistical procedures for deriving the wealth index: Standard Principal Components Analysis (PCA), Multiple Correspondence Analysis (MCA) and Uncentered Principal Components Analysis (UPCA). All analyses were adjusted for the survey's complex design using jackknife replicated weights. These weights were also applied to calculation of viral suppression rates within the quintiles.

Results: Across the PCA and MCA scenarios, viral suppression rates appear to slightly increase monotonically from lowest to the highest wealth quintile while in the UPCA scenario, viral suppression rates vary only marginally and non-monotonically across the quintiles. On the other hand, the EI for viral suppression using the standard PCA wealth index was statistically insignificant (EI value= 0.0120; p-value= 0.2860). The EI for the MCA and UPCA indices were also not statistically significant (EI values= .00743 and -0.0204; p-values of 0.5128 and 0.0860 respectively).

Conclusions: Based on the inequality index used in this study, there were no substantial differences with respect to the socioeconomic gradient in viral suppression across the three scenarios, which implies there are no socioeconomic disparities in viral suppression among PLHIV in Malawi. This result is robust to choice of method for constructing the asset index.

		PCA	MCA	UPCA
Viral suppression rates across wealth quintiles	Lowest	15.44%	15.85%	21.91%
	Second	16.64%	16.81%	18.42%
	Middle	18.8%	20.02%	20.67%
	Fourth	22.23%	21.83%	18.84%
	Highest	26.89%	25.49%	20.16%
Socioeconomic disparities	EI	0.012	0.00743	-0.0204
	p-value	0.286	0.5128	0.086

Food insecurity is common and associated with unsuppressed viral load in HIV-infected pregnant women in Kenya

K. Ronen[1], L. Osborn[2], B. Khasimwa[2], B. Chohan[2,3], D. Matemo[2], J. Unger[1], A. Drake[1], J. Kinuthia[2,4], G. John-Stewart[1]

[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]University of Nairobi, Nairobi, Kenya

Background: Viral suppression in HIV-infected pregnant women is essential to elimination of mother-to-child transmission. Limited data exist on the impact of food insecurity on viral suppression in pregnant women. We evaluated prevalence of food insecurity and its association with viral suppression among pregnant women in Kenya.

Methods: We conducted a cross-sectional analysis of enrollment data from a trial evaluating mHealth strategies to improve ART adherence (Mobile WAChX, NCT02400671). Participants were age ≥14, HIV-infected, pregnant and had daily access to a mobile phone. Participants were recruited from 6 public MCH clinics in Nairobi and Nyanza region. Self-report questionnaires and plasma viral load (VL) were collected. Viral suppression was defined as VL < 1000 copies/ml among women on ART ≥6 months. Food insecurity, depression and social support were assessed using the Household Food Insecurity Access Scale (HFIAS), PHQ9 and MOS respectively. HFIAS scores were categorized per instrument guidelines and dichotomized into secure/mildly-insecure versus moderately/severely-insecure. Correlates of food insecurity were assessed by univariable Poisson regression with robust standard errors.

Results: Eight-hundred twenty-five women were enrolled, of whom 820 had complete data for this analysis. Median age was 27 (IQR 23-31), gestational age was 24.3 weeks (18.3-29.6), monthly income was 8000 KSh (~80 $US). Women had a median of 2 (1-2) living children and 695 (84.3%) were married/cohabiting. Overall, 336 (41.0%) were food secure, 72 (8.8%) mildly insecure, 179 (21.8%) moderately insecure, and 233 (28.4%) severely insecure. Prevalence of moderate/severe insecurity was associated with older age (RR 1.02, 95%CI 1.01-1.03, per year), lower income (RR 0.95, 0.94-0.97, per $10 increase), more children (RR 1.17, 1.12-1.22, per child), ≥mild depression (RR 1.64, 1.44-1.86), and lower social support (RR 0.81, 0.76-0.86, per 1-point increase on 4-point scale). Of 442 women on ART ≥6 months, 385 (87.1%) were virally suppressed. Moderate/severe food insecurity was associated with unsuppressed VL (RR 1.88, 1.10-3.22).

Conclusions: Our findings suggest that approximately half of pregnant HIV-infected women in Kenya experienced moderate or severe food insecurity. Food insecurity was significantly associated with older age, lower income, more children, lower social support, depression and unsuppressed VL. Nutrition assistance may be useful to support viral suppression in pregnant women.

WEPDD0103

The impact of homelessness in achieving viral suppression among extremely low-income HIV-infected women living in a well-resourced US city: A longitudinal perspective of overlapping risks

E.D. Riley[1], E. Vittinghoff[2], K.A. Christopoulos[1], A. Clemenzi-Allen[1], S.E. Dilworth-Johnson[1], C.A. Koss[1], A.W. Carrico[3]

[1]University of California, Medicine, San Francisco, United States, [2]University of California, Epidemiology and Biostatistics, San Francisco, United States, [3]University of Miami, Department of Public Health Sciences, Miami, United States

Background: Current best practices and high-impact interventions focus on retention in care and ART adherence to improve HIV outcomes. Simultaneously, research consistently indicates non-clinical conditions due to poverty as predictors of clinical outcomes. We considered social, structural and clinical factors as predictors of unsuppressed viral load (VL) in a community-recruited cohort of homeless and unstably housed women living with HIV/AIDS (HUH-WLWHA). The study was conducted in San Francisco, a well-resourced US city where unsuppressed VL among HIV-infected persons is estimated to be 12-28%.

Methods: Using three years of biannual data, paired with electronic VL data from routine clinical care, we estimated the odds of unsuppressed VL (HIV RNA >200 copies/ml) between 2008 and 2012. Time periods before/after the introduction of universal ART (1/1/10) were considered. Time-dependent covariates included homelessness, food insecurity, incarceration, insurance, outpatient visits, case management, polysubstance use and violence (emotional, physical, sexual), all evaluated 0-3 months before VL assessments. Logistic models with robust standard errors were used to assess the associations of covariates with detectable VL.
Results: Among 120 HUH-WLWHA, 508 VL assessments were analyzed (median=3/patient; IQR=2-6). Median baseline age was 47 and 72% of participants reported non-Caucasian race/ethnicity. Unsuppressed VL was observed among 60% of participants during follow-up and 19% were unsuppressed at all visits. In adjusted longitudinal analysis, the odds of unsuppressed VL increased 11% for every 10 nights homeless (OR=1.11, p< 0.001) and were over 4-fold higher among recently incarcerated women (OR=4.46, p< 0.001). Adjusting for substance use, odds were also 3-fold higher among participants experiencing recent sexual violence by someone who was not a primary intimate partner (OR=3.10, p=0.009).
Conclusions: In a city where 72-88% of HIV-infected persons have undetectable viremia, only 40% of HUH-WLWHA remain undetectable for three years. Homelessness, incarceration, sexual violence and drug use increase the odds of unsuppressed VL over time; other social/structural factors and healthcare do not. Current best practices and high-impact interventions do not address the root of the problem for impoverished WLWHA in a resource-rich setting. Considered alongside prior research, results suggest multi-component interventions that prioritize housing as being critical to optimizing health outcomes in this high-risk population.

WEPDD0104

Unstable housing associated with injection risk behaviors among PWID in Ukraine

A. Mazhnaya[1,2], J. Owczarzak[1]
[1]Johns Hopkins School of Public Health, Department of Health, Behavior and Society, Baltimore, United States, [2]ICF Alliacne for Public Healtj, Treatment, Kyiv, Ukraine

Background: In Eastern Europe and Central Asia new HIV infections occur at a high rate among people who inject drugs (PWID). Moreover, PWID account for most hepatitis C (HCV) cases in EECA. Injection risk behaviors are considered to be a product of 'risk environment' which includes socioeconomic factors, such as housing. There has been, however, limited attention towards exploring association between PWID's housing situation and injection risk behaviors in Ukraine which has HIV prevalence 21-42%, and 60% HCV prevalence among PWID.
Methods: This study is based on a data from a baseline survey of PWID (n = 684) recruited to participate in a behavioral HIV prevention intervention in 4 urban settings across Ukraine. Using poisson regression model we estimated independent association between housing situation (stable vs. unstable) and injection risk behaviors within last 30 days controlling for age, sex, city, drug of choice and education.
Results: : Participants who reported unstable housing also reported more injection risk behaviors within last 30 days, including using old syringe (33% vs. 10%, p-value < 0.001), sharing cooker/cotton/water (25% vs. 15%, p-value 0.1), front/backloading (73% vs. 62%, p-value 0.1), using preloaded syringe (64% vs. 48%, p-value 0.06). In multivariable analysis having unstable housing was associated with almost 2-fold increase in using needles/syringes after someone or sharing injecting equipment (cooker, cotton, water) within last 30 days (prevalence ratio (PR) 1.91, 95% CI 1.14-3.20).
Conclusions: Understanding and addressing structural context associated with injection risk behaviors should be part of research and intervention agenda to fight HIV and HCV in Ukraine. National programs would benefit from expanding models to include structural determinants of health.

WEPDD0105

Displacement, urban gentrification and declining access to HIV/STI, sexual health and outreach services amongst women sex workers between 2010-2014: Results of a community-based longitudinal cohort

S. Goldenberg[1,2], O. Amram[3], M. Braschel[1], S. Machat[1], K. Shannon[1,4], on behalf of the AESHA Study Team
[1]Gender and Sexual Health Initiative, BC Centre for Excellence in HIV/AIDS, St. Paul's Hospital, Vancouver, Canada, [2]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [3]Washington State University, Elson S. Floyd College of Medicine, Spokane, United States, [4]University of British Columbia, Faculty of Medicine, Vancouver, Canada

Background: Despite increasing gentrification across North American cities, little is known about its impacts on work and living environments and health access amongst sex workers (SWs). Using a spatial epidemiological approach, we
(1) explored changes in land use and work/living environments in relation to gentrification exposure, and
(2) modeled the independent effect of gentrification exposure on utilization of HIV/STI testing and sexual/reproductive health (SRH) and SW-tailored services.
Methods: Data were drawn from a community-based longitudinal cohort of SWs (AESHA) and publically available land use data. Analysis was restricted to 2010-2014, given legal changes in December 2014. Changes in land use and SWs' residential and working environments were mapped for the pre-gentrification (2010) vs. gentrification (2014) periods. Using a before-and-after design, confounder modeling with multivariable logistic regression using generalized estimating equations (GEE) assessed the independent effect of gentrification exposure on utilization of HIV/STI testing and SRH and SW-led/tailored services. Analyses were restricted to 203 SWs who participated in both study periods; spatial analyses were further restricted to those who provided data on work/residential locations.
Results: In the Downtown Eastside (DTES) and Strathcona neighborhoods, major shifts away from industrial/commercial land use towards residential, newly built housing were observed. Increases in the distance between the DTES core and SWs' place of residence (547 vs. 764 meters, p=0.03) and servicing clients (528 vs. 1894 meters, p=0.06) were found; shifts away from street/public (72.9% vs. 30.5%) towards online/off-street solicitation (15.8% vs. 28.6%, p< 0.001) were also documented. In separate multivariable GEE models adjusted for key confounders, gentrification exposure was correlated with reduced utilization of HIV (AOR:0.33, 95%CI: 0.21-0.51) and STI testing (AOR:0.39, 95%CI: 0.26-0.61), and use of SRH (AOR:0.36, 95%CI: 0.23-0.56) and SW-led/tailored services (AOR:0.43, 95%CI: 0.25-0.75).
Conclusions: Observed decreases in use of HIV, STI, SRH and SW-tailored services occurred despite ongoing efforts to scale-up HIV cascade interventions for key populations in BC, Canada. Results suggest these declines may be linked to gentrification-related displacement of SWs from areas where services for key populations are concentrated. Health and housing policies that promote marginalized women's access to safe working/living environments and investment in SW-led and SW-friendly health and social services are critically needed.

WEPDE01 Keeping it up: National ownership and financial sustainability

WEPDE0101

Lessons learned from sustained global health investments

A. Downer[1], J. Johnstone[1], M. McDowell[1], E.M. Reyes[2]
[1]University of Washington, Global Health, Seattle, United States, [2]University of California, Global Health Institute, San Francisco, United States

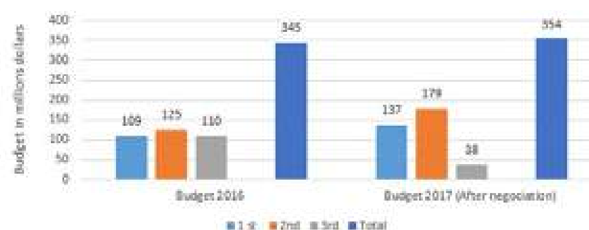
Background: There is emerging evidence to support those factors in global development that are related to successful transition and sustainability of aid investments. At the 15 year mark, the scale and scope of the the US President's Emergency Plan for AIDS Relief (PEPFAR) program provides ample opportunity to explore these factors and to confirm or identify those that can be incorporated early in project design to increase the sustainability of investments.
Description: The International Training and Education Center for Health (I-TECH) at the University of Washington in Seattle, USA, has been a PEPFAR partner since 2002. I-TECH has transitioned more than 300 programs, products, and tools to local ownership in that time. In 2017, I-TECH undertook to explore the degree to which a sub-set of these improvements have been sustained by local partners over time. Case examples were selected on the basis of geographic diversity, type of intervention, and sufficient time from transition to make an assessment. Key informants were interviewed, and the four domains and 15 elements of the PEPFAR Sustainability Index Dashboard (SID) were used to provide a framework and starting point for better understanding each example.
Lessons learned: Case studies were drafted on transitioned interventions in six resource limited countries to illustrate lessons learned on the long-term sustainability of health systems improvements, including both successes and failures. The cases reinforce the relevance of the SID in planning for sustainability, in particular the elements of advanced planning and coordination (1); human resources for health (7); quality management (9); domestic resource mobilization (11); and performance data (15). In addition, we found the actions of the implementing partner during transition to be a critical component.
Conclusions/Next steps: While aid investments in low and middle income countries can clearly be transitioned successfully to local ownership, they may not remain beneficial over time unless key elements of sustainability planning are intentionally addressed at the outset. Such lessons learned are instructive to a wide set of global audiences, from health and development specialists, government officials, economists, and social scientists to diplomats and security professionals worldwide. As such, lessons should be regularly disseminated.

WEPDE0102

How it was possible to offer Integrase Inhibitor as first line ART while maintaining the sustainability of the Brazilian policy of universal access to drugs

C.J.B. Batista[1], R.G. Corrêa[2], E. Malheiros[2], M.D.A. Freitas[2], A.S. Benzaken[2]
[1]Ministry of Health, STI/AIDS and Viral Hepatitis, Brasília, Brazil, [2]Ministry of Health, Brasília, Brazil

Background: Brazilian antiretroviral therapy is free and offered to 100% by Federal Government. In December 2016, about 500,000 people were on antiretroviral therapy (ART) and it was estimated that 100,000 new patients would be included in 2017. The Brazilian protocol recommended EFZ/TDF/3TC regimen as first line ART, and Integrase Inhibitors (II) as rescue therapy (Raltegravir - RAL 400 mg). As a result of the advances in international studies about the benefits of incorporating II in first line ART,
the Brazilian government initiated the negotiations to offer II, even considering the impossibility of generic drugs acquisition due to patent laws.
Methods: With an annual budget of approximately 350 million dollars to purchase antiretroviral drugs, the objective of the government was to offer II without significantly increasing the budget. Therefore, two strategies were used: a) price negotiation through bidding processes for the two II options available in Brazil (DTG 50mg and RAL 400mg) - only one of these would be included in the guidelines as a preferential first line drug and the same medication would be indicated for rescue regimens; b) reorganization of the guideline drug portfolio, including the removal of obsolete drugs and recommendations on switching patients to the new regimens.
Results: In 2016, treatment cost with available II in Brazil was US 8.8 dollars/day; the negotiation allowed a reduction to US 1.50/day - purchase of DTG. DTG was then included in the guidelines as the preferential drug for first line ART; switching RAL to DTG as rescue regimens was also recommended. In relation to the portfolio reorganization, the following were excluded: Fosamprenavir, Didanosine, Stavudine, and Saquinavir as well as the change in the recommendation of Atazanavir as the preferential drug for second line ART. These actions permitted ART procurement for 2017, including DTG, without significantly increasing the budget, as shown in Figure I.



[Figure I: Comparison of budget used to purchase ARV per line of ART in the years of 2016 and 2017, Brazil.]

Conclusions: The strategies used by Brazil proved advantageous and made it possible to offer a better antiretroviral treatment without significant budget changes.
Even with the increase in cost with the first and second lines, the economy generated in the third line was decisive for the expansion of the use of II.

WEPDE0103

Cost of HIV care and treatment in Mozambique

A. Berruti[1], A. Krivelyova[2], F. Mbofana[3], D. Single[4], A. Vergara[4]
[1]U.S. Centers for Disease Control and Prevention, Division of STD Prevention/NCHHSTP, Atlanta, United States, [2]ICF, Atlanta, United States, [3]Mozambique Ministry of Health, Maputo, Mozambique, [4]U.S. Centers for Disease Control and Prevention, DGHT, Atlanta, United States

Background: In 2016, approximately 990,000 adults and 76,000 children in Mozambique were receiving antiretroviral therapy. This study quantified costs of HIV treatment and care of different patient groups incurred in publicly funded HIV treatment facilities.
Methods: We collected data on the costs of the HIV treatment program, volume, and types of patients being treated. Data were collected retrospectively for two 6-month periods during 2016. Costs were categorized by source of support, type of expenditure, and program activity. Analyses focus on: total per-patient costs, cost across categories, and costs over time. Per-patient cost calculation was based on resource use intensity and allocation of costs across different patient categories.
Results: The median economic cost per patient-year was $96.73 (2017 USD) for ART patients and $22.09 for pre-ART patients. Costs were higher for newly initiated adult and pediatric patients compared to established patients. ARVs cost a median of $67.07 for ART patients, the largest single cost component for these patients. With ARVs excluded, laboratory services constituted the most substantial cost category for ART and pre-ART patients, at a median of $11.10 and $10.82, respectively. No substantial investments were made over the study period in equipment, training, or infrastructure. Per-patient cost comparisons across different types of facilities revealed lower costs in rural facilities ($88.13 versus $115.49 and $109.33 in peri-urban and urban facilities, respectively). Costs were higher in secondary level facilities ($121.07 versus $85.65 and $99.33 in primary and tertiary facilities, respectively). Analysis of costs by patient volume indicated that some economics of scale were present with larger facilities having smaller per patient costs.

Conclusions: Treatment costs varied widely between facilities, reflecting differences in the clinical models used, intensity of services, and types of drugs provided. While the costs of antiretroviral drugs may still dominate the cost per-patient, personnel and laboratory supplies costs are not insignificant. The study results indicate that HIV services can be optimized as the number of patients grows without substantial increases in investment. Under the test and start model, this study demonstrates that efficiency can be achieved if more patients start treatment, and this will in turn improve allocative efficiency.

WEPDE0104

Building sustainable HIV service delivery model at a local level in Ukraine

O. Iaremenko, A. Vasylkova, L. Khomych, N. Avaliani, N. Davydenko, M. Makovetska
USAID Project HIV Reform in Action, Deloitte, Kyiv, Ukraine

Background: In 2018, Ukraine remains the second highest-burden HIV epidemic country in Europe, with an estimated 241,000 people living with HIV/AIDS (PLWH). The significant financial dependence on external donor resources (67.41% of total HIV funding) threatens the sustainability of critical HIV services provision in the near future. As donor funding for HIV programming continues to decline in middle-income countries, Ukraine needs to revise its national HIV/AIDS response strategy and funding allocations, and optimize current service delivery models.
Description: Between February 2016 and December 2017 the USAID-funded HIV Reform in Action Project supported 14 local state administrations in 7 high-burden regions of Ukraine in developing and piloting a sustainable model for provision and scale-up of critical HIV services for PLWH and key populations.
The key components of the sustainable model include:
(1) advocacy for increased local funding for HIV rapid testing and social services;
(2) removal of policy and legal barriers to service provision by local government and NGOs;
(3) introducing new financing models for local state administrations;
(4) decentralization and integration of HIV services, and
(5) optimizing human resources for community-level service delivery.
To facilitate the pilot, we established mechanisms to coordinate efforts across regional and local authorities, primary and secondary level health care providers and civil society service providers.
Lessons learned: Local level advocacy efforts resulted in strengthening partnerships between government and civil society in HIV service delivery and increased 14 local budgets for HIV response from $225K in 2015 to $1.96M in 2017. Bridging local policy gaps in provision of HIV services at primary healthcare centers (PHCs), education and the local resource allocation allow to 10-fold increase in the number of HIV rapid testing sites at PHCs, with a 6-fold increase in the quantity of HIV rapid tests procured with local budgets. Thirty five new opioid substitution therapy (OST) sites were opened, with an increase of 536 people who inject drugs receiving OST services (compared to 2015).
Conclusions/Next steps: Pilot results and a replication plan are being shared with local state administrations beyond the pilot regions to fast-track comprehensive, integrated and sustainable HIV response at a national level.

WEPDE0105

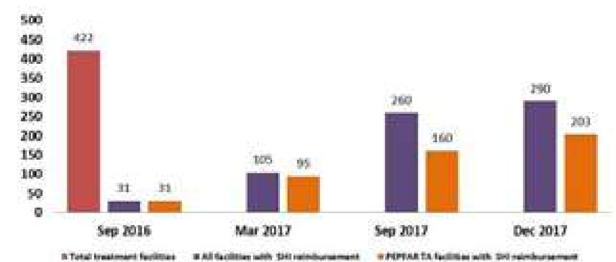
Sustainable financing of the HIV response in Vietnam: Integration of donor funded treatment facilities into public health system and the social health insurance scheme

H.T. Nguyen[1], H.T. Nguyen[1], A.T.C. Nguyen[2], H. Pham[1], A.N. Le[1], L. Dam[1], D. Nguyen[1], N. Todini[1], N.T. Do[3], H.T.T. Phan[3], T.M. Hammett[1]
[1]USAID/Health Finance and Governance Project, Abt Associates, Hanoi, Vietnam, [2]USAID Hanoi, Vietnam, Hanoi, Vietnam, [3]Vietnam Administration of HIV/AIDS Control, Ministry of Health, Hanoi, Vietnam

Background: As international donors reduce support for the HIV response in Vietnam (currently ~70%) and many other countries, the Government of Vietnam (GVN) is implementing a unique and innovative transition strategy: strengthen domestic governance and financing by integrating donor-funded HIV treatment facilities into the public health system with coverage of services through an expanded Social Health Insurance (SHI) scheme. Implementing partners of PEPFAR, including the Health Finance and Governance (HFG) project, have been providing technical assistance in support of this transition since 2015.
Description: HFG provides technical assistance to the Vietnam Administration of HIV/AIDS Control (VAAC) and other departments of the Ministry of Health (MoH), Vietnam Social Security (VSS), and 9 provinces including Hanoi and Ho Chi Minh City, the two provinces with the highest HIV burden. Beneficiaries include >51,000 ART patients (~46% of the total in Vietnam) in 115 treatment facilities. Technical assistance at national level includes: development of an integration monitoring tool and ongoing assessment of transition progress. HFG assists provinces and treatment facilities to achieve key integration steps of SHI contracting and reimbursement, and expansion of SHI coverage among PLHIV. The table and graph show the dramatic integration progress in the 9 HFG-supported provinces and the predominant contribution of PEPFAR TA to national progress on SHI reimbursement for HIV services. SHI coverage among ART patients in the 9 HFG supported provinces increased from 36% in 2016 to73 % in 2017.
Lessons learned: Multi-sectoral and multi-level technical assistance on integration of parallel systems of HIV treatment and expansion of population and service coverage of SHI can achieve remarkable progress in the transition from predominantly donor-funded to locally-funded and operated HIV responses.
Conclusions/Next steps: In Vietnam, full integration will only be completed when all HIV treatment services including viral load testing and ART are covered and reimbursed by SHI (expected to start in 2018 for VL testing and in 2019 for ART) and all PLHIV are enabled to obtain SHI through appropriate subsidies. PEPFAR and HFG will continue to provide TA to GVN at all levels to achieve these objectives, which will in turn help Vietnam achieve the 90-90-90 goals.

Indicators	Baseline (December 2015) (n/%)	December 2016 (n/%)	December 2017 (n/%)	Expected June 2018 (n/%)
HIV treatment facilities with SHI contracts	0	47/109 (43%)	83/115 (72%)	106/115 (90%)
HIV treatment facilities with SHI reimbursement	0	24/109 (22%)	70/115 (61%)	93/115 (81%)

[Integration progress in HFG-supported provinces]



[PEPFAR TA contribution to SHI reimbursement for HIV services]

PEPFAR's Sustainability Index and Dashboard: Results from SID 3.0

C. Hart, M. Ruffner, J. Timberlake, M. Wollmers
US Department of State/PEPFAR, Washington, United States

Background: The achievement of sustained control of the HIV epidemic is a critical goal for individuals, communities, and governments. However, defining sustainability and measuring progress over time has proved challenging. PEPFAR's Sustainability Index and Dashboard (SID) defines critical elements that contribute to sustainability, and enables its users to assess the current state of national HIV/AIDS responses while identifying strengths and vulnerabilities over time. After its third iteration, SID 3.0 provides results that reveal important insights into common challenges and advances across countries.

Description: SID 3.0 was implemented in 40 countries in 2017 through a participatory process. PEPFAR country teams worked with UNAIDS country directors to convene partner governments, multilateral and bilateral donor organizations, civil society organizations, private sector partners, and PEPFAR country staff. These stakeholders completed the 90-question SID tool to assess sustainability across 15 elements organized into four domains.

Lessons learned: The results of SID 3.0 demonstrate that countries are making progress towards a sustainable response to the epidemic. When analyzed by income level, low income countries generally scored lower than middle income countries on SID elements related to national health systems. Additionally, differences were observed by type of PEPFAR support, with technical assistance and technical collaboration countries generally performing better than long-term strategy countries. Among thirteen PEPFAR partner countries that are poised to reach epidemic control, scores from SID 2.0 (2015) to SID 3.0 (2017) increased significantly, by an overall average of 0.40 points (from 5.97 to 6.37, on a 0.00-10.00 scale) across all elements.

Conclusions/Next steps: PEPFAR has designed an original index that enables important cross-country comparisons that highlight which critical variables support advancement of sustainable systems to control the HIV epidemic. The SID provides essential data used to determine health systems investments and metrics to track the impact of those investments over time. Its regular implementation leads to results that in combination with epidemiologic data yield valuable insights about the most efficient path to sustained epidemic control. At the country level, the SID framework orients national stakeholders to their sustainability strengths and challenges, and facilitates informed decisions about where to target effort and resources to respond to the HIV epidemic more efficiently.

High-resolution metabolomics analysis of plasma and stool reveals marked differences in metabolism in adults with chronic, untreated HIV infection versus uninfected controls: A pilot study

T.R. Ziegler[1], K. Uppal[1], C. Ma[1], S. Mann[2], S. Serrano-Villar[3], N.S. Utay[4], T. Sainz[5], Z.-M. Ma[6], P. Troia-Cancio[2], A. Gewirtz[7], R.B. Pollard[2], C.J. Miller[6], A. Landay[8], D.M. Asmuth[9]
[1]Emory University, Atlanta, GA, United States, [2]University of California Davis Medical Center, Sacramento, CA, United States, [3]University Hospital Ramon y Cajal, Madrid, Spain, [4]University of Texas Houston Medical Center, Houston, TX, United States, [5]University Hospital La Paz, Madrid, Spain, [6]University of California Davis, Davis, CA, United States, [7]Georgia State University, Atlanta, GA, United States, [8]Rush University, Chicago, IL, United States, [9]University of California Davis Medical Center, Internal Medicine - Infectious Diseases, Sacramento, CA, United States

Background: High-resolution metabolomics (HRM) enables comprehensive evaluation of small-molecule metabolism in health and disease. In this pilot study, we hypothesized that whole-body (plasma) and gut-specific (stool) differences in metabolism would be evident using HRM in HIV-positive adults naive to ART versus HIV-negative controls.
Methods: Plasma (n=27 individuals) and stool (n=29) samples were available for HRM analysis from 32 ART-naive adults. Plasma (n=4) and stool (n=6) samples were available from 6 HIV-negative subjects similar in age and lifestyle. HRM was performed using hydrophilic interaction liquid chromatography (HILIC)-mass spectrometry (MS) for plasma and C18 LC-MS for stool analysis. Significant plasma and stool metabolites differentially expressed between groups were identified using Linear Models for Microarray Data analysis (LIMMA), followed by 2-way hierarchical clustering analysis (HCA) for data visualization. Differences in endogenous metabolic pathways were identified using the Mummichog pathway analytic package.
Results: In plasma, 11391 specific metabolites were identified, with 696 metabolites different between HIV-positive and HIV-negative ($P< 0.05$). Of these, 413 metabolites were increased and 283 decreased in HIV+ subjects vs. controls, respectively. HCA showed clear metabolite separation between the two groups. Significant differences between groups were seen in plasma Vitamin D3, Vitamin E, Vitamin B3 (niacin), histidine, linoleate, butanoate, carnitine shuttle, and squalene and cholesterol biosynthesis metabolic pathways. Stool HRM revealed 7135 specific metabolites, with 480 metabolites different between HIV-positive and HIV-negative subjects. Of these, 327 metabolites were increased and 153 decreased in HIV+ subjects vs. controls. HCA showed clear separation between groups. Stool pathway analysis showed significant differences in C21-steroid hormone biosynthesis/metabolism, glycerophospholipid metabolism, carnitine shuttle, and TCA cycle metabolism.
Conclusions: HRM analysis of plasma revealed marked differences in systemic metabolism of essential vitamins, histidine, and several lipid metabolic pathways in adults with HIV infection versus controls. Stool HRM revealed differences between groups in steroid hormone and phospholipid metabolism, and in pathways related to energy metabolism (carnitine shuttle and TCA cycle). Analysis to determine the specific metabolites within these pathways, their directionality and correlations with immune and inflammation biomarkers is underway. This data and approach have promising potential to differentiate the diverse effects of HIV on multiple systems.

WEPEA002

SIV-infected African green monkeys avoid disease progression through maintenance of the mucosal barrier integrity and prevention of intestinal dysfunction

K. Raehtz[1], G. Haret-Richter[1], C. Xu[1], B. Policicchio[1], A. Valentine[2], W. McFadden[2], E. Brocca-Cofano[1], A. Trichel[2], E. Falwell[1], F. Barrenas[3], B. Keele[4], J. Estes[4], I. Pandrea[1], C. Apetrei[1]
[1]University of Pittsburgh, Center for Vaccine Research, Pittsburgh, United States, [2]University of Pittsburgh, Pittsburgh, United States, [3]University of Washington, Department of Microbiology, Seattle, United States, [4]NCI-Frederick, AIDS and Cancer Virus Program, Frederick, United States

Background: Unlike HIV infection in humans, SIV infection of the African green monkey (AGM), a natural host of SIV, is generally nonpathogenic, with no disease progression, despite life-long viral replication. Lack of disease progression was reported to rely on the ability of SIV-infected AGMs to maintain gut integrity and avoid microbial translocation (MT), thereby preventing systemic immune activation and chronic inflammation. Yet, to date, maintenance of gut mucosal integrity in AGMs has never been proven. Our goal was to investigate the early events that may lead to the lack of disease progression in AGMs, particularly the impact of SIVagm infection on the gut mucosa.
Methods: Twenty-nine adult male AGMs were intrarectally infected with plasma containing 10^7 copies of SIVsab92018 and serially sacrificed at key time points of acute SIV infection: preramp, ramp-up and peak viremia, and early chronic SIV infection. Immunohistochemistry (IHC) was performed on histologically prepared sections of the gut and peripheral LNs for markers of immune activation, apoptosis, epithelial damage and microbial by-products. Qualitative and software-based quantitative analysis was used to assess changes in the tissues during acute and early chronic infection. Viral loads and plasma cytokine levels were also measured over the course of infection.
Results: AGMs did not display any significant increases in apoptosis of either mucosal enterocytes or lymphocytes and sustained virtually no damage or breakage of their mucosal epithelium. Little to no increases of immune activation or inflammation were observed in the gut mucosa postinfection, along with a strong but transient interferon-based response. No increase in the translocation of either microbes or microbial by-products across the mucosal barrier was detected.
Conclusions: We directly confirm, for the first time, that natural hosts preserve the integrity of their gut epithelium during the early stages of infection. These data corroborate our previous results demonstrating a superior mucosal healing capacity of the SIVagm infected AGMs. Preservation of the gut architecture in natural host limits immune activation and inflammation of the gut mucosa in response to infection. This prevents the increases in MT, and thus the generalized chronic immune activation and inflammation that drive disease progression in pathogenic infections.

WEPEA003

Unique plasma secretome of apolipoproteins in HIV-1-infected patients with two decade long successful antiretroviral therapy

M. Sperk[1], A. Sönnerborg[2], P. Nowak[2], U. Neogi[1]
[1]Karolinska Institutet, Department of Laboratory Medicine, Stockholm, Sweden, [2]Karolinska Institutet, Department of Medicine, Stockholm, Sweden

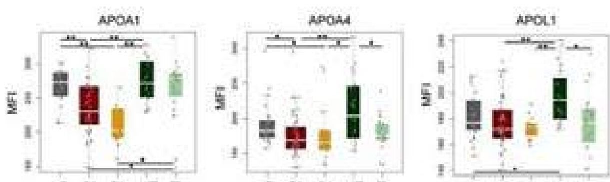
Background: Soluble plasma biomarkers could be useful to understand HIV-1 pathogenesis as they provide insights into ongoing immune responses. The effects of long-term successful combination antiretroviral therapy (cART) and the linkage between levels of plasma biomarkers remain unclear. The aim of this study is to assess the host plasma secretome by affinity antibody array from HIV-1-infected patients on successful long-term cART (>15 years) and compare it with individuals with different HIV-1 disease progression and healthy controls.
Methods: Plasma samples were obtained from five categories of individuals; elite controllers, who are able to control viral replication without ART (EC, n=19), treatment-naïve patients with viremia in primary infection

(PHI, n=15) or in chronic stage of HIV-1 infection (CHI, n=40), patients on long-term cART (cART, n=19) median (IQR) 19 (17-20) years and HIV-1-negative persons (HC, n=24) and were analyzed using antibody bead array targeting 380 plasma proteins. Only 92 could be detected and were used for statistical analyses.

Results: Among the factors members of apolipoproteins (ApoA1, ApoA4, ApoL1) showed distinct characteristics in patients both with chronic and primary HIV-1 infection and normalized to the healthy state following long-term cART (Figure 1). Apolipoprotein levels were significantly higher in individuals on long-term cART compared to PHI ($p< 0.001$ for ApoA1 and ApoL1, $p=0.019$ for ApoA4) and CHI ($p\leq0.001$) and to some extent also compared to EC ($p=0.011$ for ApoL1, $p=0.034$ for ApoA4). No difference was seen between HC and EC for any of them.

Conclusions: Our data indicates that HIV-1 infection impaired the apolipoproteins that coordinate lipid metabolism and transport of lipids at the very early stages of infection. However they normalize to a healthy level following cART. The level of ApoL1, which plays roles in lipid exchange and transport and reverse cholesterol transport from peripheral cells to the liver, is high in most of the cART patients.

As plasma ApoL1 levels correlated positively with plasma triglycerides and total cholesterol, cART patients are at high risk of lipid disorders that increases the risk of cardiovascular diseases and diabetes. In addition to its role in lipid metabolism, ApoA1 has been shown to possess broad antiviral activity.



*[Figure 1. Level of Apolipoproteins in different HIV-1 patient groups. MFI: Mean fluorescence intensity. *p≤0.05, **p≤0.001]*

WEPEA004

Small intestinal gastrointestinal-associated lymphoid tissue (GALT) Immune reconstitution and changes in systemic inflammation in a cohort of MSM initiating a protease inhibitor-based regimen compared to MSM controls

R. Güerri-Fernandez[1,2], N.S. Utay[3], T. Sainz[4], Z.-M. Ma[5], S. Mann[1], P. Troia-Cancio[6], A. Somasunderam[3], T. Yotter[1], M. Pion[7], R.B. Pollard[1], D.M. Asmuth[1]

[1]University of California Davis Medical Center, Sacramento, United States, [2]Hospital del Mar Research Institute, Infectious Diseases, Barcelona, Spain, [3]University of Texas Medical Center, Houston, United States, [4]University Hospital La Paz, Madrid, Spain, [5]California National Primate Research Center, Davis, United States, [6]University of California Davis Medical Center, Internal Medicine-Infectious Diseases, Sacramento, United States, [7]Hospital General Universitario Gregorio Marañon, Madrid, Spain

Background: The impact of protease inhibitor-based ART regimens on small intestinal immune reconstitution and changes in systemic inflammation has not been reported. To control for HIV-risk group, we matched MSM in both treatment and HIV-negative cohorts.

Methods: Participants with chronic HIV infection naïve to ART underwent upper endoscopy for duodenal biopsies before and 12-months after initiating open-label darunavir/ritonavir/tenofovir-DF/emtricitabine once daily regimens. HIV-negative controls underwent identical procedures one time. Biopsy specimens were digested in collagenase for single-cell suspension for flow cytometry (%) or preserved for T-lymphocyte immunohistochemistry (IHC) density (cells/mm²) staining in lamina propria zones. A panel of inflammatory biomarkers was measured in plasma by ELISA. Values are expressed as median values [interquartile range] and non-parametric tests were used where appropriate.

Results: 18 HIV-positive men with a median baseline CD4+ count of 431 cells/dL[272-559] and HIV load of 40,500 copies/mL[19,750-84,250], were enrolled. HIV load became undetectable and CD4+ increased to 742 cells/mm³[561,861] at 12-months. 17 HIV-negative controls were of similar demographics and age. Duodenal CD4 percent lymphocytes (flow-cytometry) and density (IHC) were lower in HIV-positive at baseline (2%[1.1-5.12]; 65 cells/mm² [34-163]) and at 12-months (7% [3.5-7.34]; 221 cells/mm² [141-293]) compared to controls (24% [19.6-37.9]; 478 cells/mm² [389-627])(all $p< 0.001$).

As expected, sCD163, IP-10, IL-6, and sCD14 levels were significantly higher in the HIV-positive cohort compared to controls and only sCD163 and IP-10 declined significantly after 12-months of protease-based cART (see table). No correlations were found between peripheral CD4 counts and any measurements of GALT CD4 count population suggesting that these two compartments are not in equilibrium. Higher baseline IL-6 levels correlated negatively with the duodenal CD4+ density (Spearman's rho=-0.458,$p< 0.05$). Duodenal immune reconstitution as measured by increases from baseline in CD4%/CD8% ratios density correlated with largest declines in sCD14 (Spearman's rho=-0.71,$p< 0.05$).

Conclusions: Correlations between the GALT immune populations and monocyte/macrophage activation biomarkers were observed in this cohort after 12-months of effective protease inhibitor-based cART. Future research must be directed to identifying the underlying mechanisms for these associations. Analysis of GI tract microbiome composition will provide insight into potential mechanisms linking mucosal and systemic compartments.

[1]Burnet Institute, Life Sciences, Melbourne, Australia, [2]Monash University, Melbourne, Australia, [3]University of Melbourne, Melbourne, Australia, [4]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA, Buenos Aires, Argentina, [5]University of the West Indies, Kingston, Australia, [6]Baker IDI Heart and Diabetes Institute, Melbourne, Australia, [7]The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [8]Rush University Medical Center, Chicago, United States, [9]University of California, San Francisco, United States

Background: A growing body of evidence highlights the crucial role of immune cell metabolic reprogramming during infections. These metabolic changes switch the cell from oxidative phosphorylation to glycolytic metabolism to modulate immune functions and inflammatory responses.

We use immunometabolic tools to gain novel insights into pathways that control CD4 T cell susceptibility to HIV, factors controlling immune functions, and inflammatory responses associated with age-related comorbidities in HIV+ persons.

Methods: Metabolic characterization was done by evaluating mitochondrial dynamics (e.g. density and membrane potential), metabolic signalling pathways (e.g PI3Kinase/Akt/mTOR) and co-stimulatory signals (e.g OX40/CD134). Glycolysis confirmed by intracellular lactate analy-

sis and Seahorse extracellular flux analysis (extracellular acidification rate, ECAR). HIV-Gag-specific T cell responses were determined by IFN ELISPOT assay.

We determined the clinical relevance and associations of selected metabolic (Glut1), exhaustion/senescence (PD-1, CD28, CD57) and inflammation (sCD163, IP-10, ADAM17) markers within

1) an HIV population enrolled in a study of frailty in ART-treated HIV+ subjects (n=80; median age 59),

2) in a population of ART-treated HIV-positive subjects with variable CD4 T cell recovery (n=163), and

3) HIV-negative controls (n=25). Clinically-approved metabolic-modifying drugs were screened in vitro for their anti-glycolytic and PI3Kinase-mTOR regulatory activity.

Results: Frailty assessed by the Frailty Index, was associated with increased monocyte Glut1 expression (OR, 2.6, p=0.04) and sCD163 (OR, 4.8, p=0.01), but not with mitochondrial dynamics. Immune non-responders exhibit a hyper-metabolic state associated with markers of T cell exhaustion and senescence. High basal Glut1 and OX40 on CD4+ T cells from ART-treated HIV+ patients represent a sufficiently metabolically-active state permissive for HIV infection in vitro precluding the need for external stimuli. Inhibition of mTOR and p110 PI3K isoform with clinically approved drugs abrogated mTOR signalling, inhibited ECAR, suppressed HIV infection in vitro, reduced CD4+ T cell death, and improved HIV-specific T-cell responses. PI3K inhibition suppressed CD16+ monocytes inflammatory response.

Conclusions: A glycolytic phenotype of immune cells may be a central underlying mechanism associated with HIV disease pathogenesis. Anti-glycolytic drugs may be explored to restore immune functions and to suppress residual HIV replication in ART-treated HIV-positive persons, as well as to limit chronic monocyte pro-inflammatory responses and delay the onset of age-associated co-morbidities.

Microbiomes and microbial translocation

Neovaginal microbial and proteomic signatures in Brazilian transgender women following gender-related surgery

K. Kratzer[1,2], C. Farr Zuend[1,2], S. Mutch[1,2], K. Birse[1,2], L. Noël-Romas[1,2], M. Abou[1], E. Jalil[3], B. Grinsztejn[3], R. Khalili Friedman[3], F. Li[4], C. Yanavich[4], A. Burgener[1,2,5], G. Aldrovandi[4]

[1]National HIV and Retrovirology Labs, JC Wilt Infectious Disease Research Centre, Public Health Agency of Canada, Winnipeg, Canada, [2]University of Manitoba, Winnipeg, Canada, [3]Instituto Nacional de Infectologia Evandro Chagas - Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [4]University of California Los Angeles, Pediatrics, Los Angeles, United States, [5]Karolinska Institutet, Stockholm, Sweden

Background: Transgender women (TGW) have disproportionally high rates of HIV infection and evidence suggests they have the heaviest burden of HIV acquisition worldwide. Both inflammation and the microbiome are important determinants of HIV risk at mucosal surfaces, but little data is available on the neovagina of transgender individuals following gender-related surgery. The primary aim of this study was to identify and characterize neovaginal microbial and proteomic signatures in TGW from Rio de Janeiro, Brazil.

Methods: Mucosal swabs collected from the neovagina (n=9) and rectum (n=10) of transgender women were analyzed by 16S rRNA sequencing and label-free tandem mass spectrometry (MS) to characterize the microbiome and metaproteome (host and bacteria), respectively. Cervicovaginal mucosal samples from 25 natal women were included for comparison.

Results: MS identified 1122 human proteins and 42 bacterial proteins from neovaginal and rectal swabs. Neovaginas had a microbial proteome dominated by *Prevotella* (23.30%), *Escherichia* (17.56%), an uncultured bacterium (16.67%), and *Jonquetella* (10.71%), whereas natal women showed a less diverse microbiome with a predominance of *Lactobacillus* (60.20%) and *Gardnerella* (22.52%). Compositional analysis identified 37 significant differences in the host functional proteome between neovaginas and natal vaginas, including a reduced proportion of immune system proteins (p = 1.07E-04, LOG2FC = 1.196), and increases (p< 0.0001) in metabolic processes (carbohydrate, LOG2FC = -1.398; amino acid, LOG2FC = -1.932), and cell growth and death (LOG2FC = -1.261) pathways, respectively. Data from the 16S sequencing analysis indicated that 36.2 +/- 10.6% of the neovaginal microbiota are derived from the rectal microbiome. Overall composition of the neovaginas was varied; 6 participants self- reported the use of penile and scrotal tissue and 3 indicated inclusion of bowel mucosal tissue for at least one gender-related surgery. Neovaginas showed no significant differences to rectal mucosa in proportions of host functional pathways (p>0.05).

Conclusions: These data suggest that the microbiome and host proteome are distinct in the neovagina, showing altered immune pathways, lower amounts of commensal bacteria (*Lactobacillus*) commonly observed in natal vaginas. Improving our understanding of these differences may help to improve our strategies for the prevention of HIV acquisition in TGW.

Comparative transcriptome analysis in endocervix and ectocervix during proliferative and secretory phases of the menstrual cycle

S. Mukhopadhyay[1], Y. Liang[2], H. Hur[2], G. Villegas[1], G. Calenda[1], A. Reis[3], L. Millen[3], L. Mamkina[1], N. Kumar[1], T. Kalir[3], R. Sperling[3], N. Teleshova[1]

[1]Population Council, Center for Biomedical Research, New York, United States, [2]Center for Clinical and Translational Science, Rockefeller University, Bioinformatics Program, New York, United States, [3]Icahn School of Medicine, Mount Sinai, New York, United States

Background: It has been suggested that HIV transmission is more likely to occur during progesterone dominating secretory phase of the menstrual cycle. To gain a better understanding of gene expression changes during menstrual cycle, we analyzed ecto- and endocervical transcriptome from women in either proliferative or secretory phase.

Methods: Ecto- and/or endocervical tissues were obtained from 16 women undergoing hysterectomies for non-malignant conditions and not using hormonal contraception/hormonal treatment for gynecological conditions. 10 of these subjects had paired tissues collected. The cycle phase was determined by histopathological assessment of endometrial tissue. Serum estradiol and progesterone concentrations were measured by RIA. RNA was sequenced by using Illumina TruSeq technology (75bp, >30M coverage). An in-house RNA-seq workflow was used to estimate the differential gene expression. Differentially expressed genes (DEGs)(adjusted p< 0.05) were used for Ingenuity Pathway Analysis. Limma outputs were ran against ImmuneSigDB for Gene Set Analysis (GSEA). Confirmatory qRT-PCR for selective DEGs was performed.

Results: Transcriptome analysis revealed 203 DEGs (101 upregulated and 102 downregulated) in proliferative vs. secretory phases of the endocervix. No DEGs were identified in ectocervix. The top significantly affected pathways in proliferative vs. secretory endocervix were remodeling of epithelial adherens junctions, epithelial adherens junction signaling and protein ubiquitination.

The analysis revealed an association of proliferative phase with epithelial barrier function and cellular assembly/organization function. Secretory phase was associated with inflammatory response, immune cell chemotaxis and gene expression signatures of stimulated DCs and NK cells. Changes in expression of selected DEGs were confirmed by qRT-PCR.

Conclusions: The study highlights differences in regulation of gene expression during menstrual cycle in endocervix and ectocervix and demonstrates significant changes in endocervical transcriptome of women in proliferative vs. secretory phases of the cycle. The data suggest that (i) weakening of epithelial barrier function and:

(ii) enhanced inflammation, influx of susceptible to HIV target cells, DC-T cell HIV transmission may be associated with higher risk of HIV acquisition in secretory phase of the cycle. This study provides insights into how mucosal susceptibility to HIV may be impacted during the menstrual cycle.

WEPEA008

Genetic variation in the activated leukocyte cell adhesion molecule affects HIV-1 disease progression

Z. Kruize, B. Boeser-Nunnink, T. Booiman, N. Kootstra
AMC, Experimental Immunology, Amsterdam, Netherlands

Background: HIV-1 infection is efficiently spread by direct cell-cell contact. Recently, the activated leukocyte cell adhesion molecule (ALCAM), which mediates cell aggregation, has been demonstrated to be required for cell to cell spread of HIV-1 *in vitro*. To determine whether ALCAM plays a role in HIV-1 pathogenesis, we analyzed whether genetic variation in ALCAM was associated with the clinical course of HIV-1 infection.
Methods: Single nucleotide polymorphisms (SNPs; n=14) in ALCAM were genotyped in a cohort of 312 HIV-1-infected MSM. Kaplan-Meier and Cox regression survival analyses were used to analyze the effect of the SNPs on HIV-1 disease progression. *In vitro* HIV-1 infection assays were performed in peripheral blood mononuclear cells (PBMCs) obtained from donors (n=22) that were genotyped for the SNPs in ALCAM.
Results: The minor allele of SNP rs9613199 in ALCAM was associated with prolonged AIDS-free survival (RH 0.51; CI 0,36-0,72; p=0.0001). This association was independent of the CCR5-D32 genotype and human leukocyte antigen alleles (HLA-B57) that were previously associated with slow disease progression. No effect of the SNP on *in vitro* HIV-1 replication in IL-2 stimulated PBMC was observed.
Conclusions: In this study we identified a SNP in the ALCAM gene that affects HIV-1 pathogenesis. Homozygosity for the minor allele of rs9613199 was associated with a delayed disease progression. No effect of the SNP in in vitro HIV-1 replication in IL-2 activated PBMC was observed, which might suggest that IL-2 stimulation is sufficient to overcome restricted HIV-1 replication in PBMC from donors homozygous or heterozygous for the major allele. Our data suggests that ALCAM mediated cell-to-cell transmission of HIV-1 is an important mechanism for the virus to spread to new target cells and supports viral replication *in vivo*. ALCAM also plays an important role during the intrathymic T cells development, and it remains to be determined whether the SNP in ALCAM affects T cell development and the antiviral immune response during the course of HIV-1 infection.

WEPEA009

Potential link between Nef immune evasion capacity and clinical parameters, but not reservoir size, in early HIV-1 infection

F.H. Omondi[1,2], S. Chandrarathna[3], S. Mujib[4], H. Sudderuddin[1], A. Rahimi[5], G. Anmole[5], N. Kinloch[5], F.Y. Yue[4], E. Benko[4,6], C. Kovacs[4,6], M.A. Brockman[1], M. Ostrowski[4], Z.L. Brumme[1]
[1]*Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada,* [2]*Kenya Medical Research Institute, Centre for Global Health Research, HIV-Research Laboratory, Kisumu, Kenya,* [3]*University of British Columbia, Vancouver, Canada,* [4]*University of Toronto, Toronto, Canada,* [5]*Simon Fraser University, Burnaby, Canada,* [6]*Marple Leaf Medical Clinic, Toronto, Canada*

Background: Rapid within-host HIV-1 evolution and diversification, particularly among the gene encoding the viral accessory protein Nef that modulates key immune evasion functions, may influence viral pathogenesis and conceivably modulate reservoir size. However, the extent of within-host Nef genetic and functional diversity in early HIV infection, and the relationship of these activities to clinical parameters and reservoir size measurements remain incompletely understood.
Methods: We isolated and cloned three plasma HIV-1 RNA-derived Nef sequences each from 29 antiretroviral therapy naïve individuals with early (< 6-months) HIV-1 infection into a GFP-reporter expression plasmid. Two of Nef´s main immune evasion functions, CD4 and HLA-I downregulation, were functionally assessed by transfecting each Nef clone into a HLA-A*02:01+ CEM-derived CD4+ T-cell line and assessing Nef-mediated downregulation of these molecules by flow cytometry. Results were then normalized to the function of the HIV-1 subtype B SF2 Nef reference sequence. Reservoir size measurements included total proviral DNA (copies per million CD4+ T-cells) and infectious units per million CD4+ T-cells (IUPM) measured by quantitative viral outgrowth assay.
Results: 24 (83%) participants harbored HIV-1 subtype B infections. The grand median HLA-A*02 downregulation capacity of all Nef clones was 75.9% of that of Nef-SF2 (range: 0-106.2, IQR: 62.6-90.7), while grand median CD4 downregulation capacity was 96.8% (range: 5.5-104.5, IQR: 92.7-100.0) of that of Nef-SF2. Within-host Nef genetic and functional diversity was substantial: within-host Nef clones differed by a mean 3.5 (range: 3.0-20.0, SD: 3.0) non-synonymous substitutions and exhibited median standard deviations of 9.3% (range: 1.1-58.5, IQR: 3.1-21.6) for HLA-A*02 downregulation and 2.4% (range: 0.3-55.7, IQR: 1.3-7.7) for CD4 downregulation. Maximal within-host HLA-A*02 downregulation capacity correlated negatively with square-root-transformed CD4 counts (Pearson´s R=0.35; p=0.07, n=29) and positively with log pVL (Pearson´s R=0.33; p=0.08, n=29). No significant relationships were observed between Nef functions and reservoir size (n=24).
Conclusions: The identification of maximal within-host Nef function as a potential correlate of HIV clinical prognosis in early infection supports Nef´s immune evasion functions as playing a key role at this critical infection stage. The relationship between Nef immune evasion function and reservoir size merits further exploration.

WEPEA010

AP-2 recruitment, CD4 downregulation, and viral replication require HIV-1 Nef dimerization in vitro and in humanized mice

S. Shu, L. Chen, T. Smithgall
University of Pittsburgh, Pittsburgh, United States

Background: The HIV-1 Nef accessory factor is essential for efficient viral replication and immune evasion in vivo. Dimerization of Nef has been linked to its interaction with multiple host cell binding partners, including the endocytic trafficking adaptor protein, AP2. Internalization of both CD4 and the SERINC5 restriction factor by Nef requires AP2 and clathrin-mediated endocytosis in order to enhance infectivity and avoid immune surveillance. Here we explored the role of Nef dimerization and AP2 recruitment in HIV-1 infectivity in vitro as well as viral replication and $CD4^{+}$ T cell loss in humanized mice.
Methods: To test the importance of Nef dimerization and AP2 recruitment in HIV-1 pathogenesis, we generated mutants that are deficient for Nef dimerization (Ile 109/Leu 112/Tyr 115/Phe 121 to Asp; 4D mutant) and AP2 binding (Asp 174/175 to Ala; DDAA mutant) based on previous X-ray crystal structures. A virus defective for Nef expression was also included (ΔNef mutant). Viruses were produced in 293T cells, and infectivity compared using TZM-bl reporter cells. BLT (bone marrow-liver-thymus) and hPBMC-NSG humanized mice were infected with each virus (2000TCID), and replication measured by real-time quantitative RT-PCR or p24 alpha assays in plasma and tissues. Human $CD4^{+}$ T cell counts were followed in PBMCs and tissues by flow cytometry as a surrogate for HIV-1 pathogenesis.
Results: In vitro, HIV-1 infectivity was significantly reduced with the 4D, DDAA and ΔNef viruses, and the most profound effect was observed with the ΔNef mutant. Humanized BLT mice infected with ΔNef viruses in either an X4 (NL4-3) or R5 (p81a) background showed significantly lower viral loads and reduced CD4 depletion compared to wild-type. hPBMC-NSG mice infected with the 4D and DDAA mutant viruses showed decreased viral loads and displayed $CD4^{+}$ T cell counts comparable to uninfected mice. Viral loads and tissue CD4 counts reflected the levels found in plasma.
Conclusions: Our results demonstrate that Nef dimerization and interaction with AP2 are both important for HIV-1 pathogenesis in humanized mouse models of HIV/AIDS. These data support a strategy to disrupt Nef dimerization as a new path to antiretroviral drug discovery.

WEPEA011

Soluble plasma PD-1 and Tim-3 as biomarkers of T cell exhaustion in primary HIV infection

E. Zilber[1], G. Martin[1], C.B. Willberg[1,2], J. Fox[3], N. Nwokolo[4], S. Fidler[5], J. Frater[1,2,6], CHERUB Investigators
[1]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, [2]National Institute of Health Research Biomedical Research Centre, Oxford, United Kingdom, [3]Guys and St Thomas' NHS Trust, Department of Genitourinary Medicine and Infectious Disease, London, United Kingdom, [4]Chelsea and Westminster Hospital, London, United Kingdom, [5]Imperial College, Division of Medicine, Wright Fleming Institute, London, United Kingdom, [6]Oxford Martin School, Oxford, United Kingdom

Background: Cell surface markers of T lymphocyte exhaustion, including PD-1 and Tim-3, are elevated in primary HIV infection (PHI) and predict clinical progression. However, analysis of these markers requires access to viable cells and a flow cytometry facility. The same markers also exist in a soluble (s) form in plasma and can be measured using a simple ELISA. However, their importance in HIV infection is unknown. We investigated plasma sPD-1 and sTim-3 in PHI, before and after antiretroviral therapy (ART), and the relationships with baseline parameters (plasma viral load (pVL), CD4 count, CD4/CD8 ratio) and respective surface exhaustion markers.
Methods: We evaluated HEATHER trial participants (n=48) recruited in PHI and starting ART a median of 46 [IQR 28-70] days after seroconversion. Plasma sPD-1 and sTim-3 concentration was quantified by ELISA at the earliest pre-therapy timepoint after seroconversion (baseline) and 1 year after ART initiation. PD-1 and Tim-3 expression were measured concurrently on CD4 and CD8 T cells by flow cytometry. Age and sex matched healthy controls (HCs) (n=10) were studied for comparison. Linear mixed effects (LME) modelling and Spearman's correlation was used to investigate the relationship between soluble and cell surface PD-1 and Tim-3 expression, and associations with clinical parameters.
Results: Compared to controls, sPD-1 and sTim-3 were significantly elevated in PHI (median 4.0 and 1.6 fold respectively) and decreased on ART to levels found in HCs. sPD-1 was positively associated with CD4 PD-1% (p=0.042), and also pVL and CD4/CD8 ratio (p< 0.005 each). sTim-3 was positively associated with CD8+ T cell Tim-3% (p=0.0027). Interestingly, plasma sPD-1 showed stronger individual correlations with pVL (rho=0.42, p=0.003), CD4 count (rho=-0.41, p=0.005) and CD4/CD8 ratio (rho=-0.50, p=0.001) than PD-1 cell surface expression on either CD4 or CD8 T cells.
Conclusions: sPD-1 and sTim-3 are perturbed during HIV infection. sPD-1 concentration associates with cell surface PD-1 expression, correlates independently with pVL and CD4/CD8 ratio, and overall correlates more strongly with clinical markers than cell surface PD-1 expression. sTim-3 concentration appears to be a good surrogate for surface Tim-3 expression. sPD-1 and sTim-3 are cheap and easy to measure and could prove useful biomarkers for studying immune exhaustion.

HIV co-morbidities

WEPEA012

Impact of tenofovir alafenamide, tenofovir disoproxil fumarate and abacavir sulphate on platelet function in healthy human subjects

K. Taylor[1], A. Khawaja[1], E. Smyth[1], F. Rauzi[1], M. Cerrone[2], M. Nelson[2,3], B. Gazzard[2,3], M. Boffito[2,3], M. Emerson[1]
[1]Imperial College London, National Heart and Lung Institute, London, United Kingdom, [2]Chelsea and Westminster NHS Trust, London, United Kingdom, [3]Imperial College London, Department of Medicine, London, United Kingdom

Background: Some cohort studies associate increased incidence of cardiovascular events e.g. myocardial infarction (MI) with certain antiretrovirals (ARVs) such as the nucleoside reverse transcriptase inhibitor, abacavir sulphate (ABC). This remains controversial and the underlying mechanism is unclear. Increased MI risk is hypothesised to result from ARV-mediated platelet dysfunction. It is therefore important to determine the impact of ARVs including newly emerging therapeutics (e.g. tenofovir alafenamide [TAF]) upon platelet activation to evaluate their potential cardiovascular risk profile.
Methods: Platelets were isolated from two populations of HIV-negative volunteers:
1) Subjects that were not taking any medication whose platelets were pre-incubated with ARV drugs *in vitro* and
2) 20 subjects enrolled in a phase I clinical trial who received TAF or TDF (tenofovir disoproxil fumarate) for 28 days.
Platelets from the clinical trial were isolated pre-dose and after achieving plasma steady-state for TAF and TDF. Intra-subject analysis was performed to compare platelet function at each time point. Platelet activation was assessed by monitoring aggregation and granule release. *In vivo* aggregation was determined in anaesthetised mice following administration of ARVs.
Results: *In vitro* platelet aggregation responses were not affected by pre-incubation with C_{max} levels of ARVs. However, we observed enhanced collagen-evoked platelet granule release from ABC-treated samples. This was not seen in TDF- or TAF-treated samples. ABC, but not TAF or TDF, also increased collagen-induced platelet aggregation *in vivo*. Intra-subject analysis revealed that steady-state TAF or TDF did not affect platelet aggregation or granule release when compared with pre-dose measurements.
Conclusions: The increased MI risk reported in some studies involving patients on ARVs may be driven pharmacologically *via* differential impacts upon granule release and platelet activation, leading to changes in platelet aggregation *in vivo*. Our studies were performed using HIV-negative volunteers and observations may be directly linked with ARVs independently of confounding factors associated with HIV infection. Furthermore, analysis of platelet activation from subjects enrolled on a phase I trial, provided evidence of a lack of impact of TAF and TDF upon platelet function at clinically relevant dosing. Future studies should evaluate the impact of ARVs on platelet function in people living with HIV.

WEPEA013

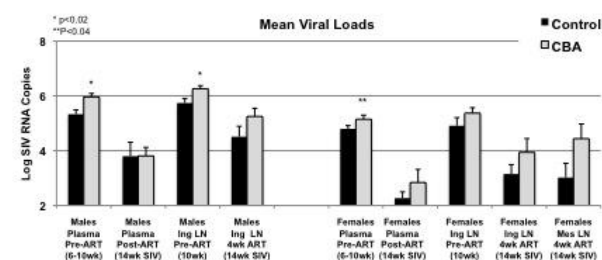
Chronic-binge alcohol increases viral expression in lymph node reservoirs of male and female macaques infected with SIV_{mac251}

A. Amedee[1], P. Mott[2], S. Robichaux[2], L. Simon[3], P. Molina[3]
[1]Louisiana State University Health Sciences Center, Microbiology, Immunology, & Parasitology, and Alcohol and Drug Abuse Center of Excellence, New Orleans, United States, [2]Louisiana State University Health Sciences Center, Microbiology, Immunology, & Parasitology, New Orleans, United States, [3]Louisiana State University Health Sciences Center, Physiology & Alcohol and Drug Abuse Center of Excellence, New Orleans, United States

Background: Chronic alcohol abuse negatively impacts HIV disease through multiple mechanisms. Using SIV-infected rhesus macaques exposed to chronic binge alcohol (CBA), we have shown that CBA increases plasma viral load and accelerates time to end-stage disease. In this study, we sought to explore the impact of CBA on the establishment of viral reservoirs in lymph nodes (LN) of the urogenital mucosa and determine their relationship with plasma viremia. Additionally, we sought to extend our studies to female animals to evaluate the influence of sex on CBA and SIV levels.
Methods: Alcohol was delivered daily to macaques via gastric catheter beginning 3 months prior to SIV_{mac251}-infection, achieving peak blood alcohol concentrations of 50-60mM. Saline or sucrose was administered to controls. Following mucosal infection (rectal for males, vaginal for females), longitudinal samples of plasma and inguinal LN were obtained for viral measures. After 10 weeks SIV, animals were administered daily ART consisting of PMPA and FTC. Samples were obtained from 16 females pre- and post-ART, 32 males pre-ART, and 16 males post-ART.
Results: Mean plasma viral loads 6-10 weeks post-SIV were significantly higher in CBA-exposed males and females, when compared to respective controls. In LN tissue reservoirs, proviral DNA levels were similar in CBA and control animals, but increased levels of viral RNA were observed in CBA LN. Following 4 weeks ART, plasma loads were signifi-

cantly reduced to similar levels in both groups. Likewise, SIV levels were reduced in LN, although higher levels of SIV-expression persisted in CBA animals compared to controls, indicating ongoing tissue expression. Comparison of male and female SIV loads demonstrated approximately 10-fold lower levels in females, reflecting sex differences in plasma and tissue loads among CBA and control groups.

Conclusions: Our results reveal that although similar numbers of LN cells harbor proviral DNA in CBA and control animals, CBA increases expression of SIV in tissues. The study highlights the negative impact that CBA has on viral expression in tissue reservoirs as well as viremia, despite the efficacy of ART. The differences in viral loads among male and female animals also emphasize the importance of sex as a variable in disease outcome.



[Viral Load]

WEPEA014

Differential effects of tenofovir alafenamide, tenofovir disoproxil fumarate and abacavir sulphate upon vascular endothelial cells

A. Khawaja[1], K. Taylor[1], M. Nelson[2,3], B. Gazzard[2,3], M. Boffito[2,3], M. Emerson[1]

[1]Imperial College London, National Heart and Lung Institute, London, United Kingdom, [2]Imperial College London, Department of Medicine, London, United Kingdom, [3]Chelsea and Westminster NHS Trust, London, United Kingdom

Background: Following the development of more effective antiretroviral therapies and decreasing numbers of AIDS-related deaths, associations with increased cardiovascular disease were reported in some studies among patients receiving the nucleoside reverse transcriptase inhibitor (NRTI) abacavir sulphate (ABC). Data from our group previously demonstrated differential effects between ABC and the nucleotide RTI (N(t)RTI) tenofovir disoproxil fumarate (TDF) and the newer N(t)RTI tenofovir alafenamide (TAF) on platelet aggregation *in vivo*, but not in isolated cells *in vitro*, implicating the vascular endothelium. We therefore examined the effects of ABC, TDF and TAF on endothelial cells to elucidate potential endothelium-dependent mechanisms of NRTI/N(t)RTI-associated cardiovascular risk.

Methods: Human umbilical cord endothelial cells (HUVEC) were pulsed for 90 minutes with plasma C_{max} NRTI/N(t)RTI concentrations over 2 days, and then stimulated with TNF-a or IFN-g for 24 hours. Endothelial viability was assessed by MTT assay. Ectonucleotidase (CD39 and CD73) expression, endothelial activation (E selectin, intercellular adhesion molecule [ICAM]-1/2 and vascular cell adhesion molecule [VCAM]-1 expression) and endothelial microparticle (EMP) production were evaluated by flow cytometry.

Results: ABC, TDF and TAF treatment did not affect endothelial viability compared to vehicle-treated cells. Whilst the mean expression of CD39 and CD73 was not affected by NRTI/N(t)RTI treatment, there was an increase in the number of HUVEC expressing both ectonucleotidases ($CD39^+CD73^+$) following treatment with TAF (p< 0.05). Interestingly, TAF, and TDF, also induced a modest reduction in baseline ICAM-1 expression. (p< 0.05). Furthermore, TAF significantly reduced TNF--induced EMP production compared to ABC-treated cells (p< 0.05). Adhesion molecule expression following TNF-a or IFN-g treatment were not affected by NRTI/N(t)RTI treatment.

Conclusions: These data elude to differential effects of NRTI/N(t)RTIs upon endothelial function. Reduced baseline adhesion molecule expression may suggest that patients receiving a TDF- or TAF-based regimen have fewer endothelial interactions with circulating platelets/leukocytes, potentially without compromising normal endothelial function during infection. Increased $CD39^+CD73^+$ endothelial populations following TAF treatment may indicate a greater propensity of endothelial cells to degrade ATP/ADP, thus curtailing ADP-stimulated platelet activation. Reduced EMP production following exposure to TAF may also suggest lower levels of microparticle-induced immune activation. Further work is required to fully elucidate the impacts of NRTI/N(t)RTIs upon endothelial function.

WEPEA015

Novel signature mutations in the Tat protein are associated with ischaemic stroke: A case-control study of HIV-infected individuals in Cape Town, South Africa

K. McMullen[1], K. Bateman[1], A. Stanley[1], A. Hardy[2], M. Combrinck[3], S. Engelbrecht[4], A. Bryer[1]

[1]University of Cape Town, Division of Neurology, Department of Medicine, Cape Town, South Africa, [2]University of Cape Town, Statistical Consulting Service, Department of Statistical Sciences, Cape Town, South Africa, [3]University of Cape Town, Division of Geriatric Medicine, Department of Medicine, Cape Town, South Africa, [4]University of Stellenbosch and National Health Laboratory Services, Division of Medical Virology, Cape Town, South Africa

Background: The pro-inflammatory and neurotoxic effects of Tat protein variants have been investigated in HIV-associated neurocognitive disorders, but not in ischaemic stroke. The pathogenesis of HIV-associated endothelial dysfunction and risk factors for its progression to stroke are unclear. This study primarily sought to determine whether Tat variants are associated with stroke. The secondary aim was to describe HIV-related and unrelated factors that may independently or cumulatively increase ischaemic stroke risk.

Methods: A case-control study of HIV-infected individuals, 18-45 years, recruited in Cape Town, South Africa between 1st August 2010 and 30th June 2013. Viral epidemiology signature pattern analysis investigated amino acid variants in Subtype-C Tat exon 1 sequenced from peripheral blood of 58 individuals with acute ischaemic stroke and 71 controls. Functional studies of signature mutations were explored with the HIV Mutation Browser. Signature pattern analysis, clinical and laboratory data were compared with Fisher's exact or Mann-Whitney tests.

Results: Stroke and control groups were mostly females (62.1%; 71.8%) of Black African ancestry; mean age 33 years. Replacement of alanine with proline at position 21, and lysine with histidine at position 29, were signature mutations associated with ischaemic stroke. These may impact on transactivation and chemoattraction of inflammatory cells. The most common causes of stroke were HIV-associated vasculopathy (43.1%) and opportunistic infections (22.4%). Individuals with stroke had a higher prevalence of treatment interruption (25.9% vs 0.0%, p= 0.003), lower CD4 nadir (median 112 cells/microlitre vs 177.5 cells/microlitre, p=0.008) and CD4 count (median 208.5 cells/microlitre vs 322.5 cells/microlitre, p=0.012) than controls. Median viral loads were elevated in both stroke and control groups (4.58; 4.13 log_{10} copies/ml, p=0.28). The stroke group had a higher prevalence of diabetes, increased fasting lipogram values, and greater pack-year smoking history than controls (all p< 0.05).

Conclusions: Novel signature Tat variants are associated with stroke. These could alter HIV-related inflammation and contribute to HIV-associated vasculopathy. Cell-culture studies are needed to explore this finding. The progression of HIV-associated endothelial dysfunction to vasculopathy and stroke may be a multiple-hit phenomenon. A comprehensive approach is needed to address possible Tat-mediated inflammation, HIV disease severity, treatment interruption and conventional cardiovascular risk factors to prevent ischaemic stroke.

WEPEA016

Increased KLRG1 and PD-1 expression on CD8 T lymphocytes in TB-IRIS

O. Goovaerts[1], M. Massinga-Loembé[2,3], P. Ondoa[4], A. Ceulemans[1], W. Worodria[5,6], R. Colebunders[7], L. Kestens[1], TB-IRIS Study Group
[1]Institute of Tropical Medicine, Biomedical Sciences, Antwerp, Belgium, [2]Albert Schweitzer Hospital, Centre de Recherches Médicales de Lambaréné (CERMEL), Lambarene, Gabon, [3]Institut für Tropenmedizin,Universität Tübingen, Tübingen, Germany, [4]Academic Medical Centre, Department of Global Health and Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, [5]Mulago Hospital, Department of Medicine, Kampala, Uganda, [6]Makerere University College of Health Sciences, Infectious Diseases Institute, Kampala, Uganda, [7]Institute of Tropical Medicine, Clinical Sciences, Antwerp, Belgium

Background: Tuberculosis-associated immune reconstitution inflammatory syndrome (TB-IRIS) is an inflammatory complication in HIV-TB co-infected patients receiving antiretroviral therapy (ART). In severely immunocompromised individuals, CD8+ T cells and NK cells are an important source of interferon-gamma for optimal antigen processing by innate cells. Nonetheless, the contribution of these cells to TB-IRIS development remains under-investigated. Here, we studied the expression of exhaustion markers on lymphocytes at different intervals during ART.
Methods: We compared 9 HIV-TB patients who developed TB-IRIS with 9 patients who did not (HIV+TB+), as well as 9 HIV-patients without TB (HIV+TB-) and 18 HIV-negative controls (9 HIV-TB+ and 9 HIV-TB-). Patients did not differ in age, gender, or CD4-count prior to ART. Frozen peripheral blood mononuclear cells, collected prior to ART and during 3 months and 9 months of ART, were thawed and analysed using flow cytometry. We examined expression of KLRG1 and PD-1 on CD4+ and CD8bright T-cells, as well as CD3-negative CD8dim lymphocytes as a proxy for natural killer cells.
Results: Prior to ART, TB-IRIS patients had higher percentages of CD8bright T cells that are KLRG1+ ($p=0.012$), PD-1+ ($p=0.047$), or both KLRG1+/PD-1+ ($p=0.012$) compared to HIV+TB+ controls. Though PD-1 expression declined during ART in all groups ($p\leq0.023$), the percentage of PD-1+, and KLRG1+/PD-1+ CD8bright T-cells remained higher in TB-IRIS patients at all time points ($p\leq0.037$). CD3-/CD8dim lymphocytes showed a similar pattern, most evident in KLRG1+/PD-1+ cells ($p\leq0.049$). In contrast, CD4+ T cells only showed a trend for higher percentages of PD1+ cells ($p=0.085$) prior to ART, which was reversed by month 3 ($p=0.070$) due to a decline over time in TB-IRIS patients only ($p=0.004$).
Conclusions: TB-IRIS is preceded by a high level of exhaustion in CD8 bright T cells, which persists during 9 months of ART. While potentially mirrored by NK cells, CD4+ T cells did not show these characteristic differences. Whereas previous findings highlight a role for innate cells during TB-IRIS' inflammation, our current results now suggest that an overstimulated/dysfunctional CD8+ lymphocyte compartment predisposes patients for this inflammation. The functional role of these cells prior to TB-IRIS development should be further explored.

WEPEA017

Enhancement of HIV-1 infection by buprenorphine

G.G. Gornalusse[1,2], L. Vojtech[1,2], C. Levy[1,2], R. Valdez[1], U. Pandey[1], J. McElrath[1,3], F. Hladik[1,2]
[1]Fred Hutchinson Cancer Research Center, VIDD, Seattle, United States, [2]University of Washington, Obstetrics and Gynecology, Seattle, United States, [3]University of Washington, Department of Pathobiology, Global Health and Laboratory Medicine, Seattle, United States

Background: Medication-assisted treatment (MAT) with buprenorphine is now widely prescribed to treat addiction to heroin and other illicit opioids. There is some evidence that illicit opioids enhance HIV-1 replication and accelerate AIDS pathogenesis, but the effect of buprenorphine is unknown.
Methods: We obtained peripheral blood mononuclear cells (PBMCs) from healthy volunteers and activated them with phytohemagglutinin and interleukin 2 for 72 hours in the presence of morphine or buprenorphine. We determined the level of expression of CCR5 both by qPCR and flow analysis. We infected the cells with a replication-competent CCR5-tropic HIV-1 reporter virus encoding a secreted nanoluciferase gene, and measured infection by luciferase activity in the supernatants over time. We also surveyed opioid receptor expression in PBMC and vaginal leukocytes, as well as Langerhans cells derived from CD34+ hematopoietic stem cells, by qPCR.
Results: Buprenorphine increased HIV-1 infectivity at the three MOIs tested (0.1, 0.2 and 0.5) and over all tested periods (24, 48 and 72 hours; n=5 experiments, n=4 donors). For example, at 72 hours, HIV infection was three to six times higher in the presence of 2 nM buprenorphine ($p< 0.0001$). Morphine also enhanced HIV-1 infection, but to a much lesser extent, and only at the higher dosage; this effect was variable across donors. At 100 µM, morphine caused a 1.4-fold increase of infection after 72 hours ($p< 0.0001$), whereas at 1 µM, HIV-1 infectivity remained unchanged. Neither CCR5 mRNA levels nor CCR5 protein expression was affected by buprenorphine treatment. In none of the leukocyte types tested, we found expression of the classical opioid receptors (mu, kappa or delta), but the nociception/orphanin FQ receptor (NOP also known as OPRL1) was present in blood and vaginal lymphocytes.
Conclusions: Our results suggest that buprenorphine, much more than morphine, increases the susceptibility of leukocytes to HIV-1 infection in vitro. Given that leukocytes do not express the classical opioid receptors, this increase in HIV susceptibility must occur through either OPRL1 or an unknown pathway. These findings are a first step toward understanding how opioids, including those used for MAT, affect HIV infection.

Systems biology approaches to HIV infection

WEPEA018

Signature of the storm: RNA-seq analysis of the extensive host transcriptome dysregulation caused by acute HIV-1 infection in a Mozambican cohort

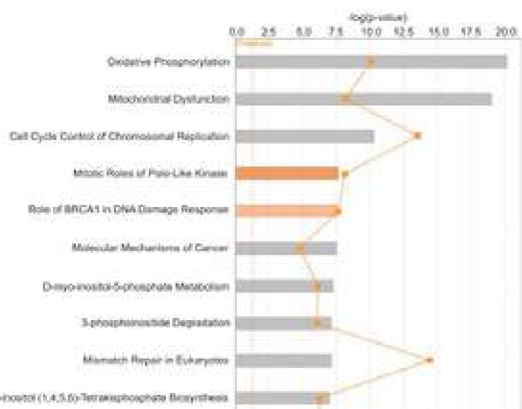
E. Parker[1], M. Judge[1], L. Pastor[2,3], L. Fuente-Soro[2], C. Jairoce[4], K. Carter[5], D. Anderson[5], D. Naniche[2,4], P. Le Souëf[1]
[1]University of Western Australia, School of Paediatrics and Child Health, Perth, Australia, [2]ISGlobal, Barcelona Centre for International Health Research (CRESIB), Barcelona, Spain, [3]AIDS Research Institute-IrsiCaixa, Barcelona, Spain, [4]Centro de Investigação em Saúde da Manhiça (CISM), Manhiça, Mozambique, [5]Telethon Kids Institute, Perth, Australia

Background: HIV causes vast and lasting immune damage during acute infection. A deeper understanding of the earliest responses to HIV is required to inhibit destructive inflammatory pathways, prevent reservoir seeding, and enable vaccine development. To our knowledge, this study is the first to employ RNA-seq transcriptomic analysis on patient samples to characterise the human host response and elucidate the pathogenic mechanisms of early HIV-induced immune damage.
Methods: Individuals with acute HIV, defined by positive viral load prior to seroconversion, contributed samples of peripheral blood mononuclear cells in the initial month of their infection. RNA was extracted using a modified protocol for the RNeasy MinElute Clean-up kit (Qiagen). Illumina 50bp, single-end RNA-seq was performed, with read quality assessed using FastQC. Reads were aligned to human reference genome hg19 using HISAT. Alignment quality was assessed using Samstat. Quantification and normalisation of read counts was performed using summarizeOverlaps (*GenomicAlignments* package) and voom (*limma* package), both from Bioconductor. Statistical analyses were performed using R version 3.2.0 and Ingenuity Pathway Analysis.
Results: Acute HIV samples (n=29) had a mean estimated time since infection of 7.5 weeks (range 4.3-11.1 weeks), with median viral load of Log_{10} 4.92 (IQR 4.48-5.49) copies/mL, and CD4 count of 595.2 (IQR 446.0-667.0) cells/mL. Gene expression profiles were compared with n=46 HIV-negative samples. RNA-seq resulted in an average of 23 million reads/sample, with 80% of reads mapped at high mapping accuracy. All samples passed pre- and post-alignment QC. Differential gene expression analysis identified 2150 significantly upregulated and 1723 significantly downregulated genes (adjusted P value < 0.05). The most significantly

differentially expressed genes (DEG), all upregulated, are presented in Table 1. The most upregulated pathways include oxidative phosphorylation, mitochondrial dysfunction, cell cycle control of chromosomal replication, and mitotic roles of polo-like kinase (Figure 1).

Gene name	HGNC gene name	Log fold change	Adjusted P value
Transmembrane protein 155	TMEM155	3.100194	3.78E-25
Cell division cycle associated 7	CDCA7	2.269544	5.61E-24
CD8b molecule	CD8B	1.461961	1.59E-18
CD8b molecule pseudogene	CD8BP	1.476977	2.57E-18
Nucleolar and spindle associated protein 1	NUSAP1	1.731505	4.19E-18
KIAA0101	KIAA0101	2.517015	8.8E-18
Thymidylate synthetase	TYMS	2.194494	2.31E-17
Non-SMC condensin I complex, subunit G	NCAPG	2.037193	6.01E-17
Chemokine (C-C motif) ligand 5	CCL5	1.277615	6.06E-17

[Table 1: The most significantly upregulated genes during acute HIV-1 infection, compared with HIV-negative controls.]



[Figure 1: Top 10 most significantly upregulated pathways during acute HIV-1 infection, compared with HIV-negative controls]

Conclusions: Our findings demonstrate an extensive, chaotic picture of gene upregulation during the early stages of HIV-1 infection, more profound than described for other acute viral infections. Changes reflect previously-described cytokine patterns, but also offer new insights into pro-inflammatory pathways and regulation of immune cell functions. Unlike previous transcriptomic studies in later stages of HIV infection, genetic downregulation was comparatively sparse.

WEPEA019

Targeting viral infection frequency but not burst size is effective at extinguishing initial infection in a model of PrEP

A. Moyano de las Muelas[1,2], H. Rodel[1,2], S. Cele[1], Y. Ganga[1], G. Lustig[1], A. Sigal[1,3]
[1]Africa Health Research Institute, Sigal Lab, Durban, South Africa, [2]University of Kwa Zulu-Natal, Nelson R Mandela Medical School, Durban, South Africa, [3]Max Planck Institute for Infection Biology, Berlin, Germany

Background: Inhibition of viral infection can be broadly categorized into two mechanisms: reduction of cellular infection frequency, and reduction in the burst size of virions produced from an infected cell. These mechanisms should in theory be equally efficient in blocking new cellular infections.
Using a combined computational and experimental approach, we set out to determine whether attenuating infection frequency or burst size as Pre-Exposure Prophylaxis (PrEP) would result in different probabilities to extinguish infection at drug concentrations where inhibition of HIV replication is incomplete.
Methods: We examined whether inhibition of burst size, by the protease inhibitor atazanavir, or infection frequency, by the reverse transcriptase inhibitor tenofovir, affected the outcome of PrEP in an *in vitro* cellular infection system. Both agents were used at concentrations not sufficient to completely block viral replication: infection in the presence of either drug resulted in a viral replication ratio of approximately 2. We used a branching process to model the probability of the infection becoming extinct.
Results: Tenofovir was effective in extinguishing infection in 67% of cases, significantly different from the no drug control (0%, p=0.0007 by ANOVA). In contrast, there was no significant difference in the frequency of terminated infections between atazanavir (4%) and the no drug control (p>0.99), as measured by detectable infection after the removal of drug. These results were consistent with our branching process model, and reproduced using *in vitro* infection of peripheral blood mononuclear cells from healthy donors.
Conclusions: Infection frequency but not burst size is effective at inhibiting initial infection in a cellular model of PrEP at suboptimal drug concentrations.

WEPEA020

Use of gene edition by CRISPR/Cas9 of tnpo3 gene in CD4+ t cells to generate a cellular model impervious to HIV-1 infection

S. Rodriguez-Mora[1], M.T. Rodríguez-Plata[2], E. Mateos[1], M.R. López-Huertas[3], J.J. Vilchez[4], G. Towers[2], M. Coiras[1], J. Alcamí[1]
[1]AIDS Immunopathogenesis Unit, National Center of Microbiology, Instituto de Salud Carlos III, Madrid, Spain, [2]Division of Infection and Immuity, University College London (UCL), London, United Kingdom, [3]Department of Infectious Diseases, Hospital Ramón y Cajal, Alcalá de Henares University, Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Madrid, Spain, [4]Department of Neurology, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: Transportin-3 (TNPO3), a karyopherin that mediates the nuclear entry of proteins with rich serine and arginine domains, is essential in HIV-1 infection. In 2013 it was discovered that a heterozygous deletion of a single nucleotide at the termination codon of the tnpo3 gene encodes additional 15aa, causing a familial genetic disease called limb-girdle muscular dystrophies 1F (LGMD1F). The main objectives of this work were:
1) to determine if the lymphocytes of patients with LGMD1F are resistant to HIV-1 infection in vitro;
2) to generate a cellular model with heterozygous and homozygous selective knockout of tnpo3 gene by gene editing using CRISPR/Cas9.
Methods:
1) PBMCs from 23 LGMD1F patients and 44 healthy donors were activated with CD3/CD28/IL-2 for 48 hours and then infected with NL4-3_renilla clone. The production of Renilla, the integration of the provirus and the synthesis of episomal forms (2LTRs) were analyzed 5 days post-infection.
2) RNA templates designed for the first exon of tnpo3 gene and cloned in vector lentiCRISPRv2 were used to generate lentiviruses in triple-transfected 293-T cells with plasmids of VSV envelope (pMG), packaging (p8.91_ex) and lentiCRISv2. JLTRG_R5 cells were used to generate knock-out (ko) mutants for tnpo3.
Results:
1) PBMCs from patients with LGMD1F showed > 90% of resistance to HIV-1 infection ex vivo, compared to PBMCs from healthy donors used as control.
2) Proviral integration was 90% reduced and episomal forms were undetectable in the patients' cells.
3) JLTRG_R5 cells were infected with lentiCRISPRv2 to generate ko JLTRG_R5 for tnpo3, homozygous and heterozygous.
4) Stabilized ko JLTRG_R5_tnpo3$^{-/-}$ cells showed complete resistance to infection by HIV-1 in vitro.
Conclusions: PBMCs from patients with LGMD1F who carry a microdeletion in a tnpo3 allele show resistance to ex vivo HIV-1 infection. The low detection of episomal forms and proviral integration suggest that restriction by this variant of tnpo3 occurs in the nuclear transport of the pre-integration complex. The cellular model generated in JLTRG_R5 cells by CRIPR/Cas9 reproduces resistance to HIV-1 infection and provides an invaluable tool for the analysis of essential steps in the viral cell cycle.

Neurodegeneration

Neuropathological mechanisms of alcohol, SIV, and antiretroviral therapy: Enhanced susceptibility of the frontal cortex in rhesus macaques

S. Edwards[1], J. Maxi[1], T. Wills[2], J. Middleton[2], K. Carzoli[2], L. Simon[1], P. Molina[1]
[1]LSU Health Sciences Center, Physiology, New Orleans, United States, [2]LSU Health Sciences Center, Cell Biology and Anatomy, New Orleans, United States

Background: Alcohol use represents a major exacerbating factor for HIV-related cognitive deficits, and persons living with HIV/AIDS (PLWHA) are more likely to be heavy alcohol drinkers. We hypothesize that pathological changes in the striatum and frontal cortex underlie alcohol- and HIV-associated cognitive deficits.

Methods: To investigate mechanisms whereby alcohol facilitates cognitive deficits in PLWHA, we developed and utilized a rhesus macaque model of chronic binge alcohol (CBA) exposure and simian immunodeficiency virus (SIV) infection (with and without anti-retroviral therapy, ART). We conducted gene expression analyses in the striatum and frontal cortex of male macaques as a neurobiological measure of potential neuropathology. As an extension of our work in males, we also measured alterations in cognitive behavior (via novel object recognition tests) and plan to measure gene expression in CBA/SIV/ART-administered female rhesus macaques, including an investigation of the contribution of ovarian hormones via inclusion of ovariectomized (OVX) animals.

Results: Our work in male rhesus macaques discovered that SIV infection is associated with greater inflammatory gene expression in the striatum and reduced growth factor signaling in the frontal cortex, while CBA administration is associated with reduced growth factor signaling in both the striatum and frontal cortex. Importantly, ART reduces inflammatory gene expression in both the frontal cortex and striatum, but does not ameliorate CBA-associated suppression of growth factor signaling. Our behavioral findings in female macaques indicate that CBA/SIV/ART/OVX animals demonstrate a reduced ability to discriminate a novel object compared to control (water-exposed and intact) animals, indicative of deficits in recognition memory. We also find that CBA/SIV/ART-administered animals spend significantly less time with the novel object relative to a familiar object, which may reflect either cognitive deficits or anhedonia-like behavior. Future gene expression analyses of female striatum and frontal cortex tissue will be directly compared with our findings in males.

Conclusions: Overall, our results are consistent with the increased prevalence of frontal cortex-associated cognitive deficits in PLWHA in the era of widespread ART and lead to the prediction that restoration of brain growth factor signaling may be beneficial for cognitive deficits in PLWHA who drink alcohol.

Investigating plasma neurofilament light chain protein (NFL), a biomarker of neuronal integrity, following treatment interruption after 48 weeks of ART in primary HIV - the SPARTAC trial

J. Alagaratnam[1], W. Stöhr[2], H. Zetterberg[3], M. Gisslen[3], G. Ramjee[4], M. Schechter[5], J.M. Miro[6], G. Tambussi[7], P. Kaleebu[8], S. Kinloch[9], D. Cooper[10], K. Porter[2], A. Babiker[2], R. Phillips[10], J. Weber[1], J. Frater[11], A. Winston[1], S. Fidler[1], SPARTAC Trial Investigators
[1]Imperial College London, London, United Kingdom, [2]Medical Research Council, London, United Kingdom, [3]University of Gothenburg, Gothenburg, Sweden, [4]Medical Research Council, Durban, South Africa, [5]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, [6]University of Barcelona, Barcelona, Spain, [7]San Raffaele Hospital, Milan, Italy, [8]Uganda Virus Research Institute, Entebbe, Uganda, [9]Royal Free Hospital, London, United Kingdom, [10]University of New South Wales, Sydney, Australia, [11]University of Oxford, Oxford, United Kingdom

Background: Although antiretroviral treatment interruption (TI) is not recommended, it is used to test efficacy in HIV cure trials. A major concern is the impact of TI on neuronal injury in the central nervous system (CNS). Plasma neurofilament light chain protein (NFL) strongly correlates with cerebrospinal fluid (CSF) NFL, a sensitive biomarker of CNS neuroaxonal injury reported to be raised in untreated HIV. We investigate plasma NFL changes over time in SPARTAC, a randomised controlled trial with protocol-driven TI in primary HIV infection (PHI).

Methods: Plasma NFL was measured using an ultra-sensitive single molecule array (Simoa) digital immunoassay in samples from participants randomised to immediate ART for 48 weeks, at the following 3 time points: week 0 (prior to commencing ART), week 48 (after 48 weeks of ART) and week 60 (12 weeks post-TI). Changes in plasma NFL over time and associations with clinical parameters were analysed using linear regression and mixed models.

Results: Of 83 individuals included, median age was 34 years (IQR 27 - 41), 33/83 (40%) participants were female, median duration from seroconversion was 88 days (IQR 64-103) and participants were recruited from Europe 42/83 (51%), Africa 30/83 (36%), Australia 9/83 (11%) and Brazil 2/83 (2%). Plasma NFL was significantly higher prior to starting ART (week 0) compared to week 48 and week 60 (p=0.036 and p=0.025 respectively). No significant change in plasma NFL was noted between week 48 and week 60 (p=0.98). In multivariable analyses, higher baseline plasma NFL was associated with female gender, older age and higher HIV RNA but not CD4 or CD4/CD8 ratio.

	Week 0	Week 48	Week 60	Association with plasma NFL at week 0, p value
Number of participants	82	71	83	
Plasma NFL, pg/mL	10.5 (8.8 - 12.6)	9.1 (7.4 - 11.2)	8.8 (7.5 - 10.5)	
HIV RNA, log10 cp/mL	4.6 (4.0 - 5.2)	1.7 (1.7 - 2.6)	3.7 (2.6 - 4.5)	0.047
CD4, cells/µL	612 (471 - 760)	794 (611 - 999)	714 (480 - 868)	0.45
CD4/CD8 ratio	0.55 (0.41 - 0.82)	0.98 (0.73 - 1.32)	0.70 (0.49 - 1.00)	0.89

[Baseline characteristics and associations with plasma NFL (Values are medians (IQR) except for plasma NFL, where values are geometric means (95%CI))]

Conclusions: Plasma NFL concentrations were raised in PHI, declined after ART was commenced and remained stable 12 weeks after TI. Based on plasma NFL as a surrogate marker, we have observed no evidence of increased neuroaxonal injury 12 weeks after the cessation of immediate ART for one year, initiated in PHI. Plasma NFL, along with other plasma biomarkers, may offer a non-invasive approach to monitor neuronal integrity in HIV cure studies.

Viral mechanisms of HIV/SIV persistence and latency

Background: It is unclear whether combination antiretroviral therapy (cART) regimens differ in their ability to suppress HIV replication. Here, we report the results of two cross-sectional studies that compared levels of HIV virological markers between people living with HIV (PLWH) receiving suppressive cART containing either a non-nucleoside reverse transcriptase inhibitor (NNRTI) or a protease inhibitor (PI).

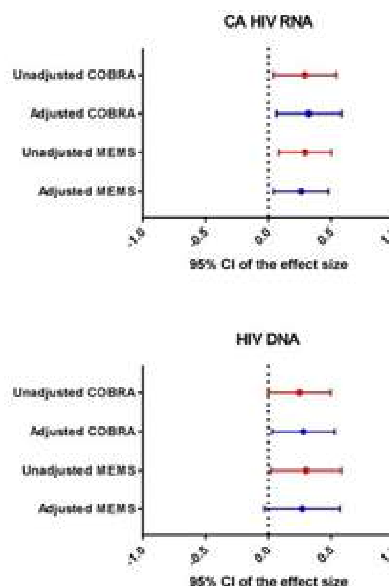
Methods: Cell-associated (CA) HIV unspliced RNA and total CA HIV DNA were quantified by seminested qPCR in two cohorts of PLWH (n=100, n=124; 11 PLWH participated in both cohorts 7 years apart) with suppressed HIV infection on a three-drug cART regimen consisting of two nucleoside reverse transcriptase inihibitors (NRTI) plus either one NNRTI or one (ritonavir-boosted) PI.

Variable	COBRA cohort (n=100)			MEMS cohort (n=124)		
	NNRTI (n=58)	PI (n=42)	P	NNRTI (n=88)	PI (n=36)	P
Age, years	55.0 (51.0-61.3)	55.5 (50.0-62.3)	0.97	46.6 (41.3-53.6)	43.6 (39.3-53.9)	0.17
Male gender, %	96.6	92.9	0.65	91.7	88.2	0.72
Current CD4+ count, cells/mm³	640 (511-796)	617 (408-782)	0.21	550 (368-798)	575 (470-745)	0.46
CD4+ count nadir, cells/mm³	180 (115-253)	200 (88-253)	0.92	150 (65-238)	155 (77.5-220)	0.78
Pre-therapy plasma viremia, log_{10} copies/ml	5.08 (4.71-5.52)	4.97 (4.44-5.52)	0.36	5.21 (4.68-5.62)	5.35 (4.96-5.97)	0.087
Duration of virological suppression, months	117.9 (68.1-151.0)	63.9 (32.8-120.0)	0.0043	45.4 (25.4-77.1)	23.2 (7.6-70.5)	0.039
Current plasma viremia <50 copies/ml, % (<400 copies/ml for all participants)	96.6	100.0	0.51	90.9	75.0	0.040

[Characteristics of PLWH treated with NNRTI- and PI-based cART regimens]

We compared CA HIV RNA and DNA between NNRTI- and PI-based cART using multivariate models adjusted for age, gender, current and nadir CD4+ count, pre-therapy plasma viremia, duration of virological suppression on cART before sampling, NRTI backbone composition, and low-level plasma viremia detectability. Generalized linear models on rank-transformed dependent variables were used.

Results: In the COBRA cohort, PLWH had a median of 99 months of continuous virological suppression prior to sampling. Median levels (Q1-Q3) of CA HIV RNA were 61 (39-194) and 225 (46-429) copies/μg total RNA in NNRTI- and PI-treated PLWH (n=58 and 42, respectively; P_{adj}=0.016), and the corresponding values of CA HIV DNA were 287 (64-428) and 395 (94-779) copies/10^6 PBMC (P_{adj}=0.028). These findings were validated in the MEMS cohort with a median of 41 months of continuous virological suppression. Levels of CA HIV RNA were 41 (15-97) and 76 (34-143) copies/μg total RNA in NNRTI- and PI-treated PLWH (n=88 and 36, respectively; P_{adj}=0.019), and those of CA HIV DNA were 228 (59-546) and 374 (177-866) copies/10^6 PBMC (P_{adj}=0.075).



[Unadjusted and adjusted associations of the cART regimen (PI vs. NNRTI) with CA HIV RNA and DNA levels in two cohorts. Effect sizes and 95% confidence intervals for HIV RNA are plotted as log_{10} copies per microgram of total cellular RNA and for HIV DNA as log_{10} copies per million cells. Effect sizes were obtained by fitting generalized linear models and adjusted for age, gender, current CD4+ count nadir, pre-therapy plasma viremia, duration of virological suppression on cART prior to the study, NRTI backbone composition, and low-level plasma viremia detectability.]

Conclusions: In both cohorts, levels of CA HIV RNA and DNA were lower in PLWH receiving NNRTI-based, compared to PI-based, cART regimens. As all current classes of antiretroviral drugs can only prevent infection of new cells but not inhibit HIV RNA transcription in infected cells, these results suggest that NNRTIs are more potent in suppressing HIV residual replication than PIs, resulting in a smaller viral reservoir size.

WEPEA024

HIV-1 Nef enhances the establishment and reactivation of inducible latent reservoirs

X.T. Kuang[1], S. Swann[1], S.W. Jin[1], T.M. Markle[1], M.A. Brockman[1,2]
[1]Simon Fraser University, Burnaby, Canada, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

Background: HIV-1 Nef modulates T cell signaling and may alter cellular activation status. To investigate Nef's role during establishment and maintenance of latency, we examined the proviral DNA integration site and reactivation efficiency of latent HIV+ T cell clones harboring functional or defective *nef* alleles.

Methods: Latent CEM-derived T cell clones (CLat) were generated using NL4.3ΔEnv viruses encoding Nef:GFP fusion ($WT_{SF2/M20A}$, G2A) or Nef-IRES-GFP ($WT_{NL4.3}$, ΔNef). The proviral integration sites were determined using nested-inverse PCR and sequencing, and characteristics of the genomic location were examined using BLAT (UCSC Genome Browser). Early (GFP+) and late (Gag-p24+) reactivation events were assessed by flow cytometry at 24h following treatment with LRA (TNF-, panobinostat, or prostratin). For selected CLat clones, the *nef* allele was disrupted using CRISPR/Cas9 strategies.

Results: We generated a panel of 95 inducible CLat clones with linked HIV integration site and viral reactivation data. The distribution and characteristics of proviral integration sites differed between clones encoding functional Nef (N=54) compared to defective Nef (N=42). The absolute number (and proportion) of unique integration sites was higher among clones encoding functional Nef (N=21, 39%) compared to defective

Nef (N=5, 12%) (P=0.005). Integration of inducible proviruses encoding functional Nef was modestly enriched in protein-coding genes that are expected to be less transcriptionally active. Clones with identical integration sites displayed similar viral reactivation phenotypes and were grouped for analysis. Following LRA treatment, early (GFP+) and late (Gag+) reactivation events were elevated in CLat clones encoding Nef_{SF2}:GFP compared to those encoding Nef_{G2A}:GFP. In addition, clones encoding ΔNef-IRES-GFP did not produce Gag efficiently after LRA treatment. We confirmed these observations by disrupting the *nef* gene in four CLat clones encoding Nef_{SF2}:GFP or Nef_{NL43}-IRES-GFP. The percent and intensity of Gag expression was reduced in all bulk Nef_{KO} cell lines. Variable reactivation phenotypes were observed in isolated Nef_{KO} clones, but the efficiency of reactivation remained notably lower in Nef_{KO} clones compared to their corresponding parental CLat clone.
Conclusions: Our results highlight Nef's ability to modulate HIV reactivation efficiency in response to LRAs. Data suggest that Nef broadens the repertoire of viable proviral integration sites to include less transcriptionally active genomic locations.

Host cellular factors and latency

Therapeutic prediction of HIV-1 DNA decay: A multicenter longitudinal cohort studyofchronically HIV-1-infected patients in China

Y. Yue, N. Wang, T. Li, W. Lv, Y. Liu, T. Lv, L. Lin, Y. Han, J. Xie, Z. Qiu, W. Cao, T. Geng, X. Song, X. Li, Y. Li, L. Luo, T. Zhu, M. Zou, L. Shi, S. Kang, F. Jing
Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: Factors predicting HIV-1 DNA reservoir size using total HIV-1 DNA in peripheral blood remain unclear in chronical infected patients under combination antiretroviral therapy (cART). Insufficient patient sample size and lack of accurate quantification methods are primary limitations for developing generalized diction models in the field.
Methods: Total HIV-1 DNA in blood at baseline, 12, 24, 48, and 96 weeks after cART initiation in 1,169 treatment-naïve patients with chronic HIV-1 infection were quantified. Generalized estimating equations and logistic regression methods were used to derive and validate predictive models with nine potential baseline predictors.
Results: With training data obtained from 307 patients who had continuously successful HIV-1 RNA suppression until 96 weeks after cART, we derived a logistic regression model with baseline total HIV-1 DNA and CD4+ T cell count. Such a model could predict patients who were with the low total HIV-1 DNA after 96 weeksof cART (< 100 copies/10^6 PBMCs) with a sensitivity of 80.0%, specificity of 69.7% and the area under the ROC curve of 0.795. With the Hosmer-Lemeshow test, the logistic model had acceptable goodness of fit (P = 0.225). The net reclassification improvement indies of using HIV-1 DNA or CD4+ T cell count alone were 0.08 and 0.31, respectively. We further used an independent and multicenter cohort of 300 patients to test the predictive capability of this model, and the sensitivity of 81.8% and specificity of 72.7% were achieved.
Conclusions: The derived model based on baseline total HIV-1 DNA and CD4+ T cell count provides a useful prognostic tool in predicting HIV-1 DNA reservoir control to a low level of< 100 copies/10^6 PBMCs during cART among chronically infected patients.

WEPEA026

The circadian transcription factors CLOCK and BMAL1 activate HIV transcription through binding to the HIV long terminal repeat

J. Stern[1], W.-J. Chen[2,3], C. Tumpach[1,2], L. Gray[2,3], M. Churchill[2,3,4], P.U. Cameron[1,5], S.R. Lewin[1,6], M. Roche[1,2]
[1]*The Peter Doherty Institute for Infection and Immunity, The University of Melbourne and Royal Melbourne Hospital, Melbourne, Melbourne, Australia,* [2]*School of Health and Biomedical Science, RMIT University, Melbourne, Australia,* [3]*Macfarlane Burnet Institute for Medical Research and Public Health, Melbourne, Australia,* [4]*Monash University, Department of Microbiology, Melbourne, Australia,* [5]*Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia,* [6]*Department of Infectious Diseases, Alfred Hospital and Monash University, Melbourne, Australia*

Background: During a recent clinical trial examining disulfiram as a latency reversing agent in HIV-positive individuals on antiretroviral therapy (ART), time-dependent variations were observed in the expression of cell associated unspliced HIV RNA (CA-US HIV RNA) in CD4+ T-cells isolated from blood. We hypothesised that circadian rhythms are exerting transcriptional control of latent HIV infection through direct interaction of the major circadian transcription factors CLOCK and BMAL1 with the HIV long terminal repeat (LTR).
Methods: The epithelial cell line, HEK 293T, were transfected with an HIV LTR-driven luciferase reporter construct in the presence and absence of CLOCK- and BMAL1-expression vectors. Activation of HIV-1 transcription was measured as an increase in luciferase expression. HIV LTR sequences containing mutations in each of the four E-boxes that could potentially bind CLOCK/BMAL1 complexes, were assessed individually or in combination. The latently infected reporter T-cell line, J-Lat Tat-IRES-green fluorescent protein (GFP) clone A2, were also transfected by nucleofection to deliver CLOCK- and BMAL1-expression vectors. Activation of HIV-1 transcription was measured as an increase in CA-US HIV RNA and GFP expression.
Results: Transfection of the HIV-LTR driven luciferase reporter construct into 293T resulted in high luciferase expression in the presence of Tat (17.13±2.03-fold induction). Transfection of CLOCK or BMAL1 alone failed to increase luciferase (1.26±0.06 and 1.22±0.09-fold induction, respectively), however, co-transfection of CLOCK and BMAL1 led to a significant increase in luciferase activity (3.56±0.25-fold induction). Mutation of E-boxes 1, 3, or 4 had no marked effect on luciferase expression following transfection of CLOCK/BMAL1, however, point mutations of E-box 2 led to a 68% reduction in luciferase expression. Similarly, the presence of CLOCK and BMAL1 together in J-Lat Tat-IRES-GFP cells led to a two-fold increase in both GFP expression and CA-US HIV RNA.
Conclusions: The major circadian transcription factors CLOCK/BMAL1 activate transcription from the HIV LTR, which specifically requires the presence of an intact E-box 2 motif. These data are consistent with direct binding of the protein complex to the LTR. CLOCK/BMAL1 could potentially be exploited to reverse HIV latency.

Cellular and tissue reservoirs of HIV/SIV

[1]University of Oxford, Peter Medawar Building for Pathogen Research, Nuffield Department of Medicine, Oxford, United Kingdom, [2]Imperial College, Division of Medicine, Wright Fleming Institute, London, United Kingdom, [3]Guys and St Thomas' NHS Trust, Department of Genitourinary Medicine and Infectious Disease, London, United Kingdom, [4]Chelsea and Westminster Hospital, London, United Kingdom, [5]National Institute of Health Research Biomedical Research Centre, Oxford, United Kingdom, [6]Oxford Martin School, Oxford, United Kingdom

Background: Initiation of antiretroviral therapy (ART) in early compared with chronic HIV infection is associated with a smaller HIV reservoir. Although both viral and immune factors may drive this effect, the role of T-cell immunity in primary HIV infection (PHI) is likely to be critical. In a large multi-parameter analysis, we investigated which pre- and post-therapy factors associate most closely with reservoir size following treatment initiation during PHI.
Methods: We studied 63 individuals (100% male; median age 34 [IQR 28-41] years) in the HEATHER cohort diagnosed with PHI and commencing ART a median of 49 [IQR 32-90] days from estimated seroconversion. Using flow cytometry, we measured the frequency of CD4 and CD8 memory subsets from PBMCs, expression of immune checkpoint receptors (PD-1, Tim-3, TIGIT), CD38 and transcription factors (T-bet and Eomes). Clinical parameters (CD4 count, CD8 count, plasma viral load [pVL]) were recorded. Total HIV DNA was quantified in CD4 T-cells by qPCR. Assays were performed on samples from the earliest available pre-therapy time-point (baseline) and one year following ART initiation. Multivariable linear regression (with variables selected by dimension reduction and machine learning techniques) was used to determine predictors of HIV DNA at one year.
Results: The best predictors of HIV DNA after one year on ART were found pre-therapy. These were pre-ART HIV DNA ($p< 0.0001$) and longer time from ART initiation to pVL suppression ($p=0.002$). Pre-therapy HIV DNA was significantly associated with the percentage of pre-ART effector memory (EM) CD8 T-cells ($p< 0.0001$) as well as pre-ART pVL ($p=0.02$). Higher expression of both CD38 and TIGIT on CD8 T-cells had significant positive independent associations with baseline HIV DNA. The percentage of EM CD8 T-cells was the only parameter that had a relationship with 1-year HIV DNA when measured contemporaneously, but not independently from baseline HIV DNA level.
Conclusions: Levels of HIV DNA after one year of ART are determined by virological and immunological factors prior to ART initiation. Reservoir size is specifically linked to pre-ART viral burden (baseline pVL and time to suppression) and CD8 T-cell activation, supporting the targeting of early stages of infection for interventions to reduce the HIV reservoir.

WEPEA028

More differentiated and senescent CD32+ cells are associated to hiv reservoir size

M. García[1,2], M.A. Navarrete-Muñoz[1,2], J. M Ligos[3], C. Restrepo[1,2], V. de Santisteban[1,2], A. Cabello[4], J.C. López-Bernaldo[5], F. de la Hera[4], C. Barros[6], M. Montoya[3], M. Fernández Guerrero[4], V. Estrada[7], M. Górgolas[4], J.M. Benito[1,2], N. Rallón[1,2]
[1]Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Universidad Autónoma de Madrid (IIS-FJD, UAM), Madrid, Spain, [2]Hospital Universitario Rey Juan Carlos, Móstoles, Spain, [3]Centro Nacional de Investigaciones Cardiovasculares, Madrid, Spain, [4]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [5]Hospital General Universitario Gregorio Marañon, Madrid, Spain, [6]Hospital Universitario de Móstoles, Móstoles, Spain, [7]Hospital Universitario Clínico San Carlos, Madrid, Spain

Background: The majority of cells harboring persistent HIV are contained in CD4 T-cells with particular phenotypes such as resting memory (TRM) or peripheral follicular helper (pTFH). However, few CD4 cells with these phenotypes are infected with HIV and the identification of a cellular marker associated with persistent HIV infection has remained elusive. Recently, a study has pointed out to CD32 as a potential surrogate biomarker of HIV-persistent CD4 cells. Herein, we have characterized the levels and phenotype of CD32+ cells contained in different CD4 T-cells subsets and its correlation with HIV-reservoir levels in HIV-infected patients.
Methods: Thirty HIV-infected patients were included: 10 typical progressors without ART (TP), 10 TP on ART (TX) and 10 elite controllers (EC). HIV-DNA content was quantified in two CD4 T-cells subsets: TRM and pTFH. CD32 along with activation, maturation, senescence, apoptosis and exhaustion markers were measured in TRM and pTFH by flow-cytometry. Differences between groups were tested by non-parametric tests and associations by Spearman´s rho coefficient.
Results: HIV-DNA levels in both TRM and pTFH subsets were lowest in EC and highest in TP ($p< 0.0001$ and $p=0.003$ for TRM and pTFH, respectively). However, there were no differences between different groups of patients in the level of CD32 expression neither in TRM ($p=0.128$) nor in pTFH ($p=0.627$) cells. Moreover, in the whole population of HIV-infected patients there was no significant correlation between the level of HIV-DNA and the level of CD32 expression neither in TRM (rho=0.259, $p=0.176$) nor in pTFH (rho=0.386, $p=0.092$) cells. However, in TRM the HIV-DNA level was significantly correlated with the level of CD57 (rho=0.511, $p=0.005$), CD28 (rho=-0,380, p=0,042) and CD127 (rho=-0,545, p=0,002) markers on CD32+ cells.
Conclusions: Our data suggest that among CD32+ cells, those with a more differentiated and senescent phenotype could be enriched in cells harboring persistent HIV. However our results do not support measurement of CD32 as a surrogate marker of reservoir size in HIV patients. Further studies with larger cohorts of patients are needed to validate these and previous results, including an analysis of certain markers expressed by CD32+ cells that could improve the utility of this marker in the clinical setting.

WEPEA029

HIV infection of *Schistosoma mansoni*

M. Bukrinsky[1], L. Dubrovsky[1], G. Rinaldi[2], V.H. Mann[1], S. Iordanskiy[3], W. Ittiprasert[1], P. Brindley[1]
[1]GWU SMHS, Washington, United States, [2]Cambridge University, Cambridge, United Kingdom, [3]USUHS, Washington, United States

Background: Schistosomiasis is a major helminthic disease affecting over 200 million people, mostly in developing countries in Africa, East Asia and South America. The areas where schistosomiasis is prevalent overlap with those affected by HIV epidemic, particularly in sub-Saharan Africa, but the interactions between these two infectious agents have not been characterized. We previously reported that VSV-G-pseudotyped HIV-1 can infect, reverse transcribe and integrate into the genome of *Schistosoma mansoni* (Suttiprapa et al., PLoS Pathog. 2016 12: e1005931), but the physiological relevance of this finding remained uncertain. We now provide evidence that wild-type HIV-1 can enter cells of *S. mansoni*, and that the contents of exosomes shed by the infected worms include HIV-related factors.

Methods: *S. mansoni* was infected with HIV-1 NL4-3 by spinoculation, 24 h later unbound virions were removed by extensive washing, and cells were maintained in culture for 10 days during which time culture supernatant was collected and replaced with fresh medium. Cell-associated viral DNA and RNA in schistosomes were assayed by qPCR, and release from the worms of p24 was measured by ELISA. Exosomes were collected from culture supernatants using Nanotrap-based enrichment, eluted from Nanotrap beads and analyzed by mass-spectrometry.
Results: HIV-specific DNA and RNA were detected in HIV-infected schistosomes for up to 10 days following exposure to wild type HIV virions and extensive washing, indicating that the virus entered the cells of the blood fluke and initiated reverse transcription. Curiously, heat inactivation (65°C or 72°C, 15 to 120 min) did not substantially reduce virus entry, but inhibited reverse transcription, suggesting that the entry was mediated by a gp120-independent mechanism. The cells of HIV-infected schistosomes produced products recognized by p24 ELISA for an extended period, at least seven days, suggesting transcriptional/translational activity of reverse transcription products. Analysis of exosomes released by HIV-infected schistosomes revealed the presence of HIV-related peptides, including Gag, Pol, Env, Tat and Nef, and TAR RNA.
Conclusions: These findings suggest that *Schistosoma mansoni* may be a reservoir of HIV-related pathogenic factors. If so, this reservoir would be insensitive to anti-HIV drugs and may contribute to persistent pathological impact in people co-infected with schistosomes and HIV.

Quantifying HIV/SIV reservoirs and rebounding virus

WEPEA030

Remarkable stability in size and composition of the latent reservoir over two decades of ART

K. Bosman[1], K. Tesselaar[2], J. Arends[3], J. Borghans[2], D. de Jong[1], S. Otto[2], T. Huisman[4], A. Pandit[2,4], R. de Boer[4], A. Hoepelman[3], A. Wensing[1], M. Nijhuis[1]
[1]Department of Medical Microbiology, Virology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Department of Immunology, Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands, [3]Department of Internal Medicine and Infectious Diseases, University Medical Center Utrecht, Utrecht, Netherlands, [4]Theoretical Biology, Utrecht University, Utrecht, Netherlands

Background: Despite suppression of replication by antiretroviral therapy (ART), HIV persists as a DNA reservoir which forms the major obstacle to HIV cure. The relative contribution of T-cell subsets to the viral reservoir over decades of ART is currently unknown. It has been postulated that over time the viral reservoir will shift towards the most differentiated T-cell subsets ("push and vanish").
Methods: Blood samples were obtained from 7 patients who are effectively suppressed with ART since 1996. Samples were taken at ART initiation and 1, 10 and 20 years post-initiation. PBMCs from large blood draws (500 mL) 10 and 20 years post-initiation were sorted into naive (Tn), central memory (Tcm), transitional memory (Ttm) and effector memory (Tem) CD4+T-cells. HIV DNA in PBMCs and T-cell subsets was quantified using a digital droplet PCR (ddPCR) assay targeting the HIV-LTR region.
Results: In the first year of ART, a significant reduction in the average HIV DNA load in PBMCs was observed (from 3260 to 794 LTR copies/10^6, p=0.018). After the first year of ART, HIV DNA remained stable for two decades (1039 LTR copies/10^6 after 10 years and 1027 LTR copies/10^6 after 20 years). Taking into account differences in T-cell subset abundance, contributions of Tcm and Ttm to the total reservoir were significantly higher than Tn and Tem ($p < 0.001$) and did not change over time. Tem infection frequency was higher (average 6633 LTR copies/10^6) than other T-cell subsets (952, 3424, and 4211 for Tn, Tcm and Ttm, respectively) and these differences remained unaltered over time. Tem infection frequency was negatively correlated with CD4-count at ART-initiation (p=0.048) whereas Tn, Tcm and Ttm infection frequencies negatively correlated with CD4-count at sampling (p = 0.023, 0.024, 0.031, respectively).
Conclusions: HIV DNA levels in PBMCs do not decline after the first year on ART. T-cell subset infection frequencies and contributions to the total reservoir were also stable over 20 years of ART. These observations indicate that treatment alone does not shift the viral reservoir towards the most differentiated T-cell subsets as was anticipated in the so-called "push and vanish" eradication strategy.

WEPEA031

Development of sensitive ddPCR assays to reliably quantify the proviral DNA reservoir in common circulating HIV clades

K. Bosman, D. de Jong, A. Wensing, M. Nijhuis
Department of Medical Microbiology, Virology, University Medical Center Utrecht, Utrecht, Netherlands

Background: The latent reservoir is the main barrier towards HIV cure and success of eradication strategies is often measured by quantification of proviral DNA. To ensure inclusiveness and representativeness in HIV cure studies, proviral DNA quantification assays that are able to detect all common circulating HIV clades, in addition to subtype B are needed. Here, three HIV DNA assays targeting three different genomic regions were evaluated for their sensitivity and subtype-tolerance using digital PCR.
Methods: A subtype-B-specific assay targeting Gag (GAG) and two assays targeting conserved sequences in LTR and Integrase (LTR and JO) were assessed for their sensitivity and subtype-tolerance in digital PCR (Bio-Rad QX200) using a panel of serially diluted subtype reference plasmids as well as a panel of clinical isolates. Both panels represent subtypes A, B, C, D, F, G and circulating recombinant forms (CRFs) AE and AG, which together are responsible for 94% of HIV-infections worldwide.
Results: HIV subtype was observed to greatly affect HIV DNA quantification results. Robust regression analysis of the serially diluted plasmid panel showed that the GAG assay was only able to linearly quantify subtype B, D and G isolates (4/13 reference plasmids, average R^2=0.99), whereas LTR and JO were able to quantify all tested isolates (13/13 reference plasmids, respective average R^2=0.99 and R^2=0.98). In the clinical isolates panel, isolates were considered detectable if at least 2 out of 3 replicates produced a positive result. The GAG assay could detect HIV DNA in 4 out of 5 subtype B, 1 out of 3 subtype C, both subtype D and 1 out of 2 subtype G isolates, whereas the LTR and JO assays detected HIV DNA in all 29 tested isolates. LTR and JO results were found to be equally precise but more precise than GAG (Welch t-tests on coefficient of variation).
Conclusions: The presented results demonstrate the need for careful validation of proviral reservoir quantification assays prior to investigations of non-B subtype reservoirs. The LTR and JO assay can sensitively and reliably quantify HIV DNA in a panel of the world-wide most prevalent subtypes, justifying their application in future HIV trials.

Developing strategies to image HIV in vivo: Combining the sarcophagine chelator MeCOSar to 3BNC117 does not affect HIV binding or neutralisation

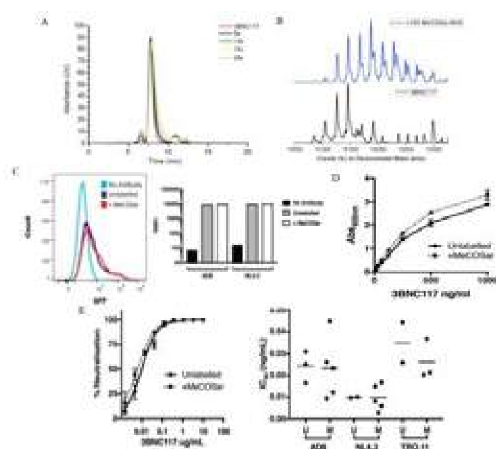
J.H. McMahon[1], C. Tumpach[2], J.L. Lange[3], M. Roche[2], K. Alt[3], J.M. Zerbato[2], J. Chang[2], N. Zia[4], M. Caskey[5], M. Nussenzweig[5,6], A. Scott[7], P.S. Donnelly[4], C.E. Hagemeyer[3], S.R. Lewin[1,2]

[1]Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia, [2]The Peter Doherty Institute for Infection and Immunity, University of Melbourne and Royal Melbourne Hospital, Melbourne, Australia, [3]Australian Centre for Blood Diseases, Monash University, Melbourne, Australia, [4]School of Chemistry, Bio21 Molecular Science and Biotechnology Institute, University of Melbourne, Melbourne, Australia, [5]Laboratory of Molecular Immunology, The Rockefeller University, New York, United States, [6]Howard Hughes Medical Institute, The Rockefeller Universit, New York, United States, [7]Olivia Newton John Cancer Research Institute, Austin Health and Latrobe University, Melbourne, Australia

Background: Non-invasive methods to detect and quantify HIV persistence in tissue and assess cure-focused interventions in HIV-infected individuals on antiretroviral therapy (ART) are needed. Infusing radiolabelled broadly neutralising antibodies (bNAbs) targeting HIV envelope (Env) then scanning with positron emission tomography (PET) identified affected tissues sites in a macaque model. Prior to a clinical trial bNAb binding to its Env target with the addition of a next generation bifunctional chelator needs to be confirmed *in vitro*.

Methods: The bNAb 3BNC117 was reacted with different molar ratios (5x, 10x, 15x, 20x) of the sarcophagine copper chelator MeCOSar-NHS and the resulting conjugates were assessed by size exclusion chromatography (SEC) and liquid chromatography-mass spectrometry (LC-MS) and the optimal molar ratio selected. Unlabelled and MeCOSar-modified 3BNC117 were then assessed for neutralisation capability of reporter viruses pseudotyped with 3 subtype B Env strains in JC53 cells, and assessed for binding using 2 assays: 1) ELISA to immobilised Env (gp140) and 2) to Env presented on the surface of human embryonic kidney cells transfected with an Env expression plasmid. The 50% inhibitory concentration, colorimetric absorbance and flow cytometry were used to compare unlabeled and MeCOSar-modified 3BNC117 to the 3 assays respectively.

Results: Different molar ratios of MeCOSar bound to 3BNC117 yielded SEC with similar elution profiles to IgG and unmodified 3BNC117. The predominant peak for unmodified 3BNC117 mass on LC-MS was 151467 Dalton (Da) and when combined with 10x molar ratio clearly demonstrated the addition of 1, 2 and 3 MeCOSar (410 Da each) per 3BNC117. 10x molar ratio was then selected to assess HIV binding and neutralization. Unlabeled and MeCOSar-modified 3BNC117 had comparable levels of binding to immobilized gp140; binding to Env expressed on the surface of 293T cells; and neutralisation of reporter viruses pseudotyped with 3 different Envs.



[Figure. Modification of 3BNC117 using a 10x molar ratio MeCOSar does not interfere with 3BNC117 neutralisation or binding in vitro. A) SEC of unlabeled and MeCOSar modified 3BNC117; B) LC-MS of unlabeled (bottom) and modified 3BNC117 bound with either one, two or three MeCOSar chelators attached (top); C) Flow cytometry of transfected cells expressing cell surface Env bound to unlabeled or Mecosar modified 3BNC117; D) Env ELISA assay; E) Neutralisation assay (U=unlabeled, M=MeCOSar)]

Conclusions: The copper chelator MeCOSar conjugates to 3BNC117 and does not interfere with binding to HIV Env or neutralisation *in vitro*. MeCOSar is appropriate to combine with 3BNC117 and is known to tightly bind the radioisotope copper-64. This construct is ideally suited to continue development for use in a clinical trial using PET to detect HIV persistence on ART.

Impact of co-factors (e.g. viral clade, tropism, genetic factors) on disease progression

WEPEB033

Cardiac vagal tone is low in HIV+ women and correlates with markers of immune activation/inflammation

K.M. Weber[1], L. McClellan[1], C. Bond[1], E. Daubert[1], A.L. French[2], M.H. Cohen[3]

[1]Hektoen Institute of Medicine, Chicago, United States, [2]Stroger Hospital of Cook County, Department of Infectious Diseases, Chicago, United States, [3]Cook County Health and Hospitals System and Rush University Medical Center, Department of Medicine, Chicago, United States

Background: Respiratory sinus arrhythmia (RSA), the high frequency component of heart rate variability, is widely used as a noninvasive measure of vagal tone representing parasympathetic influence on cardiac regulation. Lower RSA has been associated with female sex, older age, viral infection, and inflammation. We therefore sought to determine whether RSA differs by HIV and viral suppression status and its association with inflammatory/immune activation markers among midlife HIV-infected (HIV+) and demographically similar uninfected (HIV-) women.

Methods: Between October 2014 and February 2016, we collected 45 minutes of continuous ECG recordings using the Actiwave monitor across 5 consecutive rest and challenge conditions from 107 HIV+ and 47 HIV- Chicago Women's Interagency HIV Study (WIHS) participants. Cardiac data was edited and RSA calculated using proprietary software. RSA was quantified during sequential 30-second epochs within each 3-minute rest period, averaged, and then the mean of all resting RSA values was used in analyses. Descriptive variables and blood were collected during same day WIHS visits. Plasma ultra sensitive (us)CRP, usIL-6, TNFaRII, soluble (s)CD14 and sCD163 were measured using commercial ELISA. We evaluated correlations between RSA, HIV/viremia status, and plasma biomarkers.

Results: Women were predominantly black (85%), age 40-59 (69%), poor (76% ≤ $18k), unemployed (73%), obese (44%), current smokers (56%) with limited education (40% < high school) and unstably housed (28%) with no significant difference by HIV status. Among HIV+ women, 77% were on HAART/≥95% adherent; 24% were viremic. Resting mean (m)RSA was significantly lower in HIV+ compared to HIV- women (4.92 vs. 5.47; p=.03) but there was no statistically significant RSA difference by viremia status. Lower mRSA among HIV+ women significantly correlated with higher sCD14 and TNFaRII (r^2 .053, .057 respectively, both p=.01) and this correlation was strongest for viremic women (r^2 .227; p=.014 for sCD14; r^2 .309; p=.003 for TNFaRII).

Conclusions: In midlife women, cardiac vagal tone is lower in HIV+ women. Lower cardiac vagal tone appears to interact with HIV leading to higher levels of immune activation/inflammation. Assessing RSA and promoting interventions to strengthen cardiac vagal tone (ie. exercise, deep breathing, yoga) may benefit women aging with HIV.

WEPEB034

Impact of antirretroviral treatment on low level viremia in HIV infected patients

E. Bernal[1], A. Cano[1], J.M. Gomez[1], A. Alcaraz[1], A. Muñoz[1], S. Moreno[2], M. Montero[3], J. Peraire[4], G. Sanperiz[5], F. Gutierrez[6], CoRIS
[1]Hospital Reina Sofia, Murcia, Spain, [2]Hospital Ramón y Cajal, Madrid, Spain, [3]Hospital La Fe, Valencia, Spain, [4]Hospital Joan XXIII, Tarragona, Spain, [5]Hospital Miguel Servet, Zaragoza, Spain, [6]Hospital General de Elche, Elche, Spain

Background: There are patients where complete control of viral load is not achieved. The causes of low-grade viremia (LLV) are still unknown. The objetive was to assess the impact of antiretroviral therapy (ART) on LLV in suppressed HIV infected patients.

Methods: We analyzed adults, naïve to ART from the cohort of the Spanish-AIDS Research-Network (CoRIS) who initiated ART from 2004 to 2015 and achieved viral load (VL) ≤50 copies/ml within 3-9 months after ART initiation. LLV50-199 was defined as two consecutive VL between 50 and 199 copies/ml, and LLV200-499 as two consecutive VL between 50-499 copies/ml with at least one between 200-499 copies/ml. To assess the effect of ART we used an intent-to-treat approach and, thus, ignored subsequent changes in treatment, including treatment interruptions and terminations.

ART were divided into 4 categories:

(1) 2Nucleoside-Reverse Transcriptase Inhibitor (NRTI) +1Non-Nucleoside-Reverse Transcriptase Inhibitor (NNRTI),

(2) 2NRTI+1Protease inhibitor boosted with ritonavir/cobicistat (PI),

(3) 2NRTI+1Integrase inhibitor (II), and

(4) other.

Cox-regression model was used to estimate the association of ART and LLV after adjusting.

Results: Of 5986 patients included, 237 (4.0%) experienced at least one episode of LLV50-199 and 168 (2.8%) experienced LLV200-499. Median follow-up time was 3.5 (IQR: 1.5 - 5.5) years in patients not experiencing LLV, 4.9 (IQR: 3.5 - 7.2) in patients experiencing LLV50-199 and 6.3 (IQR: 4.8 - 8.3) in those experiencing LLV200-499.

In multivariable analyses, HIV viral load at cohort entry higher than 100.000 copies/ml [Relative risk (RR): 2.15; 95% confidence interval (CI): 1.47 - 3.1], male gender (RR: 2.2; CI95% 1.2-3.9) and ART regimen with 2NRTI+1PI/p (RR: 1.61; 95% CI 1.1-2.34) were associated with LLV50-199 copies/ml. ART regimen with 2NRTI+1PI (RR: 2.15; 95% CI 1.37-3.37) was associated with LLV200-499 copies/ml. PI regimens based on darunavir boosted with ritonavir/cobicistat (DRV) were compared to those containing PI other than DRV. After adjusting, DRV based regimens were not associated with LLV (RR: 0.16; CI95% 0.03-0.75).

Conclusions: In this Spanish cohort, the specific ART regimen was an independent risk factor for the development of low-level viremia. High viral load at cohort entry, male gender and ART regimens based on protease inhibitors other than darunavir had the highest risk.

WEPEB035

Toll-like receptor 4 polymorphism influence the faster HIV progression

T. Koval[1], G. Dubynska[1], O. Danilenko[2], E. Sabinina[2], A. Koval[1]
[1]Ukrainian Medical Stomatological Academy, Infectious Diseases and Epidemiology, Poltava, Ukraine, [2]Poltava Regional HIV/AIDS Center, Poltava, Ukraine

Background: Toll-like receptors (TLRs) play an impotant role in the innate immune response. The TLR4 is an essential component of the innate immune response to various microorganisms. We investigated the impact of TLR4 polymorphism on rapid CD4 decline and development of AIDS defining illness.

Methods: The presence of TLR4 Asp299Gly single nucleotide polymorphisms was determined in a cohort of 194 antiretroviral treatment-naive HIV-1 infected patients TLR4 genotyping was performed by real-time PCR. We used survival analysis (Cox regression). Two outcome measures related to faster HIV progression were considered - decline CD4 cells to < 350/ml and occurrence of AIDS defining illness.

Results: One hundred seventy-six patients were homozygous for the wild-type genotype (AA); 18 patients (9,3%) were heterozygous for the Asp299Gly (AG).

Faster development of AIDS was associated with Asp299Gly TLR4 polymorphism (HR= 3.45; 95% CI [1.22-8.25]), nadir CD4 count< 350/ml (HR= 4.15; 95% CI [2.25-9.38]) and duration HIV-infection>3 years. Faster decline of CD4 count to < 350/ml was associated with age>35 years (HR=4.15; 95% CI [2.16-7.16]), intravenous drugs abuse (HR= 2.85; 95% CI [1.54-6.17]) and Asp299Gly TLR4 polymorphism (HR= 2.23; 95% CI [1.05-9.22]).AG polymorphism was associated with more frequent development of the opportunistic infections, such as active tuberculosis (OR= 5.71; 95% CI [3.92-12.44]), herpes zoster (OR= 2.83; 95% CI [1.11-5.19]) and toxoplasmosis (OR= 6.23; 95% CI [1.19-18.67]) compared with genotype AA.

Conclusions: This study suggests a greater risk of developing of faster HIV-progression in patients with the Asp299Gly TLR4 polymorphism.

WEPEB036

Interferon lambda polymorphisms associated with normalised CD4+:CD8+ in treated HIV

W. Tinago[1], I. Freitas[2], H. Sawa[3], W. Hall[2], M. Carr[3], P. Mallon[4]
[1]University College Dublin, School of Medicine, Dublin, Ireland, [2]University College Dublin, Centre for Research in Infectious Diseases, School of Medicine, University College Dublin, Dublin, Ireland, [3]Hokkaido University, Global Station for Zoonosis Control, Global Institution for Collaborative Research and Education (GI-CoRE), Hokkaido University, Sapporo, Japan, [4]University College Dublin, HIV Molecular Research Group, School of Medicine, University College Dublin, Dublin, Ireland

Background: Type III interferon lambda (IFNL) members play important roles in both innate and adaptive immunity against viral pathogens, promoting a shift from Th2 to Th1 responses. Single nucleotide polymorphisms (SNPs) at the IFNL locus have been associated with treatment-induced and spontaneous clearance of hepatitis C virus (HCV) infection; however, whether INFL polymorphisms impact on host immune responses to HIV-1 infection remains unclear.

Methods: In a prospective cohort of ambulatory, HIV-1 positive subjects on effective antiretroviral therapy (ART) with HIV RNA < 40 copies/ml, we examined expanded T-cell subsets by flow cytometry on fresh EDTA blood to determine CD4+ and CD8+ T-cell subsets; CD45RO+CD62L+ (central memory), CD45RO+CD62L- (effector memory) and CD45RO-CD62L+ (naïve) alongside absolute and percentage CD4+ and CD8+ counts. Genomic DNA was extracted from stored buffy coats and IFNL genotyping performed for the following IFNL SNPs by allelic discrimination real-time PCR: rs368234815[TT/ΔG], which introduces a frameshift permitting IFNL4 expression; rs117648444[G/A], which gives rise to a P70S substitution in IFNL4 and rs12979860[C/T], which lies in an IFNL4 intron and is in moderate to high linkage disequilibrium with rs368234815. We explored associations between specific SNPs and CD4+:CD8+ ratio normalisation (>1) and specific CD4+ and CD8+ T-cell subsets using linear regression analysis.

Results: Of 143 subjects, 63.6% were male, 65.7% Caucasian and 23% had a CD4+:CD8+ ratio ≥1. The majority of subjects were on ART (90.2%) and 79% of the cohort had undetectable HIV RNA. Subjects with rs368234815 ΔG/ΔG minor homozygosity were significantly more likely to attain a CD4+:CD8+ ratio ≥1 (OR [95% CI] 3.11 [1.01;9.56]). In a subset of 71 HCV antibody negative, virally suppressed PLWH, rs368234815 minor homozygosity (ΔG/ΔG) was significantly associated with a higher percentage of naïve CD8+ T-cells (regression coefficient: 7.17, $p < 0.05$) compared to the T/T genotype.

Conclusions: This, the first study to report associations between type III IFNs and immunological responses in chronic HIV, suggests an important role for host IFNL4 function in driving better immune responses to ART.

Morbidity, mortality and life expectancy in clinical research

WEPEB037

High inpatient mortality from tuberculosis persists despite increasing antiretroviral therapy coverage in Botswana

T. Barak[1,2,3], D. Neo[4], T. Neo[2,5], P. Mophuthegi[2], R. Zash[2,6], M.R. Hacker[4,7], K. Kalenga[1], J. Makhema[2], S. Lockman[2,8], R. Shapiro[2,6,8]
[1]Scottish Livingstone Hospital, Molepolole, Botswana, [2]Botswana-Harvard AIDS Institute Partnership, Gaborone, Botswana, [3]Beth Israel Deaconess Medical Center, Department of Medicine, Boston, United States, [4]Beth Israel Deaconess Medical Center, Department of Obstetrics and Gynecology, Boston, United States, [5]Brigham & Women's Hospital, Department of Medicine, Boston, United States, [6]Beth Israel Deaconess Medical Center, Infectious Disease, Boston, United States, [7]Harvard Medical School, Department of Obstetrics, Gynecology and Reproductive Biology, Boston, United States, [8]Harvard T.H. Chan School of Public Health, Immunology and Infectious Disease, Boston, United States

Background: In Botswana, where adult HIV prevalence is 22%, antiretroviral therapy (ART) coverage reaching 84% has reduced HIV/AIDS-related mortality. However, few ART-era studies describe mortality in the hospital setting, where most deaths occur. Our objective was to describe mortality by HIV status among medical inpatients at Scottish Livingstone Hospital (SLH), a district hospital in Botswana.

Methods: We prospectively reviewed admissions to the SLH medical wards and recorded outcomes from December 2015-July 2017. We compared data with chi-square or t-test and evaluated risk factors for mortality using modified Poisson regression to estimate risk ratios and 95% confidence intervals, adjusting for age and sex. Results were compared with similar 2011-2012 SLH surveillance data.

Results: 2,108 admissions occurred among 1,803 patients; 42% of patients were HIV+, 46% were HIV-, and 12% had unknown HIV status. Compared with HIV- patients, HIV+ patients had similar sex (47% male), younger age (mean 44 vs. 59 years, p< 0.0001), and fewer comorbidities (p< 0.001). In total, 424 (20%) admissions resulted in death, and death was more common among HIV+ patients (22% vs. 18%, p=0.03). Table 1 shows risk factors for death per admission among HIV+ patients. Clinical or laboratory diagnosis of tuberculosis was associated with the highest mortality in both groups, but accounted for a higher proportion of deaths among HIV+ patients (43%) compared with HIV- patients (21%; p< 0.001). Bacterial pneumonia and gastroenteritis were the next most common diagnoses associated with mortality among HIV+ patients, compared with heart failure and cerebrovascular events in HIV- patients. Compared with similar surveillance at SLH in 2011-2012, HIV prevalence was lower (43% vs. 48% of admissions, p=0.02), and amongst HIV+ admissions: ART coverage was higher (66% vs. 52%, p< 0.0001), mortality was similar (22 vs. 23%, p=0.9), tuberculosis diagnoses increased (27% vs. 20%, p< 0.01) and tuberculosis mortality was higher (36% vs. 25%, p=0.05).

[Table 1. Risk factors for death per admission among HIV+ patients at Scottish Livingstone Hospital, Botswana, 2015-2017]

Conclusions: Despite high ART coverage in Botswana, HIV+ patients continue to be disproportionately represented among hospital admissions and deaths. Deaths from tuberculosis appear to contribute to lack of reduction in inpatient mortality. Our findings suggest that control of HIV and tuberculosis remain top priorities for reducing inpatient mortality in Botswana.

WEPEB038

Drug overdose is the most common cause of death among HIV infected people in Estonia

L. Lemsalu[1,2], A. Uusküla[2], B. Rice[3], M. Raag[2], K. Rüütel[1]
[1]National Institute for Health Development, Tallinn, Estonia, [2]University of Tartu, Institute of Family Medicine and Public Health, Tartu, Estonia, [3]London School of Hygiene and Tropical Medicine, Department of Social and Environmental Health Research, London, United Kingdom

Background: In Estonia, the HIV epidemic started with an outbreak among people who inject drugs in the early 2000s. Few people were diagnosed with HIV before year 2000 (n=96). According to national statistics, 606 people with HIV have died since 1994. Through linking data across healthcare registries, we aim to attain a more comprehensive understanding of mortality among persons diagnosed with HIV.

Methods: All healthcare records including an HIV diagnosis and a national identification-code were extracted from the following databases and periods: Estonian Health Insurance Fund (EHIF) (covers >94% of the population), 2000-2016; Health Board (passive HIV surveillance), 2010-2016; Prisons healthcare, 2008-2016. Data on deaths were obtained from the national Death Registry (main cause of death was analysed). Survival is calculated from the person's first HIV related healthcare record (date of the new HIV case report or the first HIV related healthcare visit).

	ICD-10	Deaths		Age at death		Survival since HIV presentation (in years)	
		N	*%*	*Median*	*IQR*	*Median*	*IQR*
Cancers	B21,C00-D48	118	7.1	41.0	31.9 - 52.1	2.4	0.5 - 5.5
Cardiovascular diseases	I00-I99	97	5.8	45.6	34.2 - 68.8	3.2	1.5 - 6.2
Infectious and parasitic diseases	A00-B99 (excl. B15-B19, B21-24,B94.2), J09-J18	322	19.2	34.4	28.5 - 41.7	1.5	0.2 - 4.1
Hepatic and liver diseases	B15-B19, B94.2, K70-K76	91	5.4	33.3	30.0 - 41.1	2.9	1.0 - 6.2

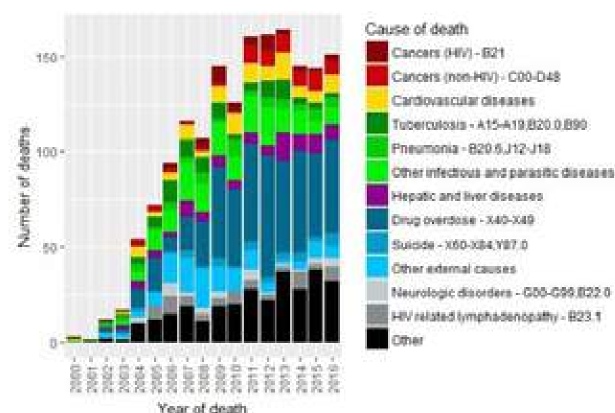
[Table. Causes of death among HIV diagnosed people in Estonia in 2000 - 2016]



[Figure. Annual cause specific number of deaths among HIV diagnosed people in Estonia in 2000-2016]

Results: Between 2000 and 2016, we identified 7518 people with an HIV diagnosis. Among these, 47% (n=4733) were men, median age at HIV presentation was 28.1 years (IQR 23.4 - 35.2), 72% (n=5380) presented with HIV at the clinical latency stage (ICD-10 B23.1, Z21), and 19% (n=1418) with

Author Index

AIDS (ICD-10 F02.4, B20-B24, excl. B23.0, B23.1). Median follow-up time from the first HIV related healthcare record until death or 31/12/2016 was 6.9 years (IQR 3.2 - 10.0). Almost one quarter (22%; n=1673) of those diagnosed with HIV died during the study period (men: 26%, n=1252; women: 15%, n=421). Shortest survival from HIV presentation was associated with death due to infectious and parasitic diseases. Over one third of deaths were attributable to external causes claiming the youngest people (Table). The most prevalent external cause of death was drug overdose (Figure).
Conclusions: For the first time, we present a comprehensive overview of mortality among HIV diagnosed people in Estonia. Our results show that the national statistics has captured only one third of the deaths. Drug overdose was the most common cause of death, especially affecting people aged under 35. Effective drug treatment services, which are integrated with HIV care, are of outmost importance to curb mortality among people living with HIV in Estonia.

Opportunistic infections (excluding TB)

WEPEB039

Incidence, timing and outcome of IRIS in relation to specific opportunistic infections - the ATHENA cohort study

I.E.A. Wijting[1], F.W.N.M. Wit[2], C. Rokx[1], M.E. van der Ende[1], P. Reiss[2], B.J.A. Rijnders[1], on behalf of the ATHENA national observational HIV cohort
[1]Erasmus MC, Rotterdam, Infectious Diseases, Rotterdam, Netherlands, [2]AMC, Stichting HIV Monitoring and Department of Global Health and Division of Infectious Diseases, Amsterdam, Netherlands

Background: Immune Reconstitution Inflammatory Syndrome (IRIS) is a pathological immune response against antigens of opportunistic infections (OI). However, comparative data on incidence, timing, and outcome of IRIS in relation to the specific OI present are lacking.
Methods: Observational study in the ATHENA-cohort. IRIS case-finding by chart review was done for all cART-naïve patients starting cART between 03-2009 and 03-2017 if they were considered at risk for IRIS according to the following criteria: (1) pre-cART CD4 < 200 cells/mm³ and (2) either an OI diagnosis before or shortly after cART initiation, or died, or received systemic corticosteroids < 12months after cART initiation. IRIS was defined according to predefined criteria as described by French et al. We evaluated the risk for developing IRIS for the following OIs: PCP, TB, MAC, CMV, Kaposi's sarcoma (KS), cerebral toxoplasmosis (Toxo), and cryptococcal meningitis (CM). We also evaluated the risk of receiving corticosteroids, (re)hospitalization, and mortality after cART-initiation in patients diagnosed with and without IRIS.
Results: We identified 672 patients at risk for IRIS with a median CD4 count of 34 cells/mm³ and 1.5 OI per patient at HIV-diagnosis; 75 (11.2%) developed IRIS. Compared with the overall study population, those diagnosed with MAC (OR 5.59 (95%CI 2.43-12.82), p< 0.001), TB (OR 2.53 (1.23-5.19), p=0.01), and CM (OR 3.21 (1.11-9.27), p=0.03) were at increased risk of IRIS while those diagnosed with PCP, KS, Toxo, or CMV were not. Patients with IRIS were (re)hospitalized more often (OR 2.78 (1.66-4.65), p< 0.001) and longer (+6 days) and tended to receive corticosteroids more often (OR 1.67 (0.95-2.94), p=0.08). The overall 1-year mortality in patients with or without a IRIS was comparable (9.3% versus 9.5%). The median time after cART initiation at which IRIS was diagnosed was 58, 51, 47, 33, 31, 29, and 11 days for IRIS related to KS, MAC, TB, CM, Toxo, CMV, and PCP (p=0.02).
Conclusions: Compared with other OIs, MAC, TB, and CM were associated with an increased risk of IRIS. Furthermore, IRIS was associated with an increased risk for (re)hospitalization but not associated with mortality. IRIS in patients with PCP was diagnosed earlier than IRIS observed with other OIs.

WEPEB040

Successful discontinuation of itraconazole for secondary prophylaxis of talaromycosis in patients with HIV in Myanmar

N.N. Tun[1,2], A. McLean[3], X. Carr-Deed[4], Z.M. Tun[4], M.M.M. Hlaing[4], Y.Y. Aung[4], E. Wilkins[4], E. Ashley[5], F. Smithuis[4,5]
[1]Medical Action Myanmar, Medical Coordination Department, Yangon, Myanmar, [2]Myanmar Oxford Clinical Research Unit, HIV/TB Research Unit, Yangon, Myanmar, [3]Myanmar Oxfor Clinical Research Unit, Yangon, Myanmar, [4]Medical Action Myanmar, Yangon, Myanmar, [5]Myanmar Oxford Clinical Research Unit, Yangon, Myanmar

Background: Talaromycosis (formerly Penicilliosis) is an important AIDS defining opportunistic infection and cause of death in HIV patients in Southeast Asia. Typical manifestations include fever, weight loss, umbilicated skin lesions and lymphadenopathy. Medical Action Myanmar is a medical organization which operates four HIV clinics in Yangon suburbs under the National AIDS Program. This analysis aimed to describe the characteristics and treatment outcomes of patients clinically identified with Talaromycosis.
Methods: We conducted a retrospective cohort analysis of patients identified with Talaromycosis among HIV patients between June 2009 and June 2017. The diagnosis was made clinically, where possible it was confirmed by Giemsa stained skin-slit smear. Most patients were treated with amphotericin for 2 weeks, followed by itraconazole (400 mg od) for 8-10 weeks, and itraconazole (200mg od) for secondary prophylaxis until the patient is stable on HAART for more than 1 year with a CD4 count greater than 100 cells/ul.
Results: Among 5,466 HIV patients, 46 patients were diagnosed with Talaromycosis. The skin smear was positive in 39 (85%) patients. Median CD4 was 24 (IQR: 14-40), 34 (74%) of patients were male (53% of all HIV patients were male) and 29 (63%) were diagnosed with Talaromycosis before starting HAART. The most common clinical findings at presentation were anaemia (92%), umbilicated skin papules (85%), and hepatomegaly (65%). Median temperature at presentation was 38 (IQR: 37.3-39.0). 31 (67%) patients were receiving TB treatment at Talaromycososis presentation. Median amphotericin treatment length was 14 days (IQR: 13-14 days) and median itraconazole treatment length was 329 days (IQR: 195-455 days).
9 (20%) patients died, with a median time to death of 106 days (IQR: 94-168 days). 33 (72%) patients recovered from illness. Median follow up of all patients was 2.9 years (IQR: 0.8-5.5 years). 25 patients discontinued secondary prophylaxis and none of these patients experienced a relapse (total person years after discontinuation of secondary prophylaxis = 75.2; median 2.2 (IQR=1.6-5.6).
Conclusions: Secondary prophylaxis was stopped in 25 patients without negative consequences. This finding contributes to the mounting evidence that secondary prophylaxis can be discontinued safely after patients are immunologically reconstituted.

Tuberculosis

WEPEB041

Utility of gene Xpert MTB/RIF as a screening assay for tuberculosis in HIV-infected patients from a rural setting of Rakai district, Uganda

R. Muwanika
Rakai Health Sciences Program, Laboratory, Kalisizo, Uganda

Background: The current practice in Uganda is that all HIV-infected patients are screened for tuberculosis. The use of gene Xpert MTB/RIF in Uganda has been extended to a hub Laboratory system at the district level as the point of care testing. We sought to evaluate the utility of gene Xpert MTB/RIF as screening assay for HIV infected patients.
Description: We reviewed gene Xpert MTB/RIF Laboratory test records for Rakai district from April 2014 to May 2017 for 36 health facilities. All facilities collected sputum samples from HIV infected patients and

referred them through a trained sample transporter to the district hub Laboratory for testing.

Lessons learned: Among the 1221 sputum samples collected, 1163 (95.3%) were smear microscopy negative while 58 (4.7%) were smear microscopy positive. All the samples were forwarded for gene X-pert testing. Among the 1163 smear negative presumptive TB patients, 61 (5.25%) had MTB on gene X-pert. Among the 58 smear positive patients, MTB was detected in 55 (94.83%) patients. The sensitivity and specificity of gene Xpert was 47.4% (55/116) and 99.7 % (1102/1105) respectively. The positive and negative predictive values were 94.8% (55/58) and 94.8% (1102/1163) respectively.

Conclusions/Next steps: The gene Xpert MTB/RIF assay improved the detection of 61 (52.59%) MTB cases. These would have missed treatment if smear microscopy alone was used. More MTB/RIF machines are needed at lower health facilities with high patient volumes to increase the case detection rate of MTB.

WEPEB042

Performance of a simple flow cytometric assay in the diagnosis of active TB

S. Ubolyam[1], T. Iampornsin[1], J. Sophonphan[1], A. Avihingsanon[1], G. Suwanpimolkul[2], K. Kawkitinarong[2], J. Ananworanich[3], K. Ruxrungtham[1], A. Kelleher[4], D. Cooper[4]

[1]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Faculty of Medicine, Chulalongkorn University Hospital, TB Center, Bangkok, Thailand, [3]Henry M. Jackson Foundation for the Advancement of Military Medicine, MD, United States, [4]The Kirby Institute for Infection and Immunity in Society, University of New South Wales, Sydney, Australia

Background: The performance of a flow cytometric assay that measures Mycobacterium tuberculosis (MTB) specific memory CD4 T cell responses using CD25/CD134 surface coexpression (OX40 assay) was explored as a potential diagnostic for patients being investigated for active tuberculosis (TB) in a Thai population with and without HIV.

Methods: Cryopreserved peripheral blood mononuclear cells (PBMC) from 133 participants collected at their first clinic visit were selected from 2 populations: 76 participants with definitive final diagnosis of TB defined as a confirmatory of TB culture and clinical diagnosis judgment by physician and 57 participants without TB. Memory CD4 T cell responses were evaluated by measuring co-expression of CD25 and CD134 on CD4 T cells after stimulation with several MTB antigens (CFP-10 and ESAT-6 peptides, PPD and combination peptides of CFP-10 + ESAT-6 (combined RD-1); OX40 assay). These were compared to the results of the sputum based Xpert MTB/RIF assay. The OX40 assay and Xpert MTB/RIF assays' sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) with 95% confidence intervals (CI) were calculated.

Results: The median age was 42 years (IQR 31.7-57.7). 87 (65.9%) were males. The majority were new TB cases; with 36 cases (27%) were retreatment cases. 45 of 133 participants (33.8%) had HIV.

The overall sensitivity of the OX40 assay was 94.7 (CI 87.1-98.5)%. In HIV seropositive cases, the sensitivity was 100 (CI, 88.8-100)%, whereas in HIV-negative cases was 91 (CI, 78.8-97.5)%. By comparison, the overall sensitivity of Xpert MTB/RIF was 90.8 (CI, 81.9-96.2)%. The specificity of the OX40 assay was 71.9 (CI, 58.5-83)% wheras the Xpert MTB/RIF was 94.7 (CI, 85.4-98.9)%. The positive predictive value (PPV) of the the OX40 assay was 81.8 (CI, 72.2-89.2)% and the PPV of Xpert MTB/RIF was 95.8 (CI, 83-99.1)% . The negative predictive value (NPV) was 91.1 (CI, 78.8-97.5)% and the NPV of Xpert MTB/RIF was 88.5 (CI, 77.8-95.3)%.

Conclusions: Using OX40 assay for the diagnosis of active TB in Southeast Asia with high TB and HIV burdens could be highly beneficial for immediate diagnosis and treatment of TB, especially for those who have difficulty providing sputum or have extrapulmonary TB.

WEPEB043

Incidence of tuberculosis among household contacts of pulmonary TB patients in northern Nigeria: A prospective study

J.P. Edor[1], D. Magaji[2], B. Dantala[3], A. Adediran[4], A. Ekpenyong[5], H. Dikko[6], O. Onifade[6], J. Mullis[7]

[1]Save the Children International, STEER Project, Bauchi, Nigeria, [2]United States Agency for International Development, Office of HIV/AIDS & TB, Abuja, Nigeria, [3]Save the Children International, STEER Project, Kano, Nigeria, [4]Save the Children International, STEER Project, Lagos, Nigeria, [5]Save the Children International, STEER Project, Calabar, Nigeria, [6]Save the Children International, STEER Project, Abuja, Nigeria, [7]SCUS, OVC STEER, Washington, United States

Background: Tuberculosis (TB) has remained a public health problem globally and in Nigeria despite the availability of treatment. Contacts of smear positive TB patients are at higher risk of acquiring either active TB or TB infection. This study seeks to determine the incidence of Tuberculosis among Household contact of pulmonary TB patients in two states in Northern-Nigeria.

Methods: This prospective study was carried out from January to September, 2017 in 64 Local Government Areas of Kano and Bauchi states where community Childhood TB care (CTBC) was integrated into an existing USAID funded project; the Systems Transformed for Empowered Actions and Enabling Responses (STEER) for Orphans and Vulnerable Children. Household contacts of smear positive Tuberculosis patient were screened using the standard National contact tracing tool and all presumptive TB cases were referred to DOTS centers for testing using the combined method of gene Xpert, Microscopy and Chest X-ray. The study covered 3796 index cases including 3457 adults and 339 Children. The age bracket for children in this study was between 11-18 years old as applicable for Orphan and Vulnerable Children (OVC) programming although the National TB classifies all children above 15 years old as adult. The 3796 index cases included in this study were in contact with 183752 persons (in approximately 36750 Households) comprising 96015 adults and 87737 children.

Results: Of the 183752 contacts of the index cases screened, 12396 presumptive TB cases were identified with 707 confirmed as TB cases. This represent an incidence of 385 per 100,000 populations which is higher than the estimated National incidence of 219 per 100,000 in 2017. Adult household contacts were more commonly infected (554 per 100,000 adults) than children who were contacts (199 per 100,000 children) with a relative risk of 2.8 (95%CI: 2.4 - 3.3). Furthermore, of the 707 contact diagnosed with TB, 23 (3.3%) tested positive to HIV.

Conclusions: The incidence of TB among household contacts of TB patients is high in Northern-Nigeria with adult contacts at greater risk than children. Active screening of household contact of TB patient should be prioritized to reduce the burden of TB in this region.

WEPEB044

One year follow up of HIV+ patients in Mozambique with and without tuberculosis at baseline

F. Ciccacci[1], M. Floridia[2], M. Andreotti[2], A. Ruiz de Andrés[3], J. Cebola[4], H. Sotomane[5], E. Mutemba[5], M. Xavernice[5], S. Orlando[1], S. Mancinelli[1], M. Giuliano[2], L. Palombi[1], M.C. Marazzi[6]

[1]University of Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy, [2]National Center for Global Health, Istituto Superiore di Sanità, Rome, Italy, [3]IrsiCaixa - Institute for AIDS Research, Hospital Germans Trial I Pujol, Badalona, Spain, [4]Community of S. Egidio, DREAM Program, Beira, Mozambique, [5]Community of S. Egidio, DREAM Program, Maputo, Mozambique, [6]LUMSA University, Rome, Italy

Background: Tuberculosis (TB) is a major cause of morbidity and mortality in many African countries, especially in HIV+ patients, with important economic and public health consequences. Integrated strategies for HIV and TB diagnosis and care are being implemented, but information on their impact in terms of mortality is still limited.

Methods: This study was conducted in the NGO DREAM health centres of Maputo, Machava and Beira (Mozambique). A cohort of HIV+ patients >15 years eligible for antiretroviral therapy (ART) and screened for TB

with Xpert MTB/RIF on sputum and with a LAM test on urine was analysed after one year of follow up. Patients positive to either Xpert or LAM were considered TB-infected and referred for TB treatment. All patients were prescribed ART. Survival was analysed using Kaplan-Meyer method and Cox regression analysis.

Results: As of October 2017, among the 1004 patients enrolled, 972 had a complete diagnostic algorithm (58.5% women, median CD4 cell count: 278 cells/mm³, WHO-HIV stage I: 66.8%, median haemoglobin 11.8 g/dL). Ninety-eight of them (10.1%) were diagnosed with TB. This diagnosis was associated with significantly lower CD4 and haemoglobin levels, more advanced WHO stage, and higher HIV-RNA levels.

One-year follow-up information was available for 926 patients, for a cumulative follow up of 812.2 person-years. Follow up status at 12 months was as follows: 33/926 deceased (3.6%), 765/926 in follow up (82.6%), 87/926 lost to follow up (9.4%), 29/926 transferred (3.1%), 12/926 study dropout (1.3%). Among patients surviving in follow up and with laboratory information, median haemoglobin and CD4 at 1 year were respectively: 12.3 g/dL (interquartile range: 11.3-13.6, n: 384) and 460 cells/mm³ (299-646, n: 406). In a Cox regression model only CD4 count< 200 cells/mm³ (HR 3.7, 1.56-9.07) and TB infection (HR 5.6, 2.63-12.21) appeared to be independently associated with death.

Conclusions: One-year mortality involved almost 4% of patients eligible for ART, and TB represented the main cause of death. The association of TB and low CD4 counts with mortality suggests the need to implement through an integrated approach an earlier diagnosis of both diseases.

WEPEB045

Mining areas, one of the hotbeds of tuberculosis and HIV AIDS. Case of mining areas in eastern Democratic Republic of Congo

O. Rusumba[1], N. Nyakabwa[2], V. Bola[3], F. Birembano[4], I. Alain[1]
[1]Ambassadeurs de Lutte contre la Tuberculose et le VIH, HIV/ Tuberculosis, Bukavu, Congo, Democratic Republic of the, [2]Catholic University of Bukavu, Bukavu, Congo, Democratic Republic of the, [3]Challenge TB Project/The Union, Communities, Kinshasa, Congo, Democratic Republic of the, [4]National TB Program, TB, Bukavu, Congo, Democratic Republic of the

Background: According to the 2017 global tuberculosis report, DRC has a population of 79 million inhabitants and an annual incidence of 323 (209-461) cases of active tuberculosis per 100,000 inhabitants and per year and 1.4% HIV prevalence rate in the province of South Kivu. Our hypothesis is that this incidence is significantly elevated in high-risk communities, especially in the important artisanal mining sector of South-Kivu province.

Methods: We involved volunteers former TB patients and people living with HIV AIDS to actively screen people for TB or HIV symptoms in the mining communities.

The intervention was implemented in 10 mining health districts. These districts provide care for an estimated population of 1.2 million. Since January to December 2016, 360 volunteers were involved to perform verbal screening for TB and HIV symptoms in the mining communities and referral TB suspects for smear microscopy, sensitized all new TB patients to HIV test. Volunteers received financial support for the logistical costs of their activities. The data are validated regularly by the National HIV and TB Programs in the provinces.

Results: Throughout 2016, 31, 961 verbal screening events were conducted, resulting in the detection of 8,690 (27%) TB suspects. All TB suspects were referred for smear microscopy testing, resulting in 1,458 new TB cases (17%) detected. Of the 1,458 TB patients, 682 (47%) were tested for HIV, of whom 117 were positive (17%); 98 or 83% were put on cotrimoxazole and only 76 patients received ARV treatment

Conclusions: This study shows,

- that minerals from DR Congo, in addition to being an opportunity for the country are also an active outbreak of tuberculosis and HIV AIDS,
- that the active and systematic search for tuberculosis in people living with HIV / AIDS and HIV / AIDS in TB patients is a solution to the problem of under-detection,
- that More than 30% of people affected by HIV / AIDS are not treated.

WEPEB046

"*Life continues*": Patient, health-care worker and community care worker perspectives on self-administered treatment for rifampicin-resistant tuberculosis in Khayelitsha, South Africa

E. Mohr[1], L. Snyman[1], Z. Mbakaz[1], V. De Azevedo[2], Y. Kock[3], L. Trivino Duran[1], T. Cassidy[4], E. Venables[5,6]
[1]Medecins Sans Frontieres, Cape Town, South Africa, [2]City of Cape Town Health Department, Cape Town, South Africa, [3]Provincal Government of the Western Cape, Cape Town, South Africa, [4]Medecins Sans Frontieres, Khayelitsha, South Africa, [5]Medecins Sans Frontieres South African Medical Unit, Cape Town, South Africa, [6]University of Cape Town, Cape Town, South Africa

Background: Self-administered treatment (SAT) for rifampicin-resistant tuberculosis (RR-TB) might address adherence challenges faced by patients and health care systems. This study explored patient, health-care worker (HCW) and community care worker (CCW) perspectives on a SAT intervention in South Africa, in which patients were given a medication supply to take at home with a CCW's support.

Methods: We conducted a mixed-methods study from July 2016-June 2017 in Khayelitsha, South Africa, a setting with a high burden of HIV. The quantitative component included standardized questionnaires with patients, HCWs and CCWs; and the qualitative component involved in-depth interviews with patients enrolled in the intervention for varying lengths of time. Interviews were conducted in IsiXosa, translated, transcribed and manually coded. Thematic analyses were conducted.

Results: Overall, 27 patients, 12 HCWs and 44 CCWs were enrolled in the quantitative component: 9 patients were also interviewed. Of note, 82% and 63% of the patients who completed the standardized questionnaires were HIV-infected and received a monthly supply of RR-TB treatment, respectively. Most HCWs and CCWs (83% and 73%, respectively) understood the intervention; approximately half (52%) of the patients could not correctly describe the intervention. Overall, 92% and 93% of HCWs and CCWs reported that the SAT intervention promoted treatment adherence. Additionally, 92% of HCWs reported that the intervention relieved pressure on the clinic. Interestingly, 70% of patients believed that not all RR-TB patients should be enrolled in SAT; listing adherence as a main concern. Key qualitative themes from patients highlighted the importance of a support person and how the flexibility of SAT enabled integration of treatment into their daily routines and reduced time spent in clinics.

Conclusions: The SAT intervention was acceptable from the perspective of patients, HCWs and CCWs and should be considered as a differentiated model of care for RR-TB, particularly in settings with high burdens of HIV in order to ease management of treatment for patients and health care providers.

WEPEB047

Tuberculosis incidence, risk factors and associated mortality in adults living with HIV, on antiretroviral therapy, in Thailand: A 12-year cohort study

A. Duclau[1,2,3], N. Salvadori[1,2], A. Nechba[1,2], S. Kawilapat[1,4], E. Cercier[3], P. Traisathit[4,5], S. Khusuwan[6], P. Kanjanavikai[7], M. Techapornroong[8], S. Thongpaen[9], Y. Chan School of Public Health, Boston, United States

Background: Tuberculosis remains a major cause of mortality in HIV-infected individuals worldwide and in Thailand, one of the 22 countries with high tuberculosis burden listed by the World Health Organization. Data on tuberculosis in HIV-infected adults on antiretroviral treatment (ART) are limited in Thailand. We estimated tuberculosis incidence, its risk factors and the contribution of tuberculosis on the risk of death using prospectively collected data from a large multicenter cohort of HIV-infected adults, on ART, in Thailand (ClinicalTrials.gov: NCT00433030).

Methods: This is an analysis of all tuberculosis cases occurring among HIV-infected adults who initiated first-line antiretroviral therapy in the cohort between 1999 and 2012. The incidence of tuberculosis was defined as the number of patients with a tuberculosis diagnosis >90 days after ART initiation divided by the total person-years of follow-up (PYFU). Risk factors for incident tuberculosis were assessed using cause-specific competing risks models treating death from other causes as a competing event, and risk factors for death using Cox models.

Results: At ART initiation, 1932 adults (79% female) had a median age of 32 years (IQR, 27-37). Median duration of follow-up was 7 years (2.5-8.3). During follow-up, median body mass index (BMI) was 21.3 (19.4-23.4) and CD4 387 cells/mL (265-504). Sixty-two patients were diagnosed with incident tuberculosis, leading to an overall incidence of 5.4 per 1,000 PYFU (95% CI, 4.2-6.9). Incidence rates sharply decreased with ART duration, from 20.3 per 1,000 PYFU (95% CI, 11.9-37.7) from 3 to 6 months after ART initiation to 2.2 per 1,000 PYFU (95% CI, 1.1-4.2) after 5 years. Higher neutrophil count and lower BMI, hemoglobin level and CD4 count, during follow-up, were associated with a higher risk of incident tuberculosis. Diagnosis of incident tuberculosis was associated with mortality (adjusted hazard ratio 3.0, 95% CI 1.3-6.8, p< 0.001).

Conclusions: Tuberculosis incidence decreased with ART duration, but remained higher after 5 years of ART compared to an estimate in the general population in Thailand (1.2 per 1,000 PYFU). Incident tuberculosis was associated with the risk of death. Our analysis suggests that lower BMI, CD4 counts, hemoglobin levels or higher neutrophil counts, may prompt clinicians to investigate possible tuberculosis infection.

WEPEB048

Pulmonary function and quality of life in HIV positive and negative patients with treated smear positive pulmonary tuberculosis at three tuberculosis clinics in Nairobi, Kenya

P. Mugo[1], J. Omonge[2], C. Muhwa[3]

[1]Nyahururu County Referral Hospital, Laikipia County, Nyahururu, Kenya, [2]University of Nairobi, Clinical Medicine and Therapeutics, Nairobi, Kenya, [3]Kenya Association for the Prevention of TB and Lung Diseases (KAPTLD), Nairobi, Kenya

Background: The effects of tuberculosis on pulmonary function and quality of life among HIV positive and negative patients has been described in selected populations. The purpose of the study was to evaluate the type of pulmonary impairment, the factors associated with such impairment and the effect of tuberculosis on quality of life of patients.

Methods: This was a cross sectional study conducted at *Riruta, Kangemi and Kibera* Health Centres, Nairobi, between May and June 2012. Patients above the age of 15 years with cured smear positive TB two years prior to the study were assessed for their health status using the St Georges Respiratory questionnaire (SGRQ) and pulmonary function using spiro lab III spirometer. The primary outcomes were abnormal lung function and SGRQ score. Data was entered using Microsoft office excel 2010 and analysis carried out using *stata statistical software version 11.*

Results: A total of 183 patients were enrolled. 58% were males and 42% were females. Out of these,33% were HIV positive. 85% of the HIV positive patients were on HAART. The median age of the study population was 29.5years (IQR 25-38 years) and the median duration after starting TB treatment was 11.4 months. 78% of the patients were nonsmokers while 22% were current or former cigarette smokers. The median BMI was 21.1kg/m^2 (Range 12.5 - 37). 53 patients (29%) had pulmonary impairment, the commonest being restrictive defects in 42 patients (23%, 95% CI, 16.8-29.1%). Patients with abnormal lung function were younger [median age, 29 years (IQR, 22-36) vs 34 years (IQR, 27-39), p= 0.036], more likely to be underweight (38% vs 9%, P= < 0.005) and had a lower prevalence of HIV (20.8% vs 37.7%, p=0.027). Low BMI was the only independent predictor of pulmonary function abnormality (p=0.001). The median QOL total score from the SGRQ was 3.16 (IQR, 0 - 8.9) signifying good QOL. There was no correlation between QOL and pulmonary function.

Conclusions: The commonest lung function abnormality post TB treatment was restrictive defect. Body mass index was the only independent predictor of abnormal pulmonary function. HIV infection was not an independent predictor of abnormal pulmonary function post TB treatment.

WEPEB049

Health-related quality of life in the A5274 trial (REMEMBER) of empirical tuberculosis (TB) therapy versus isoniazid preventive therapy (IPT) in adult outpatients with advanced HIV

R. Lando[1], X. Sun[2], S. Miyahara[2], M. Hosseinpour[3,4], G. Bisson[5], J. Kumwenda[6], A. Gupta[7], M. Nyirenda[6], K. Katendey[8], T. Torres[9], N. Suryavanshi[10], F. Beulah[11], N.S. Shah[12], A5274 Study Group

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]University of North Carolina School of Medicine, Chapel Hill, United States, [4]UNC Project, Lilongwe, Malawi, [5]Perlman School of Medicine at the University of Pennsylvania, Philadelphia, United States, [6]Malawi College of Medicine-Johns Hopkins University Research Project, Blantyre, Malawi, [7]Johns Hopkins University School of Medicine, Baltimore, United States, [8]Joint Clinical Research Centre Clinical Research Site, Kampala, Uganda, [9]Instituto Nacional de Infectologia Evandro Chagas (INI-FIOCRUZ), Rio de Janeiro, Brazil, [10]Byramjee Jeejeebhoy Government Medical College Clinical Trials Unit, Pune, India, [11]YRGCARE Medical Centre, Chennai Antiviral Research and Treatment Clinical Research Site, Chennai, India, [12]Centers for Disease Control and Prevention, Atlanta, United States

Background: TB is the leading cause of morbidity and mortality in people living with HIV (PLHIV). A5274 randomized PLHIV with CD4 < 50 cells/uL to empirical TB therapy versus IPT, in addition to antiretroviral therapy (ART). At 24 weeks, mortality did not differ (n=22 [5%] per arm). To evaluate

Tuesday 24 July | **Wednesday 25 July** | Thursday 26 July | Friday 27 July | Late Breaker Abstracts | Publication Only Abstracts | Author Index

impact on morbidity, we compared health-related quality of life (HRQoL) between arms, assessed changes over time, and examined associations with sociodemographic and clinical factors.

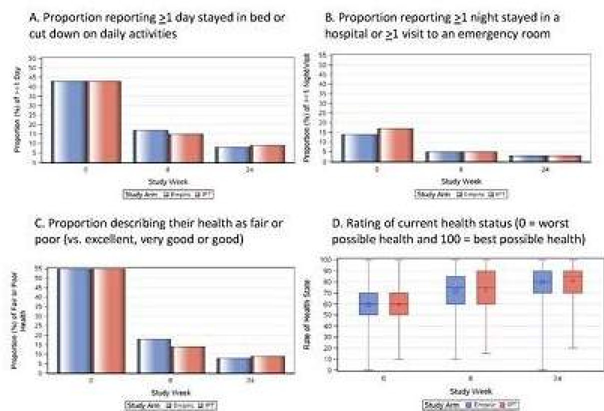
Methods: Participants ≥13 years old were enrolled from outpatient clinics in 10 countries. We assessed seven HRQoL outcomes at weeks 0, 8 and 24: number of:
1) days stayed in bed,
2) days cut down on daily activities,
3) nights spent in a hospital,
4) visits to an emergency room (ER),
5) ability to work or look for work,
6) general health status using 5-point scale, and
7) general health rating (range: 0-100).

Two composite HRQoL outcomes were created by combining (1) items 1 and 2, and (2) items 3 and 4. We used logistic regression to examine HRQoL ('none' vs '≥1 day') by arm, and association with sociodemographic and clinical factors. Changes in HRQoL over time were examined using GEE models .

Results: Among 850 participants (424 in empiric arm, 426 in IPT arm), there was no difference in HRQoL between arms at each time point, but with significant improvement in all domains by 24 weeks (Figure). At 24 weeks, participants with WHO stage 3 or 4 events and grade 3 or 4 signs/symptoms had a higher chance of ≥1 day in bed or decrease in activities [OR (95% CI): 6.5 (3.8, 11.0), p< 0.01 and 4.5 (2.4, 8.1), p< 0.01], and describing one's health as fair or poor [OR (95% CI): 4.7 (2.7, 8.1), p< 0.01 and 3.8 (2.0, 7.1), p< 0.01].

Conclusions: There were no differences in HRQoL between PLHIV receiving empiric TB treatment versus IPT. Although baseline HRQoL was poor in both arms, it improved significantly during the study. Together with the primary trial results, these findings show reduced morbidity with ART, TB screening, and IPT in persons with advanced HIV.

Figure: Health-related quality of life outcomes at baseline, week 8 and week 24 by study arm for: A) combined metric of days in bed or days cut down on daily activities, B) nights stayed in a hospital or visits made to an emergency room, C) general health status, and D) general health status on visual analog scale. Participants reported their health in the last 30 days at week 0; for post-entry visits, the health since the last visit or phone contact was reported.



[Figure. Health-related quality of life outcomes at baseline, week 8 and week 24 by study arm]

WEPEB050

Pharmacokinetics of rifabutin at different doses during atazanavir/ritonavir co-administration in HIV-infected tuberculosis patients in India

A.K. Hemanth Kumar[1], T. Kannan[2], R. Sridhar[3], S.K. Guha[4], D. Khadam[5], N.K. Poorana Gangadevi[6], G. Ramachandran[1]
[1]National Institute for Research in Tuberculosis, Biochemistry & Clinical Pharmacology, Chennai, India, [2]National Institute for Research in Tuberculosis, Statistics, Chennai, India, [3]Government Hospital for Thoracic Medicine, Tambaram, Chennai, Clinic, Chennai, India, [4]School of Tropical Medicine, Clinic, Kolkata, India, [5]B.J. Medical College, Clinic, Pune, India, [6]National Institute for Research in Tuberculosis, Clinic, Madurai, India

Background: The previously recommended rifabutin (RBT) 150mg thrice weekly dose combined with protease inhibitors (PI) in the Revised National TB Control Programme in India was associated with low RBT plasma concentrations. Subsequently, the dose of RBT was increased to 300mg thrice weekly during PI co-administration. We studied the pharmacokinetics of RBT at doses of 300mg thrice weekly and 150mg daily during concomitant atazanavir/ritonavir (ATZ/RTV) administration in adult HIV-infected TB patients treated in the Government programme in India.

Methods: : This was a multi-centric pharmacokinetic study conducted at four sites from April 2016 to July 2017. We recruited 45 adult HIV-infected TB patients, who were being treated for TB with RBT-containing regimen and an antiretroviral treatment regimen with ATZ/RTV, at RBT doses of 300 mg thrice-weekly (n = 36) or 150 mg daily (n = 9). Serial blood draws at 0,1, 2, 4, 6, 8, 12 and 24 hours after drug administration were done at steady state. Plasma RBT was estimated by Chromatographic method.

Results: The median peak concentration (C_{max}) of both doses were within the therapeutic range (0.45 - 0.90 µg/ml). No significant differences between the doses of RBT were observed with respect to median C_{max}, exposure (AUC_{0-24}), proportion of patients having C_{max} above or below the therapeutic range. A higher proportion of patients (16/36; 44%) receiving 300mg thrice weekly dose had C_{min} below the MIC (0.06 µg/ml) compared to those who received 150mg daily dose (2/9; 22%); this difference was not statistically significant. TB treatment outcomes were also similar at both doses. 81% and 71% of patients respectively treated with 300 mg thrice weekly and 150 mg daily doses of RBT had favourable outcome; difference was not statistically significant.

Conclusions: This is the first study from India reported on the pharmacokinetics of RBT at 300mg thrice weekly and 150mg daily during RTV co-administration in HIV-TB patients. From the pharmacokinetic standpoint, both doses were well tolerated, yielded similar plasma RBT concentrations and treatment outcomes. No adverse events that required stopping RBT was observed at both doses. RBT can be administered at either doses during ritonavir co-administration in HIV-TB patients.

WEPEB051

The effect of HIV status on the identification of differentially culturable tubercle bacilli (DCTB) during treatment of drug susceptible tuberculosis

J.S. Peters[1], A. Mc Ivor[1], A. Papadopoulos[1], T. Masangana[1], B.G. Gordhan[1], K. Otwombe[2], Z. Waja[2], N. Martinson[2], F. Shahim[3], B.D. Kana[1]
[1]Centre for Excellence for Biomedical TB Research National Health Laboratory Service Witwatersrand University, Chemical Pathology, Johannesburg, South Africa, [2]Perinatal HIV Research Unit, Faculty of Health Sciences, Witwatersrand University, Chemical Pathology, Johannesburg, South Africa, [3]Clinical Laboratory Services, National Health Laboratory Services, Johannesburg, South Africa

Background: Co -infection with HIV and TB, is a common occurrence in South Africa with about 60% of the TB infected population being HIV+ leading to high mortality rates. Tuberculosis is known to adapt to host stresses by adopting differentially culturable states that require the addition of growth factors to stimulate their growth *in vitro*. Previous studies have reported significant differences in the quanta of differentially culturable tubercle bacilli (DCTB) in HIV- and HIV+ patients in treatment naïve tuberculosis patients. We hypothesized that the quanta of DCTB would fluctuate differently between HIV- and HIV+ individuals during treatment. In this study we assessed the DCTB population in HIV- and HIV+ individuals during 6 months of standard tuberculosis treatment.

Methods: Eighty participants (33.7% HIV- and 66.3% HIV+) from 2 major hospitals in South Africa were enrolled into the study. Participants were TB treatment naïve, drug sensitive, consenting individuals above the age of 18. DCTB in sputum was resuscitated by supplementation of standard growth media with culture filtrate (CF) from axenic cultures of *M. tuberculosis* H37Rv. Most probable number assays (MPN) were used to assess the growth of the DCTB and comparisons with colony forming units (CFU) allowed enumeration of the quanta of DCTB in sputum. Sputum sampling was done at several points during the 6-month treatment period.

Results: Significant differences (p-value < 0.05) in the quanta of DCTB between HIV- and HIV+ were observed during the first month of TB treatment with HIV- consistently having more DCTB than HIV+. The DCTB populations followed one of four trends in response to treatment; 22.7% of patients accumulate DCTB within the first week, 26.7% decline,

22.7% resist treatment for up to 7 days and 28% were unresponsive. These trends were strongly associated with HIV status and the DCTB quanta at enrolment. HIV+ individuals tended to have a lower starting quanta of DCTB compared to the HIV- sub-group (p=0.01) however, their rates of decline over the treatment period were slower than in HIV- sub-groups (p=0.04).
Conclusions: In conclusion, HIV coinfection significantly reduces the DCTB quanta in sputum and affects the manner in which it is cleared by standard chemotherapy.

WEPEB052

Clinical predictors of *Mycobacterium tuberculosis* bacteremia in a contemporary cohort of HIV-infected patients in Rio de Janeiro, Brazil

J. Moreira, R. Castro, C. Lamas, M.C. Lourenco, S. Ribeiro, B. Grinsztejn, V.G. Veloso
Fundacao Oswado Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil

Background: *Mycobacterium tuberculosis* bacteremia (MTB) is a common cause of bloodstream infection among HIV-infected adults patients living in Brazil. We aimed to estimate the frequency, predictors, and survival of HIV- tuberculosis (TB) co-infected patients who had MTB in a cohort of HIV-infected patients in Rio de Janeiro, Brazil.
Methods: We conducted a retrospective cohort analysis of HIV-TB co-infected adults individuals who initiated TB treatment at INI/FIOCRUZ, between 2010-1015. Patients whose results of blood culture for TB were available were further selected. Results of blood culture and drug susceptibility test for first-line anti-TB treatment were collected from the laboratory records. Multivariable logistic regression was used to determine predictors of MTB bacteremia and Kaplan-Meier estimate to compared the mortality between those with and without MTB using the log-rank test.
Results: During the study period, 473 HIV individuals started TB treatment, of which 362 (76.5%) had blood culture available for TB. Fifty-six (11.8%) had MTB, including 10 (2.1%) with resistance to at least one TB drug. Three fulfilled the criteria for MDR-TB. There was a predominance of males (67.4%), with a mean age 37 ± 10.7 years. The median CD4+ was 101 cells/ul, and half of the patients were under HAART at the time of TB treatment initiation. In a multivariate analysis (Table), the presence of a miliary pattern on chest radiograph [aOR 4.07, 95% CI (1.64-10.09)], a positive acid-fast bacillus smear positivity at diagnosis [aOR 8.66, 95% CI (2.89-25.94)], CD4 < 100 cells/µL [aOR 3.78, 95% CI (1.37-10.45)], and low serum albumin [aOR 0.26, 95% CI (0.09-0.71)] were significantly associated with mycobacteremia. MTB patients had a higher 90-day mortality rate compared to patients without MTB [21.4% *vs.* 6.2%, log-rank test, *p*< 0.0001]. The median turnaround time for positive blood mycobacterial culture was 62 [IQR: 59-66] days.
Conclusions: Mycobacteremia due to *M tuberculosis* occurred in 15% of the HIV-infected patients and was associated with higher mortality compared with those without mycobacteremia.

WEPEB053

The importance and clinical relevance of baseline LTBI screening in HIV patients

N.S. Wong[1], C.C. Leung[2], K. Chan[3], W.K. Chan[3], A. Lin[3], S.S. Lee[1]
[1]Chinese University of Hong Kong, Stanley Ho Centre for Emerging Infectious Diseases, Hong Kong, China, [2]Tuberculosis and Chest Service, Department of Health, Hong Kong, China, [3]Special Preventive Programme, Department of Health, Hong Kong, China

Background: HIV patients with latent TB infection (LTBI) could be identified by screening followed by treatment, a strategy recommended to reduce TB reactivation. We hypothesize that baseline screening for HIV patients is an important measure which would predict subsequent TB disease development.
Methods: Clinical data and LTBI screening (mainly tuberculin sensitivity testing with small proportion of IGRA) results of HIV patients diagnosed between 2002 and mid-2017 in a major HIV clinic in Hong Kong were accessed retrospectively. Patients aged below 18 at HIV diagnosis or diagnosed with TB within 3 months of HIV diagnosis were excluded. In this cohort, we compared the risk of TB disease development between unscreened patients, those tested with positive and negative results. With TB disease development as an outcome, cox proportional hazard models were performed in SPSS.
Results: Among 3130 eligible patients, 2740 (88%) were male, 2796 (90%) being local residents, and 2450 (78%) were Chinese. A majority (2800, 90%) were aged between 18 and 49 at HIV diagnosis, with 99 (3%) concurrently diagnosed with diabetes mellitus. A total of 723 (23%) patients had not been tested for LTBI, 284 (9%) were positive at the first test, and 2123 (68%) were negative. With 16621 person-years' (PY) follow-up, 94 had developed TB disease. The overall TB incidence was 0.57/100PY (95%C.I.=0.45-0.68): 3.04/100PY (95%C.I.=2.21-4.08) for patients never tested for LTBI, 1.43/100PY (95%C.I.=0.94-2.08) for those tested positive, and 0.21/100PY (95%C.I.=0.14-0.30) who tested negative at the first test. Compared to patients never tested for LTBI, those tested (HR=0.09, 95%C.I.=0.06-0.13) were at significantly lower risk of TB disease development. More unscreened patients were non-Chinese (32% vs 18%), non-local residents (23% vs 7%) and younger at HIV diagnosis (median 32 year-old vs 35 year-old), compared to screened patients. Among LTBI tester, patients positive at the first test (HR=12.14, 95%C.I.=6.98-21.13) had a significantly higher risk for TB disease development, despite the implementation of LTBI treatment.
Conclusions: Baseline LTBI screening for all HIV patients is important for overall reduction of TB incidence. With screening, higher risk individuals who tested positive could be further identified for treatment intervention and subsequent monitoring.

^{18}F-FDG PET/CT scan in the evaluation of adjunctive host-directed TB therapies

R.S. Wallis[1,2], T. Beattie[1,2], M. Likoti[1,2], B. Ahidjo[1,2], M. Rassool[3], K. Ahmed[2,4], S. Ginindza[1,2], K. Fielding[5], G. Churchyard[1,2], M.D.T. Vangu[2,6]
[1]Aurum Institute, Johannesburg, South Africa, [2]ACT for TB/HIV, Johannesburg, South Africa, [3]Clinical HIV Research Unit, Johannesburg, South Africa, [4]Setshaba Research Centre, Soshanguve, South Africa, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]University of the Witwatersrand, Nuclear Medicine, Johannesburg, South Africa

Background: Inflammation in the lung in tuberculosis often results in permanent damage despite TB cure. Adjunctive host-directed therapies (HDT) may help reduce inflammation and prevent injury. We used ^{18}F-fluorodeoxyglucose (^{18}F-FDG) positron emission tomography (PET) with computed tomography (CT) to precisely locate and measure metabolic activity of inflammatory cells in the lung in TB in a phase 2 randomized controlled trial of 4 candidate HDT agents in adult TB patients.
Methods: Patients were Xpert Mtb/RIF positive, Ct< 20, rifampin susceptible, HIV-1-negative, with moderately or far advanced disease by chest radiography, and acceptable hematology and chemistry studies. Patients were randomly assigned to receive CC-11050 (a type 4 phosphodiesterase inhibitor), everolimus (an mTOR inhibitor), auranofin (an

oral gold salt), or vitamin D, with rifabutin-substituted 6-month anti-TB therapy, or that therapy alone. HDT treatment started on day 1 and continued for 4 months. PET/CT scans were performed at baseline and after 8 weeks of treatment. Total body weight-adjusted lung and thoracic lymph node glycolytic activity (SUVbw*ml) and radiographic density (HU*ml) were measured by a single treatment-blinded reader using MIM software. Sputum cultures and lung spirometry were performed at designated intervals during treatment.
Results: Paired baseline and 8wk scans are presently available from 94 subjects for analysis. Total glycolytic activity was 5178±2709 SUVbw*ml at baseline and 3183±1819 at week 8 (P< .001 by paired analysis). The change from baseline was non-normally distributed. It remained so after log transformation, potentially indicating a minority sub-population showing greater treatment effect. In contrast, radiographic density showed no treatment effect (P=.5) and was normally distributed (see figure).
Conclusions: Resolution of lung inflammation during 8 weeks of TB treatment can be detected by ^{18}F-FDG PET but not by CT. Change in PET may be a useful endpoint in phase 2 studies of TB HDT candidates.

Antiretroviral therapy (ART) contribution in reduction of tuberculosis (TB) presumptive and TB cases in people living with HIV (PLHIV) in Swaziland

N. Kisyeri[1], M. Pasipamire[2], N. Lukhele[2], P. Mndzebele[2], S. Chambers[2]
[1]Swaziland National AIDS Program, TB/HIV, Mbabane, Swaziland, [2]Swaziland National AIDS Program, Mbabane, Swaziland

Background: Despite being preventable and curable, TB remains the leading cause of HIV-related morbidity and mortality in Swaziland. In 2016 approximately 70% of TB cases were co-infected with HIV and TB/HIV mortality rate was 14%. Eligibility criteria to start ART changed over the years from CD4 count based (< 350 in 2010 and < 500 in 2015) to treating all in 2016. IPT coverage has remained low in PLHIV (< 10%). In this assessment, we reviewed the occurrence of TB symptoms and TB disease using data from Swaziland National HIV Semi-Annual Reviews (NaHSARs).
Description: Data for NaHSARs were retrospectively collected from client registers and also extracted from electronic medical records for the period October 2014 to June 2017. Pooled data analysis was conducted to describe the TB screening to diagnosis cascade. Results from each NaHSAR were used to describe the trend shown in the occurrence of TB symptoms and TB disease among HIV infected individuals.
Lessons learned: From 2014 to 2017, ART initiation for eligible clients increased from 71% to 89%. There was a progressive increase in the number of clients screened for TB in PreART (4,748 (98%) to 8,946 (96%)) and ART clients (58,320 (96%) to 179,830 (99%)). While the number of patients screened increases, there is a decrease in the proportion of presumptive TB cases from PreART clients (from 17% to 7%). The proportion of TB presumptive among ART clients remained stable at 1%. The TB diagnostic yield among TB presumptive ART patients fell from 473 (70%) to 73 (6%). However, the number of TB diagnosed patients slightly decreased despite increased proportional yield in Pre ART patients from 192(29%) to 162(43%).
Conclusions/Next steps: Occurrence of TB symptoms among PLHIV decreased indicating the possible role of ART in reducing the burden of TB. A possible background risk for developing TB symptoms still exist in HIV infected clients regardless of ART status as shown by the constant proportion of TB symptoms among those on ART. TB disease risk is more pronounced in the Pre-ART population. We urgently have to scale up provision of ART to PLHIV for TB and HIV dual epidemic control.

WEPEB056

Unfavorable TB treatment outcomes among TB/HIV co-infected people: What are we missing?

S. Mutembo[1,2], J. Mutanga[3], B. Mwangelwa[1], C. Kanene[1], J. Mvula[1], J. Chinyonga[1], N. Monze[1], C. Whalen[2]
[1]Ministry of Health, Zambia, Provincial Health Office, Southern, Choma, Zambia, [2]University of Georgia, Epidemiology and Biostatistics, Athens, United States, [3]Livingstone Central Hospital, Paediatrics and Child Health, Livingstone, Zambia

Background: Tuberculosis (TB) coinfection is one of the leading causes of morbidity and mortality among people living with HIV in Zambia. The purpose of this study was to describe TB treatment outcomes among TB/HIV coinfected people and evaluate determinants of unfavorable TB treatment outcomes among TB/HIV coinfected people in southern province of Zambia.
Methods: We used a retrospective cohort design to review medical records of children and adults treated for TB and HIV between 2006 and 2013 at 30 TB diagnostic and treatment centers in Southern province, Zambia. The primary outcome was unfavorable TB treatment outcome as defined by the WHO (treatment failure, died and lost to follow-up) at the end of TB treatment. Crude and adjusted relative risks and their 95% confidence intervals (CIs) were determined through logistic regression and compared differences in unfavorable TB treatment outcomes by age group and evaluated predictors of these outcomes.
Results: Of 13,193 patients, 1,254 (9.5%) were children (< 10 years), 325 (2.4%) were adolescents (11-18 years), 10,914 (72.6%) were adults (19 -55 years) and 700 (5%) were defined as elderly (above 55 years). 3,506 patients were sputum smear positive (26%). After 2010, 65% of TB patients were initiated on combined antiretroviral therapy (cART) either before or during TB treatment (IQR: 54-76%). Overall 11,758 (89.12%) achieved successful TB treatment outcomes (Cure: 8.2%; Completed: 80.9%). Of the patients with unfavorable TB treatment outcomes 399(3.0%) were treatment failure, 708 (5.3%) died while on treatment and 328(2.4%) were lost to follow up. The 19-55 years age group was associated with the highest risk of unfavorable TB treatment outcomes (RR=8.4, referent 0-9 years; 95%CI 5.2-12.7). Starting cART 56 days after TB treatment initiation was associated with a high risk of unfavorable TB treatment outcomes (RR=1.3; 95%CI 1.2- 1.5).
Conclusions: Death was the highest cause of unfavorable outcomes. Age 19-55 years and delay in initiating cART was associated with unfavorable outcomes. There is need to strengthen TB-HIV collaboration by enhancing early initiation of cART. People between 19 and 45 years of age account for a large proportion of TB/HIV coinfections and need special attention to avert the disproportionately higher unfavorable treatment outcomes.

WEPEB057

Data driven insight on TB and HIV co-infections amongst high risk groups in Zimbabwe: TaS4TB 2017 operational year

T. Sengai[1,2,3], F. Kavhenga[4], G. Shumba[4,5]
[1]Family AIDS Caring Trsut, Research and Knowledge Management, Mutare, Zimbabwe, [2]The Union, Harare, Zimbabwe, [3]Ministry of Health and Child Care Zimbabwe, Harare, Zimbabwe, [4]Family AIDS Caring Trust, Mutare, Zimbabwe, [5]USAID Challenge TB, Harare, Zimbabwe

Background: TB epidemic in Zimbabwe is being fueled by the parallel HIV epidemic, as in other countries in the SADC region. Collaborative TB/HIV management is essential to ensure that HIV positive TB patients are identified and treated appropriately, and to prevent TB in HIV positive patients. Another pillar, a response to ending TB deaths as noted in World Health Organization's End TB Strategy document, emphasizes on reliable measurement of progress in reducing TB incidence, TB deaths and catastrophic costs are essential and a cross sectional review with the use of program data has been used to measure TB and HIV co-infections to inform programming for an in-depth planning on further TB response initiatives after Targeted Screening Program.
Methods: A medical team carried out outreach services to communities in the prioritized districts and provided access to free TB Screening to high risk groups. Two screening tools were used to increase sensitivity and these are the symptom screening and digital chest radiography. Presumptive TB patients had a supervised spot sputum specimen collected and examined at the laboratory by XPERT/RIF machine or DSM method depending with availability. All patients due for HIV test were offered a test according to the World Health Organization and national HIV testing guidelines. In the process, a real time electronic data management system was used as an innovative data management tool introduced after tedious use of paper.
Results: 36 811 people were screened for TB and 720 were started on TB treatment. 33.5% (241) came with a known HIV positive result and 84.2% (203) were already on ART, 26.4% (190) presented with a known negative result and 40.1% (289) were tested for HIV. From those tested for HIV on site, 13.8% (40) tested HIV positive and where linked to care. From all the TB diagnosed patients 39.4% (281), either presented HIV positive or tested HIV positive.
Conclusions: HIV positivity rate is low as compared to the Zimbabwe TB prevalence survey done in 2014, which showed that 70% of TB diagnosed patients were HIV positive as compared to 39.4%. However 39.4% is significantly high and TB and HIV co-infection should be reduced significantly.

WEPEB058

Tuberculosis-associated hemophagocytic syndrome in patients living with HIV

N. Lerolle[1], M. Laanani[2], L. Galicier[3], S. Riviere[4], L. Fardet[5], J.-L. Meynard[6], A. Jebaloui[7], V. Lalande[8], F. Mougari[9], P. Coppo[10], J.-M. Molina[11], O. Lambotte[1]
[1]Service de Médecine Interne, Hôpital Bicêtre, APHP, Le Kremlin-Bicêtre, France, [2]Unité de Biostatistiques et Epidémiologie, Hôtel Dieu, Groupe Hospitalier Universitaire Paris Centre, APHP, Université Paris Descartes, Paris, France, [3]Service d'Immunopathologie Clinique, Hôpital St Louis, APHP, Paris, France, [4]Service de Médecine Interne, Hôpital St Antoine, APHP, Paris, France, [5]Service de Dermatologie, Hôpital Mondor, APHP, Créteil, France, [6]Service de Maladies Infectieuses et Tropicales, Hôpital St Antoine, APHP, Paris, France, [7]Service de Microbiologie, Hôpital Bicêtre, APHP, Le Kremlin-Bicêtre, France, [8]Service de Microbiologie, Hôpital Saint Antoine, APHP, Paris, France, [9]Service de Microbiologie, Hôpital Saint Louis, APHP, Paris, France, [10]Service d'Hématologie, Hôpital Saint Antoine, APHP, Paris, France, [11]Service de Maladies Infectieuses, Hôpital Saint Louis, APHP, Paris, France

Background: Reactive hemophagocytic syndrome (HS) is an acquired, potentially life-threatening disorder than can occur in patients with infections. Although tuberculosis is known to trigger HS in few patients, especially in patients living with HIV (PLWH), current knowledge in tuberculosis-associated HS (TB-HS) mainly relies on single-center case series.
Methods: We conducted a retrospective study in which we reviewed the medical records of adult patients diagnosed with microbiologically proved TB-HS between January 2006 and December 2015 in three French tertiary university hospitals, compared to a control group of patients with TB.
Results: Twenty-four patients with suspected TB-HS were selected, and 21 patients with confirmed TB-HS were included. The median age was 37 years (IQR: 30-48), 5 patients (23.8%) were women. Eleven patients (52.4%) were infected with HIV and 7 patients (33.3%) were immunocompromised for other reasons. HIV infection and TB-HS were diagnosed concomitantly in 5 out of 11 cases (45.5%). At HS onset, the median CD4+ cell count was 18/mm³ (IQR 15-190) and the median HIV viral load was 5 log copies/mL (IQR 3.2-5.9).
From 1849 TB cases, 63 patients were randomly selected and 50 were included as control cases. Nine out of these 50 patients were immunocompromised, 6 were infected with HIV. Compared to control cases, patients with TB-HS were younger ($p < 0.05$) and were more likely to be immunocompromised (85.7% vs. 18.0%, $p < 0.0001$). TB was disseminated in 17 TB-HS patients (80%) compared to 6 (12%) control cases ($p < 0.0001$). Median CD4 count was lower in PLWH with TB-HS compared to PLWH with TB (18 vs 252/mm³, p=0.046).
Outcome was poorer in patients with TB-HS, as death occurred in 8 TB-HS patients (38.1%) vs. 3 deaths in control cases (7.3%), p=0.005. Death rate amongst PLWH was 45.4% (5/11) in TB-HS patients vs. 0 (0/6) in control cases. Two out of 5 deaths occurred in the first month and were related to TB-HS.
Conclusions: Features of TB-HS seemed to be particular, with a higher frequency of immunocompromised patients and of disseminated TB and a poorer outcome. Amongst TB/HIV coinfected patients, low CD4 count was associated with a higher risk of HS.

WEPEB059

Two diseases, same person: Moving towards a combined HIV and TB continuum of care

R. Granich[1], S. Gupta[2]
[1]Independent Public Health Consultant, San Francisco, United States, [2]Independent Public Health Consultant, Delhi, United States

Background: The *Human Immunodeficiency Virus* (HIV) and *Mycobacterium tuberculosis* syndemic remains a global public health threat. Separate HIV and TB global targets have been set, however, success will depend on achieving combined disease control objectives along the care continua. We review available policy, budgets and data to reconceptualize TB and HIV disease control objectives by combining HIV and TB care continua.
Methods: For 22 WHO TB and TB/HIV priority countries, we used 2015 data from the published national HIV care continua, UNAIDS AIDSinfo, and WHO 2016 and 2017 Global TB Reports. Global resources available in TB and HIV/TB activities for 2003-2017 were collected from publicly available sources and policy data were collected from published guidelines.
Results: Of the 22 high burden countries, 16 are recommending 'test and treat' for HIV and all are recommending isoniazid preventive therapy (IPT). People living with HIV (PLHIV) on ART ranged from 9-70%; viral suppression of PLHIV was 38-63%. TB case detection and treatment among TB patients ranged from 15-87% and TB treatment success between 71-94%. For HIV/TB patients, ART coverage and TB treatment success were comparatively lower at 1-71% and 20-87%, respectively. Only 3% of PLHIV in the 22 countries reported course of IPT.
Viral suppression data were not available for 13 countries and none of the countries included information regarding the following combined indicators:
(a) TB treatment success and viral suppression among HIV/TB patients,
(b) TB prevention and ART for PLHIV and
(c) HIV prevention interventions for TB patients.
From 2003-2017, global international and domestic resources for HIV-associated TB and TB averaged $2.85 billion per year; the total for 2003-2017 was 43 billion dollars.
Conclusions: Reviewing combined HIV and TB targets demonstrate disease control progress and challenges. Using an integrated HIV and TB continuum supports HIV and TB disease control efforts focused on improving both individual and public health.

WEPEB060

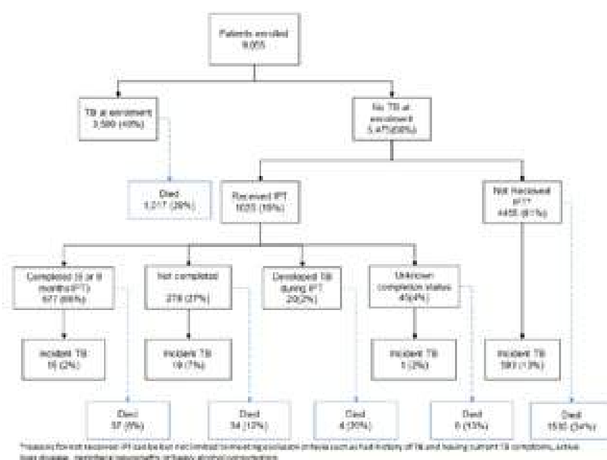
The relationship between Isoniazid preventive therapy and incident TB and all-cause mortality among HIV patients in Myanmar

N.T.T. Kyaw[1,2], K.W.Y. Kyaw[1], A.M. Kumar[3,4], M. Magee[2], M.M. Oo[1], T.K. Aung[5], J. Moe[5], S.S. Thura[5], P. Sone[6], H.N. Oo[6]

[1]International Union Against Tuberculosis and Lung Disease, Operational Research, Mandalay, Myanmar, [2]Georgia State University School of Public Health, Epidemiology and Biostatistics, Atlanta, United States, [3]International Union Against Tuberculosis and Lung Disease, South-East Asia Regional Office, New Delhi, India, [4]International Union Against Tuberculosis and Lung Disease, Center for Operational Research, Paris, France, [5]International Union Against Tuberculosis and Lung Disease, HIV Program, Mandalay, Myanmar, [6]National AIDS Program, Department of Public Health, Nay Pyi Taw, Myanmar

Background: Myanmar has a high HIV and TB burden with the HIV prevalence of 0.8% and TB incidence of 361 per 100,000 population in 2016. The Integrated HIV Care (IHC) program in Myanmar provides HIV clinical care and isoniazid preventive therapy (IPT) to people living with HIV (PLHIV) under care. We aimed to determine the association between completed IPT, and 1) incidence of active TB, and 2) all-cause mortality among PLHIV.

Methods: We conducted a retrospective cohort study among PLHIV registered into IHC program between 2009 and 2014. Patients aged ≥15 years were eligible. We defined IPT use as completed IPT, incomplete IPT, and never received IPT. Patients who took isoniazid 300 mg per day as prophylaxis for 6-9 months were defined as completed IPT. The outcome measures were 1) incident active TB and 2) all-cause mortality. Among those who received IPT, patients diagnosed with active TB >1 month after IPT completion date were defined as incident TB; in those who did not receive IPT, patients diagnosed with active TB >1 month after IHC program registration were defined as incident TB. All-cause mortality was defined as death from any cause between registration date and end of the follow-up(30 June 2017). We used log binomial regression to estimate the association between IPT use and cumulative risk of incident TB and all-cause mortality, adjusting age, sex, baseline CD4, hepatitis co-infection, anemia, and ART status.



[Fig 1: Flow diagram of patients in the program 2009 and 2014, their IPT status, TB incidence and all-cause mortality]

	total	Incident tuberculosis			Mortality		
	n	n(%)	crude RR (95% CI)	adjusted* RR (95% CI)	n(%)	crude RR (95% CI)	adjusted** RR (95%CI)
Isoniazid Preventive Therapy status							
Never received	8035	593 (7.4)	3.3 (2.0-5.5)	3.1 (1.8-5.1)	2547 (31.7)	5.8 (4.2-7.9)	3.7 (2.6-5.1)
Completed	677	15 (2.2)	1.0	1.0	37 (5.5)	1.0	1.0
Not completed	343	25 (7.3)	3.3 (1.8-6.1)	3.2 (1.7-6.0)	44 (12.8)	2.3 (1.5-3.6)	2.1 (1.4-3.3)
*adjusted for age, sex, baseline CD4 cell counts, and ART status							
**adjusted for age, sex, baseline CD4 cell counts, hepatitis B and C co-infection, anemia status and ART status							

[Table 1: Adjusted measure of association between IPT status and incident TB and all-cause mortality among people living with HIV in Myanmar]

Results: Among 9,055 PLHIV registered, 1,020 received IPT and 677 (66%) completed IPT. Overall, 633 (7%) patients developed incident TB and 2628 (29%) patients died during the follow-up (Fig 1). Patients who never received IPT had a higher risk of incident TB [adjusted risk ratio (aRR) 3.1, 95% confidence interval (CI) 1.8-5.2] and risk of mortality [aRR 3.7, 95%CI 2.6-5.1] compared to patients who completed IPT. Patients who received IPT but did not completed IPT also had a higher risk of incident TB [aRR 3.2 95%CI 1.7-6.0] and risk of mortality [aRR 2.1, 95%CI 1.4-3.3] (Table-1).

Conclusions: IPT completion significantly reduced risk of active TB and death among people living with HIV in this setting.

WEPEB061

A retrospective study to evaluate correlates of treatment outcome among HIV-TB co-infected patients from an ART centre in Mumbai, India

Y. Kabra[1], S. Acharya[2], P. Keskar[2]

[1]Seth GS Medical College and KEM Hospital, Community Medicine, Mumbai, India, [2]Mumbai Districts AIDS Control Society, NACO, Mumbai, India

Background: HIV/AIDS pandemic has caused a resurgence of TB, resulting in increased morbidity and mortality worldwide. HIV-infected persons are at markedly increased risk for progressive disease following primary TB infection, as well as reactivation of latent tuberculosis infection (LTBI). Clinical presentation of TB in HIV-infected individuals depends on the level of immune suppression resulting from HIV infection. Variables of outcome after treatment of tuberculosis among People Living with HIV/AIDS (PLHA) are not well elucidated in developing countries with limited resources. Hence this study was undertaken to assess socio-demographic correlates, clinical profile & treatment outcome of tuberculosis disease among people living with HIV/AIDS, registered at an ART centre in Mumbai.

Methods: The retrospective study was based on secondary data of TB-HIV co-infected patients, registered for treatment & care at Govandi ART centre, situated in dense overcrowded and majority migrant slum province in Mumbai city. All the patients (377) diagnosed as co-infected during period 2016-2017 were included in the study. The socio-demographic details of the patients, clinical presentation of TB disease, and progress with Anti-retroviral & anti-TB treatment were assessed from patient´s treatment cards, TB HIV line list and HIV-TB register. Tests viz Chi square test, Fishers exact test & multivariate analysis were used for significance.

Results: Among 377 patients, 226(59.9%) were Males and 151(40.1%) were females.198 (52.5%) PLHAs had Pulmonary TB, 165 (43.8%) had Extra-pulmonary TB and 14(3.7%) were diagnosed with Multi-drug resistant TB. Median CD4 count at TB diagnosis was 207/mm3. 260(68.9%) patients successfully completed Anti- TB treatment, 31(8.4%) expired, 86(22.7%) defaulted. Of the co-infected patients, 354 patients underwent CD4 testing of which 83.04% patients had cd4 count less than 350/mm3. Mean CD4 count of patients who completed treatment was 265.67/mm3(Median 228,SD 212.13/mm3 95% CI) while that of expired patients was 160.38/mm3(Median 120, SD 127.19/mm3 95% CI). The association between CD4 count & treatment outcome was statistically significant

(p< 0.0001). Similarly patients who successfully completed ant-TB treatment showed significant improvement in their CD4 count (p< 0.0001).
Conclusions: Early diagnosis of TB disease among PLHAs improved the chances of successful Anti-TB treatment which helped in immunological improvement in HIV disease.

WEPEB062

Universal anti retroviral therapy eligibility and tuberculosis case finding among HIV infected clients in Malawi - lessons learnt

P. Nyasulu[1], B. Chiwandira[2], M. Odo[2], B. Girma[3], T. Kalua[2], J. Mpunga[3], A. Jahn[2], R. Nyirenda[1]
[1]Ministry of Health, Government of Malawi, Department of HIV & AIDS, Lilongwe, Malawi, [2]Ministry of Health, Department of HIV & AIDS, Lilongwe, Malawi, [3]Ministry of Health, National TB Control Programme, Lilongwe, Malawi

Background: Malawi is a high burden TB and HIV sub-Saharan African country with co-infection rate of about 50%. Undiagnosed TB among PLHIV remains a critical challenge and contributes about 40% of facility-based HIV/AIDS-related adult deaths. In July 2016, Malawi adopted and implemented the World Health Organization (WHO) universal eligibility policy for HIV treatment initiation to improve treatment outcome among patients on ART and minimize the risk of developing HIV-related opportunistic infections such as TB. We evaluate the impact of this policy change on presumptive TB cases and notified TB cases among PLHIV attending ART clinics in Malawi.
Description: This was a retrospective evaluation of routine program data for Malawi before the policy change, between July 2015 to June, 2016, and afterwards, between July, 2016 and June 2017. The evaluation extracted data from the intensified TB case finding section of the national quarterly HIV program reports. Total presumptive TB cases and notified TB cases were compared between July 2015 to June 2016 and July 2016 to June 2017. Annual performance proportions were compared to WHO targets of 5% presumptive cases and 70% case detection rate for the reviewed period. Statistical significance measured at p< 0.05.
Lessons learned: By the end of September 2016, 732 health facilities offering integrated HIV services implemented the policy change. The number of HIV infected clients alive on treatment increased by 12% between the different periods reviewed. The number of presumptive TB cases among PLHIV in care doubled and there was statistical significant relationship with the different reporting periods before and after policy change (X^2 = 1270.96; p < 0.0001). The number of notified TB cases from HIV care increased from 3887 to 7725 after policy change. There was statistically significant relationship in the number of TB cases and the different periods reviewed (X^2 = 183.59; p < 0.0001).The estimated TB case detection rate increased from 46.3% to 58.1% leaving a gap of 11.9% to reach WHO target.
Conclusions/Next steps: Implementation of universal eligibility to ART facilitated improved performance of TB case finding indicators among PLHIV. Strengthening TB/HIV collaborative activities is needed to minimize gap with global targets.

Characteristics	July 2015 - June 2016	July 2016 - June 2017	X2	p-value^
# HIV infected Clients alive on ART	627395	709706		
Total # HIV clients ICF done	613714	693825		
% Screened	97.8%	97.8%

Genetic diversity of *Mycobacterium tuberculosis* clinical isolates in Botswana

T. Mogashoa[1], P. Melamu[1], T. Iketleng[1], L. Mupfumi[1], K. Seatla[1], N. Zetola[2], L. Letsibogo[3], M. Mokomane[3], B. Mbeha[3], S. Ley[4], E. Streicher[4], S. Moyo[5], I. Kasvosve[6], R. Warren[4], S. Gaseitiswe[5]
[1]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [2]Botswana-University of Pennsylvannia Partnership, Department of Radiation and Oncology, University of Pennsylvania, Gaborone, Botswana, [3]National Tuberculosis Reference Laboratory, Gaborone, Botswana, [4]DST/NRF Centre of Excellence in Biomedical Tuberculosis Research/SA MRC Centre for Tuberculosis Research, Division of Molecular Biology and Human Genetics, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa, [5]Botswana Harvard AIDS Institute Partnership/Department of Immunology and Infectious Diseases, Harvard T.H. Chan School of Public Health, Boston, Massachusetts, USA, Gaborone, Botswana, [6]School of Allied Health Professionals, Faculty of Health Sciences, University of Botswana, Medical Laboratory Sciences, Gaborone, Botswana

Background: Molecular typing of *Mycobacterium tuberculosis* (*M.tb)* isolates informs Tuberculosis (TB) control program on the relative proportion of transmission driving the TB epidemic. We utilized spoligotyping to describe the genetic diversity of *M.tb* strains and their respective contribution to transmission in Botswana.
Methods: A total of 502 culture-confirmed *M.tb* isolates received at the Botswana National Tuberculosis Reference Laboratory between 2012 and 2013 were analyzed. Drug susceptibility testing was done using the MTBDR*plus* line probe assay. DNA was extracted from BD Mycobacterial Growth Indicator Tubes (MGIT) using Hain GenoLyse DNA isolation kit®. Spoligotyping was done using a commercially available kit. The spoligotype patterns were compared with existing spoligotype patterns in the SITVIT Web database. Fisher's Exact test was used to determine the relationship between HIV status, geographical location, and genotype.
Results: 112 distinct spoligotype patterns were detected amongst 502 isolates. Seventy-six (68%) had been reported in SITVIT and thirty-six (32%) had not been previously described. The most predominant spoligotype patterns were: LAM (33%), S (12%), T (15%), X (16%) and Beijing (10%). Four hundred and thirty-five (87%) isolates could be grouped into 43 clusters (2-48 isolates per cluster) implying ongoing transmission; 69 isolates had unique spoligotype patterns. There was an association between genotype and geographical location (p< 0.0001), no association was found between HIV status and genotype (p=0.248). Drug susceptibility data showed that 202 (40%) isolates were resistant to at least one TB drug. Sixty-eight isolates (13%) were multidrug resistant. Among drug-resistant isolates, 140 (69.3%) were clustered.
Conclusions: This study highlights the complexity of the TB epidemic in Botswana with different strains contributing to disease. The high proportion of clustering is worrying suggesting that new interventions are required to halt transmission. The ongoing transmission of drug-resistance highlights the need for routine drug susceptibility testing for all to prevent the amplification of resistance.

WEPEB064

An innovative approach to improving TB and HIV case identification in the community using trained volunteers-a programme evaluation in Benue State, Nigeria

J. Okpala, F. Ogirima, D. Barnabas, P. Christopher Izere, J. Sagay, C. Imarhiagbe, O. Busari, B. Oyeledun, A. Ajibola
Center for Integrated Health Programs, Abuja, Nigeria

Background: Nigeria has the fourth largest TBHIV burden in the world. Benue state, in North Central, Nigeria has a high TB burden attributable to its high HIV prevalence of 5.6%. Benue state is one of the selected states by CDC due to its high HIV prevalence with some local government areas (LGAs) identified for scaling up HIV services. This is to prioritize reaching the UNAIDS HIV 90-90-90 targets.
A door to door strategy was adopted by centre for integrated health programs to reach people in the communities with HIV counselling, testing

and treatment of diagnosed HIV clients. Trained volunteers (TVs) were engaged to carry out these activities as well as TB case detection in the community.
We reviewed the impact of the TVs in improving TB case detection in some communities.
Methods: The intervention was carried out across 3 scale up LGAs -Tarka, Gwer West and Logo in Benue State, North Central zone of Nigeria from Feb to May 2017. Orientation meeting was carried out for the trained volunteers on TB case detection in the community and commodities for sputum collection for Genexpert such as sputum cups, tissue rolls and cold chain boxes were distributed. TVs carried out HIV counselling, testing and TB screening for all clients and Sputum collected for Genexpert test from identified presumptives and sent to the lab using the cold chain box for evaluation.
Pre and post intervention data were analysed after four months implementation.
Results: The number of clients identified as presumptive TB cases increased by 291% from 53 to 207 in the period under review. The number of presumptive with cough sent for Genexpert significantly increased from 4 to 58(14-fold increase, P value =0.047). 2 TB cases were diagnosed at the end of the review as against nil diagnosis pre intervention period.
Conclusions: The use of trained volunteers in the community improved TB and HIV screening, identification of presumptive TB cases and also TB diagnosis using Genexpert.
However, additional measures will be needed to improve diagnosis of Tuberculosis.

WEPEB065

Evaluating care for PLHIV co-infected with TB in the Municipal STD/Aids Services in São Paulo City

C. Basso[1], J. Caraciolo[2], R. Camargo[2], R. Del Bianco[2], Z. Khoury[2]
[1]Secretaria Municipal de Saude - São Paulo, Programa Municipal de DST/Aids, São Paulo, Brazil, [2]Municipal Health Secretariat - Sao Paulo, STD/AIDS Program, Sao Paulo, Brazil

Background: AIDS mortality in the Municipality of São Paulo, reached 6.1/100,000 inhabitants in 2016. The Aids investigation deaths between September/2015 and March/2016 revealed that 35% were associated with Tuberculosis. Improving the quality of care for co-infected patients may contribute to reducing Tuberculosis mortality and consequently AIDS. The study objective was to describe the care of HIV-infected PLHIV and to propose measures that contribute to the improvement of quality of care and reduction of Tuberculosis and AIDS mortality.
Description: Outcomes were analyzed - high for cure, dropouts and deaths - of the cases diagnosed in the first half of 2015 from the routine information of the TB-Web Information System. Data were disaggregated by health regions, by the 16 care services from 26 The Municipal STD/Aids Services of São Paulo City that accompany PLHIV. The outcomes of PLHIV co-infected with Tuberculosis are unfavorable in relation to HIV negative people with Tuberculosis, with important differences in cure rates, dropouts and deaths between services and the type of treatment (directly observed versus self-administered). The cure rates of PLHIV and HIV-negative were 55% and 84%, respectively. The percentage of dropouts was twice as high among PLHIV (20% versus 10%) and that of deaths 4.6 times more frequent among PLHIV (21.5 versus 4.6). Cure rates ranged from 55% to 100% among services and were higher among patients undergoing directly-versus-self-administered treatment (71% versus 49%). Only 60% of the new HIV cases were Tuberculin Proof (PT). Among the 14.6% with PT> 5mm, only 47% performed the treatment of Latent TB Infection (ILTB).
Lessons learned: The analysis revealed a role of opportunity to improve care for PLHIV co-infected with Tuberculosis. Also, the feasibility of the actions to be developed, once there are services with favorable outcomes and comparable to those of HIV negative people. The TB-Web Information System provides useful information for decision-making and for monitoring the performance of the Municipal STD/Aids Services.
Conclusions/Next steps: There are high chances for interventions to improve care for HIV-infected PLHIV, such as expanding directly-supervised treatment and, above all, increasing the diagnosis and treatment of Latent Tuberculosis in order to reduce the Tuberculosis incidence and mortality rate among PLHIV.

WEPEB066

Treatment outcomes of a short standardized regimen for multidrug-resistant tuberculosis patients co-infected with HIV in Mozambique

M. Bastard[1], E. Poulet[1], L. Cossa[2], E. Graglia[2], I. Manhiça[3], B. Rusch[4], L. Molfino[2], A. Telnov[4]
[1]Epicentre, Paris, France, [2]Médecins Sans Frontières, Maputo, Mozambique, [3]National TB Program, Ministry of Health, Maputo, Mozambique, [4]Médecins Sans Frontières, Geneva, Switzerland

Background: Standardized regimen of 9-11 months duration has shown high rates of success and has been recommended by WHO as an alternative for 24 months regimen for multidrug-resistant Tuberculosis (MDR-TB) patients with no additional resistance to second line drugs and pyrazinamide. However, few data on the effectiveness of this regimen in patients co-infected with HIV are available.
Methods: A prospective cohort study was conducted in Maputo, Mozambique, among MDR-TB HIV-positive patients. The study included patients with active pulmonary tuberculosis diagnosed as rifampicin resistant or children suspected of MDR-TB without bacteriological confirmation but documented as a close contact of confirmed MDR-TB patient, without previous treatment with second-line drugs and tested positive for HIV.
Results: A total of 48 HIV-positive MDR-TB patients started on short course regimen between November 2015 and March 2017: 52.1% females, a median age of 34 years [IQR 29-42], a median BMI of 18.1 kg/m2 [IQR 16.2-20.8] and 43.7% were previously treated for TB. They were 75.0% in clinical stage 4 and 44 (91.7%) received ART at MDR-TB treatment start. Baseline resistance was: 42.4% resistant to pyrazinamide, 44.1% to ethionamide, 2.8% to both injectable drugs and 12.5% to fluoroquinoles. MDR-TB treatment outcomes were: 19 (39.6%) cured, 14 (29.2%) treatment completed, 6 (12.5%) deaths, 5 (10.4%) treatment failure and 4 (8.3%) lost to follow-up. Among those who failed treatment, 2 (40.0%) were resistant to fluoroquinolones and 3 (60.0%) were resistant to pyrazinamide.
Conclusions: This study on the first MDR-TB patients co-infected with HIV receiving short course regimen in Mozambique shows a good success rate compared to the conventional MDR-TB regimen despite a high early death rate and the advanced HIV stage of the patients. Resistance to fluoroquinolones seems also to be associated with a lower success rate. This confirms the WHO recommendation to exclude them from the short course regimen and stresses the need to use rapid molecular testing for fluoroquinolones resistance.

WEPEB067

Benefit of isoniazide preventive therapy to reduce incident TB, mortality and loss to follow-up in Indonesian five-years cohort

R. Wisaksana[1], Y. Hartantri[1], M. Lestari[2], D. Azzahra[2], T. Karjadi[3], E. Yunihastuti[3], A. Ujainah[3], H. Agustin[4], E. Eppy[4], E. Burhan[4], M.R.T. Komaryani[5], E. Hastuti[6], N. Sulaiman[7], S. Wiyana[6], T. Nisa[8]
[1]Hasan Sadikin Hospital, Internal Medicine Department, Bandung, Indonesia, [2]Padjadjaran University, HIV Wiorking Group, Bandung, Indonesia, [3]Cipto Mangunkusmo Hospital, Internal Medicine Department, Jakarta, Indonesia, [4]Persahabatan Hospital, Jakarta, Indonesia, [5]Marzoeki Mahdi Hopsital, Bogor, Indonesia, [6]Ministry of Health Indonesia, National AIDS Program, Jakarta, Indonesia, [7]Ministry of Health Indonesia, National TB Program, Jakarta, Indonesia, [8]World Health Organization, Jakarta, Indonesia

Background: Isoniazide Preventive Therapy (IPT) have been recommended by WHO since 23 years ago. Despite the recognized benefit from previous studies globally, clinicians in Indonesia considered that implementation study on IPT needs to be performed. National AIDS Program and National TB Program of Indonesia initiated IPT study in 4 top-referral hospital in Indonesia in 2012, to show benefit of IPT in preventing active Tuberculosis (TB) among PLHIV in endemic countries such as Indonesia.
Methods: Group of HIV-infected subjects which receive IPT during 2012-2014 were compared with other group of HIV-infected subjects which not receive IPT matched on age, gender, CD4 cell count and ART status.

Both groups followed until 5 years. Outcome of active TB disease was the study primary end point; with all-cause mortality and loss follow-up as secondary end points.
Results: This study found IPT reduce TB incident from IR: 4.4 / 100 person-years (95% CI: 3.2 - 6.1) in non-IPT HIV-patients into IR: 1.2 / 100 person-years (95% CI: 0.5 - 2.6) in the first 3 years. In 5 years TB incident still lower in IPT group with IR: 1.7 / 100 person-years (95% CI: 0.9 - 3.0) compared to non-IPT group, IR: 3.6 / 100 person-years (95% CI: 2.7 - 4.9). For secondary outcome, this study showed risk of mortality and loss to follow-up lower in IPT group compare to non-IPT group but not significant. History of TB have higher risk of mortality and low adherence have higher risk of loss to follow-up.
Conclusions: This first study from Indonesia has confirmed other previous studies globally on IPT. As a part of TB-HIV collaborations, IPT program must be expanded and promoted to all PLHIV in Indonesia.

WEPEB068

Yield and efficiency of novel intensified tuberculosis case-finding algorithms for people living with HIV

C. Yoon[1], F. Semitala[2], L. Asege[3], J. Katende[4], S. Mwebe[3], A. Andama[2], E. Atuhumuza[3], M. Nakaye[3], D. Armstrong[5], D. Dowdy[6], C. McCulloch[7], M. Kamya[2], A. Cattamanchi[1]
[1]University of California, Zuckerberg San Francisco General Hospital, Medicine, San Francisco, United States, [2]Makerere University College of Health Sciences, Medicine, Kampala, Uganda, [3]Makerere University-University of California, San Francisco Research Collaboration, Kampala, Uganda, [4]Makerere University Joint AIDS Program, Kampala, Uganda, [5]Johns Hopkins University, Medicine, Baltimore, United States, [6]Johns Hopkins University, Epidemiology, Baltimore, United States, [7]University of California, Epidemiology and Biostatistics, San Francisco, United States

Background: The recommended tuberculosis (TB) intensified case finding (ICF) algorithm for people living with HIV (PLHIV) - symptom-based screening followed by Xpert MTB/RIF (Xpert) testing - is inefficient and insufficiently sensitive. We investigated whether novel algorithms using C-reactive protein (CRP)-based TB screening followed by confirmatory testing with urine Determine TB-LAM (TB-LAM), sputum Xpert and/or a single sputum culture could improve ICF efficiency and yield.
Methods: Consecutive PLHIV with CD4 count ≤350 cells/μL initiating antiretroviral therapy in Uganda were prospectively screened for TB by symptom-based screening and CRP (cut-point 8 mg/L) measured using a rapid and inexpensive point-of-care (POC) assay. Participants submitted sputum for Xpert testing and culture and urine (if CD4 count ≤100 cells/μL) for TB-LAM testing. We compared the yield and efficiency of the current ICF algorithm to novel ICF algorithms beginning with POC CRP-based TB screening followed by confirmatory testing with TB-LAM, Xpert, and/or a single culture.

ICF strategy	Diagnostic yield #, (%, 95% CI) all TB cases detected (N=203)	Incremental yield: # additional TB cases detected	Incremental yield: % additional TB cases detected (95% CI)	Incremental yield: p-value for the difference	Total # false-positives
Current ICF algorithm*	119 (59%, 52-65)	REF	REF	--	7
Novel ICF algorithms:					
WHO symptom screen +...					
TB-LAM + Xpert	126 (62%, 55-69)	+7	+4% (0 to +7)	0.008	13
TB-LAM + Xpert + culture	172 (85%, 79-89)	+53	+27% (+20 to +34)	<0.0001	13
POC CRP ≥8 mg/L + ...					
Xpert†	114 (56%, 49-63)	-5	-2% (-5 to +1)	0.06	4
TB-LAM + Xpert†	121, (60%, 53-66)	+2	+1% (-3 to +5)	0.59	10
TB-LAM + Xpert + culture‡	158, (78%, 71-83)	+39	+19% (+12 to +26)	<0.0001	10

Abbreviations: TB (tuberculosis); ICF (intensified case finding); WHO (World Health Organization); POC CRP (point-of-care C-reactive protein).
Legend:
*Current ICF strategy (symptom-based TB screening, followed by Xpert confirmatory testing of all those who screen-positive). Incremental yield (#, %) of all evaluated ICF strategies are shown above relative to the current ICF strategy.
†Diagnostic yield of POC CRP-based ICF algorithm similar to corresponding symptom-based ICF algorithm (p≥0.06).
‡Diagnostic yield of POC CRP-based ICF algorithm less than corresponding symptom-based ICF algorithm (p=0.0003).

[Table 1. Incremental yield, diagnostic yield, and # of false-positive TB cases of novel ICF algorithms relative to the current ICF algorithm.]*

Results: Of 1245 HIV-infected adults enrolled, 203 (16%) had culture-confirmed TB nearly half (49%, n=101) of whom had CD4 counts ≤100 cells/μL. Compared to the current ICF algorithm, POC CRP-based TB screening followed by Xpert testing had similar yield (56% [95% CI: 49-63] vs. 59% [95% CI: 51-65]) but consumed less than half as many Xpert assays per TB case detected (9 vs. 4). Addition of TB-LAM did not significantly increase diagnostic yield (+1% [95% CI: -3 to +5]) relative to the current ICF algorithm but provided same-day diagnosis for 26% of TB patients with advanced HIV. Addition of a single culture to TB-LAM and Xpert substantially improved ICF yield, identifying 78% of all TB cases.
Conclusions: POC CRP-based screening can improve the efficiency of ICF for PLHIV. Addition of TB-LAM and a single culture to Xpert confirmatory testing could enable HIV programs to increase the speed of TB diagnosis and ICF yield.

WEPEB069

Enhancement of the INSHI case definition for paradoxical tuberculosis-associated immune reconstitution inflammatory syndrome using latent class analysis

C. Stek[1,2], J. Buyze[1], J. Menten[1], C. Schutz[2], F. Thienemann[2], L. Blumenthal[2], G. Maartens[2], T. Boyles[2], R.J. Wilkinson[2], G. Meintjes[2], L. Lynen[1]
[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]University of Cape Town, Cape Town, South Africa

Background: The diagnosis of paradoxical TB-IRIS relies on characteristic clinical features synthesized as the International Network for the Study of HIV-associated IRIS (INSHI) case definition. There is no confirmatory laboratory test. We assessed whether a data-driven approach that used latent class analysis (LCA) could enhance the performance of the case definition. LCA combines multiple variables to obtain estimates of disease prevalence and diagnostic accuracy in situations where there is no gold standard.
Methods: The PredART trial evaluated prednisone for TB-IRIS prevention in high-risk patients starting ART in South Africa (n=240). TB-IRIS events were adjudicated by consensus of 3 independent experts using the INSHI case definition. All clinical and laboratory variables recorded during the first 4 weeks of ART and all individual components of the INSHI criteria were assessed for their association with TB-IRIS. Those with a strong association (OR > 3.0) were selected for LCA. We combined the selected parameters in a latent class model using LEM software. We used the LCA-predicted probability of TB-IRIS for each participant to assess the performance of the INSHI case definition and compare its diagnostic accuracy with several adapted case definitions.
Results: Data were complete for 217 participants; 41% developed TB-IRIS. Our latent class model included the following parameters: respiratory symptoms, night sweats, INSHI major criteria 1, 2, and 4 (new or enlarging lymph nodes, radiological abnormalities, and serositis respectively), maximum CRP > 90, maximum heart rate > 120, maximum temperature > 37.7, and pre-ART CD4 count < 50. None of the participants fulfilled INSHI major criterion 3 (neurologic features). The model estimated a TB-IRIS prevalence of 43% and had optimal goodness of fit (^{2} = 336.7, p = 1.0). Performance of adapted case definitions are summarized in the table.

TB-IRIS definition	Sensitivity	Specificity
INSHI case definition: [1 INSHI major] or [2 INSHI minors]	0.77	0.86
CRP > 90	0.73	0.88
1 INSHI major criterion only	0.60	0.92
[1 INSHI major], [2 INSHI minors], or [1 INSHI minor and CRP > 90]	0.85	0.78
[1 INSHI major] or [1 INSHI minor and CRP > 90]	0.86	0.83
[1 INSHI major] or [1 INSHI minor and CRP > 90 / heart rate > 120 / temperature > 37.7]	0.93	0.82
[1 INSHI major] or [any 2 of CRP > 90, heart rate > 120, or temperature > 37.7]	0.89	0.88

[Diagnostic performance of adapted TB-IRIS case definitions]

Conclusions: The INSHI case definition predicts TB-IRIS with reasonable accuracy. Amending the case definition by replacing the INSHI minor criteria with the objective variables heart rate, temperature, and/or CRP improved sensitivity without loss in specificity. A definition including only INSHI major criteria had the highest specificity.

WEPEB070

A household cluster randomised trial of active case finding for HIV/TB, preventive treatment against TB, and ART initiation to prevent TB disease and transmission in South Africa: Baseline data

P. MacPherson[1,2], E. Webb[3], E. Variava[4], S. Lala[5,6], M. Milovanovic[5], Z. Bosch[5], P. Motsomi[5], L. Lebina[5], A. Kinghorn[5], A. Ratsela[7], N. Martinson[4,5]
[1]*Malawi-Liverpool-Wellcome Trust Clinical Research Programme, HIV/TB Group, Blantyre, Malawi,* [2]*Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom,* [3]*London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom,* [4]*Klerksdorp Tshepong Hospital Complex and University of the Witwatersrand, Department of Internal Medicine, Klerksdorp, South Africa,* [5]*Perinatal HIV Research Unit (PHRU), Soweto, South Africa,* [6]*Chris Hani Baragwanath Academic Hospital, Department of Paediatrics, Soweto, South Africa,* [7]*Polokwane and Mankweng Hospitals, University of Limpopo, Department of Medicine, Polokwane, South Africa*

Background: Household contact tracing of index TB cases has been advocated as a key part of TB control for many years, but has not been widely implemented in many high HIV prevalence settings.
Methods: A household cluster randomised (ISRCTN16006202) trial of interventions aimed at improving TB-free survival and reducing childhood prevalence of *Mycobacterium tuberculosis* infection among household contacts of index TB cases is being conducted in two districts of South Africa (Botshabelo, Free State; and Capricorn, Limpopo). Households of index cases with microbiologically-confirmed TB (>7 years of age) or children (< 7 years) with microbiologically or clinically diagnosed TB were randomly allocated to receive either the intensified home screening and linkage for TB and HIV intervention (home strategy) or a referral letter strategy. We report prevalence of TB disease, TB infection and HIV in household contacts randomised to receive the home strategy.
Results: Between December 2016 and January 2018, a total of 954 index TB cases were recruited: 913 adults and 41 children. 55% of index TB cases were HIV-positive. We recruited a total of 3940 household contacts (mean of 4.1 per household). Compared to household contacts from Capricorn, contacts from Botshabelo were younger (median: 17 vs. 19 years), and more likely to have symptoms of TB (297/1783 [16.7%] vs. 195/2117 [9.2%]). In the home group, 84.6% (1014/1119) of household contacts who did not know their HIV status were tested for HIV, of whom 4.1% were HIV-infected. 417/909 (68.6%) of all household contacts not on TB therapy were sputum tested, with overall 24/909 (2.6%) having microbiologically-confirmed TB. Of household contacts with microbiologically-confirmed TB, only 41% (10/24) reported symptoms suggestive of TB; 42% of all newly diagnosed TB household contacts were HIV-coinfected. Overall, 45.6% (113/248 >10mm) of adult contacts and 55.0% (99/180 >5mm) of child contacts were TST positive.
Conclusions: We were able to promptly identify and screen household contacts of index TB cases in diverse settings in South Africa. A substantial proportion of household contacts with TB did not have TB symptoms. This trial will provide evidence of resource needs and cost-effectiveness of two approaches for contact screening in low-resource settings.

WEPEB071

Incidence of adverse events associated with isoniazid preventive therapy in adults on stable antiretroviral therapy in Blantyre, Malawi

L. Tsilizani[1], W. Nyangulu[2], O. Nyirenda[1], N. Nampota[1], F. Mkandawire[1], E. Singogo[2], J. Mallewa[3], T.E. Taylor[1], M.B. Laurens[4], M.K. Laufer[4], J.J. van Oosterhout[2,3]
[1]*Blantyre Malaria Project, University of Malawi, College of Medicine, Blantyre, Malawi,* [2]*Dignitas International, Zomba, Malawi,* [3]*University of Malawi, College of Medicine, Department of Medicine, Blantyre, Malawi,* [4]*Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, United States*

Background: Isoniazid preventive therapy (IPT) reduces tuberculosis incidence in people living with HIV. After Malawi's Ministry of Health introduced IPT in patients on antiretroviral therapy (ART) in 2017, numerous adverse events (AEs) suspected to be related to IPT were reported. High-quality data on IPT toxicity in sub-Saharan African settings are sparse because side effect monitoring is often unreliable.
We observed AEs among Malawian adults on ART who started IPT and had stringent clinical follow-up as participants in a randomized, open-label controlled trial of daily trimethoprim-sulfamethoxazole or weekly chloroquine.
Methods: The trial enrolled adults on ART (≥6 months) with CD4 count ≥250 cells/µL and HIV-1 RNA ≤400 copies/ml, followed them every 4-12 weeks and encouraged additional clinic visits in case of any illness. Six-monthly viral load, CD4 count, liver enzymes, renal function and complete blood counts were collected. Using the WHO standardized case-causality assessment tool, we categorized AEs into "certainly", "probably" and "possibly" related to IPT. We calculated incidence rates of related AEs after initiation of IPT.
Results: 853 participants initiated IPT (651 females, 76%) and accrued 310.8 person years of observation (PYO) on IPT, with a mean observation time of 3 months per individual. Mean age was 41.9 years, mean CD4 569 cells/µL, 98.1% had HIV-1 RNA < 400 copies/ml. 35.1% of participants on IPT experienced at least one IPT related AE. Of 425 IPT related AEs, 26.1% were certainly related to IPT (96.4% mild/moderate, 3.0% severe), 52.9% were probably related (98.7% mild/moderate, 1.3% severe), and 20.9% possibly related (all mild/moderate).
The most common events involved gastrointestinal (30.6%), dermatological (12.9%), hepatic (10.8%), peripheral nervous (6.4%), central nervous (5.5%) and reproductive (1.1%) systems. Events that led to IPT discontinuation (51 participants) included pellagra, peripheral neuropathy, hepatotoxicity, gynecomastia, impotence, vomiting, dizziness and confusion. The overall crude incidence of IPT-related AEs was 1.37/PYO (95% CI: 1.24-1.50), with details of incidence by severity in Table 1.

Category	Overall incidence of AEs	Incidence of mild and moderate AEs	Incidence of severe AEs
Certainly related	0.36 /PYO (95% CI: 0.29-0.43)	0.34 /PYO (95% CI: 0.28-0.42)	0.01 /PYO (95% CI: 0.00-0.33)
Probably related	0.72 /PYO (95% CI: 0.63-0.82)	0.71 /PYO (95% CI: 0.62-0.81)	0.01 /PYO (95% CI: 0.00-0.28)
Possibly related	0.29 /PYO (95% CI: 0.23-0.35)	0.29 /PYO (95% CI: 0.23-0.35)	0.00 /PYO (95% CI: 0.00-0.02)
Any relatedness	1.37 /PYO (95% CI: 1.24-1.50	1.35 /PYO (95% CI: 1.22-1.48)	0.02 /PYO (95% CI: 0.01-0.46)

[Table 1. Incidence of IPT related Adverse Events by severity]

Conclusions: We observed high incidence of IPT related AEs within a 3 month period. Although few AEs were severe, 6% of individuals discontinued IPT. We recommend careful monitoring and reporting of IPT toxicity to ensure maximal benefit of IPT.

WEPEB072

Focused assessment with sonography (FASH) in microbiologically diagnosed HIV/TB patients and controls admitted to a Malawian hospital

M. Alufandika-Moyo[1], A. Gupta-Wright[2,3], T. Mtenga[1], A. Tebulo[1], E. Mangani[1], K. Fielding[2], E.L. Corbett[2,3], T. Heller[4], S. Lawn[2], J. van Oosterhout[1,5]
[1]*Dignitas International, Zomba, Malawi,* [2]*London School of Hygiene and Tropical Medicine, London, United Kingdom,* [3]*Malawi-Liverpool-Wellcome Trust Clinical Research Programme, College of Medicine, University of Malawi, Blantyre, Malawi,* [4]*Lighthouse Trust Clinic, Lilongwe, Malawi,* [5]*University of Malawi, College of Medicine, Medicine Department, Blantyre, Malawi*

Background: Evidence suggests that HIV-associated tuberculosis (HIV/TB) diagnosed by urine-tests (Xpert MTB/RIF and TB-LAM) is indicative of disseminated, renal TB. A validated protocol for Focused Assessment with Sonography for HIV/TB (FASH) detects characteristic extra-pulmonary (EP) features such as pleural, pericardial and abdominal effusions, abdominal lymphadenopathy, and splenic micro-abscesses, and is suited for clinicians with limited ultrasound training in low-resource settings. We sought to determine the prevalence of ultrasonographic EPTB features and compare urine-test positive and negative HIV/TB patients.

Methods: The FASH protocol was used on HIV/TB patients and selected HIV-positive controls in Zomba Central Hospital, Malawi to determine the proportion of microbiologically confirmed HIV/TB patients with FASH features by trained clinicians (nested within the STAMP TB urine-diagnostic trial). Controls were HIV positive patients without evidence of TB on microbiological testing and clinical features by 2 months post enrolment. Clinicians using FASH were blinded to urine-test status (but not TB status).
Results: 93 HIV-positive adults were enrolled on admission to hospital and underwent FASH; 42 were microbiologically confirmed TB patients and 51 controls without TB; 31.2% male; mean age 39.5 years (SD 8.8); mean hemoglobin concentration 9.1g/dL (SD 3.1); median CD4 179 cells/µL (IQR 67-380). Median CD4 count (77 vs. 312 cells/µL; p<0.001) and mean Hb (7.8 vs. 10.5 g/dL; p<0.001) were lower in TB cases than controls. 38/42 (90.5%) HIV/TB patients were urine-test positive. 23/42 (54.8%) HIV/TB patients had at least one feature of EPTB on FASH compared to none of the control patients. Prevalence of pericardial effusion was (33.3%), abdominal lymphadenopathy (31.7%), splenic micro-abscesses (30.9%), pleural effusion (11.9%), ascites (2.4%). Due to the high prevalence of urine-test positive disseminated TB in this cohort, we were unable to compare FASH features with urine-test negative HIV/TB patients (n=4).
Conclusions: FASH features of EPTB are common in hospitalised HIV/TB patients, and appear specific in this cohort as patients without microbiological and clinical evidence of TB were unlikely to have FASH features. In the absence of urine-based TB tests, the FASH protocol may be useful for TB diagnosis in HIV-positive patients admitted to hospital in low-resource settings.

WEPEB073

Poor treatment outcome and higher mortality rate among TB/HIV co-infected patients compared to TB without HIV infected patients

S. Gatechompol[1], J. Sophonphan[1], K. Kawkitinarong[2], G. Suwanpimolkul[2], P. Kateruttanakul[3], W. Manosuthi[4], S. Ubolyam[1], S. Kerr[1,5], A. Avihingsanon[1], K. Ruxrungtham[2]
[1]HIV-NAT Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, [3]Rajavithi Hospital, Department of Medicine, Bangkok, Thailand, [4]Bamrasnaradura Infectious Diseases Institute, Ministry of Public Health, Nonthaburi, Thailand, [5]Kirby Institute, University of New South Wales, Sydney, Australia

Background: Thailand is one of fourteen countries that has a high burden of TB, MDR-TB and coprevalent TB/HIV. Over the past decade, the Thai heath system has sought to improve HIV/TB treatment and care. Understanding treatment outcomes and factors associated with mortality in these TB/HIV co-infected patients is essential for further improvement of TB/HIV care management.
Methods: Participants diagnosed with active tuberculosis from 2008-2016 at 3 hospitals were included in this analysis. These hospitals which form the clinical cohort network called the "Thailand Big City TB research network".The primary outcome of current study was treatment outcomes among TB/HIV co-infected patients compared with TB non HIV-infected patients. Successful treatment was defined as cure (i.e smear- or culture-negative in the last month of treatment) and treatment completed (i.e. completed treatment without bacteriologically confirmed).The secondary objective was to determine factors associated with mortality using logistic regression.
Results: A total of 998 participants were included in the study. Of these, 228 (22.8%) were HIV infected participants.The majority of participants were male (59.5%) with median age 41 (IQR 30-55) years. Among HIV infected participants, baseline median (IQR) CD4 cell count was 74 (27 - 199) cells/mm³.
Overall successful treatment outcomes occurred in 74.3% of patients. The treatment success rate was 77.3 % among non-HIV infected TB patients in contrast to 64.5% among HIV/TB patients (P <0.001).
One hundred forty- five (64%) HIV infected participants received antiretroviral treatment(ART) during course of TB treatment. Age > 50 years (adjusted odds ratio [aOR] 4.11, 95% CI 1.95 - 8.66; p < 0.001), body weight ≤45 kg (aOR 2.19, 95% CI 1.14 - 4.23; p=0.02) and HIV positive status (aOR 3.74, 95% CI 1.74 - 8.05; p < 0.001) were independently associated with the death after TB treatment.
Conclusions: Treatment success rate in HIV co-infected TB patients were lower than that observed in non-HIV infected patients. Patients with advanced age, and those with low body weight have an increased risk of mortality. Strategies to increase ART uptake and prevent active TB infection should be implemented among HIV infected patients.

	Univariate			Multivariate		
	Odds ratio	95%CI	P-value	Adjusted odds ratio	95%CI	P-value
Age >50	3.19	2.04 - 4.99	<0.001	4.11	1.95 - 8.66	<0.001
Male	1.47	0.92 - 2.35	0.11			
Weight ≤ 45 kg	2.60	1.43 - 4.95	0.002	2.19	1.14 - 4.23	0.02
Type of TB : pulmonary	0.74	0.43 - 1.27	0.28			
Prior TB diagnosis	1.38	0.82 - 2.31	0.22			
HIV-positive	1.75	1.09 - 2.81	0.02	3.74	1.74 - 8.05	0.001
Diabetes	2.14	1.13 - 4.06	0.02	1.87	0.70 - 5.03	0.21

Burden of invasive pneumococcal disease among patients attending an HIV referral center in Rio de Janeiro, Brazil

W. Jalo, M.C. Lourenco, É. Silva, V.G. Veloso, B. Grinsztejn, J. Moreira, C.C. Lamas
Fundacao Oswado Cruz, Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil

Background: Invasive pneumococcal disease (IPD) is a major cause of morbidity and mortality among HIV patients. Surveillance data of IPD in the HIV-infected patients for Latin America are lacking. We aimed to estimate the burden of IPD and to explore the impact of HIV infection on the clinical presentation, antimicrobial susceptibility, and survival.
Methods: *Streptococcus pneumoniae* isolates in sterile sites were identified in the INI/FIOCRUZ´s microbiology laboratory from 2005-2017 . Patients' charts were reviewed retrospectively for clinical, epidemiological and laboratory data. *S. pneumoniae* was identified using standard microbiological procedures, and antimicrobial susceptibility done by broth microdilution. The incidence of IPD in the HIV population was calculated based on the number of HIV-infected patients registered per year in our HIV cohort. Fisher´s exact test was used to compare categorical and Student´s *t* test for continuous variables.
Results: During the study period, 63 episodes of IPD were identified in 54 adults. Forty-eight (76%) were diagnosed in 40 HIV-infected patients. The incidence of IPD was 240 episodes per 100,000 person-years in HIV-infected patients. HIV patients were younger (41±9 *vs.* 61±18, years), median CD4⁺ was 239 (157-448) mm³ and 63.5% were on ART. Predisposing factors for IPD were smoking (52% *vs.* 28.6%, *p*=0.12), inhaled cocaine (45.8% *vs.* 0%, *p*=0.001), cannabis (29.2% *vs.* 0%, *p*=0.01), COPD (8.3% *vs.* 40%, *p*=0.003), alcohol intake (48% *vs.* 13%, *p*=0.01) in HIV positive and negative groups, respectively. Clinical syndromes were pneumonia (89.6% vs. 73%), meningitis (4.2% vs. 13%), and primary bacteremia (6.3% vs. 13%). There were no differences according to HIV status regarding the proportion of TMP-SMZ (19% vs. 13%,p=0.60), penicillin (10.6% vs. 6.7%, p=0.65), and macrolide resistance (6.4% vs. 6.7%, p=0.96) . Pneumococcal vaccination was reported more frequently in the HIV positives (29% vs. 6.7%, *p* =0.07). Hospital admissions (100% *vs.* 82%, *p*=0.07) and tuberculosis co-infections (29.4% vs. 6.9%, *p*= 0.04) were higher in those with CD4⁺

< 200. The rate of hospital (87.5% vs. 80%, *p*=0.43) and ICU admission (27% *vs.* 26.7%, *p*=0.97) did not differ according to HIV status.
Conclusions: We identified a high rate of IPD in HIV-infected patients and those with CD4+ < 200 were more often hospitalized.

Variable	Total (n=63)	HIV positive (n=48)	HIV negative (n=15)	p-value
Male - n (%)	38 (60)	30 (62.5)	8 (53.3)	0.52
Age, mean (SD) years	45.6 (14.6)	41 (9)	61 (18)	0.001
Bacteremic pneumonia, n - (%)	54 (85.7)	43 (89.6)	11 (73)	0.27
Other pathogen isolated in blood cultures n - (%)	5 (7.9)	2 (4.2)	3 (20)	0.04
History of 23-valent pneumococcal vaccination n - (%)	15 (23.8)	14 (29)	1 (6.7)	0.07
ICU admission - n (%)	17 (27)	13 (27)	4 (26.7)	0.97
In-hospital mortality n - (%)	13 (20)	8 (16.7)	5 (33.3)	0.16
Baseline neutrophils, median (IQR)	10.485 (6252-15721)	9101 (6115-12903)	16816 (13860-23400)	0.006
Hospital admission n - (%)	54 (85.7)	42 (87.5)	12 (80)	0.46

WEPEB075

Lower prevalence of Entamoeba species in children with vertically transmitted HIV infection in Western Kenya

E. Matey
Kenya Medical Research Institute, Nairobi, Kenya

Background: *Entamoeba histolytica* infections are highly prevalent among HIV-infected men who have sex with men (MSM). However, it remains unclear whether HIV-infection is a risk factor for *E. histolytica* infection. Also, little attention has been paid to other Entamoeba sp. (*E. dispar, E. moshkovskii, E. coli, E. hartmanni, and E. polecki*) even in HIV-infected population. In the present study we minimized the MSM-confounding effects by determining the prevalence Entamoeba sp. in children. Reliability of Entamoeba sp. infection as an indicator of HIV-infection was then evaluated.
Methods: Stool samples from 234 asymptomatic children [median age, 10 years [interquartile range (IQR), 7.0-12.0]] in Kisumu, comprising sex-age matched 123 HIV vertically-infected and 111 HIV-uninfected children not on anti-intestinal parasite 3 months prior were screened for Entamoeba sp. using molecular methods.
Results: The overall prevalence of Entamoeba spp. was significantly lower in the HIV-infected than in the HIV-uninfected (29.3 vs. 55.0%, P< 0.001). In HIV-infected and HIV-uninfected, the following Entamoeba species were detected: *E. histolytica*, in 0 and 0.9%; *E. dispar*, 3.3 and 5.4%; *E. coli*, 26.8 and 51.4% (P< 0.001); *E. hartmanni*, 14.6 and 27.9% (P=0.016); and *E. moshkovskii*, in 0 and 0%, respectively. Multiple logistic regression analysis showed that HIV-infected were nearly three times less likely to be infected with any Entamoeba species than HIV-uninfected (adjusted odds ratio=0.33, 95%; CI=0.19-0.60, P< 0.001). Multiple Entamoeba spp. infection was found more in HIV-uninfected than in HIV-infected children (27.9 vs. 13.0%, P ¼ 0.005). Among the HIV-infected children, CD4 T-cell counts were significantly higher in those with multiple Entamoeba spp. infection (median, 1261 cells/ml) than in those without the infection (918 cells/ml, P= 0.03) or those with the single Entamoeba spp. infection (787 cells/ml, P=0.03).
Conclusions: These findings indicate that the HIV infection is not a risk-factor for Entamoeba spp. infections, and suggest that better immunological status may play a role in the establishment of multiple-Entamoeba spp. infections. However, in this study, the prevalence of *E. histolytica* was too low (0.4%, 1/234) to conclude the relationship between *E. histolytica* infection and HIV infection. Also, social-behavioral and immunological analysis would also be needed for better understanding of these findings.

Gut homing CD4+ T cell count is associated with chronic gastritis activity

H. Sato[1], Y. Ota[1], Y. Matsubara[1], T. Kikuchi[1], M. Koga[1], T. Koibuchi[1], T. Tsutsumi[1], T. Matano[2], A. Kawana-Tachikawa[2], H. Yotsuyanagi[1], E. Adachi[1]
[1]Institute of Medical Science, University of Tokyo, Tokyo, Japan, [2]National Institute of Infectious Diseases, Tokyo, Japan

Background: Previous studies have shown people living with HIV (PLWH) with lower CD4+ T cells counts are less susceptible to chronic gastritis and *Helicobacter pylori (H.pylori)* infection. Animal model shows that host adaptive immunity is essential for the development of gastritis caused by *H.pylori* infection, which suggests that peripheral blood gut-homing CD4+ T cells have some roles in the development of chronic gastritis in PLWH.
Methods: We conducted a prospective cross-sectional study of PLWH who underwent upper gastrointestinal endoscopy from April 2014 to March 2016 in our institute. Biopsy specimens were obtained at the time of gastroendoscopy, which were used for classification of histologic gastritis by updated-Sydney system. Peripheral blood mononuclear cells were collected at the same point to determine the frequency of peripheral blood gut homing CD4+ T cells (CCR9+integrin 7+) and CD4+ memory T cells subsets (Th1; CCR6-CXCR3+CCR4-, Th2; CCR6-CXCR3-CCR4+, Th17; CCR6+CXCR3-CCR4+, Th17/1; CCR6+CXCR3+CCR4-) by flow cytometry.
Results: Sixty-six patients (median CD4 count 403 [range 2-1189] cells/µl) were enrolled in the study. Chronic active gastritis defined by histologic neutrophil infiltration using updated-Sydney system was observed in 15 (22.2%) patients. *H.pylori* was detected in 14 of the 15 (91.7%) patients. The flow cytometry data showed that the count of peripheral blood gut homing CD4+ T cells was higher in PLWH with chronic gastritis compared with those without (16.8 cells/µl vs 10.2 cells/µl; p=0.033). Additionally, those with gastritis had significantly higher gut homing Th1 cell counts (1.33 cells/µl vs 0.494 cells/µl; p=0.0057) and gut homing Th17/1 cell counts (0.404 cells/µl vs 0.245 cells/µl; p=0.020) (Fig.). No significant difference was found between the two groups on the count of peripheral blood total Th1 cells (89.8 cells/µl vs 71.4 cells/µl; p=0.24) and gut homing Th17 cells (3.40 cells/µl vs 2.49 cells/µl; p=0.37).
Conclusions: This is the first report showing the association of gut homing CD4+ T cells with chronic active gastritis in PLWH. PLWH with chronic active gastritis caused by *H.pylori* have higher count of peripheral blood gut homing CD4+ T cells, in particular Th1 cells. Our data suggest that Th1 play a key role in the development of chronic gastritis in PLWH.

The comparison of pyrimethamine-sulfadiazine and pyrimethamine-clindamycin for toxoplasmic encephalitis therapy in HIV/AIDS patients: An evidence-based case report

Y.D. Oktavianda[1], F. Prasetyawaty[2,3]
[1]Universitas Indonesia, Jakarta, Indonesia, [2]Universitas Indonesia, Internal Medicine, Jakarta, Indonesia, [3]RSUPN Dr. Cipto Mangunkusumo, Internal Medicine, Jakarta, Indonesia

Background: *Toxoplasma gondii* is one of the opportunistic pathogens in AIDS patients, known as toxoplasmic encephalitis (TE). In Indonesia, 32.8% of HIV patients who have neurologic symptoms showed a posi-

tive *T. gondii* in PCR result, with mortality reaching 81%, 2.16 times more than HIV patients with negative PCR outcomes. Some studies suggest that administration of pyrimethamine-sulfadiazine (P-S) is better than other regimens, but the regiment listed in the management guidelines in Indonesia is pyrimethamine-clindamycin (P-C) regiment. Therefore, this study was conducted to compare the efficacy of pyrimethamine-sulfadiazine (P-S) with pyrimethamine-clindamycin (P-C) as a treatment for toxoplasmic encephalitis in HIV/AIDS patients.
Methods: We searched four online scientific databases, including PubMed, Scopus, Cochrane Library, and EBSCO. The critical appraisal was conducted using an assessment from the British Medical Journal (BMJ), while the level of evidence assessment was based on the criteria of the Central of Evidence-based Medicine (CEBM), Oxford University.
Results: We found 41 articles from the databases. After screening, two meta-analysis obtained met the inclusion and exclusion criteria, to be appraised critically. Both studies are stated to meet validity, importance, and availability to answer clinical questions. The study of Yan et al (2013) states that the administration of P-S had been shown better than P-C (OR 1.63; 95% CI: 1.05-2.51) in improving clinical response. Meanwhile, the results of the Hernandez et.al (2016) showed that the administration of P-S and P-C did not differ significantly in improving clinical response (RR 0.87; 95% CI 0.70-1.08). Based on these two studies, giving P-S has more side effects than P-C. In addition, the availability of clindamycin in Indonesia is easier to find than sulfadiazine.
Conclusions: The administration of P-S and P-C have the same efficacy in improving the clinical response of toxoplasmic encephalitis in HIV/AIDS patients. However, the regiment of P-C is more available than P-S in Indonesia.

Viral hepatitis B and D

Prevalence of hepatitis B virus among HIV and non-HIV infected pregnant women in Jos, Nigeria

F.A. Magaji[1], M.O. Okolo[2], Z. Hassan[3], V.C. Pam[1], A.N. Ocheke[1], J. Musa[1], W. Golit[4], S.A. Anzaku[5], M. Doaleck[6], J. Ogwuche[6], M. Elechenu[7], C. Isiche[8], S.A. Sagay[1], A.I. Zoakah[3], S.E. Cohn[9]
[1]University of Jos, Obstetrics and Gynaecology, Jos, Nigeria, [2]University of Jos, Medical Microbiology, Jos, Nigeria, [3]University of Jos, Community Medicine, Jos, Nigeria, [4]Plateau State Specialist Hospital, Obstetrics and Gynaecology, Jos, Nigeria, [5]Bingham University Teaching Hospital, Obstetrics and Gynaecology, Jos, Nigeria, [6]Our Lady of Apostles Hospital, Obstetrics and Gynaecology, Jos, Nigeria, [7]Faith Alive Foundation Hospital, Obstetrics and Gynaecology, Jos, Nigeria, [8]Faith Alive Foundation Hospital, Chemical Pathology, Jos, Nigeria, [9]Northwestern University Feinberg School of Medicine, Division of Infectious Diseases, Chicago, United States

Background: Nigeria is among the countries with the highest burden of HBV in sub-Saharan Africa. Understanding the prevalence of HBV among pregnant women may be critical in reversing the trend of HBV infection in our population. The aim of the study was to determine the prevalence of HBV infection among HIV and non-HIV Infected pregnant women in Jos, Nigeria.
Methods: This was a facility-based cross-sectional study among antenatal care attendees in seven health facilities in Jos. Data was obtained on socio-demographics, risk factors for HBV infection, and outcome of screening for HBV using in-vitro diagnostic rapid kit (Acon Laboratories, USA) between the first of November 2017 and twelfth of January 2018. Analysis was done using STATA version 15 software.
Results: The study population was 1,358 Antenatal Attendees. The mean age ± standard deviation was 28.6 ± 5.9 years. Most (98.9%) of the women were below 40 years of age, literate (97.5%) and married (98.9%). One third (33.9%) were primids, while 56.6% and 9.5% were multiparous and grand multiparous respectively. Less than 20% were less than 16 weeks of gestation, while 76.2% were between 17-32 weeks. Most (97.7%) of the women had one sexual partner. The prevalence of HBV infection among all pregnant women was 7.3%. The prevalence among HIV infected and non-HIV infected was 20.8% and 6.7% respectively. The prevalence was significantly associated with age (p = 0.001), parity (p = 0.011) and HIV status (p = 0.001). The risk for HBV infection was twice higher among those aged 15 - 30 years, compared with those of 31 - 45 years (OR = 1.9, 95% CI = 1.3 - 3.1). The primi-gravidas were twice likely to be positive for HBV infection, than multi/grand multiparous (OR= 1.7, 95% CI=1.1 - 2.6), while the HIV positives were three times more likely to be positive for HBV infection, compared with HIV negatives.
(OR = 2.9, 95% CI = 1.3 - 5.8).
Conclusions: The prevalence of HBV among HIV infected and non-infected pregnant women in Jos was high. The prevalence rate was significantly associated with 15 - 30 years of age, primi-gravida and HIV positive pregnant women.

Variables	HBV+ (%)	HBV - (%)	Total	OR	95% CI	P -Value

Screening HIV infected women on ART for hepatitis B co-infection in Malawi: Sub-optimal sensitivity of dried blood samples

M. Landes[1,2], J. van Oosterhout[2], M. van Lettow[2], E. Nkhoma[3], T. Kalua[4], E. Teshale[5], S. O'Connor[5], E. Schouten[3], A. Jahn[4,6], R. Nyirenda[4], B. Tippett Barr[7], for the NEMAPP Consortium
[1]University of Toronto, Department of Family and Community Medicine, Toronto, Canada, [2]Dignitas International, Malawi, Malawi, [3]Management Sciences for Health, Lilongwe, Malawi, [4]Malawi Ministry of Health, Department for HIV/AIDS, Lilongwe, Malawi, [5]Center for Diseases Control, Atlanta, United States, [6]ITECH, University of Washington, Seattle, United States, [7]Center for Diseases Control, Zimbabwe, Zimbabwe

Background: Option B+ in Malawi, a test and treat strategy for HIV-infected pregnant and breastfeeding women, can provide concurrent treatment for hepatitis B virus infection (HBV). No data exist on HBV/HIV co-infection outcomes in regional Option B+ programs, partly due to logistics and costs of HBV screening in low-resource settings. Studies suggest using dried blood spot (DBS) specimens for screening. We report validation of testing DBS for hepatitis B surface antigen (HBsAg) in the National Evaluation of the Malawi PMTCT Program.
Methods: A nested cohort of 1,300 HIV-infected women (4-26 weeks postpartum) recruited from May 2015 to July 2016; 91.5% were on antiretroviral therapy (ART; tenofovir/lamivudine/efavirenz). At enrolment, DBS and venous samples were collected in field circumstances. DBS were shipped to an international reference laboratory and stored at -20°C; serum samples were stored in a laboratory in Malawi at -80°C. 500 matched DBS/serum specimens were randomly selected; all testing was conducted in the Malawi laboratory. Eluted dried blood and serum were tested with Bio-Rad Genetic Systems HBsAg EIA 3.0. Receiver operating curve analysis determined ideal cut-off for DBS. Serum was analyzed for HBV-DNA (Abbott m2000) and HBeAg (Diasorin ETI-EBK Plus). To validate DBS vs. serum as gold standard, we calculated sensitivity, specificity, positive and negative predictive values (with confidence intervals (CI;Wilson method)) and a kappa coefficient.
Results: Serum HBsAg testing yielded 27/500 (5.4%) positives. DBS HBsAg testing yielded 22/500 positives (4.4%); none were false positives. All five false negative DBS were HBeAg negative and had undetectable HBV DNA (serum). Sensitivity of DBS HBsAg testing was 81.5% (95%CI

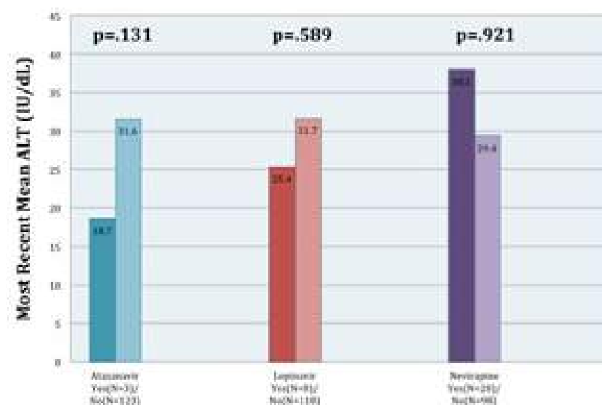
63.3-91.8) and specificity was 100% (95% CI 99.2-100.0). Positive predictive value was 100% (95% CI 85.1-100) and negative predictive value was 99.0% (95% CI 97.6-99.6). Kappa coefficient was 0.89 (95%CI 0.80-0.99).
Conclusions: Sensitivity of HBsAg testing from DBS samples collected in routine clinical circumstances in postpartum Malawian women on ART was lower than the few regional laboratory or field based studies (>98%). Investigating the role of environmental conditions on specimen management, the study population and tenofovir/lamivudine use in detecting HBsAg from DBS are recommended. We caution interpretation of DBS HBsAg screening, unless testing has been contextually validated.

WEPEB080

Antiretroviral effects on liver function in a HIV/HBV co-infected African cohort

J. Hutter[1,2], A. Esber[1,3], E. Bahemana[4], Y. Adamu[5], F. Kiweewa[6], J. Maswai[1,7,8], J. Owuoth[1,8,9], J. Ake[1], C. Polyak[1,3]
[1]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [2]Walter Reed National Military Medical Center, Infectious Diseases, Bethesda, United States, [3]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [4]Mbeya Medical Research Centre, Mbeya, Tanzania, United Republic of, [5]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Abuja, Nigeria, [6]Makerere University-Walter Reed Project, Kampala, Uganda, [7]Henry M. Jackson Foundation Medical Research International, Kericho, Kenya, [8]Kenya Medical Research Institute, Nairobi, Kenya, [9]Henry M. Jackson Foundation Medical Research International, Kisumu, Kenya

Background: Many drugs categorized as antiretroviral therapy (ART) carry some risk of liver injury. This risk may be amplified with hepatitis B virus (HBV) co-infection, which is common in sub-Saharan Africa. HBV testing is recommended in all HIV patients, and co-infection warrants specific combination therapy targeting both viruses. In sub-Saharan Africa, resource limitations may preclude hepatitis testing and vaccination. We examined ART regimens of study participants with HIV/HBV co-infection in four African countries and assessed markers of liver injury.
Methods: AFRICOS is an ongoing cohort that enrolls participants at 11 PEPFAR-supported clinics in Uganda, Kenya, Tanzania, and Nigeria. Clinical and laboratory assessments are performed every six months. The most recent alanine aminotransferase(ALT), total bilirubin(TBILI), platelet count, CD4 count, and HIV viral load(VL) were used for these analyses. Groups of HIV/HBV co-infected participants were compared based on current use of individual, potentially hepatotoxic drugs (nevirapine, atazanavir, lopinavir). We also compared each regimen for the number of participants with most recent ALT over 100 IU/dL. Associations between the drugs and hepatic outcomes were assessed using Chi-squared testing.



[Most Recent Mean ALT Compared by High Risk Antiretroviral]

Results: We enrolled 2635 HIV infected participants through June 1st 2017, of which 140 were HIV/HBV co-infected, including 106 prescribed recommended co-infection regimens. 24% were not on recommended regimens: 12 were ART-naïve and 22 were taking ART that included lamivudine or emtricitabine without tenofovir, conferring risk of development of resistant HBV. At their most recent visit, 28 of the 126 co-infected participants with ALT value assessments were on nevirapine, 8 were on lopinavir, and 3 on atazanavir. None of these groups had a significant change in mean ALT, TBILI, or platelets other than atazanavir which had an expected rise in TBILI(1.774 vs 0.397, p-value 0.031). There was a significant increase in the number of most recent ALT measurements over 100 in the nevirapine group vs. the non-nevirapine group (7%vs 0%, p=0.008).
Conclusions: While some HIV/HBV co-infected participants were not on recommended regimens, most regimens were not associated with significant increases in liver enzymes. This may have been due to small sample size of the potentially hepatoxic regimens. These results reveal gaps in the appropriate management of HIV/HBV co-infection.

WEPEB081

Vaccination with Fendrix in previously non-responding HIV-infected patients has a high success rate

E. Braam[1], J. Machiels[2], P. van Bentum[2], M. van Vugt[3], I. Schouten[4], T. de Vries-Sluijs[5], W. Bierman[6], J. Gisolf[2]
[1]University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [2]Rijnstate Hospital, Arnhem, Netherlands, [3]AMC, Amsterdam, Netherlands, [4]OLVG, Amsterdam, Netherlands, [5]Erasmus MC, Rotterdam, Netherlands, [6]University of Utrecht, Utrecht, Netherlands

Background: HIV-infected patients are at increased risk of severe complications after infection with hepatitis B-virus (HBV). Because only 50% of HIV-infected patients show serological conversion with the standard vaccination strategy, the current vaccination strategy consists of three doses of double dose hepatitis B vaccine. A previous small study in non-responding HIV-infected patients has shown that revaccination with Fendrix, a vaccine containing recombinant HBsAg and a novel adjuvant, confers much better results in HIV-infected patients. In this study we tested the effect of revaccination with Fendrix in prior non-responding HIV-infected patients and aimed to determine which factors are associated with seroconversion.
Methods: Eight Dutch HIV treatment centers participated in this study. Patients infected with HIV-1 and non-responding to prior course of vaccination against HBV (defined as anti-HBs < 10 IU/mL) and who had Fendrix as a 2nd, 3rd or 4th effort to achieve seroconversion were eligible for inclusion. Primary outcome was the proportion of patients with seroconversion after revaccination with Fendrix. Univariate binary logistic regression analyses were used to determine which factors could be used as predictors for seroconversions after vaccination with Fendrix.
Results: We included 100 HIV-infected patients, all of whom were revaccinated with Fendrix. The mean age was 47.3 (± 11.0) years. Revaccination with Fendrix showed a high seroconversion rate of 81.0%. Of the 100 patients, 86.0% were male and showed a seroconversion rate of 81.4%. Median nadir CD4+ cell count was 300 (20 - 1040) cells/mm3 and median CD4+ cell count at the time of the first vaccination with Fendrix was 605 (210 - 1190) cells/mm3. Univariate binary logistic regression analyses showed no significant factor associated with a better outcome.
Conclusions: This multicenter study that included 100 HIV-infected patients showed that revaccination with Fendrix of patients prior nonresponding to other HBV vaccination strategies has a high success rate. In total, 81.0% responded with a seroconversion, irrespective of CD4+ cell count. These findings suggest that Fendrix is an effective revaccination strategy in prior nonresponding HIV-infected patients.

Viral hepatitis C

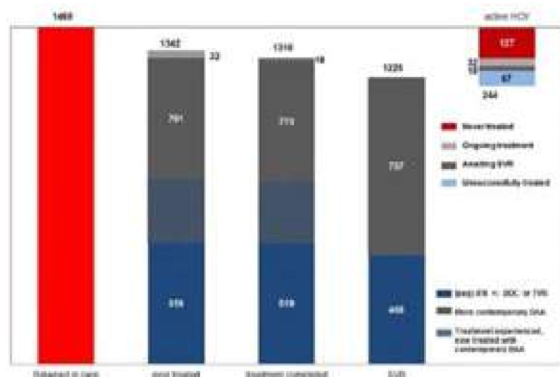
HCV treatment cascade in the Netherlands: DAA uptake varies by key population, effectiveness of HIV treatment and co-medication use

C. Smit[1], A. Boerekamps[2], A.M. Newsum[3,4], J.E. Arends[5], C. Richter[6], T.S. Boender[1], P. Reiss[1,4,7], B.J.A. Rijnders[2], K. Brinkman[8], M. van der Valk[4], on behalf of the ATHENA National Observational HIV Cohort
[1]Stichting HIV Monitoring, Amsterdam, Netherlands, [2]Erasmus Medical Center, Department of Internal Medicine and Infectious Diseases, Rotterdam, Netherlands, [3]Public Health Service of Amsterdam, Department of Infectious Diseases Reasearch and Prevention, Amsterdam, Netherlands, [4]Academic Medical Center, and Amsterdam Center for Infection and Immunity, Department of Internal Medicine, Division of Infectious Diseases, Amsterdam, Netherlands, [5]UMCU Universitair Medisch Centrum, Department of Internal Medicine, Division of Infectious Diseases, Utrecht, Netherlands, [6]Rijnstate Hospital, Department of Internal Medicine, Division of Infectious Diseases, Arnhem, Netherlands, [7]Academic Medical Center, and Amsterdam Institute for Global Health and Development, Department of Global Health, Amsterdam, Netherlands, [8]Onze Lieve Vrouwe Gasthuis, Department of Internal Medicine and Infectious Diseases, Amsterdam, Netherlands

Background: HIV/HCV co-infected patients in the Netherlands have unrestricted and fully reimbursed access to direct-acting antivirals (DAAs) since November 2015. We assessed both the uptake of DAA treatment and determinants of remaining in need of treatment for HCV, updating a published earlier analysis.

Methods: An HCV treatment cascade was constructed using data from the national ATHENA cohort up to 1 January 2018, including HIV-positive individuals in care, with a documented chronic, or acute HCV infection. Indicators were:
1) retained in care;
2) ever treated for HCV;
3) completed HCV-treatment;
4) achieved SVR;
5) evidence of active HCV infection.
Determinants of individuals remaining in need of HCV-treatment, including either never having been treated or having failed prior HCV-treatment, were identified using logistic regression, adjusted for socio-demographic and clinical characteristics. Severe liver fibrosis was defined as fibrosis stage Metavir F3 or higher.



[HCV Treatment Cascade for HIV/HCV coinfected patients eligible for HCV treatment, registered by SHM and retained in care as of 1 January 2018. *Chronic or acute HCV infection without spontaneous clearance of HCV]*

Results: In total, 1,469 people were in care and had ever been registered with HCV co-infection (figure). As of January 1, 2018, 83% (1,225/1,469) of these HIV-HCV co-infected individuals had their HCV infection cured, with the number of individuals in care with active HCV having declined to 244.
Of these 244 patients, 127 had never been treated, 67 had failed prior treatment, in 32 DAA treatment was ongoing, and 18 were awaiting SVR12 results. After excluding these 32 and 18 patients, the following factors were independently associated with remaining in need of HCV-treatment:
HIV transmission through heterosexual contact (aOR 3.55; 95% CI: 1.97-6.40) or by injection drug use (5.02; 3.09-8.28) compared to men who have sex to men; no documented current cART-use (3.05; 1.34-6.91); CD4 cell count < 200 cells/mm³ (3.02; 1.51-6.05) at time of HCV treatment initiation for previously (unsuccessfully) treated, and most recent CD4 for untreated individuals; no documented genotype (3.17; 1.79-5.60); increasing number of comedication prescriptions (1.12 (1.03-1.20 per prescription); shorter duration of HCV infection (0.95; 0.92-0.99 per year increase).

Conclusions: DAA treatment scale-up for HIV/HCV co-infected people in care in the Netherlands continues to progress, but appears to be lagging behind in more challenging subgroups of patients, including those with insufficiently treated HIV infection.

WEPEB083

High hepatitis C treatment uptake and cure rate in pilot treatment programs for HCV/HIV coinfected patients in Phnom Penh, Cambodia

A. De Weggheleire[1], M. Iwamoto[2,3], S. An[4], S.K. Chamroeun[3], S. Declercq[1], J.-P. Dousset[3], M. Sos[5], M. Sounsopheak[6], C. Dimanche[7], S. Thai[4], T. Vanwolleghem[8,9], L. Lynen[1], A. Loarec[2], S. Francque[8,9]
[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]Epicentre-Médecins Sans Frontières, Paris, France, [3]Médecins Sans Frontières-Operational Centre Paris, Phnom Penh, Cambodia, [4]Sihanouk Hospital Center of Hope, Phnom Penh, Cambodia, [5]Chhouk Sar Clinic, Phnom Penh, Cambodia, [6]AIDS Healthcare Foundation, Phnom Penh, Cambodia, [7]Preah Kossamak Hospital, Phnom Penh, Cambodia, [8]Gastroenterology Hepatology, University Hospital of Antwerp, Antwerp, Belgium, [9]Laboratory of Experimental Medicine and Paediatrics, University of Antwerp, Antwerp, Belgium

Background: As Direct Acting Antivirals (DAA) for treatment of hepatitis C (HCV) are becoming increasingly affordable, there are unprecedented opportunities for scale-up of treatment worldwide. However, experiences with these new treatments from resource-constrained settings remain limited. We evaluated the safety and effectiveness of two pilot HCV treatment programs among HIV patients in Phnom Penh, Cambodia.

Methods: Data from HIV patients from Sihanouk Hospital Center of Hope (n=98) and Médecins Sans Frontières' HCV clinic in Preah Kossamak Hospital (n=147), diagnosed with chronic HCV infection, were prospectively collected and pooled. Treatment regimens were determined following international guidelines and drug availability. We assessed treatment uptake, ITT-SVR12 (intention-to-treat, sustained virologic response 12 weeks post-treatment), serious adverse events (SAEs), and ART adaptations because of co-administered DAAs.

Results: Among 245 HCV/HIV-coinfected consenting adult patients assessed for treatment between 09/2016 and 11/2017, 15 were excluded from treatment, and 230 (93.9%) initiated DAAs - 52% (n=120) were treated with sofosbuvir/ledipasvir ± ribavirin and 41% (n=94) with sofosbuvir/daclatasvir ± ribavirin *(Figure 1)*. Among the 230 initiated on DAAs, median age was 50 years (range 28-72), 94 (41%) were men, 61 (27%) had cirrhosis (two with decompensation), and seven (3%) were treatment-experienced *(Table 1)*. Most were genotype 1b (38.3%) or 6 (43.0%).
Treatment completion was 99.6% (229/230), and ITT-SVR12 was 93.5% (95% CI: 89.5-96.3), with one lost during treatment, two deaths after treatment and before the three-month follow-up, and six patients with treatment failure, of which three were cirrhotic and one treatment-experienced. ITT-SVR12 was 95.5% for GT1b and 91.9% for GT6. SVR12 when excluding those lost to SVR12 testing was 96.4% (95% CI: 93.1-98.4). SAE occurred in 0.4% (1/230) of the patients - one death potentially caused by acute-on-chronic liver failure after SOF/LDV. No other SAEs were reported.
ART regimens of three patients were adapted at DAA start (dose reduction lamivudine with low eGFR, and one switch from atazanavir/ritonavir to lopinavir/ritonavir as 30 mg daclatasvir not available).

Conclusions: Our findings demonstrate the effectiveness, safety and feasibility of DAA treatment for HCV/HIV coinfected patients in Cambodia, and provide a solid base to encourage the national HIV program to launch an integrated HCV treatment program.

WEPEB084

Acute HCV: An emerging issue in HIV subjects in the DAAS era

A. Moreno[1], M.J. Vivancos[1], M.J. Pérez-Elías[1], J.L. Casado[1], M. Sánchez-Conde[1], C. Quereda[1], S. del Campo[1], M. Rodriguez[2], B. Romero[2], S. Moreno[1]
[1]Hospital Ramón y Cajal, Infectious Diseases, Madrid, Spain, [2]Hospital Ramón y Cajal, Microbiology (Viral Hepatitis Section), Madrid, Spain

Background: Acute HCV has increased as the indication for DAAS in HIV subjects, specially among MSM patients with maintained risk practices, including chemsex. There are few data on the incidence, features and outcomes of acute HCV in large cohorts of HIV/HCV patients treated with DAAs in real life.

Methods: Retrospective-prospective assessment of the incidence, features and outomes of acute HCV as the indication for DAAs in all HIV/HCV patients attended at the HIV Clinic in a teaching hospital in Madrid, Spain, between January 2015 (first availability of DAAs) and January 2018 (N=487).

Results: Overall, 24 patients (5%) received DAAs due to acute HCV, with a significant increase over the study period: 0,3% (1/331) in 2015, 9% (8/88) in 2016, 20% (13/64) in 2017, and 50% (2/4) in January 2018 (p=0.0001). When comparing patients with acute vs chronic HCV, there were no significant differences in baseline HCV load over 6M IU/ml (25% vs 23%, p=0.87), HCV G1 (70% vs 72%, p=0.44) or SOF/LDV use (67% vs 66%, p=0.92), but patients with acute HCV were significantly younger (mean age 39±8 vs 50±6, p=0.0001), male (100% vs 77%, p=0.009), and received more frequently DAA courses of 8w or less (67% vs 11%, p=0.0001). SVR rates were also similar (88% vs 91%, p=0.4). Acute HCV was a reinfection in 5/24 (21%) vs 3/463 (0,6%), p=0.0001, 75% within the first year after SVR (mean 34w). All 8 subjects with reinfection received a second course of DAAS (SOF/LDV in three, SOF/VPV in two, GPV/PBV in two, GZV/EBV in one), for at least 12w in 5.

Conclusions: In clinical practice, the population of young MSM with persistent risk practices explain the observed significant increase in acute HCV as the indication for DAAs, and reinfection after prior successful DAA represents 21% of the cases. It is mandatory an educational effort in this high-risk population.

WEPEB085

Characterization of the hepatitis C no show phenomena in patients living with HIV

E. Cachay[1], L. Hill[2], F. Torriani[1], C. Ballard[2], W.C. Mathews[3]
[1]University of California, San Diego, Medicine-Division of Infectious Diseases, San Diego, United States, [2]University of California, San Diego, School of Pharmacy, San Diego, United States, [3]University of California, San Diego, Medicine, San Diego, United States

Background: We aimed to calculate the trends in No Show hepatitis C (HCV) intake appointments among patients living with HIV (PLWH) and ascertain the predictors of HCV No Show appointments.

Methods: Retrospective cohort study among PLWH referred for HCV treatment from January 2014 to December 2017. We estimated by the proportion of new patients who failed to attend their HCV intake appointment (No Show), and, among them, the proportion who did not return for an HCV intake appointment within 180-days of first missed appointment (lack of HCV engagement in care). Logistic regression analysis was used to identify factors associated with HCV No Show. Potential predictors included demographics; CD4, and HIV viral load; type of insurance; HIV engagement in care; cirrhosis, and prior liver decompensation; Charlson comorbidity index; active alcohol, any illicit drug use, unstable housing and history of psychiatry illness.

Results: During the study period, 2,479 Owen HCV Clinic appointments were scheduled. Of those, 349 (201 patients) were HCV intake appointments. The 201 newly referred HCV patients had a median(IQR) age of 51 years (43-57), 47.8% of them were non-white, 18.4% female and 53.2% had Medicaid insurance and, most patients had undetectable HIV viral load (79.6%). Ongoing drug (31.7%), alcohol use (32.8%), psychiatry illness (37.8%) were prevalent among them. The overall No Show was 21.89% and increased by calendar year from 17.75%, 19.08%, 25.38% and 25.36%

in 2014, 2015, 2016 and 2017, respectively (p=0.021). Sixty-six of the 201 new patients (32.84%) did not attend their HCV intake appointment, and 32 of them (48.48%) did not subsequently engage in HCV care. Patients who failed to attend their intake HCV appointments were more often non-white, Hispanic, have detectable HIV viral load, and prevalent ongoing drug and psychiatric illness (Table 1). In logistic regression analysis, independent predictors of failing to establish HCV care were being non-white (OR: 2.4, 95% CI: 1.17-5.02) and having psychiatry illness [OR: 2.82, CI; 1.44-5.54, P=0.003].

Conclusions: Despite improved access to DAA, the proportion PLWH who failed to establish HCV care has increased. HCV elimination efforts require addressing disparities in HCV care and providing supportive services for PLWH in need.

WEPEB086

Clinical and health resource utilization comparisons of HCV treatments for HIV/HCV

J. Ernst[1], M. Brennan-Ing[2], N. Olivo[1], L. Seidel[3], T. Leach[1], Y. Vazquez[1], Y. Akulov[1]
[1]*Amida Care, New York, United States,* [2]*Hunter College, City University of New York, Brookdale Center for Healthy Aging, New York, United States,* [3]*ACRIA, New York, United States*

Background: Direct acting antivirals have improved treatment outcomes among HIV-positive patients with hepatitis C (HCV). Data were obtained from Amida Care, a Medicaid Special Needs Plan providing managed care to over 6,000 HIV-positive people with multiple comorbidities and complex psychosocial needs in New York City.

Methods: This study was an observational retrospective medical record and claims review of the plan's first 100 HIV/HCV patients treated with sofosbuvir-containing regimens since 2013 (Cohort 1). In addition, a parallel review was conducted for 53 HIV-positive members who received HCV treatment that included either telaprevir or boceprevir from 2010-2013 (Cohort 2). The two cohorts were compared to examine differences in clinical outcomes and health care utilization using Chi-square tests for categorical data and repeated-measures MANOVA to examine change in continuous data over time, from 12 months before treatment was initiated to 12 months after its completion. This research protocol was IRB approved for informed consent waiver.

Results: There were no significant differences between the two cohorts with regard to age, gender, race/ethnicity and years since HIV diagnosis. CD4 counts and HIV viral load changes were not significant for either group. While both cohorts demonstrated a significantly greater proportion of being HCV undetectable 6-months after treatment ($p < .001$), Cohort 1 had a significantly greater proportion who were undetectable compared to Cohort 2 (93% and 67%, respectively, $p < .005$). Repeated-measures MANOVA found significant change over time in AST and ALT liver function tests for both cohorts. However, there was a significant Cohort X Time interaction, with Cohort 1 demonstrating greater improvement in liver function over time compared with Cohort 2. There were no significant resource utilization differences by cohort in emergency room, inpatient, or outpatient visits. A significant Cohort X Time interaction was observed for primary care visits which significantly increased over time, but to a greater degree in Cohort 1, which may represent better engagement in care, an outcome of the health plan's model of care.

Conclusions: These findings support the improved efficacy of the newer HCV agents but do not support changes in health resource consumption, at least for the first year after treatment.

Cohort	Cohort I Before Treatment		Cohort I After Treatment		Cohort II Before Treatment		Cohort II After Treatment	
HCV VL Detectable - Total Tested/ No. (%)	76/77 (99%)		5/69 (7%)		17/18 (94%)		5/15 (33%)

Does baseline liver stiffness value influence fibrosis outcome after direct-acting antiviral treatment in HIV-HCV coinfected patients?

G. Fornaro[1], V. Guardigni[1], F. Ravaioli[2], L. Badia[1], P.L. Viale[1], D. Festi[2], G. Verucchi[1]
[1]*University of Bologna, S. Orsola - Malpighi Hospital, Department of Medical and Surgical Sciences, Infectious Diseases Unit, Bologna, Italy,* [2]*University of Bologna, S. Orsola - Malpighi Hospital, Department of Medical and Surgical Sciences, Gastroenterology Unit, Bologna, Italy*

Background: Data on whether direct-acting antiviral (DAAs) therapy can modify liver stiffness (LS) in patient with HIV-HCV coinfection are lacking. The aim of our study was to evaluate changes in liver stiffness after successful DAAs treatment in HIV-HCV coinfected patients and to determine factors associated with improvement of fibrosis.

Methods: We retrospectively studied all patients with HCV-HIV coinfection treated for HCV with DAAs-based IFN-free regimens who achieved sustained virological response 12 weeks after end of treatment (EOT) from October 2014 to May 2017 in the University Hospital of Bologna, Italy. LS was evaluated at baseline (BL) and within 24 weeks after EOT by elastography (Fibroscan). Linear Regression was used to analyze factors associated with LS improvement. Wilcoxon Matched-Pair Signed Rank Test was used to compare LS measurement before and after DAAs.

Results: A total of 53 patients (aged 52,7 ± 5,4, 22,6% male) were enrolled. 64.2% (34) of them had liver cirrhosis, and 18,9% (10) had Child-Pugh score ≥ 7. Genotypes 1a and 3 were the most frequent (45,3% and 26,4% respectively). The two most common DAAs regimens were Sofosbuvir/Ledipasvir 41,5% (22) and Sofosbuvir + Daclatasvir 37,7% (20). Median LS

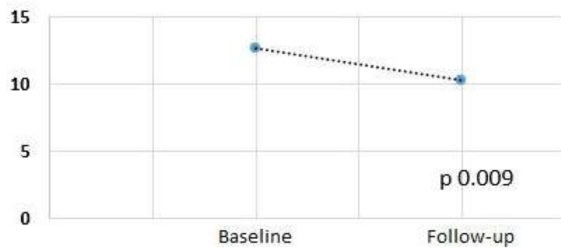
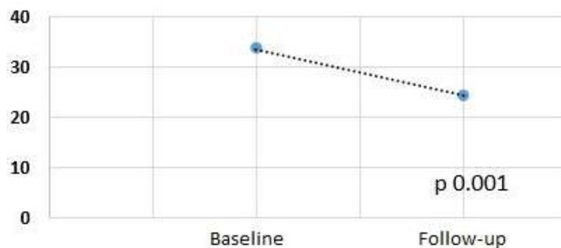
Author Index

was 14,3 kPa (IQR 10,8-22,1) at BL and 10.4 kPa (IQR 11,1-17,7) at the second evaluation during the follow up; a significant improvement in LS was observed in our population (p< 0,0001), especially in those with BL LS ≥21 (Figure 1). Overall 75.5% of subjects achieved a reduction of fibrosis, after DAAs. Factors independently associated with a greater improvement in LS were diabetes (p 0,007, B = +10) and a LS value at BL ≥21 kPa (p 0.001, B = +6,7). No association with antiretroviral therapy nor with DAAs was observed.

Conclusions: In HIV-HCV coinfected patients successfully treated with DAAs, worse liver fibrosis at BL is associated with a greater LS improvement, suggesting a major benefit from DAAs treatment in those with more advanced liver disease. Main limitations of our study are its retrospective nature and the small sample size.





[Fibrosis improvement after DAAs in our HIV/HCV population sorted by baseline liver stiffness]

WEPEB088

Interleukine-6 decline after HCV cure is associated with VACS INDEX improvement in HIV-HCV patients

L. Badia[1,2], V. Guardigni[1,2], G. Fornaro[1], E. Francalanci[1], M. Rinaldi[1], F. Volpato[1], P. Viale[1], G. Verucchi[1,2]
[1]Policlinico S. Orsola-Malpighi - Bologna, Infectious Diseases, Bologna, Italy, [2]University of Bologna, Research Centre for the Study of Hepatitis, Department of Medical and Surgical Sciences DIMEC, Bologna, Italy

Background: HCV eradication with direct antivirals agents (DAAs) can lead to a decrease in serum Interleukine-6 (IL6) and other immune activation markers, in HCV and HCV/HIV patients.

The Veteran Aging Cohort Study (VACS) index is a score estimating the risk for all-cause mortality in HIV-infected and uninfected individuals.

Aim of our study was to evaluate whether decrease in IL6 levels after DAAs treatment was correlated with improvement of VACS index, among HCV and HIV/HCV patients.

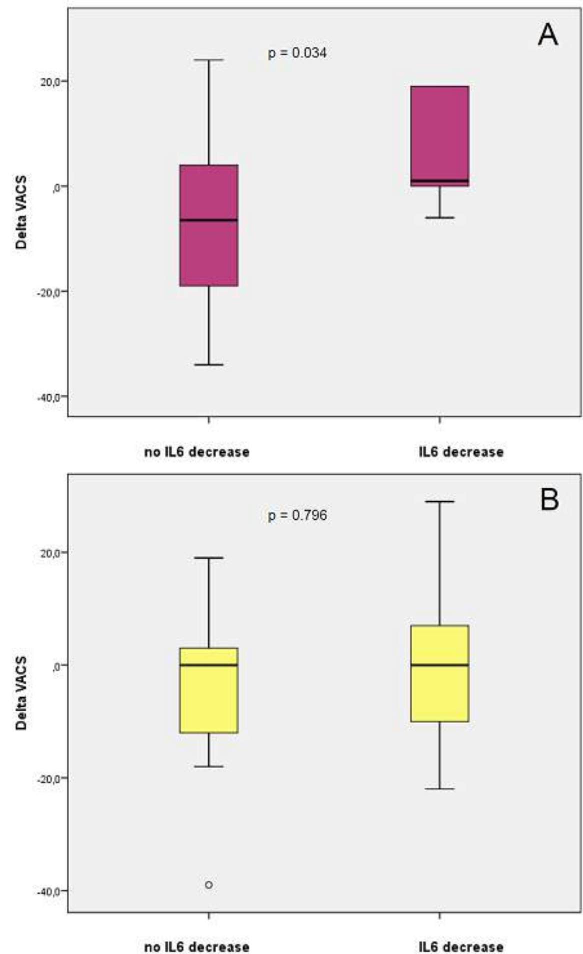
Methods: We retrospectively studied all patients cured with DAAs-based regimens from August 2015 to July 2017 in a tertiary University Hospital in Italy. IL6 levels in peripheral blood and VACS score were determined at baseline (BL), end of treatment (EOT) and 12 weeks of follow-up (FU12). Spearman´s correlation, Wilcoxon signed rank test and T-test (or Mann U-Whitney test for nonparametric variables) were used to perform all the analysis.

Results: We enrolled 110 subjects, aged 57±11 years, 61% (n=67) males. 54% (n=59) was HIV-positive. 74.5% (n=82) had cirrhosis. At BL, mean VACS index was 40±20 and median IL6 was 4.15 pg/ml (IQR 2-8), with no difference according to HIV status; a positive correlation between VACS index and IL6 was found only in HIV+ (p< 0.001, R +0.47).

In subjects (n=55) with BL IL6 above median value (≥4.15 pg/ml), greater decrease in IL6 levels (i.e. larger Δ-IL6) was positively associated with a greater improvement in VACS index (i.e. larger Δ-VACS), p 0.016, R +0.4, only among HIV+ subjects.

Consistently with these findings, Δ-VACS (from BL to FU12) was significantly different between patients who experienced a reduction in IL6 levels and those who did not only in HIV+ subset (p 0.034), with a larger improvement of VACS index among those with a decline in IL6 (Figure 1).

Conclusions: In HIV/HCV patients cured with DAAs, an improvement in immune activation status, as measured by decrease in serum IL6 level, is associated with a reduction of VACS Index, suggesting a benefit on global health and overall survival. The lack of this finding in HCV monoinfected population might be explained by a weaker association between IL6 and VACS Index in absence of HIV infection.



[Figure 1. Comparison between median Delta VACS in HIV-positive (A) and HIV negative (B) patients with or without IL-6 decrease]

WEPEB089

Molecular epidemiology of acute HCV infection in HIV-positive patients from Hong Kong, Taipei and Tokyo

H.-Y. Sun[1], N.-S. Wong[2], H. Uemura[3], D.P.-C. Chan[2], S.-Y. Chang[4], C.-C. Hung[1], S.S. Lee[2], S. Oka[3]
[1]National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, Province of China, [2]Stanley Ho Centre for Emerging Infectious Diseases, Chinese University of Hong Kong, Hong Kong, Hong Kong, [3]AIDS Clinical Center, National Center for Global Health and Medicine, Tokyo, Japan, [4]National Taiwan University College of Medicine, Department of Clinical Laboratory Sciences and Medical Biotechnology, Taipei, Taiwan, Province of China

Background: A large international network of hepatitis C virus (HCV) transmission among HIV-positive men who have sex with men (MSM) with recent HCV infections has been reported in several European coun-

tries. Whether this international network of HCV transmission also occurs in Asia-Pacific region, where increasing incidences of recent HCV infections have been reported, remains unknown.
Methods: HIV-positive patients with acute HCV infection in Hong Kong, Taipei, and Tokyo between 2010 and 2016 were included in this virologic and phylogenetic study. The NS5B region of the HCV genome (365 bp) was amplified by nested polymerase chain reaction (PCR) and sequenced. Acute HCV infection was defined as the seroconversion of HCV antibody in a year or documented acute hepatitis with the seroconversion. Concurrent sexual transmitted diseases (STDs) were defined as the episodes of STD occurring within 1 year of the diagnosis of acute HCV infection.
Results: Three large major institutions with HIV services participated in this collaboration and a total of 232 HIV-positive patients with acute HCV infection were included from Hong Kong (n=58), Taipei (n=140), and Tokyo (n=34). Their mean age was 29.9 (standard deviation, 14.3) years, 100% of them were men, and 94.0% were MSM. At the diagnosis of HCV infection, 73.7% had concurrent STDs and 88.4% were receiving combination antiretroviral therapy. The derived HCV sequences included 43 (74.1%) from Hong Kong, 132 (94.3%) from Taipei, and 30 (88.2%) from Tokyo, all of which were subjected to the phylogenetic tree analysis. The most prevalent HCV genotype in Hong Kong was genotype 3a (81.4%, n=35), followed by 1a (7.0%, n=3) and 3 (7.0%, n=3), in Taipei 2a (55.3%, n=73), followed by 1b (25.8%, n=34), and in Tokyo 1b (63.3%, n=19), followed by 2a (26.7%, n=8). Multiple clusters were identified, including 5 independent clusters within genotype 2a (4 in Taiwan and 1 in Japan), 1 within genotype 2c from Japan, 1 within genotype 6a from Taiwan, and 1 within genotype 1b from Japan.
Conclusions: No international network of HCV transmission was identified among HIV-positive patients in this study, while independent clusters of HCV infections occurred in each city.

Real world data of a novel multidisciplinary hepatitis C program in an established HIV program

D. Kahal[1,2], C. James[1], N. Goldstein[3,4], K. Cantwell[1], L. Preininger[1], W. Mazur[1], S. Szabo[1]
[1]Christiana Care Health System, Wilmington, United States, [2]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, United States, [3]Christiana Care Health System, Newark, United States, [4]Dana and David Dornsife School of Public Health at Drexel University, Philadelphia, United States

Background: Delaware has among the highest chronic hepatitis C virus infection (HCV) prevalence rates nationwide although there is limited access to HCV specialist care. In response, the Christiana Care HIV Community Program, the only Ryan White-funded HIV treatment program statewide, expanded to provide comprehensive HCV mono-infection care through a dedicated HCV Program in 2014. We hypothesize that extension of the HIV care model from HIV/HCV co- to HCV mono-infection results in comparable and highly effective real-world treatment outcomes.
Methods: We performed a retrospective chart review of all co- and mono-infected patients from May 2014 through August 2017 with extraction of demographic, HCV disease and treatment status data. HCV treatment points were independently compared using an equality test for proportions between groups with an alpha of 5% (R version 3.2.1).
Results: 209 co- and 177 mono-infected patients underwent HCV evaluation with 130 and 98 patients respectively initiating HCV DAA treatment (table 1). The HCV treatment cascade follows patients through eligible HCV treatment points (figure 1). There were no statistical differences between groups throughout the cascade except for HCV treatment initiations (100% of co- versus 94% of mono-infected patients). 9 co- and 8 mono-infected patients were overdue for SVR12. 2 mono- and 4 co-infected patients experienced treatment failure; one co-infected patient was re-infected with HCV and 1 mono-infected patient died prior to SVR12.
Conclusions: The groups were prescribed treatment and achieved virologic response and cure at high, comparable rates. The difference in group's treatment initiation reflects an extended time interval between treatment approval and start in mono-infected patients due to scheduling capacity within the HCV Program. The most common reasons for lack of treatment prescription amongst both groups includes insurance-mandated fibrosis staging restrictions and drug screening requirements as well as lack of requisite lab data. The refinement of an HCV cascade may further reveal gaps in the HCV care continuum amongst co- and mono-infected patients.
The treatment of mono-infected patients within an established, urban HIV program is a novel care model. This real-world data emphasizes that implementation of a multi-disciplinary model of care results in effective HCV care delivery data for co- and mono-infected patients.

Characteristic		HIV/HCV (n=209)	HCV (n=172)
Sex	*Male*	141 (67%)	116 (67%)
Race	*African American*	170 (81%)	86 (50%)
	Caucasian	27 (13%)	75 (44%)
Age (years)	*26-50*	25 (12%)	42 (25%)
	≥ 51	184 (88%)	130 (75%)
HCV genotype 1		191 (91%)	140 (81.5%)
Cirrhosis		57 (27%)	49 (29%)
HCV treatment-experienced		13 (6%)	18 (11%)

WEPEB091

Decreased hepatitis C virus (HCV) treatment uptake among HIV-HCV co-infected patients in Canada with a history of incarceration

N. Kronfli[1], R. Nitulescu[1], J. Cox[1,2], E. Moodie[2], C. Cooper[3], A. Wong[4], S. Walmsley[5], M.B. Klein[1], on behalf of the Canadian Co-Infection Cohort Investigators
[1]McGill University Health Centre, Montreal, Canada, [2]McGill University, Department of Epidemiology, Biostatistics, & Occupational Health, Montreal, Canada, [3]Ottawa Hospital Research Institute, Ottawa, Canada, [4]University of Saskatchewan, Regina, Canada, [5]Toronto General Hospital Research Institute, Toronto, Canada

Background: Rates of HIV and HCV are 10- and 50-fold higher, respectively in Canadian correctional facilities than in the general population; thus, treatment strategies must target this vulnerable group in order to eliminate HCV in Canada. We aimed to determine whether incarceration impacts HCV treatment uptake in the direct-acting antiviral (DAA) era.
Methods: We analysed data from the Canadian Co-infection Cohort, a prospective multicentre cohort of 1795 co-infected participants from 18 sites in Canada. HCV RNA+ participants who completed baseline information on incarceration were included and followed from November 21, 2013 (when second-generation DAAs were approved by Health Canada) until September 30, 2017. A Cox proportional hazards model was used to assess the effect of time-updated incarceration on time to treatment uptake, and was adjusted for patient-level characteristics known to be associated with treatment uptake in the DAA era.
Results: 965 HCV RNA+ participants were included; 72% had a history of incarceration. There were 280 second-generation DAA treatment initiations (96% with interferon-free regimens) during follow-up (14/100

person-years). Overall, 40% (105/264) of participants never incarcerated were treated (22/100 person-years) compared to 25% (175/701) of previously incarcerated participants (12/100 person-years). Cure rates (sustained virologic response (SVR) at 12 weeks) were 94% and 91%, respectively. Independent of other factors, participants with a history of incarceration (adjusted hazard ratio (aHR): 0.71, 95% CI: 0.53-0.95) were less likely to initiate treatment (Table), as were those with a monthly income < $1500 (aHR: 0.62, 95% CI: 0.46-0.84) or those who reported active injection drug use (aHR: 0.65, 95% CI: 0.43-0.99). Participants with undetectable HIV viral loads (aHR: 2.32, 95% CI: 1.63-3.32) or significant fibrosis (aHR: 1.61, 95% CI: 1.24-2.1) were more likely to initiate treatment.
Conclusions: People with a history of incarceration were significantly less likely to access treatment in the DAA era even after accounting for several patient-level characteristics such as ethnicity, income, and injection drug use. Given SVR rates above 90%, increased efforts are needed to improve access to HCV treatment for previously incarcerated persons in Canada if HCV elimination is to occur by 2030.

Variable	Adjusted HR (95% CI)
Time-updated incarceration status	0.71 (0.53 ; 0.95)
Age	1.01 (0.99 ; 1.02)
Female sex	0.89 (0.65 ; 1.2)
Indigenous ethnicity	0.76 (0.5 ; 1.17)
Monthly income ≤ 1500 CAD	0.62 (0.46 ; 0.84)
Active injection drug use	0.65 (0.43 ; 0.99)
Undetectable HIV RNA (≤ 50 copies)	2.32 (1.63 ; 3.32)
APRI > 1.5	1.61 (1.24 ; 2.1)
HCV genotype 3	0.76 (0.53 ; 1.1)

[Cox proportional hazards model - HCV treatment uptake during the DAA era]

Wild genotype Gln11Gln TLR7 gene contributes the accelerated fibrosis progression in HIV/HCV coinfected patients in Ukraine

T. Kyrychenko[1,2], T. Koval[2], G. Dubynska[2], O. Danilenko[1], O. Sabinina[1], K. Mykhailova[1], I. Kaidashev[2]
[1]*Poltava Regional HIV/AIDS Prevention and Control Center, Poltava, Ukraine,* [2]*Higher State Educational Establishment of Ukraine 'Ukrainian Medical Stomatological Academy', Poltava, Ukraine*

Background: Approximately 40- 75% of people living with HIV (PLHIV) in Ukraine are coinfected with HCV that impairs the course and treatment of HIV infection. Access to the antiviral therapy of HCV is limited in Ukraine. Despite the free access of ART, the numbers of reported deaths due to advanced liver diseases continue to rise in PLHIV.
Methods: The study has analyzed the clinical data of 104 HIV/HCV coinfected patients aged 25-47 y.o. admitted to Poltava (central region of Ukraine) HIV/AIDS clinic in 2013-2016. We included patients with known genotype HCV and stages of fibrosis in retrospective cohort study. The stage of fibrosis has been determined with transient elastography. We analyzed the contributing factors of accelerated fibrosis progression including socio-demographic and clinical data, as well as polymorphism of Gln11Leu TLR7 gene. We used Cox proportional hazards regression model to outcome measure included time from the first positive HCV test to diagnosis advanced liver fibrosis (F_3-F_4).
Results: Accelerated fibrosis progression was associated with age over 40 years (HR= 1.9; 95% CI [1.1-2.1]), male sex (HR= 2.4; 95% CI [1.2-4.5]), lower level of CD4 (HR= 1.5; 95% CI [1.2-1.9]), presence of TB (HR= 1.9; 95% CI [1.4-5.3]) and genotype Gln11Gln TLR7 gene (HR= 1.6; 95% CI [1.1-3.7]) was associated with accelerated fibrosis progression.
Conclusions: This study suggests a greater risk of accelerated fibrosis progression in HIV/HCV coinfected patients with older age, male sex, lower level of CD4, presence of TB and genotype Gln11Gln TLR7 gene. Presence of11Leu allele of TLR7 gene is a protective factor of fibrosis progression in HIV/HCV coinfected patients.

WEPEB093

Clinical effectiveness of guideline-recommended antiretroviral therapy core agents in HIV/HCV co-infected patients in the OPERA Observational Database

D. Dieterich[1], L. Brunet[2], J. Fusco[2], R. Hsu[3,4], V. Vannappagari[5], L. Curtis[5], M.C. Nascimento[5], G. Fusco[2]
[1]*Mt. Sinai Healthcare System, New York, United States,* [2]*Epividian, Durham, United States,* [3]*AIDS Healthcare Foundation, New York, United States,* [4]*NYU Langone Medical Center, New York, United States,* [5]*ViiV Healthcare, Inc., Research Triangle Park, United States*

Background: HCV progression in HIV/HCV co-infected patients can become comparable to HCV mono-infection progression with effective HIV treatment. Clinical guidelines recommend the use of dolutegravir (DTG), elvitegravir (EVG), raltegravir (RAL), or darunavir (DRV) as antiretroviral therapy (ART) core agents. However, most trials included very few co-infected patients. We compared the effectiveness of recommended core agents in HIV/HCV co-infected patients in the U.S.
Methods: HIV/HCV co-infected patients in the OPERA® Observational Database initiating a recommended core agent between 08/12/2013 and 06/30/2016 were included and stratified by ART experience. Probability and time to viral suppression by core agent were assessed with Kaplan-Meier methods and a multivariate Cox proportional hazards model. Grade 3-4 liver enzyme elevation (LEE) incidence was estimated for each core agent among HCV treatment naïve patients with normal baseline liver enzyme levels.
Results: Most patients were male and received care in the South of the U.S.; over a third were African American (Table 1). Of the 527 **ART-naïve** patients initiating DTG (27%), EVG (31%), RAL (12%) or DRV (30%), >98% were HCV treatment-naïve. The 12-month viral suppression probability was lower for DRV (47%) than DTG (69%), EVG (69%) and RAL (68%) use. Compared to DTG, viral suppression was achieved slower with DRV (HR: 0.49, 95% CI: 0.35, 0.70), but was not statistically different with EVG (HR: 1.03, 95% CI: 0.76, 1.40) or RAL (HR: 0.94, 95% CI: 0.64, 1.39, Figure 1A). Of the 1,966 *ART-experienced* patients initiating DTG (29%), EVG (17%), RAL (27%) or DRV (27%), >85% were HCV treatment-naïve. The 12-month viral suppression probability was lower with DRV (64%) than with DTG (83%), EVG (74%) and RAL (81%, Figure 1B). Among HCV treatment-naïve patients, there were no statistically significant differences in grade 3-4 LEE incidence in ART-naïve (DTG: 2/43, 5%; EVG: 2/66, 3%; RAL: 0/21, 0%; DRV: 4/65, 6%) or ART-experienced patients (DTG: 3/130, 2%; EVG: 3/103, 3%; RAL: 4/124, 3%; DRV: 3/417, 2%).
Conclusions: Regimens containing DTG, EVG, or RAL may be better choices for treating HIV/HCV co-infected patients. Compared to DTG, suppression was less likely and slower with DRV use only. LEE incidence was comparable across core agents.

Heavy drinking and treatment among HIV/HCV co-infected patients

J. Elliott[1], N. Shalev[2], D. Hasin[1]
[1]Columbia University Medical Center / New York State Psychiatric Institute, Psychiatry, New York, United States, [2]Columbia University Medical Center, Division of Infectious Diseases, New York, United States

Background: Individuals co-infected with HIV and Hepatitis C virus (HCV) face increased health risks when compared with those with HIV or HCV alone. Heavy drinking can contribute to health problems and interfere with engagement in care in this population. In the era of direct-acting antiviral medication for HCV infection, it is important to know how problem drinking relates to engagement in HCV treatment. The current study aims to assess how problem drinking relates to HCV medication access among individuals with HIV/HCV coinfection.

Methods: We sampled 210 patients in a New York City sexual health clinic waiting room in 2017; of these, 39 reported HIV/HCV coinfection. These 39 patients were in middle adulthood (mean age = 53.08 [SD = 11.31]). Most were male (79.49%), racial/ethnic minority (56.41% Black; 25.64% Hispanic), and most had a high school education (84.62%). Patients reported on binge drinking, drinking despite health problems, and HIV and HCV treatment history in a brief tablet-based survey. We assessed associations between drinking and HIV and HCV treatment using Chi-Squared and Fisher's Exact Tests.

Results: Regarding HCV treatment, drinking despite health problems was associated with lower likelihood of ever taking HCV treatment (Fisher's Test, p=0.035; Figure 1).

Of those who drank despite health problems, only one in seven (14.3%) had ever had treatment. Of those who did not, almost two thirds (20 of 32; 62.5%) had received treatment. Drinking despite health problems did not relate to whether HCV treatment had been recommended, and binge drinking did not relate to either HCV outcome (ps>0.10). Neither drinking variable was associated with current or lifetime HIV treatment (ps>0.10).

Conclusions: Among HIV/HCV co-infected individuals, those who drank despite health problems were less likely to have had HCV treatment. This did not appear to be due to provider unwillingness to recommend such medication. Although our sample is small and relied on self-report, these findings suggest that risk behaviors such as drinking despite known risk and not engaging in HCV treatment may cluster together, with potential damaging effects. Interventions to address drinking and HCV health among HIV/HCV co-infected drinkers is needed.

WEPEB095

8 weeks of grazoprevir/elbasvir for acute HCV: A multicenter clinical trial (DAHHS2)

A. Boerekamps[1], A. De Weggheleire[2], G. van den Berk[3], F. Lauw[4], M. Claassen[5], D. Posthouwer[6], W. Bierman[7], T. Dofferhoff[8], S. Hullegie[1], E. Florence[2], J. Arends[9], B. Rijnders[1]
[1]Erasmus MC, Internal Medicine and Infectious Diseases, Rotterdam, Netherlands, [2]Institute of Tropical Medicine, Clinical Sciences, Antwerp, Belgium, [3]OLVG Oost, Internal Medicine and Infectious Diseases, Amsterdam, Netherlands, [4]Slotervaart MC, Internal Medicine and Infectious Diseases, Amsterdam, Netherlands, [5]Rijnstate, Internal Medicine and Infectious Diseases, Arnhem, Netherlands, [6]MUMC+, Internal Medicine and Infectious Diseases, Maastricht, Netherlands, [7]UMCG, Internal Medicine and Infectious Diseases, Groningen, Netherlands, [8]Radboudumc, Internal Medicine and Infectious Diseases, Nijmegen, Netherlands, [9]UMCU, Internal Medicine and Infectious Diseases, Utrecht, Netherlands

Background: Direct-acting antiviral (DAA) therapy for *chronic* hepatitis C infection (HCV) led to speculations about HCV elimination. However, high reinfection rates might become an obstacle, as well as the lack of approval of DAA for the treatment of *acute* HCV.

Few studies evaluated DAA therapy for *acute* HCV and included only a small number of patients. Sustained virological response (SVR) varied between 77-100%. The Dutch Acute HCV in HIV Study2 (NCT02600325) was designed to prove that 1. grazoprevir/elbasvir is effective when given during the *acute* phase of HCV and 2. treatment can be shortened during *acute* HCV without loss of effectiveness.

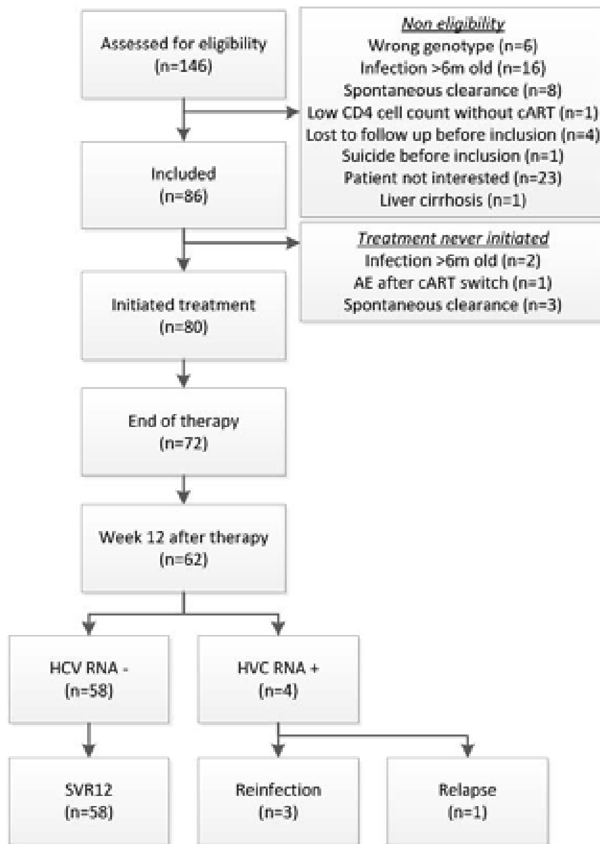
Methods: Single-arm open-label trial in patients with *acute* HCV. Patients were recruited in fifteen Dutch and Belgian hospitals. Patients received 8 weeks of grazoprevir/elbasvir QD and treatment was initiated ≤26 weeks after the estimated date of infection (=midpoint between last negative and first positive HCV test).

The primary endpoint was the SVR 12 weeks post-treatment in the intention to treat population. By protocol, absence of the HCV virus that had been present at baseline at the SVR12 evaluation was considered an SVR. Therefore, a documented reinfection defined as a new HCV genotype or a phylogenetically proven new HCV infection was not considered as treatment failure.

Results: From 02/2016, 144 patients were evaluated for eligibility and 86 were enrolled of which 6 never initiated therapy (figure). Of the 80 patients that started therapy, 62 reached the primary endpoint at the time of abstract submission. All 80 were MSM and all but 7 were HIV+. CD4 at baseline in HIV+ patients was 600/μl (IQR 484-762) and HIV RNA was < 50 c/ml in 97%.

The genotype 1a/1b/4 distribution was 65/0/35%. Median HCV viral load at study entry was 3.14E5 IU/ml (IQR 3.39E4-1.28E6) and 23% of the patients had a HCV *re*infection. At SVR12, 1 patient was diagnosed with a relapse and 3/62 patients had a phylogenetically proven new infection. Therefore therapy was successful in 61/62 (98%; exact 95%CI 91-100%). Final results of the entire study population will be presented.

Conclusions: The shortened 8-week course of grazoprevir/elbasvir was highly effective for the treatment of *acute* HCV.



[Figure 1 Flow diagram]

WEPEB096

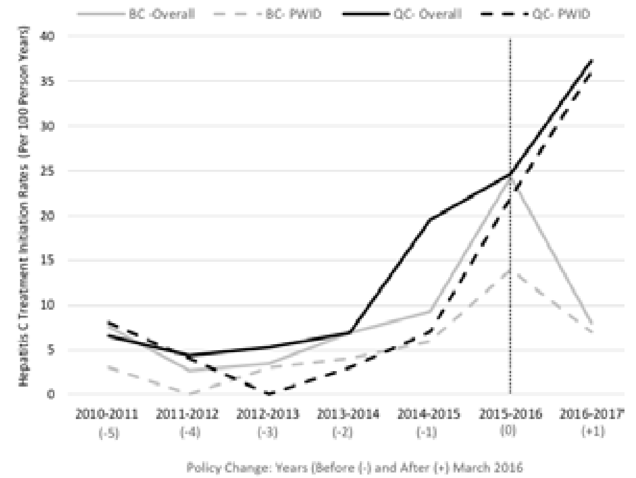
Impact of fibrosis stage restrictions on hepatitis C (HCV) treatment initiation rates: Overall and among PWID in HIV-HCV co-infected populations in Canada

S. Saeed[1], E. Strumpf[1], E. Moodie[1], J. Cox[1], M. Tyndall[2], C. Cooper[3], M. Hull[4], L. Barrett[5], V. Martel-Laferriere[6], M. Klein[7], Canadian HIV/HCV Co-Infection Cohort Study
[1]McGill University, Epidemiology, Montreal, Canada, [2]UBC Centre for Disease Control, Vancouver, Canada, [3]University of Ottawa, Ottawa, Canada, [4]BC Centre of Excellence in HIV/AIDS, Vancouver, Canada, [5]Dalhousie University, Halifax, Canada, [6]L'Université de Montréal, Montreal, Canada, [7]McGill University Health Center, Montreal, Canada

Background: Direct acting antivirals (DAAs) have revolutionized Hepatitis C (HCV) treatment with cure rates of >90%. However, despite clinical guidelines that recommend everyone to be treated regardless of fibrosis stage, healthcare insurers worldwide have imposed restrictions due to high costs. As a result, those that maybe at the greatest risk of transmitting HCV, people who inject drugs (PWID), may face barriers to access treatment. Using a natural experiment occurring in Canada, we evaluated the impact fibrosis stage restrictions on HCV treatment initiation rates overall and specifically among PWID.

Methods: We used data from the Canadian HIV-HCV Co-Infection Cohort Study which prospectively follows 1800 participants from 18 centers. In 2016, one province in Canada, Quebec (QC) removed fibrosis stage requirements, as a restriction for people co-infected with HIV, while other provinces maintained their policies. Using a difference-in-difference framework, among HCV RNA+ participants, we determined the change in HCV treatment initiation rates before and after the fibrosis stage restrictions were removed in QC using British Columbia (BC) as the control group. Anderson-Gill generalized Cox models were used to account for recurrent outcomes and estimate adjusted hazard ratios (aHR) of initiating treatment 1-year post policy change.

Results: Between 2010-2017, there were 158 treatment initiations from 442 participants in BC and 220 initiations from 523 participants in QC. Figure 1 illustrates the overall temporal trends of HCV treatment initiations in QC and BC before and after the policy change, overall and among PWID. One-year post-policy change, QC's initiation rate (per 100-person years) continued to increase from 24 (95% CI, 18-33) to 37 (95% CI, 28-50) while in BC initiation rates declined from 24 (95% CI, 18-33) to 8 (95% CI, 4-16). Same trends applied to PWID. The difference-in-difference aHR which accounts for both temporal trends and time-invariant differences between the provinces overall was 3.3 (95% CI, 1.4-7.4) and was 2.9 (95% CI, 0.7-12.1) among PWID.



[HCV Treatment Initiation Rates Comparing British Columbia (BC) and Quebec (QC) Before and After Fibrosis Stage Restrictions Removed]

Conclusions: Relative to BC, removing fibrosis restrictions in QC resulted in a three-fold increase in DAA treatment initiation. To meet the WHO targets of eliminating HCV by 2030, it will be essential for countries to minimize restrictions allowing for maximum treatment uptake.

WEPEB097

High rates of HCV/HIV co-infection and important correlates among people who inject drugs in Hanoi, Vietnam

G. Le[1,2], T. Vu[1], D. Doan[3], A. Nguyen[1], A. Nguyen H.[1], H. Van[1,4]
[1]Hanoi Medical University, Center for Training and Research on Substance Abuse-HIV, Hanoi, Vietnam, [2]Hanoi Medical University, Department of Global Health, Hanoi, Vietnam, [3]Vietnam Network of People Who Use Drugs (VNPUD), Hanoi, Vietnam, [4]Hanoi Medical University, Department of Epidemiology, Hanoi, Vietnam

Background: HCV/HIV co-infection in people who inject drugs (PWIDs) has increasingly become a major challenge for both the health care system and for the PWIDs themselves even though an increasing number of them are entering HIV care. Vietnam is one of the countries where PWIDs have driven the HIV epidemic, and yet information on the rates of HCV/HIV co-infection and associated are limited.

Methods: From October 2015 to April 2017, peer outreach workers in Hanoi, the capital of Vietnam, recruited PWIDs who reportedly injecting or ever injected. At the research clinic of Hanoi Medical University, HCV and HIV status were ascertained by a combination of rapid Anti-HCV, HCV RNA tests, HIV confirmatory test and by certificate of enrollment in HIV care. A short questionnaire on socio-demographic and risk characteristics were conducted. All participants were assessed with FibroScan. Multinomial logistic regression analyses identified differences among groups (uninfected, HCV mono-infected and HIV/HCV co-infected) according to socio-demographic, drug use and sexual risk characteristics.

Results: Of the study sample (N=509) 78.4% were men and the average age was 39 years. Infection rates were 61.7% and 51.1% for HCV and HIV, respectively, and 26.3% of the sample were not infected with either. Among those infected with HCV, 22.6% were HCV mono-infected and 39.1% were HCV/HIV co-infected. Among those with co-infection, 19.6% were at F4 or F3 stages in FibroScan. HCV mono-infection was positively associated with being male, prior incarceration, drug injection history of more than 10 years, and previous experience with HCV testing. HCV/

HIV co-infection was positively associated with age, male gender, currently living with family, having injected for 6 to 10 years and more than 10 years, no condom use in the last 6 months, and previous experience with HCV testing.
Conclusions: Convenience sampling yielded a study sample with high prevalence of HCV and HIV and HCV/HIV co-infection. FibroScan results show high demand for HCV treatment. Those having co-infection tend to live with their families and have better understanding of HCV from previous experiences with testing, which could potentially be important resources of PWIDs during their courses of treatment.

WEPEB098

Is hepatits-virus C therapy in HCV/HIV-Co-infected patients CNS effective?

G. Arendt, A. Müntefering, E. Orhan
Heinrich-Heine University, Dep. of Neurology, Dusseldorf, Germany

Background: Since modern hepatitis virus C (HCV) eradication treatment has been established, prognosis for HCV/HIV co-infected individuals has improved considerably. However, both viruses are neurotropic; thus, the question is A): whether neuro-cognitive deficits are worse in co-infected patients in comparison to HIV-mono-infected persons and B) whether cognition improves in co-infected individuals after HCV eradication. The to date existing studies come to different results.
Methods: We prospectively examined 44 HCV/HIV co-infected patients with neuro-cognitive deficits and eradication therapy (group A) and 43 co-infected persons with neuro-cognitive decline, but without anti-HCV-treatment (group B) neuropsychologically (NP testing) and compared the results with those of age- and sex-matched HIV-mono-infected patients with neuro-cognitive deficits when starting antiretroviral combination therapy (cART) (group C). All patients were caucasian MSM of comparable age, education and immune status before starting HCV eradication treatment or cART, respectively. Motor and neuropsychological tests were routine tests according to Antinori et al., Neurology, 2007.
Results: Motor tests revelaed more pathological results in the co-infected groups, whereas neuropsychological test performance was comparable in all three groups before therapy. There were also no differences in NP testing in co-infected patients over time (76.5% in eradicated and 75.6% in the non-eradicated individuals); thus, eradication did not provoke neuro-cognitive improvement within one year after eradication, whereas HIV-mono-infected individuals showed better test results 6 months after being started on cART. However, while the percentage of patients with pathological NP test perfomance in HCV patients with eradication therapy was 2.2% higher after one year, it was 9.4% higher in not-eradicated individuals.
Conclusions: Our data suggest that HCV/HIV co-infected patients perform neuropsychologically worse than HIV-mono-infected patients. Eradication treatment does not improve NP deficits, but seems to prevent deterioration. These results must be confirmed in larger studies over longer periods of time.

HCV reinfection following effective all-oral DAA therapy in HIV/HCV-coinfected individuals in Madrid-CoRe

J. Berenguer[1], Á. Gil-Martín[2], I. Jarrín[3], M. Montes[4], L. Domínguez[5], T. Aldamiz-Echevarria[1], M.J. Téllez[6], I. Santos[7], J. Troya[8], J.E. Losa[9], R. Serrano[10], M.T. De Guzmán[11], M.J. Calvo[2], J. González[4], and Madrid-CoRe Study Group
[1]Hospital General Universitario Gregorio Marañón/IiSGM, Madrid, Spain, [2]Subdirección General de Farmacia y Productos Sanitarios/SERMAS, Madrid, Spain, [3]Instituto de Salud Carlos III, Madrid, Spain, [4]Hospital La Paz/IdiPaz, Madrid, Spain, [5]Hospital Universitario 12 de Octubre/i+12, Madrid, Spain, [6]Hospital Clínico Universitario San Carlos, Madrid, Spain, [7]Hospital Universitario de La Princesa, Madrid, Spain, [8]Hospital Universitario Infanta Leonor, Madrid, Spain, [9]Fundación Hospital de Alcorcón, Alcorcón, Spain, [10]Hospital del Henares, Coslada, Spain, [11]Hospital Infanta Cristina, Parla, Spain

Background: High rates of HCV reinfection following sustained viral response (SVR) have been observed among injection drug users (IDU) and men who have sex with men (MSM) who engage in high-risk sexual practices with concomitant drug use. We analyzed HCV reinfection among participants in a large real-world registry of HIV/HCV-coinfected patients treated with all-oral DAA therapy.
Methods: Madrid-CoRe is a prospective registry of HIV/HCV-coinfected patients treated with all-oral DAA-based therapy in the region of Madrid. We analyzed HCV reinfection in patients who achieved SVR in 21 out of 25 hospitals contributing to Madrid-CoRe. SVR was defined as negative HCV-RNA 12 weeks after completion of treatment. The study period started on the date SVR was confirmed. The censoring date was December 31, 2017.
Results: A total of 3,139 patients started all-oral DAA therapy at the participating centers from November 2014 to December 2017. We analyzed reinfections in 2,359 HIV/HCV-coinfected individuals with SVR. We excluded 780 patients with ongoing therapy, pending SVR results, or treatment failure. Reinfections were detected in 17 patients (0.72%) overall, in 12 of 177 MSM (6.78%) who acquired HIV through sexual relations, in 5 of 1,459 patients (0.34%) who acquired HIV by IDU, and 0 of 723 patients with other or unknown mechanisms of HIV transmission. The incidence of reinfection (95% CI) per 100 person-years was 0.48 (0.30-0.77) overall, 5.93 (3.37-10.44) for MSM, and 0.21 (0.09-0.52) for IDU (*Table*). Reinfections were detected a median of 14.86 weeks (IQR 13.43-25.71) after SVR. In 10 (58.82%) patients, the reinfection was caused by a different HCV genotype. All 12 MSM with reinfection acknowledged unprotected anal intercourse with several partners, 7 used chemsex, 6 reported fisting, and 4 practiced slamming. A concomitant STI was detected in 5 patients. Four IDU with reinfection reported injecting drugs following SVR.
Conclusions: HCV reinfection is a matter of concern in HIV-positive MSM treated with all-oral DAA therapy in the region of Madrid. Our data suggest that prevention strategies and frequent testing with HCV-RNA should be applied following SVR in MSM who engage in high-risk practices.

HIV transmission category	N	Reinfections	Years of follow-up	Rate	95% CI

Current hepatitis A outbreaks in men who have sex with men - epidemiological situation in HIV patients in Chile

C.P. Cortes[1,2], M. Wolff[1,2], L.M. Noriega[3,4], A. Marcotti[3,4], C. Palavecino[1], P. Mateluna[3,4], L. Porte[3,4], T. Weitzel[3,4]
[1]*University of Chile School of Medicine, Medicine, Santiago, Chile,* [2]*Fundacion Arriaran, Santiago, Chile,* [3]*Clinica Alemana, Santiago, Chile,* [4]*Universidad del Desarrollo, Facultad de Medicina, Santiago, Chile*

Background: In 2017, various countries in Europe and the Americas (including Chile) experienced outbreaks of hepatitis A virus (HAV) infections in men who have sex with men (MSM). In Chile, the rate of hepatitis A susceptibility in this population is unknown. Hepatitis A vaccines are available, but not widely used. Our study aimed to analyze the epidemiology of feco-orally transmitted viral hepatitis (A and E) in HIV patients in Santiago, Chile.
Methods: The study used preserved samples from a previous cross-sectional multicenter hepatitis B study in adult HIV patients attending public (Fundación Arriarán, FA) and private health centers (Clinica Alemana, CA) in Santiago. Specimens were tested for antibodies against hepatitis A (Elecsys® anti-HAV total, Roche) and hepatitis E (recomWell HEV IgG, Mikrogen). Demographic, clinical and laboratory data were obtained from medical records.
Results: A total of 394 patients (FA, 348; CA, 46) were included (93% male). Median age was 38 years and 99% acquired HIV sexually (83% MSM, 17% heterosexual). 15% had AIDS and 96% were on ART. In 79%, HIV viral load was undetectable and median CD4 cell count was 499 cells/µL. Of all patients, 77% (CI95%, 72-81%) were HAV seropositive (FA, 79% [74-82%]; CA, 65% [51-77%]). Patients born before 1960, in the 1960s, and the 1970s had high HAV seroprevalences of 97%, 92%, and 87%, respectively. Those born in the 1980s had intermediate (64%) and those born in the 1990s very low rates (18%). Overall seroprevalence of hepatitis E was 10.4% (7.7-13.8%), age-dependently ranging from 18% (born before 1960) to 0% (born in 1990s).
Conclusions: Our study highlights that a large proportion of HIV-patients of younger generations are susceptible to HAV. For risk groups such as MSM, vaccination should therefore be provided to control the current outbreak and prevent further spread. More patients of the private health sector in Chile are HAV susceptible, reflecting the more hygienic living conditions, but also the underuse of vaccination. Surprisingly, we detected hepatitis E antibodies in more than 10% of the study population. The epidemiology and clinical relevance of HEV, which has not been described HIV-patients in Chile, requires further studies.

STI's including HPV

WEPEB101

High prevalence of sexually transmitted infections among HIV-positive women on ART: The WETIV-R cohort study in Abidjan, Ivory Coast

C. Chedid[1,2], S. Arikawa[1], E. Messou[3], T. Tiendrebeogo[1], A. Horo[4], A. Zahui[5,6], X. Anglaret[1], A. Minga[5,6], R. Becquet[1]
[1]*Université de Bordeaux, INSERM, Bordeaux Population Health Research Center, Team IDLIC, UMR 1219, Bordeaux, France,* [2]*Ecole Normale Supérieure de Lyon, Département de Biologie, Lyon, France,* [3]*Centre de Prise en Charge de Recherche et de Formation, CePReF-Aconda-VS, Abidjan, Cote D'Ivoire,* [4]*CHU de Yopougon, Service de Gynécologie Obstétrique, Abidjan, Cote D'Ivoire,* [5]*Programme PACCI, site ANRS, Abidjan, Cote D'Ivoire,* [6]*Centre Médical de Suivi de Donneurs de Sang (CNTS), Abidjan, Cote D'Ivoire*

Background: The management of sexually transmitted infections (STI) is insufficiently addressed among African HIV-infected populations. We assessed STI prevalence and associated factors in HIV-positive women of reproductive age on antiretroviral therapy (ART) enrolled in a cohort study integrating reproductive health (RH) services into HIV care at two clinics in Abidjan.
Methods: We selected cohort participants aged 18-49 years, not pregnant, and on ART since less than 24 months. In 2017, socio-demographic and RH characteristics were collected using questionnaires. Collected blood samples and endocervical swabs were tested for *Chlamydia trachomatis* (CT), *Mycoplasma genitalium* (MG), *Trichomonas vaginalis* (TV), *Neisseria gonorrhoeae* (NG), *Candida albicans* (CA), syphilis, herpes (HSV), and bacterial vaginosis (BV). Risk factors were identified with adjusted logistic regression.
Results: Overall, 431 women were included. Median age was 36 (interquartile range 31-40), median CD4 count was 371 cells/mm³ (IQR 227-508), and 23.6% received no formal education. Condom use was infrequent globally (26.9%, 116/431). Among women in a stable partnership (75.8%, 326/431), 22.5% (73/324) had an HIV-positive partner and 64.3% disclosed their HIV status to their partner. Women whose stable partner was HIV-negative were more likely to report using condoms regularly (42.2%, 46/109) than those whose partner was HIV-positive (20.5%, 15/73, p=0.005) or of unknown HIV status (26.4%, 38/144, p=0.009). Overall STI prevalence excluding BV was 36.9% (95% confidence interval: 32.3-41.4). Prevalences of CA, CT, and syphilis were 25.0% (95% CI: 20.9-29.2), 7.2% (95% CI: 4.2-9.6), and 2.3% (95% CI: 0.9-3.7). Prevalence of HSV and TV was below 1.0%. No cases of NG or MG were detected. BV prevalence was 50.8% (95% CI: 46.0-55.6). After adjusting for age, education, study site, and condom use, women with an HIV-positive partner were at a higher risk of STIs than single women or those whose partner's HIV status was negative or unknown (adjusted odds ratio 2.1, 95% CI: 1.2-3.8).
Conclusions: There is an urgent need to integrate STI management into HIV care. Further investigation is needed to address the vulnerability of women in seroconcordant couples. Strategies for better male involvement in STI testing and management are necessary to ensure treatment efficacy.

WEPEB102

Collating molecular assays Abbott RealTime™ highrisk HPV and Roche Linear Array® HPV genotyping test for detection of high-risk human papillomavirus: A means for facilitating HPV screening in HIV-1 positive women

P. Khopkar[1,2], A. Mane[3], M. Ratnaparkhi[3], J. Andil[1], A. Nirmalkar[4], U. Katti[5], S. Godbole[4], S. Kulkarni[1,2]
[1]*National AIDS Research Institute, Virology, Pune, India,* [2]*Symbiosis International University, Health and Biomedical Sciences, Pune, India,* [3]*National AIDS Research Institute, Microbiology, Pune, India,* [4]*National AIDS Research Institute, Epidemiology & Biostatistics, Pune, India,* [5]*National AIDS Research Institute, Clinical Sciences, Pune, India*

Background: HIV-positive women are at higher risk of cervical cancer. Testing HIV-positive women for HR-HPV using molecular assays could improve cervical cancer screening. Abbott Real Time™ High-Risk HPV (AB) is a recent assay that detects 14 high-risk HPV genotypes, whereas Roche Linear Array® HPV Genotyping (RLA) is an established assay detectsing 37 HPV genotypes. The present study evaluates the clinical performance of AB with RLA using identical cervical cytobrush specimens.
Methods: Cervical cytobrush specimens from 129 HIV-1 positive women from Pune, India with known cervical cytology were analyzed using two molecular assays: AB and RLA. As the response variables were categorical, Kappa () statistics was used to evaluate the agreement between the two assays with 95% Confidence Interval. Chi-square test (trend test) was used for estimating positive rates of cervical HPV testing by the two assays according to genotypes and cervical status. Concordance among the results obtained for two assays were determined for any detectable HPV genotype. Additionally, percent positivity for HR HPV detection for two molecular assays was calculated.
Results: The median age and CD4 counts of 129 HIV-1 positive women were 33 years (IQR: 30, 37) and 386 cells/mm³ (IQR: 234, 552) respectively. Overall, 93/129 (72.09%) specimens showed concordant results for molecular High-Risk HPV detection [= 0.46, p< 0.001], and high concordance rate for HPV 18 detection [= 0.89, p< 0.001]. The positive rates of cervical HPV tested by molecular assays according to genotypes and

previously known cervical status portrayed a statistical significance for 'all detectable HPV' 'HPV 16' and 'HPV 18'. The molecular HPV detection based on stratified genotypes suggests overall good concordance between the two assays, being maximum for HR HPV 18 detection (Table 1).
Conclusions: No significant difference between both the tests for detection of HR-HPV was noted and the molecular assays compared well. Considering the turn-around time for both the assays, AB (8 hours) in comparison with RLA (48 hours); AB offers a rapid, robust molecular HPV screening option for HIV-positive women in resource limited Indian settings.

HPV genotype	RLA	AB			Concordance rate (%)	Kappa (κ)	95% CI
		Positive	Negative	Total

[Concordance between the two molecular assays according to HPV genotypes]

WEPEB103

Integrating cervical cancer screening into HIV clinical care for women: A mixed methods study on adherence to screening guidelines, opportunities and challenges in an urban HIV center in Uganda

M.S. Nabaggala[1], E. Phelps[2], S. Nakalema[1], H. Tibakabikoba[1], B. Zanika[3], I. Kalule[1], M. Lamorde[3], B. Castelnuovo[1], A. Kiragga[1]
[1]Infectious Diseases Institute, Research, Kampala, Uganda, [2]Yale University, New Haven, United States, [3]Infectious Diseases Institute, Prevention Care and Treatment, Kampala, Uganda

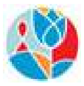
Background: HIV-infected women remain at higher risk of cervical cancer compared to their negative peers (incidence rates of 7.3 vs 2.5 per 1,000 person years). Annual cervical cancer is recommended for HIV positive women however; little data exists on adherence to the recommendation and factors influencing integration of screening into HIV care. We assessed the rates of cervical cancer screening and identified opportunities and challenges of integrating screening at the Infectious Diseases Institute (IDI), a non-profit organization that provides HIV care in Uganda.
Methods: The IDI started routine screening for cervical cancer in 2014 for women < 50 years using Visual Inspection with Acetic Acid (VIA). Patients with a positive VIA result are referred to Uganda Cancer Institute (UCI) while those with a negative result are rescreened yearly. We conducted a retrospective study among 4,618 eligible out of 5,604 women who registered at IDI between 2014 and mid-2017 to assess proportion of patients who received cervical cancer screening using patient records. In addition, we conducted in-depth interviews in July 2016 among seven randomly selected reproductive health staff to understand opportunities and barriers to program.
Results: Of 4,618 women 1,408(30.5%) had ever screened; with median time to screening of 18(IQR:7-29) months. Of the screened, 133/1,408(9.5%) had a positive result and were all referred to UCI. Of 1,275/1,408(90.5%) with a negative result, 764/1,275(60%) were eligible for annual repeat screening-procedure and 192/764(25.1%) were rescreened in the study period.
Among the opportunities identified by healthcare providers: cervical cancer screening can be tied to the patients' routine clinic visit, tailored messages can be used to emphasize the importance of screening and patients who miss scheduled screening could be tracked alongside those who miss general clinic visit. Challenges identified include limited human resources, inadequate space and long waiting times.
Conclusions: The rate of cervical cancer screening in this urban clinic was comparable to the estimated national baseline-screening rate of 30% in urban areas but lower than the national guidelines target of 80% screening coverage. The findings emphasize need for additional measures geared towards increasing the number of HIV positive females screening for cervical cancer.

WEPEB104

High prevalence of HIV infection, cervicovaginal oncogenic HPV harboring unusual genotypes and HPV-related cervical lesions in immigrate women originating from sub-Saharan Africa and living in France

R.-S. Mboumba Bouassa[1], C. Gubavu[2], T. Prazuck[2], L. Robin[1], D. Veyer[1], H. Péré[1], L. Bélec[1]
[1]Laboratoire de Virologie, Hôpital Européen Georges Pompidou, Paris, France, [2]Service des Maladies Infectieuses et Tropicales, Centre Hospitalier Régional d'Orléans, La Source, Orléans, France

Background: More Than 300,000 immigrate women originating from sub-Saharan Africa were living in France. The yet unknown HPV epidemiology in this population could reflect the high HPV endemicity in Africa that is frequently associated with HIV. We herein focused on HPV molecular detection in immigrate African women living in France.
Methods: In 2017, first-generation immigrate African women attending for sexual health the Centre Hospitalier Régional d´Orléans were prospectively included. A total of 28 women (mean age, 43; range, 25-66) living in France for an average of 10 years (range, 1-27) were subjected to anal and endocervical swabs, HIV and HSV-1 and 2 serology and Pap smear. HPV DNA was detected by multiplex real-time PCR (Anyplex™ II HPV28, Seegene, Seoul, South Korea).
Results: Women were mainly from Central Africa (60.7%), while a minority (39.3%) was from other divers African countries. The prevalence of HIV infection was high (85.7%) and most of these women were also seropositive for HSV (82.1%) infection. Two-third (64.3%) of women showed cervical HPV DNA including 72.3% of high-risk (HR)-HPV and 25.0% of multiple genotypes (mean, 1.4 genotypes; range, 1-3 HR-HPV). HPV-58 (33.3%) was predominant, followed by HPV-42 (16.7%), HPV-18 (11.1%), HPV-40 (11.1%) and HPV-68 (11.1%) (Figure). Most of the HPV-positive cervical samples (55.5%) contained Gardasil-9® vaccine (Merck & Co. Inc., New Jersey, USA) genotypes. One-third (28.6%) of anal swabs were positive for HPV, with 66.6% of low-risk HPV-42, 50% of HR-HPV, including HPV-16 (n=1), and 50% of multiple genotypes (Figure). Two (7.1%) HIV-infected women (38 and 66 years positive for HPV-58 and HPV-42/HPV-68, respectively) showed low- and high- grade cervical squamous intraepithelial lesions, respectively, whereas cytology of remaining women was normal.
Conclusions: We report unexpected high prevalences of cervical and anal HR-HPV frequently harboring unusual genotypes that may be associated with cervical precancerous lesions and high HIV prevalence in a series of immigrant women originating from sub-Saharan Africa. These observations point that immigrant women from sub-Saharan Africa constitute *per se* high-risk population for cervical and anal HPV infection, HPV-related cervical lesions, and HIV infection.



WEPEB105

Increasing trends of HIV-syphilis coinfection among pregnant women in Cameroon highlights a population-based re-emergence of syphilis infection

C. Kengne Nde[1], J.D.D. Anoubissi[1], J. Fokam[2,3,4], A. Zeh Meka[1], D.G. Toghoua Tseuko[5], A. Messeh[1], R. Toukam Fodjo[1], Y. Moussa[1], M. Ngo Nemb[1], D. Same Kob[6], E. Kembou[7], S.-M. Sosso[4], G. Loni-Ekali[1], C. Nguefeu Nkenfou[4,8], M.-C. Okomo[5], A. Ndjolo[2,4], S.-C. Billong[1,2,3], J.-B. Elat Nfetam[1,3]

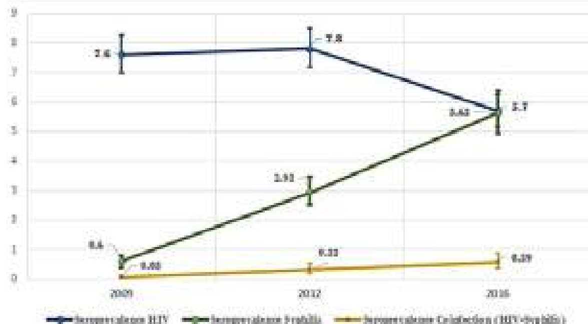
[1]Central Technical Group, National AIDS Control Committee, Yaounde, Cameroon, [2]Faculty of Medicine and Biomedical Sciences (FMBS), University of Yaounde 1, Yaounde, Cameroon, [3]National HIV Drug Resistance Surveillance and Prevention Working Group, National AIDS Control Committee, Yaounde, Cameroon, [4]Chantal BIYA International Reference Centre (CBIRC) for Research on HIV/AIDS Prevention and Management, Yaounde, Cameroon, [5]National Laboratory of Public Health, Yaounde, Cameroon, [6]USAID, Yaounde, Cameroon, [7]WHO, National Office, Yaounde, Cameroon, [8]Higher Teachers' Training College, University of Yaounde I, Yaounde, Cameroon

Background: Syphilis and HIV can be transmitted by pregnant women to their children and it remain a public health problem in Africa. Unlike HIV, there are limited efforts in monitoring the trends of co-infection with syphilis, which thereby suggest risks of re-emergence and spreading overtime. Our study aims were to determine the trends of HIV/syphilis coinfection and syphilis infection overtime through the national surveillance system in Cameroon.

Methods: Based on a prospectively designed analysis, we conducted a study of HIV and syphilis, targeting 7000 first antenatal care (ANC-1) attendees (4000 from urban and 3000 rural sites) in the 10 regions of Cameroon during the 2009, 2012 and 2016 sentinel surveillance surveys. HIV serological testing was performed by serial algorithm as per the national guidelines. Syphilis testing was performed using the Treponema Palladium Hemagglutination assay (TPHA) / Veneral Diseases Research Laboratory (VDRL) as per the manufacturer's instructions. Trends were assessed for HIV, syphilis and HIV/syphilis by estimating prevalences from one study to another.

Results: As of the 2016 survey, a total of 6859 women coming at their first ANC-1 were enrolled. The median age was 26 years [IQR: 21-30] and 46.47% of them were housewife. Acceptability of HIV test was 99.19% (6513/6566). We found a significant increasing trend of the coinfection HIV/Syphilis ranging from 0.05% (95% CI:0.01-0.13) in 2009 to 0.59% (95% CI:0.37-0.88) in 2016. Moreover, while HIV epidemic was on a decline from 2009, prevalence of 7.6% (95% CI: 6.99 - 8.28) to 5.7% (95% CI: 4.93 - 6.4) in 2016, a huge significant increase of syphilis prevalence was observed, going from 0.6% (95% CI:0.40 - 0.80) in 2009 to 5.63% (95% CI:4.93 - 6.40) in 2016 (Figure 1).

Conclusions: HIV/syphilis co-infection is on an increasing trend, due to the re-emergence of HIV syphilis among ANC-1 attendees in Cameroon. This epidemiological dynamics of syphilis confirms a growing burden of syphilis in the general population of Cameroon, and the need to reinforce surveillance and prevention strategies to fight STIs, alongside current efforts on HIV prevention in resource-limited settings similar to Cameroon.



[Figure 1: Evolution of seroprevalence of coinfection HIV-Syphilis, HIV and Syphilis from 2009 to 2016 in Cameroon.]

WEPEB106

Seroprevalence of syphilis, hepatitis C and hepatitis B markers and associated risk factors in a Brazilian cohort of individuals with a newly diagnosis of HIV infection

A. Furtado Costa[1], L.F. Jamal[1], R.S. Nogueira[1], A.C.Q. Leão[1], G. Mizuno[1], P. Menezes[1], M.S. Biagioni Santos[1], M.V. Tancredi[1], J.V.R. Madruga[1], L.P.O. Coelho[2], L.F.M. Brigido[2],
CRT -DST/AIDS Recent Infection Study Group

[1]Centro de Referencia e Treinamento DST/AIDS, São Paulo, Brazil, [2]Instituto Adolfo Lutz, São Paulo, Brazil

Background: Rates of sexual transmission of Hepatitis C virus (HCV), Syphilis and Hepatitis B (HBV) are rising in most countries with great impact in public health. Sexually Transmitted Infections (STI) can increase the susceptibility and infectiousness of HIV and can have severe clinical repercussion in co-infected patients.

The objective of this study is to describe the prevalence of serological markers for syphilis, hepatitis C, hepatitis B and verify associations with epidemiological data in a cohort of HIV newly diagnosed individuals.

Methods: Epidemiological, demographic and laboratorial data from participants of prospective cohort of newly diagnosed individuals with HIV infection were collected at the enrollment. The study was conducted at the STD/AIDS Reference and Training Center (CRT-DST/AIDS) in São Paulo, Brazil, from September/2013 to September/2017.

Data analysis showed that 490 (89.3%) patients are MSM (men who have sex with men). Laboratorial markers of Syphilis, HBV and HCV serologies were analyzed.

Results: Prevalence of hepatitis C was 2.1% (11/531); 72.7% (8/11) MSM, age ranging 22-34 years old; 81,8% (9/11) reported casual partners; 80%(8/10) more than 2 occasional partners (p=0,046).

Susceptible individuals to hepatitis B (anti-Hbc, anti-HBS, HBsAg negative) represented 38.1%(180/472); vaccine immunization (anti-HBs ≥10m UI/ml) 46.0%(217/472).

Having occasional partners was associated with either natural or vaccine immunity (p=0.003); occasional sexual partners was reported by 72%(112/156)of HBV susceptible patients. Available data showed 51.2% (193/377) with positive treponemal test (TPHA); 87% (146/168) TPHA an non-treponemic test (VDRL) with titre ≥1/4.

Conclusions: Data of this cohort, predominantly composed of MSM patients, showed that sexual transmission can play a major role in HCV widespread. The use of condoms is important to prevent HCV infections in HIV infected individuals.

Further, less than 50% of patients had immunity to HBV, showing the importance to improve vaccine coverage for this population.

Better understanding of sexual behavior, vaccine coverage and other factors associated with transmission can be crucial to improve STI prevention strategies.

WEPEB107

Sexually transmitted infection prevalence among high-risk adolescents in Los Angeles and New Orleans: A comparison by HIV status

C.L. Shannon[1], M. Koussa[2], S.J. Lee[2], M.J. Rotheram-Borus[2], J.D. Klausner[1]

[1]University of California Los Angeles, David Geffen School of Medicine, Division of Infectious Diseases, Los Angeles, United States, [2]University of California Los Angeles, Department of Psychiatry and Biobehavioral Sciences, Los Angeles, United States

Background: Sexually transmitted infection (STI) rates are on the rise in the United States, particularly among adolescents. STIs increase the transmissibility of HIV. Gay, bisexual, and transgender youth (GBTY) and homeless youth are at uniquely high risk for both HIV and STIs. However, there is limited data on the prevalence of STIs in that population, as they often have limited access to healthcare services. In this study, we compared the prevalence of *Chlamydia trachomatis* (CT) infection, *Neisseria gonorrhoeae* (NG) infection, and syphilis antibodies among HIV infected and HIV uninfected high-risk adolescents.

Methods: Adolescents 12-24 years of age were recruited from homeless shelters, LGBTQ organizations, and community health centers in Los Angeles, California and New Orleans, Louisiana beginning in May

2018. Eligibility was determined through a risk assessment and a rapid, 4th generation HIV test. Enrolled participants were predominantly homeless youth, GBTY, and racial minorities. We recruited 494 HIV-uninfected adolescents and 49 HIV-infected adolescents. Upon enrollment, participants received point-of-care pharyngeal, rectal, and urethral / vaginal CT and NG testing using the GeneXpert, a 90-minute nucleic acid amplification test (Cepheid, Sunnyvale, CA). Participants also received a syphilis antibody test using the Syphilis Health Check, a 10-minute assay detecting *treponema pallidum* antibodies (Diagnostics Direct, Stone Harbor, NJ). STI testing was conducted by trained paraprofessionals. Prevalence was calculated for each STI and compared between HIV-infected and HIV-uninfected youth. 95% confidence intervals (CIs) were calculated using the exact binomial method.

Results: Prevalence values are shown in Table 1.

Conclusions: Both HIV-infected and HIV-uninfected adolescents had a high prevalence of STIs. However, HIV-infected youth had a much greater prevalence of all three STIs, with particularly high rates of rectal CT, rectal NG, and syphilis antibodies. These data highlight the importance of extragenital CT and NG screening in this population, and underscore the need for community-based STI testing programs targeting both HIV-infected and HIV-uninfected high-risk adolescents.

	HIV-uninfected	HIV-infected
CT infection- pharyngeal (%)	1.1 (CI: 0.4, 2.5)	2.0 (CI: 0.1,10.9)
CT infection - rectal (%)	6.3 (CI: 4.2, 9.0)	12.5 (CI: 4.7, 25.2)

Syphilis among HIV positive patients in Gaborone, Botswana: A cross-sectional study utilising a dual antibody point of care test

D. Lawrence[1,2], I. Maan[1], N. Tlhako[2], K. Tsholo[2], K. Ramontshonyana[3], C. Morroni[2,3,4]

[1]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom, [2]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [3]Botswana UPenn Partnership, Gaborone, Botswana, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Background: Syphilis remains a major global health issue with over 18 million cases of syphilis worldwide, the majority of which occur in Africa. There is a lack of prevalence data in low and middle income countries, partly due to the complexity and cost of syphilis diagnostics and the widespread use of syndromic STI management, reducing the imperative to secure diagnosis. Point of care tests have been promoted by the WHO to expand the availability of testing but traditionally have only included treponemal tests which cannot distinguish between active and previous infection. Using a point of care test for both treponemal and non-treponemal antibodies, we aimed to estimate the prevalence of active and previous syphilis among patients attending an HIV clinic in Botswana.

Methods: All patients attending the HIV clinic at Princess Marina Hospital, Gaborone over a four-week period in 2017 were invited to participate. Participants completed a questionnaire to ascertain any active or historical symptoms and diagnoses of syphilis. Participants were tested with a point of care test utilising a simultaneous treponemal and non-treponemal antibody test.

Results: 390(49%) of clinic attendees agreed to participate. 118(30%) male, median age 45 years(IQR 40-51), median CD4 565 cells/mm³(392-729) and 344(91%) viral load < 40 copies/mL. 99(25.5%) reported previous genital ulcers and 72(19%) had previously tested for syphilis, of which 11(15%) had tested positive. 5 tested positive for active syphilis infection(1.3% 95%CI 0.5-3.0%). 64 had positive treponemal antibody(16.4% 95%CI 13.0-20.4%). Increased age, low levels of education and a history of painless genital ulcers were associated with positive treponemal serology.

Conclusions: Syphilis prevalence among these self-selected patients attending a HIV clinic in Botswana is comparable with local ante-natal data. It is acceptable and feasible to use a syphilis point of care test in an HIV clinic which allows patients to be tested and treated the same day. These tests could facilitate a paradigm shift away from syndromic management of genital ulcer disease.

Antibody Test Result (n=390)	Number (Prevalence)	95% CI
Treponemal and Non-Treponemal	5 (1.3%)	0.5 - 3.0%
Treponemal Only	64 (16.4%)	13.0 - 20.4%
Non-Treponemal Only	10 (2.6%)	1.4 - 4.7%
Non-Reactive	311 (79.7%)	75.4 - 83.5%

[Results of dual antibody point of care test]

WEPEB109

CMV Replication and HIV Persistence in Pre- and Post-menopausal HIV-Infected Women on Suppressive ART

S. Gianella[1], S. McDonald Tran[1], M.F. Oliveira[1], S. Lada[1], M. Zhao[1], M. Vargas[1], J.S. Mathad[2], T. Wilkin[2]

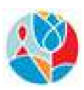
[1]University of California San Diego, La Jolla, United States, [2]Weill Cornell Medicine, New York, United States

Background: Asymptomatic CMV replication is common in HIV infected men, and is associated with increased immune activation, T cell proliferation and larger HIV reservoirs (Gianella et al.). The prevalence of CMV shedding and its relationship to HIV persistence have not been systematically investigated in HIV-infected women.

Methods: Fifty virologically suppressed HIV-infected women with an intact uterus were prospectively enrolled in New York City between July 2014 and September 2016. Participants provided genital samples (self-collected vaginal swabs N=50, provider collected cervical swabs N=15 and cervicovaginal lavage (CVL) N=15), oral samples (rinses N=50, swabs N=40), peripheral blood mononuclear cells (PBMCs, N=50) and urine (N=50) at one cross-sectional time-point. CMV DNA was quantified in each specimen by real-time PCR. Cellular HIV DNA (pol and 2-LTR) and HIV RNA (encoding gag, tat-rev and PolyA) were quantified by droplet digital (dd)PCR. Clinical data collected included menopausal status, current and nadir CD4+, and time on suppressive ART. One woman was CMV seronegative and excluded from the analysis.

Results: Median age was 53 years; 28 women (56%) were post-menopausal; 43 women (86%) acquired HIV through heterosexual contact. Median time on suppressive ART was 7.8 years (IQR:4.2-13.1). Median current CD4+ was 721 cells/ml (490-930) and Nadir CD4+ was 172 cells/ml (56-265). Of the 49 CMV-seropositive women, 15/49 (29%) had detectable CMV DNA in at least one specimen type, most frequently self-collected vaginal swabs (16%) and PBMCs (15%), followed by oral swabs (3%) and rinse (6%), CVL and urine (both 0%). Presence of detectable CMV was not associated with any clinical variable. Higher levels of HIV DNA were associated with a lower Nadir CD4+ and post-menopausal status (both $p < 0.01$ in adjusted analysis) but not with presence of detectable CMV DNA as hypothesized. There was no difference in cellular HIV transcription between pre- and post-menopausal women.

Conclusions: Unlike HIV-infected men, CMV is less frequently detected in women and was not associated with increased HIV reservoir in this study. Interestingly, post-menopausal status was independently associated with increased HIV reservoir, even after adjusting for age and duration of HIV infection. The exact mechanism is under investigation as it was unrelated to increased cellular HIV replication.

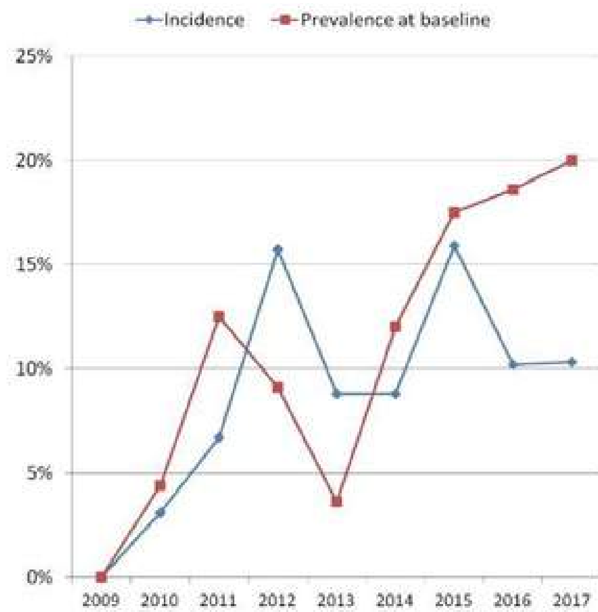


WEPEB110

Syphilis prevalence and incidence are high among HIV-infected MSM in Thailand

D. Colby[1], S. Pinyakorn[2,3], P. Chan[1], E. Kroon[1], P. Prueksakaew[1], C. Sacdalan[1], M. Robb[2,3], P. Phanuphak[4], J. Ananworanich[2,3], N. Phanuphak[1], SEARCH010/RV254 Study team
[1]Thai Red Cross AIDS Research Centre, SEARCH, Bangkok, Thailand, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]U.S. Military HIV Research Program, Silver Spring, United States, [4]Thai Red Cross AIDS Research Centre, HIVNAT, Bangkok, Thailand

Background: Syphilis infection among men who have sex with men (MSM) has been increasing worldwide. We report here on syphilis prevalence and incidence in a cohort of HIV-infected individuals in Thailand.
Methods: Syphilis diagnosis was analyzed during 2009-2017 in the SEARCH 010/RV254 cohort of acute HIV infection (AHI) in Bangkok and Pattaya, Thailand. VDRL was performed routinely at baseline and every 24-48 weeks on all participants and in addition when clinically indicated. Positive results are confirmed with titer and TPHA. All participants were offered antiretroviral therapy (ART) at AHI diagnosis with clinical and virological monitoring performed every 12 weeks.
Results: Among 523 participants with AHI median age was 26 (IQR 22-31) years, 97% were male and 93.5% were MSM. Syphilis prevalence at enrollment was 14.1% (n=74), rising from 4.4% in 2010 to 20% in 2017 (Figure 1)(chi-square test for trend p=0.001). Incident syphilis occurred in 21.8% (n=98), annually increasing from 3.1% in 2010 to 15.7% in 2012 and remaining in the range 8-16% through 2017 (chi-square for trend p=0.42). Cumulatively, 32.9% of the cohort had at least one episode of syphilis. Participants with syphilis were more likely to be MSM (OR 3.93, 95% CI 1.36-11.3), have multiple sex partners (OR 2.28, 1.55-3.36) and use recreational drugs during sex (OR 2.00, 1.30-3.07). Syphilis was not associated with age, education, alcohol use, or Fiebig stage at HIV diagnosis. Among 30 participants with incident syphilis who were on ART for at least 24 weeks and for whom data were available, all had undetectable viral loads at syphilis diagnosis and both 12 weeks before and 12 weeks after treatment.
Conclusions: Syphilis infection is very common among HIV-infected MSM in Bangkok and Pattaya, Thailand. Syphilis appears to have no effect on viral load among patients on ART for more than 6 months. Routine syphilis screening should be performed at diagnosis and routinely every 6-12 months while on ART for MSM with HIV in Thailand.



[Syphilis baseline prevalence and incidence among HIV-infected MSM in Bangkok and Pattaya, Thailand]

Sex-specific issues of ART efficacy, adverse reactions and complications

WEPEB111

Patterns of antiretroviral drugs use and co-morbid conditions in a cohort of older women living with HIV in Argentina

R. Mauas, M. Laurido, L.M. Cabral, M.C. Niccodemi, I. Cassetti
Helios Salud, Buenos Aires, Argentina

Background: although women represent one third of the HIV infected population in Latin America, studies addressing HIV infection, antiretroviral (ARV) therapy and age-related events in older women living with HIV (WLHIV) within the region are limited. Hence, we describe the patterns of ARV drugs use and co-morbid conditions in a cohort of older WLHIV receiving care at our institution.
Methods: retrospective, observational study including WLHIV over 50 years old assisted at Helios Salud, Buenos Aires, Argentina from 1997 to 2017. Clinical, laboratory and demographic data from electronic medical charts were reviewed. History of ARV use and prevalence of common co-morbidities were assessed. The information was collected in an Ad Hoc database and T-test, Chi², Fisher exact or Mid P tests, maximum likelihood odds ratio, and multiple regression were used as appropriate.
Results: 250 patients were included. Age, mean (±SD): 58.1 (6.1) years. Time since HIV diagnosis, mean (±SD): 13.8 (6.9) years. AIDS at HIV diagnosis: 46.4%. On ARV therapy: 98.4%. Time on ARV, mean (±SD): 11.7 (5.9) years. Viral suppression: 88,2%. Latest CD4 count, mean (±SD): 673 (312) cells./µl. Only 48 women (19.5%) remain on their first ARV regimen. Currently, 134, 73, and 28 subjects are on NNRTI, PI and INI-based regimens, respectively. No preferred backbone between ABC/3TC or TDF/3TC was noted (119 vs. 107); 12 patients are still receiving AZT/3TC. In average, 2.7 co-morbidities per subject were observed. Prevalent chronic conditions were: dyslipidaemia (63,6%), low bone mineral density (66,7%) and psyquiatric disorders (61,2%). Table 1 summarizes the associations among variables.
Conclusions: chronic conditions related to metabolic syndrome were strongly associated. CVE also correlate with advanced HIV disease. Aging process negatively impacts on women's BMD and fracture risk, as well as TDF and PI exposure. INI-based regimens demonstrate the better metabolic profile of the class, however they are almost not included as first-line therapies in our setting yet. Health care providers should be aware of this multi-morbidity when selecting treatment options for older women.

Gender differences in antiretroviral treatment outcomes in patients accessing care at a tertiary HIV care center in Southern India - need for dolutegravir based ART

P. Selvamuthu, E. Chandrasekaran, A. Pradeep, C. Devaraj, R. Balakrishnan, N. Kumarasamy
YRGCARE Medical Centre, VHS, Chennai, India

Background: Women and men differ in terms of susceptibility to HIV infection, disease progression and treatment outcomes .WHO guidelines recommend treatment for all. We undertook this analysis in our patient population to examine gender based differences in antiretroviral treatment outcomes after initiation of ART in a resource-limited setting.
Methods: Patients who were >18 years of age, attending YRGCARE Medical Centre, a tertiary HIV care centre between Jan 1996 and Dec 2017 were included.
Data analyses was carried out using YRGCARE HIV observational database.Descriptive statistics were calculated with mean and standard deviation (SD) for variables that were normally distributed, and the median and Interquartile ranges (IQR) were calculated for variables influenced by extreme values. To compare proportions, chi-square statistics were used, and the Mann-Whitney U test was used to compare median durations.
Statistical analyses were performed with IBM SPSS software 24.0. A p-value <0.05 was considered statistically significant.
Results: 5291 patients who initiated ART were studied. Women were younger (41yrs vs 45yrs p=<0.001), had higher CD4 at enrollment (318cells/uL vs 200cells/uL p=<0.001) and at ART initiation (246cells/uL vs 194cells/uL p=<0.001) and were less viremic (7733copies/ml vs 37915copies/ml p=< 0.001).
Women initiated treatment later than men (3 months vs at enrollment p=<0.001). TDF/XTC/EFV was the ART most commonly prescribed (47.4% vs 41.8%). 1.1%women and 1.5%men were on TDF/XTC/DTG.

	Women	Men	p- value
Median CD4 in cells/uL at one year after ART initiation	450	386	<0.001
Median Viral load (in copies /ml)at one year after ART initiation	<150	<150	NS
Median Years of follow up	5.4	6.7	<0.001
First line failure	28.1%	39.4%	<0.001
Median Time to first line failure in years	5.8	6.9	<0.001
Second line failure	6.3%	8.7%	<0.001
Median time to second line failure in years	4.0	4.2	NS

[Gender differences in treatment outcomes]

More women experienced giddiness (p=0.00380), headache (p=0.04), sleep disturbances (4.3 vs 3.2 %) and other CNS adverse events than men (56% vs 39% p=<0.001). NCDs/clinical failure events were similar in both groups.
Women who initiated ART with CD4 cell counts >500cells/uL experienced treatment failure less often than women who initiated ART at <500cells/uL (17.2% vs 25.2% p=<0.001) and had fewer adverse events (37.7% vs 90.1% p=<0.001).
Conclusions: Gender differences affect treatment outcomes in our cohort. Women experienced more CNS related toxicities to EFV and hence Dolutegravir based ART should be a preferred option for ART initiation in women. Initiating ART at higher CD4s is associated with better treatment outcomes.

WEPEB113

Advanced HIV disease among males and females initiating HIV care in rural Ethiopia

A. Lifson[1], S. Workneh[2], A. Hailemichael[2], R. Maclehose[1], K. Horvath[1], R. Hilk[1], A. Sites[3], T. Shenie[2]
[1]University of Minnesota, Division of Epidemiology and Community Health, Minneapolis, United States, [2]National Alliance of State and Territorial AIDS Directors, Ethiopian Office, Addis Ababa, Ethiopia, [3]National Alliance of State and Territorial AIDS Directors, Global Program, Washington, United States

Background: Despite recommendations for early initiation of HIV treatment, many persons living with HIV in sub-Saharan Africa enter care with advanced HIV disease. Studies from some countries report than men initiate HIV care with more advanced HIV disease than women. As part of a community trial assessing impact of peer support workers for HIV patients newly entering care, baseline survey and clinical data were collected on 1,799 adults sequentially recruited from 32 district hospitals or local health clinics in rural southern Ethiopia.
Methods: Baseline surveys included questions on presence of each of six clinical symptoms that lasted >1 month (defined as chronic) and the 10-item Center for Epidemiologic Studies Depression Scale, with a score ≥10 indicating significant depressive symptoms. CD4+ count, body mass index (BMI) and WHO clinical stage were abstracted from participants' HIV clinic records. Advanced HIV disease was defined based on UNAIDS criteria as either a CD4+ count < 200 cells/mm³ or WHO stage III or IV disease.
Results: 733 (41%) males and 1066 (59%) females were enrolled. Advanced HIV disease was present in 66% of males and 56% of females (p<0.001). Males (compared to females) had a lower CD4+ count at enrollment (287 vs. 345 cells/mm³) and were more likely to be WHO Stage III or IV (46% vs. 37%) (p< 0.001). Men were also more likely to have chronic diarrhea (23% vs 17%), fevers (47% vs 40%), cough (43% vs. 32%), pain (41% vs. 36%), fatigue (70% vs. 64%), and weight loss (70% vs. 65%). Men also had a lower BMI (19.3 vs. 20.2 kg/m²). Fifty-two percent of males and 57% of females had significant depressive symptoms.
Conclusions: The majority of those initiating care in this resource-limited setting already had advanced HIV disease, stressing importance of earlier diagnosis and linkage to care. Men compared to women had more advanced HIV disease and poorer physical health status when initiating treatment. The majority of men and women had significant depressive symptoms, stressing the need to assess and address mental as well as physical health needs.

WEPEB114

Trends in antiretroviral switching and discontinuation among Canadian women living with HIV

N. Kronfli[1], N. O'Brien[2], K. Proulx-Boucher[1], D. Rouleau[3], M. Loutfy[4,5], A. Kaida[6], M. Ndung'u[5,7], B. Gagnier[5], H. Dubinsky[1], M. Lee[6], A. de Pokomandy[1,2], on behalf of the CHIWOS Research Team
[1]McGill University Health Centre, Chronic Viral Illness Services, Montreal, Canada, [2]McGill University, Department of Family Medicine, Montreal, Canada, [3]Université de Montreal, Montreal, Canada, [4]University of Toronto, Toronto, Canada, [5]Women's College Research Institute, Women's College Hospital, Toronto, Canada, [6]Simon Fraser University, Vancouver, Canada, [7]Africans in Partnership Against AIDS, Toronto, Canada

Background: Studies on antiretroviral therapy (ART) switching and discontinuation are lacking among women living with HIV (WLWH). We aimed to describe trends in ART use, and to identify characteristics associated with switches or discontinuation of ART among WLWH in Canada.
Methods: We analysed baseline (2013-2015, n=1422) and 18-month follow-up questionnaires (2015-2017, n=1252) from the Canadian HIV Women's Sexual and Reproductive Cohort Study (CHIWOS). The outcome of interest was self-reported use of ART at 18-months compared to baseline. Multivariable logistic regression was used to identify correlates of ART regimen switching and discontinuation.
Results: A higher proportion of women reported taking ART at 18 months compared to baseline (85.5% vs. 82.6%). Of the 1232 women retained for current analyses, 49.5% continued the same ART, 9.0% started ART, 28.1%

Tuesday 24 July

Late Breaker Abstracts

Publication Only Abstracts

Author Index

switched their ART regimen, 4.4% discontinued therapy and 9.0% remained off ART between baseline and 18-month visits. The most commonly switched agent was lopinavir/norvir (46.0%); most commonly discontinued were efavirenz (8.0%) and darunavir (7.9%). At 18 months, more women were prescribed integrase inhibitors (30.6% from 12.4%) and the proportion of women on single tablet regimens increased (21.7% from 17.6%).
In multivariable analysis, the odds of an ART switch were significantly lower among women of Indigenous ethnicity (aOR 0.55; 95% CI:0.34-0.86) vs. Caucasian, women living in Quebec (aOR 0.66; 95% CI:0.48-0.93) vs. Ontario, and were higher among women with a baseline CD4 count < 200 cells/ml (aOR 1.91; 95% CI:1.02-3.51) vs. >500 cells/ml. The odds of ART discontinuation were significantly lower among women born outside Canada (aOR 0.19; 95% CI:0.08-0.49) vs. Canadian-born and higher among women aged 16-30 years (aOR 11.2; 95% CI:3.25-38.65) vs. ≥50 years, women living in Ontario (aOR 8.9; 95% CI:2.38-33.34) or in British Columbia (aOR 6.6; 95% CI:1.62-26.42) vs. Quebec, or those who perceived that taking ART would somewhat reduce the risk of transmission (aOR 2.66; 95% CI:1.23-5.76).
Conclusions: Changes in ART are relatively common (28.1% over 18-months) among Canadian WLWH, likely reflecting rapid changes in available ART options and guidelines. While a smaller proportion (4.4%) have discontinued therapy, women 16-30 and those who may have a misunderstanding of HIV transmission should receive particular attention.

Pregnancy (clinical management issues and pharmacokinetics)

WEPEB115

Timing of initiation of ART before or after conception is not associated with adverse pregnancy outcomes: Findings from the ANRS 12136 TEMPRANO trial in Côte d'Ivoire

T. Tiendrebeogo[1], A. Badje[2], S. Arikawa[1], M.-L. Newell[3], C. Danel[2], D. Gabillard[1], S. Eholié[2], X. Anglaret[1,2], R. Becquet[1], ANRS 12136 TEMPRANO Study Group
[1]*University of Bordeaux, Inserm, Bordeaux Population Health Research Center, Bordeaux, France,* [2]*Programme PAC-CI, French National Agency for Research on AIDS and Viral Hepatitis (ANRS) Research Center, Abidjan, Cote D'Ivoire,* [3]*University of Southampton, Global Health Research Institute, Southampton, United Kingdom*

Background: ART-initiation before or early pregnancy has been associated with adverse pregnancy outcomes; however such findings could be confounded by ART eligibility, ART regimen and methodological issues. We assessed the risk of adverse pregnancy outcomes by ART initiation pre- or post- conception using data from a randomized trial in Abidjan to provide evidence on pre-conception ART safety.
Methods: We investigated adverse pregnancy outcomes (stillbirth, small for gestational age [SGA], preterm delivery [PTD] and low birthweight [LBW]) in first pregnancies; a composite outcome was calculated as any adverse pregnancy outcome. In the TEMPRANO trial women were assigned to either early (irrespective of CD4 count) or deferred (WHO standard) TDF-based ART. Risks of adverse outcomes were analyzed by trial randomisation strategy (intent-to-treat) to account for timing of ART initiation in relation to conception; further, in a per-protocol analysis, women in the deferred ART strategy who became ART eligible and initiated ART before conception (e.g. before the end of the first pregnancy trimester) were excluded. Pregnancy was determined at each follow-up visit and confirmed by urine test. Gestational age was based on ultrasound. Adjusted Odds Ratios (aOR) were estimated in logistic regression allowing for women's age, parity, and the nearest CD4 cell count before conception.
Results: In total, 119 and 122 pregnancies were reported, with 83 and 86 deliveries leading to 80 and 83 live births, in the early and deferred ART strategy respectively; 17 women in the deferred ART strategy started ART before conception, their exclusion resulted in 66 live births in this group. Overall, about 3.5% of pregnancies resulted in stillbirths; among livebirths 21% were LBW, 19% PTD and 23% SGA. Risk of adverse pregnancy outcomes did not differ significantly by randomisation strategy in either intent-to-treat or per-protocol analysis (Table 1). Risk of any of adverse pregnancy outcome (composite variable) was not associated with trial arm (intent-to-treat) or timing of ART initiation (before or after conception).
Conclusions: Using data from women randomly allocated to initiate ART immediately or deferred, our results provide reassuring evidence on the lack of association with timing of ART pre- or post-conception. Adverse pregnancy outcomes were common in this population however.

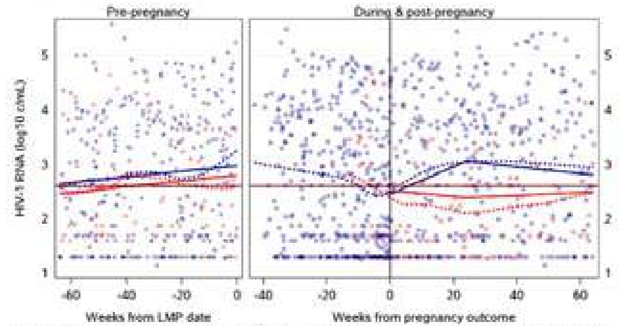
Pregnancy rates and postpartum virologic control among perinatally HIV-infected young women in the US

K. Patel[1], B. Karalius[1], K. Powis[2], C. Berman[1], D. Kacanek[3], A.-B. Moscicki[4], M. Paul[5], K. Tassiopoulos[1], Pediatric HIV/AIDS Cohort Study (PHACS)
[1]*Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States,* [2]*Massachusetts General Hospital, Internal Medicine and Pediatrics, Boston, United States,* [3]*Harvard T.H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States,* [4]*David Geffen School of Medicine, UCLA, Pediatrics, Los Angeles, United States,* [5]*Baylor College of Medicine, Pediatrics, Houston, United States*

Background: There is limited data describing pregnancy and postpartum health among perinatally HIV-infected (PHIV) young women. We compare pregnancy rates among PHIV and perinatally HIV-exposed, uninfected (PHEU) women, and describe pre-conception and postpartum HIV-1 RNA trajectories among PHIV women.
Methods: Pregnancy rates were calculated among PHIV and PHEU women in the PHACS AMP Up protocol. LOESS plots and linear mixed-effects models described trends in HIV-1 RNA starting one year prior to conception, during pregnancy, and through one-year postpartum for all pregnancies among PHIV women by pregnancy outcome (live-birth or spontaneous/elective abortion).
Results: Of 323 young women enrolled in AMP Up, 273 (234 PHIV, 39 PHEU) who reported age at sexual debut and history of heterosexual vaginal intercourse were included in analyses. Pregnancy rates were higher among PHEU compared to PHIV women (IR per 100 person-years [95% CI]: 16.5 [11.4, 23.8] vs. 10.2 [8.4, 12.3]). Of the 99 PHIV women with at least one pregnancy, 60% had 1 pregnancy, 20% had 2, 12% had 3, 4% had 4, 3% had 5, and 1% had 6, with a total of 172 reported pregnancies. 72% of the pregnancies resulted in a live-birth, 9% were spontaneous abortions, and 19% were elective abortions. At one year prior to conception the average HIV-1 RNA was 475 copies/mL in all women and slowly increased over time up through conception (Figure). During pregnancy, HIV-1 RNA levels decreased with average HIV-1 RNA < 400 copies/mL at delivery. In the first 24 weeks postpartum, HIV-1 RNA levels increased by 1.3 (0.4, 2.2) $\log_{10}$ copies/mL per year after a live birth and subsequently stabi-

lized with a small decreasing slope from 24 weeks to one-year post-partum (slope: -0.3 [-0.8, 0.1] $\log_{10}$ copies/mL per year). In comparison, the average postpartum trajectory of HIV-1 RNA after a spontaneous/elective abortion remained at levels < 400 copies/mL.

Conclusions: Compared to PHEU women, PHIV women had lower pregnancy rates. Among PHIV women however, HIV-1 RNA levels increased after a live birth in the first 6 months post-partum, potentially indicating a vulnerable time period for HIV progression among new mothers and the importance of continued engagement in HIV care.



[Figure. LOESS and modelled trajectories of HIV-1 RNA during the pre-conception, pregnancy and post-partum periods by pregnancy outcome (live-birth or spontaneous/elective abortion)]

WEPEB117

Tuberculosis diagnosis and treatment outcomes among HIV+ pregnant women in Haiti

M.M. Deschamps[1], M. McNairy[2], J. Bonhomme[1], V. Rouzier[1], J. Pierrot[1], J. Mathad[3], L. Byers[1], M. Driver[1], P. Cremieux[1], J. Pape[1]
[1]GHESKIO, Port au Prince, Haiti, [2]Weill Cornell Medicine, Center for Global Health, New York, United States, [3]Weill Cornell Medicine, New York, United States

Background: Tuberculosis is a leading cause of maternal mortality in TB-endemic countries. We evaluated TB prevalence, incidence, and maternal/ infant outcomes among a cohort of HIV+ pregnant women in Haiti.

Methods: All HIV+ pregnancies among women ≥15 years who enrolled in the Prevention of Mother-to-Child Transmission program at the GHESKIO clinic from January 2011 through July 2015 were included. TB diagnosis was defined as positive AFB smear, culture, gene Xpert or clinical diagnosis based on a positive symptom screen and abnormal chest radiograph per national guidelines. Prevalence was defined as a TB diagnosis at enrollment. Incident TB was any new TB diagnosis during pregnancy through 24 months postpartum. Factors associated with TB diagnosis were identified using logistic regression.

Results: Among 2,091 unique pregnancies, median age was 29 years (IQR 10-38). Of the 45 TB diagnoses, 8 (18%) were diagnosed during pregnancy and 37 (82%) in the postpartum period. Median CD4 count of women TB+ women was 346 cells/uL at baseline compared to 464 cells/uL among TB- women (p=0.05). TB prevalence was 0.14% (3 cases). There were 42 incident cases (1.15 cases/100 Person Years [PY]). The incident rate was 0.82 cases/100 PY during pregnancy versus 1.35 cases/100PY postpartum. The most common symptoms among TB+ women were cough (89%), fever (47%), weight loss (16%), and diarrhea/vomiting (4%). Among the 45 TB+ women, 12 (27%) were cured, 11 (24%) completed treatment, 17 (38%) abandoned treatment, and 5 (11%) died. Five infants were HIV+ among 45 TB+ mothers (11%) as compared to 49 HIV+ infants among 2,078 TB- mothers (2%) (p=0.007). Three infants of TB+ mothers had active TB (7%) as compared to 22 (1%) among TB- mothers (p< 0.001). Factors associated with TB diagnosis in women were age 19-24 and symptoms listed above (p< 0.05).

Conclusions: TB incidence of HIV+ women was ~1.5 fold higher during the postpartum period as compared to pregnancy and infants born to TB+ women had increased HIV and TB transmission. Increased screening for TB during pregnancy and the postpaturm period is urgently needed.

Pharmacokinetics of darunavir boosted with cobicistat during pregnancy and postpartum

J.D. Momper[1], B. Best[1], J. Wang[2], A. Stek[3], D.E. Shapiro[2], K. George[4], E. Barr[5], K. Rungruengthanakit[6], E. Smith[7], N. Chakhtoura[8], E.V. Capparelli[1], M. Mirochnick[9]
[1]University of California, San Diego, La Jolla, United States, [2]Harvard University, Boston, United States, [3]University of Southern California, Los Angeles, United States, [4]FHI 360, Durham, United States, [5]Children's Hospital Colorado, Aurora, United States, [6]Chiang Mai University, Chiang Mai, Thailand, [7]National Institute of Allergy and Infectious Diseases, Bethesda, United States, [8]National Institute of Child Health and Human Development, Bethesda, United States, [9]Boston University, Boston, United States

Background: Darunavir (DRV), an HIV-1 protease inhibitor, is primarily metabolized by CYP3A and must be administered with a pharmacokinetic (PK) booster. The PK of DRV co-administered with ritonavir have been described in pregnancy; however, DRV co-formulated with cobicistat (COBI) has not been studied in pregnant women. This study described DRV exposure when administered in fixed-dose-combination with COBI during pregnancy and postpartum.

Methods: IMPAACT P1026s is an ongoing, nonrandomized, open-label, multi-center study of antiretroviral PK in HIV-infected pregnant women. Steady-state 24-hour PK profiles of DRV following once-daily dosing of 800/150 mg DRV/COBI were performed during the 2nd and 3rd trimesters (2T/3T) and 6-12 weeks postpartum (PP). DRV plasma concentrations were measured by a validated HPLC method. A two-tailed Wilcoxon signed rank test (= 0.10) was employed for paired within-subject comparison of PK parameters.

[Maternal Darunavir Pharmacokinetic Parameters, Median (IQR)]

Results: Nine subjects from the US were enrolled with a median age of 24 years at delivery (range 17-43). DRV PK data were available for 5, 7, and 6 women in 2T, 3T and PP, respectively. DRV exposure was lower and clearance higher in 3T compared to PP (Table 1). Compared to previously reported values in non-pregnant adults receiving DRV/COBI 800/150 mg once-daily, 24-hour trough DRV concentrations were 78%, 85%, and 61% lower in 2T, 3T, and PP, respectively. Overall, 2/5, 1/7, and 5/6 mothers had AUC_{0-24} values above the 10th percentile in non-pregnant adult patients at 2T, 3T, and PP, respectively. All subjects had 24-hour trough concentrations above 0.055 ug/mL, the threshold for the average protein binding-adjusted EC50 for wild-type virus. Viral load at delivery was < 50 copies/mL for all women. Median infant gestational age at birth was 37.86 weeks. A patent foramen ovale and ventricular septal defect were reported in one infant and determined possibly treatment related. 7/9 infants were HIV-negative based on best available data, and 2 are indeterminate or pending evaluations.

Author Index

Conclusions: In women taking DRV in fixed-dose-combination with COBI, the exposure to DRV appeared to be lower in pregnancy compared to postpartum. Additional PK, safety, and outcome data in pregnant women are needed before DRV/COBI can be recommended for use during pregnancy.

WEPEB119

HIV testing, retesting, and seroconversion among pregnant women attending antenatal and maternity services in Manzini Swaziland

A. Kidane[1,2], A. Mutiti[1], H. Kamiru[1], R. Mudekereza[1], F. Tsiouris[1], R. William[1], S. Mthethwa[3], B. Nhlabat[3]
[1]*ICAP, TB/HIV Care and Treatment, Mbabane, Swaziland,* [2]*University of Swaziland, Mbabane, Swaziland,* [3]*ICAP, TB/HIV, Mbabane, Swaziland*

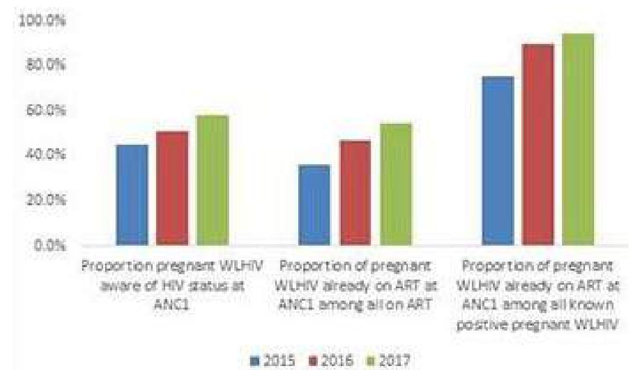
Background: Ensuring HIV testing for pregnant and breastfeeding women at points along the prevention of mother-to-child (PMTCT) cascade is of critical importance. In Swaziland, which has a national HIV prevalence and incidence among women aged 15+ of 32.5% and 1.7% respectively, national guidelines require retesting for HIV-negative pregnant women every 2 months. Understanding the frequency of seroconversion in this population is also important, as incident infections in pregnant women pose substantial risk for transmission to the child. We describe the proportions of pregnant women in Manzini Region, Swaziland, who tested positive after initial negative HIV test.
Methods: All HIV negative pregnant/lactating women are to be retested every 8 weeks during their antenatal/postnatal visits. We analyzed aggregate PMTCT data routinely reported to the Swaziland Ministry of Health between January 2016-September 2017. We examined the numbers of women newly attending ANC, with a known HIV status at first visit, completing HIV retesting in ANC or at delivery in the maternity, and the numbers testing HIV-positive at first visit or during retesting.
Results: Of the 17,739 pregnant women newly attending ANC during the period, 98% (17,384) were tested and/or had a known HIV + status including 4,132 (24%) who were already known to be HIV-positive and 1,945 (11%) who newly tested HIV positive. Of the 10,588 women that tested HIV-negative at first ANC visit, 9439 (89 %) women were retested during their ANC visits and 1149 (11 %) at delivery. Among women retested in ANC, 178 (1.9%) tested HIV-positive; in maternity, 27 (2.3%) tested HIV-positive.
Conclusions: In Swaziland, high numbers of pregnant women who test HIV negative on initial visits test HIV positive on repeat testing possibly representing acute infection and/or false negatives during initial testing. The maternal seroconversion can contribute significantly to the pediatric HIV burden, and needs attention as the country seeks to avert new HIV infections. In view of this and considering the limitations of aggregate data, further study is required to validate the findings. It is critical to continue supporting HIV prevention services including PrEP in pregnant women.

WEPEB120

Changes in proportion of new diagnoses of HIV infection in pregnant women living with HIV (WLHIV) and of entering pregnancy already on ART in PEPFAR programs

D.H. Watts[1], A.K. Radin[1], K. O'Connor[2], K. Kelling[2]
[1]*U.S. Department of State, Office of the Global AIDS Coordinator, Washington, United States,* [2]*Centers for Disease Control and Prevention, US DHHS, Division of Global HIV and TB, Atlanta, United States*

Background: Regimens for prevention of mother-to-child transmission (PMTCT) of HIV have evolved from single-dose Nevirapine to lifelong combination antiretroviral therapy (ART). Among women entering pregnancy on suppressive ART, transmission risk to the infant is below 1% and maternal mortality is reduced. Ideally, all women would enter pregnancy with known HIV status, and those WLHIV would be on suppressive ART. We evaluated the rates of HIV testing and positivity, including new versus known diagnosis, and of entering pregnancy on ART among pregnant women over time.
Methods: PEPFAR PMTCT program results from 2015-2017 for 20 countries were evaluated for the proportion of pregnant women with HIV status documented, and among those positive, the proportion who knew their status and those newly diagnosed. Among pregnant women receiving ART during pregnancy, the proportion entering pregnancy already on ART was evaluated over time and the proportion of women with a known diagnosis of HIV entering pregnancy on ART was calculated.
Results: During the three-year period, 36,947,696 pregnant women (95% of ANC attendees) had their HIV status documented and of these, 2,454,209 (6.6%) were LHIV. The proportion of WLHIV with known status at first antennal (ANC) visit, the proportion already on ART among all who received ART, and the proportion already on ART among WLHIV known before pregnancy across all 20 countries are shown below. The proportions of each increased annually, with 94.6% of women known to be LHIV already on ART at first ANC in 2017. All three indicators increased over time in each country. The proportion of known positive/total positive varied by country, ranging from 27% to 71% in 2015 and from 33% to 78% in 2017.



[Pregnant women with known HIV status and on ART at first antenatal visit]

Conclusions: The proportion of pregnant WLHIV aware of their HIV status has increased annually, but remains below 60%, emphasizing the need for additional efforts for HIV prevention and testing in young women even before pregnancy. Since the introduction of Option B+ and test and start policies, among women with known HIV infection, an increasing proportion enter pregnancy already on ART, optimizing maternal health and minimizing the risk of maternal-to-child transmission.

WEPEB121

Adverse perinatal outcomes associated with maternal HIV infection in South Africa

W.B. Santosa[1], E.S. Urias[1], S. Norris[2], J. Villar[1], S. Kennedy[1], J. Hemelaar[1]
[1]*University of Oxford, Nuffield Department of Women's & Reproductive Health, Women's Centre, John Radcliffe Hospital, Oxford, United Kingdom,* [2]*University of the Witwatersrand, School of Medicine, Developmental Pathways for Health Research Unit, Johannesburg, South Africa*

Background: HIV-positive mothers are at increased risk of having babies with adverse perinatal outcomes (APOs). The objective of this study was to assess the association between maternal HIV infection and APOs in accurately dated pregnant women in South Africa.
Methods: We conducted a prospective cohort study at the Chris Hani Baragwanath Hospital, Soweto, South Africa. Eligible women were those aged ≥18 years, Black South African, with singleton pregnancy and gestational age <14 weeks. Gestational age was estimated using a first-trimester ultrasound measurement of the crown-rump length in all women. Outcomes of interest included preterm birth (PTB), very PTB (VPTB), low birth weight (LBW), very LBW (VLBW), small for gestational age (SGA), very SGA (VSGA), stillbirth, neonatal death (NND), composite of APOs (composite outcome of PTB, LBW, SGA, stillbirth and NND) and composite of severe APOs (composite outcome of VPTB, VLBW, VSGA, stillbirth and NND). We used multiple logistic regression models to adjust for potential confounders: maternal age, education, marital status, socioeconomic status, smoking status, alcohol consumption, pre-pregnancy body mass index, parity, hypertensive disorders during pregnancy, history of PTB, history of LBW, history of stillbirth and history of NND.

Results: Data were collected on 404 HIV-negative and 229 HIV-positive mother and infant pairs. HIV-positive mothers were significantly more likely to be older (p< 0.001), less educated (p=0.0001) and parous (p=0.02) than HIV-negative mothers. Most HIV-positive mothers (98.4%) received antenatal antiretroviral therapy. Overall, there was a trend towards higher rates of each of the APOs in HIV-positive mothers compared to their HIV-negative counterparts. Maternal HIV infection was significantly associated with SGA (OR: 1.55; 95%CI:1.01, 2.38), NND (OR: 6.37; 95%CI:1.31, 30.91) and a composite of APOs (OR: 1.44; 95%CI:1.03, 2.03). After adjusting for potential confounders, NND (adjusted OR: 8.98; 95%CI:1.56, 51.65) and a composite of APOs (adjusted OR: 1.48; 95%CI:1.02, 2.16) remained significantly associated with maternal HIV infection.
Conclusions: Maternal HIV infection is associated with adverse perinatal outcomes, especially neonatal death and composite of APOs, in accurately dated pregnant women in South Africa. HIV-positive mothers should receive counselling regarding APOs, in addition to mother-to-child-transmission of HIV. Larger studies are needed to more accurately estimate APOs.

WEPEB122

Time of HIV diagnosis, viral load and CD4 count at antenatal care start in South Africa

D. Onoya[1], C. Nattey[1], C. Mongwenyana[1], N. Jinga[1], G. Sherman[2,3]
[1]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [2]University of the Witwatersrand, Department of Paediatrics and Child Health, Johannesburg, South Africa, [3]National Institute for Communicable Disease, Johannesburg, South Africa

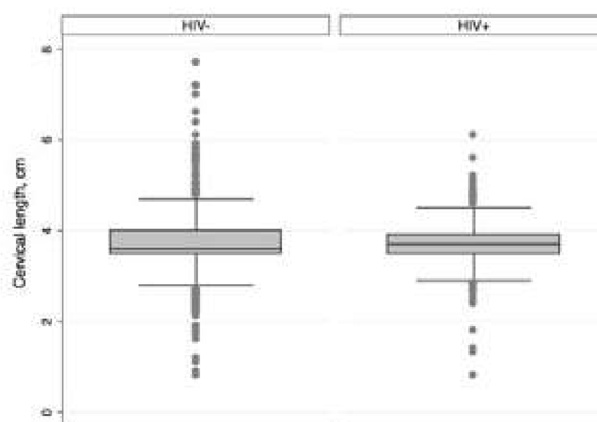
Background: The PMTCT program in South Africa is the most successful HIV prevention program given the effort in scaling up and maintaining the coverage of the service. However, as long as one third of women of childbearing age are HIV infected, the risk of HIV transmission will remain high. Therefore in the long run, it is important to ensure that the benefit of ART are sustained among previously initiated women and health care providers can focus more attention on women who newly enter the HIV care cascade through the PMTCT program.
Methods: We conducted an analysis of a cross-sectional survey among 411 HIV positive adult (>18 years) women who gave birth at Midwife Obstetrics Units (MOUs) in Gauteng between October 2016 and May 2017. Demographic, viral load (VL) and CD4 data at antenatal care (ANC) initiation were obtained from medical records of consenting women. We compared the CD4 count and VL suppression rates around ANC initiation (≤6 months before or ≤3 months after ANC start) among women with a pre-pregnancy HIV diagnosis to those who were diagnosed at ANC initiation. Predictors of having a suppressed VL at ANC initiation was assessed by logistic regression.
Results: Of the 411 participants, 239 (58.2%) had CD4 data and 172 (41.7%) had VL data for the period of interest. Overall women with a pre-pregnancy HIV diagnosis were more likely to present at ANC at higher CD4 (OR 2.5, 95%CI: 1.4-4.6 for CD4 >500, OR 2.0, 95% CI: 1.0-3.9 compared to CD4≤350 cell/µl) compared to those who were newly diagnosed. Similarly viral suppression rates were higher among women with pre-pregnancy HIV diagnoses (OR 2.3, 95% CI: 1.1-4.0 for VL< 100 copies/ml rather than VL>500 copies/ml).
Conclusions: The results suggest that HIV positive women with prior HIV care experiences enter ANC at better health levels than women who are diagnosed during ANC. This is encouraging and also means that the ANC processes can be streamlined to ensure that more resources are allocated to ensure that newly initiated women are adherent to ART and remain in care in the postpartum period.

WEPEB123

HIV status and viral load are not associated with shortened mid-trimester cervix, a major risk factor for preterm birth

J.T. Price[1], B. Vwalika[2], J. Winston[1], K. Rittenhouse[1], A. Kumwenda[2], E.M. Stringer[1], K.M. Lubeya[2], M.P. Kasaro[3], J.S.A. Stringer[1]
[1]University of North Carolina at Chapel Hill, Chapel Hill, United States, [2]Women and Newborn Hospital, Lusaka, Zambia, [3]University of North Carolina Global Projects Zambia, Lusaka, Zambia

Background: Maternal HIV and its treatment are associated with preterm birth (PTB) and other adverse birth outcomes in many studies. The mechanism(s) underlying this association is not well understood. It is conceivable that HIV could cause cervical shortening - a key risk factor for spontaneous PTB and an indication for vaginal progesterone prophylaxis. We evaluated whether maternal HIV serostatus or plasma viral load (VL) were associated with mid-trimester cervical length (CL).
Methods: We followed pregnant women prospectively in the Zambian Preterm Birth Prevention Study (ZAPPS) at the Women and Newborn Hospital in Lusaka, Zambia. Women underwent early ultrasound for gestational age determination at screening and returned for CL measurement between 16 and 24 weeks of gestation. We used logistic regression to evaluate the association between dichotomous variables (HIV infection, detectable VL) and CL.
Results: Between August 2015 and October 2017, 1451 women were enrolled into the ZAPPS cohort, of whom 1175 had at least one cervical length measurement performed at ≥ 16 weeks' gestation. Among the 293 (25%) HIV+ women, 261 (89%) had a recorded viral load, of whom 122 (47%) had detectable virus. Median CL was 3.6cm (IQR 3.5,4.0). In both univariate and multivariable logistic regression (adjusting for age, parity, and gestational age at the time of cervical measurement), CL did not vary by HIV status (aOR 0.88, p=.29). Among HIV-infected women, CL was not associated with detectable VL (aOR 0.80; p=.43).
Conclusions: In this urban African cohort, we found no evidence of association between HIV infection and shorter CL. We conclude that the risk of preterm delivery known to be associated with HIV is likely not derived from mid-trimester cervical shortening. Routine CL screening is therefore not warranted in women with the sole risk factor of HIV.



[Box plot of cervical length by HIV status]

WEPEB124

Mother-to-child transmission of HIV, pregnancy and infant outcomes among HIV-positive women from a tertiary care facility

I.C. Ianache[1], R. Radoi[1], R. Horghidan[1], A.C. Oprea[1,2]
[1]Victor Babes Hospital, HIV Department, Bucharest, Romania, [2]Carol Davila University of Medicine and Pharmacy, Infectious Diseases, Bucharest, Romania

Background: Due to particular HIV epidemiological aspects in Romania, we divided HIV positive women of childbearing age in 3 categories: with HIV acquired sexually, by parenteral mode (in early childhood) or by in-

jecting drug use (IDU). The aim of our study was to compare mother-to-child transmission rates (MTCT) and the pregnancy outcomes between the 3 categories.

Methods: Prospective study on HIV-positive mothers admitted to a Romanian tertiary health care facility between 1 January 2000 and 31 December 2016.

Comparison between the groups were performed using Fischer's exact or Chi square test for nominal variables and ANOVA test for continuous variables. Statistical analysis was performed using SPSS version 20.0.

Results: During the study period, 330 HIV-exposed live infants were born to 269 mothers. The overall MTCT rate was 10.9% (36/330), higher in IDU mothers 13.9% (6/43) and mothers with sexual mode of HIV acquisition 16.5% (25/151), compared to parenterally infected mothers 3.6% (5/136), (p= 0.001).The major risk factor for MTCT was late diagnosis in mothers, 28 (77.7%) of them being diagnosed after delivery.

Almost all IDU mothers (97.6%) were co-infected with hepatitis C, hepatitis B co-infection being more frequent in parenterally infected mothers (18.3%). Infants born to IDU mothers had higher rates of preterm delivery (37.2%) and lower birth weight (55.8%). (Table 1).

Congenital anomalies, diagnosed in 11 cases (3.3%), were more often in children born to parenterally infected mothers 3.6% (5/136) compared to mothers infected by sexual mode 3.3% (5/151) and IDU mothers 2.3% (1/43), but with no statistical significance (p=0.881). There were 2 cardiac anomalies (Fallot tetralogy with ventricular septal defect and atrial septal defect), 2 gastro-intestinal birth defects (intestinal atresia with gastroschisis and a malformation of the jejunum), agenesis of the diaphragm (1), planovalgus foot (2) strabismus (1), acro-mandibular syndrome (1) and hypospadias (1).

Conclusions: The MTCT transmission rate of HIV was significantly higher in injectable drug users and mothers infected by sexual mode, compared to parenterally infected mothers. Low birth weight, preterm delivery and co-infection with hepatitis C were associated more frequent with injecting drug use. However, the risk of congenital anomalies seems to be higher in parenterally infected mothers.

Maternal and infants characteristics	Mother infected by sexual mode (n=151)	Mother infected by parenteral mode (n=136)	IDU mothers (n=43)	p value
HIV transmission rate n (%)	25 (16.5)	5 (3.6)	6 (13.9)	0.001
HBV co-infection n (%)	7 (4.6)	25 (18.3)	1 (2.3)	0.001
HCV co-infection n (%)	8 (5.2)	5 (3.6)	42 (97.6)	<0.0001
CD4 cell count/mm3 median (IQR)	545 (382, 773)	553 (377, 676)	540 (455, 666)	0.399
Undetectable HIV viral load at delivery n (%)	33 (21.8)	72 (52.9)	2 (4.6)	<0.0001
Preterm births (< 37 months) n (%)	25 (16.5)	29 (21.3)	16 (37.2)	0.004
Low birth weight (<2500g) n (%)	31 (20.5)	34 (25.0)	24 (55.8)	<0.0001
Congenital anomalies n (%)	5 (3.3)	5 (3.6)	1 (2.3)	0.881

The relationship between depo-medroxyprogesterone acetate and herpes simplex virus infection: Implications for HIV risk

J.D. Yssel[1], N.S. Abbai[2], T. Reddy[3], G. Ramjee[1,4,5]
[1]Medical Research Council South Africa, HIV Prevention Research Unit, Durban, South Africa, [2]University of KwaZulu-Natal, School of Clinical Medicine, Nelson Mandela School of Medicine, Durban, South Africa, [3]Medical Research Council South Africa, Biostatistics Unit, Durban, South Africa, [4]London School of Hygiene and Tropical Medicine, Department of Epidemiology and Population Health, London, United Kingdom, [5]University of Washington, School of Medicine, Department of Global Health, Seattle, United States

Background: In Sub-Saharan Africa, 8 million women preferentially use depot medroxyprogesterone acetate (DMPA) and norethisterone enanthate (Net-EN) for preventing pregnancy. Data from randomised control trials suggest a link between hormonal contraceptives (HC) and HIV acquisition among women in high HIV endemic areas; specifically injectable DMPA. There are however conflicting data, placing women at no such elevated HIV risk. With that in mind we sought to determine if women using HCs were at an increased risk of acquiring Herpes simplex virus-2 (HSV-2) infection that may act as a indirect proxy for HIV acquisition.

Methods: A restrospective sub-analysis of women enrolled in the Microbicides Development Programme (MDP) 301 trial at three Durban sites was performed. Demographic, behavioural and biological characteristics were collated and stratified by contraceptive use. HSV-2 and HIV testing was performed at enrollment and at follow up (week 40 and 52). Univariate and multivariate logistic regression assessed the effect of HC on HSV-2 acquisition. A Chi-squared test determined if the proportion of women with incident HIV infection was significantly different between HSV-2 incident and negative cohorts.

Results: 621 females were eligible for analysis. 58% used DMPA followed by 22% Net-EN and 20% oral contraceptives. 111 women had acquired an incident HSV-2 infection. Crude HSV-2 incidence was 12.8%, 20.1% and 18.8% per 100 woman-years in pill, DMPA and NET-EN users respectively. Regression univariate analysis revealed DMPA users at a 1.75 times elevated HSV-2 risk compared to women on oral contraception (OR 1.75, 95% CI 0.97-3.15). Women with an incident HSV-2 infection were 5 times more likely to be infected with HIV than their HSV-2 seronegative counterparts (15.93% vs. 3.17%; p=< 0.001).

Conclusions: Women using DMPA were at a moderate increased risk of acquiring an incident HSV-2 infection over oral contraceptives. Furthermore, we have identified a recent HSV-2 infection as a plausible contributing factor to the local HIV epidemic. It is a recommendation that women who reside in high HIV endemic communities be continually counseled about the importance of condom use, especially those using DMPA. This may be the most important strategy to ease the burden of both HSV-2 and HIV epidemics in the region.

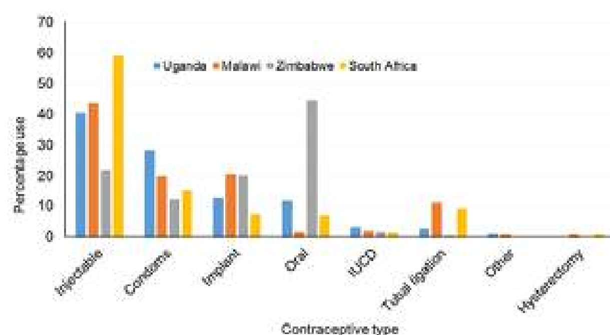
Background: The demand for modern family planning methods in Africa is inadequately met. Furthermore, finding a suitable method of contraception is challenging in the context of HIV given various drawbacks with currently available options. Long acting reversible contraception (LARC) has the potential to curb maternal morbidity and mortality; however the World Health Organization advises against concurrent use of implants and hepatic enzyme-inducing antiretroviral therapy (ART). Additionally there are negative perceptions towards intrauterine devices (IUCD); short/intermediate acting injectable and oral contraception (OCP) rely on user adherence; and use of progestogen injectables is not recommended long term due to effects on bone mineral density (BMD). This study aims to describe current contraception choices among African HIV-infected women.

Methods: In a prospective longitudinal cohort study across 8 sites in South Africa, Uganda, Zimbabwe and Malawi, HIV-infected women were enrolled between December 2016-June 2017. Reported contraception use was collected through structured enrolment interviewer-administered questionnaires. Descriptive analyses of overall and country-specific methods, and categories of contraceptive choices are presented.

Results: Overall, 1986 HIV-infected women were enrolled. Mean age was 31 years and 97.8% were on ART (including efavirenz). The prevalence of modern contraception use in all women was 80.2 % (1298/1617). Excluding pregnancy and not currently sexually active, contraceptive data was available on 1294 women. The frequency of contraception methods used was: injectables 545(42.1%); condoms 231(17.9%); progestogen implant 203(15.7%); OCP 190(14.7%); tubal ligation 88(6.8%); IUCD 24(1.9) %; Hysterectomy 7(0.5%), other 6(0.5%). Regular 569(28.7%) and infrequent 581(29.3%) condom use were in combination with other contraception. Preferred Contraceptive methods varied by country (figure). Categories of contraception methods included: 966(74.6%) short/intermediate acting (Injectable/OCP/Condoms), 227 (17.5%) LARC (Implant/IUD) and 95 (7.3%) permanent (TL/Hysterectomy). There were 1603 women on Efavirenz-based regimen; of these 166 (10.4%) received Implants.



[Contraception use by country]

Conclusions: Injectable and oral contraceptives remain popular choices in African women, followed by implants. However, long-term effects of injectable contraception in combination with ART on BMD and potential interactions with ART, require additional evaluation. Likewise, further education of health professionals/providers is needed to increase wider usage of LARC and IUDs; and to re-educate against use of progesterone implants among women on EFV-ART.

WEPEB127

Changes in peripheral blood mononuclear cells after use of depot-medroxyprogesterone acetate (DMPA)

A.C. Roxby[1], N. Hwang[2], E. Munene Muriuki[3], B. Chohan[4], K. Tapia[2], J. Kiarie[5], S.C. De Rosa[2]
[1]University of Washington, Medicine and Global Health, Seattle, United States, [2]University of Washington, Seattle, United States, [3]University of Nairobi, Nairobi, Kenya, [4]Kenya Medical Research Institute, Nairobi, Kenya, [5]World Health Organization, Geneva, Switzerland

Background: Depot-medroxyprogesterone acetate (DMPA), a commonly used hormonal contraceptive, may contribute to HIV acquisition risk in women. DMPA is a steroid hormone analogue. We hypothesized that DMPA use could lead to immune activation in peripheral blood, which is associated with increased HIV acquisition risk.

Methods: We enrolled postpartum HIV-negative women initiating DMPA in Kenya, and a control group of postpartum women using non-hormonal contraception (NHC). Peripheral blood mononuclear cells (PBMC) were collected at baseline (immediately before DMPA injection) and after 12 weeks. Using multicolor flow cytometry, we assessed markers of immune activation (CD38, HLA-DR, Ki67), senescence, differentiation state (naïve vs. memory), and CCR5 expression on CD4+ T cells (targets of HIV infection) and compared mean percentages using t-tests.

Results: In 2014-2015, 33 women enrolled after choosing DMPA and 21 women enrolled after choosing NHC. Women choosing NHC were further from delivery (9.9 weeks v. 6 weeks) than women choosing DMPA. Baseline PBMC measurements were similar in both groups except for one marker: women in the DMPA arm had higher mean percentages of activated CD4+CD38+HLA-DR+ T cells (0.57% NHC v. 1.05% DMPA, p< 0.001). Women in the NHC arm demonstrated no significant change in mean percentages of all cell subsets over 3 months of follow up. Compared to NHC, women using DMPA had a 1.8% increase in mean percentage of T cells expressing CD4+ (p=0.05), a 2.1% decrease in mean percentage of T cells expressing CD8+ (p= 0.03), and increases in CD27+CD45RA-CCR7+ central memory cells: (CD4+: 1.9% increase, p=0.02; CD8+: 2.3% increase, p< 0.001). Women using DMPA also had significant decreases over time in the mean CD16+CD56+ NK cell percentage of lymphocytes (2.4% decrease, p=0.05) and in CD4+CD28-CD57+ anergic T cells (1.5% decrease, p=0.02).

Conclusions: In this cohort study, DMPA use was associated with statistically significant, modest increases in peripheral CD4+ T cells and central memory cells. Strengths of this study were that DMPA dose was observed and a control group allows us to account for T cell changes in the postpartum period. These results could reflect tissue-level changes at the site of HIV infection and should be correlated with genital findings.

Cell Subset	Baseline mean %cells in NHC arm	Baseline mean % cells in DMPA arm	3 months change in % cells in NHC arm	3 months change in % cells in DMPA arm	Change in mean % cells (DMPA arm)-Change in mean % cells (NHC arm)	p-value

Menopause

WEPEB128

The association between menopausal symptoms and antiretroviral adherence in women living with HIV

D. Solomon[1], F. Burns[2], R. Gilson[2], A. Rolland[1], C. Sabin[1], L. Sherr[3], S. Tariq[1], PRIME Study Group
[1]University College London, Institute for Global Health, London, United Kingdom, [2]University College London, Centre for Sexual Health & HIV Research, London, United Kingdom, [3]University College London, Health Psychology Unit, London, United Kingdom

Background: Despite increasing numbers of older women accessing HIV services, there remains a paucity of data on HIV and the menopause. We explore the association between severe menopausal symptoms and adherence to antiretroviral therapy (ART) in women living with HIV (WLWH).

Methods: Analysis of data on 625 women on ART recruited to the PRIME Study, an observational study of WLWH aged 45-60 in England in 2016-17. We used the Menopause Rating Scale to ascertain symptom severity (score ≥17 indicating severe menopause symptoms). This validated scale captures data on psychological, somatic (e.g. vasomotor symptoms) and urogenital (e.g. vaginal dryness) symptoms, Adherence was measured using the CPCRA Antiretroviral Medication Adherence Self-Report Form, with patients dichotomised into optimal (100% adherence in past 7 days) or suboptimal (< 100% adherence in past 7 days) adherence. Odds ratios (adjusting for ethnicity, employment, alcohol use, current smoking and basic needs met) were obtained using logistic regression.

Results:

	Optimal adherence N=565 (n,%)	Suboptimal adherence N=60 (n,%)	p-value[a]

[a] χ^2 or Kruskal-Wallis test; [b] equivalent to completing US Grade 10; [c] equivalent to completing US Grade 12; [d] using the Alcohol Use Disorders Identification Test (AUDIT-C) screening tool

[Characteristics of WLWH with optimal and suboptimal adherence]

Median age was 49 years (interquartile range: 45-59). The majority were Black African (n=445, 72.5%), with low rates of recreational drug use (n=16, 2.6%). A minority had a CD4 count< 200 cells/mm3 (n=38, 6.9%) or detectable HIV viral load (n=65, 10.9%); 10% (n=60) reported sub-optimal adherence. The majority were either peri- (n=283, 45.6%) or post-(n=201, 32.4%) menopausal; nearly a third of women (n=180) reported severe menopausal symptoms.

Adherence was associated with severity of menopausal symptoms, as well as employment status, financial ability to meet basic needs, and current smoking. Women who reported severe menopausal symptoms were almost twice as likely to report suboptimal adherence (AOR 2.47; 95% CI 1.27,4.82, p=0.008). In adjusted analyses, there was no association between adherence and severe symptoms in the psychological, somatic and urogenital menopausal domains individually (all p>0.1).

Conclusions: We present one of the largest studies to explore menopausal symptoms and ART adherence. The majority of our participants reported optimal adherence. Severe menopausal symptoms were significantly associated with sub-optimal adherence, however we cannot assess the direction of this relationship, highlighting the need for longitudinal data. Holistic care that assesses and addresses menopausal symptoms may support midlife WLWH in maintaining optimal ART adherence.

WEPEB129

Immunological differences and increased HIV susceptibility of CD4+ T cells from healthy post- verses pre-menopausal women

C. Tasker[1], N. Roche[2], T. Chang[1]
[1]Rutgers New Jersey Medical School, Public Health Research Institute, Newark, United States, [2]Rutgers New Jersey Medical School, Obstetrics Gynecology and Women's Health, Newark, United States

Background: Post-menopausal women are at a higher risk for HIV transmission compared to pre-menopausal women. Reasons for increased HIV risk are multi factorial and include hormone associated changes to vaginal and cervical epithetical structure, vaginal pH, condom use, and age associated immune suppression. We compared immunological markers associated with preferential HIV infection, HIV susceptibility, and the cytokine/chemokine profile of mucosal HIV transmission sites between healthy pre- and post- menopausal women.

Methods: 38 healthy women who met the eligibility criteria were enrolled. Patients were categorized into three age groups: group 1 pre-menopausal age range 18-28 (median age 23; IQR 20-26); group 2 pre-menopausal age range 30-43 (median age 37; IQR 34.5-40); group 3 post-menopausal age range 43-64 (median age 53; IQR 50-57). Peripheral blood and secretions from vaginal, endocervical, and rectal sites were collected. PBMCs were characterized by flow cytometry and the expression of cytokine/chemokines in vaginal, endocervical, and rectal secretions was determined by multiplex luminex assay.

Results: CD4+ T cells from group 1 had a significantly higher percentage of cells positive for integrin a4b7 compared to group 2 and a higher percentage of CD38+ cells (activation marker) compared to group 2 and 3. The percentage cells positive for HIV co-receptor CCR5 was higher in group 3, however this difference did not reach significance. Group 1 and 2 had a higher percentage of terminal effector memory cells (CD45RA+CCR7-) compared to group 3 while populations of naïve, central memory, and effector memory CD4+ T cells were unchanged between groups. Assessment of the susceptibility of PBMCs to HIV-1_{BaL} infection ex vivo found CD4+ T cells from post-menopausal women had higher percentage of HIV p24+ cells compared to group 1. Analysis of the cytokine/chemokine expression profile in vaginal, endocervical, and rectal secretions found older women in group 2 and group 3 had significantly lower levels of multiple soluble immune mediators compared to group 1.

Conclusions: This study presents clinically important information regarding immunological differences between pre- and post- menopausal women in regard to HIV transmission.
Developing a better understanding of the mechanisms involved in increased HIV transmission risk has important relevance in HIV prevention.

Clinical issues in men who have sex with men

WEPEB130

Alarming rates of pretreatment HIV drug resistance in key populations: Results of a global systematic review

V. Macdonald[1], L. Mbuagbaw[2], A. Verster[1], S. Bertagnolio[1]
[1]World Health Organization, Geneva, Switzerland, [2]McMaster University, Hamilton, Canada

Background: Key populations (KPs) (people who inject drugs (PWID), men who have sex with men (MSM), transgender people (TG), sex workers (SW) and prisoners) are disproportionately affected by HIV in all settings. HIV drug resistance (HIVDR) in KPs is poorly understood. We performed a systematic review to understand levels of pretreatment HIVDR (PDR) in treatment naive KPs.
Methods: We searched 10 electronic databases to identify studies reporting PDR in treatment naive KP groups. The search results were screened and data were extracted in duplicate, including study sample size, PDR prevalence and previous exposure to ARVs. Our analysis focuses on studies comparing levels of PDR in KP to those in the general population.
Results: Our search retrieved 602 articles of which 146 (81,835 participants) were eligible for inclusion. A subset of 50 studies comparing HIVDR in treatment naive general population and at least one KP group were included for analysis, allowing for within study comparison.
Prevalence of any HIVDR was higher in treatment naive MSM, SW and PWID compared to the general population although given limited data and heterogeneity between studies this difference only reached statistical significance for MSM (see table). A sub-analysis by WHO geographic region showed that in the Americas, PWID were more likely to carry HIVDR mutations than the general population (OR 1.55; 1.06- 2.77; p=0.02).
Conclusions: Treatment naive MSM, SW and PWID had consistently higher levels of any HIVDR compared to the general population, resulting in an increased risk of subsequent treatment failure and further spread of resistance. Our results have implications for HIV treatment in KP: 1) better surveillance of HIVDR in KP; 2) consideration of first-line ARV choices; and 3) increased viral load monitoring to promptly identify treatment failure. Our findings suggest that HIVDR mutations could be transmitted within KP groups and to their sexual and drug injecting partners making provision of prevention interventions for HIV positive KP and their partners imperative. Further research to understand the dynamics of HIVDR transmission and levels of virological suppression in treatment exposed KP is warranted. More data on HIVDR among prisoners and TG is needed.

	Individuals with any HIVDR / total number genotyped (%)	Individuals with any HIVDR / total number genotyped (%)		
	Key population	General population	Odds ratio	p value*
MSM	3077/21166 (14.5%)	1684/14925 (11.3%)	1.28 (1.08 - 1.52)	0.004
SW	23/90 (25.6%)	42/240 (17.5%)	1.04 (0.36 - 3.02)	0.940
PWID	839/2538 (33.1%)	1123/10015 (11.2%)	1.14 (0.81 - 1.59)	0.450

Clinical issues in people who use drugs

WEPEB131

Depressive symptoms and association with substance abuse in the Miami adult studies in HIV (MASH) cohort

S. Martinez, A. Campa, G. Zarini, M. Mudgal, J. Tamargo, A. Sneij, A. Alohaly, M. Baum
Florida International University, Miami, FL, United States

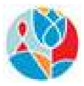
Background: Depression is common among people living with HIV (PLWH) and especially prevalent in drug using populations. Depression in PLWH has been associated with greater disease progression and mortality and reduced antiretroviral therapy (ART) adherence. This study examined the prevalence of depressive symptoms using the Center for Epidemiological Depression Scale (CES-D) and its association with substance abuse in HIV infected adults on ART in MASH cohort.
Methods: A total of 251 HIV+ adults from the MASH cohort were consented. Questionnaires on demographics, socioeconomic status, ART, illicit drug use and Alcohol Use Disorders Identification Test (AUDIT) and CES-D were completed. CES-D score of 15-21 was considered moderate depressive symptoms, and > 21 major depressive symptoms. Illicit drug use was determined with questionnaires and urine toxicology. CD4 cell count and HIV viral load were obtained from medical records. Regression models were controlled for age, gender, race/ethnicity and CD4 count.
Results: The median age was 53 years (IQR=49-58), 59% were male, and 65.7% were African American. The prevalence of moderate depressive symptoms was 35.5%; 22.3% had major depressive symptoms. Depressive symptoms were associated with higher AUDIT score (=0.172, SE=0.121, P=0.008). Although, depression was not associated with CD4 count or HIV viral load, there was a significant positive association between AUDIT and HIV viral load (=0.255, SE=0.654, P=0.039). Those with moderate depressive symptoms had greater odds of using marijuana (OR=1.94, 95%CI:1.07, 3.52, p=0.030), >1 illicit drug (OR=1.63, 95%CI:1.12, 2.37, P=0.011), sedatives (OR=1.95, 95%CI:1.08, 3.55, P=0.028) and any type of illicit drug (OR=1.86, 95%CI:1.07, 3.25, P=0.028). Drug use, regardless of type was associated with higher odds of higher viral load (OR=1.82, 95%CI:1.03, 3.24, P=0.041). Major depressive symptoms were associated with sedative use (OR=2.07, 95%CI:1.06, 4.03, P=0.033).
Conclusions: Depressive symptoms were prevalent and associated with substance abuse in the HIV+ adults on ART in the MASH cohort. Although HIV viral load was not directly associated with depression, substance abuse that included alcohol, sedatives, and illicit drug use were predictors of depression. A better understanding of depression and how it may affect risky substance use behaviors among PLWH is crucial to improving their care, quality of life, and adherence to ART.

WEPEB132

Medical and non-medical cannabis use among HIV-positive people who use illicit drugs in Vancouver, Canada: Implications for the planned legalization of cannabis

S. Lake[1,2], T. Kerr[1,3], N. Fairbairn[1], R. Barrios[4], J. Montaner[3,4], E. Wood[1,3], M.-J. Milloy[1,3]
[1]British Columbia Centre on Substance Use, Vancouver, Canada, [2]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [3]University of British Columbia, Department of AIDS, Vancouver, Canada, [4]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada

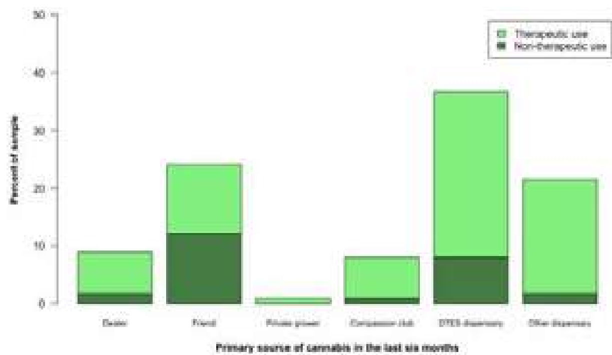
Background: The legalization of cannabis for medical and non-medical purposes is imminent in Canada. Cannabis is frequently reported among people living with HIV to manage symptoms of the disease and address side effects of antiretroviral therapy (ART). People who use illicit drugs (PWUD) living with HIV report comparatively higher rates of cannabis use, but little is known about reasons for cannabis use, particularly as they relate to HIV disease management, in this highly marginalized population.



Methods: Data was drawn from the AIDS Care Cohort to evaluate Exposure to Survival Services (ACCESS) study, a cohort of HIV-positive PWUD in Vancouver, Canada. This cross-sectional study was restricted to 224 participants who reported cannabis use in the previous six months between June 1 and December 1, 2016. Descriptive statistics were used to summarize sources of cannabis and reasons for use. Chi-square and Wilcoxon rank-sum tests were used to compare characteristics of therapeutic and non-therapeutic cannabis users.

Results: In total, three-quarters of participants (n=169) reported using cannabis for therapeutic purposes, most commonly to address nausea or loss of appetite (40.2%), pain (31.7%), sleep (29.9%), and stress (23.2%). About two-thirds of participants (n=148) obtained cannabis from local dispensaries or compassion clubs rather than dealers or other illicit means. None reported accessing medical cannabis through the government-approved system. Compared to participants who reported non-medical use only, those who reported therapeutic use were more likely to use cannabis daily, have an undetectable viral load, and have a higher CD4 cell count in the previous six-month period ($p < 0.05$).

Conclusions: The majority of HIV-positive PWUD in this study reported using cannabis therapeutically, including to manage HIV symptoms/ART side effects, substitute higher-risk substances, and treat mental or physical health. Despite this, no participants had government-authorized access to medical cannabis and most obtained cannabis through a "quasi-legal" source. Although longitudinal research is needed, the findings suggest that therapeutic cannabis use may be associated with favourable HIV disease and treatment outcomes. Monitoring the impact of Canada's planned regulatory system for legal cannabis on access to medical cannabis for this key vulnerable population should be prioritized.



[Figure. Sources of cannabis by type of use among 224 HIV-positive PWUD in Vancouver, Canada]

WEPEB133

Universal ART among people living with HIV who have problem substance use in NYC, 2014-2017

A. Campbell[1], D. Des Jarlais[2], M. Pavlicova[3], T.-H. Choo[4]
[1]Columbia University Medical Center and New York State Psychiatric Institute, Department of Psychiatry, New York, United States, [2]Icahn School of Medicine Mount Sinai, Department of Psychiatry, New York, United States, [3]Columbia University Mailman School of Public Health, Department of Biostatistics, New York, United States, [4]Columbia University Medical Center, Department of Psychiatry, New York, United States

Background: The intersection of HIV-related health outcomes and problem substance use is well documented. Since 2011, the New York City (NYC) Department of Health recommends that all HIV infected individuals be offered antiretroviral therapy (ART) regardless of disease progression. The "ART for All" study was designed to inform modifications to the implementation of universal ART among people living with HIV (PLWH) who have problem substance use. The current analysis seeks to describe this sample and identify classes of PLWH with problem substance use.

Methods: PLWH were recruited from sexual health clinics (n=35) and a detoxification unit (n=64) between 2014-2017 to participate in interviews every 6 months for 2 years. Baseline characteristics included: demographics, substance use, healthcare, social support and discrimination. Based on characteristics, a Latent Class Analysis (LCA) defined sub-classes of PLWH with problem substance use.

Results: The LCA model defining 3 latent classes was the best fit. Class 1 (91% detox participants) were older (84.5% ≥46), less employed (12.5%), receiving public insurance (100%), and had lower social support (M=38.5); 75% met alcohol use disorder, 87.5% stimulant use disorder, and self-reported ART adherence (≥90%) was 55.2%. Class 2 (100% sexual health participants) were younger, more likely employed (66.7%), had public insurance (56.7%) or were uninsured (26.7%), and had higher social support (M=59.3); 60% reported an alcohol use disorder and self-reported ART adherence was 100%. Class 3 (89.7% detox patients) were older (81.2% ≥46), less likely employed (5.6%), receiving public insurance (100%), and had higher social support (M=67.3). 64.1% had a stimulant use disorder, but reported more heroin use (62.9% of days) than cocaine (25.0%); and self-reported ART adherence was 82.4%. Viral suppression (≤ 200 copies/mL) at 6-month visit was 50% for Class 1, 66.7% for Class 2, and 35.1% for Class 3 (p=.04).

Conclusions: Although access to ART initiation did not appear to differ, detox participants had less stability, were more likely to have opioid or stimulant use disorders, and lower viral suppression rates. Continued focus on harm reduction strategies and psychosocial factors appear crucial to improving HIV outcomes; LCA may be useful in identifying key sub-classes of PLWH.

WEPEB134

„Defensive drugging" - preventing drug overdose in a dynamic opioid market

P. Coffin[1,2], E. Behar[1], K. Countess[1], J. Chang[3], T. Matheson[1]
[1]San Francisco Department of Public Health, San Francisco, United States, [2]University of California San Francisco, Medicine, San Francisco, United States, [3]University of California San Francisco, San Francisco, United States

Background: The U.S. is amidst an opioid overdose epidemic, increasingly characterized by fentanyl-related deaths that may not be as amenable to peer response due to rapid progression from overdose to death. There is thus an urgent need to develop interventions that avert the occurrence of any overdose event. To improve our understanding of behavioral factors contributing to overdose, we utilized data from a pilot intervention trial addressing the syndemics of opioid overdose, HIV, and HCV to assess subjects' understanding of the causes of personal compared to witnessed overdose events.

Methods: We analyzed 43 interviews from participants enrolled in REBOOT, a randomized-controlled trial of a behavioral intervention based on motivational interviewing to reduce overdose and HIV/HCV risk conducted from 2014-2016. Subjects were current users of illicit opioids (all but 2 injected) with opioid use disorder, had received take-home naloxone, and had overdosed within the past 5 years. Interviews were audio-recorded, transcribed verbatim, and analyzed using thematic content analysis rooted in grounded theory by three independent analysts to ensure interrater reliability. Analysts developed a codebook, including *a priori* codes and codes generated inductively from data, which was applied to all interviews. Any coding discrepancies were discussed with the entire research team.

Results: Participants described their personal overdoses differently from those they witnessed, in a manner consistent with actor-observer theory. The actor-observer theory is an explanatory framework used in social psychology positing that individuals may be more likely to assign responsibility of one's own actions to external factors, while assigning responsibility for others' actions to internal mechanisms. We identified three external themes central to how individuals characterized their personal overdose:
(1) change in potency or batch,
(2) luck, or
(3) ascribing blame to others.
Conversely, participants attributed witnessed overdoses to three primary internal factors:
(1) greed,
(2) inexperience, or
(3) stupidity/foolishness.

Conclusions: The differences between perceived causes of personal versus witnessed overdose align with actor-observer theory. Utilizing this theory in overdose prevention could support behavioral interventions aiming to encourage safer opioid use by teaching participants to employ universal safety precautions and always "expect the unexpected", akin to defensive driving courses developed for at-risk operators of motorized vehicles.

WEPEB135

Experiences and lessons learned in implementing the differentiated care model in HIV clinics in Nyamira County, Western Kenya, Jan -Sept 2017

J. Obunga[1], L. Odero[1], B. Kanyango[1], B. Burmen[2]
[1]PATH, HIV Prevention, Care and Treatment, Kisumu, Kenya, [2]Kenya Medical Research Institute Centre for Global Health Research, HIV Implementation Science and Services, Kisumu, Kenya

Background: Kenya, which is globally fourth with approximately 1.6 million PLHIV, adopted "Differentiated care model" (DCM) in 2017 to alleviate the burden on the health system. We describe experiences in implementing the DCM approach within Nyamira County of Kenya that has a HIV burden of 6.4% against the country's national average of 5.6%.

Description: Between January and September 2017DCM was rolled out in 103 HIV clinics; it commenced with an induction to the DCM as per the Kenyan national guidelines to health workers. The criteria for qualification for "DCM package for stable PLHIV", was that patients should have been on ART over 12months, aged above 20 years, completed IPT, be HIV virally suppressed, should have a BMI of ≥18.5 kg/m², not been treated for an opportunistic infection in the preceding 6 months, and if female should not be currently pregnant. Stable- PLHIV would be offered an option of long-ART prescription refill via a facility-based fast track option (FFT) or a community-based ART group (CAG) comprised of 3-6 persons that belonged to a community psychosocial support group or were drawn from the same locality.

Lessons learned: Twenty-six percent (3110/12257) of patients met criteria for stable-PLHIV. Forty (41.7%) health facilities had introduced DCM among (78%) 2419/3110 patients; other facilities did not due to patients not having completed IPT (68.2%) 9346/12257 or not being virally suppressed (20.6%), other reasons (11.2%). FT was highly preferred to CAG (84.7% vs. 15.3%) due to fear of inadvertent disclosure of a positive status to community members. With the introduction of "family clubs" (groups of 2 to 6 extended family members that opted to form a CAG on their own initiative), patients found it easier to adhere to medication and clinic visits.

Conclusions/Next steps: DCM did not alleviate patient workload as majority of patients preferred FFT. HIV programs should provide the necessary infrastructure to enhance health status of majority of PLHIV to well-PLHIV. An expanded definition of "stable patient" may be considered to include younger persons (e.g. school-going children) with committed care-givers. Specific adaptations of the recommended strategies may be required to facilitate the implementation of DCM.

WEPEB136

Clinical characteristics and hepatitis C (HCV) treatment outcomes among people who actively use drugs in an HIV cohort in Churachandpur and Moreh districts of Manipur, India

H. Mohan Kumar[1], C. Fortas[2], A. Mesic[3], A. Loarec[4], J. Shougrakpam[5], K. Romeo Singh[6], S. Sharmin[1]
[1]Médecins Sans Frontières, Mission Coordination, New Delhi, India, [2]Epicentre, Médecins Sans Frontières, Paris, France, [3]Médecins Sans Frontières, Operational Center, Amsterdam, Netherlands, [4]Epicentre, Paris, France, [5]Médecins Sans Frontières Manipur, Churachandpur, India, [6]Regional Institute of Medical Sciences, Imphal, India

Background: Hepatitis C treatment outcomes in active drug users coinfected with HIV/HCV is of interest to design programs of care. Treatment outcome in drug users is infrequently reported from limited resource contexts. MSF provides care to HIV/HCV coinfected patients through two clinics in Manipur state of eastern India. HCV care program includes integrated treatment for HCV, HIV, co-morbidites, psychosocial support and harm reduction services. Context experiences low-intensity conflict and high burden of HIV, HCV, Tuberculosis and drug use. This study explored HCV treatment outcomes among active drug users in a HIV/HCV coinfected population.

Methods: Retrospective cohort analysis was conducted on HIV/HCV coinfected patients treated for HCV between Oct 2017 & Jan 2018 at MSF clinics. Demographic, biological, clinical characteristics, treatment and outcome data of patients were retrieved from electronic database. Risk of negative treatment outcomes which included SVR12 failure, lost to follow up and death among patients actively using drugs was tested using step-wise logistic regression.

Results: Among 356 patients registered, treatment outcomes of 230 patients (74.1% male) were available. 28 (12.1%) patients, majority being male (n=26, 92.8%) actively used drugs during HCV treatment. Between active and non-drug users, 17/28 (60.7%) & 178/202(88.1%) cured, 10/28 (35.7%) & 18/202 (8.92%) failed, 1/28 (3.6%) & 4/202 (1.98%) were LFU and 0/28 & 2/202 (0.99%) died. Six patients failed SVR12 but attained SVR24; among whom 5 (83.3%) were treated with sofosbuvir+peginterferon+ribavirin. Of 11 patients with negative outcome and active drug use, four (44.5%) received interferon treatment. Negative treatment outcome risk in active drug users relative to non-users was 4.5 (95%CI 1.8-11.27, n=227) in model adjusted for sex, cirrhosis and interferon treatment.

Conclusions: Provision of HCV care in people actively injecting drug is feasible, when integrated with HIV and TB care, with link to psychosocial support and harm reduction. In our small sample size HIV/HCV coinfected patients actively using drugs during HCV treatment had higher risk of negative treatment outcomes. However, there was a strong association between the negative outcome with liver cirrhosis and interferon treatment, characteristics not linked to active drug use. Use of DAAs without delay is a pre-condition for successful treatment outcomes in this population.

Characteristics	Failure (%)	Success (%)	RR of failure (95%CI)	p value
Patients with treatment outcome (n=230)	35 (15.22)	195 (84.78)		
Drug use status				
Non user (n=202)	24 (11.88)	178 (88.12)	1.00	
Active user (n=28)	11 (39.29)	17 (60.71)	4.7 (2.0 - 11.45)	0.007
Genotype distribution (n=219)				
1 (n=75)	13 (37.14)	62 (31.79)	1.00	0.67
3 (n=78)	12 (34.29)	66 (33.85)	0.86 (0.36 - 2.0)	
4 (n=2)	1 (2.86)	1 (0.51)	4.76 (0.27 - 81.2)	
6 (n=64)	9 (25.71)	55 (28.21)	0.78 (0.30 - 1.96)	

[Table 1.0 Association of patient's key characteristics with treatment outcome]

WEPEB137

Tuberculosis testing and treatment among people who use drugs in Abidjan: Results and perspectives for a community-based approach implemented in Abidjan, Côte d'Ivoire

A. Bernier[1], G. Colin[2], N. Luhmann[1], L. N'zi[2], S. Houndji[2], A. Assoumou[2], D. Ramatou[3], J. Bouscaillou[1], L.-H. Adjahi[2], J. Evanno[2], R. Boulet[2], C. Doumenc-Aïdara[2], C. Dézé[2], A. Kouamé[3], R. Kouassi N'Guessan[4]
[1]Médecins du Monde, Paris, France, [2]Médecins du Monde, Abidjan, Cote D'Ivoire, [3]Programme National de lutte contre la Tuberculose, Abidjan, Cote D'Ivoire, [4]Institut Pasteur, Abidjan, Cote D'Ivoire

Background: Tuberculosis (TB) remains a major public health issue, which strongly affects high-risk populations - such as people living with HIV, prisoners and people who use drugs (PWUD). Despite a growing number of PWUD in the last decade in Sub-Saharan-Africa, data on TB prevalence and cascade of care among PWUD in this region are scarce. The objective of this study was to estimate TB prevalence and establish the TB testing and treatment cascade using a community-based approach for precarious PWUD in Abidjan, Côte d'Ivoire.

Methods: A cross-sectional study with prospective follow-up of TB positive participants was implemented in the two main open drug use scenes of Abidjan. Tuberculosis screening was offered to all PWUD by peer-educators (PE) and done in a mobile unit close to the drug consumption place. Participants with GeneXpert positive results were considered having a confirmed pulmonary TB. Linkage to public healthcare centers and community-based support (i.e., close follow-up by social workers and PE, regular psychosocial interviews, financial support for nutritional intake, self-support groups and family mediation visits) was offered to all TB positive participants who came to seek their results. Treatment outcomes were retrieved at the end of treatment.
Results: In total, 532 PWUD were enrolled (485 men (91.2%) and 47 women (8.8%)). The mean age was 35 years ; 75.8% of them had unstable housing. Almost all participants (99.6%) smoked heroin. Fifty-two pulmonary TB cases were confirmed (9.8%), including 9 rifampicin-resistant TB (17.3% of TB cases) and 8 (15.4%) HIV co-infections. Of the 52 TB positive participants, 40 started treatment. As of 26 January 2018, 22 of them (55.0%) were cured, 4 (10.0%) were still receiving treatment, 3 (7.5%) had treatment failures, 3 (7.5%) had died during the study and 8 (20%) were lost-to-follow up.
Conclusions: This study describes very high pulmonary and rifampicin-resistant TB among PWUD in Abidjan. Encouraging results were obtained in the tuberculosis testing and treatment cascade among PWUD using a community-based approach, despite strong challenges with this hard-to-reach population. Further research needs to look into TB epidemiology and care access in PWUD to make better progress in TB control in this region.

WEPEB138

Lack of effective opioid dependence and alcohol abuse treatment leads to high rates of treatment discontinuation among patients initiated on antiretroviral therapy in Kazakhstan

A. Deryabina[1], T. Ellman[2], B. Baiserkin[3], V. Ivakin[1], W. Killam[4]
[1]ICAP at Columbia University, Central Asia, Almaty, Kazakhstan, [2]ICAP at Columbia University, New York, United States, [3]Republican Center on Prevention and Control of AIDS, Almaty, Kazakhstan, [4]U. S. Centers for Disease Control and Prevention, Almaty, Kazakhstan

Background: Limited data are available on factors associated with treatment interruption among people living with HIV (PLHIV) initiated on antiretroviral therapy (ART) in Kazakhstan. Although, approximately 60% of all PLHIV have a history of injection drug use, access to opioid maintenance therapy remains limited.
Methods: We conducted a retrospective cross-sectional analysis of routinely collected data on 6339 ART-naive patients (≥15 years old) that initiated ART from 2014-2016. Bivariate and multivariate logistic regression analyses were conducted to assess factors associated with treatment interruption within 12 months of ART initiation.
Results: 3693 men and 2646 women initiated ART during the study period, including 2724 (43%) that ever injected drugs. The median age at ART initiation was 36 years (IQR=31-42 years). The median time between HIV diagnosis and ART initiation was 791 days (IQR=77-2129 days). Median baseline CD4 cell count at ART initiation was 257 cells/μl (IQR=144-361 cells/μl). 620 (9.8%) patients died and another 1106 (17.4%) stopped ART within the first 12 months after ART initiation. Median number of days between ART initiation and the first ART interruption was 170 (IQR=95-254 days).
On multivariate analysis, discontinuation of ART within the first 12 months of initiation was independently associated with reported ART toxicities (OR=2.87, 95% CI=1.94-4.26, p< 0.0005), injection drug use (OR=2.03, 95% CI=1.31-3.16, p=0.002) and reported alcohol abuse (OR=2.16, 95% CI=1.48-3.15, p< 0.0005).
Conclusions: Substance abuse including injecting drugs and harmful use of alcohol were associated with treatment discontinuation among patients initiated on ART in Kazakhstan. Implementation of effective alcohol abuse treatment and scale-up of opioid dependence treatment are needed to improve ART retention and adherence among PLHIV in Kazakhstan.

Clinical issues in transgender and non-binary populations

WEPEB139

Health resource utilization and health outcomes in a cohort of persons of transgender experience living with HIV/AIDS in New York City

E. Fusaris, J. Ernst, Y. Vazquez, S. Toussi, K. Steffens
Amida Care, New York, United States

Background: Transgender persons living with HIV/AIDS experience some of the highest rates of health disparities due to the contextual factors in which HIV occurs. There are significant research gaps related to comorbidities and integrated approaches to care among this population. There is a need for more data to answer pressing questions related to care for this population; comprehensive knowledge about health care outcomes is the first step needed in order to develop primary and secondary prevention interventions for persons of transgender experience.
Methods: Amida Care is a community sponsored, not-for-profit, Medicaid Special Needs health insurance Plan that serves over 6,400 individuals living with HIV/AIDS in New York City needing intensive services; approximately 400 are people of transgender experience. Amida Care developed a research cohort of 401 transgender persons living with HIV/AIDS served by the Plan in an effort to identify patterns in care that could inform effective strategies and priority interventions for reducing morbidity among persons of transgender experience.
Results: The mean age of the cohort is 38.5, the race/ethnicity breakdown is 63% Black, 27% Hispanic, 5% White, 5% Other, and the majority of the cohort resides in the Bronx borough. As a Managed Care Organization, Amida Care has access to claims data that is often difficult to obtain and centralize into one data warehouse. The top 3 co-morbidities experienced by the cohort as evidenced by ICD 9/10 codes are drug dependence (55%), depression (42%), and nutritional deficiency (29%). 88 (22%) of cohort members had gender affirming surgeries (since March of 2015) covered by the Plan. CD4 and viral load counts of cohort members were similar when compared to cisgender Plan members.
Conclusions: The results suggest that interventions for this population should focus on substance use programs, mental health initiatives, and nutrition. HIV-related laboratory results suggest that secondary HIV prevention medication/primary care adherence initiatives are working; however, more research is needed. Managed Care Organizations, with their access to claims, have a unique opportunity to mine and analyze data for populations disproportionately affected by health disparities that has the potential to inform primary and secondary HIV prevention strategies based on real-life data.

WEPEB140

Co-occurring psycho-social problems in transgender women living with HIV enrolled in a clinical trial in Argentina

I. Aristegui[1,2], P.D. Radusky[1,3], V. Zalazar[1], C. Frola[1], N. Cardozo[1,4], A. Gun[1], E. Fojo[1], M. Romero[4], P. Cahn[1], O. Sued[1]
[1]Fundacion Huesped, Buenos Aires, Argentina, [2]Universidad de Palermo, Buenos Aires, Argentina, [3]University of Buenos Aires, Department of Psychology, Buenos Aires, Argentina, [4]Asociación de Travestis, Transexuales y Transgéneros de Argentina (ATTTA), Buenos Aires, Argentina

Background: Despite universal access to public health in Argentina, and the Gender Identity Law passed in 2012, transgender women (TGW) continue being one of the most vulnerable communities. Estimated life expectancy is 35 years old and HIV prevalence is 34%. Co-occurring health problems, including poor mental health, stigma and discrimination, and economic hardship are syndemic factors that cumulatively determine HIV vulnerability in TGW. The objective of our research is to evaluate the impact of co-occurring psycho-social factors in the retention and adherence of TGW in HIV treatment. This abstract depicts preliminary baseline data.

Methods: 50 treatment-naïve HIV-1 TGW were enrolled in a longitudinal clinical trial and completed a series of social and psychological assessments (CES-D; 4-item suicidal-ideation screener; PID-5; Wellbeing Index; STAI). Frequencies, independent sample t-tests and bivariate correlations were calculated with SPSS 24.

Results: TGW's median age was 29 (IQR: 26-33), 74% reported current survival sex work and 62% drug use during the last year. 62% has incomplete secondary education, and 44% lives in community housing rooms. 50% has advanced HIV infection (27.1% CD4< 350, 22.9% CD4< 200). No significant differences in experiences of stigma and discrimination, mental health outcomes, and maladaptive personality traits were observed between advanced and non-advanced HIV TGW. However, the higher the Gender Identity Stigmatization (GIS), the higher the suicidal ideation (r=.52), depression (r=.51), and anxiety (r=.50) and the lower the quality of life (r=-.37). GIS was also associated with maladaptive personality traits (DSM-5): more negative affectivity (r=.48) and psychoticism (r=.39). More than half of the sample (70%) experienced clinical levels of negative affectivity (negative emotions and poor self-concept).

Conclusions: Results of this baseline analysis show that half of TGW initiate treatment with advanced HIV infection and present poor living conditions and co-occurrences of gender stigmatization and negative psychological outcomes. Since these factors might negatively impact in retention and adherence of HIV treatment, these results highlight the need of a multidisciplinary approach and a multi-component intervention (e.g., psychological assessments and gender affirmative practices) as standard of care when working with HIV TGW in clinical settings.

Clinical issues in migrants

WEPEB141

Comparing clinical outcomes of immigrants and citizens living with HIV in Botswana: A retrospective cohort study

T. Marukutira[1,2,3], D. Yin[4,5], B.R. Lee[5], L. Cressman[3], R. Kariuki[3], B. Malone[3], T. Spelman[1], S. Crowe[2,6], M. Stoove[1,2], M. Hellard[1,2], D. Dickinson[3]
[1]Burnet Institute, Public Health, Melbourne, Australia, [2]Monash University, Epidemiology and Preventive Medicine, Melbourne, Australia, [3]Independence Surgery, Gaborone, Botswana, [4]Children's Mercy, Kansas, United States, [5]University of Missouri-Kansas City School of Medicine, Kansas City, United States, [6]Burnet Institute, Melbourne, Australia

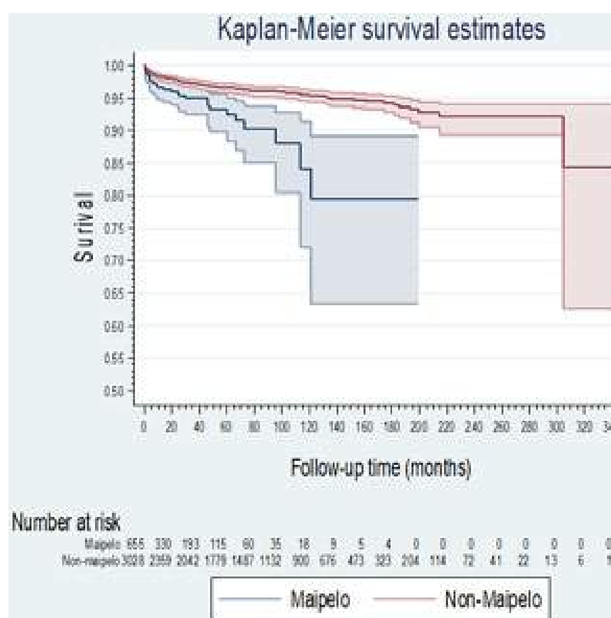
Background: Reaching the Joint United Nations Program on HIV/AIDS 90-90-90 targets requires inclusion of key and vulnerable populations. Mobile populations, especially immigrants living with HIV (ILHIV), encounter difficulties accessing healthcare. Botswana provides free access to HIV care for citizens, while non-citizens fund their own HIV care. Maipelo Trust, a non-governmental organization (NGO) in Botswana, offers financial support to ILHIV through an urban general practice clinic which also offers HIV care to citizens. We aimed to compare differences in antiretroviral therapy (ART) coverage, viral suppression, and mortality in ILHIV and citizens living with HIV attending the clinic between 2002 and 2016.

Methods: We conducted a retrospective cohort study using electronic medical records capturing clinical and laboratory data. Proportions were compared using chi-squared tests and logistic regression. Mortality was evaluated using Kaplan-Meier estimates and Cox proportional hazards model adjusted for age, baseline CD4, and time on ART. Viral suppression was defined as a viral load (VL) < 400 copies/mL.

Results: 4,042 people living with HIV were enrolled: 768 immigrants and 3,274 citizens (Table 1). Only 29% of ILHIV paid for own HIV care or had personal medical insurance; the remainder required NGO financial support. Most citizens (85%) had personal medical insurance, while 15% were government funded.

606 (79%) ILHIV initiated ART over the study period compared to 3,033 (93%) citizens (p< 0.001). Mean time on ART was 5 years in ILHIV and 12 years for citizens (p< 0.001). Half of ILHIV did not have a follow up VL after ART initiation compared to 8% of citizens (p< 0.001). Among those who had VL done, 66% of ILHIV and 73% of citizens had viral suppression (p< 0.001).

Mortality was higher among ILHIV. Overall 5-year survival was ~93% for ILHIV and ~97% for citizens (Figure 1). The ILHIV group was associated with 1.98 (95%CI 1.23-3.21) times the rate of death relative to citizens.



[Kaplan-Meier Survival estimates for immigrants (Maipelo) and citizens (Non-Maipelo) living with HIV]

Variable	Immigrants (%) (n=768)	Citizens (%) (n=3,274)	p-value
Median age (range), years	39 (0.25-84	48 (0.25-92)	
Male, n (%)	335 (44)	1,283 (39)	
Self-paying/medical insurance	226 (29)	2,773 (85)	
Initiated on ART, n (%)	609 (79)	3,033 (93)	<0.001
Proportion of all patients on ART with current (2016) VL results	296 (48.6)	2,798 (92.3)	<0.001
Proportion of patients with viral suppression	195 (66%)	2,042 (73%)	<0.001
Mortality:			
Hazard Ratio	1.98 (1.23-3.21)	Reference	0.005

[Table1: Demographic and clinical outcomes of Immigrants and Citizens]

Conclusions: ILHIV had poorer clinical outcomes compared to citizens and were unlikely to have capacity to fund their own HIV care. These results highlight the need to ensure inclusion of immigrants in mainstream-funded HIV treatment programs to reach HIV epidemic control.

Clinical issues in other vulnerable populations

WEPEB142

Longitudinal virological outcomes and factors associated with virological failure in behaviourally HIV-infected young adults on combination antiretroviral treatment in the Netherlands, 2000-2015

A. Weijsenfeld[1,2], C. Blokhuis[1], M. Stuiver[3], D. Pajkrt[1], F. Wit[2,4],
On behalf of the ATHENA Observational HIV Cohort
[1]Academic Medical Center, Emma Childrens Hospital, Pediatric Infectious Diseases, Amsterdam, Netherlands, [2]Academic Medical Center, Internal Medicine, Amsterdam, Netherlands, [3]Academic Medical Center, Department of Clinical Epidemiology Biostatistics and Bioinformatics, Amsterdam, Netherlands, [4]HIV Monitoring Foundation (Stichting HIV Monitoring), Amsterdam, Netherlands

Background: To maintain viral suppression in HIV-infected young adults is challenging. Studies show overall low HIV viral suppression rates in young adults (18-24 years) as compared to adults. Longitudinal data can

provide valuable insight on dynamics of viral suppression and variables of potential influence on virological failure (VF), but is scarce in HIV-infected young adults on cART.

Methods: We analysed data from 2000-2015 from the Dutch national HIV database of 827 HIV-infected young adults (YAs) on cART for a minimum of six months. VF was defined as two consecutive detectable plasma HIV-1 RNA measurements > 200 copies/ml. Generalized linear mixed model analyses were used to assess HIV VF over time and identify risk factors associated with VF.

Results: HIV VF during the young adult age occurred at least once in 28% of cases. The probability of experiencing VF decreased over the study period per calendar year (OR 0.80, 95% confidence interval [CI];0.75; 0.85). Factors significantly associated with VF were being infected through heterosexual contact (OR 4.21, 95%CI 1.64; 10.82) and originating from Latin America or the Caribbean (OR 3.08, 95%CI 1.33; 7.12). Effect was smaller yet significant in patients that started cART with a nadir CD4 count >500 (OR 5.96, 95%CI 1.63; 21.72). The occurrence of HIV VF decreases with older age, but after correcting for calendar year, not significantly.

Conclusions: In our large cohort of YA, a decrease in HIV VF was observed with older age. However, the effect of calendar time on improved outcomes was larger, with current suppression levels approaching the Dutch adult HIV population. These findings suggest that behaviourally HIV-infected YAs have greatly benefitted from improved cART regimes over time, that have become more potent, more forgiving and have fewer side effects. Specific subgroups continue to be at risk for suboptimal treatment.

WEPEB143

Same-day medical visit in newly diagnosed HIV patients decreases time to viral suppression

D.Y. Mohammed[1,2], E. Martin[3], Y. Babyants[4], J. Slim[5]
[1]Saint Michael's Medical Center, Infectious Diseases, Newark, United States, [2]William Paterson University, Nursing, Wayne, United States, [3]Rutgers University, Department of Pathology & Laboratory Medicine, New Brunswick, United States, [4]Rowan University, School of Osteopathic Medicine, Stratford, United States, [5]Saint Michael's Medical Center, Newark, United States

Background: Previous attempts to link patients to medical care involved meeting with a non-medical provider and obtaining baseline lab-work. The current impetus towards viral suppression (VS) includes rapid initiation of antiretroviral therapy(ART) which can only be accomplished if patients are seen in a timely manner by a medical provider. This study compared the proportion of patients with VS before and after implementation of a same- day medical visit for newly-diagnosed HIV patients in an adult inner-city clinic.

Methods: This is a retrospective review of data collected from 2014-2017 among newly-diagnosed patients in an inner-city clinic. Patients were included if they had at least one medical visit, one viral load and an antiretroviral prescription documented in the electronic medical record. Same-day visit with a medical provider was implemented in 2016. Fishers Exact test was used to evaluate the proportions of newly diagnosed and suppressed patients by demographic characteristics. Survival analysis for competing risks evaluated time to 1st suppressed viral load after

a) HIV diagnosis, and

b) ART initiation.

Results: Overall, 137 patients were newly diagnosed; 8 patients were censored as they were lost to care or moved prior to VS. New patients included males (81%), those aged 20-29 (45%), those with public insurance (43%), and those with non-AIDS status (79%). From 2014 to 2017, same-day medical visits for newly-diagnosed patients increased from 18% to 69%, the median time to VS decreased from 101 to 88 days after diagnosis and 70 to 35 days after receipt of ART. Overall VS increased from 91% to 97% and was similar among all population groups.

Conclusions: From 2014 to 2017, same-day medical visits as diagnosis increased almost four-fold, the median time to VS after diagnosis decreased by 13% and VS increased by 8%. This change in practice predates the current recommendations for rapid initiation of ART, which may become a reality when patients are seen by a medical provider on the same-day as a new diagnosis. This evaluation presents the potential to further decrease the median time to VS at this clinic with initiation of ART on the same-day as diagnosis.

WEPEB144

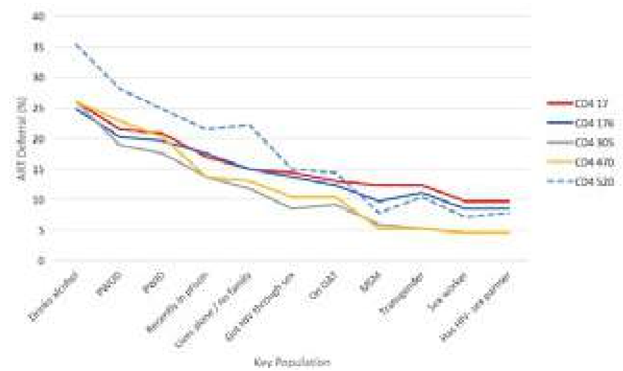
High rates of anti-retroviral treatment deferral for HIV-infected patients who use alcohol and drugs: Results from a national sample of medical doctors in Ukraine

T.D. Ottesen[1], J.A. Wickersham[2], O. Zezuilin[3], S. Antoniak[4], S. Antonyak[4], M. Polonsky[5], J. Lawrence[2], J. Rozanova[2], S. Dvoryak[3], I. Pykalo [3], A. Taroyants[3], M. Filippovych[3], F. Altice[2]
[1]Yale School of Medicine, Department of Infectious Diseases, Center for Interdisciplinary Research on AIDS, New Haven, United States, [2]Yale School of Medicine, Department of Internal Medicine, Section of Infectious Diseases, AIDS Program, New Haven, United States, [3]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [4]Viral Hepatitis and AIDS Department of the Gromashevsky Kiev Institute of Epidemiology and Infectious Diseases, Kyiv, Ukraine, [5]Quinnipiac University School of Business, Hamden, United States

Background: Despite reductions in global HIV incidence and mortality, Ukraine continues to exhibit elevated HIV concentration in key populations and sub-optimal antiretroviral therapy (ART) coverage. Physicians are the gatekeepers to ART prescription and are understudied as barriers to scale-up in key populations.

Methods: A national sample of current ART-prescribing physicians (N=153) in Ukraine were surveyed between August and November 2017. Participants underwent a series of randomized, hypothetical clinical scenarios of PLWH and decided whether to initiate or defer ART. Scenarios varied based on 5 different CD4+ counts (CD4+: 17, 176, 305, 470, or 520) and 10 different patient prototypes (key populations). *Z* scores and McNemar's test for paired samples were used to test differences between key patient prototype and CD4+ count.

Results: Physicians were mostly female (80.4%), with 19 mean years of medical experience and trained in infectious diseases (76.5%); clinical work sites include dedicated HIV/AIDS centers (50.3%) or hospital (32.0%). Results are illustrated in Figure 1 below.



[Physician decisions to defer ART by CD4 count and key population (N=153)]

Patients who drink alcohol were most likely to have ART deferred (range: 24.8%-35.1%), even at the lowest CD4+ count (26.1%). Similar decisions to defer ART were observed for patients who use (PWUD range: 19.0%-28.1%) or inject (PWID range: 17.6%-24.8%) drugs. Patients on opioid agonist therapy like methadone (range: 9.2%-14.4%), however, were significantly (p< 0.001) less likely to have ART deferred compared with PWID and PWUD overall and when compared by CD4+ counts. Men who have sex with men (range: 5.2%-12.4%), transgender women (range: 5.2-12.4%), sex workers (range: 4.6%-9.8%), and having an HIV-uninfected sex partner (range: 4.6%-9.8%) had the lowest likelihood of ART deferral.

Conclusions: Irrespective of national guidelines recommending ART prescription to all PLWH irrespective of risk or CD4+ count, deferral of ART remains high in certain key populations, especially in PLWH who drink alcohol or have a substance use disorder. Concerning is the high deferral of ART for CD4+=17, relative to other CD4+ counts < 520, a group with markedly high risk for death. While ART deferral in substance-using PLWH may be related to concerns about adherence, adherence support rather than ART deferral should be prioritized to truly mitigate the current epidemic in Ukraine.

WEPEB145

Barriers and facilitators of higher patient activation levels among HIV-infected and uninfected midlife U.S. women

K.M. Weber[1], C. Bond[1], E. Daubert[1], L. McClellan[1], A.L. French[2], M.H. Cohen[3]

[1]Hektoen Institute of Medicine, Chicago, United States, [2]Stroger Hospital of Cook County, Department of Infectious Diseases, Chicago, United States, [3]Cook County Health and Hospitals System and Rush University Medical Center, Department of Medicine, Chicago, United States

Background: Higher levels of patient activation (PA) are associated with better health outcomes with chronic disease. Hibbard (2005) identified four stages of PA:
1) believing the patient role is important,
2) having confidence to take action,
3) actually taking action to maintain/improve health, and
4) staying the course under stress.
We sought to identify barriers/facilitators to achieving high activation levels among midlife women with HIV who experience significant life stressors and chronic disease burden.

Methods: We administered the well-validated 13-item Patient Activation Measure to 174 HIV-infected (HIV+) and 69 HIV-uninfected (HIV-) Chicago Women's Interagency HIV Study (WIHS) participants during a semiannual visit in 2017. We conducted cross sectional analyses using concurrently collected covariates. Resilience and PTSD were measured using the Connor-Davidson Resilience Scale (CD-RISC) and PTSD Civilian Checklist (PCL-C) respectively. Logistic regression was used to predict odds of being in the highest and upper two stages of activation.

Results: Women were predominantly black (77%), age≥50 (56%), poor (62% ≤ $18k), unemployed (59%), obese (49%), current smokers (44%), former/current drug use (37%), unstably housed (17%); 54% had hypertension, 24% had diabetes; with no significant difference by HIV status. Among HIV+, 75% were on HAART/≥95% adherent; 24% were viremic. Overall, 8% were in PA Stage (PAS)-1, 11% in PAS-2, 32% in PAS-3, and 49% in PAS-4 with similar distribution by HIV status. Employment, stable housing, and higher mean CD-RISC predicted greater odds of being in the highest PAS while current smoking, former/current substance use, and a PCL-C score≥44 predicted lower odds of PAS-4. With the exception of PTSD symptoms, all factors remained statistically significant for increasing/decreasing odds of PAS-4 after adjustment for age (per 10 years), race/ethnicity, education, and income (Table 1). Similar factors were statistically significant for predicting odds of PAS≥3 except PCL-C≥44 remained associated with lower likelihood even after adjustment.

Conclusions: HIV-infected and demographically similar uninfected U.S. women in this cohort study have high levels of activation. Programs that build resilience, reduce PTSD symptoms and substance abuse, and address housing instability may help facilitate greater patient activation among women with chronic disease.

	Unadjusted model OR (95% CI)	p-value	Adjusted model OR (95% CI)	p-value

WEPEB146

Housing instability increases rates of urgent care visits, emergency department visits and hospitalizations among PLHIV

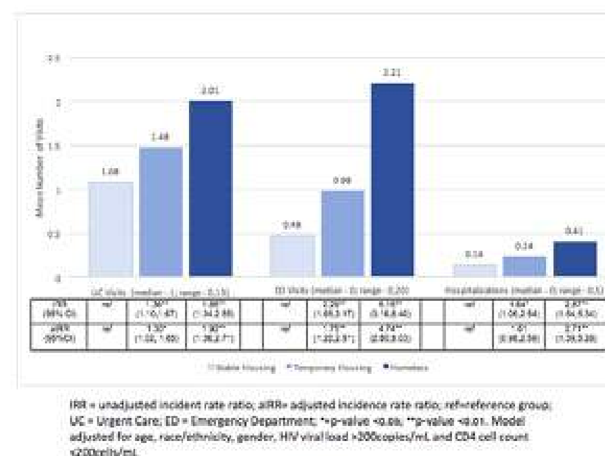
A. Clemenzi-Allen[1], E. Geng[1], D. Sachdev[2], S. Buchbinder[2], D. Havlir[1], M. Gandhi[1], K. Christopoulos[1]

[1]University of California, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States, [2]San Francisco Department of Public Health, San Francisco, United States

Background: Housing instability is associated with acute care visits (ACV) among people living with HIV (PLHIV), but few analyses have evaluated how different levels of housing instability affect different ACV types. We evaluated the association between a three-category predictor variable of housing with urgent care (UC) visits, emergency department (ED) visits and hospitalizations in a large urban clinic-based cohort.

Methods: We collected self-reported housing data during check-in at a safety-net primary care HIV clinic in San Francisco from 2/1/17-7/21/17 using a pictorial survey depicting 6 different living arrangements. We defined housing as stable (Rent/Own, Hotel/Single Room Occupancy), temporary (Treatment/Transitional Program, Staying with Friends), or homeless (Homeless Shelter, Outdoors/In Vehicle). ACVs included visits to UC, ED or hospitalizations from 11/2016-11/2017 and included only ACVs in our hospital system. We calculated unadjusted and adjusted incident rate ratios (IRR) by ACV type using separate negative binomial regression models given over-dispersion of the outcome variable. We adjusted for age, gender, race/ethnicity, baseline CD4< 200 cells/mL and VL >200 copies/mL.

Results: 1,220 patients completed the survey. Median age was 50 years (IQR 41 to 57); 13% were female; 41% white, 24% black, 26% Latino, 9% other. 10% had CD4 < 200cells/mL and 29% had VL >200copies/mL. 1371 UC visits, 719 ED visits and 199 hospitalizations were observed. Of all patients, 13% had ≥1 hospitalization, 27% had ≥1 ED visit and 47% had ≥1 UC visit. Mean ACVs increased in a monotonic fashion by housing instability. Unadjusted and adjusted IRR of UC visit, ED visit or hospitalization were statistically significantly higher for those at all levels of housing instability compared to those stably housed, except when comparing the frequency of hospitalizations for those temporarily housed (Figure).



[Mean Acute Care Visits by Housing Status and Visit Type]

Conclusions: We demonstrate a "dose-response" between category of housing instability and frequency of ED visits, UC visits and hospitalizations among PLHIV. Although homelessness is associated with the highest rates of ACVs, temporary housing (compared to stable housing) is also associated with increased care utilization. Interventions are needed to mitigate the potential impact of housing instability on the least cost-effective forms of accessing care (e.g. ED visits, UC visits, hospitalizations) among PLHIV.

WEPEB147

Hazardous alcohol screening rates among persons with HIV following implementation of screening, brief intervention and referral to treatment in a large healthcare system in the United States

M. Silverberg[1], T. Levine-Hall[1], S. Sterling[1], J. Lam[1], C. Ellis[1], M. Horberg[2], A. Williams[3], C. Weisner[1,4], P. Volberding[4], S. Parthasarathy[1], D. Satre[1,4]
[1]Kaiser Permanente, Oakland, United States, [2]Kaiser Permanente Mid-Atlantic States, Mid-Atlantic Permanente Research Institute, Rockville, United States, [3]Tufts Medical Center, Institute for Clinical Research and Health Policy Studies, Boston, United States, [4]University of California, San Francisco, United States

Background: Hazardous drinking is common among persons with HIV (PWH) and associated with reduced antiretroviral adherence, HIV viral control and substantial morbidity and mortality. Effective alcohol interventions in routine clinical care rely on robust screening for hazardous alcohol use.
We evaluated the equality of screening rates across key subgroups among PWH following the rollout of Screening, Brief Intervention and Referral to Treatment (SBIRT) in a large integrated healthcare system in the United States.
Methods: We identified all adult PWH who were healthcare system members between July 2013 (rollout of SBIRT) and December 2017. Patients were followed until they were first screened (event of interest), or until death, lost-to-follow-up or December 2017. Factors evaluated included baseline age, sex, race/ethnicity (Black, White, Hispanic, Other), HIV transmission risk (heterosexual, injection drug use [IDU], men who have sex with men [MSM]), and prior AIDS defining illness (ADI). We estimated proportions screened from Kaplan-Meier plots and adjusted hazard ratios (HRs) from Cox Regression models.
Results: A total of 11,330 PWH were included, with 70% MSM, 52% White, 45% ≥50 years of age at baseline and 46% with prior ADI. Overall, 89% of PWH were screened by four years after SBIRT rollout. Screening was less likely among those 50-59 years (87%; HR 0.93, 95% CI 0.89-0.98) compared with those 18-49 years of age (90%; reference); less likely among Blacks (83%; HR 0.78, 95% CI 0.74-0.83) compared with Whites (90%; reference); less likely among heterosexuals (84%; HR 0.89, 95% CI 0.82-0.96) and higher among IDU (93%; HR 1.19, 95% CI 1.10-1.29) compared with MSM (89%; reference); and less likely among those with prior ADI (86%; HR 0.83, 95% CI 0.80-0.87) compared with those without prior ADI (91%; reference).
Conclusions: Screening for hazardous alcohol use was highly successful with 89% of all PWH screened after four years. However, demographic and clinical disparities suggest strategies are needed to reduce such screening disparities among PWH to allow for equal access to appropriate treatment.

WEPEB148

Comparison of viral load suppression rates between military and civilians on antiretroviral therapy (ART) in military facilities in Uganda

D. Bwayo[1], M. Ssemmanda[1], C. Wamundu[2], F. Young[3], R. Flueckiger[3], J. Akao[4], J. Bosco Ddamulira[1]
[1]RTI International, Global Health, Kampala, Uganda, [2]UPDF, HIV and AIDS Directorate, Kampala, Uganda, [3]RTI International, Global Health, Research Triangle Park, United States, [4]US Mission, Uganda, Department of Defence, Kampala, Uganda

Background: Despite global evidence that military personnel are disproportionately affected by HIV, data on HIV treatment outcomes among military men living with HIV remain sparse. Military personnel on antiretroviral therapy (ART) are subject to a risk-taking culture, which increases exposure to infection, and deployment in clinically-underserved areas, which limits treatment adherence.
This study, funded by United States President's Emergency Plan for AIDS Relief (PEPFAR) compared treatment outcomes between civilians and military personnel after initiating ART at military-managed health facilities in Uganda.
Methods: This cross-sectional study used data obtained from chart reviews and participant interviews. In total, 543 people living with HIV were randomly sampled from eight military ART clinics. Chi squared and t-tests were done to compare proportions and means, respectively. HIV viral load (VL) suppression was defined as a VL of < 1,000 copies/ml.
Results: Of the 543 participants, 229 were military (95% men) and 314 were civilian (30% men). The age structure between the two groups was comparable, with a mean age of 39.8 years (SD = 9.7). Levels of HIV VL suppression and those reporting >95% adherence were not significantly different between the two groups (i.e., 86.0%-87.3% and 85%-86.5%, respectively). There was no difference between baseline CD4 count, ART regimens, condom use, and level of education. Military participants had been on treatment longer (3.1 years compared to 2.9 years [p = 0.02]), were more likely to have disclosed their status to a spouse (57% compared to 44% [p = 0.01]), be married (91% compared to 61% [p = 0.001]) and have higher income (50% military compared to 11% civilians with >$100/month [p = 0.01]). Additionally, military participants were more likely to be recent transfers to the clinic (40.7% compared to 19.4% [p< 0.001]) and report alcohol use (49% compared to 29% [p< 0.001]).
Conclusions: Levels of HIV VL suppression were similar between military and civilians despite differences in socioeconomic, clinical, and behavioral characteristics. Military personnel on ART can achieve similar levels of treatment success when consistent care packages are offered. This implies that targeted military HIV treatment programs can contribute to attainment of national HIV control goals.

New PrEP products (e.g. TAF and other antiretrovirals, long acting oral and injectable drugs, topical PrEP/microbicides)

WEPEC149

Effectiveness of Pre-Exposure Prophylaxis (PrEP) in Brazilian public health facilities: One-year results of the combine! study

A. Grangeiro[1], M. Couto[1], D. Ferraz[2], E. Zucchi[3], M. Escuder[4], L. Denize[5], J. Oliveira[6], A. Fachel Leal[7], O. Carmo Luiz[6], T. Freitas[8], J. Villela Santos[9], L. Rosso[10], É. Arruda[11], R. Moraes[11], R. Munhoz[12], M.C. Giana[12], T. Pinheiro[13], A. Silveira[6], B. Kauss[13], G. Gomes[13], C. Brasileiro[11], A.C. Venci[13], G. Ardila[13], T. Areco[13], A.L. Eberi[13], M. Silvestrini[13]
[1]Universidade de São Paulo, Department of Preventive Medicine, São Paulo, Brazil, [2]Fundação Oswaldo Cruz, Ministry of Health, Brasilia, Brazil, [3]Universidade Católica de Santos, Graduate Program on Collective Health, University, Santos, Brazil, [4]Instituto de Saúde, São Paulo, Brazil, [5]Centro de Referência em DST e Aids, SES, SP, São Paulo, Brazil, [6]Universidade de São Paulo, São Paulo, Brazil, [7]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [8]Secretaria Municipal de Saúde de Porto Alegre, Porto Alegre, Brazil, [9]Secretaria Municipal de Saúde de Curitiba, Curitiba, Brazil, [10]Secretaria Municipal de Saúde de Ribeirão Preto, Ribeirão Preto, Brazil, [11]Hospital de Infectologia São José, Fortaleza, Brazil, [12]Centro de Referência e Treinamento DST/Aids, SES-SP, São Paulo, Brazil, [13]Universidade São Paulo, São Paulo, Brazil

Background: PrEP can be an important tool to address the recent increase of the HIV epidemic. We present the results of 1-year follow-up of PrEP implementation in public health facilities in Brazil.
Methods: PrEP, with daily use of TDF/FTC, was offered to users of five public health facilities (two voluntary testing centers, one general hospital specialized in infectious diseases and two HIV ambulatories). Candidates had to be over 16 years old, have high risk (eg, history of unprotected anal and vaginal sex or multiple casual partnerships) or high vulnerability to HIV (ie, drug use and sex work). Quarterly clinical consultations were conducted, including testing for HIV and syphilis, and monitoring of adverse events. Behavioral questionnaires were applied every six months. Associations were analyzed using Odds Ratio (p < 0.05), calculated by logistic regression.
Results: Between Nov 2016 and Nov 2017, 526 people took PrEP (uptake of 74%), with a mean time of 107 follow up days (IQ: 41-156), with a total of 1542 person-month. Main motivations reported for using PrEP

included desiring to improve sexual life quality (57%) and recognizing being at risk for HIV (42%). The odds of choosing PrEP increased among those who had more than 50 casual partners in the past 6 months (OR: 3.1, 95% CI 1.9-5.1), who treated an STI (OR: 2.0, 95% CI, 1.4- 2.7) and being male, white, with homosexual practices and higher schooling (OR: 1.9, 95% CI 1.4-2.5). No HIV infection was observed in the period. Retention was high (90%) and 65% returned to obtain medication before finishing their tablets. Half of the dropouts occurred in the first 30 days and were associated with being a sex worker (OR: 3.3; 95% CI: 1.3-7.9). The odds of dropout decreased among those who chose PrEP to increase protection (OR 0.4, 95% CI 0.2-0.8) and who previously used post-exposure prophylaxis (PEP) (OR 0.5, 95% CI 0.2-0, 9).

Conclusions: PrEP delivery in the routine care of Brazilian public health facilities was highly effective. Nevertheless, highly vulnerable groups, such as sex workers, had restricted access and a greater chance of abandonment in the initial period of PrEP use.

WEPEC150

Impact of long-acting cabotegravir as pre-exposure prophylaxis on the emergence of HIV drug resistance among men who have sex with men: A modelling study

B. Marshall[1], W. Goedel[1], M. King[1], A. Singleton[1], D. Durham[2], P. Chan[3], J. Townsend[4,5,6], A. Galvani[4,6,7]

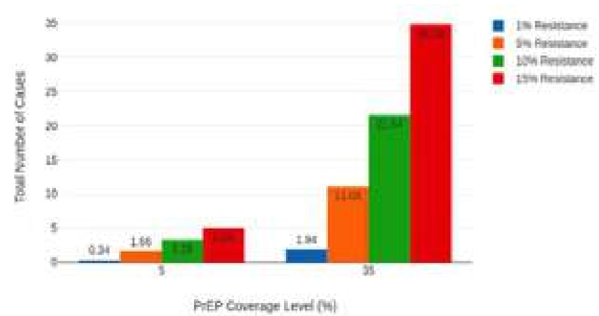
[1]Brown University, Department of Epidemiology, Providence, United States, [2]Yale University, Epidemiology of Microbial Diseases, New Haven, United States, [3]Brown University, Department of Medicine, Providence, United States, [4]Yale University, Department of Ecology and Evolutionary Biology, New Haven, United States, [5]Yale University, Department of Biostatistics, New Haven, United States, [6]Yale University, Program in Computational Biology and Bioinformatics, New Haven, United States, [7]Yale University, Center for Infectious Disease Modeling and Analysis, New Haven, United States

Background: Long-acting cabotegravir (LA-CAB) is currently being tested in phase III trials for use as long-acting injectable pre-exposure prophylaxis (LAI-PrEP) to prevent HIV infection. However, the emergence of drug resistant mutations with subtherapeutic levels of LA-CAB when injections are discontinued is a concern. We used an agent-based model (ABM) to estimate the impact of LAI-PrEP use on the development of drug-resistance among men who have sex with men (MSM).

Methods: We simulated HIV transmission in a dynamic sexual network representing 11,245 MSM in Atlanta, Georgia from 2015 to 2024. The model was calibrated to reproduce current HIV prevalence and incidence among MSM in Atlanta (30.3% and 3.9 per 100 person-years). We assumed agents received bimonthly LA-CAB injections, with retention in care rates based on phase II trial data (85% retained at 3 months). The efficacy of LA-CAB was estimated from published macaque data, and LA-CAB concentrations over time were estimated from human pharmacokinetic data. The impact of LA-CAB on the emergence of drug-resistant infections was modeled across different LAI-PrEP coverage levels (5% to 35%) and discontinuation rates, with varied probabilities of developing drug resistance as LA-CAB concentrations waned up to 12 months following LAI-PrEP discontinuation.

Results: Without PrEP use, there were an estimated 2,374 new infections from 2015 to 2024 among MSM. With 5% of MSM using LAI-PrEP, the cumulative number of new HIV infections over ten years was reduced by 5.8% compared to the scenario without PrEP. At this coverage level, infections resistant to LA-CAB were rare, ranging from 0-5 cases over ten years (Figure). With 35% of MSM using LAI-PrEP, the cumulative number of new HIV infections over ten years was reduced by 43.9%. At this level, infections resistant to LA-CAB were also rare, ranging from 2 to 35 incident drug resistant infections over the ten-year period. In sensitivity analyses, the number of drug resistant infections was proportional to discontinuation rates.

Conclusions: Simulations incorporating phase II clinical data and efficacy estimates from macaque models suggest that the emergence of resistance to LA-CAB will be rare. Further research is needed to monitor the development of drug resistance in ongoing LAI-PrEP efficacy trials.



[Total cumulative number of drug resistant HIV infections over a 10-year time period (2015-2024) among MSM in Atlanta]

WEPEC151

Updating communities on ASPIRE and ring studies in Zimbabwe

C. Mashoko

International Partnership for Microbicides (IPM), External Affairs, Cape Town, South Africa

Background: Lack of meaningful involvement of communities in HIV Prevention research, in particular clinical research targeting women - risk jeopardizing a study. While Community Advisory Boards play a critical role, this is often limited due to a number of factors, chief among them lack of resources. Good Participatory Practices have moved beyond simplistic definitions of ´community´ to encompass a diverse set of actors with various levels of proximity that impacts a women´s day to day lived realities. These include but are not limited to kinship networks, community services, and media agencies. The International Partnership for Microbicides partnered with the Southern African AIDS Trust Zimbabwe (SAT Zim) to keep the Zimbabwean community informed of two phase III randomized control studies (The Ring & ASPIRE studies); evaluating the safety and effectiveness of the Dapivirine vaginal ring for HIV prevention. Stakeholder engagement activities with journalists in trial communities sought to build correct knowledge facilitate discussion and participation with affected communities.

Description: SAT Zim provided training to 30 advocates and journalists in the communities of Harare and Chitungwiza, Zimbabwe. This resulted in a partnership with the Health Journalist Association of Zimbabwe, where health journalists were trained on the Ring Study and ASPIRE. Trained journalists mobilized other journalists within their networks and encouraged their participation across different stakeholder engagement activities hosted by SAT Zim.

Lessons learned: Meaningfully engaging journalist associations in clinical trials as part of stakeholder engagement strategies resulted in reaching a large community audience and led to sustained engagement that extended beyond the initial training. Engaging journalists from the onset of clinical trials resulted in ownership, timely and accurate reporting. To date, Zimbabwe has recorded zero negative media reports

Conclusions/Next steps: A cohort of 20 Health journalists who successfully finished the training was maintained and has further expanded knowledge gained to networks within their own journalistic spheres of influence. Resources are being mobilized to support Health Journalists Association of Zimbabwe to facilitate monthly research update meetings.

Determinants of voluntary or coerced sexual debut among Black female adolescents in Soweto, South Africa: Findings from the birth to twenty cohort study

D. Nyemba[1], M. Cornell[2], M. Mabaso[3], L. Richter[4], J. Ramjith[1]
[1]University of Cape Town, Division of Epidemiology & Biostatistics, School of Public Health & Family Medicine, Cape Town, South Africa, [2]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health & Family Medicine, Cape Town, South Africa, [3]Human Sciences Research Council of South Africa, HIV/AIDS, STIs and TB, Cape Town, South Africa, [4]University of Witwatersrand, 4DST-NRF Centre of Excellence of Human Development, Johannesburg, South Africa

Background: Early sexual debut whether voluntary or coerced increases exposure to high risk sex which leads to unplanned teenage pregnancy, sexually transmitted infections including HIV and reproductive health problems during adolescence. Black African female adolescents in South Africa have been identified as a key population at increased risk of coerced sexual debut and HIV infection.
Methods: We used sample data from 908 Black African female adolescents collected longitudinally from the Birth to Twenty cohort in Soweto, South Africa, between 13 and 18 years of age. Primary outcome was sexual debut, and whether voluntary or coerced. We used logistic regression to investigate odds ratios and the associated significance. Cox Proportional Hazards regression analysis was conducted to examine the effect of potential risk factors on the time to overall sexual debut. We further explored the effect of these risk factors on time to first voluntary and time to first coerced sexual debut respectively (multiple event types) using competing risks method.
Results: Approximately 41% of the sample had experienced sexual debut by 18 years of age; 78% of these sexual debut experiences were voluntary while 18% were coerced and 4% were undisclosed. Coerced sexual debut was 2.6 (95% CI: 0.9; 7.7) times more likely to occur in adolescents with partners of the same age than adolescents who initiated sex with age-disparate partners. The overall median age at sexual debut was 18 years. High socio-economic status was protective of the hazard to experience coerced sexual debut (hazard ratio = 0.23). Secondary level for maternal education had a reduced hazard of 0.37 on experience of coerced sexual debut.
Conclusions: There is a need for interventions to delay sexual debut among Black female adolescents from low socio-economic backgrounds and lower maternal education. Interventions should target coercion between peers and partners of similar ages as well.

WEPEC153

Impact of a behavioral intervention on health outcomes among rural women living with HIV/AIDS at six month follow-up

A. Nyamathi
University of California, School of Nursing, Irvine, United States

Background: In India, women living with HIV (WLA) in rural regions face significant barriers to disease maintenance. Challenges include critical nutrition deficits related to access to and knowledge about diets that promote health and address HIV/AIDS-specific needs: Nutrition is a critical component of immune functioning, particularly for those living with HIV/AIDS who have an increased metabolic need to help fight the disease. This community-engaged intervention, based on a nurse-led Asha (Accredited Social Work Activist)-support healthcare model, sought to address this problem.
Methods: A prospective, randomized-controlled 2x2-factorial design assessed the impact of an Asha-support nutrition intervention. 20 Primary Health Centers serving WLA were randomized into one of four arms that included basic Asha-support: Asha-support only (control group), nutrition supplementation, nutrition education, and the combination of supplementation and education. Difference scores between baseline and 6-month follow-up for key physiological outcomes (body mass index [BMI], CD4 count) were analyzed using a mixed-models approach that accounted for clustering within geographic area. Covariates included age, MET, quality of life, food insecurity, social support, adherence, and years of education.
Results: Mean age was 34; 51% were widowed; average monthly income was $32 U.S. dollars; and about half had no formal education. On average, HIV diagnosis occurred 4 years earlier; average baseline CD4 count was 447. All groups improved CD4 count over the 6-month period: Asha only (difference=343.97), nutrition supplement (difference=356.15), nutrition education (difference=469.66), and nutrition supplement + nutrition education (difference=530.82). In fully adjusted models, compared to Asha-support only, both intervention groups demonstrated significantly greater improvements in CD4 count; the interaction term was also significant (p=.006). BMI also increased for all groups: Asha only (difference=.96), nutrition supplement (difference=1.28), nutrition education (difference=2.38), and nutrition supplement + nutrition education (difference=4.07). In comparison to control group, both intervention groups demonstrated higher mean increases in BMI; the interaction term was not significant (p=.799).
Conclusions: An Asha-based-nutrition intervention was efficacious at improving CD4 count and BMI in WLA in India. Interventions run by nurse-led community workers may be beneficial at meeting critical healthcare needs for vulnerable WLA. Implications for promoting effective HIV/AIDS care in India and other nations will be discussed.

WEPEC154

Calibrating estimators of HIV-1 infection time and founder multiplicity towards improved vaccine efficacy assessment

R. Rossenkhan[1], M. Rolland[2], P. Labuschagne[3], C.A. Magaret[1], L.N. Carpp[1], Y.H. Huang[1], E.E. Thommes[1], L. Zhang[1], N. Ndabambi[4], M. Logan[4], T. Holzman[1], M.-R. Abrahams[4], C. Anthony[4], S. Tovanabutra[2], C. Warth[1], G. Botha[3], D. Matten[3], S. Nitayaphan[5], K. Rono[5], A. Sekiziyivu[5], N. Michael[5], D. Chopera[6], L.A. Eller[2], F.A. Matsen IV[1], S. Travers[3], A. Poon[7], M.L. Robb[2], C. Williamson[4], P.B. Gilbert[1], P.T. Edlefsen[1]
[1]Fred Hutchinson Cancer Research Center, Vaccine and Infectious Disease Division, Seattle, United States, [2]U.S. Military HIV Research Program and Henry M. Jackson Foundation for the Advancement of Military Medicine Inc, Bethesda, United States, [3]South African Medical Research Council Bioinformatics Unit, South African National Bioinformatics Institute, University of the Western Cape, Cape Town, South Africa, [4]University of Cape Town, Cape Town, South Africa, [5]U.S. Military HIV Research Program, Bethesda, United States, [6]SANTHE (Sub-Saharan African Network for TB/HIV Research Excellence), Durban, South Africa, [7]University of British Columbia, Vancouver, Canada

Background: Knowledge of the time of HIV-1 infection and multiplicity of viruses that establish HIV-1 infection is crucial for in-depth analysis of the efficacy of various prevention modalities. Better estimation methods would improve the ability to characterize immunological and genetic sequence correlates of efficacy within preventive efficacy trials of HIV-1 vaccines and monoclonal antibodies.
Methods: We developed new methods for infection timing estimation and multiplicity estimation using maximum likelihood estimators that shift and scale (calibrate) estimates by fitting true infection times and founder multiplicities to a linear regression model. These methods also incorporate non-sequence covariates, including measurements of the viral load, HIV-1 diagnostics and alignment statistics, such as the mean entropy across alignment positions. Using Poisson models of measured mutation counts and branching process models (phylogenetic trees), we analyzed longitudinal HIV-1 sequence data from the RV217 and CAPRISA 002 acute HIV-1 infection cohort studies.
Results: We used leave-one-out cross validation to evaluate the prediction error of these calibrated estimators versus that of existing estimators, and found that both infection time and founder multiplicity can be estimated with improved accuracy and precision by calibration. Calibration considerably improved all estimators of time since HIV-1 infection, in terms of reducing bias to near zero and reducing root mean squared error (RMSE) to 5-10 days. Calibration of multiplicity assessments yielded strong improvements with near-perfect predictions in most cases.

Conclusions: Our study addresses an important and globally relevant need to improve HIV prevention and treatment intervention assessment through improved approaches to estimate timing of HIV infection and founder multiplicity. The unique granularity of the viral sequence data generated in recent HIV-1 acute infection trials has provided a valuable opportunity to build and evaluate our comprehensive pipeline, which brings together available tools and provides statistical calibration for estimators of the time of HIV-1 acquisition and founder multiplicity with enhanced accuracy and in a systematic and reproducible way.

WEPEC155

Feasibility and acceptability of symptom screening of sexually transmitted infections: HPTN0 71 (PopART) trial in Zambia and South Africa

C.R. Phiri[1], A. Schaap[1,2], M. Phiri[1], S. Floyd[2], S. Griffith[3], R. Hayes[2], S. Fidler[3], K. Shanaube[1], H. Ayles[1,2]

[1]Zambart University of Zambia Ridgeway Campus, Lusaka, Zambia, [2]London School of Tropical Medicine and Hygiene, London, United Kingdom, [3]Imperial College, London, United Kingdom

Background: HPTN071 (PopART) is a 3-arm community-randomized trial in 21 communities, 12 in Zambia and 9 in South Africa. The trial will determine the impact of a combination prevention intervention on HIV incidence. Community HIV care-providers (CHiPs) deliver the intervention to all households in intervention communities. Due to the close association between HIV and sexually transmitted infections (STIs) screening questions for symptomatic STIs are included as part of the intervention.

Methods: Verbal consent was obtained for individuals 18 years and older, with assent for those < 18. An STI screening tool was delivered by CHiPs to identify signs or symptoms suggestive of an STI (presence of genital sores/growth, vaginal/urethral discharge, dysuria, lower abdominal pains). All those screening positive were referred to the clinic for routine STI diagnosis and treatment. We present data for the period September 2016 to November 2017.

Results: Overall 94.8% of households (70,831/74,657) were enumerated, including total of 192,697 household members aged ≥15 years. 139,892 individuals consented to the intervention and 95.7% (133,985/139,892) were screened for STIs. Overall, among those screened, 1.3% (1,775/133,985) reported STI symptoms. Prevalence of STI symptoms was higher in South Africa 1.6% than Zambia 1.2% (p=0.0031), and commonest among the 20-24 age-group in South Africa (2.3%) and among 25-29 age-group in Zambia (1.7%). Prevalence was similar in both males and females in Zambia, but higher in females in South Africa (OR1.37, 95%CI 1.17-1.61). Those testing HIV-positive at this visit by the CHiPs were more likely to report STI-symptoms than those testing HIV-negative (OR3.9, 95%CI 2.8-5.3 in Zambia and OR4.4, 95%CI 3.6-5.5 in South Africa), and were also more likely to report symptoms than those who were already diagnosed with HIV previously (self-reported HIV). Individuals not previously known to have HIV and who declined testing at this visit had the lowest prevalence of STI symptoms (Table 1).

Conclusions: Large scale community-based STI symptom screening of individuals using a simple tool is acceptable and feasible. Symptoms of STIs were more common amongst young adults in both countries, and also in those newly identified with HIV. STI screening should be incorporated into community based HIV testing programs.

Factor	SA	OR*)	95% CI	Zambia	OR*)	95% CI
STI symptomatic	669/41,390 (1.62%)			1,106/92,595 (1.19%)

Reaching and recruiting key populations for HIV services (online, offline, online-to-offline)

WEPEC156

Reaching the hard-to-reach: Strategies to maximize recruitment of youth at risk or living with HIV, ATN CARES project

M. Koussa[1], S.-J. Lee[1], L. Kozina[2], M.I. Fernández[3], M.J. Rotheram-Borus[1], Adolescent Medicine Trials Network (ATN) CARES

[1]UCLA, Psychiatry & Biobehavioral Sciences, School of Medicine, Semel Institute, Los Angeles, United States, [2]Tulane University, School of Medicine, New Orleans, United States, [3]Nova Southeastern University, Fort Lauderdale, United States

Background: The Centers for Disease Control and Prevention (CDC) estimates that 22% of new HIV infections diagnosed in 2015 were among youth 13 to 24 years of age. Youth with HIV are the least likely to be linked to care and achieve long-term viral suppression.Itis critical to identify youth living with HIV to ensure they receive optimal treatment and care services. Itis also imperative to identify high-risk HIV negative youth to ensure they are linked to appropriate HIV prevention services. This study highlights the Adolescent Medicine Trials Network (ATN) CARES' community-based strategy to identify, recruit and engage youth at risk, living with HIV, or acutely infected with HIV.

Description: Youth 12 to 24 years of age are being recruited in Los Angeles County and New Orleans. Initial screening with the 4th generation Alere™ HIV Combo test assigns youth to one of three studies (acute infection study (n=36), HIV-positive (n=220) stepped care intervention study (n=220), and HIV-negative randomized four-arm intervention study (n=1500).

Lessons learned: To successfully identify and recruit youth at risk or living with HIV, the following five steps were applied:

1). Identify the underserved key vulnerable youth through key community based organizations (CBOs) serving the homeless, incarcerated, and lesbian, gay, bisexual, or transgender (LGBT) youth;

2). Examine the context and needs of youth (e.g., HIV testing, STI testing and referral, housing services, mental health service referrals, and substance abuse treatment referrals);

3). Utilize multiple engagement approaches (e.g., automated messaging, online peer support, in-person coaching);

4). Select and support the right implementation strategy (e.g., recruitment by CBO staff vs. recruitment by research team); and

5). Provide ongoing monitoring and iterative adjustment of recruitment strategies with CBO staff.

Conclusions/Next steps: To date, ATN CARES successfully recruited 11 youth with acute/treatment naïve recent HIV-infections, 49 HIV-positive youth, and 494 high-risk HIV-negative youth. Community engagement plays a vital, often lifesaving role for vulnerable youth, especially in contexts where support services are underutilized and hindered by many structural factors. The five steps outlined here can serve as a guide to effectively recruit and engage youth at risk or living with HIV.

WEPEC157

Navi*gay*te Brooklyn - using online outreach to connect Black and Latino men who have sex with men to PrEP/PEP services in New York City, USA

O. Anene, M. Montgomery MPH, E. Koffler MPH, L. Cambar

CAMBA Inc., HIV Prevention and Navigation Services, Brooklyn, United States

Background: In New York City, Brooklyn had the highest number of HIV diagnoses among the five boroughs in 2016. This may be attributed, in part, to cultural biases, misinformation, and poorer health-seeking behaviors associated with recently migrated, undocumented, and uninsured residents. HIV programs have focused efforts on the hardest to reach populations and have adopted novel outreach strategies, including using social media and dating apps. Funded by the New York City

Department of Health, CAMBA's Navi*gayte* Brooklyn program aims to engage and connect men who have sex with men (MSM) to HIV prevention and care services, via traditional and non-traditional outreach.
Description: Navi*gayte* Brooklyn conducts in-person and online outreach to Black and Latino MSM, providing PrEP/PEP education, linkages to biomedical and behavioral interventions and supportive services. Community influencers are hired to conduct outreach on gay dating/hook up sites. Their profiles designate them as health educators who provide HIV and sexual health information. Through direct messaging, anonymous sexual health assessments are conducted, PrEP/PEP information is provided, and appointments are scheduled.
Lessons learned: Navi*gayte* Brooklyn has been successful at engaging clients via online outreach. From April to December 2017, 20 clients were enrolled into PrEP and PEP services; 16 (80%) were engaged from gay hook up applications. Often clients are seeking non-HIV related services, and HIV services are introduced after successful linkages to food pantry, immigration, or housing programs. Our anonymous assessments indicate MSM in Brooklyn have access to sexual health information, but experience barriers to accessing services, including fear of disclosing sexual behaviors and issues with navigating the healthcare system. Online outreach provides some anonymity, potentially reducing the fear and stigma of discussing sexual and social service needs and of seeking an LGBT health provider.
Conclusions/Next steps: Online outreach has great potential for engaging hard-to-reach populations, by providing information conveniently and privately through users' electronic devices or accounts. Interventions must include strategies to manage barriers in settings where services are available, but access might be low.

WEPEC158

Using social networking in reaching subpopulations of hard-to-reach men who have sex with men in Lagos, Nigeria

C.C. Ifekandu[1], D. Offie[1], E. Shoyemi[1], J. Njab[1], W. Tun[2]
[1]*Population Council, HIV Division, Abuja, Nigeria,* [2]*Population Council, HIV Division, New York, United States*

Background: Due to multiplicity of factors, especially with the introduction of the Same Sex Marriage Prohibition (SSMP) Act, key populations, especially men who have sex with men (MSM), no longer consider physical hotspots as safe spaces. Thus, innovative strategies are needed to reach these highly hard-to-reach MSM. The Elton John AIDS Foundation (EJAF) Project explores innovate ways of reaching MSM through partnership with MSM-friendly public and private healthcare facilities in order to increase HIV positivity yield, HIV testing service (HTS) coverage, and linkage to and retention in HIV treatment.
Methods: Thirty (30) focal persons drawn from various MSM networks in Lagos were trained on how to conduct HTS from October 2016 to May 2017. These persons had responsibilities of recruiting and enrolling MSM into care and treatment. Clients were recruited via the physical hotspots (e.g., bars/clubs) and social media platforms. A cross-sectional analysis of data collected of MSM reached with HTS by focal persons between May and July 2017 were used for this analysis.
Results: A total of 525 MSM were recruited for HIV testing, 32% of whom were recruited through social networking sites (e.g., Badoo, WhatsApp, Grindr, Facebook); the remaining were recruited at physical hotspots. The mean age was 21 years, and 22% had never been tested for HIV within the past 6 months. The positivity rate was 9.6% among all who tested; the positivity yield was 36% among those recruited through social networking sites and 5.4% among those recruited at hotspots. [WT1]
Those recruited through social network were more likely to have paid for sex within the past 6 months (34% versus 28%; p-value) and more likely to have had unprotected anal sex with casual sex partners in the last 3 months (67% versus 51%; p-value) compared to those recruited by other means. Retention in ART treatment was 92% for clients being tracked through social networking versus 64% through the physical approaches.
Conclusions: This analysis shows that risk behaviors are linked to network factors and that risk behaviors are clustered within networks. HIV interventions in Nigeria need to leverage social media for HIV prevention and treatment purposes.

WEPEC159

Finding the men: Lessons on using workplace-based structural interventions targeting uniformed personnel to meet the 90-90-90 targets

A. Watsemba[1], G. Luboobi[1], L. Ayebale[1], J. Hayuni[1], B. Wandera[2], A. Mitchell Le Few[3], R. M Flueckiger[3], M. Lopez[4], E. Tanga[2]
[1]*RTI International, USAID/Uganda HIV and Health Initiatives in Workplaces Activity, Kampala, Uganda,* [2]*World Vision Uganda, USAID/Uganda HIV and Health Initiatives in Workplaces Activity, Kampala, Uganda,* [3]*RTI International, Research Triangle Park, North Carolina, United States,* [4]*World Vision, Inc., Federal Way, WA, United States*

Background: The USAID/Uganda HIV and Health Initiatives in Workplaces Activity (HIWA) endeavors to reduce incidence of HIV among Uganda Police Force (UPF), the Uganda Wildlife Authority (UWA), private security guard (PSG), and hotel employees, and to improve quality of care for those infected and affected. Many of these workers are men deployed in hard-to-reach areas and thus have limited access to HIV services. USAID/HIWA aims to increase availability of, access to, and uptake of comprehensive, high-quality HIV services at the workplace to contribute to achievement of UNAIDS 90-90-90 targets.
Description: To achieve the first 90 target—90% diagnosed—HIWA supports workplace HIV policy development and dissemination, behavior change communication, and targeted workplace HIV testing services at times aligned to work schedules. To achieve the second 90 target of 90% of the diagnosed on antiretroviral therapy (ART), HIWA promotes enabling policies that link HIV-positive people to ART and encourage disclosure of HIV-positive status to supervisors to ensure time off to access HIV treatment. To achieve the third 90 target of 90% of those on ART achieving viral suppression, HIWA supports establishing workplace support groups for HIV-positive employees to encourage adherence to treatment, and a mobile health platform, with a 24-hour hotline.
Lessons learned: The contexts within sectors and workplaces are unique, so interventions must be adapted to the individual needs of the specific workplace. During the first two years, HIWA successfully implemented HIV initiatives in UPF, UWA, PSG, and hotel workplaces to increase access to quality HIV services and improve men's use of HIV services. HIWA identified 1,234 HIV-positive men among hard-to-reach populations and successfully linked them into HIV care and support. HIWA found success through adopting a participatory process where HIV workplace policies were developed with input from partners across sectors.
Conclusions/Next steps: Workplace structural interventions are essential to reach the UNAIDS 90-90-90 targets and strengthen sustainability, which is particularly important as external donor funding for HIV declines. In male-dominated workplaces, these interventions can effectively reach the men who have proven difficult to find in the community setting.

WEPEC160

Sabrang: Reaching the un-reached among MSM and transgender people through a mobile health application

N. Kumar[1], P. Dhall[2]
[1]*MAMTA - Health Institute for Mother and Child, Chronic Diseases, New Delhi, India,* [2]*Varta Trust, Leadership and Management of the Organisation, Kolkata, India*

Background: The national HIV response in India has no focussed online outreach programmes on information provision, stigma reduction, addressing discrimination and services access among MSM and transgender women (adolescents and young adults). The m-health intervention addresses this gap. It consists of Sabrang, an interactive learning mobile application with textual, video-graphical and gamified content on sexuality, gender identity, self-stigma, and STI/HIV/AIDS and legal rights. It includes features of GPS enabled health services and chat with community-friendly health professionals. The intervention is led by MAMTA in partnership with three community groups active in the National Capital Region of India.

Description: A mixed research methodology was undertaken to quantitatively and qualitatively measure the results of the intervention against key indicators among the application users. Cross sectional pre-post study, design with purposive and convenient sampling was used to select respondents among MSM and transgender women aged 15-24 years for the quantitative evaluation. Five focus group discussions with different sub-sections and age groups of the target audiences were conducted. Key informant interviews were conducted with three lead representatives of the partner organisations.
Lessons learned: Knowledge on mode of HIV transmission increased from 62.7% to 78.7% and HIV transmission myths decreased from 51.3% to 34.2%. Users reported receiving useful information on the risk of STI/HIV infection, STI/HIV prevention and treatment, HIV testing and counselling, gender identity, sexuality, self-stigma and legal rights. GPS enabled services access and chat facility were reported to be among most useful features. Around 78% of the users recommended the application to others emphasizing the privacy element of the application.
Conclusions/Next steps: Large sections of MSM and transgender women in India are believed to have moved on to digital media for social and sexual networking. But most sexual health interventions continue with physical outreach. Sabrang experience shows that online interventions with interactive and culturally sensitive content can successfully impact sexual health attitudes, knowledge and health-seeking behaviours, But they must address felt needs around stigma, gender transition and legal aid, avoid text heaviness, and gain the trust of the users around confidentiality concerns.

WEPEC161

Innovative approaches to advancing key populations programming in Ghana despite inauspicious environment

P. Ayamah[1], H. Nagai[2], C. Ohene-Adjei[1], A. K. Nyanor[2], R. Afriyie[1], R. Aperko Sackitey[1]
[1]Ghana AIDS Commission, Technical Services Division, Accra, Ghana, [2]JSI Care Continuum, Accra, Ghana

Background: Ghana, like many other African countries have laws that criminalise KP activities. Besides, the two major religions in Ghana, Christianity (71.2%) and Islam (17.6%) regard homosexuality and sex work as abominable. There exist traditions, cultural values and a vibrant media which are highly averse to KP lifestyles. In spite of these odds, KP interventions in Ghana are yielding remarkable results.
Description: The Ghana AIDS Commission (GAC) initiated a legal audit in 2010 in which a team of experts analysed anti-KP laws in Ghana to identify toeholds which could be leveraged to advance KP interventions. To ensure evidence-based KP programming, in 2011, the first Integrated Bio-Behavioral Surveillance Study (IBBSS) for MSM and FSW were conducted. In the same year, the KP Strategic Plan; and KP Standard Operating Procedures (undergoing revision) were developed. In 2014, the first PLHIV Stigma Index study was conducted. KP competent health workers were trained, deployed and drop-in centres have been established. Helpline Counsellors (HLCs) have been engaged to provide live telephone-based counselling to KPs (FSW & MSM). KP BCC materials were developed, (undergoing revision) and distributed with strict care. In 2016, a new GAC Act was passed which provides for non-discrimination against PLHIV and KPs. There exists a strong collaboration with law-enforcement agencies and the media.
Lessons learned: HIV prevalence among FSW plummeted from 11.1% in 2011 to 7% in 2015. The prevalence among MSM was 17.5% in 2011; current prevalence is to be determined through an ongoing IBBSS. Between April and September 2017, HLCs referred 1,100 KPs for HTS, 430 (39%) of whom tested positive for HIV. 340 (79%) of those who tested positive were initiated on ART. The outcome of the legal audit empowered a strong public health argument for making services available to KP. Effective collaboration with law enforcement agents and the media has resulted in humane enforcement of anti-KP laws and professional reportage.
Conclusions/Next steps: A multi-facetted approach to KP programming helps improve their access to services despite widespread prejudice. Second Ghana Men's Study, PrEP and HIV Self Testing acceptability study are currently underway - all in furtherance of KP programming and the national HIV response.

WEPEC162

Casting a broader net: Increasing HIV case-finding among key populations using performance-based incentives and social networks in Cote d'Ivoire

T. Lillie[1], D. Kamali[2], R. Prakash[3], J. Dje[2], N. Persaud[1]
[1]Family Health International 360, Washington, DC, United States, [2]Family Health International 360, Abidjan, Cote D'Ivoire, [3]Karnataka Health Promotion Trust (KHPT), Bengaluru, India

Background: Identifying people living with HIV, and linking them to treatment is critical to controlling the epidemic. USAID- and PEPFAR-supported and FHI 360-led LINKAGES/Cote d'Ivoire project implemented the enhanced peer outreach approach (EPOA) to expand the delivery of HIV services to female sex workers (FSWs) and men who have sex with men (MSM) to engage those not previously reached by the project. The EPOA used incentives and social networks to improve HIV case-finding.
Description: The EPOA was implemented among FSWs in 14 communes and MSM in eight communes over five weeks (JuneJuly 2017). Eighty-nine peer outreach workers (POWs) (73 FSWs, 16 MSM) were trained within three community-based organizations. Three hundred and fifty-six peer mobilizers (PMs) were selected, and each mobilizer was given four or more coupons to distribute. Each POW and PM received $1-3 USG per successful recruitment, HIV test, or link to treatment. Programmatic data were analyzed to review newly registered KPs, testing, HIV case-finding, treatment initiation, and social network dynamics.
Lessons learned: A total of 18,796 coupons (15,524, FSWs; 3,272, MSM) were distributed and 3,476 FSWs and 744 MSM (22.3%, FSWs; 22.7%, MSM) were reached and tested. Ninety percent of those tested were new to the program, and 92% of individuals were recruited through PMs. The average network size for FSWs was 7.4 and MSM was 28.3. FSW PMs recruited outside of their age group whereas MSM recruited within the same age group.
Of those tested, 194 (5.6%) FSWs and 110 (14.2%) MSM were newly diagnosed with HIV. Of those tested positive, 149 (77%) FSW and 95 (87%) MSM were successfully linked to ART. By comparison, 5,840 FSWs and 1,539 MSM were tested (62% and 67% of the total), but only 106 FSWs (1.81%) and 93 MSM (6.04%) were diagnosed HIV positive during traditional outreach. For both FSWs and MSM, HIV case-finding was significantly higher during EPOA than during routine outreach ($p < 0.01$).
Conclusions/Next steps: EPOA was successful in recruiting new KP individuals and increasing HIV case-finding. In future implementation, findings can be used to improve targeting to ensure that KPs receive testing and treatment services.

WEPEC163

Project moxie: A pilot-study of video counseling and home-based HIV testing for transgender youth

R. Stephenson[1], S. Sullivan[2], E. Riley[2]
[1]University of Michigan School of Nursing, Health Behavior and Biological Sciences, Ann Arbor, United States, [2]University of Michigan, Center for Sexuality and Health Disparities, Ann Arbor, United States

Background: Transgender youth experience some of the highest HIV rates in the United States, and experience a number of structural barriers that may limit their engagement in HIV testing, prevention and care. Telehealth may provide an opportunity for transgender youth to experience HIV testing in their own home. This project aims to examine whether the addition of counseling provided via telehealth coupled with home-based HIV testing can create gains in routine HIV testing among transgender youth.
Methods: Project Moxie involves a pilot randomized control trial (RCT) of 110 transgender- identified youth ages 15-24, who are randomized on to a 1:1 basis to a control or intervention arm.Participants are recruited online via social media from across the US. Participants in the control arm are sent a home HIV testing kit. Participants in the intervention arm receive a home HIV testing kit plus a video-chat counseling session with a remotely located counselor. The video-chat session provides pre and post prevention counseling and examines barriers to future HIV testing.

Motivational interviewing techniques are used to problem solve barriers to future HIV testing. The pilot study aimed to examine acceptability, willingness and safety of the intervention.
Results: 110 transgender youth aged 15-24 are enrolled, with study assessments at baseline, 3 and 6 months. Retention was high, over 90% at all study assessments. All participants ordered HIV testing kits and all were successfully delivered. Participants reported high levels of satisfaction (>95%) with the telehealth intervention, willingness to regularly repeat the intervention (92%) and willingness to recommend the intervention to others (91%). No dropped calls were experienced during the video-chat sessions. A small number of participants selected to have kits delivered to addresses other than their familial home, and conducted the video-chat sessions from other locations.
Conclusions: A low bandwidth, HIPPA compliant video-chat software offers a unique opportunity to provide counseling coupled with home-based HIV testing for transgender youth. Youth reacted favorably to the ease of the telehealth intervention. Telehealth may provide an opportunity not only to provide counseling for those testing at home, but to also provide the behavioral skills to encourage future participation in HIV prevention and care.

WEPEC164

What characteristics predict whether intervention participants successfully recruit previously undiagnosed HIV-positives from their risk networks?

L.D. Williams[1], A. Korobchuk[2], P. Smyrnov[2], G. Nikolopoulos[3], D. Paraskevis[4], J. Schneider[5], S.R. Friedman[1]
[1]National Development and Research Institutes, Institute for Infectious Disease Research, New York, United States, [2]Alliance for Public Health, Kyiv, Ukraine, [3]University of Cyprus, Medical School, Nicosia, Cyprus, [4]National and Kapodistrian University of Athens, Medical School - Department of Hygiene, Epidemiology, and Medical Statistics, Athens, Greece, [5]University of Chicago Medical School, Department of Medicine and Center for HIV Elimination, Chicago, United States

Background: Although case-finding interventions using social and risk networks show great promise for diagnosing the HIV-unaware and linking them to care (Smyrnov et al., in press), such interventions can be limited by the extent to which participants are willing and able to recruit their network members. Participant characteristics predicting successful recruitment of targeted network members, if identified, might be leveraged to modify or refine such interventions and improve their efficacy.
Methods: The TRIP project in Odessa, Ukraine recruited and tested 1271 (injection and sex) risk network members (79.2% male; 44.7% reporting injection) of 42 HIV-positive "seeds" (i.e., initial participants). Networks were recruited two "Steps" (i.e., network links) from each seed. 183 network members were newly diagnosed as HIV-positive (NDP) based on a combination of self-report and medical records. These NDPs were recruited by 75 participants (seeds and Step 1 network members). Exploratory bivariate logistic regression analyses were conducted predicting successful recruitment of an NDP from participant characteristics.
Results: Seeds and Step 1 network members were significantly more likely to recruit NDPs to TRIP if they reported injecting drugs (O.R.=2.51; p< .0001); were recently infected (O.R.=2.95; p=.001); or were themselves NDP (O.R.=2.25; p=.004).
HIV-positive participants overall were more likely than HIV-negative network members to recruit NDPs (O.R.=2.35; p=.001), but HIV-positive participants who were neither recently infected nor NDP were not significantly more likely than HIV-negative network members to recruit NDP.
Participants reporting exchange sex (O.R.=9.32; p=.07) and those who reported always using condoms (O.R.=1.81; p=.077) were marginally more likely to recruit NDPs. Homelessness, employment status, drug treatment participation, education level, number of sexual partners, syringe sharing, gender, and age were not significant predictors of NDP recruitment.
Participants who reported more HIV-related stigma, both in terms of personally experiencing stigmatizing events (O.R.=0.12; p=.022) and in terms of observing stigmatizing attitudes of friends and family (O.R.=0.36; p=.043), were less likely to recruit NDP.
Conclusions: Findings suggest that case-finding efforts should prioritize high-risk individuals (NDP, recently-infected, PWID, sex workers) and their networks for locating undiagnosed HIV-positives. Future work should test this in other settings and should develop on-site, pre-network-recruitment stigma-reducing interventions to address stigma's negative effects on recruiting.

WEPEC165

A pilot randomized, controlled trial of financial incentives and commitment contracts to promote HIV retesting among at-risk, HIV-uninfected adults in rural Uganda

G. Chamie[1], A. Ndyabakira[2], D. Emperador[1], K. Marson[1], M. Kamya[3], D. Havlir[1], D. Kwarisiima[4], H. Thirumurthy[5]
[1]University of California, San Francisco, San Francisco, United States, [2]Makerere University-University of California, San Francisco Research Collaboration, Mbarara, Uganda, [3]Makerere University College of Health Sciences, Kampala, Uganda, [4]Makerere University-University of California, San Francisco Research Collaboration, Kampala, Uganda, [5]University of Pennsylvania, Philadelphia, United States

Background: Retesting for HIV is critical to identify newly infected persons and reinforce prevention services among at-risk adults. The Uganda Ministry of Health recommends retesting key populations every three months. However, optimal strategies to promote retesting are unclear. We sought to test incentive strategies to promote retesting among at-risk, HIV-uninfected adults in rural Uganda.
Methods: We distributed recruitment cards at venues frequented by adults considered at-risk for HIV, including bars and transport hubs. Each card could be exchanged for a free, clinic-based health evaluation, with a cash incentive (~US$4) for one-time HIV testing. Adults who tested HIV-negative were offered enrollment in a randomized trial comparing incentives for retesting 2-3 months later. We randomized participants to three groups (1:1:3):
a) no incentive;
b) standard cash incentive (~US$4); and
c) commitment contract, in which participants could voluntarily make a deposit that would be returned with added interest (totaling ~US$4) upon retesting.
The contract group had low- and high-value deposit arms (~US$0.70 or $1.40). Outcomes included feasibility (i.e. % of contract group who made a deposit), HIV retesting, and HIV seroconversion.
Results: Of 164 recruitment cards distributed, 151 (92%) adults presented cards and tested for HIV. Median age was 31 years (IQR: 25-37), 112 (74%) were men, and 23 (15%) tested HIV-positive. Of 128 HIV-negative adults, 123 (96%) enrolled and were randomized: 74 (60%) to commitment contracts, 25 (20%) to standard incentives, and 24 (20%) to no incentive. Of contract participants, 93% made a deposit and 7% declined (**Table**). Participant characteristics and HIV retesting uptake are shown (**Table**). Overall, 76% retested: uptake was highest in the standard incentive group (88%) and lowest in high-value contract (69%) and no incentive (70%) groups. Among contract participants who made a deposit, retesting was 81% in low- and 76% in high-value groups. No seroconversions were observed.

	No Incentive (Control)	Standard Incentive	Commitment Contract: Low-value deposit	Commitment Contract: High-value deposit	Total
Number enrolled	24	25	38	36	123
Median age (IQR)	30 (28-36)	30 (25-37)	32 (25-37)	31 (25-35)	31 (25-37)
Male, n (%)	19 (79)	17 (68)	31 (82)	24 (67)	92 (75)
Married, n (%)	18 (75)	18 (72)	28 (74)	27 (75)	91 (74)
Self-reported earnings in 1 week in USD, median (IQR)	$14 (11-29)	$14 (9-23)	$14 (7-20)	$14 (6-20)	$14 (7-20)
Successful deposits, n (%)	N/A	N/A	36 (95)	33 (92)	69/74 (93)
Reported willing to deposit, n (%)	23 (96)	23 (92)	N/A	N/A	46/49 (94)
HIV Retesting Uptake	17 (70.8)	22 (88.0)	29 (76.3)	25 (69.4)	93 (75.6)

[Table. Characteristics and HIV retesting uptake of at-risk, HIV-uninfected adults enrolled in a randomized trial of incentive strategies to promote retesting]

Conclusions: In a pilot, randomized controlled trial of incentive strategies to promote HIV retesting among at-risk adults in Uganda, randomization to commitment contracts was feasible and had high acceptability (93%). Our findings suggest use of incentives for HIV retesting is feasible and merits further comparison in a larger trial.

WEPEC166

Can online interventions enhance HIV case finding and linkages to care? Comparing offline and online monitoring data from a combination prevention program with MSM and transgender women in Central Ameria

A.J. Cabrera Oliva, S. Lungo, C. Castellan, C. Palma
Pan American Social Marketing Organization, Guatemala City, Guatemala

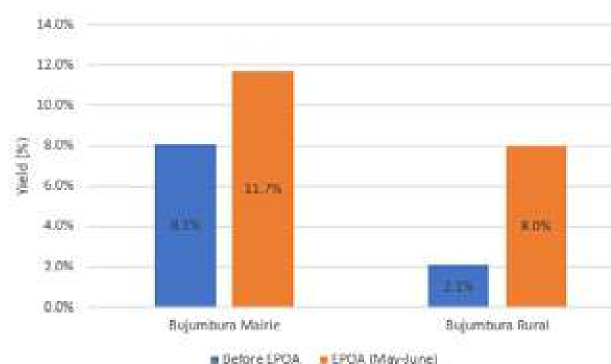
Background: Under the USAID Combination Prevention Program for HIV in Guatemala, El Salvador, Honduras and Panama, the Pan American Social Marketing Organization (PASMO) implements offline and online interventions to increase HIV testing services (HTS) uptake among at-risk MSM and transgender women (TW), and link reactive cases to care. Offline interventions use an adapted respondent driven sampling recruitment model with "recruiters" (peers who refer individuals in their social network), and "seeds" (reactive individuals who refer partners and others in their social network). Online recruitment is performed by PASMO "cyber-educators" trained to use social media platforms (i.e. Facebook and WhatsApp) to generate demand for and refer to HTS among at-risk MSM and TW with emphasis on "hidden" populations. HTS is performed by PASMO counselors, laboratory technicians, or private laboratories.
Methods: PASMO uses a Unique Identifier Code (UIC) to track program participants from initial engagement through entry of care. The UIC is assigned by the counselor performing HTS or the cyber-educator and the information is documented in print monitoring forms. Print or online vouchers are used to refer to HTS. On a monthly basis, PASMO enters the monitoring data into its management information system, allowing it to track the number of individuals reached, percentage of individuals who receive HTS, yield (number of reactive cases identified per number of tests), and percentage linked to care.
Results: From October 2016 to September 2017, PASMO reached a total of 10,343 MSM and TW across the four countries through offline interventions, of which 10,187 (98%) received HTS, 406 were reactive (yield of 1 of every 26), and 52% were linked to care. When comparing to those reached through online interventions alone, PASMO reached 6,219 individuals, of which 2,096 (34%) received HTC, 152 were reactive (yield of 1 of every 13 tests), and 64% were linked to care.
Conclusions: PASMO's offline and online strategies contribute to HIV case finding among MSM and TW in Central America. Although online interventions reach a smaller number of individuals and test a smaller percentage, a better yield is produced, and a greater proportion of individuals are linked to care, proving an effective intervention for concentrated epidemics.

WEPEC167

The domino effect: Tapping into female sex workers' social networks to increase demand and use of HIV services from previously unengaged women in Burundi

T. Lillie[1], D. Gashobotse[2], T. Niyongabo[2], D. Sakubu[2], G. Kamariza[2], V. Ranebennur[3], M. Hamdallah[1], N. Persaud[1]
[1]*Family Health International 360, Washington, DC, United States,* [2]*Family Health International 360, Bujumbura, Burundi,* [3]*Family Health International 360, New Delhi, India*

Background: HIV case finding is the cornerstone to treatment initiation yet many programs struggle to engage populations not already reached through existing services. The enhanced peer outreach approach (EPOA) complements traditional outreach by incorporating performance based incentives linked to program milestones and working through untapped social networks to engage unidentified, hard-to-reach, and high-risk key population (KP) members — including female sex workers (FSWs) — for HIV services. The goal is to increase HIV case finding, link HIV-positive KP members to treatment, and connect HIV-negative KP members with services that will help them remain negative.
Description: Through the USAID- and PEPFAR-funded LINKAGES project, EPOA was implemented for nine weeks in two districts in Burundi—Bujumbura Mairie and Bujumbura Rural. Seventy-five peer outreach workers (POW) were trained in EPOA through two community-based organizations and provided with four or more coupons for free HIV testing. They distributed the coupons to peers, and in turn asked their peers to distribute the coupons to other peers in each of their networks. If friends or acquaintances of those peers got tested for HIV, both the peer and POW received an in-kind incentive.
Lessons learned: In both districts, a total of 2,451 coupons were distributed. A total of 929 (37.9 percent) FSWs were tested, 100 (10.7 percent) were found positive, and 90 (90 percent) were initiated on treatment. The average HIV case-finding rate was 11 percent, compared to the 5 percent HIV case finding found in the three months before the introduction of EPOA. Compared to KPs tested during routine programming, those who were tested through EPOA were 2.5 times (95 percent CI: 1.97-3.25; $p < 0.01$) more likely to test HIV positive. There were no significant differences in HIV case-finding rates between Bujumbura Marie and Bujumbura Rural (11.7 percent [84/717] vs. 8.0 percent [16/212]; p=0.09). See Figure 1.



[Figure 1. Burundi, HIV-positive case finding before and after EPOA]

Conclusions/Next steps: The preliminary data demonstrate the potential effectiveness of EPOA in identifying HIV-positive KPs and initiating them on treatment. LINKAGES/Burundi is scaling up EPOA in the other provinces where it operates. More widespread implementation of EPOA with high-risk populations not currently engaged in HIV programs could accelerate progress towards the UNAIDS' 90-90-90 goals.

WEPEC168

Applying innovative methods to improve HIV testing uptake and case finding among men who have sex with men in Mali

S. Garangue Souko[1], T. Madani Moctar Saidou[2], A. Lambert[3], A. Ag Altini[1], E. Papworth[4], D. Bore[2], D. Mohamed Amadou[5], F. Sidibe[1], M. Hamdallah[3], E. Cooper[3], A. Dit Agali Wele[5], H. Rodriguez Sherman[3], S. Cisse[6], J. Bashi Bagendabanga[2]
[1]*SOUTOURA, Bamako, Mali,* [2]*FHI360, LINKAGES, Bamako, Mali,* [3]*FHI360, LINKAGES, Washingtown, United States,* [4]*4Avery Franklin Consulting llc, Atlanta, United States,* [5]*CSLS, Bamako, Mali,* [6]*USAID, Bamako, Mali*

Background: In Mali, the USAID- and PEPFAR-supported LINKAGES project provides HIV prevention, care, and treatment services to key populations (KP). Social stigma, discrimination, and violence against men who have sex with men (MSM) constitute major barriers to accessing services. Due to challenges reaching MSM during the first six months of the project, a reinforced MSM outreach approach was designed to increase use of HIV prevention services.
Description: In July 2017, the USAID and PEPFAR supported LINKAGES project, through the local NGO Soutoura, and in collaboration with the government, implemented an innovative outreach approach to reinforce the MSM program in four regions: Bamako, Kayes, Segou, and Sikasso.

The reinforced approach consisted of training in and implementation of: i) community-based programming integrating an MSM environment assessment; ii) HIV risk assessment; iii) sub-group MSM engagement; and iv) an peer networking approach. Aggregate monthly data of MSM reached and tested for HIV by age group and location were analyzed for the pre-intervention period (January-June 2017) and post-intervention period (July-December 2017). The younger sub-group was defined as MSM under 24 years. A chi-square test was used to compare the HIV case finding between periods.

Lessons learned: During the intervention period, the project experienced a 30% increase in MSM reached compared to the pre-intervention period, mainly due to increases reaching older MSM (135%). However, HIV screening in the two age groups was mixed; older MSM reached were less likely to be screened post-intervention while younger MSM were more likely to be screened post-intervention. Among those screened, HIV case finding increased from pre- to post-intervention (2% to 7%, p=0.001), with similar results across age groups.

Conclusions/Next steps: The increase in HIV case finding indicates that the reinforced outreach approach was effective at engaging MSM at higher risk for HIV. MSM sub-group engagement of older MSM was also successful, as was HIV testing for younger MSM. LINKAGES will continue to implement this approach in Mali, examine gaps, such as barriers to testing in older MSM, and find potential solutions. This approach may be feasible in other African countries where MSM experience stigma and discrimination.

		Intervention		
	Before	(Qpr period)	After	(Qpo period)
MSM screened for HIV	397/758	52%	577/983	59%
MSM HIV+*	8	2%	38	7%
Younger MSM screened for HIV	223/587	38%	393/581	68%
Older MSM screened for HIV	174/171	102%	184/402	46%
Younger MSM HIV+*	5	2%	26	7%
Older MSM HIV+*	3	2%	12	7%
*p<0.05

[Impact of MSM outreach intervention on HIV prevention, testing, and case finding among MSM in Mali]

WEPEC169

Quadrupling HIV case finding: Social media improves HIV testing and HIV case finding among key populations in Myanmar

K. Gustafson[1], M.M. Lwin[1], H. Ko Ko[1], T.N. Oo[1], R. Kelly[2]
[1]Population Services International (PSI) Myanmar, Yangon, Myanmar, [2]USAID Burma, Yangon, Myanmar

Background: At Population Services International's TOP clinics serving key populations, there was consistently high HIV yield among peers using social media. Myanmar experienced a digital technology leapfrog. From 2013 to 2017, the cost of SIM cards dropped from $1,000 to $1.50. By 2017, there were 14 million new social media users and 14 million new internet users in Myanmar -- 70% of whom accessed the internet through mobile phones. Sweeping policy changes and rapid introduction of smart phones presented an unprecedented opportunity to reach key populations in Myanmar.

Description: In January 2017, PSI invested in a dedicated social media team at TOP to responded to private messages (on Facebook, Line, Beetalk, GRINDR and Viber), fielded hotline calls and offered online referral vouchers, which allowed us to track each conversation from online messaging to arrival at the clinic. Patients show their online referral vouchers at registration at the clinic and are eligible to receive a $1 incentive. TOP also posted daily to its separate MSM-targeted and FSW-targeted Facebook pages, private Facebook groups, and Instagram account. TOP also supplied phones to peer outreach workers, enabling them to hold private outreach conversations through Viber, overcoming a common barrier for sex workers to learning about services.

Lessons learned: Before the social media team, yields from clients recruited through the Facebook page were high - 21% in Yangon - but total numbers of clients coming from the site were still low (121 tested, 26 HIV+). After establishing the social media team with support from USAID and PEPFAR, the total number of clients reporting to TOP centers for HIV testing quadrupled from 121 to 589. Yield remained high at 19%. Rates of ART enrollment among these clients (93%) were similar to the high rates among those reached through traditional outreach (90%). TOP clients often send in photographs of opportunistic infections by private message, suggesting there are still substantial numbers of PLHIV among Myanmar's hidden populations who have progressed to AIDS and are not on ART.

Conclusions/Next steps: Active engagement with social media for case finding has produced significant increases in HIV testing yields.

WEPEC170

The role of social media in sexual connectivity among men who have sex with men (MSM) in Kenya & South Africa: Potential for innovative online sexual health promotion interventions

A. Bourne[1], S. Tenza[2], A. Smith[3], J. Liku[4], K. Moodley[2], A. Tukai[4], R. Kabuti[4], E. Fearon[5], W. Nutland[5], P. Weatherburn[5], J. Kimani[4,6], T. Palenee-Phillips[2]
[1]La Trobe University, Australian Research Centre in Sex, Health & Society, Melbourne, Australia, [2]Wits Reproductive Health Institute, Johannesburg, South Africa, [3]University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom, [4]Partners for Health & Development, Nairobi, Kenya, [5]London School of Hygiene & Tropical Medicine, Department of Social & Environmental Health Research, London, United Kingdom, [6]University of Manitoba, Nairobi, Kenya

Background: MSM in both Kenya and South Africa are at significant risk for HIV, other STIs and mental ill-health. Social stigma and, in Kenya, political hostility, has created significant barriers to the provision of traditional health promotion interventions to MSM. With the rapid escalation of smartphone use across both countries, new avenues for intervention may exist. This study sought to understand the challenges and opportunities that online platforms present for health promotion with MSM.

Methods: Between June 2016 and July 2017, in-depth interviews were carried out with 60 MSM (aged 19-56) equally recruited via purposive sampling from Nairobi and Johannesburg. Semi-structured interviews examined if and how men used social media (including generic and gay-specific sites/apps) for online interaction with other MSM, including the mechanisms, benefits and challenges of use.

Results: Thirteen men were living with HIV and 31 had not tested within the previous 6 months. The majority (n=54) of participants across the age spectrum used social media on a regular basis to engage with other MSM, most frequently Facebook and WhatsApp groups. Both platforms were used for sexual facilitation purposes in manner less common in high-income settings, allowing for the exchange of sexual material, access to sex workers or clients, and the organisation of one-on-one/group sex. Although not risk free, social media platforms afforded a safer environment in which to meet other MSM, helping to build confidence in accessing MSM safe spaces in person (e.g. bars or community-based services) and enabled risk-management conversations ahead of time. Careful management of online identities was required so as not to inadvertently disclose sexual orientation or lose control of identifying images, such a profile photos.

Conclusions: Social and sexual media spaces provide an opportunity for MSM in Kenya and South Africa to meet, make friends and facilitate sex. There is significant scope for the delivery of HIV prevention and care interventions for MSM in these countries via social media. Promoting techniques for safer sexual connections in social media should therefore be prioritised. Sufficient resources should also be directed towards delivering and evaluating high quality online peer-based education and healthcare referrals.

WEPEC171

Assessment to determine reasons for repeat testing amongst key populations and the general population

O. Fajemisin
Society for Family Health, Research, Measurement and Results, Abuja, Nigeria

Background: The burden of HIV in Nigeria is high, especially amongst key populations (KPs). Nigeria seeks to identify at least 90% of the persons who are HIV positive these identified persons on treatment. The SFH supports this process amongst KPs and the general population. Analysis of the program data revealed a percentage of persons who identified as positive had known previously. This study aims to determine the factors leading to repeat testing amongst persons who knew their HIV status.
Methods: The assessment used mixed method approach. All data generated during programming in the year 2017 available at the time of the study was analyzed. Knowledge gained from the assessment of existing data was used to carry out guided interviews with the implementers in focal states.
Results: As many as 40% of PWID, 59% of FSW, 50% of MSM and 20% of the general population who tested positive for HIV previously knew their HIV status in the first semester of 2017. While this decreased slightly in the second semester of the year. It remained high. This was attributed to the fact that refusal to test for HIV by KPS can be looked on by their peers as evidence of the fact that they are known positives. Retesting was therefore a means to conceal a known HIV status. Beyond this, some were in denial and sought a second opinion. Others were checking to see if "miracle cures" (had occurred.
Mot all persons with a known status had commenced HIV care. Retesting, therefore, offered the opportunity to reach these persons who have yet commenced HIV care/ART or who were "lost to follow-up".
Conclusions: Effort must be made to ensure that all identified HIV positive KPs complete their referral within a week. Counselling and follow-up of persons who already know their status but are **not** on treatment should mirror to reflect that of those persons who are newly identified. Counsellor Testers may need further training to overcome these new issues emerging especially amongst key populations.

WEPEC172

PrEP-plus: An unanticipated outcome of a program for pre-exposure prophylaxis

W. Valenti[1], A. Zuppelli[1], M. Lecker[1], D. Hall[2]
[1]Trillium Health, Rochester, United States, [2]MOCHA Center, Rochester, United States

Background: Trillium Health (TH) is a community health center in Rochester, NY USA, a medium-sized city. Founded in response to the AIDS epidemic (1989), TH offers multidisciplinary primary/specialty care for HIV, HCV, STIs, and LGBTQ health.
Description: TH's PrEP program began in 2014 with print advertising/ marketing, and outreach at community events, bars/clubs in response to New York State's End the HIV Epidemic by 2020 inititiative (EtE), similar to global 90/90/90. 550 patients are enrolled. Staff includes 4 peer "PrEP specialists," and insurance navigator. An outreach specialist piloted „digital outreach" (DO) using smartphone "hookup" apps for MSM. Recently, TH merged with The MOCHA Centers for LGBTQ people of color where programs focus on linkage to care (PrEP, PEP, STI screening/ treatment, care management, and primary care (PC). A support group for transgender people of color has also linked people to care. PrEP-Plus includes a Clinical Pharmacist who sees patients, orders labs and medications to improve access. Nursing staff obtains STI screening specimens. Our in-house pharmacy offers 24/7 PEP.
Lessons learned:
1. PrEP is a gateway to primary care; 60% of PrEP patients receive PC with TH.
2. DO is 3 times more effective than physical outreach at linking people to care.
3. Support groups link people to care.
4. PrEP-Plus has identified acute HIV infection and established HIV infection candidates for Rapid Start Antiretrovirals (RSA).
5. Peer PrEP specialists (mean age 24) relate well to patients, perform rapid HIV testing, patient sexual history taking, identify barriers to care and, with supervision, screen for acute HIV infection and identify PEP candidates.
Conclusions/Next steps: PrEP-Plus is critical to EtE. PrEP programs can develop into "PrEP-Plus" and provide opportunities beyond traditional HIV prevention. We have used our experience to plan for both program and for PrEP target enrollment using an evidence-based ratio of 13 people taking PrEP to prevent 1 HIV infection. Planning includes extending DO to The MOCHA Center, a PrEP support group for people of color, aggressive care management services to ensure adherence to treatment and to address housing, transportation and other social determinants of health, and a standardized approach to RSA among all TH providers.

Innovative HIV testing strategies (peer-led testing, peer-mediated testing, self-testing with and without online/offline support, use of fourth generation and recency assays)

WEPEC173

Utilisation of HIV self-testing among rural gay and bisexual men and ethnic minorities in New Zealand

J.G. Rich, G. Agbozo, J. Beaumont, J. Myers
New Zealand AIDS Foundation, Auckland, New Zealand

Background: HIV transmission in New Zealand is concentrated among gay, bisexual, and men who have sex with men (GBM) and migrant communities. In 2016, GBM accounted for 89% of HIV notifications where infection was considered locally acquired. Past HIV prevention efforts have kept HIV prevalence, and incidence low in New Zealand, compared to other countries. Yet, the rise of new infections is indicative of the need for improved prevention strategies.
HIV self-testing (HST) was identified as a tool to address barriers to testing for typically hard to reach GBM, including indigenous Māori and other ethnic minorities, those in rural areas, and African migrants. An ongoing HST pilot project, consisting of 500 HST kits, seeks to study the utilization, acceptability, and pre and post test health seeking behaviours.
Description: The HST service was promoted to GBM through community events and social media. Individuals searching for the nearest HIV testing service on the NZAF website, are shown HST as an option.
Clients are asked to verify order details using a unique code via SMS. The shipped order contains an Oraquick Advance Rapid Test, printed instructions, educational materials, and links to an instructional video. During the order process an option is provided for additional telephone support. Two SMS reminders to report results are sent to clients. If no results are reported at 28-days after shipment, a peer educator attempts to contact the client.
Lessons learned: The uptake of the service among target groups, and HIV positivity rate, compared favourably with rapid HIV tests conducted in community settings.

	HIV self-test kits shipped by NZAF between 1 Dec 2017 and 31 Jan 2018 (n=126)	Rapid HIV tests completed at NZAF community centres 1 Oct - 21 Dec 2017 (n=1089)
% clients GBM	86%	83%
% GBM clients indigenous Māori	9.9%	4.5%
% GBM clients Pacific Islander	4.5%	2.3%
% clients African	7.1%	1.3%
% clients outside Auckland, Wellington or Christchurch	54%	1.4%
% GBM reporting non-recent testing (never or not in last 12 months)	90%	34%
# preliminary positive results	2 (both linked to care)	2 (1 linked to care)
Positivity rate (positives per 1000 tests)	15.9	1.8

[HIV self-testing service utilisation, compared with testing in community settings]

Tuesday 24 July

Wednesday 25 July

Thursday 26 July

Friday 27 July

Late Breaker Abstracts

Publication Only Abstracts

Author Index

Conclusions/Next steps: Thus far, HST is increasing utilisation of HIV testing among typically hard to reach GBM in New Zealand. Full results will be available by June 2018 with recommendations on whether to scale-up this strategy.

WEPEC174

Understanding who accepts and who is reached through secondary distribution of HIV self-tests in a cluster-randomised trial of door-to-door offer of HIVST nested in four HPTN071 (PopART) communities in Zambia

B. Hensen[1], A. Schaap[1,2], C. Mulubwa[2], K. Shanaube[2], S. Floyd[1], M. Phiri[2], V. Bond[1,2], B. Chiti[2], M. Simwinga[2], A. Mwinga[2], H. Ayles[1,2], on behalf of the HPTN 071 (PopART) Study Team
[1]*London School of Hygiene and Tropical Medicine, London, United Kingdom,* [2]*Zambart, Lusaka, Zambia*

Background: In sub-Saharan Africa, men are harder to reach with HIV-testing services (HTS) than women. HIV self-testing (HIVST) and secondary distribution of HIVST are strategies that may increase men's HTS uptake. Measuring HIVST outcomes through secondary distribution is challenging. In a cluster-randomised trial of door-to-door offer of HIVST as an option for HTS, lay counsellors also offered HIVST for secondary distribution to absent partners. We describe characteristics of individuals accepting HIVST for their partner and of individuals for whom a secondary distribution HIVST result was recorded.

Methods: This study was nested within a community-randomised trial of a universal test-and-treat intervention (HPTN071(PopART)). Sixty-six zones in four PopART communities were randomized to the HIVST intervention or PopART standard-of-care. In HIVST intervention clusters, lay counsellors offered individuals choosing to test the option of HIVST or finger-prick HIV-testing. Individuals aged ≥18-years whose partner was absent were offered HIVST for this partner. We describe characteristics of individuals accepting a secondary distribution HIVST and of the individuals for whom a secondary distribution HIVST result was recorded. In this abstract, data on use and results of secondary distribution HIVST are reported by the distributor.

Table. Characteristics of individuals accepting an HIVST for secondary distribution and those reported to have used a secondary distribution HIVST

Characteristics of index client who accepted HIVST for secondary distribution (N=822)			
		%	n
Sex	Male	10.6	87
	Female	89.4	735
Age	<30	53.5	440
	30+	46.5	382
Previously resident in the in same zone*	No	34.7	285
	Yes	65.3	537
HIV status as reported to lay counsellor	Never self-reported HIV+	97.9	805
	Ever self-reported HIV-positive	2.1	17
Accepted HTS among individuals eligible for HTS (not self-reported HIV-positive; n=805)	No	8.2	66
	Yes - finger prick only (no HIVST)	17.0	137
	Yes - HIVST (either supervised or unsupervised)	74.8	602
Characteristics of individuals for whom a secondary distibution HIVST result was reported (N=323)			
		%	n
Sex	Male	87.6	283
	Female	12.4	40
Age	<30	33.4	108
	30+	66.6	215
Previously resident in the community*	No	38.7	125
	Yes	61.3	198
Participation in previous rounds (round 1 (R1); round 2 (R2)) of PopART service delivery	Resident in R1 and R2 of PopART, but did not consent to participate in R1 or R2	8.7	28
	Resident in R2 (but not R1) of PopART, but did not consent to participate in R2	14.9	48
	Participated in PopART in R1 and/or R2, and self-reported HIV+ status	1.6	5
	Participated in R1 and/or R2 of PopART, and tested HIV-negative with lay counsellor	26.0	84
	Participated in R1 and/or R2 of PopART, but declined HIV testing offer from lay counsellor	10.2	33
	Was not resident in the zone in R2, or aged ≤15 at the time of R2	38.7	125
Result of HIVST as reported by partner (distributor of HIVST)	Non-reactive	93.5	302
	Reactive	6.5	21

* PopART delivers services in rounds of service delivery, the current study is a third round of service delivery. Before this third round, there were rounds 1 and 2 of service delivery

[Characteristics of individuals accepting an HIVST for secondary distribution and those reported to have used a secondary distribution HIVST]

Results: In HIVST clusters, 9.0% (n=822) of 9,105 individuals aged ≥18-years seen by lay counsellors accepted a secondary distribution HIVST (Table). 89.4% (n=735/822) were female and 2.1% (n=17/822) self-reported their HIV-positive status. Half (n=401/822; 48.8%) reported that their partner used the distributed HIVST. Among the 3,105 individuals absent at a first household visit, results of secondary distribution HIVST were recorded for 10.4% (n=323); 87.6% (n=283/323) were male, 66.6% (n=215/323) were aged ≥30. 38.7% (n=125) had not previously been seen in the PopART intervention as they had only recently become resident, 8.7% (n=28) were resident but had not previously participated in PopART; 10.2% (n=33) previously declined an offer of HTS.

Conclusions: In this trial, relatively few HIVST were distributed for secondary use. About half of secondary distribution HIVST were reportedly unused by study end-date. Secondary distribution reached men, and individuals who previously declined to participate in PopART or an offer of HTS. Targeted secondary distribution of HIVST could be considered in settings where men are harder-to-reach with HTS.

WEPEC175

More than just a testing service: Evolution of a peer-led rapid HIV and STI testing service in response to shifting community needs

D. Leitinger[1,2], K. Ryan[2,3], P. Locke[1], K. Burgess[1], A. Pedrana[2,3,4], M. Stoové[2,3]
[1]*Victorian AIDS Council, Services, Melbourne, Australia,* [2]*Burnet Institute, Disease Elimination, Melbourne, Australia,* [3]*Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia,* [4]*Harvard T.H. Chan School of Public Health, Department of Nutrition, Cambridge, United States*

Background: PRONTO! opened in August 2013 as Australia's first shop-front and peer-led community-based rapid HIV testing service for gay, bisexual and other men who have sex with men (GBM) in the context of a resurgent HIV epidemic driven by undiagnosed infection. While initially offering standalone peer-delivered HIV testing to overcome structural and stigma-related barriers to frequent testing, broader aims emerged in response to community needs. These included creating a safe space supporting entry into regular sexual health testing and knowledge transfer, particularly for younger GBM, providing comprehensive STI testing, becoming a major part of PrEP expansion and supporting the creation of a dedicated gender diverse health service.

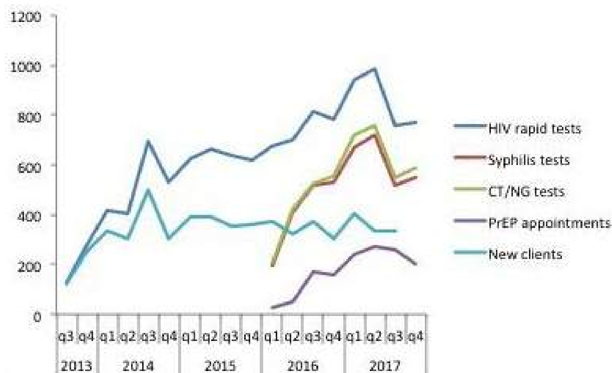
Description: PRONTO!'s evolution is detailed in Table 1 and service utilisation summarised in Figure 1. Developments were informed and supported by a mixed-methods evaluation and a governance structure including local government (responsible for funding), evaluators, reference laboratory experts, peak community HIV organisations and all major local GBM-focussed sexual health services.

Lessons learned: While the original service model's convenient, comfortable and engaging peer environment appeared to overcome barriers to frequent testing, standalone HIV testing contributed to suboptimal return HIV testing rates and missed opportunities to detect STIs. Service expansion was required to respond to client needs for comprehensive sexual health care, demand for new biomedical intervention approaches and improve reach to gender and geographically diverse populations while preserving the valued peer relationship. Outcomes of service changes included significantly increased return testing after introducing STI testing and SMS reminders, the PrEP clinic rapidly reaching capacity and strong uptake of outreach services.

Conclusions/Next steps: Cooperative partnerships between government, evaluators, health service providers and community organisations enabled PRONTO! to respond to shifting community needs and prevention priorities. While a lack of government subsidy for rapid HIV tests (unlike conventional serology) has limited their rollout in Australia, the PRONTO! experience demonstrates their capacity to facilitate community-engaged and responsive models of care. Further directions include meeting rising demand for PrEP and addressing persistent financial, social and geographical barriers to frequent testing for rural populations and migrants ineligible for free STI testing through Australia's universal healthcare system.

Date	Service introduced
August 2013	PRONTO! opens offering rapid HIV testing only, funded for two years
July 2014	PRONTO! outreach in gay social and sex on premises venues begins
January 2015	PRONTO! pop-up testing at LGBTIQ festivals begins
February 2015	PRONTO! rapid HIV testing trial within an existing primary care clinic begins
May 2015	Additional four years of funding announced
February 2016	STI testing (syphilis, chlamydia, gonorrhoea) and parallel HIV serology begins; SMS reminders introduced; Co-location with a gender diverse health clinic PrEP clinic opens
August 2017	Dedicated peer-delivered STI and rapid HIV testing for gender diverse clients begins
December 2017	Satellite PRONTO! clinic opens in a regional centre

[Table 1: timeline of service evolution at PRONTO!]



[Figure 1: service utilisation at PRONTO!, August 2013-December 2017 (new client data only to September 2017)]

WEPEC176

HIV testing strategies in Europe

S. Desai[1], L. Tavoschi[2], L. Combs[3], S.F. Jakobsen[3], A. Sullivan[4], D. Raben[5], V. Delpech[1], S. Croxford[1]
[1]Public Health England, London, United Kingdom, [2]European Centre for Disease Prevention and Control, Stockholm, Sweden, [3]CHIP, Centre of Excellence for Health, Immunity and Infections, Rigshospitalet, Copenhagen, Denmark, [4]4. Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom, [5]CHIP, Centre of Excellence for Health, Immunity and Infections, Rigshospitalet, Department of Infectious Diseases, Copenhagen, Denmark

Background: In recent years, new technologies and approaches to the implementation of HIV testing have emerged. The objective of this systematic review was to critically appraise and synthesise recent evidence on strategies/approaches aimed at increasing the uptake of HIV testing in Europe.

Methods: Systematic searches were run in Medline, Embase, PsycINFO, Cochrane and Scopus including studies published between January 2010 and March 2017. Abstracts from relevant conferences (2014-2017) were also reviewed. Title and abstract screening was used to select studies presenting strategies to improve HIV testing. Study selection, data extraction and critical appraisal were performed by two independent reviewers. Outcomes of interest included uptake and positivity.

Results: The searches resulted in 368 studies; over half were from Northern Europe (55%) and many of the remainder from Spain and France. A number of approaches to improve HIV testing were identified: HIV testing implementation (n=156), audits to identify gaps in testing (n=80), education interventions (n=16), campaigns (n=16), economic evaluations (n=13), communication technologies (n=8) and clinical and decision making tools (n=8). Testing implementation included 63 studies targeting risk groups (10-99% tested for HIV), 18 self-testing/sampling (10-78%), 18 emergency departments (3-66%) and 28 primary care (4-94%); 70 utilised rapid testing (4-98%) and 13 focussed on indicator condition testing (4-91%). Audits revealed between 22-64% of patients with indicator conditions were not tested for HIV at an earlier attendance. Only 28 studies presented before and after intervention data with testing rates 4-72% before and 12-85% after. Education interventions focussed on medical staff/students (n=14) and inpatients (n=3). The majority of campaigns promoted national/European HIV testing week (n=10). Innovative use of technology to increase HIV testing included: use of social media to offer testing (n=1), active testing recall via text message (n=1), educational videos for testing offer (n=2), computer testing prompts (n=1), automatic test ordering (n=2) and risk assessing (n=4).

Conclusions: This review has identified several promising strategies to achieve high HIV test uptake across a variety of settings in Europe. However, there are considerable missed opportunities for earlier HIV diagnosis. Few interventions reported before/after data, preventing evaluation of improvement in test coverage and very few studies were from Eastern Europe.

WEPEC177

Increased HIV case finding rate among MSM and TG in Laos from a community-led HIV oral fluids screening project

K. Sayabounthavong[1], V.-A. Souriyo[2], S. Mills[3], P. Girault[3], R. Vannakit[4]
[1]Lao Center for HIV/AIDS and STI, Vientiane, Lao People's Democratic Republic, [2]Lao Positive Health Association, Vientiane, Lao People's Democratic Republic, [3]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [4]United States Agency for International Development Regional Development Asia, Bangkok, Thailand

Background: HIV prevalence among men who have sex with men (MSM) in Laos has been estimated to 1.6% in 2014 while for transgender (TG) this prevalence was around 3.1% in 2012. Based on the regional epidemiological context, particularly in neighboring countries, the HIV prevalence among MSM and TG remain low.

Furthermore, HIV testing services are only provided in governmental structures, mainly health facilities, where stigma and discrimination is still impeding the access to services for these populations.

Methods: The USAID LINKAGES Project in collaboration with the Lao Center for HIV/AIDS and STI and LaoPHA, a local community-based organization, developed a community-based peer-driven HIV oral fluids screening (test-for-triage) project since September 2016 in three provinces bordering with Thailand. On-to-offline outreach activities were initiated during the last two quarters of 2017. Monitoring data were collected in real time using a mobile data collection application.

Results: The positivity rate using all reactive results (n=46) during September-December 2017 reached almost 6%. As depicted in Figure 1, there was a steady increase of MSM and TG screened reactive under test-for-triage from October 2015 to December 2017. During the last quarter of 2017, positivity rate significantly varied across key populations (p-value = 0.016) and was higher among MSW and TGSW: 18 (4.5%) out of 398 MSM screened; 3 (2.4%) out of 126 TG tested; 20 (9.7%) out of 206 MSW tested; and 5 (8.2%) TGSW tested (Fisher exact: 0.016). Those recruited through social media were more likely to be screened reactive when meeting offline.

Out of the total recruited and screened through on-to-offline (n =55), 8 (14.5%) were screened reactive, and all of them accessed HTC services for HIV confirmatory testing; while out of the total recruited and screened through face-to-face recruitment (n=736), 38 (5.2%) screened reactive (p-value = 0.004) and 36 (95%) accessed HTC services.

[Figure 1. Calendar Quarter]

Conclusions: It is critical that CBSs are encouraged to recruit more peers, as it seems a promising strategy contributing to the increase case finding. Program data will be compared with the last IBBS recently conducted in December 2017. Profile of individuals screened reactive versus non-reactive will be assessed to further target outreach.

WEPEC178

Improving access to HIV testing services among clients of FSWs: Experiences of the LINKAGES project in Zomba and Machinga, Malawi

W. Mtonga Kamphale[1], D. Kanthunzi[2], B. Nkhoma Somba[3], P. Mkukumira[1], M. Mkandawire[4], B. Sabao[5], M. Mkandawire[6]
[1]Youth Net and Counseling (YONECO), Programs, Lilongwe, Malawi, [2]Youth Net and Counseling (YONECO), M & E, Zomba, Malawi, [3]Youth Net and Counseling (YONECO), Media, Zomba, Malawi, [4]Youth Net and Counseling, Adminstration, Zomba, Malawi, [5]Youth Net and Counseling (YONECO), Programs, Zomba, Malawi, [6]FHI 360, Programs, Lilongwe, Malawi

Background: In Malawi, HIV prevalence among clients of female sex workers is 16.2% compared to the national prevalence of 8.8%. Clients are regarded as a priority population because they are vulnerable to HIV infection and transmission due to their interaction with female sex workers (FSWs) and other risk behaviors, like not using condoms. Though clients are typically difficult to identify and reach with comprehensive HIV services, we were successfully able to reach them through peer outreach in the Zomba and Machinga districts of Malawi through the PEPFAR/USAID-supported LINKAGES project.
Description: The LINKAGES project held focus group discussions with FSWs to identify categories of clients. We then conducted additional focus group discussions with 112 of the identified clients (who were bicycle, minibus and taxi operators; minibus touts; fishermen; and truck drivers) to explore their service needs. The project trained 50 peer educators among clients of FSWs to reach out to their peers with a wide range of comprehensive HIV messages. The project also trained 50 peer navigators among HIV-positive clients of FSWs to reach out to their HIV-positive peers with treatment adherence messages. Day and moonlight outreach services were provided on weekly basis to the clients within hot spots, at times that were convenient to them.
Lessons learned: Between January and September 2017, a total of 6,187 clients were reached with HIV prevention, care, and treatment interventions; 5,059 tested for HIV and received results, of whom 284 (6%) tested HIV positive and were all initiated on treatment. There were 5,023 clients screened for STIs, and 249 (5%) of them were diagnosed and treated. We also did repeat HIV testing at 3 months, and of the 248 people who were tested this time, only one seroconverted (0.4%).
Conclusions/Next steps: · We successfully identified a hard-to-reach group and provided them with comprehensive HIV prevention, care, and links to treatment.
· A seroconversion rate of 0.4% among repeat testers, which is similar to national incidence, will serve as a bench mark against which continuing prevention efforts can be evaluated.

[HIV services Cascade for clients of FSWs]

WEPEC179

Enhancing HIV testing coverage through peer-driven recruitment models among transgender women in Pattaya

P. Potasin[1], T. Nakpor[1], K. Krajan[1], M. Avery[2], S. Mills[2], S. Charoenying[2], A. Arunmanakul[2], R. Vannakit[3]
[1]Sisters Foundation, Pattaya, Thailand, [2]LINKAGES/Thailand, FHI 360, Bangkok, Thailand, [3]United States Agency for International Development Regional Development Asia, Bangkok, Thailand

Background: Transgender individuals (specifically transgender women and transgender sex workers) are at elevated risk of HIV infection due to stigma and discrimination against their gender and illegal status of work. Although HIV testing is key to achieving epidemic control, only a limited number of transgender people know their serostatus. The USAID- and PEPFAR-supported LINKAGES project in Thailand introduced the Enhanced Peer Mobilization (EPM) model to improve access to high-risk transgender women and transgender sex workers and strengthen HIV testing uptake among these groups.
Description: The EPM model was adopted by Sisters Foundation, a transgender-led organization in Pattaya that provides quality and non-discriminatory comprehensive health services to transgender women. Under the EPM, a small team of full-time and trained Community-Based Supporters (CBS) was responsible for managing an informal network of incentivized Peer Mobilizers (PMs) to recruit peers from their social networks to receive an HIV testing Data on risk behaviors and referral were collected real-time on smartphones with a reminder system to inform CBS to monitor referral to an HIV testing service.
Lessons learned: The introduction of EPM by Sisters led to greater reach in the transgender community as well as increased uptake of testing among transgender women. Prior to the introduction of EPM, between October 2015 and September 2016, Sisters reached 945 transgender women and transgender sex workers and tested 387 trans individuals. Among those tested, 38 were diagnosed HIV positive. During October 2016-September 2017, the number of transgender people reached increased significantly to 1,549. The HIV testing rate doubled, compared to the previous year, to 783 individuals, 52 of which tested positive. The contribution of engaging PMs in cabaret theatres accounted for 25% (n=189) of clients tested and 37% (n=19) of the HIV case finding.
Conclusions/Next steps: The EPM recruitment strategy leveraging transgender social networks improved access to those at elevated risk of HIV infection and uptake of HIV testing among transgender individuals. Sisters will continue to work with existing networks of key opinion transgender leaders as well as to scale up recruitment of transgender peer mobilizers in different contexts, especially factories and educational institutions.

WEPEC180

Who is using the HIV Self-test among Black/African-American MSM and transgender women in New York City? Baseline results from project TRUST

V. Frye[1,2], L. Wilton[3], M.Q. Paige[2], D. Lucy[2], G. Ortiz[2], V. Nandi[2], B. Koblin[2]
[1]City University of New York School of Medicine, Community Health and Social Medicine, New York, United States, [2]New York Blood Center, New York, United States, [3]Binghamton University, Binghamton, United States

Background: Increasing consistent HIV testing is critical to the United States' HIV prevention strategy, particularly among Black/African-American gay/bisexual and other men who have sex with men (MSM) and transgender women (TW). HIV self-testing may increase consistent testing.
Methods: We analyzed baseline survey data from 347 MSM and TW enrolled in 2016/17 in "TRUST," a randomized controlled trial of a dyadic (friend pairs) intervention to increase consistent HIV self-testing among young (mean age = 23.7 [sd=4.8]) MSM and TW. We describe frequency, motivations, contexts and characteristics of HIV self-testing in the sample.

Results: The majority (87%) had HIV tested in their lifetimes; 50% in the last three months. 54% knew about the HIV self-test and 13% had self-tested in their lifetimes; 3% in the last 3 months. There were no statistically significant differences in age, race/ethnicity, US-birth, sexual identity, or socioeconomic status between those who had and had not ever self-tested. Of those who had ever self-tested, most (64%) had only used it once; 18 reported that their most recent test was a self-test. Almost a quarter (23%) got the self-test from a drug store; 23% from a friend; 20% on-line. A third (34%) received the test from a health professional or test counselor. Two-thirds did the self-test at home; 16% at a friend/sex partner's home. The majority tested themselves, although 16% reported having a friend or sex partner test them and 2 reported being tested by their mothers. Approximately half conducted the test alone, with the remainder having friends, counselors or mothers present. The most common reason for self-testing was wanting to do it themselves (34%); having one available (29%); wanting to do it in private (27%); and easier than going to clinic (20%).
Conclusions: HIV self-testing offers another option for those at risk of infection. These results suggest that, among at-risk Black/African-American MSM and TW, there is significant room for increased uptake of self-testing. Further, those who are self-testing are not typically self-testing alone and are motivated by a desire for privacy, control and easy access. Dissemination should integrate these findings into efforts to promote self-testing to increase consistent testing among at-risk populations.

WEPEC181

Development and application of a social entrepreneurship testing model to promote HIV self-testing among men who have sex with men

F. Zhong[1], W. Cheng[1], W. Tang[2], H. Xu[1], G. Meng[3], P. Lin[4], Y. Gu[1]
[1]Guangzhou Municipal Center for Disease Control and Prevention, Section of AIDS Control and Prevention, Guangzhou, China, [2]University of North Carolina, Chapel Hill, United States, [3]Lingnan Partners Community Support Center, Guangzhou, China, [4]Guangdong Center for Disease Control and Prevention, Guangzhou, China

Background: HIV self-testing (HIVST) offers an opportunity to increase HIV testing among people not reached by facility-based services. However, the promotion of HIVST is limited as a consequence of insufficient community engagement. We built a social entrepreneurship testing (SET) model to reach more hidden people and promote HIVST linkage to care among Chinese men who have sex with men (MSM).
Description: The SET model includes a few key online steps. Each participant paid a US$23 (refundable) deposit to receive a kit for HIVST and syphilis self-testing. The test results were sent to the platform by the participants and interpreted by the Community based organizations (CBO). Meanwhile, the deposit was returned to each participant. The CBO can provide online counselling services in any step anytime. For participant who was HIV-positive, the CBO provided referring to confirmation testing in Center for Disease Control and Prevention, psychological supporting, and linkage to care.
Lessons learned: During the evaluation phase of April-June 2015, 198 MSM in Guangzhou purchased self-testing kits. Most of them were aged from 18 to 34 years (84.4%) and met partners online (93.1%). 123 (62.2%) of them had more than 2 male partners in the last 6 months. In addition, 27.8% of participants had never been tested for HIV before. Overall, feedback was received from 192 participants (97.0%) and the HIV prevalence was 4.5% (8/178). All of the screened HIV-positive individuals sought further confirmation testing and were linked to care. Therefore, the SET model of HIVST is feasible and acceptable. In the promotion phase of 2016 and 2017, 1696 and 1740 HIVST kits were purchased in Guangzhou, the percentages of feedback were 82.0% and 85.5%, and the HIV prevalences were 2.0% (28/1391) and 2.1% (31/1487) respectively. Furthermore, the SET model was also promoted successfully in other cities or counties in Guangdong and Shanxi province, delivering about 700 kits and receiving feedback from more than 80% of participants in 2017.
Conclusions/Next steps: Using an online SET model to promote HIV self-testing among Chinese MSM is promising and effective. This model can be utilized well in many cities and adds a new testing platform to the current testing service system.

WEPEC182

Results from a randomized controlled trial of an intervention to match young Black men and transwomen who have sex with men or transwomen to HIV testing options (All About Me)

B. Koblin[1], V. Nandi[2], S. Hirshfield[3], M.A. Chiasson[3], L. Wilton[4], D. Usher[1], D.R. Hoover[5], V. Frye[1,6]
[1]New York Blood Center, Project ACHIEVE, New York, United States, [2]New York Blood Center, New York, United States, [3]Public Health Solutions, New York, United States, [4]Binghamton University, Binghamton, United States, [5]Rutgers University, Department of Statistics, Piscataway, United States, [6]City College of New York, CUNY, New York, United States

Background: HIV testing is critical to HIV prevention and treatment. In the U.S., it is recommended that high-risk individuals test every 3-6 months. Among Black/African-American MSM, who are disproportionately affected by HIV, there is a critical need to increase consistent HIV testing. Current testing options include self-testing, couples HIV test-counseling (CHTC), and clinic-based testing, though few efficacious HIV testing interventions exist for young Black MSM and transwomen. "All About Me" was developed as a brief, web/mobile-based intervention that provided a personalized recommendation for an individual's "optimal" HIV testing method, hypothesized to increase HIV testing.
Methods: From 2016-2017, 236 Black/African-American, HIV-negative (self-report), sexually active (past 12-month insertive/receptive anal intercourse with a man/transwoman), aged 16-29, MSM or transwomen living in the New York City area were randomized to one of two conditions (1:1 in randomly ordered age blocks). Participants in the experimental condition completed an algorithm, based on behaviors and personal characteristics found to be associated with HIV testing option preferences, yielding the personalized recommendation. Controls were given information about various testing approaches, but no recommendation. Analysis of outcomes, self-reported testing over 6 months of follow-up, was conducted on an intent-to-treat basis.
Results: Self-reported HIV testing during the 6-month follow-up period increased from 62.4% to 84.6% ($p< 0.001$), but did not differ by study arm (experimental: 67.9% to 85.3%; control: 57.1% to 83.9%) ($p=0.85$). Use of the HIV self-test did not differ by study arm at 3- or 6-month time points (3-month: experimental: 12.0%; control: 12.7%; $p=0.88$; 6-month: experimental: 8.6%; control: 4.9%; $p=0.30$).
Use of CHTC did not differ by study arm during follow-up (3-month: experimental: 10.2%; control: 8.2%; $p=0.61$; 6-month: experimental: 10.8%; control: 5.9%; $p=0.22$). Among intervention participants, 19.5% reported using their recommended testing method at 3-months and 16.1% at 6-months.
Conclusions: Increasing consistent HIV testing among high-risk groups is a National HIV/AIDS Strategy priority. Although testing among study participants increased by 20%, receiving a personalized recommendation did not impact HIV testing rates. It may be that engaging in a study about HIV testing motivated participants to increase HIV testing regardless of study arm, obscuring the impact of the algorithm.

WEPEC183

Profile and motivations of people who are using the HIV self-test: Results from the "VIH: Teste-Toi Toi-même" study in France

K. Champenois[1], V. Coquelin[2], V. Supervie[3], D. Rahib-Kersaudy[4], N. Lydié[4], A. Velter[4], J. Ghosn[5], T. Greacen[1]
[1]EPS Maison Blanche, Laboratoire de Recherche, Paris, France, [2]AIDES, Pantin, France, [3]Inserm UMR1136, Paris, France, [4]Santé Publique France, Saint-Denis, France, [5]AP-HP Hôpital Hôtel-Dieu, Paris, France

Background: HIV self-tests (HIVST) are expected to increase the uptake and frequency of HIV testing, particularly for key populations. One year after the HIVST received approval for sale in France, are people from vulnerable populations actually using HIVST?
Methods: An online survey was launched in October 2016 with the objective of describing the profile and motivations of people interested in or having already used the HIVST. Participants were recruited via ads on

Facebook, dating aps and websites, and community networks, with a particular focus on social media for two key communities in France: men who have sex with men (MSM) and migrants from Sub-Saharan Africa.

Results: Of the 4554 respondents who completed the survey, 355 (8%) declared having already used an HIVST. A total of 308 (87%) were MSM; 21 (6%) were women. People who had used the self-test were more likely to live in the Paris area (35% vs. 25% in the overall sample), to have a university diploma (62% vs. 49%), to be currently employed (77% vs. 61%) and to have a monthly income over 1600€ (59% vs. 42%). All MSM (100%) and 93% of non-MSM had had sexual intercourses in the preceding year with a median of 10 partners for MSM versus 3 for non-MSM. Non-MSM were more likely to have a steady partner than MSM (68% vs 53%), but less likely to use a condom with casual partners (13% vs 28% stated always wearing a condom).

Participants gave three main reasons for having used an HIVST: rapidity accessing results (74%), autonomy (60%) and convenience (57%). One in four (27%) had used an HIVST more than once. All participants who had used an HIVST declared having already done an HIV test during their lifetime and 83% had been tested in the preceding year. However, of the three respondents who declared receiving a positive result, only one had sought confirmation for this test result.

Conclusions: The present survey targeting vulnerable populations highlights rapidity accessing results, autonomy and convenience as key motivations for self-testing. However the question of linkage to care remains open and clearly requires further investigation.

WEPEC184

Online self-testing service yields yearly growth, high user satisfaction, stable STI positivity rates and lower HIV rates among MSM in the Netherlands

K. Vermey[1], H. Götz[2,3,4], M. Kroone[5], U. Davidovich[5], W. Zuilhof[1]
[1]Aidsfonds - Soa Aids Nederland, Amsterdam, Netherlands, [2]Municipal Public Health Service Rotterdam-Rijnmond, Rotterdam, Netherlands, [3]National Institute for Public Health and the Environment, Bilthoven, Netherlands, [4]University Medical Center Rotterdam, Rotterdam, Netherlands, [5]GGD Amsterdam, Amsterdam, Netherlands

Background: In the Netherlands, men who have sex with men (MSM) are at elevated risk for HIV and other STIs. To enable early diagnosis and treatment, MSM are recommended to test twice a year. To facilitate regular STI screening of MSM who are asymptomatic and did not receive partner notification, Dutch public health organisations (PHOs) piloted Man tot Man Testlab, a free online self-testing service in 2008. Ten years after its first implementation, Testlab has become a structural component of PHOs' testing services across the Netherlands.

Description: Testlab is embedded in a comprehensive online resource for MSM (Man tot Man) that provides pre- and post-test information and tailored advice about sexual risk. Users register online and answer questions about their sexual history. Eligible users receive a testing form for a nearby diagnostic laboratory. Here users get tested for HIV, syphilis, gonorrhoea and chlamydia without scheduling an appointment. PHOs communicate the results online and refer positive cases to their STI clinic for free treatment and counselling.

Lessons learned: Between 2008-2017, the number of consultations grew from approximately 530 to more than 7.000 per year. Despite this growth the overall STI positivity rate remained high around 14%, while HIV rates dropped to 0.5%. Over time, the amount of users ever tested for HIV before increased to 93% while median age decreased to 33 years. Testlab primarily reached higher educated, younger MSM at considerable risk for bacterial STIs. One in four reported an STI diagnosis in the previous year. An online survey among users showed high satisfaction and recurrent use of the service; 88% would choose Testlab for their next STI test. Two out of three were tested via Testlab in the past six months, meeting national recommendations for regular testing.

Conclusions/Next steps: Continuously reaching MSM at high risk for STIs, Man tot Man Testlab has been successfully implemented since 2008, achieving yearly growth, high STI positivity rates and good user satisfaction. In the coming years, the need and opportunities for online self-testing are expected to grow further as MSM, especially those taking PrEP, will be advised to be tested up to four instead of two times a year.

WEPEC185

Experiences with use of oral HIV self-testing (HIVST) among men who have sex with men (MSM) and linkage to care: Translating evidence to programmatic strategies for HIVST scale-up in Nigeria

O.O. Dirisu[1], W. Tun[2], A. Sekoni[3], L. Vu[2], E. Shoyemi[1], J. Njab[1], S. Ogunsola[3], S. Adebajo[1]
[1]Population Council, Abuja, Nigeria, [2]Population Council, Washington DC, United States, [3]University of Lagos, Lagos, Nigeria

Background: HIV self-testing (HIVST) offers an alternative to facility-based HIV testing services, particularly for highly stigmatized populations such as men who have sex with men (MSM). HIVST facilitates privacy, confidentiality, and convenience. Lessons learned from user experiences are invaluable in developing programmatic strategies for scale-up of HIVST programs and facilitating linkage to care.

Methods: MSM aged 17-59 years (N=319) who were HIV-negative or of unknown status were recruited by peer educators for a pilot HIVST distribution intervention study in Lagos, Nigeria. Participants completed a baseline survey and received two HIVST kits. A helpline counselor followed-up with calls at 5/30/80 days from baseline to provide support. After three months, a post-intervention survey (N=257), in-depth interviews with 20 MSM purposively selected from the cohort and two focus group discussions (with 12 peer educators) were conducted to explore MSM self-testing experience, operational aspects of HIVST kit distribution, and linkage to HIV care. Interviews were audio-recorded, transcribed verbatim and analyzed using thematic analysis. We report the post-intervention qualitative findings here.

Results: Qualitative results indicated that majority of participants were very satisfied with their use of the test kit because it made HIV testing less cumbersome, demystified the testing process, and improved confidentiality. Most participants found the pictorial illustrations to be self-explanatory and easy to follow. There was consensus among participants that a 24/7 helpline was a critical resource for addressing concerns with the kit use, receiving counselling and guidance on linkage to care for those who test positive. Most who reported using the helpline did so to receive confidential, non-judgmental advice from the counselor about the next steps to take, and those who tested positive found the guidance for linkage to care extremely valuable. Some participants, however, reported that inclusion of pre-counselling information on the HIVST kit would help reassure MSM who are prone to self-harm prior to testing.

Conclusions: Lessons learned from user experiences in this study show that the scale-up of HIVST in Nigeria must include provision of adequate pre-and post- test counselling information as well as the availability of helpline support to improve user experience and linkage to care for those who test positive.

WEPEC186

Willingness to use HIV self-testing: Results from the Malawi Population-based HIV Impact Assessment (MPHIA) 2015-16

J.M. Cuervo Rojas[1], E. Radin[1], S. Saito[1], S. Delgado[1], S. Jonnalagadda[2], D. Payne[3], E. Kim[3], M. Tsoka[4], M. Nzima[5], T. Kalua[6], A. Auld[3], MPHIA Study Group
[1]ICAP at Columbia University, New York, United States, [2]Centers for Disease Control and Prevention (CDC), Atlanta, United States, [3]Centers for Disease Control and Prevention (CDC), Lilongwe, Malawi, [4]Centre for Social Research University of Malawi, Zomba, Malawi, [5]UNAIDS Malawi, Lilongwe, Malawi, [6]Malawi Ministry of Health, Lilongwe, Malawi

Background: HIV self-testing (HIVST) is an innovative strategy recommended by the World Health Organization (WHO) to increase HIV testing coverage. National estimates of its acceptability are lacking in Malawi.

Methods: MPHIA was a nationally representative survey with a stratified cluster sample design, in which 11,386 households and 19,652 adults aged 15-64 were interviewed. HIV testing was performed in consenting participants. This analysis excludes respondents who tested HIV positive and were aware of their status, and presents weighted estimates of the percentage of the population that would use an HIV self-test kit if it were

available. Analysis weights account for sampling selection probabilities and adjust for nonresponse and noncoverage. Logistic regression was used to determine factors associated with the willingness to perform self-testing.

Results: Among 17,799 eligible respondents aged 15-64 years, 72% (95% CI 71%,73%) indicated that they would use HIVST. The willingness to use HIVST was significantly higher among males (76%, 95%CI 75%,77%) than among females (68%, 95%CI 67%,69%). Among females, age, education, socioeconomic status, and HIV testing history were independently associated with the willingness to use self-testing; while among males, only education, and testing history were independently associated (Table). The willingness to use self-testing was significantly lower among females aged 15-24 and 45-64 than among those aged 25-44 years, among males and females who had never tested for HIV in comparison with those who ever tested, and among those whose HIV status was unknown for the survey (did not consent to testing). Among females but not among males, those in the two highest wealth quintiles in comparison with those in the three lowest, and those HIV-positive who were unaware of their status in comparison with the HIV-negative were more willing to use HIVST.

Conclusions: In Malawi, the willingness to perform HIVST is high, especially among two priority populations: males and those HIV-positive unaware of their status. This represents an opportunity to increase testing coverage in a country where the major gap for the achievement of the UNAIDS 90-90-90 targets is in diagnosis, with 27% of those infected unaware of their status, and low testing frequency in the general population.

WEPEC187

"If you don't have the courage to go get a test, you won't have the courage to go for treatment": Consumer perspectives on the introduction of HIVST in Central America

J. Wheeler[1], I. Fortin[2], N. Gallardo[2], P. Letona[2], S. Lungo[2]
[1]PSI, Washington, United States, [2]PASMO, Guatemala, Guatemala

Background: The introduction HIV self-testing (HIVST) could overcome stigma-related barriers to HIV testing among Central America's vulnerable populations. The Pan American Social Marketing Organization, through the USAID Combination Prevention Program in Central America, explored knowledge and acceptability of HIVST among vulnerable populations in four studies. This analysis summarizes HIVST knowledge and intentions among men who have sex with men (MSM), online MSM and female sex workers (FSW), and describes factors that may support or hinder the success of HIVST introduction in Central America.

Methods: The results presented come from four 2017 research studies: population-based RDS/time location studies among 1922 MSM and 617 FSW in three Honduran cities; an online study among a convenience sample of 622 MSM residing in Guatemala, El Salvador, Honduras, Nicaragua and Panama; and an ethnographic study among 50 NGO-affiliated MSM and TW (Transgender Women) in Guatemala. Univariate and bivariate statistics are presented for quantitative indicators. Qualitative data was analyzed thematically. Results were validated through a consultative focus group with the target population.

Results: Twenty percent of MSM and FSW, and one-third of TW had heard of HIVST in Honduras, despite their unavailability. After a brief description, >90% of respondents agreed that they would take and HIVST if presented the opportunity. Key reasons for not accepting one included not trusting the test (36%-40%) and preferring to receive services at a clinic (18%-20%). Results from the qualitative study highlight that there is limited exposure to HIVST, but strong feelings (favorable and unfavorable) regarding the introduction of HIVST in the MSM/TW community. Some view HIVST as a means to increase the frequency, regularity, access and privacy of HIV testing. While other MSM/TW NGO/community leaders suggested that, absent counseling, HIVST could lead to risk behaviors and potential violence. Participants also expressed confusion and doubts regarding HIVST and operationalizing linkages to care and access to medications.

Conclusions: While there is little knowledge of the HIVST in the region, vulnerable populations have favorable intentions toward accepting HIVST. These results are consistent with studies in other contexts. Successful introduction of HIVST will require engagement and buy-in of civil society groups.

WEPEC188

The role of youth champions in linkage of adolescents and youth from the community for HIV testing services

M. Buwembo[1], A. Kabarambi[2]
[1]Protecting Families Against HIV/AIDS, Masaka, Uganda, [2]MRC/UVRI and LSHTM Research Unit, Entebbe, Uganda

Background: At national level, young people find challenges accessing HIV testing services at health facilities because they do not fit in or even fear stigmatization from their parents and health workers. Others do not know where to get youth friendly services. We describe how youth champions played a key role in linking up their peers to youth friendly centres for HIV testing services in Kalungu district.

Methods: PREFA with support from UKAID set up youth friendly centres in 12 health facilities in Kalungu District run by 24 health workers trained in handling youth as they come for services including HIV counselling and testing.

24 active youth who could ably mobilize and sensitize their peers were selected by the health facility management committee and trained by PREFA in counselling and mobilization skills. These are called youth champions whose main role is to go to the community targeting 40 households per month to identify peers eligible for HIV testing. Linkage was done using carbonated referral notes. The youth champion retained

a copy of this note which had locator details of the referred person. Follow up at the facility was made to check whether those referred reached. In case they did not reach, a home visit was made after a week to establish reasons for not reaching the referral point. Those from far were referred to the nearest outreach station attached to the youth friendly center.
Results: Between October 2016 and September 2017, 11520 households were reached, 4366 youths were referred to the 12 health facilities. The biggest number of youth referred was 1653 in 10-14 years' category.
2656 were tested for HIV and given results 45 were linked to care 4321 were linked to HIV prevention services. The biggest number of youth tested was 1127 in 20-24 years' category.
Youth champions play a great role in reaching out to peers and linking them to the designated youth friendly centers to get services. Documentation of referrals helps to track linkage completion.
Conclusions: Having youth reach out to their peers and training health workers reduces stigma associated with HIV testing among the youth.

WEPEC189

Integrating voluntary referral from HIV-positive people into a risk-network engagement approach to improve case detection and linkages from outreach in India

P. Mugundu Ramien[1], R. Bandi[2], J.R. Nagadasu[2], N.M. K[2], D. Damara[2], A.K. Reddy[1], M. Mathew[1], G. Shreenivas[1], B. George[1], J.J. Baishya[3]
[1]FHI 360, LINKAGES Project, New Delhi, India, [2]FHI 360, LINKAGES Project, Vijayawada, India, [3]USAID India, Project Management Specialist (HIV/AIDS), New Delhi, India

Background: In India, key population (KP) outreach is associated with relatively low HIV case-finding rates, despite surveillance estimates of high HIV prevalence among KPs. In response, the USAID- and PEPFAR-supported LINKAGES/India project, led by FHI 360, introduced the enhanced peer outreach approach (EPOA). The EPOA adapts respondent-driven sampling from surveillance to improve the capacity of outreach to engage KPs at highest risk of HIV and link them to services. To further optimize this approach, we explored opportunities to extend the EPOA with voluntary partner referrals from identified HIV-positive individuals.
Methods: From July to October 2017, we conducted the EPOA, targeting men who have sex with men (MSM) and transgender (TG) women not covered by the national KP intervention program in four subdistricts of Andhra Pradesh, India. Primary seeds were encouraged to serve as peer mobilizers (PMs), referring peers within their social or sexual networks to nearby HIV testing services. Clients who were successfully referred to HIV testing were then asked if they would serve as PMs and were provided four coupons with unique identifying codes to refer their peers. In November and December 2017, we supplemented the EPOA with an index-based HIV testing approach, by offering HIV-positive clients voluntary assisted partner notification in a manner consistent with World Health Organization guidelines.
Results: The distribution of 648 EPOA coupons through 12 primary PM seeds and 150 secondary PMs resulted in 353 successful referrals (54.5%) to HIV testing. Of these 353 participants (286 MSM and 67 TG women), 67 (18.9%) were confirmed HIV positive. Over time, the clients reached through the EPOA declined from 160 (July) to 43 (October). However, 28 HIV-positive index clients identified were counselled to provide voluntary referrals of their partners for HIV testing; they successfully referred 44 additional clients (38 MSM and 6 TG women) and 13 (29.5%) of whom were diagnosed HIV positive. Ninety-two percent of all newly identified cases were linked to HIV treatment services to date.
Conclusions: Augmenting the EPOA with HIV index-based referral approaches has contributed to additional HIV case detection among KPs, and underscores the dividends of innovating to combine and integrate prevention approaches.

WEPEC190

Improving voluntary HIV testing in low and middle income countries (LMIC): A report from a field experiment in Ecuador

M. Macis[1], M. Grunauer[2], R. Izurieta[3], P. Phan[1], M. Reina Ortiz[3], E. Terán[2]
[1]Johns Hopkins University, Carey Business School, Baltimore, United States, [2]Universidad San Francisco de Quito, Escuela de Medicina, Quito, Ecuador, [3]University of South Florida, College of Public Health, Tampa, United States

Background: HIV/AIDS prevention and control relies heavily upon timely diagnosis and treatment. UNAIDS has set the 90-90-90 target by 2020 (i.e. 90% of PLHIV know their status, 90% of those diagnosed will be under treatment, and 90% under treatment will achieve viral suppression). HIV/AIDS under-detection may stretch scarce public health resources in LMIC. We conducted a field experiment in a LMIC to test the hypothesis that a financial incentive intervention, compared to an information-only or to a behavioral nudge, will significantly increase voluntary HIV testing.
Methods: A randomized controlled trial was conducted in a large Ecuadorian city that carries a disproportionate burden of HIV/AIDS from June to December 2017. Consented participants were randomly assigned to one of three arms: 1) control arm where participants received information on HIV testing; 2) soft-commitment (behavioral nudge) arm, where participants received a narrative to overcome social stigma and activate the sense of social responsibility; and, 3) financial incentive arm where participants were offered a US$10 reward received either at time of testing or when they picked up their test results. Participants were recruited from three heavily trafficked public sites around the city. Socio-demographic information was captured using a self-administered survey. The identities of the participants were masked. Outcomes included testing rate and HIV seropositivity rate. Chi-square tests were used to compare rates across treatment arms.
Results: 7,721 participants were approached and 1,321 got tested. Randomization was effective and no systematic biases were identified. Socio-demographic variables (age, ethnicity, education and previously tested for HIV) did not differ between treatment arms ($p>0.05$). Testing rate was 12.2%, 11.3% and 33.5% for control, behavioral nudge and financial incentive treatment arms, respectively ($p< 0.05$). HIV seropositivity rate was 1.2% for participants in both control and behavioral nudge arm and 1.5% for financially incentivized participants ($p>0.05$). These were individuals that would have gone undetected but for the intervention.
Conclusions: Our preliminary results indicate that financial incentives provided at the time of outreach can overcome the psychosocial barriers of voluntary HIV/AIDS testing. The subsequent detection of new HIV/AIDS cases support infection control with early intervention, limit economic costs, and improve surveillance accuracy.

WEPEC191

Towards 90-90-90: Findings from innovative peer driven outreach approach for rapid HIV case detection among people who inject drugs in Kyrgyzstan

A. Moldokmatova[1], D. Saliev[1], M. Kan[2], A. Estebesova[1], O. Samoilova[2]
[1]Populations Services International/Central Asian Branch, Bishkek, Kyrgyzstan, [2]Populations Services International/Central Asian Branch, Almaty, Kazakhstan

Background: The HIV epidemic in Kyrgyzstan is mainly concentrated among people who inject drugs (PWID). The last size estimation was 25,000 PWID (2014). Nearly 50% of those infected with HIV do not know their status, making clear the need for innovative case finding strategies as peer driven outreach (PDO) in addition to traditional prevention. PDO is based on chain recruitment within the target groups.
Methods: The paper attempts to explore the effectiveness of PDO in case finding in Kyrgyzstan. Routine data collected through MIS online database is analyzed in STATA 13.0, including descriptive and explorative (multivariate) analysis.
Results: During 4 months' period, 5,349 PWID were recruited and tested through PDO and 106 HIV+ cases were found (23% of all cases in the country for the same period). Recruitment continued for an average of

5 waves (Range: 0-15). The majority of clients were male (80.9%), from urban areas (58.6%) and aged 25-49 years old (82.4%).
The majority of HIV+ cases (71.7%) were identified at waves 2-6, and no cases were detected after wave 12. Clusters with HIV+ seeds were on average shorter than those with HIV- seeds (4 vs. 5 waves, p< 0.05) and had fewer PWID tested (538 vs. 4,811, p< 0.01). However, the odds of having an HIV+ test result were higher in clusters with HIV+ seeds (OR=1.89, 95% CI: 1.13-3.17). Further, the yield among clients recruited by HIV+ PWID was significantly higher compared to those reached through HIV- PWID (5.0% vs. 1.8%, p< 0.001) though most of HIV cases were found through HIV-PWID (89 of the total 106 cases). Yield was highest in the first wave of recruitment by an HIV+ client, and decreased as waves continued (9.1% in 1st wave, 2.5% in 2nd wave).
Conclusions: The PDO approach is effective in quick reaching a high number of PWID with HIV testing or HIV prevention activities. Case detection can be increased through recruitment of effective HIV+ seeds and controlling the length of negative waves in clusters. Training or education for better recruitment of partners and other support to seeds can increase their effectiveness.

WEPEC192

OptTEST programme interventions for Indicator Condition HIV testing are effective in significantly increasing HIV testing rates in non-specialist healthcare settings across Europe

A. Sullivan[1], C. Rae[1], I. Sperle[2], S. Jakobsen[2], J.D. Kowalska[3], R. Lugo Colon[4], L. Lemsalu[5], M.J. Perez Elias[6], A. Vassilenko[7], N. Badridze[8], V. Sikolova[9], G. Kutsyna[10], M. Rayment[1], D. Raben[2], J. Lundgren[2], OptTEST for HIV in Europe
[1]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom, [2]Rigshospitalet, University of Copenhagen, CHIP, Copenhagen, Denmark, [3]Hospital for Infectious Diseases, Warsaw, Poland, [4]CEEISCAT, Barcelona, Spain, [5]National Institute for Health Development, Tallinn, Estonia, [6]Hospital Ramon y Cajal, Madrid, Spain, [7]Belarusian State Medical University, Minsk, Belarus, [8]AIDS and Clinical Immunology Research Centre, Tbilisi, Georgia, [9]National Institute of Public Health, Prague, Czech Republic, [10]Hospital Rubejnoe, Rubejnoe, Ukraine

Background: OptTEST, an EU co-funded project, aimed to improve HIV detection and linkage to care across Europe. Part of this programme was to improve HIV Indicator Condition (IC) testing (HICT) by introducing a clinic policy, utilising implementation tools and delivering quality improvement (QI) interventions.
Methods: From Jan 2015, an HICT policy was introduced for up to 3 ICs (Pneumonia, Hepatitis B and C, Infectious Mononucleosis-like syndrome (IM)) in different clinical settings (primary care, emergency department, Acute Medical Unit, Specialist OPD) in 10 pilot countries. Baseline retrospective audits (offer and number of tests/total presenting with IC) were performed. Programme data collection included IC, age, HIV status, test offer, test performed, test result and transfer to care details (including CD4 cell count and treatment initiation). Implementation tools included a strategic pack (slide set, guideline review protocol, financial calculator), interactive service design module, staff training module and resource pack. Plan-do-study-act interventions were designed and implemented by local study teams and monitored using run charts.
Results: To the end of July 2017 43 sites had begun testing in 8 countries. Of the 9661 HIV tests performed 97 were positive: 1.00% [95%CI 0.82-1.22]. Offer (where data was available) and testing rates all increased significantly, overall: 48.12% [46.24-50.00] to 93.1% [92.5-93.58] and 39.82% [38.10-41.57] to 90.8% [90.27 - 91.37] respectively, both p< 0.05 . Uptake of offer was above 90% for all ICs at baseline (range 90.03 - 91.58%) and increased significantly for all except IM (range 92.10 - 99%). Of those patients testing positive, data is currently available for 95, of whom 74 (78%) transferred to care, with a median CD4 count of 345 cells/ul (range 2-1304); 53% were late presenters.
Conclusions: Introduction of HICT policy, supported by implementation tools and QI increased HIV testing offer rate by 81% and testing rate by 128%; this approach is an effective way to increase HIV testing and identify cases of undiagnosed HIV in non-specialist healthcare settings.

Developing a voluntary partner referral strategy for HIV testing among key populations: A pilot program in the Dominican Republic

C. Barrington[1], J. Knight[2], H. Gomez[2], M. Perez[2], Y. Donastorg[2], D. Kerrigan[3,4]
[1]University of North Carolina at Chapel Hill Gillings School of Global Public Health, Health Behavior, Durham, United States, [2]Instituto Dermatalogico y Cirugia de Piel Dr. Huberto Bogaert Diaz, Unidad de Vacuna e Investigacion, Santo Domingo, Dominican Republic, [3]American University, Department of Sociology, Washington DC, United States, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: Partner notification strategies are a hallmark of sexually transmitted infection prevention/control programs. There is renewed interest in such approaches to increase HIV testing yield and early diagnosis. We previously piloted partner referral with female sex workers living with HIV in the Dominican Republic (DR) and their steady partners and found high levels of acceptability, unmet need for HIV testing, and yield.
Description: Our team, under the USAID/PEPFAR-supported and FHI 360-led LINKAGES Project, reviewed peer-reviewed and grey literatures and consulted with local key informants to develop a voluntary partner referral (VPR) strategy in the DR including:
1) a manual for passive and active referral modalities;
2) participatory training on implementing VPR and strengthening cultural competency for working with diverse types of partners and; and
3) protocol and tools for documenting implementation and outcomes data.
Lessons learned: The first lesson was the need to shift away from "partner notification", which emphasizes the act of informing a partner, to "partner referral", which focuses on the act of supporting a partner to test. We also included "voluntary" to emphasize the importance of both voluntary referrals among index patients (IPs) as well as voluntary uptake among partners. From August to December 2017, across four clinics, 76 IPs were offered VPR. Among IPs,10 identified as MSM and one as transgender; six reported active involvement in sex work. Sixty-eight (89%) accepted participation and identified 69 partners for referral, mostly steady partners (70%). Forty-three (62%) partners came for HIV testing, 42 (98%) were tested, and 17 (45%) were newly diagnosed. All newly diagnosed partners initiated treatment. The most common modality of referral was passive/patient-initiated (83%). Implementation has required continuous training. The time burden has created challenges to wider use of VPR in participating clinics.
Conclusions/Next steps: Based on the initial findings documenting acceptability and yield, we are training seven new NGO and governmental HIV clinics. We will continue to monitor acceptability and outcomes and conduct qualitative interviews with providers, IPs, and referred partners on their experiences with VPR. Future scale-up should consider the cost and value-added of each VPR modality and how to tailor VPR to different partner types.

Utilizing a network model in HIV case-finding among people who inject drugs (PWID) in Northeast India

P. Goswami[1], B. George[1], S. Mathew[1], A. Singh[2], K. Ditya[1], N. Bakshi[1], R. Khiangte[1], T. Jamir[1], N. Roshan[1]
[1]FHI 360, India, New Delhi, India, [2]FHI 360, Project Sunrise, New Delhi, India

Background: Success in achieving the UNAIDS 90-90-90 target largely depends on reaching the first 90, i.e. 90% of people living with HIV know their HIV status. It is critical to reach out to individuals who have not yet been tested for HIV. It is also challenging to reach and test people who inject drugs (PWID), especially in remote locations in Northeast India.
Description: Project Sunrise, funded by President's Emergency Plan for AIDS Relief (PEPFAR) and implemented in Northeast states, initiated HIV case-finding through the network of known HIV-positive PWID. Known HIV-positive PWID within the government-supported targeted interventions (TIs) were selected and approached by outreach workers to refer spouses and individuals from their injecting and sexual networks who had not yet been reached by the TI. The outreach workers of the TI contacted the referred clients, counseled them, and accompanied them for HIV testing. The project has completed two periods of this chain referral process and will continue for several more months until there is no more HIV case detection.
Lessons learned: During October and November 2017 we identified 383 injecting partners through 237 index PWIDs. Of these 383, 238 injecting partners were contacted and counseled, and 211 PWID were tested for HIV. Among these 211 all had never been tested for HIV, 20 (9.5%) were confirmed HIV positive, and 19 were initiated on ART. Out of 12 spouses of index HIV-positive PWID contacted, three were tested for HIV and two were confirmed HIV-positive. No HIV cases were found among sexual partners of index HIV-positive PWID. Based on our experience, reaching out to individuals within injecting networks is easier than reaching those in sexual networks. PWID were reluctant to disclose their sexual partners due to social taboos.
Conclusions/Next steps: This innovative network model improved HIV case detection among PWID and reached injecting networks outside the coverage of the Indian national program. More efforts are required to reach out to the sexual partners by adopting more targeted strategies. Project Sunrise will advocate with the National AIDS Control Organization (NACO) to incorporate and scale up such approaches within the national TI program.

WEPEC195

Partner notification based on urine self-sampling for officially-sanctioned HIV testing in cooperation with community-based organizations among men who have sex with men in Beijing, China

Y. Lyu[1], X. Feng[2], X. Nie[3], Y. Tian[4], W. Xing[1], J. Yao[1], Y. Jiang[5]
[1]National Center for AIDS/STD Control and Prevention, Chinese Center for Disease Control and Prevention, National HIV/HCV Reference Laboratory, Beijing, China, [2]Beijing YouAn Hospital, Capital Medical University, Beijing, China, [3]Beijing Jingjing Concentric Volunteers Development Center, Beijing, China, [4]Zhongnan Hospital of Wuhan University, Department of Blood Transfusion, Wuhan, China, [5]Chinese Center for Disease Control and Prevention, National HIV/HCV Reference Laboratory, Beijing, China

Background: Partner notification (PN) in generally acknowledged to be an important element of controlling sexually transmitted infections (STIs) and HIV. However, given that both HIV infection and homosexuality remain highly stigmatized in China, health department and clinics face great challenges in performing sexual partner mobilization among MSM. We developed a model of urine self-sampling for HIV testing (USST) to conduct a PN and HIV testing program for MSM in cooperation with MSM-serving Community-based organizations (CBOs) in Beijing.
Methods: We cooperated with MSM-serving CBOs to conduct HIV testing intervention in MSM gathering areas of Beijing from December 2015 to January 2016. MSM who were reached and were willing to have a HIV test were referred as on-site MSM in our study. They were referred to CBO-run HIV testing points for HIV oral rapid testing and urine self-collection. The staff of CBO interviewed them face-to-face to complete a questionnaire, collect information on their sexual partners, and encourage them to take packages of oral rapid testing kit together with disposable urine sampling kit for their sexual partners who would perform oral rapid testing, collect urine, and mail them back to the designed laboratory. Personal details including socio-demographic characteristics and results of oral rapid testing were collected through self-administered questionnaires.
Results: In total, 60 on-site MSM were reached and were willing to take 70 packages for their sexual partners. Of 70 packages, 69 urine samples and questionnaires were obtained. For on-site MSM, the positive rate of HIV oral rapid testing and urine ELISA were 3.3% (2/60) and 6.7% (4/60), separately. Nevertheless, the positive rate of HIV oral rapid testing and urine ELISA among their sexual partners were 7.2% (5/69) and 15.9% (11/69), respectively. In addition, 100% (15/15) of the individuals screened as urine ELISA HIV positive were followed up within five weeks. Of these, 50% (2/4) and 72.7% (8/11) were reported as newly identified for on-site MSM and their sexual partners, respectively.
Conclusions: Combining the advantages of CBOs and officially-sanctioned HIV testing services, it was feasible and efficient to implement the promotion of PN based on USST model among MSM in cooperation with CBOs.

WEPEC196

Are US black, Hispanic and white YMSM at risk for HIV acquisition being tested in accordance with national HIV testing recommendations? Results from a national study

R. Merchant[1], S. Marks[2], M. Clark[3], T. Liu[4], J. Rosenberger[5], J. Bauermeister[6], K. Mayer[7]
[1]Harvard Medical School, Emergency Medicine, Boston, United States, [2]Brigham and Women's Hospital, Boston, United States, [3]University of Massachusetts Medical School, Worcester, United States, [4]Brown University, Providence, United States, [5]Pennsylvania State University, University Park, United States, [6]University of Pennsylvania, Philadelphia, United States, [7]Harvard Medical School, Boston, United States

Background: Since 2006, the United States (US) Centers for Disease Control and Prevention (CDC) has recommended HIV testing for men-who-have-sex-with-men (MSM) at least once annually, with more frequent testing based on continued risk of HIV acquisition. Given the recent increases in HIV acquisition among US black, Hispanic and white young adult MSM (YMSM), there is concern that YMSM are not being tested in accordance with CDC recommendations. Among a national sample of US black, Hispanic and white YMSM at higher risk for HIV based on self-reported sexual behaviors, we aimed to: (1) determine how well their HIV testing history aligns with CDC HIV testing recommendations, and (2) identify structural and other barriers to testing.
Methods: Using multiple social media platforms, we recruited black, Hispanic, and white US YMSM (18-24 years-old) who reported condomless anal intercourse (CAI) within the prior year. Participants completed an online survey regarding their sexual behaviors, HIV testing history, HIV risk perception, and healthcare access. Multivariable logistic regression was used to examine factors associated with HIV testing in accordance with national guidelines.
Results: Of the 1,835 YMSM who had CAI within the prior year, 30% (95% CI: 28-32%) had not been tested for HIV in the past year. Of the 552 not tested within the past year, 62% (95% CI: 58-66%) had never been tested. Factors associated with not being tested in the past year included not having a primary care provider, discomfort with asking a provider for an HIV test, living outside of a large city/suburb, younger age, and greater self-perception of having an undiagnosed HIV infection.
Conclusions: Almost a third of YMSM at high risk for HIV infection had not been tested for HIV in the past year in accordance with national guidelines, and a substantial proportion never had been tested. Structural, knowledge, risk perception, and clinician relationship barriers must be overcome to improve HIV testing in this higher risk population. Implementation research examining how to address structural and health systems barriers, such as lower access to and trust in medical care, to promote adoption of HIV testing guidelines among this population are warranted.

Assisted and unassisted notification and HIV testing for the sexual and injecting partners of people living with HIV in Vietnam: Preliminary results of the HIV testing-to-treatment cascade

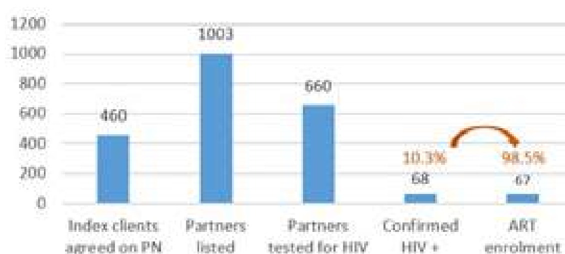
H.A. Doan, H. Ngo, B. Vu, K. Green, A. Bao, Y. Nguyen
PATH, Hanoi, Vietnam

Background: Vietnam adopted the 90-90-90 targets in December 2014 but annual HIV testing uptake among key populations (KP) was low and steady (~30%). In October 2015, USAID/PATH Healthy Markets (HM) launched pilot HIV lay provider and self-testing services, with the aim of increasing the uptake of HIV testing and HIV-positivity yield among KP. By December 2016, this pilot demonstrated a significantly improved positivity rate: 5.4%, compared to 1.6% among KP in conventional testing. To determine if partner notification (PN) was acceptable among those recently HIV-diagnosed and their partners, and effective in further increasing HIV positivity yield, HM piloted integrative assisted and unassisted PN into these services.

Methods: HM trained HIV lay providers—community-based organizations (CBO) and village health workers—provided partner notification counseling to index clients (HIV-infected individuals, mostly men who have sex with men or people who inject drugs), who were either identified through HIV lay and self-testing or already receiving antiretroviral treatment. From May-December 2017, both assisted and unassisted PN were offered, based on client preference. We analyzed monthly service reports to measure PN acceptability, percentage of index client that agreed to participate in PN, and effectiveness: HIV testing-to-treatment cascade for both assisted and unassisted PN.

Results: Between May and December 2017, 460 out of 488 (94.3%) index clients agreed to provide a list of high risk partners. Among 1,003 sexual and injecting partners identified, averaging 2.2 partners per index client, 66% of listed partners were successfully reached and tested for HIV. 10.5% were newly HIV diagnosed and 98.5% were successfully enrolled in treatment services

Conclusions: The pilot demonstrated high acceptability for PN services, better outcomes for assisted PN and resulted in a doubling HIV-positivity yield and a very strong HIV testing-to-treatment cascade. Results suggest that PN could be a valuable addition to HIV lay testing, supporting Vietnam to achieve the 90-90-90 targets by 2020.



[Figure 1. Cascade of HIV testing through partner notification approach (May to December 2017)]

WEPEC198

High-yield HIV testing, facilitated linkage to care, and prevention for female youth in Kenya (GIRLS Study): Preliminary baseline findings

I. Inwani[1], K. Agot[2], C.M. Cleland[3], N. Chhun[4], S.O. Rao[2], M. Anam[2], P. Macharia[1], J. Kinuthia[1], P. Cherutich[5], R. Nduati[6], A.E. Kurth[4]
[1]Kenyatta National Hospital, Nairobi, Kenya, [2]Impact Research and Development Organization, Kisumu, Kenya, [3]NYU Rory Meyers College of Nursing, New York, United States, [4]Yale University, School of Nursing, New Haven, United States, [5]Ministry of Health, Nairobi, Kenya, [6]University of Nairobi, Nairobi, Kenya

Background: Adolescent girls and young women (AGYW) ages 15-24 years are twice as likely as their male peers to be infected, making females in sub-Saharan Africa the most at-risk group for HIV infection.

Methods: Within a framework of implementation science, we are evaluating interventions to increase uptake of HIV testing, linkage to and retention in care, and prevention among AGYW. We compare two "seek" recruitment strategies, three "test" strategies, and pilot "linkage" to care interventions among AGYW in western Kenya. Participants are recruited from Homa Bay, Mbita, and Ndhiwa subcounties representing urban, fishing, and rural communities. AGYW are recruited via home-based or community-based strategies that run concurrently. AGYW are offered three testing options: oral fluid HIV self-testing; immediate staff-aided rapid HIV testing; or health care facility referral. Newly diagnosed HIV positives are enrolled in a trial (SMART design) to pilot adaptive interventions to support initial linkage to care. We also evaluate a primary prevention messaging intervention to support high risk HIV-negative AGYW to reduce their HIV risk behavior and adhere to HIV retesting recommendations.

Results: We have enrolled 664 participants, 518 (78.0%) in the home; 146 (22.0%) at mobile health events. Mean age was 19.6 (SD:2.4); 118 (17.8%) are 15-17 years old. 86% reported ever having sex, with sexual debut mean age of 16 years (SD:1.96). Only 34.9% reported condom use at last sex. Most, 534 (80.4%) chose staff-aided testing, with 126 (19.0%) choosing self-testing, and 4 (0.6%) health care facility referral. Newly diagnosed HIV-positive participants (21/664) all enrolled in the pilot, and 15 (71.4%) have been confirmed linked to care. Out of 631 HIV negatives, 112 (17.7%) were identified as high risk and 68 randomly selected have been enrolled to the HIV-negative cohort.

Conclusions: Preliminary findings indicate AGYW prefer the home-based recruitment strategy and staff-aided HIV testing regardless of recruitment site. Although HIV prevalence among AGYW (3.2%) is lower than reported for the region (27.8%), prevalence of high risk HIV-negative AGYW demonstrates the importance of prevention interventions at the point where it is most needed.

Building mobile phone-connected diagnostics and online pathways for HIV care: Early findings from the m-Africa formative study in KwaZulu-Natal, South Africa

O. Adeagbo[1], C. Herbst[1], N. Dlamini[1], T. Mhlongo[1], P. Sonnenberg[2], C. Estcourt[3], A. Blandford[4], V. Turbe[5], M. Thomas[6], K. Herbst[7], D. Pillay[7,8], R. McKendry[5], M. Shahmanesh[7,9]
[1]Africa Health Research Institute, Social Science Research Unit, Somkhele, Mtubatuba, South Africa, [2]University College London, Infection and Population Health, London, United Kingdom, [3]Glasgow Caledonian University, School of Health and Life Sciences, Glasgow, United Kingdom, [4]University College London, Institute of Digital Health, London, United Kingdom, [5]University College London, London Centre for Nanotechnology, London, United Kingdom, [6]Imperial College London, Department of Materials, London, United Kingdom, [7]Africa Health Research Institute, Somkhele, Mtubatuba, South Africa, [8]University College London, Division of Infection and Immunity, London, United Kingdom, [9]University College London, Institute for Global Health, London, United Kingdom

Background: Globally, South Africa has the highest number of people living with HIV/AIDS. The Province of KwaZulu-Natal (KZN) has a prevalence of 45% in antenatal clinics, and within our vicinity, 30% of people are unaware of their status and only 50% of those diagnosed reach clinical services within one year. Uptake of confidential HIV testing services is key to achieving the 90-90-90 objectives. However, extant HIV counselling and testing strategies are inadequate in our settings and new approaches are needed. This study aims to develop a new generation of mobile phone-connected HIV diagnostic tests and online clinical care pathways to support decentralised HIV testing (including self-testing), linkage to care, and prevention in South Africa.

Methods: Twenty-five semi-structured in-depth interviews and four focus group discussions were conducted (between November 2017 and January 2018) with healthcare providers and potential end-users (both sexes aged 18-58 years) in uMkhanyakude district in KZN, to understand their views of HIV care including HIV self-testing (HIVST) and their willingness to use the proposed technology. Themes were identified from the interview transcripts, manually coded and thematically analysed following an interpretivist approach.

Results: Participants (particularly males) believe that HIVST and the proposed technology for diagnostics and linkage to care will benefit them and others given its privacy and time saving when compared to fixed clinics. Most participants would like to make an appointment via phone with a health worker (non-community member) and meet at home or elsewhere for consultation or treatment to reduce stigma. However, some potential end-users raised concerns that people may commit suicide after testing HIV positive, without provider support. This was deemed less of an issue by providers, given the community awareness of HIV management. Overall, participants believe that community awareness (involving traditional leaders) is key to the success of HIVST and the proposed technology.

Conclusions: Despite a few concerns, participants show high levels of willingness to perform HIVST and to use online pathways technology for HIV care. The proposed technology could be a game-changer in achieving the 90-90-90 objectives given its potential to attract first-time testers and hard-to-reach populations. Implementation must draw on the support of community leaders.

Rapid/Same-Day ART initiation

WEPEC200

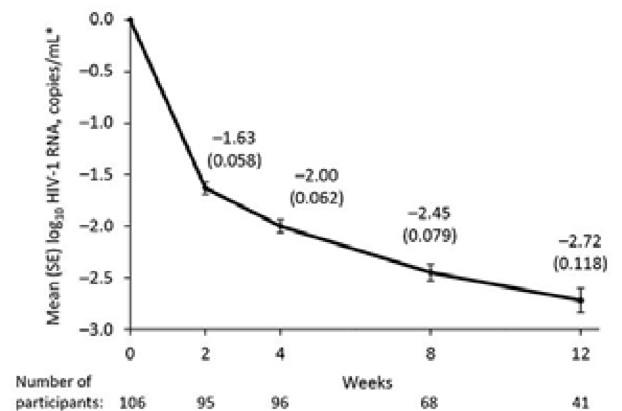
Darunavir/cobicistat/emtricitabine/tenofovir alafenamide (D/C/F/TAF) in a Test-and-Treat model of care for HIV-1 infection: Interim analysis of the DIAMOND study

G.D. Huhn[1], G. Crofoot[2], M. Ramgopal[3], J. Gathe Jr.[4], R. Bolan[5], C. Bicer[6], R.B. Simonson[7], R.E. Nettles[7], K. Brown[7], K. Dunn[7]
[1]The Ruth M. Rothstein CORE Center, Chicago, United States, [2]Crofoot Research Center, Houston, United States, [3]Midway Immunology and Research Center, Fort Pierce, United States, [4]Therapeutic Concepts, Houston, United States, [5]Los Angeles LGBT Center, Los Angeles, United States, [6]BICER Consulting & Research, Antwerp, Belgium, [7]Janssen Scientific Affairs, LLC, Titusville, United States

Background: Test-and-Treat models in newly diagnosed, HIV-1-infected patients have led to improved virologic outcomes, retention in care, and decreased mortality. Antiretroviral regimens used in this setting should optimally be a single-tablet regimen (STR), abacavir-sparing, well tolerated, and have a clinically-proven high genetic barrier to resistance. D/C/F/TAF (approved in Europe; under regulatory review in the US) is the only STR that possesses these qualities.

Methods: DIAMOND (ClinicalTrials.gov: NCT03227861) is an ongoing, phase 3, single-arm, open-label, prospective, multicenter study assessing the efficacy/safety of D/C/F/TAF 800/150/200/10 mg in a Test-and-Treat model over 48 weeks. Adults diagnosed with HIV-1 infection within 14 days were immediately enrolled and started on D/C/F/TAF without screening/baseline laboratory information. Investigators reviewed screening/baseline laboratory findings as results became available; patients not meeting predefined safety or resistance stopping rules continued treatment. A planned interim analysis for retention and clinical outcomes was conducted when all patients reached Week 4 of enrollment.

Results: Baseline patient (N=109) characteristics were: median (range) age 28 (19-66) years; 13% women; 32% African American; median (range) HIV-1 RNA 4.6 (1.3-8.2) $\log_{10}$ copies/mL; 24% ≥100,000 copies/mL; median (range) CD4+ count 369 (7-1,082) cells/mm^3; 21% < 200 cells/mm^3. Median (range) time from diagnosis to screening/baseline was 5 (0-14) days; 29% of patients enrolled within 48 hours of diagnosis. At the interim analysis, 95.4% (104/109) of patients continued on D/C/F/TAF and only 5/109 discontinued (3 due to safety stopping rules, 1 protocol violation, 1 adverse event [AE]). Through Week 12, mean HIV-1 RNA decreased by 2.72 $\log_{10}$ copies/mL (n=41; Figure). Incidences of grade 3 (5.5%) and serious (2.8%) AEs were low, with no grade 4 AEs or deaths. Week 24 results will be available for presentation.



[Figure. Mean (SE) change from baseline in $\log_{10}$ HIV-1 RNA over time.]

Conclusions: In the first known phase 3 trial of an STR in a Test-and-Treat model, a decline in HIV-1 RNA ≥2.00 $\log_{10}$ by Week 4 and patient retention of >95% on D/C/F/TAF were achieved at interim analysis, with no discontinuations due to predefined resistance stopping rules or lack of

efficacy. Organizations utilizing Test-and-Treat models should consider D/C/F/TAF as a preferred treatment option as it is the only agent with phase 3 data supporting its use in this setting.

WEPEC201

A comparison of outcomes of same day versus delayed Antiretroviral treatment (ART) initiation in the 'Test and Treat era' in Kenyatta National Hospital

S. Juliet Eshiwani, K. Mutai, P. Muiruri, E. Kubo
University of Nairobi/Kenyatta National Hospital Center of Excellence HIV Management (KNH/UoN CoE HM), Care and Treatment, Nairobi, Kenya

Background: A generation free from HIV is now feasible through universal Antiretroviral treatment for all people living with HIV. Late HIV diagnosis, late ART initiation and poor retention in care are challenges in achieving the UNAIDS 90-90-90 targets . Structural barriers such as poor linkages, patient and providers attitudes on willingness and readiness to start ART are the main impediments to same day ART initiation . Kenya adopted test and treat strategy in September 2016. This study compared viral suppression rates, ART adherence, development of new opportunistic infections and death events in patients who chose to initiate ART on the same day of HIV diagnosis versus those who delayed during the implementation period.
Methods: A retrospective cohort study analyzed electronic medical records of HIV positive patients 18 years and above, enrolled from September 2016 - June 2017. HIV-positive individuals were offered ART using a targeted approach by fast linkage, point of care CD4 testing and intensified counseling about HIV . Patients ultimately made the choice on when to initiate ART. Baseline characteristics and outcomes associated with same day ART were tested using Chi square, independent t and Mann Whitney U tests.
Results: Of the 367 patients who were eligible to initiate ART, 167(45.5%) started ART on the same day of HIV diagnosis. The average time taken to initiated ART in the delayed group, was 15 days. After 6 months of ART, more patients on the same day ART arm, 98 (78.5%) had achieved viral suppression HIV RNA< 20 copies/ml compared to 125 (71.3%), p=0.163. At baseline, 122 (77.7%) of patients in the same day arm were in WHO stage 1 and 2. Adherence to appointments was at 73.1% in the same day ART arm compared to 78% among those who delayed (p=0.269). Attrition from care was similar in both arms at 27.5% vs 26.5%, of note no death or transfer was reported in the same day arm.
Conclusions: Similar clinical outcomes are seen in patients in both arms of the study. Sub optimal adherence to ART and poor retention in care pose significant barriers to the effectiveness of the test and treat strategy.

WEPEC202

Peer navigation is strongly associated with increased uptake of same-day ART initiation among KPs living with HIV in Angola

M.D.R. Domingos Ferreira Nunes[1], M.L. Furtado[2], R. Pedro[3], C. Pedro[4], M. Goggin-kehm[5], D. Boyee[6], A. Diaz[4], G. Cristino[4], J. Cardao[7]
[1]Management Sciences for Health, Health Programs Group, Luanda, Angola, [2]Instituto Nacional de Luta contra a SIDA (INLS), Luanda, Angola, [3]Associação de Mulheres Vivendo com o VIH, MWENHO, Luanda, Angola, [4]Management Sciences for Health, Luanda, Angola, [5]FHI 360, Washington, DC, United States, [6]FHI 360, Dar E Salaam, Tanzania, United Republic of, [7]USAID, Luanda, Angola

Background: In October 2015, the PEPFAR-funded LINKAGES project in Angola began working with civil society organizations (CSOs) to provide key populations (KPs) — sex workers (SWs), men who have sex with men (MSM), and transgender people — with access to the full cascade of HIV services. While CSOs improved their ability to reach and test KPs, they struggled to link those who tested positive into care and treatment. The antiretroviral therapy (ART) initiation rate for KPs who tested positive in the first seven months of the program was only 19 percent (11/53). LINKAGES Angola integrated peer navigation into the program to improve ART initiation.
Methods: In May 2016, LINKAGES introduced HIV-positive peer navigators (PNs). The PNs would meet positive KPs for posttest counseling and accompany them to the health facility to start ART. We started with few PNs, and in May 2017, the program increased its number so that each team of peer educator and HIV counsellor had a navigator. The government of Angola supported in principle same-day ART initiation for KPs since October 2015 but did not make official the policy until September 2016. This is a retrospective analysis of routine program data on ART initiation.
Results: Same day ART-initiation is strongly associated (p< 0.0001, Fisher's exact test) with being assigned to a PN. Out of 355 KP+ patients, 62,8% (n=159) who were accompanied by a PN were initiated on ART the same day of their first medical consultation compared to only 29,4% (n=30) who initiated ART on the same day without the support from a PN. The rates of same-day ART initiation have improved over time, as shown in fig 1. From May 2017, with 68% of patients being initiated on ART the same day to 100% of patients on same-day ART by January 2018.
Conclusions: Employing PNs can substantially increase ART initiation rates. It is important that PNs meet beneficiaries on the day their test results are provided so that they can forge a bond right away. Well trained PNs are educating health professionals and empowering patients. LINKAGES in Angola will work with more PNs to maintain 100% same-day ART initiation.

WEPEC203

Operational feasibility and scope of same-day ART initiation under the WHO treat-all approach in the public sector of southern Swaziland- a prospective cohort study

B. Kerschberger[1], R. Nesbitt[1], Q. Mpala[1], C. Mamba[1], E. Mabhena[1], S.M. Kabore[1], M. Pasipamire[2], A. Telnov[3], B. Rusch[3], I. Ciglenecki[3]
[1]Medecins Sans Frontieres (OCG), Mbabane, Swaziland, [2]Ministry of Health (SNAP), Mbabane, Swaziland, [3]Medecins Sans Frontieres (OCG), Geneva, Switzerland

Background: Since 2017 WHO recommends antiretroviral therapy (ART) initiation on the day of HIV diagnosis. However, its feasibility in resource constrained settings remains uncertain. We describe predictors and outcomes of same-day ART in a well-established routine public sector HIV programme in Swaziland.
Methods: This is a prospective cohort of adults (≥16 years) newly enrolled into HIV care and eligible for ART irrespective of CD4 cell count (WHO treat-all approach) at 9 health facilities in southern Swaziland, between 10/2014 and 3/2016. ART was offered on the day of HIV care registration (same-day ART) and deferred for up to 3 months for patients not ready to start treatment. Follow-up time was until 12/2016. We identified predictors of same-day ART initiation utilizing multivariate logistic regression analysis. Flexible parametric survival models were built to compare time from facility-based HIV-care registration and time from ART initiation (for patients successfully initiated on ART) to the composite endpoint loss to follow-up/death.
Results: Of 1726 patients registered in HIV-care, with median age of 30 (IQR 25-36) years, 413/1726 (23.9%) were pregnant, and 556/1726 (32.2%) and 332/1726 (19.2%) had CD4 cell counts ≤200 and >500 cells/microliter. Overall, 842 (48.8%) patients initiated same-day ART. In deferred ART (n=884), 747 (84.5%) initiated treatment at a median of 10 (IQR 7-22) days and 137 (15.5%) did not start ART. The probability of same-day ART initiation was increased for pregnant women (vs men) (aOR 3.55, 95%CI 2.46-5.11), HIV diagnosis ≥15 days (vs diagnosis on day of registration) (2.14, 1.64-2.81) and recent study period (1.93, 1.49-2.50). It was decreased for secondary (vs primary) care facility (0.24, 0.19-0.30) and presumptive TB cases (0.47, 0.30-0.74). For same-day ART, crude 2-year HIV-care attrition was lower (27.6% vs 32.5%; p=0.009) while ART-attrition was higher (27.6% vs 21.3%; p=0.003) compared to deferred ART. Confounder adjusted analyses also showed a tendency of decreased risk of HIV-care attrition (aHR 0.85; 95%CI 0.69-1.05) while the risk of ART-attrition remained increased (1.65; 1.30-2.10).

Conclusions: Although same-day ART retained more patients in HIV-care, attrition was increased in patients on ART. Improved understanding of patient readiness is required to reduce adverse outcomes of same-day ART and inform its scale-up.

Demonstration and pilot projects for PrEP, PEP, male circumcision

WEPEC204

A comparative study of risk among adolescent girls and young women who accept or decline PrEP uptake from a community-based mobile clinic

E. Rousseau-Jemwa[1], C.L. Celum[2], J.M. Baeten[2], L.-G. Bekker[1]
[1]*Desmond Tutu HIV Centre, Institute of Infectious Diseases and Molecular Medicine, University of Cape Town, Cape Town, South Africa,* [2]*University of Washington, Department of Global Health, Medicine and Epidemiology, Seattle, United States*

Background: Achieving an AIDS-free generation critically depends on identifying populations at highest HIV risk and scaling up HIV testing, knowledge of HIV status, and HIV prevention uptake, including PrEP. An understanding about adolescent girls and young women (AGYW) acceptance or declining PrEP uptake is needed, which we evaluated in a PrEP delivery project through an adolescent mobile clinic.

Methods: A demonstration project (POWER) was implemented to determine whether AGYW at risk for HIV are motivated to start PrEP and what the preferable mode of distribution could be. Prevention including PrEP was offered to all sexually active AGYW ages 16-25 accessing sexual reproductive health services (SRHS) from an accessible, friendly, adolescent-tailored mobile clinic servicing limited-resource high disease-burden communities of Cape Town, South Africa. All AGYW completed a standardized sexual behaviour HIV risk assessment and risk reduction counselling. A causal-comparative approach, using chi-squared and t-tests, explored the potential effect of HIV risk factors comparing AGYW accepting to those who declined PrEP.

Results: Between June-December 2017, 347 AGYW accessed SRHS in which PrEP was offered and 25% (n=87) initiated PrEP on the same day. Overall, there was no significant difference in total HIV risk factors reported by acceptors (median=3 risk factors) and decliners (median=3) of PrEP. No significant difference in correlates of PrEP accepters and decliners were observed in age of sexual debut, whether her primary partner has other partners, knowing her partner's HIV status, or being involved in intergenerational or transactional sex. Factors significantly associated with PrEP uptake were visiting the mobile clinic previously ($p< 0.001$); frequent HIV testing (every 3 months; $p< 0.001$); inconsistent condom use ($p< 0.023$); and reporting multiple partners themselves ($p< 0.011$).

Conclusions: No significant difference existed in risk factors in AGYW accepting or declining PrEP uptake from the mobile. PrEP uptake in this cohort was associated with AGYW's 'personal agency' in sexual and health-seeking behaviour more than the risks associated with their current partners. The incongruity between HIV risk awareness and how that translates to behaviour (PrEP uptake) indicates that demand creation should include messaging to build AGYW's confidence to take ownership of their health and thus apply self-using prevention options.

WEPEC205

Worldwide PrEP: Online-to-offline HIV prevention for foreigners in Bangkok

N. Yaemim[1,2], B. Yaemim[1], K. Jonas[2]
[1]*Pulse Clinic Bangkok, Bangkok, Thailand,* [2]*Maastricht University, Maastricht, Netherlands*

Background: Formal Pre-Exposure Prophylaxis (PrEP) as a form of bio-medical prevention is not available in many countries, while generic PrEP available in Thailand offers low threshold access to this form of HIV prevention. Yet this form of access requires special online-to-offline measures and a counselling procedure that is tailored to the needs of foreign clients and a travelling population.

Description: Pulse Clinic Bangkok implemented an online-to-offline procedure to counsel men-having-sex-with-men (MSM) for PrEP and to provide HIV & STI testing, PrEP provision and regimen advice on location. From January till September 2017, after engaging in online counselling first, 2028 became so-called "PrEP tourists" with visits to the clinic. A total of 1703 (84%) returned for follow up visits after the initial visit. MSM can engage via different social media channels and gay dating apps with the clinic prior to their visit. During these chats knowledge about PrEP is provided. Later visits can be scheduled also outside regular office hours. Special online and offline counselling for substance users and alternative HIV prevention strategies for MSM who later (have/want to) stop using PrEP are offered. Clients are empowered and furnished with the knowledge to arrange HIV testing and continuous medical follow-up in their home countries.

Lessons learned: There is a large number of so-called "PrEP tourists" who regularly procure PrEP in Thailand and make use of local medical service provision. While continuously procuring PrEP via Bangkok, HIV testing and continuous medical follow up is also executed with local health care providers in their home countries. Overall, this mode of provision allows PrEP access for vulnerable MSM populations who cannot access PrEP at home. Yet at the same time, due to split health care provision, potential sero-conversions cannot always be traced.

Conclusions/Next steps: Affordable PrEP can contribute to a successful individual HIV prevention strategy even for MSM who cannot access PrEP formally in their home countries (e.g. due to lack of availability, high costs or stigmatizing health services). The model applied here comes with high counselling demands for medical service providers, and demands a high level of independent, responsible individual health care management by the PrEP users themselves.

WEPEC206

Pre-exposure prophylaxis in Zambia: Policy engagement and initial implementation

C. Claassen[1], L. Mwango[2], M.-C. Lavoie[3], I. Gashongore[2], E. Mubanga[4], D. Mumba[4], L. Mulenga[5], R. Sheneberger[1]
[1]*University of Maryland Baltimore, Center for International Health, Education, and Biosecurity, Institute of Human Virology, Lusaka, Zambia,* [2]*Maryland Global Initiatives Corporation - Zambia, Lusaka, Zambia,* [3]*University of Maryland Baltimore, Center for International Health, Education, and Biosecurity, Baltimore, United States,* [4]*National HIV/AIDS/STI/TB Council, Lusaka, Zambia,* [5]*Ministry of Health, Lusaka, Zambia*

Background: Pre-exposure prophylaxis (PrEP) is a highly effective HIV prevention measure not yet widely deployed in sub-Saharan Africa. The University of Maryland Baltimore (UMB) has worked with the Zambian Ministry of Health (MOH) to develop and implement national guidelines for PrEP. Since September 2016, UMB has engaged MOH and stakeholders on key population (KP) health services, leading to the first implementation of PrEP in Zambia.

Description: UMB provided medical and technical expertise to MOH to introduce PrEP in the 2016 Zambia National Consolidated ART Guidelines for sero-discordant couples (SDCs) and persons at high risk of HIV infection. The 2017 guidelines expanded eligibility with risk-based criteria targeting KPs, including SDCs, men who have sex with men (MSM), female sex workers (FSWs), and transgender (TG) persons. From April to November 2017, UMB piloted a PrEP intervention package at Railway Clinic, a KP referral site in Lusaka, that included community education about PrEP and trained 24 health care workers (HCWs) on PrEP service delivery. We present programmatic data on PrEP initiation and follow-up at one month.

Lessons learned: Discussions with KPs show near-universal positive perception of PrEP, but cite KP stigma, HCW reluctance, and negative media reports as barriers to PrEP access. In eight months of program implementation, UMB identified 649 HIV-negative clients: 168 (26%) were screened for PrEP, 57 (34%) were eligible, and 50 (88%) enrolled in PrEP; of those, 32 (64%) followed up at one month. Enrollment among SDCs (5/5), MSM (31/31), and TGs (5/5) was 100%, but 54% among FSWs (9/16). One-month follow-up was 100% among FSWs (9/9), 80% among SDCs (4/5), 60% among TGs (3/5), and 52% among MSM (16/31).

Conclusions/Next steps: A concerted collaboration between MOH, UMB, and other implementing partners resulted in the introduction of PrEP into Zambian national guidelines. Initial implementation shows high interest but rapid loss to follow-up following initiation. SDCs demonstrate high uptake and adherence; MSM and TG high uptake but moderate adherence, and FSWs moderate uptake but high adherence. Low screening rates may reflect HCW reluctance to offer PrEP. Further work should focus on HCW training and sensitivity, client education and adherence, and decreasing social barriers to accessing PrEP.

WEPEC207

Predictors of low medication possession ratio (MPR) in individuals receiving PrEP in the EPIC-NSW study in New South Wales (NSW), Australia

F. Jin[1], J. Amin[1,2], R. Guy[1], S. Vaccher[1], C. Selvey[3], I. Zablotska[4], J. Holden[3], K. Price[5], D. Weerasinghe[1], B. Yeung[1], G. Levitt[1], E. Ogilvie[1], A. McNulty[6], D. Smith[7], D. Cooper[1], A. Grulich[1], Expanded PrEP Implementation in Communities NSW South Wales (EPIC-NSW) Research Group
[1]The University of New South Wales, The Kirby Institute, Kensington, Australia, [2]Macquarie University, Department of Health Systems and Populations, Sydney, Australia, [3]NSW Government, Ministry of Health, Sydney, Australia, [4]Sydney University, Westmead Clinical School, Sydney, Australia, [5]AIDS Council New South Wales, Sydney, Australia, [6]Sydney Sexual Health Centre, Sydney, Australia, [7]North Coast HIV/Sexual Health Services, Lismore, Australia

Background: Medication adherence is a critical determinant of the efficacy of daily TDF/FTC as HIV PrEP, and adherence has varied widely in clinical trials and in some population-based settings. We report one-year medication possession ratio (MPR) as a proxy measure of adherence, and predictors for low MPR in a population-based study of rapid, targeted, and high-coverage PrEP implementation in NSW, Australia.
Methods: EPIC-NSW is a single arm study of daily TDF/FTC as PrEP. Adherence was evaluated in the 3,700 individuals at high-risk of HIV who were enrolled between March and October in 2016 and followed for a minimum of 12 months. Drug dispensing logs were reviewed and one-year MPR was determined as the total number of TDF/FTC pills dispensed from the date of first dispensing to the end of the first year of follow-up divided by 365. Total dispensing was truncated to a maximum of 365 doses. We examined predictors of low MPR (less than 80%).
Results: Participants were almost all men (99.4%) and identified as gay (95.5%). Median age was 36 years (interquartile range (IQR) 30-45 years). Most (55.6%) were Australian-born, lived in suburbs with a high concentration of gay men (gay Sydney, 38.2%) or elsewhere in Sydney (47.7%). The median one-year MPR was 97.8% (IQR: 74.0%-100.0%), and low MPR (< 80%) was recorded in 30.1% of participants. Younger men were significantly more likely to have low MPR than their older counterparts (46.5% aged under 25 and 23.1% aged above 45, p trend< 0.001). Low MPR was also more common in transgender people (50.0%) than in cisgender men (30.0%, p=0.033), and in bisexual (36.9%) and heterosexual (58.8%) men compared with gay men (29.7%, p=0.006). Participants who lived outside Sydney (35.9%) and other metropolitan areas of Sydney (30.3%) were more likely to have low MPR than those who lived in gay Sydney (28.0%, p=0.007). In multivariate analysis, younger age (p< 0.001) and sexual orientation other than gay (p=0.005) were significant predictors for low MPR.
Conclusions: Median MPR was high in EPIC-NSW. Low MPR, possibly indicating poor coverage of risk events, was more common in the young and in those who were not gay-identified.

WEPEC208

Understanding risk among male participants enrolled at clinicians' discretion in a PrEP demonstration trial in Victoria, Australia

J. Asselin[1], K. Ryan[1], V. Cornelisse[2,3,4], B. Price[2], N. Roth[2,3], J. Wilcox[5], B. Tee[6], C. Fairley[4,7], C. Chang[2], J. Armishaw[2], O. Vujovic[2], M. Penn[6], P. Cundill[6], G. Forgan-Smith[8], J. Gall[9], C. Pickett[10], L. Lal[1,2], A. Mak[2], T. Spelman[1,11], D. Murphy[12,13], C. El-Hayek[1,14], S. Ruth[6], C. Batrouney[6], J. Lockwood[2], J. Hoy[2], R. Grant[15,16], M. Stoové[1,14], E. Wright[1,2,11]
[1]Burnet Institute, Melbourne, Australia, [2]Alfred Hospital, Department of Infectious Diseases, Monash University, Melbourne, Australia, [3]Prahran Market Clinic, Melbourne, Australia, [4]Melbourne Sexual Health Centre, Alfred Health, Melbourne, Australia, [5]Northside Clinic, Melbourne, Australia, [6]Victorian AIDS Council, Melbourne, Australia, [7]Monash University, Central Clinical School, Faculty of Medicine, Nursing and Health Sciences, Melbourne, Australia, [8]Collins Street Medical, Melbourne, Australia, [9]ERA Health, Melbourne, Australia, [10]Ballarat Community Health, Ballarat, Australia, [11]Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [12]University of Sydney, Department of Gender and Cultural Studies, Sydney, Australia, [13]University of New South Wales, Centre for Social Research in Health, Sydney, Australia, [14]Monash University, School of Population Health and Preventive Medicine, Melbourne, Australia, [15]University of California, San Francisco, United States, [16]San Fransisco AIDS Foundation, San Francisco, United States

Background: PrEPX is a large population-level, multi-site, HIV pre-exposure prophylaxis (PrEP) implemenation project in Victoria, Australia. PrEPX eligibility criteria reflected the updated 2017 Australasian Society for HIV, Viral Hepatitis and Sexual Health Medicine (ASHM) PrEP guidelines and are based on sexual behaviour, a diagnosis of sexually transmitted infections (STI) and/or methamphetamine use in the prior three months; clinicians have discretion to enroll individuals not meeting these criteria. We explore HIV risk and motivation for PrEP among individuals enrolled at clinicians' discretion.
Methods: We identified PrEPX study participants enrolled at clinicians' discretion between July 26, 2016 and July 31, 2017 and conducted a thematic analysis of clinicians' free-text responses, to explore reasons for discretionary enrolment. Using data from sites participating in the ACCESS sentinel surveillance system we evaluated baseline bacterial STI (syphilis, chlamydia and gonorrhea) positivity and using self-reported ACCESS behavioural survey results we identified men at high HIV risk (>10 anal sex partners, condomless anal sex, group sex, recreational drug use in past six months) among participants not meeting PrEP prescribing guidelines.
Results: 1067 of the 3343 participants (32%) were enrolled at clinicians' discretion. The most common reasons reported for discretionary enrolment were the 'added protection of PrEP' (n=413, 39%), reporting sexual risk beyond the three-month recall period (n=296, 28%), psychological or emotional benefit (e.g. HIV related anxiety) (n=175, 16%) and perceived/intended future HIV risk (n=87, 8%).
Of the 2384 participants enrolled at ACCESS clinics with baseline behavioural and STI data available, 748 were enrolled at discretion (31%). Of these, 73/748 (10%) had an STI at baseline and 423/748 (57%) reported high HIV acquisition risk behaviour in the past six months in their survey. At baseline only 172 participants enrolled at discretion within ACCESS clinics (7%) did not have an STI diagnosis, or a history of high HIV acquisition risk identified by the clinician or in their behavioural survey.
Conclusions: Greater than 90% of PrEPX participants were at high risk for HIV acquisition at baseline in addition to having several other motivators to seek PrEP. These findings support the revised 2017 ASHM PrEP guidelines that include discretionary PrEP prescription.

WEPEC209

Barriers to PrEP implementation: The Ministry of Health demonstration projects in Swaziland

N. Gambu[1], S. Matse[1], M. Pasipamire[1], D. Chilongozi[2]
[1]*Ministry of Health (Swaziland), Mbabane, Swaziland,* [2]*Fhi360, Mbabane, Swaziland*

Background: Whilst the efficacy of HIV pre-exposure prophylaxis (PrEP) is proven, little is known about feasibility and acceptability of implementing (PrEP) in Swaziland. We present our experience in implementing oral PrEP demonstration projects amongst population at substantial risk of acquiring HIV infection from August to December 2017.
Methods: We used a Ministry of Health national implementation framework in collaboration with three partners; FHI 360, Clinton Health Access Initiative and Medicine San Frontiers using oral PrEP preparations of TDF/3TC 300mg or TDF/FTC 200mg. Ethical approvals were obtained from Swaziland Ethics Committee. Eighteen MoH clinics were chosen to implement the projects. Consenting participants aged 16 and above, who are sexually active, HIV sero-negative and at substantial risk of acquiring HIV infection were enrolled in the project. HIV testing was conducted at 0, 1 and 3 months visits. Clients who missed an appointment were followed-up three days after their scheduled visit expired and three phones calls at 2-days intervals were made. MoH approved tools were used to collect quantitative and qualitative data.
Results: A total of 1003 clients were screened, 76%(n=762) were established at substantial risk. Of these, 55%(n=422) were eligible and 93%(n=360) were initiated on PrEP. Among those initiated 75%(n=281) were females (10 self-identified as female sex workers and 1 man who have sex with men). Non-condom use was cited as the reason for accepting PrEP in 84%(n=303) of the PrEP initiates. Sixty percent(n=216) returned for their one-month follow-up visit and among those who did not, 27%(n=39)) were contacted by phone calls and 38%(n=15) cited various personal reasons for not showing up including distance to travel to clinic for PrEP refills. Twenty three percent (n=9) cited that they were no longer at risk and opted out.
Conclusions: PrEP uptake is promising and the demonstration project appears well integrating in existing MoH clinics. Key barriers to PrEP implementation remains as retention. PrEP demonstration projects should consider innovative ways to improve retention, for meaningful impact in HIV prevention.

WEPEC210

"It's like plan B for HIV!" Formative research results of PEPTALK: A study to design and test a media campaign to drive demand for, uptake of and adherence to PEP

J. Fagan[1], V. Frye[2], A. Lawal[3], M. Mosley[3], J. Yap[4,5], E. Greene[6,7], B. Zingman[4]
[1]*Montefiore Mecial Center, Albert Einstein College of Medicine, Bronx, United States,* [2]*City University of New York School of Medicine, Community Health and Social Medicine, New York, United States,* [3]*City University of New York School of Medicine, New York, United States,* [4]*Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, United States,* [5]*City University of New York School of Public Health, New York, United States,* [6]*New York Blood Center, Project ACHIEVE, New York, United States,* [7]*Columbia University, Epidemiology, New York, United States*

Background: PEP is an effective and underutilized HIV prevention tool in the United States. The PEP treatment period offers opportunities for promoting uptake of PrEP. However, among some gay/bisexual and men who have sex with men (MSM) and transgender women (TW) PEP awareness and uptake is low. PEPTALK conducted formative research to inform a multi-media campaign to drive demand for PEP among Black/African-American MSM/TW in upper Manhattan and the Bronx, NY.
Methods: We conducted 38 in-depth interviews and 5 focus groups (N=48) with participants: 18+; male at birth; Black/African-American; at-risk (condomless insertive/receptive anal intercourse with a man past 6 months); HIV-negative/unknown status; Bronx or upper Manhattan resident/worker. Interviews and groups covered sexual health; "exposure"; PEP awareness/experiences; barriers to and facilitators of PEP use; and diffusion of innovation (DoI).
Results: What behaviors constitute "exposure" varied by HIV knowledge level and the term itself was not consistently understood or well-received. PEP knowledge tended to be low and PEP was sometimes confused with PrEP. Among those who knew about PEP, several compared it to "Plan B" for pregnancy prevention.
When participants knew about PEP, they had often learned from friends or fellow MSM/TW and sometimes health professionals. Concerns about PEP focused on access and cost, and effectiveness. PEP users reported that PEP reduced anxiety, noting however that sometimes anxiety persisted since one cannot tell if PEP is "working" (observability). In terms of other DoI domains, disadvantages of PEP are that it cannot be tested or observed; positives are that it is relatively simple to use and is a good "back-up" (but not the first line of prevention).
Media messages and images were generated and tested, with feedback emphasizing the need to clarify the difference between PEP and PrEP; the desire to see PEP effectiveness data; and use of analogies that increase understanding ("Plan B for HIV"). Diversity in images presented was assessed to crucial.
Conclusions: PEP awareness is low; campaigns must make a distinction between PEP and PrEP. Simple and easy to understand messaging is needed. Increasing access via accessible PEP/PrEP providers and pharmacies is important, but without awareness and demand, these will not increase PEP uptake.

WEPEC211

Men who have sex with men (MSM) eligible for PrEP: Do they differ from other MSM clinic attendees?

D. Ogaz[1], H. Mohammed[1], J. Saunders[1], H. Reaney[2], N. Iyanger[1], P. Blomquist[1], G. Hughes[1], A. Williams[3], S. McCormack[4], M. Desai[5], L. Waters[6], C. Priestley[7], K. Manavi[8], A. Sullivan[4], A. Nardone[1], B. Gazzard[4], N. Gill[1]
[1]*Public Health England, HIV/STI Department, London, United Kingdom,* [2]*St Stephen's Clinical Research, London, United Kingdom,* [3]*Bart's Health NHS Trust, London, United Kingdom,* [4]*Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom,* [5]*The National Institute for Health and Care Excellence, Manchester, United Kingdom,* [6]*Central and North West London NHS Foundation Trust, London, United Kingdom,* [7]*Dorset County Hospital NHS Foundation Trust, Dorchester, United Kingdom,* [8]*University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom*

Background: The PrEP Impact Trial, a non-randomised trial, began recruitment in October 2017 in sexual health clinics in England. We report early findings from participating clinics on MSM PrEP-eligible by clinical assessment compared to other MSM attendees.
Methods: GUMCAD, the national sexually transmitted infection surveillance system, collects clinical and demographic data for each patient attendance, and since the start of the trial, has included PrEP eligibility codes. We extracted data from GUMCAD for HIV-negative MSM aged ≥16 who attended participating clinics from trial start to 30-Nov-2017. A proxy indicator of high HIV risk was based on data available from the preceding year, defined as: a prior HIV-negative test and an ano-genital bacterial STI. Using Pearson's ^{2} test, we compared PrEP-eligible MSM to other MSM attendees by ethnicity, age-group, clinical history and our proxy HIV risk indicator.
Results: A total of 13,967 MSM attended 41 trial clinics during the study period. Of these, 3,657 (26%) were identified at high HIV risk. Of all MSM attendees, 16% (2,262/13,967) were assessed as PrEP-eligible by clinicians; compared to those not assessed eligible, there was a higher proportion of PrEP-eligible MSM aged ≥35 (50% vs 41%; p< 0.001) and of white ethnicity (81% vs 79%, p=0.006).
Among attendees, there was greater proportion of PrEP-eligible MSM with a history of an HIV test in the previous year (75% vs 57%; p< 0.001) and identified at high HIV risk (39% vs 24%; p< 0.001).
Conclusions: Initial data indicate that MSM assessed as PrEP-eligible are at higher HIV risk than those not eligible, suggesting that PrEP is being appropriately targeted. Nonetheless, a quarter of MSM not coded as eligible for PrEP met proxy high HIV risk indicators; this may represent poor coding or missed opportunities for PrEP.
Our proxy measure for high-risk was based on historical GUMCAD data where patients cannot be tracked across clinics, a key limitation of our

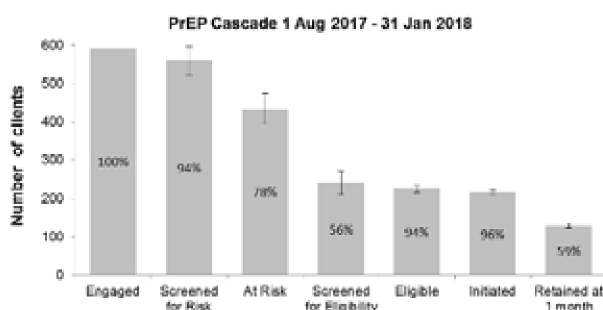
analysis. Based on these preliminary analyses, there are significant differences in clinical and demographic characteristics in MSM assessed as eligible for PrEP; these characteristics will need to be monitored as the trial continues.

WEPEC212

HIV pre-exposure prophylaxis (PrEP) for the general population in Swaziland: A detailed cascade study

A. Hettema[1], A. Hughey[1], C. Oldenburg[2], S. McMahon[3], S. Kohler[3], C. Lejeune[1], S. Matse[4], T. Bärnighausen[3]
[1]Clinton Health Access Initiative, Mbabane, Swaziland, [2]University of California, San Francisco, United States, [3]Heidelberg University Institute of Public Health, Heidelberg, Germany, [4]Ministry of Health, Swaziland National AIDS Program, Mbabane, Swaziland

Background: Under the leadership of the Swaziland Ministry of Health (MOH) a prospective cohort study was started in August 2017 with the aim to assess the operationalization of oral pre-exposure prophylaxis (PrEP) in one of the world´s first public-sector demonstration projects of PrEP for the general population in sub-Saharan Africa.
Methods: Between 1 August 2017 and 31 January 2018, clients attending any of the six public-sector primary care clinics participating in the PrEP demonstration project were informed about PrEP. Those interested in PrEP received counselling and clinical eligibility screening. If eligible, same-day PrEP initiation was offered. Data from the six clinics was extracted from MOH risk assessment forms and client files, and analyzed. A clustered linear probability model was used to identify differences in males and females progressing across each step of the cascade.
Results: Among the 592 clients individually engaged in PrEP, 94% (95%CI: 88-101) consented to HIV risk screening. A majority of clients screened were female (85%), which reflects clinic attendance composition. Overall 78% (95%CI: 69-87) of clients screened were identified as at risk for HIV. Those at risk and expressing interest (55%; 95%CI: 42-68) were assessed for clinical eligibility and 94% (95%CI: 90-97) of those were eligible to start PrEP. The majority of eligible clients (96%, 95%CI: 94-99) initiated PrEP, and 59% (95%CI: 55-63) returned 1-month after PrEP initiation. Comparing behaviors across the cascade by gender, the proportion of males identified as at risk, interested in PrEP and assessed for clinical eligibility was higher than those of females ($p< 0.05$). There was no difference in PrEP clinical eligibility. Although males were found to be more likely to initiate PrEP ($p< 0.05$) there was no statistically significant difference in the proportion of males and females retained at 1 month.



[Overall PrEP cascade showing percentages of clients engaged in PrEP who progressed across each step of the PrEP cascade.]

Conclusions: PrEP engagement of the general population attending public-sector primary-care clinics is acceptable but engagement of males is lagging. Large proportions of those who can benefit from PrEP do not initiate, or they disengage within one month. Increased efforts are needed to understand the reasons for PrEP decline and early discontinuation, and to find innovative ways to bring men into the PrEP cascade.

WEPEC213

Safety and acceptability of day 0 Foreskin Removal PrePex™ circumcision among men in Kenya

K. Agot, R. Bosire, J. Ambia, D. Muhuaya, J. Juma, M. Onyango, O. Spala, B. Ayieko, H. Ogola
Impact Research and Development Organization, Research, Kisumu, Kenya

Background: PrePex™ is a nonsurgical circumcision device being promoted to speed up the scale-up of voluntary medical male circumcision (VMMC) in Africa. However, concerns over odour and the risk of anaerobic infection such as tetanus when the foreskin is left for a week, undermines its acceptability. A modified PrePex™ procedure where the foreskin is removed on day 0 (Day0 Foreskin Removal Procedure (Day0 FRP)) may address these concerns. We assessed the safety and acceptability of Day0 FRP in Kisumu, western Kenya.
Methods: A phase IV, open-label, single-center, single-arm study was conducted among men aged 13-49 years seeking VMMC. After written informed consent (parental consent with minor assent for those aged 13-17 years), participants were offered HIV testing services, educated on the PrePex™ circumcision, assessed for contraindications to circumcision, administered a questionnaire, then offered Day0 FRP. They were scheduled for phone follow-up on days 3, 21, 28, 35 and 42 and in-person follow-up on days 7, 14 and 49. Outcome measures were safety and acceptability. Pain was assessed using visual analog scale (VAS). Percentages were used to summarize selected attributes on safety and acceptability.
Results: Between September and November 2017,515 participants underwent Day0 FRP, with 4 (0.77%, 95% CI 0.23-2.06) adverse events (AEs) reported between day 0 to 22: 3 were moderate (2 self-removals and 1 device displacement that were corrected by surgical intervention) and one was severe (mild tetanus possibly related to circumcision). Of the 505 participants contacted 3 days post device placement, 2.3% reported unusual odour and 5% (25/496) had difficulty in passing urine. Pain was highest (2, IQR; 2-4) during device removal, with 22% (114/512) and 97% (497/512) reporting pain before and after device removal, respectively. Only 5% (23/511) reported being disturbed while wearing the device or that it affected their usual daily activities. Wound healing, as assessed by full epithelialization and no granular tissue formation, showed that 97% were completely healed by day 49.
Conclusions: This study demonstrates that Day0 FRP PrePex™ circumcision method is acceptable and relatively safe, hence should be considered for men concerned about surgical circumcision or odour following PrePex Day7 FRP.

WEPEC214

Provision of youth-friendly VCT and VMMC during football training sessions and sports tournaments to drive hard-to-reach adolescents to clinical services

L. Brooks[1], O. Mezouar[2]
[1]TackleAfrica, Programme Management, Kilifi, Kenya, [2]TackleAfrica, Programme Management, Nairobi, Kenya

Background: Lack of youth-friendly and affordable services, peer- and self-stigma, fear and low level of understanding of the benefits of both Voluntary Counselling and Testing (VCT) and Medical Male Circumcision over traditional practices can pose significant barriers to effective HIV prevention for adolescents.
Description: Observations from a program in Kenya funded by a grant from PEPFAR as part of the DREAMS Innovation Challenge, managed by JSI, indicated the effectiveness of using weekly football sessions and regular football tournaments as tools for reaching, mobilizing, educating and providing adolescents with VCT and VMMC information and services. Football coaches trained as sexual health educators provided adolescents with a trusted source of information. The football team provided a natural support network for adolescents that can be lacking in a clinical setting. In January 2017 a cohort of forty community football coaches were trained to deliver innovative and interactive football drills, with VCT and VMMC sexual health messages built-in to the sessions.

All learning and information unfolded through play, making education interactive and experiential. By linking with the Ministry of Health and local NGOs, free, confidential VCT and VMMC were provided at pitch side, taking services to where the young people were and removing significant barriers to access. In one year, 895 interactive football sessions with integrated sexual health messaging reached 1314 players; 859 of those attended more than 5 sessions. 1211 VCT services completed; 414 VMMC performed.

Lessons learned: Weekly football sessions and quarterly tournaments, where medical advice and clinical services are available for free to adolescents in a youth-friendly setting, are key ways to create demand and drive uptake of VCT and VMMC.

Conclusions/Next steps: The intervention will expand in year 2 to additionally reach the wider community, and not just those adolescents enrolled in the weekly football sessions. Tournaments and other outreach events proved successful in engaging older age groups and people who do not play football, but who took advantage of the free services offered in a friendly non-clinical setting in the heart of their communities.

WEPEC215

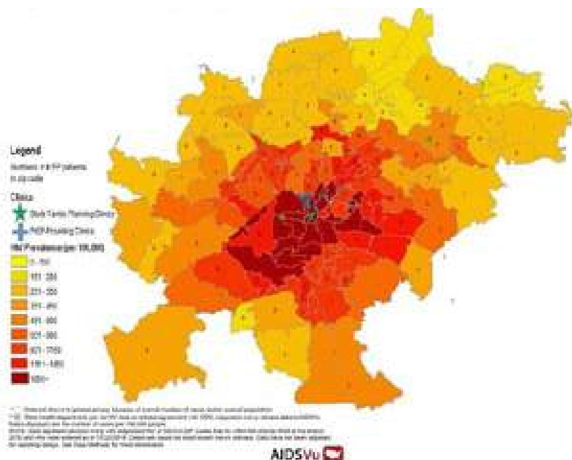
Evidence for public family planning clinics as potential PrEP delivery sites in the Southern U.S.

J. Sales[1], R. Steiner[1], A. Phillips[1], A. Patel[2], T. Renfro[1], C. Cwiak[2], A. Sheth[2]
[1]Emory University, Rollins School of Public Health, Behavioral Sciences and Health Education, Atlanta, United States, [2]Emory University, School of Medicine, Atlanta, United States

Background: Atlanta is a geographic "hot spot" for HIV in minority women. Public family planning (FP) clinics are vital sources of care for women in high HIV burden areas, and could be ideal delivery sites for pre-exposure prophylaxis (PrEP), which is currently underutilized by women. Little is known about PrEP interest and eligibility among women seeking care at public FP clinics.

Methods: We performed a PrEP screening and referral training for providers in 4 of the 25 public FP clinics in the Atlanta metropolitan statistical area (AMSA). Among 500 women seen in these clinics after the training (47% ≤28 years; 69% Black; 12% Hispanic), we conducted a pre-visit survey of HIV risk indicators (e.g., partner HIV status, recent STI, transactional sex) and post-visit survey of PrEP interest, provider counseling, and referral. We mapped patients and clinics against zipcode-level HIV prevalence data to assess clinic reach and contextualize patient geographic risk.

Results: FP clinic patients lived in 103 of 113 (91%) AMSA zip codes; 313 (63%) lived in zip codes with HIV prevalence >0.8%, and 196 (39%) in zip codes with prevalence >1.85% (Figure 1). Of the 376 sexually active women, 110 (29%) had ≥1 risk indicator consistent with PrEP eligibility. Among PrEP-eligible women, 72 (66%) reported the provider talked to them about PrEP and 32 (29%) were interested in taking PrEP; only 20 (18%) accepted a referral to an off-site public PrEP clinic. Overall, 19% previously knew about PrEP, and 76% were more willing to take PrEP if provided by the FP clinic.



[Figure 1. Number of Atlanta Family Planning Clinic Patients Enrolled by Zip Code-Level HIV Prevalence]

Conclusions: Public FP clinics in AMSA overwhelmingly serve women who reside in communities with high HIV prevalence. Despite nearly a third of women reporting HIV risk indicators consistent with PrEP eligibility, few knew about PrEP. Once informed about PrEP by FP providers, most women expressed interest if it were offered at the FP clinic, but few accepted an off-site referral. Our results demonstrate strong patient acceptability and interest in PrEP delivery in public FP clinics and highlight the potential impact that PrEP capacity building in this setting may have on PrEP scale up for women in high HIV burden areas.

WEPEC216

Willingness and actual use of pre-exposure prophylaxis in men who have sex with men in Taiwan: Results from a 2017 Hornet/HEART survey

S.W.-W. Ku[1], P. Huang[2], A. Garner[3], A. Bourne[4], C. Strong[5], S.-S. Chen[6], P.-C. Huang[7], F.-M. Jan[6], S. Howell[3], N.-Y. Ko[8], W.-W. Wong[6]
[1]Taipei Veteran General Hospital Hsinchu Branch, Division of Infectious Diseases, Department of Medicine, Hsinchu, Taiwan, Province of China, [2]University of California, Department of Communication, San Diego, United States, [3]Hornet Networks Limited, Hong Kong, Hong Kong, [4]Australian Research Centre in Sex, Health & Society La Trobe University, Melbourne, Australia, [5]National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Department of Public Health, Tainan, Taiwan, Province of China, [6]Taipei Veterans General Hospital, Division of Infectious Diseases, Department of Medicine, Taipei, Taiwan, Province of China, [7]HIV Education And Research Taiwan (HEART), Taipei, Taiwan, Province of China, [8]National Cheng Kung University and Hospital, Department of Nursing, Tainan, Taiwan, Province of China

Background: Men who have sex with men (MSM) remain the most affected population by HIV infection in Taiwan. Taiwan CDC implemented the first pre-exposure prophylaxis (PrEP) demonstration project in 4 major cities from October 2016 to December 2017. However the willingness and actual use of PrEP in the MSM community since PrEP implementation in Taiwan remained unknown.

Methods: We conducted a survey by convenience sampling of the users of a social network application for MSM in Taiwan. The survey was conducted between November 22 and December 22, 2017. The survey included 15 questions regarding age, residence, HIV serostatus, PrEP-related indications, PrEP awareness, willingness and current use. The users were invited to take the survey by responding the app inbox messages. Responses from the same IP address were excluded.

	Without willingness Without current use		With willingness Without current use		With willingness With current use	
	AOR (95% CI)	P	AOR (95% CI)	P	AOR (95% CI)	P
Age (18-25 vs. >25)						
	1.00	Ref	.77 (.59, 1.02)	.065	.27* (.10, .74)	.011

*P< 0.05

[Table. Multinominal logistic regression for factors associated with willingness and current PrEP use]

Results: There were a total of 2,009 responses, of which 1,734 were eligible for analysis. The respondents had a mean age of 28.3 years (SD, 7.8), and nearly 80% lived in the major cities. There were 10.3% of the respondents reported HIV-positive. More than half of the respondents were aware of PrEP (58.0%). Nevertheless, there were only 1.4% used dai-

ly PrEP and 1.7% used on-demand PrEP currently. Among those who reported HIV-negative or unaware of one's serostatus, there were a quarter reported willingness to use PrEP in the coming 6 months. The major reasons affecting PrEP willingness were difficult access (52.3%) and high cost (48.4%). Multinominal logistic regression model revealed previous use of post-exposure prophylaxis (PEP) and having condomless anal intercourse (CLAI) were significantly associated with PrEP willingness; meanwhile younger age, residence in major cities and having Chemsex, in addition to previous PEP use and having CLAI, had significant correlation with the respondents' willingness and actual use of PrEP. (Table)
Conclusions: While the actual use of PrEP remained low in Taiwan, our research has identified a gap between awareness, willingness and initiation of PrEP. To bridge PrEP efficacy to the real world setting, policy makers, the providers and the community should address these barriers with different strategies to scale up PrEP use in the future.

WEPEC217

HIV preexposure prophylaxis uptake after low-intensity outreach to patients with sexually transmitted infections

R. Guinness[1], J. Volk[2], L. Hurley[2], T. Tobias[2], J. Marcus[3]
[1]Kaiser Permanente, Graduate Medical Education, San Francisco, United States, [2]Kaiser Permanente, San Francisco, United States, [3]Harvard Medical School, Cambridge, United States

Background: Patients with rectal sexually transmitted infections (STIs) and syphilis are at risk for HIV acquisition, yet many are not using preexposure prophylaxis (PrEP). We assessed the feasibility and preliminary effectiveness of a one-time email or letter to individuals in this at-risk population to increase linkage to PrEP care.
Methods: We identified all HIV-uninfected adult members of a large integrated healthcare system, Kaiser Permanente (KP), in San Francisco and Oakland, who were not on PrEP and were diagnosed with rectal gonorrhea or chlamydia, or treated for syphilis, during January-July 2017. These patients were sent a secure, password-protected email message through the KP electronic health record, or a letter if email was not available. Information about PrEP was provided, as well as information about how to access PrEP at KP, including a phone number for self-referral or additional information. We assessed feasibility by the proportion of emails opened, and preliminary effectiveness by the proportion of patients linked to PrEP care in the following three months, using Fisher's exact tests to identify characteristics associated with linkage to PrEP care.
Results: A total of 128 HIV-uninfected patients had a rectal STI (56.3%) or syphilis (43.7%), and were sent a one-time email (77.3%) or letter (22.7%). Patients had a median age of 36 (IQR 28-52), most were male (94.5%), and 37.6% were White, 28.1% Hispanic, 15.6% Asian, and 14.8% Black. Of those sent an email, 78.8% read the message, 12.4% were linked to PrEP care, and 11.3% initiated PrEP; no individuals sent letters were linked to PrEP care (p=0.07). Among those sent an email, Hispanics were more likely to be linked (32.0%) compared with White (4.8%) and Black (0%) individuals (p=0.019; Table 1).

	Outreach by email or letter			Outreach by email		
	No linkage	Linkage	*P*	No linkage	Linkage	*P*
Race/ethnicity, n (row %)			0.037			0.019
White	46 (95.8)	2 (4.2)		40 (95.2)	2 (4.8)	
Hispanic	28 (77.8)	8 (22.2)		17 (68.0)	8 (32.0)	
Asian	16 (88.9)	2 (11.1)		15 (88.2)	2 (11.8)	
Black	19 (100.0)	0 (0.0)		10 (100.0)	0 (0.0)	
Other/Unknown	5 (100.0)	0 (0.0)		3 (100.0)	0 (0.0)	

[Table 1. Characteristics associated with linkage to PrEP care after outreach via email or letter]

Conclusions: A one-time secure email to HIV-uninfected patients with recent STIs is feasible and may be sufficient to increase linkage to PrEP care, while there were no patients linked to PrEP care in the group sent letters. Linkage to PrEP care was higher among Hispanic individuals compared with other racial/ethnic groups. Additional outreach may be needed to overcome barriers to PrEP uptake among Black individuals at risk of HIV acquisition.

WEPEC218

Rapid uptake of care by men who have sex with men who use informally and self-obtained pre-exposure prophylaxis in Amsterdam: The InPrEP project

S.H. Hulstein[1], E. Hoornenborg[2], A. Matser[2], A. Hogewoning[1], Y. van Duijnhoven[2], M. Prins[2,3], H. De Vries[1,4]
[1]GGD Amsterdam, STI Clinic, Amsterdam, Netherlands, [2]GGD Amsterdam, Infectious Diseases, Amsterdam, Netherlands, [3]Academic Medical Center, Internal Medicine, Amsterdam Infection & Immunity Institute (AI&II), Amsterdam, Netherlands, [4]Academic Medical Center, Dermatology, Amsterdam, Netherlands

Background: Pre-exposure prophylaxis (PrEP) is a highly effective method to prevent HIV among men who have sex with men (MSM). In the Netherlands, an unknown number of MSM have chosen to self-obtain PrEP through informal ways, as PrEP is not yet implemented and costs are not reimbursed . We initiated a program to prevent potential harm caused by unmonitored PrEP use and assessed the uptake of informal PrEP and related care.
Description: Starting September 2017, with additional funding from the Amsterdam City Council we implemented a program at the Amsterdam sexually transmitted infections (STI) Clinic, InPrEP, providing PrEP-related health care for informal PrEP users and intended future users. Care encompassed quarterly monitoring visits in accordance with Dutch PrEP guidelines. STI, including hepatitis C virus, HIV and kidney function tests were performed at each visit and visitors were counseled on PrEP related subjects, e.g. adherence and sexual health. PrEP is prescribed if indicated, however not provided by the STI clinic.
Lessons learned: In less than 4 months 2928 MSM visited the Amsterdam STI clinic of which 273 (9.8%) reported PrEP use in the past 3 months. 140 informal PrEP users (mostly highly educated MSM, median age 32; IQR 26-42) have been included into the program, which shows that MSM want to use PrEP even if they have to obtain PrEP informally and have to cover medication costs. Several different dosing regimens were used or combined: 54.4% of users used daily PrEP, 36.5% event-driven PrEP or both 7.0%. Other non-evidence based regimens (e.g. alternately one day on, on day off PrEP) were used by 2.1% of users. No incident HIV infections nor serious adverse events (e.g. renal failure) were observed.
Conclusions/Next steps: The very rapid uptake of PrEP-related health care shows the popularity of PrEP use among MSM and the high need for PrEP-related care among informal self-obtaining PrEP users. Upscaling of PrEP-related care is needed in the Netherlands to meet the demand. Informal PrEP users used both daily and event-driven dosing regimens, indicating that implementation programs should offer both modalities to ensure optimal uptake of PrEP.

WEPEC219

Sexual behavior and PrEP uptake among young African women in a demonstration project about PrEP delivery

D. Travill[1], L.G. Bekker[2], S. Delany-Moretlwe[1], E. Bukusi[3], J. Imrie[1], E. Rousseau-Jemwa[2], V. Omollo[3], L. Kidoguchi[4], J. Morton[4], G. O'Malley[4], G. Barnabee[4], R. Heffron[4], A. van der Straten[5], S. Roberts[5], J. Haberer[6], R. Johnson[4], J. Baeten[4], C. Celum[4], POWER Study Team
[1]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [2]Desmond Tutu HIV Foundation, Cape Town, South Africa, [3]Kenya Medical Research Institute, Kisumu, Kenya, [4]University of Washington, Seattle, United States, [5]Research Triangle Institute, San Francisco, United States, [6]Massachusetts General Hospital, Boston, United States

Background: Adolescent girls and young women (AGYW) in sub-Saharan Africa are an important population who could benefit from PrEP. We assessed PrEP uptake and sexual behavior in the Prevention Option for Women Evaluation Research (POWER) cohort.
Methods: POWER is an open label PrEP implementation project investigating PrEP delivery for AGYW aged 16-25 years. PrEP is integrated with reproductive health services at family planning clinics (Kisumu, Kenya), an adolescent and youth-friendly clinic (Johannesburg, South Africa [SA]) and a mobile van for reproductive health services for youth (Cape Town, SA). AGYW are offered PrEP according to national guidelines at quarterly visits over three years. Using baseline demographic and behavioral data,

a standardized risk score derived from the VOICE clinical trial was calculated. This VOICE risk score (VRS) was modified to exclude bacterial STIs and HSV2 seropositivity, which are not available at screening, and has a maximum score of 8; VRS ≥4 correlated to an annual HIV incidence >3% and VRS ≥5 correlated to >9% annual HIV incidence in VOICE.
Results: From June through December 2017, 330 AGYW enrolled in POWER (Kisumu n=137, Johannesburg n=107, Cape Town n=86). The median age is 20.5 years (interquartile range [IQR]=19-22) and marital status varied by geographic region (30% married in Kenya vs. 0% in SA). Most participants (82%) were single but had a steady sexual partner, and 17% reported >1 partner in the past three months. Two-thirds (68%) did not know their partners' HIV status and only 4% were in a known serodiscordant relationship. Self-reported consistent condom use was low (18%) and half (54%) reported contraceptive use. HIV risk, as measured by the VRS, was high: 72% had a VRS ≥5 and 93% had a VRS ≥4. PrEP uptake at the initial visit was 90% across all sites. The main reasons for declining PrEP were fears of HIV stigma or partner reactions.
Conclusions: AGYW in Kenya and South Africa had evidence of high HIV risk using a previously validated risk score, indicating that women initiating PrEP would benefit from it. Notably, they also had high willingness to initiate PrEP when delivered in these youth-friendly settings.

WEPEC220

Outcomes of a pilot intervention of voluntary medical male circumcision and HIV education program for adolescent street youth in Western Kenya

P. Shah[1], M. Kibel[2], D. Ayuku[3], D. Makori[1], E. Kamaara[4,5], E. Choge[4,5], J. Nyairo[5], P. Abuya[5], M. Wahome[4,5], J. Wachira[3], P. Braitstein[1,2,3]
[1]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [2]University of Toronto, Dalla Lana School of Public Health, Department of Epidemiology, Toronto, Canada, [3]Moi University, College of Health Sciences, Department of Behavioural Sciences, Eldoret, Kenya, [4]Moi University, School of Arts and Social Sciences, Department of Philosophy and Religious Studies, Eldoret, Kenya, [5]African Christian Initiation Program, Eldoret, Kenya

Background: There is a substantial epidemic of HIV among street-connected children and youth (SCY) in Eldoret, Kenya. Voluntary male medical circumcision (VMMC) is extremely effective in reducing the risk of HIV transmission. For many Kenyans, circumcision and traditional teachings are a cultural rite of passage. This paper describes the outcomes of a pilot project offering a coming-of-age initiation retreat that included VMMC and educational modules to this population.
Methods: Through outreach and sensitization, male street youth aged 12-24 were invited to participate. The retreat took place over 10 days in three groups from December 2016 to May 2017. After circumcision and healing, youth participated in education modules covering sexual health, substance abuse, HIV/AIDS, and life skills. Pre- and post quantitative surveys assessed HIV knowledge and attitudes, resilience, and self-esteem. HIV knowledge was scored out of 20, and the RS-14 and the Rosenberg Self-Esteem Scale were used to measure resilience and self-esteem, respectively. Pre- and post-intervention response frequencies were compared using McNemar's test, and composite scores were compared using the paired Student's T-test or the Wilcoxon Sign-Rank test.
Results: One hundred and sixteen male SCY (median age 14, IQR 13-15) took part. There was a significant increase in HIV knowledge scores before and after the retreat (15.6 vs. 17.6, p=0.001), with those aged 12-14 showing a greater increase compared to the older age group. There was a significant increase in the number of youth who thought condoms were safe (85.2% vs. 95.7%, p< 0.005), who said a man and a woman should decide to use a condom together (27.8% vs. 56.5%, p< 0.001), and who said they would treat a friend the same way if they found out they were HIV positive (68.7% vs. 87.0%, p=0.001). RS-14 scores increased after the retreat (77.5 vs. 80.8, p< 0.001), and there was a non-significant increase in RSES scores (26.0 vs. 26.4%).
Conclusions: This pilot project demonstrated that it is possible to effectively engage SCY, a hard-to-reach and high-risk population, in HIV prevention interventions. Tailored HIV education may improve knowledge, attitudes, and perceptions around HIV, as well as contribute to positive mental wellbeing of SCY.

WEPEC221

PrEP for HIV prevention in Shiselweni, Swaziland: Early uptake and month one retention

R. Nesbitt[1], Q. Mpala[1], C. Mamba[1], B. Kerschberger[2], E. Mabhena[1], M.L. Tombo[1], L. Garcia Abrego[1], M. Daka[1], S. Mathurin Kabore[2], S. Matse[3], M. Pasipamire[3], A. Telnov[4], N. Staderini[4], J. Goiri[4], I. Ciglenecki[4]
[1]Médecins Sans Frontières, Nhlangano, Swaziland, [2]Médecins Sans Frontières, Mbabane, Swaziland, [3]Ministry of Health, Swaziland National Aids Program, Mbabane, Swaziland, [4]Médecins Sans Frontières, Geneva, Switzerland

Background: Despite a major reduction in HIV incidence of 44% from 2011-2016 in Swaziland, specific populations remain at high risk, particularly young women and sero-discordant couples. In 2015, the WHO strongly recommended that oral pre-exposure prophylaxis (PrEP) be offered to people at substantial risk of HIV. The Ministry of Health and Medecins Sans Frontieres are conducting a prospective cohort study of PrEP to determine uptake and retention among people at high risk in the rural region of Shiselweni since September 2017.
Methods: Adults (≥16 years) testing HIV negative at 10 sites were offered a risk assessment with a counsellor, comprising six risk behaviours. Those at risk and interested in PrEP were screened for eligibility by a nurse, excluding acute HIV infection (AHI), renal impairment, and hepatitis B. Here we report predictors of early uptake using logistic regression and one month retention in clients screened between September and December 2017.
Results: Out of 438 HIV negative people screened for risk of HIV infection, 333(76%) were identified at risk, reporting a median of 2 risky behaviours in the past six months. Of those, 170 (51%) were interested in PrEP, and 121 (36%) initiated PrEP. Median age was 26.7 years (IQR 21-36), 99 (82%) were female. Females initiating PrEP were younger than males (p=0.01), and all clients initiated on PrEP below 20 years were female. Among those initiated, 47 (39%) reported an HIV positive partner. In multivariable analysis among clients at risk, age below 20 and above 40 years (aOR 2.53, 95 %CI: 1.22-5.26, p=0.01; OR 4.67, 95% CI 1.53-14.22, p=0.007) and an HIV positive partner (aOR 4.13, 95 %C I1.75-9.74, p=0.001) were predictive of PrEP initiation. Among 108 clients initiating between September and November 2017, 69 (64%) returned for month one follow up visit, with no difference by gender (p=0.67).
Conclusions: The majority of HIV negative people screened for risk in Shiselweni are at risk of HIV infection. Interest in PrEP is moderate; however, there is demand among high risk target groups, namely young women and those reporting sero-discordant relationships. Strategies to increase PrEP demand and retention are required in order to optimize this intervention.

WEPEC222

Retention and adherence to PrEP among MSM and transgender women in Thailand's 'Princess PrEP program': The key population-Led PrEP program

J. Jantarapakde[1], S. Pengnonyang[1], T. Sungsing[1], P. Meekrua[2], P. Brutrat[2], P. Panpet[3], F. Suwan[3], S. Pangpoom[4], S. Sangtong[5], S. Singhor[6], S. Promthong[1], P. Phiayura[1], W. Sirisakyot[1], P. Rattakitvijunnanakorn[1], P. Mingkwanrungruang[1], D. Trachunthong[1], S. Charoenying[7], S. Mills[7], R. Vannakit[8], N. Phanuphak[1], P. Phanuphak[1]
[1]The Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]Service Workers In Group Foundation, Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]Sisters Foundation, Chonburi, Thailand, [5]MPlus Foundation, Chiang Mai, Thailand, [6]Caremat, Chiang Mai, Thailand, [7]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [8]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

Background: Key population (KP)-led PrEP service delivery is an innovative and promising way to deliver PrEP in a non-judgemental and accessible way to people truly in need of PrEP. The 'Princess PrEP program' in Thailand provides PrEP without cost to MSM and transgender women (TGW) in KP-led clinics by trained KP community health workers (KP-CHW).

Methods: PrEP was provided to MSM and TGW in 7 KP-led clinics in Bangkok, Chiang Mai, Chonburi, and Songkhla, using 'Same-Day PrEP flow'. KP-CHW assessed risks, screened for acute retroviral symptoms, performed HIV testing, and collected blood for creatinine clearance (CrCl) and HBsAg. HIV test results were available within an hour and 1 PrEP bottle was given on the same day. KP-CHW contacted PrEP clients 1-2 days later to inform them of their CrCl and HBsAg and provide guidance to continue/discontinue PrEP. Self-administered questionnaires were used to collect demographic and behavioural risk data. We used binary logistic regression to identify factors associated with PrEP adherence and retention.
Results: During January 2016-June 2017, 937 MSM and 146 TGW accessed PrEP through this program. Mean (±SD) age was 28.7 (±7.2) years and 32.7% aged <18 years at first sex. In the past 3 months, 62% had multiple partners, 46.9% self-perceived moderate/high HIV risk, 42.5% used condoms inconsistently, 32% reported substance/stimulant drug use, and 19.3% had group sex. At months 1, 3 and 6, 72.4%, 61%, and 52% were retained, respectively. Among those retained, 95.8% reported taking PrEP >/=4 pills/week. There was no seroconversion among PrEP-adherers. HIV incidence (95% CI) among PrEP non-adherers was 3.65 (1.52-8.77). Age >25 years (aOR=1.96, 95%CI=1.46-2.62, *P*=0.007), being MSM (aOR=3.49, 95%CI=2.29-5.31, *P*=< 0.001), and having bachelor degree and above (aOR=2.30, 95%CI=1.72-3.08, *P*=0.04) increased PrEP adherence. Being MSM (aOR=1.83, 95%CI=1.24-2.69, *P*=0.005) and being ≥18 years at first sex (aOR=1.42, 95%CI=1.08-1.86, *P*=0.048) increased retention.
Conclusions: This KP-led PrEP program successfully reached MSM and TGW who were at high risk for HIV. Innovative approaches to address inadequate retention and adherence among PrEP users, especially those who are TGW, young, and have low education, are urgently needed in order to achieve the maximum prevention benefit of PrEP.

WEPEC223

High prevalence of curable STIs among young women initiating PrEP in Kenya and South Africa

J. Morton[1], E. Bukusi[2], S. Delany-Moretlwe[3], L.-G. Bekker[4], V. Omollo[2], D. Travill[3], E. Rousseau-Jemwa[4], L. Kidoguchi[1], R. Johnson[1], C. Celum[1], J. Baeten[1], for the POWER Study Team
[1]*University of Washington, Seattle, United States,* [2]*Kenya Medical Research Institute, Kisumu, Kenya,* [3]*Wits Reproductive Health and HIV Institute, Johannesburg, South Africa,* [4]*Desmond Tutu HIV Foundation, Cape Town, South Africa*

Background: Sexually transmitted infections (STIs) are common worldwide, although data on STI prevalence are often lacking for settings in Africa due to limited diagnostic resources. For women interested in initiating pre-exposure prophylaxis (PrEP) for HIV prevention, diagnosis of an STI is a potential marker for HIV risk and treatment can reduce onward STI transmission as well as HIV risk.
Methods: The Prevention Options for Women Evaluation Research (POWER) Cohort is an open label PrEP implementation project for sexually active HIV-negative women ages 16-25 in Cape Town and Johannesburg, South Africa and two clinics in Kisumu, Kenya. PrEP is delivered in accordance with national guidelines; nucleic acid amplification testing for gonorrhea and chlamydia is conducted at baseline and if positive, national standard of care treatment provided.
Results: To date, 330 women have enrolled, of whom 300 (91%) women accepted PrEP. Median age was 20.5 years. Most women (86%) were unmarried and 17% reported having more than one current sex partner. A third of women (34%) tested positive for a curable STI (29% *Chlamydia trachomatis* and 11% *Neisseria gonorrhoeae*, with 6% having both infections). STI prevalence was high at all sites: 40% and 16% at the two clinics in Kisumu, 38% in Cape Town, and 35% in Johannesburg (Table). Younger women were significantly more likely to have an STI than older women (53% prevalence among ages 16-17 years, 39% ages 18-21, and 22% ages 22-25, p<0.01). Only 5.5% of women reported symptoms of an STI at the time of testing.
Conclusions: Young women in Kenya and South Africa participating in a PrEP implementation project had high prevalence of gonorrhea and chlamydia, a marker of high HIV risk as well as a cause of adverse reproductive health consequences. Interventions for STI prevention, diagnostic testing, and optimized treatment for young women are urgently needed.

	Gonorrhea and/or Chlamydia	Gonorrhea	Chlamydia	Both Gonorrhea and Chlamydia
Kenya - Kisumu (private family planning clinic) (n=81)	32 (40%)	12 (15%)	28 (35%)	8 (10%)
Kenya - Kisumu (public family planning clinic) (n=49)	8 (16%)	4 (8%)	5 (10%)	1 (2%)
South Africa - Cape Town (mobile service delivery) (n=79)	30 (38%)	9 (11%)	27 (34%)	6 (8%)
South Africa - Johannesburg (youth-friendly clinic) (n=98)	34 (35%)	9 (9%)	29 (30%)	4 (4%)
Total (n=307)	104 (34%)	34 (11%)	89 (29%)	19 (6%)

WEPEC224

A PrEP demonstration project among female sex workers in India: Lessons for scaling up

S. Reza-Paul[1], L. Lazarus[1], R. KN[2], V. MS[2], M. Ramaiah[2], M. Becker[1], S.M. Mahmud[1], R. Lorway[1], S. Moses[1]
[1]*University of Manitoba, Winnipeg, Canada,* [2]*Ashodaya Samithi, Mysore, India*

Background: Despite the success of HIV prevention interventions for female sex workers (FSW), reducing HIV incidence in this population remains a challenge. The efficacy of PrEP has been well-established, but the ability to scale-up PrEP among FSW in India is uncertain. We implemented a PrEP demonstration project over the past 3 years, in partnership with Ashodaya Samithi, a community-based organization of FSW in Mysore and Mandya, south India.
Methods: We examined prospectively the introduction of PrEP, together with HIV prevention services. Community mobilizers regularly followed-up and monitored progress. Community-led strategies promoted and supported adherence to the drug regimen, a daily oral single dosage of tenofovir disoproxil fumarate (TDF) 300mg + emtricitabine 200mg. Eligibility criteria included: FSW >18 years old; tested negative for HIV, pregnancy, and hepatitis B; creatinine clearance >60ml/min. Participants underwent follow-up every 3 months for 15 months to test for HIV, pregnancy, and renal function, along with physical examination, reinforcement of HIV prevention measures, and a questionnaire on socio-demographic characteristics and drug adherence. A sample of women provided blood for TDF levels.
Results: 707 FSW were screened for the study, and 55 were ineligible. Of the 652 eligible, 647 were enrolled. To date, 617 have completed 15 months follow-up and 23 are still being followed, for 99% retention. The median age was 35, 91% practiced home-based sex work, and the remainder street-based; 86% reported a regular sex partner. GI side effects were reported initially by 82 FSW, decreased over time, and did not require stopping PrEP. No other adverse events were reported. Reported condom use remained high, and only 6 episodes of STIs were identified and treated (syndromic). There were no positive RPR or HIV tests. In two separate rounds, 85 and 84 participants underwent TDF blood testing; drug levels >40ng/ml were detected among 80% and 90% respectively.
Conclusions: We documented high levels of study retention and PrEP adherence. Generating community consensus around PrEP and fostering community-driven mobilization and adherence support strategies were central to high and consistent uptake. Low STI prevalence supports self-reported high condom usage. Policy advocacy to include PrEP as an additional HIV prevention tool is planned.

Scale-up of PrEP, PEP, male circumcision

WEPEC225

PrEP implementation in New York State: Using technical assistance to support clinical scale-up

C. Ferraris, T. Wilder, N. Harris
Mount Sinai Institute for Advanced Medicine, New York, United States

Background: Fewer than 10% of people in the U.S. who meet criteria for HIV pre-exposure prophylaxis (PrEP) have received a prescription. In tandem with education and awareness efforts for consumers, clinical settings need to scale-up efforts on PrEP delivery. However, providing PrEP comes with its own challenges ranging from staff buy-in, limited resources, and revisiting existing clinic workflows. More research is needed to understand what guidance and tools sites require to expand PrEP service provision.
Description: Seven PrEP implementation technical assistance (TA) sessions were held across New York State (NYS) over a two-year period. These sessions were initiated by leadership teams in various medical settings seeking to streamline and expand their PrEP services and facilitated by program staff and clinical content experts. A preliminary conventional content analysis of the TA sessions was performed to understand larger themes and devise next steps.
Lessons learned: Clinical sites requesting TA sessions comprised of two family planning settings, two community health clinics, two hospital centers, and a student health center. Initial themes from the content analysis showed that clinical sites required the most assistance with clinic flow, HIV testing technologies, and electronic medical record (EMR) utilization. Clinic flow as a theme related to the understanding of how PrEP screening, education, adherence counseling, and STI testing can be split between multiple staff roles. Most sites indicated they wanted to follow a comprehensive health approach, usually used for HIV positive individuals, and sought guidance on how to leverage this model for HIV negative individuals. Sites also sought guidance about HIV testing technologies and testing best practices when initiating and following a consumer on PrEP. Lastly, sites were interested in examining how EMRs can be used to help medical providers screen candidates, discuss the necessary points of education, and provide counseling in a streamlined manner.
Conclusions/Next steps: To ensure PrEP reaches its potential, more guidance and assistance is needed. Clinical sites indicated a need for more implementation resources around best practices in clinic flows, incorporation of the latest HIV testing technologies, and utilizing EMRs to support medical providers in screening for and prescribing PrEP.

WEPEC226

PrEParing for implementation: Very low PrEP awareness in a sample of men who have sex with men and transgender women reporting condomless receptive anal intercourse in Lima, Peru

W. Gonzales-Saavedra[1], R.C. Passaro[2,3], E.R. Segura[2], A. Perez-Brumer[4], A. Florez[1], M. Reyes[1], R. Lama[1], E. Cachay[1], J.L. Clark[2], R. Cabello[1,2]
[1]*Asociación Civil Via Libre, Lima, Peru,* [2]*South American Program in HIV Prevention Research, David Geffen School of Medicine, University of California, Los Angeles, United States,* [3]*College of Medicine, University of Tennessee Health Science Center, Memphis, United States,* [4]*Columbia University Mailman School of Public Health, New York, United States*

Background: While men who have sex with men (MSM) and transgender women (TW) have been the focus of numerous combined HIV prevention strategies, these groups still account for more than 60% of new HIV infections in Peru. To improve understanding of factors influencing pre-exposure prophylaxis (PrEP) knowledge and uptake, we studied PrEP awareness and motivations/barriers to PrEP use among MSM and TW in Peru.
Methods: In a 2017 cross-sectional study of rectal STI screening and HIV prevention, MSM/TW reporting condomless receptive anal intercourse (cRAI) were tested for rectal gonorrhea (GC) and chlamydia (CT), syphilis, and HIV. PrEP awareness was assessed by asking participants if they had heard about "PrEP", "Pre-Exposure Prophylaxis," or "Daily Truvada to Prevent HIV". Poisson regression analyses (adjusted for age, education, sexual orientation, size of the participant's gay-identified social network, and HIV testing history) estimated correlates of PrEP awareness separately for HIV-negative MSM and TW.
Results: Out of 465 MSM (median age 27 years) and TW (median age 30 years), only 24.0% (87/357) of MSM and 23.2% (25/108) of TW had heard of PrEP. While PrEP awareness among MSM was associated with prior HIV testing (aPR, 95% CI: 3.74, 1.57-8.92), no factors were associated with PrEP awareness in TW. MSM and TW with prior knowledge of PrEP reported similar barriers (fear of adverse effects (46.9%) and cost (27.8%)) and motivations to use PrEP (lapses in condom use (66.2%) and additional protection against HIV infection (40.3%)). 95.0% of MSM and 93.5% of TW surveyed stated they would be interested in learning more about and/or using PrEP in the future. MSM and TW who were not aware of PrEP had higher frequencies of syphilis (7.6% vs. 1.1%; p=0.02) and rectal GC/CT (23.6% vs. 15.2%; p=0.06) than those who were aware of PrEP.
Conclusions: Despite a history of clinical research assessing PrEP efficacy and implementation in Peru, PrEP awareness among MSM/TW at high-risk of HIV infection is very low. Innovative strategies, like incorporating PrEP education into rectal STI screening programs, are needed to increase awareness and uptake among MSM and TW who have not previously been engaged by HIV prevention services.

WEPEC227

A self-administered internet survey on socioeconomic disparities in access to and willingness to take PrEP among Latino MSM in San Antonio, TX

M. García[1], G. Saw[2]
[1]*Houston Health Department, Houston, United States,* [2]*UTSA, San Antonio, United States*

Background: Latino Men who have Sex with Men (LMSM) are the second largest group affected by HIV in the US and incidence rates continue to grow for LMSM ages 25-34 in 2016. Racial disparities persist among PrEP use and LMSM are less likely to consider PrEP as a viable option, which requires further research to enhance access to PrEP for LMSM.
Methods: LMSM in San Antonio, TX were recruited to complete a self-administered Internet survey. Participants were asked about their awareness and current use of PrEP. Only LMSM currently not on PrEP were asked about their willingness to take PrEP. Chi-square and multiple regression analyses were conducted to test the significant differences in PrEP-related measures between higher and lower socioeconomic status (SES) groups, measured by education (some college or below vs. bachelor's degree or above) and household income (< $49,999 vs. ≥$50,000).
Results: Of 154 LMSM (Mean age = 25.2) who self-reported HIV negative, 52.6% had a bachelor's degree or higher and 50.6% had an annual household income of ≥$50,000. Higher-educated and higher-income LMSM reported significantly higher rates of PrEP awareness (92.6% vs. 32.9% and 93.6% vs. 34.2%) and PrEP usage (72.8% vs. 1.4% and 75.6% vs. 1.3%). Lower-educated and lower-income LMSM currently not on PrEP had significant lower level of willingness to take PrEP daily (56.9% vs. 86.4% and 54.7% vs. 100%) and concerns associated with PrEP-related side effects such as "nausea, dizziness, vomit, diarrhea, or stomach pain" (15.3% vs. 59.1% and 13.3% vs. 73.7%), "liver damage" (5.6% vs. 40.9% and 5.3% vs. 47.4%), and "kidney damage" (6.9% vs. 40.9% and 8.0% vs. 42.1%). Lower-income LMSM not on PrEP reported significant higher levels of mistrusting the government giving them PrEP (46.7% vs. 21.1%) and PrEP as an experimental drug (57.3% vs. 21.1%). Higher-educated and higher-income LMSM not on PrEP had significant higher levels of being stigmatized as sexually promiscuous for taking PrEP (86.4% vs. 61.1% and 84.2% vs. 62.7%).
Conclusions: Prevention programs promoting PrEP should address concerns for low-SES LMSM on PrEP side effects and misconceptions of PrEP as an experimental drug, whereas for high-SES LMSM on PrEP related stigmatization.

WEPEC228

Exploring the use of pre-exposure prophylaxis (PrEP) for HIV prevention among high risk drug users in treatment

R. Shrestha, M. Copenhaver
University of Connecticut, Allied Health Sciences, Storrs, United States

Background: Despite unequivocal evidence supporting the use of pre-exposure prophylaxis (PrEP), its scale-up has been gradual overall, and nearly absent among people who use drugs (PWUD). We implemented the use of PrEP as a part of an integrated primary HIV prevention approach among PWUD who exhibited high HIV transmission risk behaviors. In the present study, we explored the experiences, attitudes, acceptability, disclosure status, risk compensation-related attitudes, and barriers to adherence among PWUD using PrEP.

Methods: Between September 2016 and July 2017, we recruited 40 HIV-uninfected, methadone-maintained people, who reported HIV-risk behaviors, and initiated on PrEP. We conducted both quantitative and in-depth semi-structured qualitative interviews that primarily focused on experiences, attitudes, acceptability, disclosure status, risk compensation-related attitudes, and barriers related to PrEP adherence.

Results: Results showed that participants were highly satisfied and perceived PrEP as valuable and acceptable (mean: 77.7±13.9) for HIV prevention. Participants reported high adherence to PrEP with a mean adherence score of 87.6 (±18.6). A considerable proportion of the participants reported to have disclosed their PrEP status to other people (77.5%), and out of these, 67% disclosed their status to their friends, 45.2% to their spouse, followed by their parents (25.8%) and children (6.5%). The most highly endorsed facilitators to PrEP adherence were use of memory aids, no out-of-pocket cost, perceived benefit, and support from social network. The barriers to adherence included side-effects, stigmatization, requirement of daily dosing, and accessibility of PrEP services. Additionally, participants expressed disagreement with the overall risk compensation-related attitudes (i.e., decreased personal concern about engaging in HIV risk behavior due to their perception that PrEP is now fully protecting them from contracting HIV) and indicated no increased engagement in risk behaviors while on PrEP.

Conclusions: The results from the current study provide preliminary evidence supporting the successful integration of PrEP within the substance abuse treatment setting, where high risk PWUD can be readily reached. We believe our findings have encouraging implications for future public health research and for health promotion interventions, practices, and policies for PWUD, particularly in real world treatment settings.

WEPEC229

Describing levels of uptake and non-uptake of voluntary medical male circumcision services during HPTN 071 (PopART) study, Zambia

E. Sakala
Zambart, PopART Intervention, Lusaka, Zambia

Background: : HPTN 071 (PopART) is a 3-arm community-randomized trial in 21 communities, 12 in Zambia and 9 in South Africa, which will determine the impact of a combination prevention intervention on HIV incidence. Community HIV-care Providers (CHiPs) delivered the intervention door-to-door for 4 years, offering HIV testing, TB screening, referral to care for HIV or TB, and providing other services, including information and referral for voluntary male medical circumcision (VMMC). We analyzed VMMC uptake by men who received the intervention from 8 Zambian intervention communities.

Methods: Participants eligible for circumcision were males who were not circumcised and not known to be HIV positive. VMMC status was determined by self-report and entered electronically. Those who were not known to be HIV positive and not circumcised were referred to the health facility. CHiPs followed up referred clients a month later or during any subsequent visits to establish if they had been circumcised. During follow up those found not circumcised if still HIV negative, and expressing a willingness to be circumcised, were referred again.

The data analyzed were collected from CHiPs records for the final year of the intervention (September, 2016 to September 2017).

Results: During this period, 60,274 males consented to participate in the PopART intervention, and we were able to ascertain the circumcision status of 55,722. Of these, 24,547(44.1%) were already circumcised (17.5% traditional & 82.5% medical methods). Of those not circumcised, 4,273 (13.7%) were known HIV positive leaving 26,902 who were not known to be HIV positive and uncircumcised, and therefore eligible for VMMC referral. Of those eligible, 6,549 (24.3%) accepted referral and were referred for VMMC, and of those referred, 4,739 (72.4%) were followed up at least once after referral. Among those followed up, 1,260 (26.6%) had attended a health facility for VMMC, and of those attending the health facility 1,171 (92.9%) received VMMC. Males aged between 18-24 years were more likely to be circumcised than those ≥25 years (Table 1)

Conclusions: Door to door information delivery and referral can contribute to more males taking up VMMC, but there is still a large drop-out between referral and seeking circumcision.

Age group (years)	Community 1	Community 2	Community 5	Community 6	Community 8	Community 9	Community 10	Community 11	All
18-19	20/74 (27.0%)	5/36 (13.9%)	38/127 (29.9%)	28/68 (41.2%)	38/199 (19.1%)	32/160 (20.0%)	17/32 (53.1%)	12/22 (54.5%)	190/718 (26.5%)
20-24	28/131 (21.4%)	14/70 (20.0%)	73/236 (30.9%)	75/144 (52.1%)	104/437 (23.8%)	70/338 (20.7%)	37/79 (46.8%)	10/29 (34.5%)	411/1,464 (28.1%)
25-34	15/149 (10.1%)	12/70 (17.1%)	55/197 (27.9%)	62/160 (38.8%)	70/427 (16.4%)	51/306 (16.7%)	53/100 (53.0%)	9/41 (22.0%)	327/1,450 (22.6%)
35-44	11/67 (16.4%)	6/27 (22.2%)	22/101 (21.8%)	31/81 (38.3%)	34/188 (18.1%)	32/146 (21.9%)	18/34 (52.9%)	3/14 (21.4%)	157/658 (23.9%)
45+	6/29 (20.7%)	3/12 (25.0%)	14/81 (17.3%)	19/95 (20.0%)	13/107 (12.1%)	15/87 (17.2%)	14/31 (45.2%)	2/7 (28.6%)	86/449 (19.2%)
All	80/450 (17.8%)	40/215 (18.6%)	202/742 (27.2%)	215/548 (39.2%)	259/1,358 (19.1%)	200/1,037 (19.3%)	139/276 (50.4%)	36/113 (31.9%)	1,171/4,739 (24.7%)

[Table 1: Proportion of clients who received VMMC among those referred and had follow up data available, by community and age group]

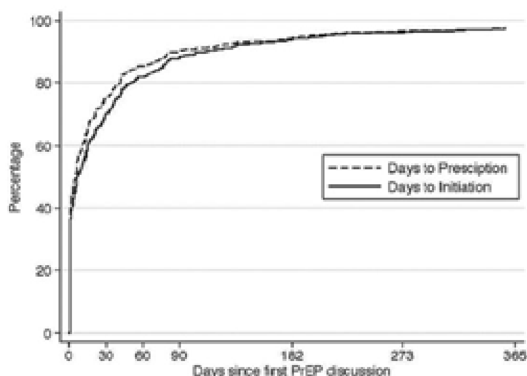
Delays in PrEP initiation among at-risk patients in a large network of primary care clinics

M.A. Spinelli[1], H. Scott[1,2], E. Vittinghoff[3], A.Y. Liu[2], A. Morehead-Gee[4], R. Gonzalez[2], M. Gandhi[1], S.P. Buchbinder[2,3]
[1]University of California, Division of HIV, ID and Global Medicine, San Francisco, United States, [2]San Francisco Department of Public Health, Bridge HIV, San Francisco, United States, [3]University of California, Department of Epidemiology and Biostatistics, San Francisco, United States, [4]University of California, Department of Medicine, San Francsico, United States

Background: Reducing delays in PrEP initiation is critical in high-risk populations to reduce HIV incidence. We sought to examine factors associated with timely PrEP initiation in the San Francisco Public Health Primary Care Clinics (SFPCC).
Methods: Demographic data, prescriptions, and dates of first PrEP discussion and patient-reported PrEP initiation date were abstracted from charts of SFPCC PrEP users from 3/1/13-7/31/17. We examined factors associated with shorter intervals between first chart-documented PrEP discussion and: 1. first PrEP prescription; 2. patient-reported PrEP initiation date, using a Cox proportional-hazards model, with hazard ratios (HR) >1 indicating associations with earlier prescription/initiation.
Results: Overall, 403 PrEP-using patients had pharmacy and visit data available. Mean age was 37; 85% were male; 8% Asian, 13% African-American, 27% Latino, 17% other, 36% White. PrEP starts increased every year, from 67 in 2013/14 to 165 in 2016. Overall, 65% were prescribed PrEP with an indication of MSM; 16% sero-different relationship, 13% transgender women having sex with men, 5% high-risk heterosexual, and 1% IDU. Of initiators, 24% received panel management/patient navigation support. Patients received a prescription and initiated PrEP after first PrEP discussion after a mean of 34 days and 37 days respectively. For 30%, PrEP initiation was delayed >30 days, and 10% waited >90 days. In an adjusted Cox proportional-hazards model, only receipt of panel management/patient navigation was associated with shorter intervals between PrEP discussion and PrEP prescription (HR:1.57; 95% CI:1.16-2.12). When examining the alternate outcome of time between PrEP discussion and patient-reported PrEP initiation date, panel management/navigation remained significant (HR:1.54; 1.14-2.09). However, African-American race compared to White race was now associated with longer delays in PrEP initiation (HR: 0.69; 0.49-0.97).

	Adjusted HR for PrEP Prescription (95% CI)	p-value	Adjusted HR for PrEP Initiation (95% CI)	p-value
Age	1.00 (0.99-1.01)	0.420	0.99 (0.99-1.00)	0.046
Male sex at birth	0.98 (0.69-1.40)	0.930	0.89 (0.62-1.27)	0.530
Race/ethnicity vs. White: Asian	1.18 (0.78-1.78)	0.440	1.05 (0.69-1.58)	0.830
Black	0.82 (0.58-1.15)	0.250	0.69 (0.49-0.97)	0.032
Latino	1.08 (0.82-1.41)	0.590	1.02 (0.77-1.34)	0.910
Other	0.74 (0.55-1.01)	0.060	0.70 (0.51-0.95)	0.022
Insurance vs. uninsured: public	0.84 (0.61-1.15)	0.270	0.84 (0.61-1.16)	0.290
private	0.93 (0.56-1.54)	0.770	1.02 (0.61-1.69)	0.950
Panel management/ patient navigation	1.57 (1.16-2.12)	0.004	1.54 (1.14-2.09)	0.006

[Factors Predictive of Earlier PrEP Prescription and PrEP Initiation in a Cox Proportional-Hazards Model (Also Adjusted for PrEP Indication and Year)]



[Kaplan-Meier Curve Depicting Time from PrEP Discussion to Initial PrEP Prescription and Patient-Reported PrEP Initiation]

Conclusions: Nearly 1/3 of at-risk patients experienced delays of >1 month in initiating PrEP, and 10% had delays of >3 months. African-Americans, who have the highest HIV incidence in San Francisco, were more likely to experience delays in PrEP initiation, but not in receipt of a prescription. Close follow-up after initial PrEP prescription, with the support of patient navigation and panel management, could reduce delays in PrEP initiation and racial/ethnic disparities across all high-risk groups.

WEPEC231

Proportion of early infant male circumcisions (EIMC) performed compared to male deliveries in eight pilot sites in Iringa, Tanzania

A. Hellar[1], K. Ngonyani[1], A. Christensen[1], M. Machaku[1], T. Maokola[1], M. Drake[1], F. Phiri[1], A. Maganga[1], M. Mohamed[2], R. Salim[2], G. Lija[3], J. Mushy[3], E. Mlanga[4]
[1]Jhpiego, AIDSFree/VMMC, Dar es Salaam, Tanzania, United Republic of, [2]President's Office Regional Authority and Local Goverment, Iringa RHMT, Iringa, Tanzania, United Republic of, [3]Ministry of Health Community Development Gender Elderly and Children, National AIDS Control Program (NACP), Dar es Salaam, Tanzania, United Republic of, [4]USAID, Dar es Salaam, Tanzania, United Republic of

Background: Following attainment of 80% Voluntary Medical Male Circumcision (VMMC) coverage for HIV prevention among adolescents and adults in Iringa and Njombe regions, Jhpiego, with support from PEPFAR through USAID under the AIDSFree Project started implementing EIMC services to maintain circumcision prevalence over time. The initial EIMC pilot started in four health facilities, then expanded to eight. The facilities included five hospitals, two health centres and one dispensary, all of which provide labor and delivery services. Lessons learned from this pilot will be used to inform other regions in the country during EIMC scale-up.
Methods: We conducted a retrospective review of the client-level EIMC database and of facility delivery statistics to determine the average number of EIMCs per males born in the eight pilot EIMC sites from January - December 2016.
Results: In total, 924 infants received EIMC services in the eight facilities during the review period. The average monthly number of circumcisions conducted per facility ranged from 6-17 EIMCs. Facilities with low number of male deliveries were more effective in providing EIMC services compared to sites with high number of male deliveries (See Table 1). One facility had reached >100% of male infants circumcised possibly by reaching infants born a home or from other facilities.
61.5% of infants circumcised were born in the same facility where they received EIMC services, 33.3% in another facility and 5.1% were born at home. There was no huge difference in the absolute number of infants circumcised in the facilities based on the geographical location or level of the facility.

Facility Name	Geographical location	Total EIMCs Jan-Dec 2016	% out of Total EIMCs	Average monthly EIMCs	Total male deliveries Jan-Dec 2016	Average monthly male births	% of males circumcised
Frelimo Hospital	Urban	119	12.9	10	521	43	23%
Igumbilo Dispensary	Urban	71	7.7	6	84	7	85%
Ilula District Hospital	Semi-urban	167	18.1	14	1151	96	15%
Ipogolo Health Centre	Urban	199	21.5	17	323	27	62%
Iringa Referral Hospital	Urban	81	8.8	7	2285	190	4%
Kidabaga Health Centre	Rural	68	7.4	6	54	5	126%
Mafinga Hospital	Urban	114	12.3	10	908	76	13%
Tosamaganga District Hospital	Urban	106	11.5	9	509	42	21%
Grand Total		924	100.0				

[Table 1: Proportion of EIMCs conducted by facility level, location and number of male infant deliveries in Iringa, January - December 2016]

Conclusions: There is a potential to increase the proportion of infants circumcised especially in sites with a higher volume of male infant births. This shows a need to enhance demand creation efforts during antenatal care and immediate after delivery. Our analysis revealed that the number of EIMCs performed might not be affected by the geographic location or level of the facility. With the proportion born at home who were reached with EIMC services, EIMC services may represent a pathway to health services for male infants.

WEPEC232

Baseline characteristics and risk behaviors among men who have sex with men and transgender women who chose On PrEP and Off PrEP in PrEP demonstration project in Northern Thailand

S. Chariyalertsak[1,2], Q. Kaewpoowat[2,3], T. Supindham[2], P. Saokhieo[2], R. Songsupa[2], S. Taejaroenkul[2], R. Khampan[2]
[1]Chiang Mai University, Faculty of Public Health, Chiang Mai, Thailand, [2]Chiang Mai University, Research Institute for Health Sciences, Chiang Mai, Thailand, [3]Chiang Mai University, Faculty of Medicine, Chiang Mai, Thailand

Background: With an HIV incidence >3% annually among Thai MSM and TGW, the new effective HIV prevention tool as Pre-Exposure Prophylaxis (PrEP) with daily TDF/FTC should be considered as part of comprehensive HIV prevention in people at substantial risk of HIV infection recommended by WHO. We explored baseline factors between MSM/TGW who chose On-PrEP and Off-PrEP in PrEP demonstration project in northern Thailand.
Methods: "PrEP@Piman" is the PrEP demonstration project run at one VCT Clinic (namely "Piman") in Chiang Mai. MSM/TGW aged ≥18 years old who came for HIV testing were informed about daily PrEP as free services for one year if they interested to participate. There were 117 participants who were screened and 105 clients enrolled into PrEP@Piman study between December 2015 and February 2017. Demographic, sexual/behavioral data, and reason to choose On-PrEP or Off-PrEP were collected by computer-assessed self-interview at baseline. Consented HIV testing, HBS-ag, Syphilis, Creatinine Clearance and Urine Protein were performed at baseline. HIV testing will be checked every 3 months when they came back and for drug refill if they were On-PrEP.
Results: Twelve clients were excluded at screening, 1 had HIV+, 4 had HBS-ag+. All screening participants had normal kidney function test. Among 105 clients, 82(78%) chose On-PrEP and 23(22%) Off-PrEP at baseline. Compared between On-PrEP and Off-PrEP, 14.6% and 8.7% were TGW, mean age 26.7 years and 22.8 years, 7 clients and none had Syphilis positive, and 30 % (21/72) and 6.3% (1/16) estimated their own current risk of HIV infection above 40%. There were 7 On-PrEP and 3 Off-PrEP clients reported having HIV+ partners. Common reasons to choose On-PrEP were; 97% prevent HIV infection with other tools, 47% engaged in higher sexual risk and 46% inconsistent condom used. Common reasons for Off-PrEP were; 78% concerned side effects, 47% hated to take daily drug, 34% no problem with other prevention methods and 17% fear stigma as HIV+ people.
Conclusions: Our finding showed main factors and reasons to choose On-PrEP and Off-PrEP among MSM/TGW in Chiang Mai. Both providers and users need to understand these complexities and have better strategies to implement PrEP services for these population.

WEPEC233

Understanding willingness to use oral pre-exposure prophylaxis for HIV prevention among men who have sex with men in China

X. Wang[1], A. Bourne[2,3], P. Liu[1], J. Sun[4], T. Cai[5], G. Mburu[6,7], M. Cassolato[6], B. Wang[6], W. Zhou[1]
[1]Wuhan Centers for Disease Prevention and Control, Wuhan, China, [2]Australian Research Centre in Sex, Health & Society, La Trobe University, Melbourne, Australia, [3]Sigma Research, London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]AIDS Care China, Kunming, China, [5]AIDS Care China, Nanning, China, [6]International HIV/AIDS Alliance, Brighton, United Kingdom, [7]Division of Health Research, Lancaster University, Lancaster, United Kingdom

Background: Oral pre-exposure prophylaxis (PrEP) is recommended as an additional prevention choice for men who have sex with men (MSM) at substantial risk of HIV. The aim of this study was to evaluate the extent, and reasons, for MSM's willingness to use oral PrEP in Wuhan and Shanghai, China.
Methods: Between May and December 2015, a cross-sectional survey was conducted among 487 MSM recruited through snowball sampling in physical locations frequented by MSM and through social media applications. Exploratory factor analysis was used to group reasons for being willing or not willing to use PrEP. Chi-square tests were used to explore bivariate associations between groupings of reasons for being willing or unwilling to use PrEP, and key sociodemographic and sexual-behavioral characteristics of MSM.
Results: Overall, 71.3% of respondents were willing to use PrEP. The most commonly reported reasons for being willing to use PrEP were preventing HIV infection (91.6%), taking responsibility for own sexual health (72.6%) and protecting family members from harm (59.4%). The main reasons for being unwilling to use PrEP were being worried about side effects (72.9%), the necessity of taking PrEP for long periods of time (54.3%) and cost (40.4%). Individual characteristics that influenced the type of reasons given for being willing or unwilling to use PrEP included being married to a woman, having a regular sex partner, rates of condom use with regular and casual sex partners, and the number of casual sex partners.
Conclusions: The introduction of PrEP in China could benefit from promotion campaigns that emphasize its role in preventing HIV infection, in taking responsibility for own sexual health, and in protecting family members from potential harm. To reduce uptake barriers, it will be essential to provide accurate information to potential PrEP users about the mild and short-term nature of side effects, and the possibility of taking PrEP only during particular periods of life when the risk of HIV exposure might be highest.

WEPEC234

Experience with introduction of PrePex device for medical male circumcision for HIV prevention in Kenya (2013-2017)

E. Odoyo-June[1], N. Owuor[2], K. Agot[3], S. Davis[4], J. Hines[4], P. Musingila[1], C. Kisia[5], K. Serrem[6], A. Wanyonyi[6], K. Bartilol[6]
[1]US Centers for Disease Control and Prevention (CDC), DGHT, Nairobi, Kenya, [2]JHPIEGO, Kisumu, Kenya, [3]Impact Research and Development Organization, Kisumu, Kenya, [4]US Centers of Disease Control and Prevention, DGHT, Atlanta, United States, [5]World Health Organization Kenya Office, Nairobi, Kenya, [6]Ministry of Health, National STD/AIDS Control Program, Nairobi, Kenya

Background: Since 2013 Kenya has undergone the three stages outlined in the World Health Organization (WHO) framework for clinical evaluation of male circumcision devices to introduce PrePex in its Voluntary Medical Male circumcision (VMMC) program for HIV prevention. We present experiences from this process.
Description: PrePex was first introduced in Kenya in 2013 during pilot research which assessed its effectiveness, safety and acceptability among 417 adult men. Its safety and operational requirements were further evaluated among 2,195 men under active adverse events (AE) surveillance in routine health care settings in 2015 and 2016. In August 2016, PrePex was endorsed for an open-ended passive roll out which continues to date.
Lessons learned: In the pilot research phase, PrePex circumcision was effective and well-accepted but associated with a higher rate of moderate/severe AEs (5.9% vs 0.2%) and 1-2 weeks longer time to healing than conventional surgical circumcision. Under active AE surveillance, PrePex remained well accepted and with lower moderate/severe AE rate (0.3%) as providers gained experience in its use. In the ongoing passive roll out, 1,134 PrePex circumcision have been conducted and 5 AEs (including one non-fatal tetanus) reported. In 2017, WHO reported a 30 fold higher risk of tetanus associated with PrePex compared to conventional surgical circumcision and recommended full immunization against tetanus (TT) prior to PrePex placement; this let to operational challenges undermining its further roll out.
Conclusions/Next steps: Although PrePex circumcision was initially shown to be effective, safe and well accepted in Kenya, the new requirement for documented full TT immunization before its application has revealed a gap in immunization coverage among Kenyan males. This has hampered widespread use of PrePex as few Kenyans have documentary evidence of full TT immunization and logistics for multiple clinic visits for immunization before PrePex placement are challenging. Thus, PrePex circumcision should only be rolled out in settings with high TT coverage among eligible males or where provision of protective doses of TT before each placement is feasible. Innovative Strategies are needed for efficient use of PrePex in VMMC while minimizing the risk of tetanus.

WEPEC235

Predictors of male circumcision uptake during the Botswana Combination Prevention Project (BCPP) mobilization

T. Marukutira[1,2,3], L. Block[4], L.A. Mills[5], J. Moore[4], P. Bachanas[4], T. Schissler[6], R. Mosha[6], N. Bock[4], O. Komotere[6], K. Mukokomani[7], T. Diswai[6], S.M. Davies[4]
[1]US Centers for Disease Control and Prevention, Botswana Combination Prevention Project, Gaborone, Botswana, [2]Burnet Institute, Public Health, Melbourne, Australia, [3]Monash University, Epidemiology and Preventive Medicine, Melbourne, Australia, [4]US Centers for Disease Control and Prevention, Atlanta, United States, [5]US Centers for Disease Control and Prevention, Gaborone, Botswana, [6]Jhpiego, Gaborone, Botswana, [7]Botswana-Harvard AIDS Institute Partnership, Gaborone, Botswana

Background: Male circumcision (MC) is a proven HIV prevention intervention in sub-Saharan Africa, but uptake has been low in some countries, including Botswana. Better characterization of men who accept versus reject MC could inform demand creation efforts, but information on men who reject MC is rarely available. The Botswana Combination Prevention Project (BCPP) collected population-level data on demographics and HIV risk factors and offered free MC, allowing comparison of those who did and did not accept MC.
Methods: BCPP, a community-randomized trial, enrolled 16-49 year old citizen residents of 30 communities randomized to receive either intensified standard-of-care services or HIV prevention interventions including mobile HIV testing and MC, between October 2013 and February 2016. During the 6-8 week MC surge in the 15 intervention communities, MC was offered in tents or a mobile clinic. All male participants with an HIV-negative test or unknown status who reported being uncircumcised were offered linkage to MC by peer escort, phone-based and in-person mobilization, appointments, reminder calls, and transport. Demographic and risk factors were compared between those who did and did not undergo MC using chi-squared testing.
Results: Of the 15,970 eligible men, 8,534 (53%) reported being uncircumcised. Of these, 577 (7%) underwent MC during the surge. Men who did not get MC were substantially older and more likely to be employed and ever married (Table 1). They had a statistically higher but essentially identical likelihood of reporting two or more sex partners in the past year. They were substantially more likely to believe their recent partner was HIV-positive (15% vs. 5%).

Demographic and risk factors	Underwent MC (n=577)	Did not undergo MC (n=7957)	Chi-sq	p value
Mean age in years (standard deviation)	25 (8)	29 (9)	N/A	<0.001
Completed secondary school	473 (82%)	6252 (79%)	2.83	0.09
Never married	534 (93%)	6521 (83%)	39.68	<0.001
Employed	183 (32%)	3231 (45%)	32.86	<0.001
Reported last sexual partner HIV-positive*	17/354 (5%)	816/5250 (16%)	36.89	<0.001
>1 sexual partner in past 12 months	45 (8%)	469 (7%)	37.38	<0.001
*Among those with at least one sexual partner in the past 12 months				

[Table 1: Demographic and risk factors of men undergoing or not undergoing male circumcision (MC)]

Conclusions: Older age, ever having married, employment, and an HIV-positive partner were factors associated with not seeking MC. Male circumcision programs could improve outreach to men with HIV-positive partners due to their high risk, while also reaching out to the general population. Characterizing and addressing unique barriers to MC for employed and older men may also improve general uptake.

WEPEC236

Depression, network influences and uptake of HIV pre-exposure prophylaxis (PrEP) in men and transgender individuals screening for HIV prevention trial participation

S. Wood[1], K. Morales[2], D. Metzger[3], A. Davis[4], D. Fiore[4], Q. Jackson[1], H. Koenig[5], N. Dowshen[6], R. Gross[7], I. Frank[5]
[1]Children's Hospital of Philadelphia, Division of Adolescent Medicine, Philadelphia, United States, [2]University of Pennsylvania Perelman School of Medicine, Department of Biostatistics, Epidemiology and Informatics, Philadelphia, United States, [3]University of Pennsylvania Perelman School of Medicine, Department of Psychiatry, Philadelphia, United States, [4]University of Pennsylvania Perelman School of Medicine, HIV/AIDS Prevention Research, Philadelphia, United States, [5]University of Pennsylvania Perelman School of Medicine, Division of Infectious Diseases, Philadelphia, United States, [6]University of Pennsylvania Perelman School of Medicine, Pediatrics, Philadelphia, United States, [7]University of Pennsylvania Perelman School of Medicine, Infectious Diseases, Philadelphia, United States

Background: We aimed to assess the relationship between depression and HIV pre-exposure prophylaxis (PrEP) uptake, and determine whether social network PrEP awareness increased utilization. We hypothesized that depression would decrease HIV prevention behavior, and social network influences would increase PrEP uptake and modify the hypothesized association between depression and uptake.
Methods: Cross-sectional study of men and transgender (TG) individuals pre-screening for HIV Vaccine Trials Network and HIV Prevention Trials Network clinical trial participation in Philadelphia, PA. Participants were aged >18 years, born male or identifying as TG, with a history in the preceding six months of anal intercourse with ≥2 TG partners or with any male or TG partners if intercourse was condomless. Survey measures assessed demographics, sexual practices, depression (Patient Health Questionnaire-8, cutoff >10), PrEP use, and network PrEP awareness (# individuals with whom participants discussed PrEP in the prior week). Multivariable logistic regression assessed associations between depression and PrEP uptake, adjusting for age, race, gender, and high HIV risk (Menza score ≥1). An interaction term between network PrEP awareness and depression tested for effect modification.
Results: Participants (n=214) were 88% cisgender males, 7% TG females, 1% TG males, and 3% other gender; and were 44% African-American and 19% Latino. Median age was 27 years (IQR 23-33). Prior PrEP awareness was reported by 92% and PrEP uptake by 33%. Depression was identified in 11%, and median PHQ-8 score was 3 (IQR 0-7). In multivariable logistic regression, there was no significant association between depression and PrEP uptake (aOR 1.71, 95% CI: 0.66-4.44), and no effect modification by network PrEP awareness (aOR 0.97, 95% CI 0.71-1.33). Each additional social contact with whom participants discussed PrEP conferred a 16% greater odds of PrEP uptake (aOR 1.16, 95% CI: 1.02-1.31). African-American race (aOR 2.01, 95% CI: 1.04-3.88) and high HIV risk (aOR 2.51, 95% CI: 1.23-5.1) were also associated with greater odds of uptake.
Conclusions: In this diverse U.S.-based sample, there was no association between depression and PrEP uptake. The greater uptake with increasing PrEP-related network interactions, suggests that social network norms influence initiation. Network-level interventions may hold promise for increasing PrEP uptake.

WEPEC237

Perceived barriers to pre-exposure prophylaxis use among HIV-negative men who have sex with men and transgender women in Tijuana, Mexico: A latent class analysis

R. Patrick[1], J. Jain[1], A. Harvey-Vera[1], S.J. Semple[2], G. Rangel[3], T.L. Patterson[2], H.A. Pines[1]
[1]University of California, San Diego, Department of Medicine, La Jolla, United States, [2]University of California, San Diego, Department of Psychology, La Jolla, United States, [3]US-Mexico Border Health Commission, Tijuana, Mexico

Background: Pre-exposure prophylaxis (PrEP) is an effective intervention to prevent HIV infection among high-risk populations, including men who have sex with men (MSM) and transgender women (TW). Although not currently approved for use in Mexico, PrEP demonstration projects are underway. Understanding barriers to PrEP uptake among those at greatest risk is essential to informing future PrEP programs. We aimed to identify classes of perceived barriers to PrEP use among HIV-negative MSM and TW in Tijuana, Mexico, and identify HIV risk factors associated with class membership.
Methods: From 03/2016-09/2017, 397 participants recruited via venue-based and respondent-driven sampling completed interviewer-administered surveys assessing socio-demographics, sexual and drug use behaviors, and perceived barriers to PrEP use. Barriers were assessed across 4 domains: individual, interpersonal, structural, and product. Latent class analysis was performed to identify distinct classes with respect to perceived barriers to PrEP use. Multinomial logistic regression was used to identify HIV risk factors associated with class membership.
Results: Participants had a median age of 39 years (IQR 29-46), 97% were male, and 34% were gay-identifying. Nearly half perceived themselves at elevated risk for HIV (49%) and 72% reported condomless anal sex (past 4 months). We identified 3 distinct classes characterized by
(1) a high level of perceived barriers across domains (14%),
(2) a low level of perceived barriers (50%), and
(3) perceived product barriers (i.e., side-effects and cost) (37%).
Compared to membership in the class characterized by a low level of perceived barriers, membership in the class characterized by a high level of perceived barriers class was associated with greater levels of internalized stigma related to being MSM/TW (AOR=1.10; 95% CI: 1.04-1.18) and meeting sex partners at sex venues (AOR=6.32; 95% CI: 1.34-29.75), while membership in the class characterized by product barriers, was associated with greater levels of internalized stigma related to being MSM/TW (AOR=1.04; 95% CI: 1.00-1.08), seeing a healthcare provider (past year) (AOR=1.77; 95% CI: 1.01-3.11), and meeting sex partners at bars/discos (AOR=2.13; 95% CI: 1.09-4.18).
Conclusions: Programs which reduce stigma related to being MSM/TW and engage MSM/TW attending high-risk venues may decrease barriers to PrEP uptake within these populations in Tijuana.

WEPEC238

Successful implementation of PrEP among LGBT youth at an urban Community Health Center

U. Belkind[1], P. Carneiro[2], P. Meacher[2], A. Radix[2]
[1]Callen-Lorde Community Health Center, Health Outreach to Teens (HOTT), New York, United States, [2]Callen-Lorde Community Health Center, New York, United States

Background: PrEP is an effective way to prevent HIV infection. It is currently approved for 18 years and older, but there is great interest in studying its efficacy in younger adolescents. Initial studies show barriers to initiation and retention (lack of parental consent, low PrEP knowledge, financial issues, lower adherence) but have concluded that it is a safe and viable alternative for this age group. Real-life experiences providing PrEP for youth will hopefully inform better practices and help reduce barriers to access.
Description: This is an overview of PrEP implementation in a multi-disciplinary, youth-focused, urban community health center based in New York City that yearly serves over 1,500, mainly LGBTQ youth age 13-24 years. We have prescribed PrEP for the last 4 years in a team-based approach consisting of clinicians, case managers, dedicated nurses, outreach coordination, and a PrEP access specialist, insurance navigators and an on-site pharmacy.
Early on, we recognized that patients accessing PrEP did not reflect the demographics of our program with an overrepresentation of white, cis-males. Subsequent data-driven quality improvement measures included creating information materials reflecting our clinic's racial and gender diversity, enhanced HIV testing and one-on-one counseling about PrEP especially for patients with rectal STIs regardless of self-described sexual behaviors and risk-taking. Alongside these measures, ongoing advocacy efforts resulted in legislative changes allowing youth younger < 18 years to access PrEP without parental consent.
From January 2014 to December 2017, we have started 242 youth on PrEP.
Table 1 describes the changes in patient population accessing PrEP over the last 4 years.
Lessons learned: PrEP is a viable option for youth. Clinic-wide interventions such as educational materials (handouts, videos) that reflect gender, racial and ethnic diversity, along with clinician-driven counseling, and insurance navigation promote PrEP uptake.
Conclusions/Next steps: Close monitoring of clinic-wide data is necessary to monitor access to PrEP services and expose gender/race/age disparities. Multidisciplinary teams, development of multi-media messaging to address knowledge gaps and incorporating patient input are necessary to driving success.

Year	2014	2015	2016	2017	TOTAL

[Table 1]

WEPEC239

Young male's uptake and acceptability of medical male circumcision in South Africa: A mixed method, longitudinal community-based study

P. Smith[1], K. Gill[1], T. Bennie[1], J. Dietrich[2], G. Gray[2], L.-G. Bekker[1]
[1]Desmond Tutu HIV Centre, Cape Town Area, South Africa, [2]Perinatal HIV Research Unit, Johannesburg, South Africa

Background: Young South Africans are at risk of HIV infection due to sexual risk behaviour in endemic HIV. While evidence suggests that scaled medical male circumcision (MMC) can help curb HIV infection rates in countries such as South Africa, evidence for MMC acceptability is needed. Both MMC and traditional circumcision are practised in South Africa, with certain cultural ethnicities preferring one over the other. Traditional circumcision may occur after sexual debut and foreskin removal may be incomplete. We investigated the acceptability of MMC versus traditional circumcision in Cape Town and Soweto, two culturally distinct settings in South Africa in the MACHO study.
Methods: MACHO was a mixed methods, longitudinal cohort study which investigated preferences for, attitudes, and uptake of elective MMC in 100 males (14-17 years), their guardians and other key informants in Cape Town and Soweto. Data were collected via researcher administered surveys, interviews, and focus groups and the dyads were followed up over a 24 month period.
Results: Results: 100 adolescent boys (Cape Town n=50;, Soweto n=50;) and their guardians were enrolled with a mean age of 15 (IQR: 14-16.)
Cultural ethnic composition (Table 1) was as follows:
Cape Town: 44 (88%) Xhosa, 1 (2%) Zulu, 3 (6%) Sotho/ Tswana, 2 (4%) Other

Soweto: 12 (26%) Xhosa, 25 (54%) Zulu, 9 (20%) Sotho/ Tswana, 0 Other
At baseline 27% had sexually debuted with a median age of 16 (IQR: 15-17). Prior to circumcision 0/50 boys in Cape Town preferred MMC, while in Soweto 42/50 preferred MMC. Each boy had on average 13,6 months (range 12-24 months) follow up, with 13 circumcisions done in 1361 months follow up time. Soweto participants were 11 times more likely to have been circumcised than those in Cape Town (p=0.001, HR 11,11 95% CI: 1,09 - 113,33).
Conclusions: Cultural beliefs and tradition strongly influenced MMC acceptability and uptake. Despite reasonable knowledge about the benefits of early MMC, many young males delay uptake, reducing the benefits of MMC before sexual debut. Programs to promote circumcision should take into consideration cultural and traditional mores and efforts should be made to ensure all circumcision is safe, effective and acceptable.

	Xhosa	Zulu	Sotho/ Tswana	Other
Cape Town	44 (88%)	1 (2%)	3 (6%)	2 (4%)
Soweto	12 (26%)	25 (54%)	9 (20%)	0

[Table 1: Cultural Ethnic Composition]

WEPEC240

Pre-exposure prophylaxis (PrEP) implementation, uptake and retention in Germany - results of the PRIDE study

P. Mysior[1,2], A. Schafberger[3], I. Perea[4], A.-L. Brillen[1], B. Bartmeyer[5], V. Bremer[5], E. Tenberken[2], U. Marcus[5], H. Streeck[1]
[1]Institute for HIV Research, Essen, Germany, [2]Birken Apotheke, Cologne, Germany, [3]Deutsche AIDS Hilfe, Berlin, Germany, [4]Bundesministerium für Gesundheit, Berlin, Germany, [5]Robert-Koch-Institute, Berlin, Germany

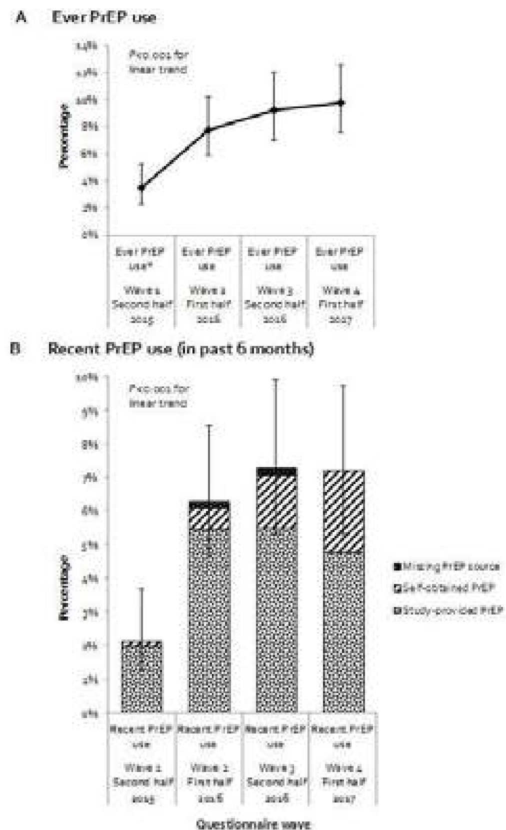
Background: Pre-exposure prophylaxis (PrEP) for HIV prevention was approved by the European Medical Agency in 2016, however, high costs prevented widespread use in Germany. We therefore implemented a novel distribution pathway by October 2017 that reduced monthly PrEP costs by 16fold.
Methods: Access to PrEP was linked to a monitoring system for prescriptions. Users were asked to participate in a questionnaire to understand motivation, PrEP intake frequencies, perceived HIV risk and recent STD diagnosis.
Results: Within a month prescriptions doubled from 514 to 1082. While an estimated minority of 10% had previously obtained PrEP from outside sources (e.g. online pharmacies), 98% had now switched to the new available system. Extrapolation of the current available data suggest an estimated PrEP use of ~2500 PrEP user/month within the first year in Germany. Interim-evaluation of 550 questionnaires from PrEP users demonstrated a homogenous population of well-educated men who have sex with men, median age 38 (range:18-71) and 83% of German descent. The overwhelming motivation to use PrEP was to compensate for HIV risk while having condomless anal intercourse. However, at start of PrEP implementation the majority perceived their own risk to acquire HIV as low to medium (81%), while only a subset (17%) considered themselves to be at risk for HIV infection. In contrast, 39% of the PrEP user had a diagnosis of gonorrhoea, syphilis or chlamydia in the 6 months before starting to use PrEP and 28% had condomless anal intercourse in the absence of other prevention methods. Those that had an STD within the last 6 months had a significant higher risk perception than those that did not (p=0.008; Fishers Exact). Analysis of the follow up questionnaire (n=56) revealed that 78% of the PrEP user indicated to have not missed any PrEP dose, while 20% indicated that they forgot to take at least 1 pill (avg. 1,25 pills ±1,25). Furthermore, 25% indicated to have been diagnosed with an STD since last visit.
Conclusions: Taken together, our data from PrEP implementation in Germany demonstrates a large uptake of the new prevention method in individuals, who wish to compensate for HIV risk while having condomless anal intercourse.

WEPEC241

Pre-exposure prophylaxis among men who have sex with in the Amsterdam Cohort Studies: Use, eligibility and intention to use

W.P.H. van Bilsen[1], L.N. Coyer[1], J.P. Bil[1], U. Davidovich[1], E. Hoornenborg[1], M. Prins[1,2], A. Matser[1]
[1]Public Health Service of Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, [2]Academic Medical Center, Department of Internal Medicine, Amsterdam Infection & Immunity Institute (AIII), Amsterdam, Netherlands

Background: In the Netherlands, HIV pre-exposure prophylaxis (PrEP) is not covered by health insurance and is not available free-of-charge except to participants of two PrEP studies. We examined time trends in use of PrEP, characteristics of PrEP users, PrEP eligibility and intention to use PrEP among HIV-negative MSM from the Amsterdam Cohort Studies (ACS).
Methods: We used data from four 6-monthly questionnaires, collected between 2015-2017. PrEP use over time was examined in logistic regression models using generalized estimating equations. Using descriptive statistics, we compared PrEP users before first initiation and non-PrEP-users. Based on national guidelines, MSM were considered eligible for PrEP if they had one of the following: condomless anal sex (CAS) with a partner with unknown/seropositive HIV status, rectal STI (chlamydia/ gonorrhea) and/or a post-exposure prophylaxis prescription in the past six months. The number of potential PrEP users was estimated based on observed eligibility and intention to use PrEP.



[Reported ever and recent PrEP use among MSM participating in the Amsterdam Cohort Studies between 2015-2017 (four 6-montly waves of questionnaires).]

Results: We included 687 HIV-negative MSM. Most were born in the Netherlands (n=545, 79%) and educated to at least college degree (n=529, 77%). Median age was 40 (IQR 33-47) years at wave 1. Recent PrEP use (in past 6 months) was reported by 57/687 (8%) MSM. Recent PrEP use increased over calendar time (p<0.001) to 7% in 2017. PrEP users did not differ from non-PrEP users in socio-demographics, but had

a significantly higher median number of casual sex partners, more often reported CAS and chemsex with casual partners, and more often had an STI in the 6 months before initiation (all p<0.05). Overall, PrEP eligibility criteria were met by 32%, of whom 22% ever reported use of PrEP. The proportion with a high intention to use PrEP was higher among eligible than among non-eligible MSM (51% vs. 24%, p<0.001). Based on these findings, we estimate that between 2,903-5,370 eligible MSM in Amsterdam can be expected to use PrEP.
Conclusions: PrEP use increased over time but remained under 10%, even though 32% met the eligibility criteria, of whom 51% had a high intention to use PrEP. This suggests that a large proportion of Dutch MSM at risk could benefit from PrEP.

WEPEC242

From PrEP to "We are PrEPARED" - the Dutch example of preparing health care providers and MSM users for PrEP

C.A. Blom, 'PrEPARED' Dutch National PrEP Working Group
Aidsfonds - Soa Aids Nederland, Amsterdam, Netherlands

Background: In the Netherlands, PrEP is not yet reimbursed, awaiting advice of the Dutch Health council in 2018. At the same time, activist groups promote access to informal PrEP, and generic versions of PrEP have become available since July 2017. However, health care providers and the primary PrEP users (mainly MSM) both lack knowledge on PrEP; this impedes PrEP uptake and proper use. To improve this we initiated a national working group in June 2015, developing a comprehensive approach to PrEP implementation in the Netherlands.
Description: A national working group with all relevant parties was facilitated by Soa Aids Nederland. Representatives from policy planning, research, general practitioners, STI clinics, national public health institutes, pharmacies, target group and activist groups met bi-monthly. This group mapped main barriers to the implementation of PrEP, coordinated activities addressing these barriers, collated and analyzed data to inform policy making, protocol development, knowledge development and lobby. Finally, funding was obtained to roll out a three-tiered approach to prepare all relevant stakeholders for PrEP implementation. This included:
(1) information for MSM-eligible for PrEP,
(2) training programmes for health care professionals,
(3) development of structures (manuals, forum, registration) within national (public) health care.
Lessons learned: Although informal and formal PrEP use increased, knowledge gaps among health care providers and MSM still need to be addressed. The coordination in the national working group made it possible to implement a comprehensive approach, to influence policy and to obtain funding, with broader and quicker impact than single actor activities.
Conclusions/Next steps: We developed a structured and coordinated national approach to roll out PrEP among health care services, supporting formal and informal PrEP use, prior to reimbursement. This approach can serve as a model for other countries facing the same challenges.

WEPEC243

Awareness, understanding and barriers to oral pre-exposure prophylaxis (PrEP) use among gay, bisexual and other men who have sex with men (GBMSM) in Nairobi and Johannesburg: A two-site qualitative study

R. Wanjiru[1], S. Tenza[2], W. Nutland[3], P. Weatherburn[3], A. Smith[4], J. Kimani[5], T. Palanee-Phillips[2], A. Bourne[6]
[1]Partners for Health and Development, Research, Nairobi, Kenya, [2]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [3]London School of Hygiene and Tropical Medicine, Department of Public Health, Environments and Society, London, United Kingdom, [4]University of Oxford, Oxford, United Kingdom, [5]Partners for Health and Development, Clinical, Nairobi, Kenya, [6]La Trobe University, Melbourne, Australia

Background: South Africa and Kenya are among the first African countries to approve use of oral PrEP for those at high risk of HIV acquisition. High rates of HIV prevalence and sexual risk behaviors are reported among GBMSM in Nairobi and Johannesburg. GBMSM also face substantial challenges in accessing HIV prevention, testing and treatment. However, initial PrEP uptake has not been as high as expected. Our study examined likely acceptability and potential barriers to PrEP use in both cities.
Methods: Between June 2016 and July 2017, in-depth interviews were carried out with 30 GBMSM in Nairobi and 30 in Johannesburg, recruited in clinical and community settings and via snowballing. Interviews used standardized question route to assess prior awareness of PrEP; acceptability and perceived barriers to use. We also explored the likely acceptability of future PrEP delivery options. Transcribed data were subjected to thematic analysis using NVivo.
Results: In Johannesburg no interviewee had ever used PrEP and less than a third knew what it was, but up to three-quarters would consider future use. In Nairobi, two GBMSM had tried PrEP in a demonstration project but only a quarter knew what PrEP was. Two thirds would consider future use. In both cities among those that heard of PrEP most confused it with Post-Exposure Prophylaxis (PEP). Among GBMSM who expressed an interest in future use, the primary motivations were avoiding HIV and managing anxieties associated with sex. Willingness to consider future use was high, but most perceived PrEP as an addition to condoms not a replacement. There were widespread concerns about potential side effects and the stigma that might arise if users were perceived to have HIV or be "promiscuous". Considerable scepticism was expressed about potential future topical formulations (rectal microbicides) but potential users expressed interest in long-term (injectable) formulations and intermittent dosing.
Conclusions: In both Nairobi and Johannesburg awareness and understanding of PrEP remains very limited and considerable health promotion efforts will be required to explain its utility and create demand for it. GBMSM recognize PrEP's potential to reduce incidence and anxiety about HIV but remain concerned about potential stigmatization of users.

WEPEC244

PrEP uptake among middle age and older individuals in rural Kenya

W. Olilo[1], M. Petersen[2], E. Wafula[3], C. Koss[3], D. Kwarisiima[4], K. Kadede[1], T. Clark[3], E. Charlebois[3], C.R. Cohen[3], E.A. Bukusi[1], M.R. Kamya[4], D. Havlir[3], J. Ayieko[1]
[1]Kenya Medical Research Institute, Centre for Microbiology Research, Nairobi, Kenya, [2]University of California, Berkeley, Berkeley, United States, [3]University of California, San Francisco, San Francisco, United States, [4]Makerere University, Kampala, Uganda

Background: Pre-exposure prophylaxis (PrEP) markedly reduces HIV acquisition and is an important tool for HIV prevention. In Africa, implementation of PrEP has largely focused on young women and adolescent girls, sex workers and men who have sex with men. Middle age and older adults may also be at high risk for HIV acquisition, yet little is known about their risk perception and willingness to start PrEP. We sought to understand HIV risk perception and uptake of PrEP among individuals aged ≥45 years in rural Kenya.

Methods: Community-wide HIV testing was conducted in the SEARCH study (NCT01864603) using mobile community health campaigns (CHCs) supplemented by home-based testing. HIV-negative individuals were eligible for PrEP based on either self-referral or a HIV-acquisition risk score derived from HIV seroconversions in the region. Data on PrEP uptake and HIV risk perception were collected among PrEP eligible individuals aged ≥45 years in six rural communities in Kenya. Logistic regression was used to identify factors associated with uptake of PrEP.
Results: Individuals aged ≥45 years comprised 26% (N=4792) of 18,251 HIV-negative adults (≥15 years) in the six communities; 401 (8%) of these older individuals were classified as PrEP-eligible (265 by risk score, 136 through self-referral), and 143 (36% of those eligible) initiated PrEP within two weeks of testing. Men were more likely to initiate PrEP than women (41% vs. 30%; aOR 2.89; 95%CI:1.33,6.29), while those employed in the fishing, transportation, and entertainment industry were less likely to initiate than other occupations such as farming (23% vs. 58%; aOR 0.17; 95%CI:0.08,0.36). Men who were head of household were more likely to initiate PrEP, while women who were head of household were less likely to initiate PrEP.
Common reasons to initiate PrEP among the older adults included multiple sexual partners of unknown HIV-serostatus (48%), known discordant relationships (22%), polygamous marriage (20%), and being inherited or a wife inheritor (3%).
Conclusions: In a rural Kenyan population with high HIV prevalence, those ≥45 years demonstrate interest in starting PrEP. However, uptake remains relatively low. New approaches to improve PrEP delivery are required to reduce HIV acquisition among older adults at high risk of infection.

WEPEC245

Community level PrEP programming addressing the challenges of facility-based follow-up for pre-exposure prophylaxis (PrEP) ART refills among PWUD, SW and MSM in Uganda: MARPI clinic experience

R. Kansiime[1], J.R. Lule[2], P. Kyambadde[1], M. Kinawa[1], I. Kakooza[1], R. Kindyomunda[3]
[1]Most At Risk Populations Initiative, National STI Control Unit, Kampala, Uganda, [2]Most At Risk Populations Initiative (MARPI), Programs, Kampala, Uganda, [3]UNFPA, Programmes, Kampala, Uganda

Background: The Ministry of Health with support from PEPFAR are piloting pre-exposure prophylaxis among selected health sites in Uganda including those providing key populations´ friendly services. Specific attention has been to provide SW and PWUD who are at high risk of exposure to HIV given the high HIV prevalence and increased sexual and injection risks. MARPI clinic, one of the KP partners who are implementing PrEP among SW and MSM has integrated PrEP in its facility and community level services delivery.
Description: MARPI implemented PrEP starting from July 2017 to KPs (SW, PWUD and MSM) in Kampala and the surrounding districts. KPs were referred to MARPI and initiated on PrEP. During follow-up there were challenges with re-fills and follow-up. As a solution to the challenges, a community component was added. of the 646 (MSM, SW and PWUD), 78% returned for drug re-fills while 22% did not. The main reason for failed return were not contactable by telephone (41%), travelled (14%), ART side effects (9%), wrong telephone contacts (8%) and temporal stoppage (8%). Follow-up after addition of the community-based PrEP programme, 69% of the 144 who had failed to return received PrEP refills at community level but there were challenges with 45 (31%). The main challenges at community level were having travelled (44%), not at home and not contactable by phone (33%), side effects (11%), being busy (7%).
Lessons learned: Adding a community component to the MARPI facility PrEP programme reduces the challenges of failed telephone contact and decreases missed drug re-fills. The challenges of facility-level PrEP program differ from community-level PrEP. Lack of telephone contact and travelling are major challenges at the two program levels for SW, MSM and PWUD in Kampala. Side effects to ART is a challenge that is common to both.
Conclusions/Next steps: Facility PrEP programmes when integrated with community-based components reduces failed refills by reducing telephone call-based failures. More resources are needed to enhance community level services delivery to SW, MSM and PWUD as a complement to the facility-level PrEP program.

WEPEC246

A systematic review of interventions to increase adult men's uptake of voluntary medical male circumcision for HIV prevention in East and Southern Africa

C. Figueroa[1], J. Samuelson[2], S. Taoka[3], B. Hensen[4]
[1]World Health Organization, HIV, Geneva, Switzerland, [2]World Health Organization (WHO), Geneva, Switzerland, [3]King's College Hospital, London, United Kingdom, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: According to WHO data, 14.5 million men and boys were circumcised by the end of 2016 in East and Southern Africa, representing a dramatic increase in availability and uptake of VMMC services. Despite this level of scale up showing the feasibility of VMMC and efforts to increase demand in 14 countries of East and Southern Africa that included VMMC as an additional HIV prevention strategy, progress in increasing coverage among adult males, particularly over 25s, has been modest relative to the 90% target for 2020. We conducted a systematic review to evaluate interventions that led to an increase in VMMC uptake among adult men and should be considered for implementation by decision-makers of VMMC programmes.
Methods: We systematically searched electronic databases (EMBASE, PubMed and Global Health Library) for peer-reviewed articles for two different periods, 01 January 2005 to 22 October 2015 and 23 October 2015 to 17 January 2017. We included studies reporting the uptake of male circumcision among adult men (>18 years). Interventions were coded as communication, structural, compensation or incentive based or mixed. We analyzed data by country and setting, type of intervention, time to seek circumcision and study design.
Results: 12 studies were included. Study methodological quality (randomized and non-randomized trials Cochrane risk of bias) was variable and most studies (n=10/12) were in low or low-middle income countries. Studies were not excluded based on the quality assessment. The reported increase in the uptake of VMMC ranged from 1.9% to 62%, 83% (n=10/12) used mixed interventions. 50% (n=9/18) of reported interventions arms showed a positive effect; all used a mixed intervention (structural and communication or compensation and communication). Limitations of the review included exclusion of abstracts; the authors defined interventions types of which the communication component was inconsistently reported. Due to heterogeneity we did not perform a meta-analysis.
Conclusions: Interventions to increase VMMC uptake among adult men should include a mixed approach and consider local context. Combinations of communication with home-based testing, enhanced provider capacity or fixed compensation were effective. Implementation should occur with systematic monitoring to permit adjustments and improvements.

WEPEC247

Community delivery increases PrEP program retention in SEARCH study in Uganda and Kenya

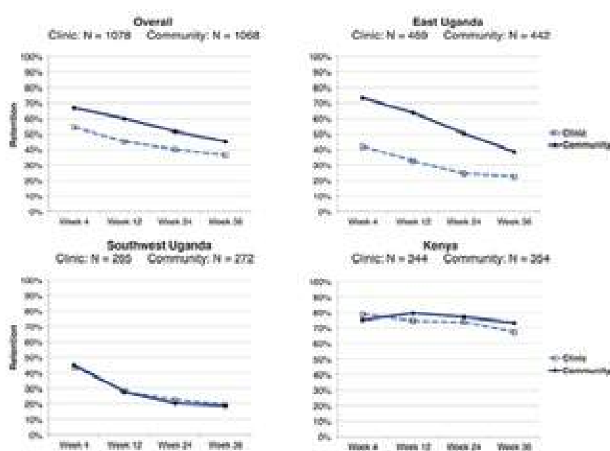
B. Jewell[1,2], J. Ayieko[3], A. Owaraganise[4], F. Mwangwa[4], D. Kwarisiima[5], C.A. Koss[6], A. Plenty[6], D. Black[6], E. Bukusi[3], C.R. Cohen[6], T.D. Clark[6], E.D. Charlebois[6], M.R. Kamya[7], M.L. Petersen[1], D.V. Havlir[6]
[1]University of California, Berkeley, Berkeley, United States, [2]Institute for Disease Modeling, Seattle, United States, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Infectious Diseases Research Collaboration, Kampala, Uganda, [5]Makere University, Joint AIDS Program, Kampala, Uganda, [6]University of California, San Francisco, San Francisco, United States, [7]Makere University, College of Health Sciences, Kampala, Uganda

Background: Rollout of pre-exposure prophylaxis (PrEP) in sub-Saharan Africa faces potential barriers to retention in care, including distance to clinic and stigma. Delivery of ART at home or other community sites can improve retention in HIV care; this strategy may also improve PrEP retention. The SEARCH Study (NCT01864603) is investigating a targeted, population-based approach to PrEP in rural East African communities. We conducted a multisite stratified individually-randomized controlled trial of community vs. clinic PrEP visits with medication delivery among PrEP starters in SEARCH intervention communities and assessed the effect on PrEP program retention.

Methods: From August 2016-January 2017, we randomized adult (≥15 years) participants starting PrEP in 11 communities (4 in East Uganda, 4 in Southwest Uganda, and 3 in Kenya) to PrEP visits at either clinic or community site (home or other non-clinic location). Randomization was stratified on age, sex, and community. Participants were followed for ≥36 weeks. PrEP program retention was assessed at 4, 12, 24, and 36 weeks, with a pre-specified primary outcome of 4-week retention. Participants were considered retained if seen for a follow-up visit within -2/+4 weeks of the scheduled visit date, and not retained if they missed the visit or withdrew. In this intention-to-treat analysis, logistic regression was used to test the association between delivery site and PrEP retention, adjusted for stratification variables.

Results: Of 2146 participants in the study, 1116 (52%) were female, 540 (25%) were aged 15-24, and 911 (42%) were in East Uganda, 537 (25%) were in Southwest Uganda, and 698 (33%) were in Kenya. At week 4, 1298 (60%) were retained, 585/1078 (54%) and 713/1068 (67%) in the clinic and community arms, respectively. Retention over time varied by region, somewhat due to non-compliance with randomization in Southwest Uganda and Kenya. Community visits were associated with higher retention at weeks 4 (aOR 1.76 [1.47-2.12]), 12 (aOR 2.03 [1.69-2.45]), 24 (aOR 1.73 [1.44-2.08]), and 36 (aOR 1.52 [1.26-1.84]). Effect sizes were stable across age/sex strata, but larger in East Uganda.

Conclusions: Community PrEP delivery increased retention, but the observed effect differed by region. PrEP retention was sub-optimal and further strategies to improve retention should be investigated.



[PrEP retention over time (weeks 4, 12, 24, and 36) by PrEP visit site (clinic vs. community) in the intention-to-treat analysis.]

WEPEC248

Message framing strategies for PrEP education with men who have sex with men in North America: Results of three randomized trials

K. Underhill[1,2], K.M. Guthrie[3], D. Operario[4], S.K. Calabrese[5], C. Kahler[4], K.H. Mayer[6]
[1]Columbia University, Mailman School of Public Health, New York, United States, [2]Columbia University, Columbia Law School, New York, United States, [3]The Miriam Hospital, Providence, United States, [4]Brown School of Public Health, Providence, United States, [5]George Washington University, Washington DC, United States, [6]The Fenway Institute, Boston, United States

Background: Implementation of pre-exposure prophylaxis (PrEP) requires messaging strategies for describing PrEP's effectiveness, benefits, and use of condoms with PrEP. These trials investigated message framing strategies for communicating about PrEP with men who have sex with men (MSM), focusing on messaging regarding PrEP effectiveness, PrEP benefits, and dual use of PrEP and condoms.

Methods: We recruited North American MSM using a mobile dating app (n=3078) for three factorial randomized trials of six message framing strategies, evaluating effects on PrEP acceptability. Trials randomized participants to several frames to communicate effectiveness:
(1) success-based vs. failure-based vs. two-sided messages;
(2) messages using numerical information vs. verbal paraphrases; and
(3) messages with numerical ranges vs. point estimates for efficacy.
Frames also varied information about PrEP benefits, using the following frames:
(1) benefits for reducing HIV risk vs. HIV-related fear and worry;
(2) loss-based and gain-based messages about PrEP benefits.
Finally, one frame considered condom messaging, using mandatory, flexible, and no messages about dual condom-PrEP use. We evaluated willingness to use PrEP, attitudes about PrEP user behaviors, predicted PrEP efficacy, and anticipated PrEP stigma.

Results: Frames for communicating PrEP effectiveness and dual method use with condoms generally did not affect willingness to use PrEP or attitudes regarding PrEP user behaviors. But framing PrEP's benefits to encompass anxiety reduction as well as risk reduction significantly increased PrEP acceptability and willingness to use PrEP, and increased perceived PrEP effectiveness among men who believed that their HIV risk was low.

Conclusions: Message framing strategies for communicating about PrEP's benefits, including ancillary benefits beyond risk-reduction, can increase acceptability. Messages emphasizing PrEP's secondary benefits (e.g., reduced HIV-related worry) may be particularly useful in outreach with MSM with low perceived risk.

WEPEC249

"For someone whose life is very busy and unpredictable, this service is like a dream." Reaching young men of color who have sex with men through on-line prep services

K. Koester[1], S. Hughes[2], H. Gangeskar[3], E. Engesæth[3], M. Hawkins[3], R. Grant[2]
[1]University of California, San Francisco, Medicine, Mill Valley, United States, [2]University of California, San Francisco, Medicine, San Francisco, United States, [3]Nurx, San Francisco, United States

Background: HIV pre-exposure prophylaxis (PrEP) can limit new HIV infections when used as directed. PrEP uptake is increasing in the United States in communities with lower levels of HIV-related stigma and increased access to primary or sexual health care. Innovative delivery settings such as online access to PrEP services, may reach those who might not otherwise avail themselves to biomedical prevention technologies such as young men of color who have sex with men (YMCSM). Whether online PrEP services are acceptable to this vulnerable population is unknown.

Methods: We utilized an implementation science approach (REAIM) to evaluate online PrEP services offered by Nurx, a telehealth service initially developed to deliver oral birth control. We conducted chart re-

Tuesday 24 July

Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

views and in-depth interviews with persons requesting PrEP through the online platform. We characterize clients presenting for PrEP, describe the acceptability of services and identify service refinement opportunities for current and future Nurx clients including YMCSM.

Results: From April-August 2017 Nurx personnel messaged 272 PrEP requesters (made in CA, FL, IL, NY) with study information; 77 indicated interest and 32 were interviewed including cisgender men (n=26) and women (n=6), active and former Nurx PrEP clients, and those who requested, but did not start PrEP. Median age was 28.5 years, 73% non-White; nearly all insured through employers, public programs, or parents. Online PrEP services were acceptable to participants, including YMCMS for the following reasons: utilization of Nurx due to discomfort with approaching their own primary care provider (PCP) or after approaching a PCP who was unwilling or felt unable to prescribe PrEP; due to convenience and accessibility of PrEP during times of transition between jobs, providers and/or insurance.

Reasons for not pursuing or discontinuing PrEP included low motivation to use PrEP due to lack of sexual activity or misperception of risk (females). Greater assistance when discontinuing, re-starting or using PrEP in the context of monogamous relationships and messaging specific to female PrEP requesters is needed.

Conclusions: Online PrEP services hold strong appeal to patients seeking convenient and non-judgmental healthcare providers and may be an optimal setting to reach vulnerable populations including young men of color who have sex with men.

WEPEC250

Achievements and lessons learned in efforts to achieve optimal site capacity in a voluntary medical male circumcision program In Mozambique

Z. Mwandi[1,2], F. Zita[3,4], M. Tanque[5,6], D. Sarama[3,4], P. Devos[5,6], N. Gaspar[7], V. Kiggundu[8], J. Come[9], E. Gold[10,11], J. Sallet[2,12], E. Njeuhmeli[8]
[1]Jhpiego, Nairobi, Kenya, [2]AIDSFree, Arlington, United States, [3]Jhpiego, Maputo, Mozambique, [4]AIDSFree, Maputo, Mozambique, [5]JHCCP, Maputo, Mozambique, [6]Health Communication Capacity Collaborative, Maputo, Mozambique, [7]USAID/Mozambique, Maputo, Mozambique, [8]USAID, Washington, DC, United States, [9]Mozambique Ministry of Health, Maputo, Mozambique, [10]JHCCP, Baltimore, United States, [11]Health Communication Capacity Collaborative, Baltimore, United States, [12]JSI, Arlington, United States

Background: To control the HIV epidemic among 15-49 year olds, the Mozambique Ministry of Health (MOH) aims to offer voluntary medical male circumcision (VMMC) to 2 million men by 2018. Despite availability of VMMC services in Manica and Tete provinces since 2012, a high site level provision of VMMC to males had not been achieved. In 2015, efforts were made to act on external quality assessment (EQA) recommendations to increase availability and quality of VMMC services.

Description: VMMC sites received MOH and partners' support in using site specific action plans to address the gaps identified. Redistribution of staff (providers, counsellors and mobilizers) within sites and recruitment of additional staff was done to match the defined site-staffing needs based on bed capacity. All staff members were retrained on client-provider interaction, focusing on barriers to service uptake, VMMC follow-up rates and wound care. USAID's VMMC Site Capacity and Productivity Assessment Tool was used to analyse data from 2015 to 2017. The number of males receiving VMMC rose from 21,824 to 100,636. The proportion of 15 to 29 years old males receiving VMMC increased from 45% to 58%. Achievement of targets increased from 34% to 105%. Despite the rise in volumes of clients served, adverse event rates were stable at below 2%.

Lessons learned: Several interventions accounted for the considerable increase in uptake and production of the VMMC services: i) Optimising staff availability at each site to match site capacity, ii) Redistribution and retraining of all VMMC staff on communication with clients, at all stages of the VMMC services, from early mobilization to post-surgery follow-up; iii) Intense supervision, data monitoring and data-based decision making to fine-tune the activities, iv) Opening services on Saturday to extend services for those clients not able to reach services during the week and; v) a spirit of collaboration and cooperation among all players in using analysed data to improve on gaps identified.

Conclusions/Next steps: High site productivity which was observed as increased uptake of services among 10-29 years olds is critical for achieving efficiency within VMMC programs. Lessons from the Manica and Tete VMMC program can assist other programs to improve site performance.

Indicator	FY 2015	FY 2016	FY 2017
VMMC Target	65,054	62,166	95,296
VMMC done	21,824	35,389	100,636
Achievement Vs Target (%)	34	57	105
Proportion of 15-29yrs (%)	48	50	58
Proportion of =>15yrs (%)	48	54	60
Site Utilization (%)	38	50	100
Adverse events rate (%)	0.07	0.14%	0.14%

WEPEC251

Creating PrEP awareness amongst adolescent girls and young women through peer mobilization in Kenya and Uganda

B. Auma[1], J. Stevenson[2], V.R. Musavi[1], H. Nagadya[3], A. Akoth[1], J. Amoli[3], L. Wangari[1], C. Nyambura[4], K. de Graaf[2]
[1]Personal Initiatives for Positive Empowerment (PIPE), Nairobi, Kenya, [2]ATHENA Initiative, London, United Kingdom, [3]ICWEA, Kampala, Uganda, [4]ATHENA Initiative, Nairobi, Kenya

Background: Young Women Lead, Evidence, Advocate, Research, Network (LEARN) is a young women-led mobilization, advocacy, and research project promoting PrEP awareness among adolescent girls and young women (AGYW) in Uganda and Kenya. LEARN provides evidence to inform effective PrEP rollout for this population. Led by the ATHENA Initiative, in partnership with PIPE in Kenya and ICWEA in Uganda, LEARN is part of the DREAMS Innovation Challenge funded by PEPFAR and managed by JSI Research & Training Institute, Inc.

Description: LEARN combines leadership, participatory research, and peer mobilization. Ten young women were identified, recruited, and trained to act as LEARN Ambassadors, leading project activities. In a week-long residential training, Ambassadors gained or developed skills and knowledge in advocacy, public speaking, leadership, gender and human rights, HIV prevention, PrEP, and research. Each Ambassador then identified 10 AGYW in her community to join LEARN as Peer Mobilizers, providing them with support to share information about PrEP with peers. LEARN Ambassadors and Peer Mobilizers organize mobilization activities and create safe spaces for AGYW to learn about PrEP. They provide a LEARN PrEP factsheet, designed for and by young women, and direct AGYW to additional information or services.

Lessons learned: Between May and December 2017, LEARN reached 2017 AGYW with PrEP and HIV prevention information, in 100 safe spaces. AGYW shared questions, concerns and misconceptions about PrEP and identified the value in having other young women providing information and support. Demand exceeded expectations, demonstrating the huge appetite for targeted and accessible PrEP information among AGYW, and the potential for significant reach of a model that supports and empowers young women to lead.

Conclusions/Next steps: AGYW are disproportionately affected by HIV, and while PrEP, as a discreet, individually-controlled prevention tool has potential to meet the needs of some AGYW, there have been challenges in effective uptake and implementation, as well as providing access for AGYW in both Uganda and Kenya. LEARN provides a model to address myths and misconceptions, and support interest in PrEP, through safe, young-women led learning spaces. The model is replicable in other settings, and is cost-effective.

WEPEC252

Bringing Voluntary Male Medical Circumcision (VMMC) services to the community: VMMC mobile clinic campaigns on the islands of Lake Victoria in Tanzania

J. Zelothe[1], D. Msalilwa[1], S. Zidana-Ndovi[2], G. Mkemwa[1], S. Dane[2], C. Madevu-Matson[2], B. Senyana[2], J. Soares Linn[2]
[1]ICAP at Columbia University in Tanzania, Dar es Salam, Tanzania, United Republic of, [2]ICAP at Columbia University, Mailman School of Public Health, New York, United States

Background: VMMC is an evidence-based, high-impact, biomedical HIV prevention method that can reduce a man's risk of acquiring HIV from a female sex partner by 60%. Tanzania is one of 14 VMMC priority countries, where VMMC services have been scaled-up with a goal of 90% VMMC coverage among males ages 10 to 29. From 2009 to 2015, ICAP at Columbia University, in partnership with the Tanzania's Ministry of Health and Social Welfare, successfully implemented VMMC services in non-traditionally circumcised lake areas of Kagera and Geita regions.

Description: ICAP's package of VMMC services included contribution to national VMMC policies and M&E tools; development of a training package for health care workers; demand generation; provision of supplies and commodities; and completion of VMMC feasibility assessments. To reach fishermen in high HIV prevalence areas on 20 Lake Victoria islands, ICAP organized mobile clinic campaigns using outreach boats and tents to perform VMMC. To generate demand within these communities, ICAP supported innovative drama groups and performances, radio announcements, and sensitization meetings with key community, religious, and political leaders. In order to ensure linkage to HIV services, ICAP also supported mobile HIV care and treatment services.

Lessons learned: From 2009-2015, ICAP supported numerous mobile campaigns and the expansion of VMMC services to nine health facilities in Tanzania's Lake region. A total of 125,046 men received VMMC through ICAP-supported services. Over 80,176 (67%) circumcisions were conducted through mobile campaigns and 1,067 (0.8%) men were diagnosed HIV-positive and referred to care. Of the 786,310 VMMCs conducted in all of Tanzania during this period, one out of seven were supported by ICAP.

Conclusions/Next steps: Innovative, client-centered strategies were critical to reach Tanzania saturation goals in the Great Lakes region. The utilization of mobile clinics can help VMMC programs ensure that they are providing services to communities not in easy reach of healthcare facilities. In particular, combining mobile clinic models with outreach boats allow remote islands to successfully participate in time-limited health campaigns, particularly with mobile populations such as fishermen. Partnerships with health, education, public- and private-sector, community, and religious leaders are key to this strategy.

WEPEC253

Is availability of clinics that prescribe PreP associated with greater willingness to use it? Results from the national survey on HIV in the Black community (NSHBC)

B. Ojikutu[1], Y. Ransome[2], L. Bogart[3], S. Bogan[4], T. Stopka[5], P. Sullivan[6], K. Mayer[7]
[1]Brigham and Women's Hospital, Boston, United States, [2]Yale School of Public Health, New Haven, United States, [3]RAND Corporation, Santa Monica, United States, [4]Harvard University, Boston, United States, [5]Tufts University School of Medicine, Boston, United States, [6]Emory University, Atlanta, United States, [7]Fenway Institute, Boston, United States

Background: Black Americans have the highest rate of HIV diagnoses in the US. However, uptake of pre-exposure prophylaxis (PrEP) to prevent HIV infection among them is low and may be associated with limited availability of clinics where PrEP is prescribed. In this study we investigated the association between availability of PrEP clinics and willingness to use this intervention.

Methods: We obtained locations of clinics where PrEP is prescribed from all cities in AIDSVu.org, geocoded the addresses in ArcMap 10.5, and calculated the density of PrEP clinics per 10,000 (10K) residents per ZIP code. Individual-level data were obtained from the NSHBC, an online survey assessing willingness to use PrEP among a nationally representative sample of Black Americans in 2016. Distances from PrEP clinics to the population-weighted geocentroid of ZIP codes for participants were calculated using ArcGIS. A multilevel, multivariate model to estimate the association between willingness to use PrEP and PrEP clinic density adjusting for individual (age, gender, education, insurance, last doctor visit, HIV risk, and region of residence) and ZIP code-level covariates from the 2010 US Census (% living in poverty, % unemployed, % uninsured, %Black population) was constructed.

Results: 787 participants and 700 distinct ZIP codes were included in the multilevel analysis. Among participants, 45% were male, 23% were high-risk based upon self-reported behavioral characteristics, mean age was 34 years (SD=9), and 54% resided in the South. Among survey participants, 26% were willing to use PrEP. The mean number of PrEP clinics per ZIP code was 1.73 (SD .64), density per 10k population was 0.07 (SD 0.22), and mean walking distance was 26 minutes (SD=20). The mean walking distance was longest in the South versus the Northeast (32 versus 23 minutes, Tukey-t=2.76, p=0.03). Participants living in areas with higher PrEP clinic density were significantly more willing to use PrEP [one standard deviation higher density of PrEP clinics per 10K population was associated with 20% higher willingness (Adjusted Prevalence Ratio =1.20, 95% CI=1.05, 1.37)].

Conclusions: Willingness to use PrEP is associated with the spatial availability of clinics that prescribe PrEP. This finding highlights the importance of widespread scale-up of PrEP access at healthcare facilities.

WEPEC254

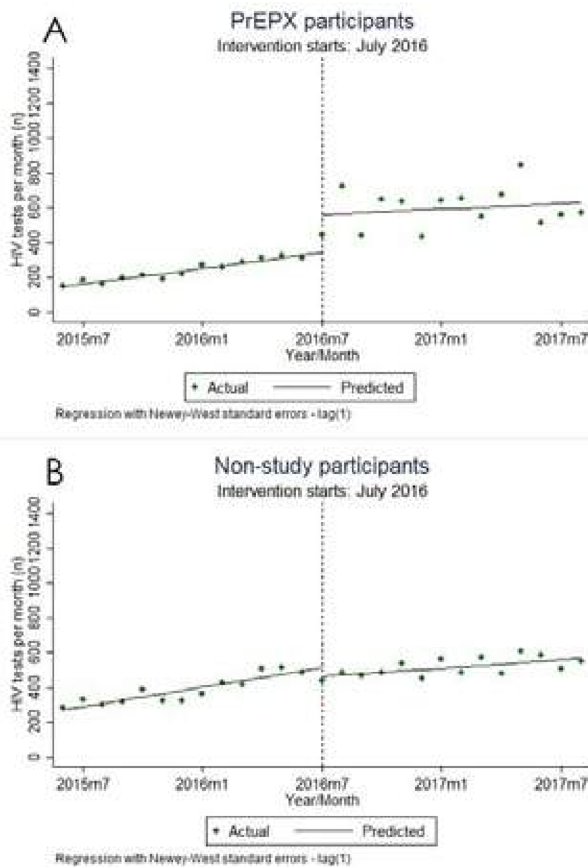
Impact of a population-level PrEP implementation project on clinical capacity and HIV testing among gay and bisexual men in Melbourne, Australia

J. Asselin[1], K. Ryan[2], V. Cornelisse[3,4,5], B. Price[4], N. Roth[4,5], J. Wilcox[6], B. Tee[7], C. Fairley[3,8], C. Chang[4], J. Armishaw[4], O. Vujovic[4], M. Penn[7], P. Cundill[7], G. Grant[16,17], E. Wright[2,4,12], M. Stoové[2,15]
[1]Burnet Institute, Centre for Population Health, Melbourne, Australia, [2]Burnet Institute, Melbourne, Australia, [3]Melbourne Sexual Health Centre, Alfred Health, Melbourne, Australia, [4]Alfred Hospital, Department of Infectious Diseases, Monash University, Melbourne, Australia, [5]Prahran Market Clinic, Melbourne, Australia, [6]Northside Clinic, Melbourne, Australia, [7]Victorian AIDS Council, Melbourne, Australia, [8]Monash University, Central Clinical School, Faculty of Medicine, Nursing and Health Sciences, Melbourne, Australia, [9]Collins Street Medical, Melbourne, Australia, [10]ERA Health, Melbourne, Australia, [11]Ballarat Community Health, Ballarat, Australia, [12]Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [13]University of Sydney, Department of Gender and Cultural Studies, Sydney, Australia, [14]University of New South Wales, Centre for Social Research in Health, Sydney, Australia, [15]Monash University, School of Population Health and Preventive Medicine, Melbourne, Australia, [16]University of California, San Francisco, United States, [17]San Fransisco AIDS Foundation, San Francisco, United States

Background: In July 2016, PrEPX, a population-level, PrEP implementation project in Melbourne, Australia, began rapidly enrolling gay and bisexual men (GBM) in clinics. Using data from the Australian Collaboration for Coordinated Enhanced Surveillance (ACCESS), we assessed changes to number of HIV tests conducted at four of the largest study recruitment sites pre- and post-study enrolment to explore the study's impact on overall clinic capacity to offer HIV testing.

Methods: Test records were extracted from ACCESS for three general practice clinics and one peer-led community HIV testing service enrolling PrEPX participants. HIV tests conducted between June 1, 2015 and August 30, 2017 among GBM were included in this analysis. HIV testing was compared between pre- (June 2015-June 2016) and post-intervention (July 2016-August 2017) periods. Segmented linear regression of monthly aggregate data assessed changes in the number of HIV tests among PrEPX participants and non-participants across pre- and post-intervention periods. We report comparative pre-intervention slope (1), change in intercept at intervention (2), and pre- to post-intervention change in slope (3).

Results: This analysis included 23,695 HIV tests among 8,431 individuals; 11,520 (48.6%) tests were included among 2,353 (27.9%) PrEPX participants. Pre-intervention, we observed on average an extra 15 monthly tests among PrEPX participants (1=15.1, 95%CI:13.1-17.1, p<0.001) and an extra 19 among non-study participants (1=18.6, 95%CI:13.8-24.5, p<0.001). At intervention, there was a significant increase of 219 monthly tests among PrEPX participants (2=218.7, 95%CI:145.0-292.5, p<0.001) and a marginal decrease of 48.8 monthly tests among non-participants (2, 95%CI:-97.1- -0.4, p=0.048). Post-intervention, the trend in monthly tests was stable among PrEPX participants (3=-9.7, 95%CI:-23.2-3.9, p=0.153) and decreased by 11 monthly tests among non-study participants (3= -10.8, 95%CI:-17.5--4.1, p=0.003). Tests per month continued to increase in non-study participants (7.8, 95%CI:3.3-12.3, p=0.002) post-intervention.



[Figure 1: Monthly HIV tests pre- and post-study start July 2016, among PrEPX participants (A) and non-study participants (B)]

Conclusions: In the year pre-intervention, there was already a significant increase in monthly HIV tests conducted among GBM. Study enrolment resulted in a dramatic increase in testing associated with baseline and follow-up visits for PrEPX participants, which initially impacted on non-participants as seen by the initial decline at intervention. Encouragingly, the number of tests among non-participants increased since enrolment suggesting that clinics have adapted to increased demand.

WEPEC255

Willingness to take daily oral HIV pre-exposure prophylaxis (PrEP) among young women and female sex workers in Kenya

R. Karuga[1], W. Mukoma[2], S. Nduta[2], N. Kilonzo[3], R. Eakle[4], M. Kiragu[2], H. Larson[5], H. Musyoki[6], C. Ngunu[7], J. Kyongo[2], L. Otiso[2]
[1]LVCT Health, Research and Strategic Information, Nairobi, Kenya, [2]LVCT Health, Nairobi, Kenya, [3]National AIDS Control Council, Executive Director, Nairobi, Kenya, [4]London School of Hygiene and Tropical Medical, London, United Kingdom, [5]London School of Hygiene and Tropical MEdicine, London, United Kingdom, [6]National AIDS and STI Control Programme, Nairobi, Kenya, [7]Nairobi County, Department of Preventive and Promotive Health, Nairobi, Kenya

Background: Kenya launched an implementation framework for scaling-up pre-exposure prophylaxis (PrEP) for preventing HIV among individuals at continuous ongoing risk in May 2017. Little is known about the willingness to take PrEP for HIV prevention among young women (YW) and female sex workers (FSW). Our research aimed to determine the willingness to take daily oral PrEP and barriers to uptake and adherence among YW and FSW in Kenya.
Methods: This cross-sectional survey collected data on demographics, HIV risk behavior and willingness to take PrEP among 150 YW and 68 FSW. We collected qualitative data from a sub-set of these women on motivators and barriers to uptake and adherence using in-depth interviews and focus group discussions.
Results: 89.7% of FSW and 85.3% YW were willing to take daily oral PrEP to prevent HIV infection. YW involved in transactional sex were significantly more willing to take daily oral PrEP (AOR=4.7 (95% CI: 1.4 to 15.7, p=0.011). YW with high self-perceived risk of HIV were more likely to be willing to take PrEP (OR=3.54 (95% CI: 1.3 to 9.6, p=0.013). HIV risk factors such as having multiple sexual partners, sexual coercion by drunk partners, and consuming alcohol before sex were associated with higher willingness to take PrEP among YW. There was no statistically significant association between willingness to take daily oral PrEP and HIV risk factors (frequency of condom use, duration of sex work and alcohol use) among FSW. Packaging of PrEP, history of low adherence to medication, fear of side effects and HIV stigma were identified as potential barriers to daily oral PrEP adherence among both sub-populations of women.
Conclusions: Self-perception of HIV risk and engagement of risky behavior were associated with willingness to take PrEP among YW. Screening for HIV risk perception and risky behavior of YW and FSW would allow targeted and focused delivery of PrEP for HIV prevention among YW and FSW.
It will be important to evaluate how this high level of willingness translates to actual uptake of PrEP for HIV prevention during scale up. Stigma is a key barrier to willingness and can be addressed by sensitizing the population on PrEP.

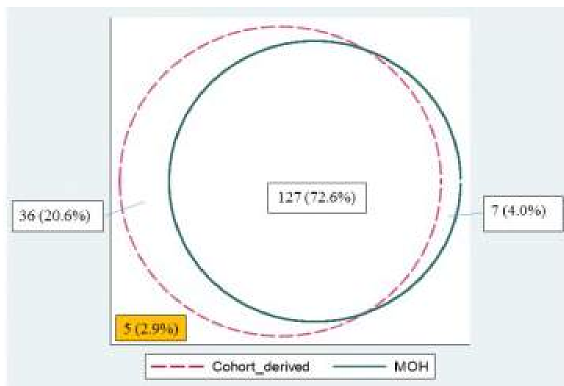
WEPEC256

Assessing PrEP eligibility in a HIV-1 vaccine feasibility MSM cohort using MOH guidelines and a cohort-derived HIV-1 risk score in Kenya

E. Wahome[1], A. Thiong'o[1], O. Chirro[1], K. Mohamed[1], E. Gichuru[1], J. Mwambi[1], M. Price[2,3], S. Graham[1,4], E. Sanders[1,5]
[1]KEMRI-Wellcome Trust Research Programme, International AIDS Vaccine Initiative, Kilifi, Kenya, [2]International AIDS Vaccine Initiative, New York, United States, [3]University of California at San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States, [4]University of Washington, Seattle, United States, [5]Nuffield Department of Medicine, University of Oxford, Headington, United Kingdom

Background: The Ministry of Health (MOH) recommends pre-exposure prophylaxis (PrEP) for sexually active HIV-negative individuals at risk for HIV-acquisition in Kenya. However, anal intercourse is not assessed prior to PrEP initiation. We set out to determine PrEP eligibility among MSM enrolled in an HIV-1 vaccine feasibility cohort, comparing the number eligible by MOH criteria to those determined eligible by a cohort-derived HIV-1 risk score.

Methods: From June-December 2017, we compared the number of MSM identified as eligible for PrEP by MOH risk criteria with those identified by a published cohort-derived HIV-1 risk score (age 18-24 years and a report of receptive anal intercourse, having male sex partners only, group sex, and any unprotected sex). We then compared performance of the two eligibility criteria to predict HIV-1 acquisition in the vaccine feasibility MSM cohort (HIV-1 incidence of 5.0 per 100 person years) that followed men monthly for HIV-1 testing, risk assessment, and risk reduction counselling.
Results: Out of 175 MSM assessed for PrEP eligibility, 127 (72.6%) were identified by both MOH and cohort-derived HIV-1 risk score criteria. However, the cohort-derived HIV-1 risk score identified 36 (20.6%) more cohort MSM for PrEP eligibility than the MOH criteria, of whom the majority (75.0%) reported receptive anal intercourse. Five (2.9%) men were not identified as at risk for HIV-1 by either method. The area under the operator characteristic curve for prediction of eventual HIV-1 acquisition of the MOH criteria and cohort-derived HIV-1 risk score were 0.49 [95% confidence interval (CI): 0.21-0.77] and 0.73 (95% CI: 0.39-1.00) respectively, P = 0.002.
Conclusions: Assessing PrEP eligibility in an HIV-1 vaccine feasibility cohort study of high-risk MSM using a cohort-derived HIV-1 risk score identified 21% more at-risk MSM for PrEP initiation than when MOH criteria were used. Consideration should be given to incorporating established risk factors for HIV-1 acquisition among MSM, especially receptive anal intercourse, into MOH guidelines, to enhance impact of PrEP programming among MSM in Kenya.



[Figure. Venn diagram of cohort-derived HIV-1 risk score and the MOH criteria for PrEP]

WEPEC257

MSM Prep users in Europe: Who is and is not having regular medical follow-up? Findings from the community-based research study Flash! PrEP in Europe

D. Rojas Castro[1,2,3], R.M. Delabre[1], A. Vilotitch[2,4], A. Bernier[1], V. Schlegel[5], S.B. Duken[6], R. Stranz[5], J. Ghosn[7,8], G. Cairns[9], G.M. Corbelli[10], H. Sweers[11], K. Jonas[12], B. Spire[2,5]
[1]Coalition PLUS, Community-based Research Laboratory, Pantin, France, [2]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, INSERM U1252, Marseille, France, [3]Univ Lyon 2, Social Psychology Research Group (GRePS), Lyon, France, [4]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [5]AIDES, Pantin, France, [6]University of Amsterdam, Amsterdam, Netherlands, [7]University Paris Descartes, EA7327, Paris, France, [8]Hôpital Hôtel Dieu, APHP, UF de Thérapeutique en Immuno-Infectiologie, Paris, France, [9]NAM/ Aidsmap.com, London, United Kingdom, [10]Plus Onlus, Rome, Italy, [11]Deutsche AIDS-Hilfe e.V., Berlin, Germany, [12]Maastricht University, Work and Social Psychology, Maastricht, Netherlands

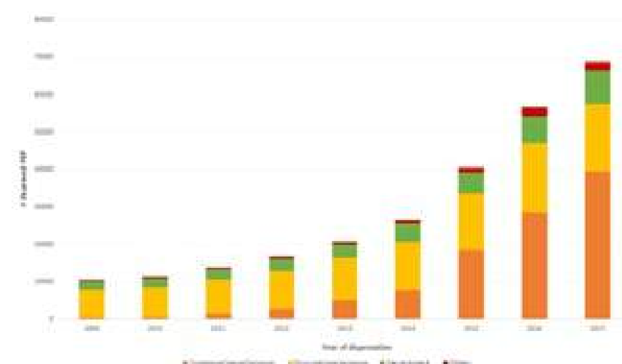
Background: Pre-exposure prophylaxis (PrEP) is a biomedical HIV prevention tool recommended for key populations including men who have sex with men (MSM). Medical follow-up visits are recommended (EACS, CDC) for PrEP users every 3 months for HIV testing, side effects and adherence assessment. In the context of variable PrEP access across Europe, we identified characteristics associated with formal and informal PrEP use among EU MSM participants in the Flash! PrEP in Europe (FPIE) survey.
Methods: FPIE online survey was a community-based research study aiming to assess PrEP interest and prior/current use among respondents from 12 European countries. Data were collected from June-July 2016 while PrEP was officially available and reimbursed in France. Participants were ≥18 years old and self-reported HIV-negative or unaware of their serological status. This analysis was restricted to MSM. Formal PrEP use (FPU) was defined as a PrEP follow-up visit every 3 months; lower frequencies were considered informal use (IPU). Four risk reduction profiles were identified using a prior hierarchical classification. High objective HIV risk (HOR) was based upon certain established criteria (EACS, CDC). Multinomial logistic regression was used to identify factors associated with FPU and IPU, compared with no PrEP use.
Results: Among 10 969 MSM, median age was 37 [IQR: 29; 46], 89 (0.8%) reported FPU and 195 (1.8%) reported IPU. Seventy-four percent (74.2%,n=66) of FPUs followed a continuous regimen compared to 39.8% (n=76) among IPUs (p< 0.001). After adjustment, similar risks factors were associated with higher chance of FPU or IPU: ≥10 occasional sex partners, drug use in a sexual context, recent STI diagnosis and HOR (FPU (AOR: 5.04 [2.10;12.08]); IPU (AOR: 1.77 [1.13;2.75])). Average perceived HIV risk was associated with lower probability of PrEP use (FPU: AOR 0.11 [0.06;0.23]; IPU: AOR 0.58 [0.39;0.88]).
Conclusions: Among MSM respondents, informal and formal PrEP users were at HOR but had, however, lower perceived HIV risk likely due to PrEP use. Informal PrEP users represented 68.7% of PrEP users, showing the necessity to authorize and implement PrEP services that address the needs of populations most at risk of HIV infection.

WEPEC258

Users profile, regimen choices and types of exposure in HIV post-exposure prophylaxis before and after the guidelines implementation in Brazil

I. Ornelas Pereira, G. Mosimann, A.R. Pascom, M. Meireles, F. Perini, A. Benzaken, F. Rick
Ministry of Health of Brazil, Department of Surveillance, Prevention and Control of STIs, HIV / AIDS and Viral Hepatitis, Brasilia, Brazil

Background: Post-exposure prophylaxis (PEP) is one of the tools to prevent HIV infection. PEP is available in health services in Brazil since 1999, in 2010 it was implemented for sexual exposure and in 2015 the first PEP guideline was launched. In September 2017, Dolutegravir containing (DTG-C) regimen was included as preferred regimen for PEP. The objective of this study is to identify the profile of PEP users in Brazil since 2009.
Methods: Programmatic data from PEP dispensation were analyzed for people aged 10+ from 2009-2017. Data were described using proportions to investigate associations. Social Vulnerability Index (SVI) is a combination of indicators related to urban infrastructure, human capital, income and work.



[PEP dispensation according to type of exposure. Brazil, 2009-2017]

Results: A total of 265,996 PEP regimen were dispensed in Brazil between 2009 and 2017, 68,685 (26%) of them, only in 2017. Non-occupational exposure dispensations increased significantly, approximately 274% between 2014 and 2017. 39,541 people (58%) had PEP pre-

scribed because consensual sexual exposure in 2017 (compared to 30% in 2014 - 7,839 dispensations); and 14% of them occurred in municipalities with median, high or very high SVI.
Also in 2017, 8,912 (13% of total) people sought for PEP because of sexual assault, among those 10% were 10-14yo. Furthermore, in the same year, sexual assault represents 76% of the reasons people 10-14yo received PEP. Approximately 23% of PEP dispensations because of sexual assault were in municipalities with median, high or very high SVI. DTG-containing regimen represented 11% of those dispensed in that year.
Conclusions: This study shows a change in the profile for PEP users, initially the main reason was occupational exposure and currently is sexual one. These results determines the importance of implementation of guideline for public health policies improvements. Since September of 2017, the number of dispenses DTG-containing regimens raised, reflecting the changes proposed by the current guidelines. This choice of regimen offers more virological power, greater genetic barrier, greater tolerance and greater security for users. Despite these advances, remains the challenge of making PEP available in the recommended 'window of opportunity' for those presenting higher SVI. SVI is an important tool to identify priority areas for PEP implementation.

WEPEC259

Integrating traditional male circumcision with voluntary medical male circumcision for better HIV prevention outcomes among the Shangani in Zimbabwe

F. Dube[1,2], E. Makoni[3], M. Dube[4]
[1]National AIDS Council, Monitoring and Evaluation, Harare, Zimbabwe, [2]National AIDS Council, Harare, Zimbabwe, [3]National AIDS Council, Masvingo, Zimbabwe, [4]National AIDS Council, Communications, Harare, Zimbabwe

Background: For decades, Government had banned traditional male circumcision camps in Chiredzi Districts following mounting deaths due to poor safety. In 2009, the Shangani community partnered the Ministry of Health in delivering safe voluntary medical male circumcision that satisfies both the needs of tradition and HIV prevention. The chief's interest in the integration centred on appeasing the increasing number of people who feared the traditional approach on safety grounds; and the promise of financial support and food that comes from the medical side. The medical side's drive has been to reach intended targets for HIV prevention, with the circumcision being done in a safe environment. Publicising the Chiredzi VMMC results would also motivate other communities to pursue VMMC for HIV prevention.
Description: To maintain cultural fidelity, chiefs drive the circumcision agenda with the medical side coming in to support. Chiefs mobilize their people and the Ministry of Health mobilizes partners for transport, allowances for health workers, equipment, HIV counseling and testing and food. Chiredzi almost always faces a drought and people struggle with providing food for their children in camp. Non Shangani people including health workers who may participate in HIV counseling and testing are only involved at entry level, with the actual VMMC performed during camp by circumcised Shangani health workers. Partners mobilise non-Shangani people who may be willing to go through the circumcision rite, provide food and payment of mandatory token fees to the chief, which may preclude some participants from joining camp. In camp the men are also equipped with HIV prevention education, including debunking the myth that circumcision is a magic bullet against infection. Since 2009, 117,000 men have been circumcised in over 10 camps, some of which are from traditionally non-circumcising areas with no single death.
Lessons learned: The integration has allowed for win-win outcomes for tradition and HIV prevention. Dialogue on misconceptions about the real intentions of the medical side in targeting the Shanganis for VMMC has helped.
Conclusions/Next steps: Following interest and success, the programme is now being taken to districts where there are traditionally circumcising communities, while also attracting men from non-circumcising families and districts.

WEPEC260

The PrEP life: Female sex workers' perspectives on uptake and use of daily pre-exposure prophylaxis for HIV prevention in South Africa

R. Eakle[1], R. Bothma[1], A. Bourne[2], S. Gumede[1], K. Motsosi[1], H. Rees[1], TAPS Demonstration Project
[1]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [2]LaTrobe University, Melbourne, Australia

Background: Pre-exposure prophylaxis (PrEP) has the potential to reduce new infections among populations at highest HIV risk, so end-user perspectives in 'real-world' settings are critical to informing scale-up. This paper presents findings from in-depth interviews (IDIs) with FSW participants exploring the lived experiences and perceptions of taking up and using PrEP during the TAPS Demonstration Project.
Methods: Between June 2015 and July 2017, serial IDIs were conducted with randomly selected participants, in Johannesburg and Pretoria, during their 3, 6, and 9 month clinic visits to record evolution of perspectives and experiences of PrEP use over time. IDIs were conducted in English, IsiZulu, or Setswana, then translated and transcribed by research assistants. Transcripts were uploaded and analysed in NVIVO by the senior research team using thematic analysis which focused on elucidating the broader perspectives and positioning of PrEP within women's lives.
Results: In total, 34 interviews with 18 women were conducted, ages 23-40. Participants perceived risks arising from their work, such as personal safety and potential for HIV infection, such as personal safety and potential for HIV infection, as prominent drivers for taking up and using PrEP. Personal responsibility for staying healthy and being able to support families was also a major motivating factor. Those who stayed on PrEP felt empowered to have control over their own, added HIV protection beyond condoms. All women reported devising their own strategies for managing use, especially when trying to maintain logistical and confidential adherence. Overall, distrust in the existence and/or efficacy of PrEP affected the motivation of women to come to the clinic and to maintain use when questioned by others outside the project.
Conclusions: As one of the first reports of PrEP use among FSWs outside clinical trial settings, this research shows that it will be important to ensure community-based, clear and widespread messaging to generate demand and support for PrEP. The larger TAPS study demonstrated certain successes and challenges in a complex population, further contextualized by this research. To achieve its potential, PrEP implementation must take into account influences on women's lives and what motivates them to take up and use PrEP.

WEPEC261

Willingness of Black and Latino adolescents in New York City to use daily oral HIV pre-exposure prophylaxis (PrEP)

T. Taggart[1], T. Albritton[2], P. Pina[3], Y. Liang[4]
[1]Yale University, Center for Interdisciplinary Research on AIDS, New Haven, United States, [2]CUNY School of Medicine, New York, United States, [3]St. Barnabas Hospital, New York, United States, [4]Yale School of Public Health, New Haven, United States

Background: In the United States, Black and Latino adolescents remain disproportionately affected by the HIV epidemic. In 2012, the US Federal Drug Administration approved daily oral pre-exposure prophylaxis (PrEP) for HIV prevention for people ages 18 and older. Results from clinical trials with people under age 18 have provided the safety data needed to expand oral PrEP to adolescents. However, daily drug regimens can be challenging for adolescents, and PrEP is only effective if used as prescribed. Therefore understanding adolescents' preferences for daily oral PrEP, or other PrEP modalities, is important for guiding future research and practice.
Methods: Who's on Board is a community-based mixed-methods study to determine strategies for implementing PrEP among Black and Latino adolescents. 200 HIV-negative or status unknown Black and Latino adolescents who attend an adolescent clinic in New York City completed an online survey assessing sexual health, willingness to use PrEP, PrEP

preferences, and sociodemographic characteristics. Data collection is ongoing and will be complete by May 2018. Correlates of preferring daily oral PrEP to another modality will be identified using multivariable logistic regression.
Results: 56% of the sample identified as male. 29.4% of the sample had ever heard of PrEP. 44% of the sample said they would prefer daily oral PrEP, 17.6% prefer PrEP injections, and 14.7% prefer a PrEP implant. Reasons for preferring daily oral PrEP over other modalities included: "not liking needles", "pills are painless", and "pills are easy to take". Reasons for preferring PrEP injections over other modalities included: "long lasting" and "would not have to take a pill everyday". Reasons for preferring PrEP implant over other modalities included: "easier to hide", and "safer". Adolescent males were more likely than adolescent females to select daily PrEP pills (aOR 1.21).
Conclusions: While the majority of the sample had heard of daily oral PrEP, interests and preferences for other PrEP modalities were present. These preferences vary by sociodemographic characteristics. Findings offer insight into PrEP preferences which may inform implementation efforts for this population.

WEPEC262

A community-based ethnography to inform future PrEP engagement and adherence among transgender women sex workers

K.H.A. Footer[1], J. Glick[1], E. Cooney[2], A. Passaniti[3], M. Howes[3], R. Cook[1], S.G. Sherman[1]
[1]Johns Hopkins Bloomberg School of Public Health, Health Behavior and Society, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States

Background: Transgender women sex workers (TSW) face a unique HIV risk context due to intersectional stigma and oppression at interpersonal and structural levels as well as individual and interpersonal risk behaviors. A global meta-analysis of 25 studies estimated HIV prevalence among TSW at 27.3% compared to 14.7% in trans women not engaging in sex work. PrEP represents the next generation of high-impact, biomedical HIV prevention. This study examines the socio-structural context in which TSW conceptualize HIV risk and PrEP acceptability, with the intention of informing PrEP uptake and adherence intervention development.
Methods: The study was conducted in Baltimore City, Maryland, USA between 2017-18 and employed ethnographic and participatory research methods (i.e., observations [n=4], participant photo diaries [n=5], in-depth interviews [n=20] and key informant interview [n=7]) with twenty TSW recruited from an existing cohort (the SAPPHIRE study). Analysis followed an inductive and deductive approach, allowing for the emergence of new themes.
Results: Preliminary analyses indicate multi-level factors influence the PrEP continuum from awareness, interest, access, uptake to adherence. Awareness and uptake were shaped by a sociocultural context in which PrEP is perceived as marketed to MSM and at-risk individuals, with attending stigmas. Though most participants reported accessing a health provider, reports of PrEP street sales within the trans-community point to complexities in healthcare access and utilization. Individual level factors shaping pill adherence include experimental dosing, rectal insertion and concerns around interactions with hormones, highlighting previously unexplored practices around oral PrEP usage and adherence. The complex web of health priorities (e.g., hormone therapy) and structural vulnerabilities including, client violence and drug use provided important insights into barriers and facilitators to a daily PrEP pill.
Conclusions: Ethnographic engagement with TSW lived experiences is key to understanding the complexities of PrEP adherence, as well as barriers and facilitators to uptake. Moving forward, PrEP interventions for TSW need to consider competing priorities and how best to integrate PrEP into trans women's lives. Utilizing existing health regimens (i.e. daily hormones) and existing prescribers, as well as social networks, including peers and community leaders, to promote PrEP uptake and adherence should be considered in future intervention development.

Integrating STI, sexual and reproductive health, HBV and HCV services in HIV prevention programs

WEPEC263

Urgent need to integrate PMTCT service for HIV and hepatitis B: An interim report from a prospective cohort study in rural districts, Zambia

M. Chirwa[1], K. Komada[2], C. Msiska[1]
[1]Chongwe District Health Office, Chongwe, Zambia, [2]National Center for Global Health and Medicine, Bureau of International Medical Cooperation, Tokyo, Japan

Background: HIV, syphilis and hepatitis B virus infection in a pregnant woman poses a serious risk to her infant. While the program for HIV prevention of mother to child transmission (PMTCT) has been expanded in Zambia, the screening for hepatitis B is not conducted enough for clients coming to antenatal clinic and less information is available for current prevalence of hepatitis B especially in rural area.
We launched the prospective cohort study to evaluate operational challenge in option B+ program in rural Zambia but also focused on hepatitis B burden and care for that.
Methods: The prospective cohort study was launched in 11 health facilities in Chongwe district June 2015, where all the HIV positive pregnant women coming to antenatal clinic and diagnosed by HIV rapid test were registered for the study. The screening for Hepatitis B was also conducted by rapid test for HBs antigen. HIV and Hepatitis prevalence among the clients coming to antenatal clinic were estimated using data abstracted from the testing registers in antenatal clinic at each facility. Logistic regression analysis was used to evaluate independent factors associated with HIV-ab and HBs-ag carriers.
Results: Total 2772 pregnant women and 19.2% of their partners were screened for HIV and hepatitis B from June 2015 to May 2016 in the 11 facilities. HIV-ab and HBs-ag prevalence were 9.9% [95%CI:8.7-11.0] and 3.7%[3.0-4.4] in pregnant women and 5.4% [3.5-7.3] and 6.7%[4.5-8.8] in their partners. 4.6% of HIV positive pregnant women were co-infected with hepatitis B.
The elder (>=25) pregnant women were more likely to be infected with HIV (OR:2.30, 95%CI:1.77-3.01) but there was no significant correlation between HIV and HBV status. (OR: 1.14, 95%CI: 0.60-2.20) 87.6 % of pregnant women infected with Hepatitis B were positive only for HBs-ag and not covered by current ART program for HIV.
Conclusions: Hepatitis B burden in rural Zambia including the risk of vertical transmission can't be ignored. To save mothers and children, integrating the PMTCT programs for HIV and Hepatitis B should be enhanced. Further analysis are required to clarify the effective integrated service model as well as feasible options in resource limited settings.

WEPEC264

Are STI testing programmes acceptable and feasible for adolescents in South Africa?

R. Marcus[1,2], K. Gill[1], P. Smith[1], S. Rouhani[1], E. Mendel[1], S. Osman[1], K. Naidoo[1], A. Mendelsohn[1], N. Ngetu[1], M. Tembo[1], N. Ahmed[1], L.-G. Bekker[1]
[1]Desmond Tutu HIV Centre, University of Cape Town, Cape Town, South Africa, [2]Barts Health NHS Trust, London, United Kingdom

Background: Adolescents in South Africa remain at high risk of HIV and sexually transmitted infections (STIs). Despite the epidemiological and biological link between STIs and HIV transmission and acquisition, curable and often asymptomatic *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoeae* (NG) infections remain widely undiagnosed and untreated in the context of syndromic management, the current standard of care.
We conducted a prospective study to assess the acceptability and feasibility of a rapid STI test-and-test service for adolescents in Cape Town.
Methods: Adolescents attending a youth centre clinic were offered a rapid STI test-and-treat service between February and August 2017. Urine testing for CT and NG using a molecular point-of-care test (GeneXpert)

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

was conducted and treatment provided as appropriate. Data was collated on demographics, sexual behaviour, uptake of same-day treatment, service acceptability and prevalence of infections.

Results: We enrolled 255 participants, 209 female and 46 male. Mean age was 19.9 years for females and 19.7 years for males, with mean age at sexual debut reported as 16 and 14.9 years for females and males respectively. Seventy-eight participants (30%) consented to HIV testing, with four testing positive. Seventy-one (34%) females and 9 males (20%) tested positive for chlamydia. Thirty-six (17%) females and 8 (17%) males tested positive for gonorrhoea. 38% (96/255) had either CT/NG overall. Seventy-four (29%) opted for same day results and treatment, 179 (70%) opted to return the following day. Self-reported STI symptoms had a sensitivity of 50% and specificity of 53% for the diagnosis of CT/NG. The majority of participants (89%) reported the service as being highly acceptable.

Conclusions: Curable STIs are highly prevalent in this adolescent population in South Africa. STI screening using near-patient testing was popular amongst adolescents, and acceptability was high. Clinical symptoms were insensitive in diagnosing infection with CT/NG, suggesting a high prevalence of undiagnosed genital tract infection in this population that may increase the risk of HIV and reproductive complications. There is an urgent need for the implementation of accurate and timely diagnostics and treatment of STIs, and for increased efforts to support adolescent HIV testing uptake in the context of sexual and reproductive health services.

WEPEC266

High HIV PrEP adherence is associated with syphilis incidence

C. Bristow[1], M.P. Dube[2], K. Corado[3], E. Ellorin[1], J. Blumenthal[1], S.R. Morris[1], CCTG Team
[1]University of California San Diego, Medicine, La Jolla, United States, [2]University of Southern California, Keck School of Medicine, Los Angeles, United States, [3]Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Los Angeles, United States

Background: High sexually transmitted infection (STI) incidence has been reported among HIV pre-exposure prophylaxis (PrEP) users. We aimed to assess if PrEP adherence was associated with syphilis incidence in a PrEP adherence trial.

Methods: We conducted a randomized clinical trial to assess if text-messaging could be used to increase adherence to PrEP among men who have sex with men. Syphilis testing was conducted every 12 weeks with rapid plasma reagin and confirmed with a treponemal test. A syphilis diagnosis was made by the study clinician. PrEP adherence was measured by intracellular tenofovir diphosphate (TFV-DP) using dried blood spots collected at weeks 12 and 48. "Highly adherent" was considered ≥1246 fmol/punch, consistent with 7 doses per week (near perfect dosing) and "adequate adherence" was ≥719 fmol/punch, consistent with 4 or more doses of TDF in the past week. The incidence-rate ratio (IRR) and 95% confidence intervals (CIs) for syphilis among those adherent as compared with those non-adherent to PrEP by each definition was examined in Poisson regression models.

Results: A total of 381 of 398 participants enrolled in the study were assessed prospectively for syphilis at one or more follow-up visits, with a total of 26 incident syphilis cases occurring over a 2-year study period. The overall incidence rate of syphilis in the study was 5.4 (95% CI: 3.3, 7.5) per 100 person years. The incidence rates stratified by PrEP adherence status are shown in the Table. Among those highly adherent to TFV-DP at week 12 and week 48, the incidence rate of syphilis was over 3 times higher compared to those not highly adherent at week 12 and 48 (IRR week 12: 5.2 (95% CI: 2.0, 13.8); IRR week 48: 3.4 (95% CI: 1.5, 7.9)).

Conclusions: High incidence rates of syphilis among individuals taking PrEP may suggest increased or sustained risk behavior. Highly adherent individuals as measured at week 12 and week 48 were at higher risk for syphilis. Further research is needed to assess change in risk behaviors and risk compensation over time to inform public health efforts and HIV PrEP programs.

TFV-dp Adherence Measure Week	Adherence status	Number of incident cases	Number of people at risk	Number of person years spent at risk	Incidence density per 100 person years (95% CI)	Age adjusted incidence rate ratio
Week 12	Not highly adherent (≤1246 fmol/punch)	5	213	264.6	1.9 (0.2, 3.5)	ref
Week 12	Highly adherent (>1246 fmol/punch)	21	168	216.7	9.7 (5.5, 13.8)	5.2 (2.0, 13.8)
Week 12	Not adequately adherent (≤719 fmol/punch)	1	66	64.0	1.6 (0.0, 4.6)	ref
Week 12	Adequately adherent (>719 fmol/punch)	25	315	417.3	6.0 (3.6, 8.3)	3.9 (0.5, 29.01)
Week 48	Not highly adherent (≤1246 fmol/punch)	8	240	285.7	2.8 (0.9, 4.7)	ref
Week 48	Highly adherent (>1246 fmol/punch)	18	141	195.6	9.2 (5.0, 13.5)	3.4 (1.5, 7.9)
Week 48	Not adequately adherent (≤719 fmol/punch)	3	117	109.7	2.7 (0.0, 5.8)	ref
Week 48	Adequately adherent (>719 fmol/punch)	23	264	371.6	6.2 (3.7, 8.7)	2.3 (0.7, 7.7)

WEPEC267

High rate of unplanned pregnancy despite integration of family planning into HIV care

O.V. Adeniyi[1], A. Ajayi[2], D. Goon[2], C. Carty[3], J. Lambert[4], East London Prospective Study Group
[1]Walter Sisulu University, East London, South Africa, [2]University of Fort Hare, East London, South Africa, [3]Relevance Network, Johannesburg, South Africa, [4]University College, Dublin, Ireland

Background: Family planning was integrated into HIV services with the aim to ensure that all pregnancies are planned and to prevent mother to child transmission of HIV. A good measure of the impact of this integration would be the rate of unplanned pregnancy among women infected with HIV who are pregnant. This paper examined the prevalence and correlates of unplanned pregnancy among HIV infected women attending antenatal care service in three largest hospitals in Eastern Cape Province of South Africa.

Methods: A total of 594 women infected with HIV were recruited. Questionnaires probing whether women desire pregnancy at the time they got pregnant, and demographic characteristics were administered using an interviewer guided approach. To examine correlates of unplanned pregnancy, chi-square statistics and binary logistics regression were employed.

Results: The analysis reveals a high rate of unplanned pregnancy (71%) among women infected with HIV. Unplanned pregnancy was significantly associated younger age, single marital status, newly diagnosed at first presentation, high parity, and previous abortion. Women who reported unplanned pregnancy were more likely to book late and have lower CD4 counts. After adjusting for confounding variables (previous abortion, peri-partum and CD4 count), having one child and five to seven children (AOR=2.2; CI=1.3-3.1), age less 21 years (AOR=3.3; CI=1.1-9.8), presenting for antenatal care at more than 27 weeks (AOR=2.7; CI=1.5-5.0), not married (AOR=4.3; CI=2.7-6.8) and negative and unknown HIV status at first visit (AOR=3.0; CI=1.6-5.8) were significant predictors of unplanned pregnancy.

Conclusions: Unplanned pregnancy is high among women infected with HIV despite the integration of family planning services into HIV care and PMTCT. HIV infected women with unplanned pregnancy are more likely to be young, presented late for antenatal care services, not married, negative or with unknown status at first antenatal care visit, and carrying their first pregnancy or with five to seven children. High rate of unplanned pregnancy has huge implication for ending the AIDS epidemic, especially elimination of mother to child transmission of HIV in South Africa. Integration of HIV and reproductive health services needs to intensify in order to maximise the benefits of services' integration.

WEPEC268

Increasing male partner involvement in antenatal services for elimination of mother-to-child transmission of HIV

A. Watsemba[1], C. Derrick Opio[2], R. Kyapa[3], B. Wandera[2], J. Hayuni[1], A. Mitchell Le Few[4], R. M Flueckiger[4], M. Lopez[5], E. Tanga[2]
[1]RTI International, USAID/Uganda HIV and Health Initiatives in Workplaces Activity, Kampala, Uganda, [2]World Vision Uganda, USAID/ Uganda HIV and Health Initiatives in Workplaces Activity, Kampala, Uganda, [3]Uganda Police Health department, Kampala, Uganda, [4]RTI International, Research Triangle Park, North Carolina, United States, [5]World Vision, Inc., Federal Way, WA, United States

Background: Previous studies demonstrate a positive association between attendance by male partners at antenatal care (ANC) visits and improved maternal health outcomes. Hence, the elimination of mother-to-child transmission of HIV program in Uganda emphasizes male partner involvement in ANC. However, male partner attendance in Uganda remains low (10.3%). To increase male partner ANC attendance, a pilot was conducted in Mbale Police Health Center III, where a male-partner-package aimed at engaging men in the ANC process was distributed. This package includes: 1) education about pregnancy and nutrition with messages for both men and women, 2) couples given priority in accessing ANC services, 3) medical check-ups for male partners, and 4) male partner attendance at the examination of the pregnant partner. The objective of this study was to determine if the male-partner-packages increased male partner ANC attendance.
Methods: The male-partner-package was distributed to women who sought ANC services at Mbale Police Health Center III from June to October 2017. Male partner attendance in this intervention group was compared with male partner attendance in this same setting, prior to the implementation, from June to October 2016. A multivariate logistic regression model was fit to male partner participation, including receipt of the male-partner-package and additional covariates. Variables were removed through a backwards stepwise approach until all indicators were significant at the 5% level.
Results: The estimated regression relationship between male partner ANC attendance and receipt of the male-partner-packages was significant. The estimated increase of partner attendance associated with the male-partner-package receipt was 24% (4.9% vs. 29.3%, p=0.000). Further, increased male partner attendance was significantly associated with the fourth and fifth ANC visits (27%), increased gestation age (18%), and woman's HIV positive status (38%).
Conclusions: The study found evidence of association between male partner ANC attendance and receipt of the male-partner-package, along with additional covariates. These results suggest increased awareness of ANC visit attendance benefits among men may contribute to an increase in male partner ANC involvement.

WEPEC269

Innovative prevention using social media

L. Piel, C. Winkelmann
German Federal Centre for Health Education, Prevention of HIV/AIDS and other Sexually Transmitted Infections (STI), Cologne, Germany

Background: »The Infectastic STIs«
In addition to the real world, virtual worlds in the form of social media are increasingly becoming an avenue of communication and a place for discussion of messages about health. LIEBESLEBEN has created a brave and lively element in prevention work with its 'The Infectastic STIs': five humorous characters, each of whom represents a different sexually transmitted infection (STI), conquer the social internet in amusing clips. A recent study has shown that in Germany the general public is well informed about HIV but not to the same extent about other STI, their transmission paths and symptoms (BZgA 2016).
Description: Chlam Chlamydie, Trippo Tripper (gonorrhoea), Feig Feigwarze (genital warts), Hepp Hepatitis and Philis Syphilis - they all convey the LIEBESLEBEN messages with a lot of humour, emotional empathy and striking looks; their primary target group is young people and young adults who are active on social media. Their brief stories about infection and protection, failed dates and selfies connect them to their target group and also make them a helpful companion to prevention work taking place locally. The videos, less than one minute in length, were integrated in a social media ad-campaign on Facebook for 8 weeks in late 2017. The goal was to reach as many people as possible between the ages of 18 and 40, including people with a low level of education, to create a basic awareness about STI in the target group.
Lessons learned: The campaign achieved a total reach of 9 million contacts and a total of nearly 4.5 million clicks, likes, shares and comments (engagement) on Facebook. Many people commented and linked their friends, so a snowball effect took place. The campaign analysis from Facebook shows that those videos were successful that provided clear contents about condom-use and STI-symptoms.
Conclusions/Next steps: For the second series in 2018 the videos will get more detailed in their content and try to reach more specific target groups, like women up to 25, to inform them about the costless chlamydia screening programme in Germany. This will be an additional goal besides getting more noise floor.

[The Infectastic STIs]

WEPEC270

The HIV/AIDS response succeeds when integrated in the reproductive maternal newborn child and adolescent health platform: The Kingdom of Swaziland's Experience

B.R. Dlamini[1], N. Dlamini[2], B. Nhlabatsi[3], M. Thwala-Tembe[1], S. Myeni[4], L. Malaza[5]
[1]UNFPA, SRH, HIV & Youth, Mbabane, Swaziland, [2]Minstry of Health, M & E, Mbabane, Swaziland, [3]Ministry of Health, SRH, Mbabane, Swaziland, [4]MoH, M & E, Mbabane, Swaziland, [5]MoH, SRH, Mbabane, Swaziland

Background: The need to link HIV/AIDS and Sexual Reproductive Health (SRH) response is important due to the interconnectedness of HIV and SRH. Swaziland is implementing the Primary Health Care strategy which involves integration of a number of health services. However,

in the early years of the HIV/AIDS epidemic, its programming and funding was prioritized in a vertical manner due to the scale and scare of the epidemic. Over the years, the country recognized that addressing HIV/AIDS and Sexual Reproductive Health and Rights (SRHR) services as totally separate entities is counterproductive in achieving targets for neither HIV nor SRHR. This assessment was aimed at documenting the extent of SRH and HIV integration.
Methods: A mixed-methods approach was used to document the extent of SRHR and HIV integration. The quantitative approach included secondary data analysis using national data and reports on SRHR and HIV integration indicators between 2009 and 2016. The qualitative approach included key informant interviews. Trend analysis regression of proportions across was used to test for true trends in observed changes over the years of the integration. Different datasets were used as proxies in the estimation of the extent of the integration along the linkages project indicators whenever applicable and data trends were available.
Results: RMNCAH and HIV integration is supported by enabling policy environment across all levels. In 2016, 94% (28978 clients) accessed HIV services and 95% of those testing HIV positive were initiated within the RMNCAH platform, while 92% of clients attending FP services eligible for HIV testing were tested and 75% of those tested HIV positive linked to care and treatment. An observed increasing trend of HIV testing within TB clinics from 66% in 2012 to 92% in 2016. A significant p-value (pr>chi2=< 0.0001) indicating HIV testing in STI clinics.
Conclusions: The bi-directional integration of RMNCAH and HIV provides a concrete ground for reaching the ambitious UNAIDS targets (90-90-90). This integration is not only logic to the health delivery system; it's also beneficial to the clients. Having one strategy, one coordinating structure and one M&E system may significantly lead to attainment of the UN-SDGs.

WEPEC271

Perspective of young people living with HIV in the Federal Capital Territory (FCT) Nigeria on their sexual reproductive health needs

A. Ogunrombi[1], I. Takuma[2]
[1]YouthRISE Nigeria, Policy/Programs, Abuja, Nigeria, [2]APYIN Nigeria, Programs, Abuja, Nigeria

Background: Young people age 15-30 years constitute 60 percent of people living with HIV (PLHIV) in Nigeria. The HIV epidemic constitutes a public health challenge and it has been established that effective response to the epidemic also require meeting the sexual and reproductive health (SRH) needs of PLHIV. However, not much is known about the SRH needs of young PLHIV in Nigeria and whether available HIV services are meeting these needs.
Methods: The study aimed to explore the perception of young PLHIV in the Federal Capital Territory (FCT), Nigeria on their SRH needs and whether these needs are being met by available HIIV services. The study guided by interpretivist epistemology used qualitative approach for data generation and through purposive sampling, 30 young PLHIV who are of ages 18-26 years were recruited from the association of young people living with HIV in the FCT and interviewed individually. Collected data was then analyzed using thematic content analysis.
Results: Five themes emerged and findings show young PLHIV in the FCT has many unmet SRH need which include forming sexual relationships, fertility intentions, preventing unwanted pregnancy, managing sexually transmitted infections and abortion-related issues. Also evident is how economic burden of accessing free ART services contributes to poor treatment adherence. YPHLIV are desirous of youth friendly health services that encourage their participation in program design and delivery, ensure confidentiality and integrate socio-economic support into healthcare.
Conclusions: Addressing HIV epidemic in Nigeria will require meeting the SRH need of YPLHIV which could be done through SRH/HIV service integration. However, meeting the need of YPLHIV is not limited to scaling up of interventions but also how these services are delivered in a way that is acceptable to the recipients.

WEPEC272

Integration of sexual and reproductive health services into HIV testing service: A unique delivery model for optimising the uptake of HTS among female sex workers in Nigeria

G. Ekon[1], E. Godwin[2], P. Umoh[2], A. Kalaiwo[3], T. Jaiyebo[4], A. Yusuf[2], R. Abang[5]
[1]Initiative for Young Women's Health and Development, Monitoring and Evaluation, Calabar Municipal, Nigeria, [2]Heartland Alliance International Nigeria, Abuja, Nigeria, [3]United States Agency for International Development, Abuja, Nigeria, [4]Heartland Alliance International Nigeria, Programs, Abuja, Nigeria, [5]Heartland Alliance International Nigeria, Calabar, Nigeria

Background: Female Sex Workers (FSWs) in Nigeria continue to be exceptionally vulnerable to acquiring HIV infection with a prevalence rate of 19.4% and 8.6% for Brothel Based and Non-Brothel Based FSWs respectively. In Cross River State, HIV Testing Services (HTS) has been advanced as a key prevention strategy for early diagnosis of HIV to reduce the risks of transmission and promote early treatment. However, HTS is not optimised among FSWs.
This study looks at integration of sexual and reproductive health services as a means of optimising HTS uptake.
Description: Initiative for Young Women's Health and Development (IY-WHAD) was sub granted by Heartland Alliance International Nigeria to implement the Integrated MARPs HIV Intervention Prevention Program (IMHIPP) for FSWs in Cross River, Nigeria. In May 2017, IY-WHAD began an innovative idea to integrate Sexual Reproductive Health services (Sexual reproductive health education, menstrual hygiene management, referrals for STIs syndromic management and referrals for Family planning services) into HTS outreaches. Before this, only HIV prevention services including HTS was provided to FSWs during outreaches in Brothels and hotspots. A comparative analysis of data reported in the period before integration and the period after integration of SRH services was done.
Lessons learned: There was an increase in participation of FSWs in HTS outreaches as the number of FSWs who received HTS doubled from an average of 375 monthly before SRH integration to 800 monthly after integration. Over 80% of the Female Sex Workers who came for other Sexual Reproductive Health services accessed HIV testing services and received their test result.
Conclusions/Next steps: Integrating Sexual Reproductive Health services into HIV Testing Services can lead to scale up in the number of Female Sex Workers who take up HIV Testing Services. Female Sex Workers who come for sexual reproductive health education, sanitary pads/tampons, referrals for Sexually Transmitted Infection syndromic management or referrals to access family planning services; present an opportunity for the Counselor Testers to discuss HIV Counseling and Testing as a tool to attain the first 90% of the 90:90:90 hence increasing utilization of HIV Testing Services among Female Sex Workers in Nigeria.

Developing tailored and comprehensive services for specific key and vulnerable populations

WEPEC273

Gender affirmation and healthcare empowerment: Two intervention-amenable targets to enhance viral suppression among transgender women of color living with HIV in the United States

J.M. Sevelius[1], D. Chakravarty[1], T. Neilands[1], J. Keatley[2], G. Rebchook[1], HRSA SPNS Transgender Women of Color Study Group
[1]*University of California, Medicine, San Francisco, United States,* [2]*University of California, Family and Community Medicine, San Francisco, United States*

Background: Globally, transgender women of color are disproportionately impacted by HIV and are less likely than other groups to be virally suppressed. Transgender women of color also experience higher rates of transphobic discrimination (TD) than other transgender subgroups. The association between TD and poor health outcomes, such as unsuppressed viral load (VL), is documented but little is known about potential targets for intervention on this association. We sought evidence for the Gender Affirmation (GA) Model of transgender health in these analyses.

Methods: A demonstration project to evaluate interventions targeting enhanced engagement and retention in HIV care recruited 858 HIV-positive transgender women of color across four US urban centers between December 2013 and August 2016. A self-administered survey measured HIV care engagement, TD (in healthcare, employment, housing), gender affirmation (GA) (transgender-competent care, need for and satisfaction with GA) and healthcare empowerment (HCE). We used structural equation modeling (SEM) to test the direct association between TD (latent) and viral suppression (VS) as well as their indirect association via GA (latent) and HCE in a serial mediation model. Inferences were based on the bias-corrected bootstrap (5000 samples).

Results: Participants' mean age was 37 years (SD=10.8), 49% were Latina, 42% were Black, 57% had at least a grade12 education and 36% were virally suppressed. Global fit statistics demonstrated good model fit (Hu & Bentler, 1999): CFI=0.96, RMSEA=0.06, WRMR=1.26. The SEM provided statistically significant direct pathways between TD and GA (B=-0.18, p< 0.001), GA and HCE (B=1.09, p=0.001), and HCE and VS (B=0.18, p=0.001). The significant indirect pathways were from TD to VS via GA and HCE (B=-0.04, p=0.036, 95% CI:-0.08,-0.01) and GA to VS via HCE (B=0.19, p=0.028, 95% CI:0.08,0.44). The direct effect from TD to VS was not significant (B=-0.04, p=0.58).

Conclusions: GA and HCE significantly and fully mediated the total effect of TD on VS; however, TD and GA did not demonstrate significant direct effects on VS. These data provide empirical evidence for the Gender Affirmation Model of transgender health. Interventions that boost gender affirmation and healthcare empowerment may improve rates of viral suppression among transgender women of color living with HIV.

WEPEC274

Perceptions do matter: The impact of perceived risk of HIV acquisition on HIV testing among gay male couples

D. Chakravarty[1,2], T. Neilands[2], L. Darbes[3], C. Hoff[1]
[1]*San Francisco State University, Center for Research and Education on Gender and Sexuality, San Francisco, United States,* [2]*University of California, Center for AIDS Prevention Studies, Department of Medicine, San Francisco, United States,* [3]*University of Michigan, Department of Health Behavior and Biological Sciences, Center for Sexuality and Health Disparities, School of Nursing, Ann Arbor, United States*

Background: Regular HIV testing is a critical component of a multimodal HIV prevention strategy. In the US, the CDC recommends that sexually active gay men test every 3 to 6 months. However, research shows that HIV-negative men in gay couples do not test regularly even in the presence of sexual risk. We sought to test if perceived risk of HIV acquisition (PRH) plays a role in this.

Methods: We recruited 441 gay couples (336 concordant negative, 105 serodiscordant) from the San Francisco Bay Area between February, 2012 and February, 2015 to complete computerized self-administered surveys every six months (baseline+3 follow-ups) regarding their HIV testing behavior, PRH (using an 8-item pre-validated instrument; sample: 'I feel vulnerable to HIV infection'), sexual behavior and relationship characteristics. We used generalized estimating equations with an exchangeable correlation structure, with individuals clustered within couples, to test the association of testing within past three months (TEST3M) with PRH. The model controlled for couple-serostatus, sexual risk (defined as condomless anal sex with a serodiscordant/unknown serostatus partner in the previous 90 days (CAS-DISC)), sexual agreement type and relationship length. Testing within past six months (TEST6M) and twelve months (TEST12M) were also separately modeled.

Results: The sample consisted of 48.3% interracial and 41.5% White couples. At baseline, the median relationship length was 5 years; median age was 41.7 years. CAS-DISC was reported by 14% to 16% of the HIV-negative men across visits and TEST3M by 24% to 26%. Controlling for other variables, a one standard deviation increase in PRH produced a 1.38 times increase in the odds of TEST3M (Table 1). Results were similar for outcomes TEST6M (aOR=1.39, p< 0.01, 95%CI:1.25,1.55) and TEST12M (aOR=1.42, p< 0.01, 95%CI:1.27,1.59) (not in table).

Explanatory Variable	Adjusted Odds Ratio (aOR)	95% Confidence Limits of aOR	p-value
Perceived Risk of HIV (Standardized Score)	1.38	(1.22, 1.57)	<0.01
CAS-DISC (Sexual Risk)	1.78	(1.32, 2.4)	<0.01
Agreement Type - Monogamous	0.60	(0.45, 0.79)	<0.01
Relationship length (in years)	0.98	(0.956, 0.996)	0.02
Couple Serostatus - HIV-negative	0.99	(0.7, 1.39)	0.95
Time	1.02	(0.94, 1.11)	0.60

[Table 1: Output from Model Predicting Presence of HIV Test in Previous 3 Months]

Conclusions: Among HIV-negative men in gay couples, we found empirical evidence that perception of being at greater risk for HIV is associated with greater odds of testing. Since perceptions are only as accurate as the knowledge they are based upon, it is imperative that gay couples are provided with the skills to accurately assess their risk for HIV and test with appropriate regularity. Prevention programs that equip couples with these skills are greatly needed.

WEPEC275

Project Shikamana: Positive effects of a phase II trial of community empowerment-based combination prevention to respond to HIV among female sex workers in Iringa, Tanzania

D. Kerrigan[1,2], N. Galai[2], S. Beckham[2], A. Mwampashi[3], C. Shembilu[4], D. Gitagno[5], A. Mantsios[2], A. Leddy[6], W. Davis[1], S. Aboud[3], S. Likindikoki[3], J. Mbwambo[3]
[1]*American University, Washington, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, United States,* [3]*Muhimbili University, Dar es Salaam, United Republic of Tanzania,* [4]*Johns Hopkins Bloomberg School of Public Health, Iringa, United Republic of Tanzania,* [5]*Muhimbili University, Iringa, United Republic of Tanzania,* [6]*Johns Hopkins Bloomberg School of Public Health, Baltimore, United Republic of Tanzania*

Background: Community empowerment approaches have been effective in responding to HIV among female sex workers (FSW) in South Asia and Latin America. Few rigorous evaluations of these approaches have been evaluated in sub-Saharan Africa (SSA). We conducted a Phase II randomized controlled trial of a community-based combination HIV prevention model among FSW in two matched communities in Iringa, Tanzania.

Methods: A longitudinal cohort of 496 venue-based FSW (203 HIV+ and 293 HIV-) were surveyed and screened for HIV and viral load at baseline (2015-6) and 18-month follow-up (2017-8). The intervention sought to address structural constraints to optimal HIV outcomes by promoting social cohesion to address stigma, discrimination, violence and financial insecurity through community-led drop-in-center workshops and mo-

bilization activities. Additional intervention elements included: venue-based peer education, condom distribution and HIV testing; peer service navigation and SMS ART adherence reminders, and sensitivity trainings for providers. Intervention effects on HIV incidence and care continuum outcomes, including viral suppression, were estimated with logistic models adjusting for venue clustering and robust Poisson regression.
Results: Baseline HIV prevalence was 40.9%. At follow-up, HIV incidence was 55% lower in the intervention community (6/120 or 5.0%) compared to the control community (10/96 or 10.4%) (OR=0.45; 95% CI: 0.18, 1.14; p-value=0.092). Inconsistent condom use with clients at follow-up was significantly associated with a higher odds of incident HIV infection (AOR=2.92 95% CI: 1.02, 8.34; p-value=0.046). Whereas, gender-based violence at baseline was associated with an increased odds of incident HIV infection (AOR=2.97; 95% CI: 1.24, 7.11; p-value=0.015). There were significant differences across study arms in engagement in HIV care (RR=1.44, p=0.002) and treatment initiation (RR=1.22, p=0.029). A positive trend was observed in viral suppression below 400 copies/ml (50.5% in intervention vs. 47.4% in control, RR=1.07, NS) with 34.3% vs 28.4% respectively having sustained viral suppression (RR=1.21, NS). Binge drinking was associated with lower odds of being virally suppressed (AOR=0.54; 95% CI: 0.30, 0.97; p-value=0.039).
Conclusions: Phase II trial findings indicate positive effects of a tailored community empowerment-based combination prevention on incident HIV prevention and treatment outcomes among FSW in this SSA context, justifying the conduct of a Phase III trial.

WEPEC276

Co-dispensation of low-barrier methadone maintenance therapy (MMT) and antiretroviral therapy (ART) linked to improved ART adherence among people living with HIV who use illicit drugs in a Canadian setting

N.A. Mohd Salleh[1,2], L. Richardson[1,3], J. Shoveller[4], H. Dong[1], N. Fairbairn[1], R. Barrios[5], E. Wood[1], M.-J. Milloy[1,6]
[1]British Columbia Centre on Substance Use, Vancouver, Canada, [2]University of British Columbia, Interdisciplinary Studies Graduate Program, Vancouver, Canada, [3]University of British Columbia, Department of Sociology, Vancouver, Canada, [4]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [5]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [6]University of British Columbia, Department of Medicine, Vancouver, Canada

Background: Methadone maintenance therapy (MMT) has been shown to promote adherence to antiretroviral therapy (ART) among HIV-positive individuals who use illicit drugs. While existing integrated models have emphasized the role of primary HIV care providers and addiction specialists, empirical data outlining the relationship between integrated co-dispensation of methadone and ART and clinical outcomes is limited. To fill this gap, this study sought to examine the relationship between MMT-ART co-dispensation and achieving optimal adherence to ART among ART-experienced people living with HIV who use illicit drugs (PWUD) in Vancouver, Canada, a setting with universal no-cost healthcare access, community-based low-barrier methadone delivery and a community-wide seek, test and treat effort.
Methods: We used data from the ACCESS study, a long-running community-recruited cohort of HIV-positive PWUD linked to comprehensive HIV clinical records, including ART dispensation. Dispensing locations for methadone and ART were reported by participants and extracted from HIV clinical records, respectively. The longitudinal relationship between methadone and ART co-dispensation and the odds of ≥95% ART adherence was analyzed using multivariable generalized linear modeling. As a sensitivity analysis, we conducted a marginal structural model with inverse probability of treatment weights, a strategy used to produce estimates of causal effects from observational data.
Results: This study included data from 379 ART-exposed participants who completed ≥ 1 interview between June 2012 to May 2015. At baseline, 222 (58.6%) achieved ≥95% adherence at some point during the follow-up period and 96 (25%) reported MMT-ART co-dispensation. In the final multivariable model, MMT-ART co-dispensation was associated with greater odds of achieving ≥95% adherence (Adjusted Odds Ratio [AOR] = 1.70, 95% Confidence Interval [95% CI]: 1.25 - 2.31). A marginal structural model estimated a 1.66 (95% CI: 1.11 - 2.26) greater odds of ≥95 adherence among participants reported MMT-ART co-dispensation compared to those who reported non-co-dispensation.
Conclusions: We found that the likelihood of achieving optimal adherence was higher among participants whose MMT and ART medications were dispensed at the same facility. Our findings highlight the need to consider the role of integrated treatment delivery in planning and improving services for HIV-positive individuals who use drugs to optimize the benefits of MMT and ART.

WEPEC277

Service delivery barriers to accessing HIV-related services for key populations in Southern Ghana

S. Ayisi Addo[1], M. Abdulai[1], A.N. Baddoo[1], M.G. Chandi[2], F. Frimpong[1], E. Kenu[3]
[1]Ghana Health Service, National AIDS/STI Control Programme Accra, Accra, Ghana, [2]University of Ghana, School of Public Health, Accra, Ghana, [3]University of Ghana,School of Public Health, Department of Epidemiology and Disease Control, Accra, Ghana

Background: Structural factors contribute to disproportionate rates of HIV infection among Men who have sex with men (MSM) and female sex workers (FSW) otherwise known as key populations. However, access to HIV-related services remains a challenge in some settings. To achieve global agenda on reducing the burden of HIV by 2030, these barriers need to be addressed to increase access of KPs to health care. This study assessed the service delivery barrier to HIV service in Kumasi and Accra in Ghana.
Methods: We conducted a cross sectional mixed quantitative and qualitative study. Random sampling technique was used to select 80 Ghana Health Service staff engaged in HIV control services in six health facilities Kumasi and Accra and interviewed using a structured questionnaire. In addition, eight FGD (N=198) and 90 in-depth interviews were conducted among various stakeholder including self-identifying MSM and FSW. STATA 13 an NVivo 11 was used to analyse the quantitative and qualitative data respectively.
Results: Lack of confidentiality and privacy, stigmatization and poor attitude of health workers were identified as important consideration in use of health facility by KPs. About 52 (65%) of the respondents strongly agreed that their facility provided enough confidentiality. Sixty-seven (83.7%) and 61 (76.3%) of the respondents believed their health facilities did not have facilities available to specifically address the needs of FSW and MSM. Training on ways to reduce stigma to FSW and MSM was low as only 25 (31.3%) had received training in this direction. Poor service provider attitudes and poor service delivery such as long waiting times, poor logistics management (shortage of essential drugs and lack of basic equipment) and dispersed or non-available KP services deter KPs from accessing and staying consistently in HIV care.
Conclusions: Service delivery barriers for meeting the specific needs of KPs exist in health facilities in Ghana. One stop service outlets are essential for KPs related HIV services. Health facilities must improve their services to meet the needs of KPs in order to increase the utilization by KPs.

WEPEC278

Risk behavior and low HIV testing awareness among Roma (Gypsy) adolescents and young adult men who have sex with men (MSM) in Sofia, Bulgaria

J. Kelly[1], Y. Amirkhanian[2], S. Vassileva[3], E. Kabakchieva[3], T. Varleva[4]
[1]Medical College of Wisconsin, Psychiatry and Behavioral Medicine, Milwaukee, United States, [2]Medical College of Wisconsin, Department of Psychiatry and Behavioral Medicine, Milwaukee, United States, [3]Health and Social Development Foundation, Sofia, Bulgaria, [4]Bulgaria Ministry of Health, Sofia, Bulgaria

Background: Roma (Gypsies) are the largest and most marginalized ethnic minority group in Europe, and Roma communities in most of Eastern Europe are geographically segregated and characterized by pervasive poverty, widespread social health problems, educational disadvantage,

and poor living conditions. Almost no research has examined the social circumstances, risk, and HIV testing awareness and attitudes of adolescent and young adult Roma MSM. This study employed qualitative methods to identify HIV prevention needs of young Roma MSM.

Methods: Participants were 27 young MSM ages 16 to 24 (mean age=19.6) living in a large urban Roma settlement in Sofia, Bulgaria, purposively selected to maximize diversity in backgrounds. Participants were located by outreach staff familiar with same-sex neighborhood meeting venues and by snowball recruitment. Participants completed in-depth interviews following a topic guide that elicited information on behavior, sexual relationships, and HIV testing and treatment views. Interviews were transcribed verbatim and analyzed for emergent themes in areas of interest.

Results: Although all participants reported sex with other men, most self-identified as heterosexual, had female partners, or were married to females. Approximately half of participants said they had sex with other young men for pleasure, and all reported commercial sex with older men. Transactional sex contacts were made in cruising areas or online, and clients were usually older non-Roma men. Although participants were aware of AIDS, misconceptions were prevalent, most believed the disease cannot be treated, and few felt personal risk because they did not consider themselves as gay. Most participants had never been tested, and stigma was a barrier to disclosing same-sex practices even to health care providers because admissions would create shame and embarrassment.

Conclusions: Few HIV prevention efforts, including HIV VCT with linkage of infected persons to medical care, have been undertaken with adolescent and young adult Roma MSM, even though Roma are Europe's largest ethnic minority population and enabling factors for high HIV transmission are present in many Roma communities. Outreach testing and care linkage programs are needed in Roma communities. Because of high stigma and infrequent gay self-identification, testing efforts should universalize the importance of testing and be tailored to Roma cultural circumstances.

WEPEC279

Barriers and facilitators of adherence to HIV pre-exposure prophylaxis among young men and transgender women of color who have sex with men

S. Wood[1], R. Gross[2], J. Shea[3], J. Franklin[3], D. Petsis[1], L. Lalley-Chareczko[4], H. Koenig[3], N. Dowshen[1]
[1]Children's Hospital of Philadelphia, Division of Adolescent Medicine, Philadelphia, United States, [2]University of Pennsylvania Perelman School of Medicine, Infectious Diseases, Philadelphia, United States, [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, United States, [4]Philadelphia FIGHT, Philadelphia, United States

Background: Young men and transgender women who have sex with men (YMSM), particularly those of color, are disproportionally infected with HIV; however, their adherence to pre-exposure prophylaxis (PrEP) in clinical trials has been suboptimal. Our primary aim was to discover barriers to and facilitators of PrEP adherence in YMSM of color.

Methods: This qualitative study enrolled HIV-negative YMSM of color prescribed daily oral tenofovir-emtricitabine PrEP for ≥ three months. Participants were recruited from Philadelphia-area clinics, social media, and mobile dating applications. Adherence was measured via urine tenofovir (TFV) concentration at the study visit and proportion of days covered (PDC) by pharmacy refills over the prior three months. Protective short-term adherence was urine TFV concentration >1000 ng/ml per prior studies. Protective sustained adherence was PDC≥57% (four doses/week). Participants completed individual, semi-structured interviews regarding barriers and facilitators to PrEP adherence. De-identified transcripts were double-coded and analyzed using grounded theory technique to identify key themes.

Results: Participants (n=25) were 60% African-American, 8% Asian and 28% multiracial; and 8% were Latino/a. Median age was 22 years (range 18-24), and 12% were transgender women. Eighteen (75%) participants had adequate short-term and n=17 (68%) had adequate sustained adherence. Nearly all participants (96%) endorsed at least one barrier to adherence. Reported barriers included perceived and enacted stigma; feared and attributed side effects; low perceived vulnerability to HIV; health systems barriers such as insurance and pharmacy access; and competing life stressors such as school, family and employment-related responsibilities. Facilitators of adherence included social support from partners, friends and healthcare providers; a personal commitment to wellness; heightened perception of HIV risk; health systems factors including supportive clinic environments and low or no-cost PrEP; and reminder systems such as mhealth applications, cell phone alarms, and pill cases.

Conclusions: Participants highlighted a number of themes to target in future PrEP adherence research such as stigma reduction, enhancing social support, and promoting life skills to improve adherence. Next steps should include robust quantitative studies to further explore which components of these themes are most salient, prevalent and modifiable, in order to develop interventions with maximum impact on the population.

WEPEC280

Who are the male sexual partners of adolescent girls and young women? Comparative analysis of population data in three settings prior to DREAMS roll-out

A.M. Doyle[1], S. Floyd[1], K. Baisley[1,2], B. Orindi[3,4], D. Kwaro[5], N. Mthiyane[2], S. Muuo[3], M. Shahmanesh[2,6], A. Ziraba[3], I. Birdthistle[7]
[1]London School of Hygiene & Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom, [2]African Health Research Institute, uMkhanyakude, South Africa, [3]African Population and Health Research Centre, Nairobi, Kenya, [4]Katholieke Universiteit Leuven, Leuven, Belgium, [5]Kenya Medical Research Institute, Kisumu, Kenya, [6]University College London, London, United Kingdom, [7]London School of Hygiene & Tropical Medicine, Population Health, London, United Kingdom

Background: The DREAMS (Determined, Resilient, Empowered, AIDS-free, Mentored, and Safe women) Partnership aims to reduce HIV incidence among adolescent girls and young women (AGYW, 15-24y) with a core package of evidence-based interventions. Some interventions, including voluntary HIV counselling and testing and circumcision, are targeted at the male sexual partners of AGYW. A priority of DREAMS is to characterise male partners of AGYW for effective targeting.

Methods: Using population-based data from three DREAMS impact evaluation settings in Gem, rural Kenya (2014/15); Nairobi, urban slums Kenya (2010); and uMkhanyakude, rural South Africa (2015), we describe the demographic characteristics and sexual behaviour of male partners reported by AGYW, and the characteristics of males who report sexual activity with AGYW.

Results: In all three settings, >90% of male partners in the past year reported by AGYW were aged < 35 years. In uMkhanyakude and Nairobi, median ages of spousal and non-spousal partners reported by AGYW were 29 and 23 years, and 21 and 20 years, respectively. In all settings, most males reporting an AGYW partner had never been married (63%-99%) and many were in school (32%-44%). Most male partners of AGYW reported only 1 AGYW partner in the past year; but in Gem and Nairobi 25%-29% reported ≥2 (AGYW or older female) partners. Concurrent partners were reported by 16% of male partners in Gem and 2-4% of partners in uMkhanyakude (data not available for Nairobi). Two in three male partners of AGYW in Gem reported testing for HIV in the past 6 months and less than half of male partners in uMkhanyakude reported testing for HIV in the past year. Almost all (96%) partners in Nairobi were circumcised medically, compared to 45% in Gem and 43% in uMkhanyakude.

Conclusions: With almost all AGYW's sexual partners aged 15-34 years, this is an appropriate target group for DREAMS interventions. Encouraging men in this age group to adopt safer sexual behaviours, and uptake prevention and treatment services is crucial in the effort to reduce HIV among both AGYW and young men. Interventions in schools and work places may be an efficient way to target some male partners.

WEPEC281

Identifying more HIV positive males through Homebased index case HIV testing as compared to facility based HIV testing: Case of an FHI 360-Zimbabwe Project

T. Tafuma[1], N. Mahachi[1], K. Webb[2], P. Mawora[1], T. Moga[1], A. Muchedzi[1], T. Zulu[1], T. Nyagura[3], D. Harbick[1], V. Chitiyo[2]
[1]FHI 360, Technical, Harare, Zimbabwe, [2]Organization for Public Health Interventions & Development, Technical, Harare, Zimbabwe, [3]United States Agency for International Development, Technical, Harare, Zimbabwe

Background: The recently released Zimbabwe Population Based HIV Impact Assessment, reported 72.9% of people living with HIV aged 15 to 64 years know their HIV status in Zimbabwe (76.1% females and 68.2% males). Testing remains the greatest challenge for Zimbabwe to attain the 90-90-90 UNAIDS targets especially in terms of reaching males. FHI360 Zimbabwe implements a five-year USAID funded mechanism with the main activity being homebased index case HIV testing and counselling (HIHTC). FHI360 collaborates with facility based partners to get the index cases. Reported here are the findings of a targeted assessment on the gender distribution of newly diagnosed HIV positive clients from two testing modalities.
Methods: A retrospective assessment of HIV testing registers for clients who were tested positive between September 2016 - December 2016 in Manicaland province and December 2016 to March 2017 in Midlands province of Zimbabwe, at 13 purposively selected health facilities in 6 Districts was done. Facility registers were reviewed to determine the sex, age and testing modality of newly diagnosed HIV positive clients. Data analysis was conducted using descriptive statistics in Microsoft Excel and STATA. A chi-square test was used to test the difference in the proportion of men reached by each modality at 5% significance level.
Results: Overall, a total of 2 297 were newly diagnosed HIV positive clients over a four-month assessment period through facility and HIHTC. Age disaggregation showed that 101 (4%) were children 0-14 years of age, 2 183 (95%) were adults 15 years and above and the age for 13 (1%) individuals was not recorded. More than half of the newly diagnosed clients were females, 57% (n=1 326), 42% (n=955) were male and 1% (n=16) the gender was not recorded. A further analysis of the data show that HIHTC model diagnosed a significantly greater proportion of men (47%) compared to health facility based testing model (39%); (p=0.003), Table 1.
Conclusions: Facility testing contributes more than half of the new diagnosis; however, HIHTC identified a greater proportion of the males. Strengthening collaboration between homebased index case HIV testing and facility based testing improves the reach to men with HIV testing services.

Place of testing/Testing Modality	Female	Male	Total	% Males Diagnosed
Health Facility	900	578	1,491	39%
Home-based Index Case Testing	426	377	806	47%
Total	1,326	955	2,297	42%

[Table 1: Gender Distribution of the newly diagnosed HIV positive clients by IV testing model]

WEPEC282

Comparing behavioural and health seeking outcomes among young and older female sex workers using the polling booth survey 2017, Kenya

S. Malaba[1,2,3], H. Musyoki[3], P. Bhattacharjee[2], J. Kioko[1,3], S. Kaosa[1,3], J. Musimbi[1,3], S. Isac[4], P. Javalkar[4]
[1]Partners for Health and Development in Africa, Key Populations Technical Support Unit, Nairobi, Kenya, [2]University of Manitoba, Centre for Global Public Health, Winnipeg, Canada, [3]National AIDS and STI Control Program, Nairobi, Kenya, [4]Karnataka Health Promotion Trust, Bangalore, India

Background: The Kenya Key Population Programme conducts annual outcome surveys using a Polling Booth Survey (PBS) methodology. The 2017 PBS included a sample of young key populations (YKP) to generate evidence on their risk and vulnerability and advocate for prioritization of YKP in the HIV response.
Methods: PBS is a group interview method, where individuals give their responses through a ballot box. Individual responses are anonymous and unlinked which improves reporting on sensitive and personal behaviors. Participants were selected using probability sampling and organized into small homogenous groups of 10-12 people. YKP sample was included in 2017 for the first time in three cities, Nairobi, Mombasa and Kisumu.
This abstract analyses data of from 1403 adult female sex workers (AFSW) and 280 young female sex workers (YFSW) who participated in the PBS 2017 from these 3 cities.
Results: Significant differences were noted between YFSW and AFSW in inconsistency of condom use with sex clients, with condom non-use at least once in last month (26% vs 16%, p< 0.002), condom non - use due to unavailability (35% vs 25%, p< 0.002), condom non-use as the sexual partner did not want (35% vs 22%, p< 0.0001), condom non- use due to alcohol consumption (25% vs 13%, p< ???), injected heroin in the last 3 months (25% vs 13%, p< 0.04), enrolment in PrEP (29% vs 19%, p< 0.001), experienced of coercion in sex in last 6 months (24% vs 18%, p< 0.02) and visit to DIC in last 3 months (69% vs78%, p< 0.004). 18% of YFSW reported being HIV positive compared to 25% of AFSW (p< 0.008).
Only 37% of YFSW were enrolled in ART compared to 61% of AFSW (p< 0.002). No significant differences were noted in the behavioural outcomes of the AFSW and the YFSW in aspects such as HIV testing, STIs diagnosis and treatment and peer educator contact.
Conclusions: The PBS results point to the need for tailored programmatic efforts for YFSWs. The findings should be used to prioritise YFSW in the national KP programme and define the appropriate service package and approach to interventions for YFSWs.

WEPEC283

Adapting a multi-level intervention to promote HIV care and wellbeing for transgender women sex workers in the Dominican Republic

C. Barrington[1], M. Perez[2], D.A. Davis[3], H. Gomez[2], Y. Donastorg[2], D. Kerrrigan[4,5]
[1]University of North Carolina at Chapel Hill Gillings School of Global Public Health, Health Behavior, Durham, United States, [2]Instituto Dermatologico y Cirugia de Piel Dr. Huberto Bogaert Diaz, Unidad de Vacuna e Investigacion, Santo Domingo, Dominican Republic, [3]University of North Carolina at Chapel Hill Gillings School of Global Public Health, Health Behavior, Chapel Hill, United States, [4]American University, Department of Sociology, Washington DC, United States, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: Transgender women are disproportionately affected by HIV across the globe. To address the multi-level factors that affect transgender women's experiences with HIV care, there is a need for holistic, stigma-free services. We adapted the *Abriendo Puertas* (AP) multi-level intervention for transgender sex workers living with HIV in Santo Domingo, Dominican Republic, including a 6-session individual counseling program, peer navigation to provide emotional support, accompaniment and advocacy, and community mobilization to address structural factors such as poverty and to generate more solidarity.

Description: We consulted with transgender women living with HIV about their needs and assets with regard to HIV care and treatment and iteratively adapted the content of the AP individual counseling, navigation, and community mobilization components. We recruited 30 transgender women sex workers in for the pilot implementation of the adapted intervention components in 2016. We conducted surveys and qualitative in-depth interviews (n=20) to assess their experiences and analyzed data using descriptive statistics and narrative and thematic analysis.

Lessons learned: Among the 30 participants, 26 completed the pilot (87%). Participants repeatedly described how being treated with respect and compassion across intervention components allowed them to experience and complete the intervention without fear. Intervention acceptability was highest for individual counseling (95%), followed by community mobilization (85%) and navigation (69%). The sexual health session required substantial revision to address experiences related to participants' biological sex and the consequences of hormone use. Participants requested having navigators who were not transgender as they were perceived to be vulnerable to the same stigma/discrimination faced by participants. The community mobilization activities were concentrated in "open houses" with content tailored to the interests of transgender women. HIV outcomes improved, including: not missing an HIV appointment in the last 6 months (34% to 20%); increased uptake of ART (72% to 81%); and not stopping ART over the past weekend (24% to 6%).

Conclusions/Next steps: Participants were highly satisfied with the content and approach but indicated they needed more extensive support and accompaniment from navigators. There is a need to address lack of trust and cohesion within the transgender community to improve community mobilization, which is critical to sustainability and addressing structural factors.

WEPEC284

Implicit drivers of HIV transmission between adolescent girls and young women (AGYW) and their male sex partners (MSPs): Key findings from South African male sex partners mapping and characterization study

A.O. Adebayo[1], R. Mufute[2], M. Merrigan[3], J. Livingston[4], M. Madibane[4], J. Mthembu[5], M. Mabaso[6], M. Shahmanesh[7], F. Tanser[8], A. Simpson[9], N. Mamabolo[10]

[1]FHI 360, Strategic Information/M&E, Pretoria, South Africa, [2]FHI 360, Program Management, Pretoria, South Africa, [3]FHI 360, SI/M&E, Garborne, Botswana, [4]USAID, HIV Prevention and Youth, Pretoria, South Africa, [5]HSRC, HIV, AIDS, STI and TB Research, Cape Town, South Africa, [6]HSRC, HIV, AIDS, STIs and TB Research, Durban, South Africa, [7]AHRI, Adolescent RH Research Group, Mtubatuba, South Africa, [8]AHRI/UKZN, Epidemiology, Durban, South Africa, [9]USAID, Health/HIV Prevention and Youth, Pretoria, South Africa, [10]FHI360, MER Unit, Pretoria, South Africa

Background: Prevailing perception in Sub-Saharan Africa is that adolescent girls and young women (AGYW) engage in transactional sexual relationships with and are infected with HIV and sexually-transmitted infections (STIs) by much older men. However, recent findings from epidemiological studies now show otherwise in terms of the age-relationships and HIV transmission between AGYW and their male sex partners. To understand the sexual network, risk behaviours, and nature of age-disparity relationships that may contribute to new HIV infections in AGYW in South Africa (SA), an AGYW male sexual partners (MSPs) mapping and characterization study was commissioned by PEPFAR SA under the DREAMS initiative. Information obtained was intended to inform the design of highly impactful interventions targeting MSPs in a bid to reduce HIV risk in AGYW.

Methods: This descriptive study incorporated mixed methods including a literature review, a behavioural monitoring survey (BMS), and focus group discussions (FGDs). A secondary analysis of epidemiological and phylogenetic data which are crucial to comprehending characteristics of MSPs, the age groups of men having sexual relationships with AGYW, and those contributing the most to HIV infections amongst AGYW was also conducted. Data obtained from each method was then triangulated.

Results: Types of men most frequently identified as partners of AGYW were men aged 18-35 years old who: recently migrated into an area and entered into a sexual relationship with local AGYW, reported being engaged in multiple relationships, had never tested for HIV, and had perpetrated intimate partner violence. Critical also were men classified as boyfriends in non-cohabiting relationships with AGYW. Average age difference between AGYW (18-24 years old) and their MSPs was 5-7 years. Most of these men have disposable income, are highly mobile, and report "hooking-up" in neighbourhood pubs, taverns and male-dominated settings.

Conclusions: In order to help reduce the risk and vulnerabilities of AGYW with respect to acquiring HIV infection in South Africa, highly impactful interventions targeting MSPs must focus on upscaling access to HIV testing and retention in care and treatment and also address structural and gender-related issues.

WEPEC285

Efficacy of community intervention in generating demand for ANC and PMTCT services in rural areas of Bayelsa State, Nigeria

S. Ojemuyide[1], O. Shobo[2], K. Oyeniyi[3], A. Ahmad-Shehu[4], E. Kuhlik[5]

[1]Pact West Africa, Result and Measurement, Abuja / FCT, Nigeria, [2]Pact West Africa, Result and Measurement, Abuja, Nigeria, [3]Pact West Africa, Program Advancement and Delivery, Yenagoa, Nigeria, [4]Pact West Africa, Global Health, Abuja, Nigeria, [5]Pact Inc., Washington, United States

Background: Poor uptake of ANC and PMTCT services at health facility level in rural areas of Nigeria remains a major challenge (National PMTCT Scale-Up Plan). To achieve elimination of paediatric HIV infection, interventions should work closely with communities to increase demand and utilization of ANC/PMTCT services among women of reproductive age. This abstract reviews efficacy of community interventions in increasing demand for ANC and PMTCT services in rural communities of Bayelsa State, Nigeria.

Description: Chevron Corporation funded Pact Nigeria to implement community based "PROMOT" project in Bayelsa State, Nigeria. The current phase of "PROMOT II" project is being implemented in 20 target communities in 3LGAs of Bayelsa State. To increase awareness on PMTCT services and influence positive health-seeking behavior, an integrated approach of peer-led women groups to carry out health promotion activities was employed in 20 target communities by the project. Targeting women of reproductive age, particularly pregnant women, Community Health Extension Workers paired up with women groups to support HIV and PMTCT education activities including accompanying pregnant women to nearby health facilities to access ANC/PMTCT services. Community level HIV Testing Services were introduced to complement temporary cessation of healthcare service provision at health centers due to health workers' strike action.

Lessons learned: Over 19 months of Project implementation, a total of 11,528 women were reached with HIV/ANC/PMTCT messages. 3,106 women received counselling and testing for HIV at community outreach events, of which 1,736 (55.9%) were pregnant women. 29 (1.7%) of pregnant women tested HIV positive and have been linked to comprehensive care and treatment services. Number of pregnant women who received HIV counselling and testing for PMTCT at health facilities rose from 1,160 to 2,159(an 86% increase), while percentage of pregnant women who initiated ANC and completed four ANC visits increased by 25% (from 40% to 50 %) across 27 health facilities in 20 target communities.

Conclusions/Next steps: Outcome of this project has reinforced the effectiveness of community based PMTCT interventions in generating demand for increased uptake of ANC and PMTCT services in rural settings. Capacity of women's groups should be strengthened to continue supporting sustainable community-based outreach interventions that generate demand for PMTCT services.

WEPEC286

Transforming systems of care to address the needs of MSM of color in HIV prevention, care and treatment

M. Shankle, M. Stanley
HealthHIV, Washington, United States

Background: Men who have sex with men (MSM) of color continue to be disproportionately impacted by HIV. If HIV diagnoses rates persist, 1 in 2 black MSM and 1 in 4 Latino MSM in the United States will be diagnosed with HIV during their lifetime. HIV is fueled by interrelated social determinants of health (SDH), often not addressed systematically in traditional care settings. The nexus of stigma, homophobia, and racism further marginalize MSM of colors' engagement, retention, and adherence to HIV prevention, care, behavioral health and social services.
Description: A transformational, first-of-its-kind, competency-based curriculum consisting of 28 hours of interactive content was developed and implemented with multidisciplinary partners to enhance collaboration, understanding, and mitigation of SDH for this marginalized population. MSM of Color Leadership Team informed all aspects of program development. The curriculum moves beyond clinical health care, by routinizing behavioral health service delivery into practice. Health Departments (HD) participate in communities of practice, share resources and tools, and expand networks of care. Engaging nontraditional providers allows for expanded programs and accountable systems of care to work collaboratively addressing the underlying SDH. Program also provides a robust offering of technical assistance to HD.
Lessons learned: It is critical to openly discuss the impact that racism, homophobia and other cultural factors have on individual and community health to address health disparities. Services must be adapted to be accessible and welcoming for MSM of color. Collaborative learning is the most effective method to address stigma and improve cultural competency. To holistically address the needs of the community, programs must increase involvement of MSM of color in the design, development, implementation and evaluation of services.
Conclusions/Next steps: Culturally responsive education and training programs are necessary for systems transformation. Provider networks should address the needs of and reflect the MSM of color community. It cannot be business as usual if the desire is system change with demonstrated, sustainable population health impacts. Health Department have embraced the education and training and are diffusing content to the MSM of color community.

WEPEC287

Attitudes towards PrEP among drug-involved men under community supervision with their female partners in New York City

D. Goddard-Eckrich[1], T. Hunt[1], S. Sardana[2], L. Gilbert[1], M. Chang[1], K. Johnson[1], B. Baholli[1], B.T. Abbas[1], N. El-Bassel[1]
[1]*Columbia University, Social Work, New York, United States,* [2]*Teacher's College, Clinical Psychology, New York, United States*

Background: Drug-involved men under community supervision are at elevated risk for HIV acquisition. There is an urgent call to action to develop, test and implement novel HIV prevention interventions that reduce HIV transmission. The study aims to examine the acceptability for using pre-exposure prophylaxis (PrEP) among drug-involved men under community supervision and their main female sexual partners in New York City.
Methods: Utilizing 12-month data of a couple-based HIV study for drug-involved men under community supervision and their main sexual partners, 460 participants met inclusion criteria of the study (aged 18 or older, in relationship for 3 or more months, reported unprotected sex in the past 90 days, reports drug use or enrolled in a drug treatment program in the past 12 months) and were randomized. 390 participants (85%), completed the 12-month follow-up assessments. We collected data on PrEP pertinent question(s): (1) likelihood to use PrEP as a form of HIV prevention; (2) willingness to use PrEP if made available for daily use; (2) readiness and willingness to disclose use of daily PrEP to their main partner; and (3) using condoms alongside daily PrEP. Responses were rated as "very unlikely", "unlikely", "somewhat likely" and "very likely".
Results: Of the sample, 51% identified as male (N=196) and 49% identified as female (N=194). The average age was 35 (SD12.98). The majority identified as Black/African American (72.4%). Almost sixty percent (59.1%) were single or never married. 68% were unemployed and 40.4% earned less than $400 per month. Nearly one-fourth (25.9%, n=102) of the participants were very likely to use PrEP as an HIV prevention method; at least one-third of the participants reported being very willing to disclose using PrEP to their main sexual partner and were similarly highly likely to use PrEP as a daily medication (38.3% and 38.8%; n= 151; 153 respectively).
Conclusions: Findings suggest that PrEP may be an acceptable and useful form of HIV prevention among drug-involved men under community supervision with their sexual partners. However, there is an urgent need for more PrEP studies to better understand the barriers and attitudes to PrEP and integrated HIV prevention and treatment among this vulnerable population.

WEPEC288

The Intersection of violence, law enforcement, and HIV risk in drug users residing in the U.S.-Mexico border: Implications for intervention development

J. Lechuga[1], S. Beachy[2], K. Melo[2], O. Nevola[2], K. Janousek[2], C. Prieto[2]
[1]*Lehigh University, Education and Human Services, Bethlehem, United States,* [2]*Lehigh University, Bethlehem, United States*

Background: Residents of the sister cities of Ciudad Juarez and El Paso on the U.S.-Mexico border suffer some of the most serious health disparities in the world including infectious diseases such as HIV. In addition, Ciudad Juarez has the second highest drug use prevalence rate in Mexico and a corresponding high infectious disease rate among drug users. Important, research suggests that border cities such as Ciudad Juarez, Mexico are well-known destinations for drug use and sex tourism. Ciudad Juarez, experienced an unprecedented increase in violent crime in 2008 and the unprecedented levels of violence has accentuated structural level precursors of HIV risk including increased police persecution. The purpose of the study is to understand the manner in which violence and police persecution of substance users has accentuated their HIV risk.
Methods: 40 in-depth interviews were conducted with injection and non-injection drug users residing in Ciudad Juarez (N=20) and El Paso (N=20). Participants taking part in the in-depth interviews answered a short demographic survey and open-ended questions about the effect that violence had on interaction with police including increased policing, harassment and arrest and the effect this has had on adoption of preventative behaviors and cross-border mobility to use and buy drugs.
Results: Results of content analysis following a grounded theory approach revealed an increase in substance use as a result of cartel-related violence in the region. Furthermore, increased police persecution of substance users occurred in both cities of the border and corresponded with a spike in violent crime. In Ciudad Juarez, despite the fact that needle exchange programs are legal, increases in violence was associated with substance users' refusal to accept clean syringes and other prevention tools for fear of police arrest if searched. Cartel-related violence affected patterns of drug selling in the region leading substance users residing in El Paso to resort to new and riskier forms of obtaining drugs.
Conclusions: HIV prevention interventionists need to consider the intersection of contextual factors when designing HIV prevention interventions. Implications of our findings for intervention development will be discussed.

WEPEC289

Chemsex and PrEP: Do individuals engaging in "chemsex" have the intention to take PrEP? Results from the community-based survey "Flash! PrEP in Europe"

D. Rojas Castro[1,2,3], R.M. Delabre[1], A. Vilotitch[2,4], M. Meulbroek[5], P. Zantkuijl[6], S. Chanos[7], G.M. Corbelli[8], A. Bernier[1], V. Schlegel[9], S.B. Duken[10], R. Stranz[9], K. Jonas[11], B. Spire[2,9]

[1]Coalition PLUS, Community-based Research Laboratory, Pantin, France, [2]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, INSERM U1252, Marseille, France, [3]Univ Lyon 2, Social Psychology Research Group (GRePS), Lyon, France, [4]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [5]Projecte dels NOMS-Hispanosida, Barcelona, Spain, [6]Soa Aids Nederland, Amsterdam, Netherlands, [7]'Positive Voice', Greek Association of PLWHA, Athens, Greece, [8]Plus Onlus, Rome, Italy, [9]AIDES, Pantin, France, [10]University of Amsterdam, Amsterdam, Netherlands, [11]Maastricht University, Work and Social Psychology, Maastricht, Netherlands

Background: Psychoactive drug use in sexualised contexts ("chemsex") is associated with heightened risk for HIV infection, especially among men who have sex with men (MSM). Pre-exposure prophylaxis (PrEP) may be an important HIV prevention method for individuals engaging in chemsex (IC). However, little is known about the intention to use PrEP among IC in the context of variable PrEP access in Europe. We identified factors associated with intention to use PrEP among MSM respondents to the Flash! PrEP in Europe (FPIE) survey who have engaged in chemsex.

Methods: FPIE was an online, community-based research study (June/July 2016) aiming to assess knowledge and intention to take PrEP among respondents from 12 European countries. Information on drug use in a sexualised context was collected. Respondents were ≥18 years old and self-reported HIV-negative or unaware of their serological status. This analysis was restricted to MSM IC (respondents reporting drug use (injection and/or other) in a sexual context). Multivariate logistic regression identified factors associated with intention ("yes, definitely") to take PrEP.

Results: Among 1812 MSM IC, median age was 37 [IQR: 30-45], 65.4% (n=1185) resided in Germany, 48.4% (n=878) had a "fair" perceived financial status, and 30.8% (n=548) reported systematic condom use for occasional partners. More than one third (37.0%, n=671) "definitely" had the intention to take PrEP. After adjustment, migrant status (born in another Northern country (AOR: 1.41 [1.04; 1.93]) or born in a Southern country but living in the North (AOR: 2.09 [1.23; 3.55]), recent STI diagnosis (AOR: 1.47 [1.13; 1.90]), having ≥10 occasional sex partners (AOR: 1.33 [1.05; 1.67]), high perceived HIV risk (AOR: 3.91 [2.92; 5.22]) and recent PEP use (AOR: 2.47 [1.50; 4.08]) were significantly associated with higher intention to use PrEP. Reporting consistent condom use with occasional sex partners or having no occasional sex partners was associated with lower intention.

Conclusions: MSM FPIE respondents who have engaged in chemsex and have the intention to use PrEP report "high risk" behaviors and have "high" perceived HIV risk. There is an urgent need for a comprehensive prevention package for IC (including PrEP), to reduce HIV and other risks related to chemsex practices.

WEPEC290

Community-based HIV screening tool identifies children at high risk of testing positive to HIV

N. Kamwesigye

World Education, Inc./Bantwana Initiative, Case Management, Kampala, Uganda

Background: Since 2015, the Bantwana Initiative of World Education, Inc. (WEI/B) has implemented the USAID-funded Better Outcomes Project which prevents and responds to HIV while promoting the resiliency of 150,869 OVC across 14 districts of Uganda. As in all high HIV-burden countries, it is challenging to cost effectively deploy HIV test kits to identify HIV+ children as part of an integrated epidemic control strategy. Methods for reaching vulnerable OVC are often expensive, inaccurate, with low HIV yield.

Description: WEI/B developed a community-based assessment tool that identifies children vulnerable to HIV, to be administered by community resource persons. The tool assesses six risk factors: poor health, recurring skin problems, hospital admission, loss of a parent, a chronically ill family member, and school performance. WEI/B applied this tool to 65,661 children age 0-17; the assessment found that children with more risk factors had higher HIV prevalence. The HIV prevalence among all children screened was 2.1%, but was 13.8% among children with any four risk factors, and increased to 25.4% and 39% for children with five and six risk factors, respectively. WEI/B prioritized HIV testing and counseling for children with unknown HIV status and four+ risk factors, linking them to treatment and care.

Lessons learned: A community-based HIV screening tool is a cost effective approach for identifying HIV+ children and linking them into care. OVC programs have traditionally tested large cohorts with low rates of positivity. WEI/B can now test a smaller cohort with increased accuracy of referrals for clinical services. Further, the tool enables community resource persons, who are best positioned to reach the most vulnerable children, to make targeted referrals for HIV testing, care and treatment with confidence. This increased accuracy in turn strengthens the collaboration between clinic and community.

Conclusions/Next steps: The tool is being scaled up to reach all children with four or more risk factors and unknown HIV status; then those with four+ risk factors and self-reported negative status, and then those with three+ risk factors, and so on. The project is continuing to assess the tool's effectiveness; the next step includes scale- up for use with other OVC partners in Uganda.

WEPEC291

Harm reduction for youth in Ukraine: Pioneer intervention results

I. Zharuk, V. Kushakov, M. Varban, I. Sazonova

ICF 'Alliance for Public Health', Kyiv, Ukraine

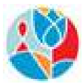
Background: IIn 2015 Alliance for Public Health with support from EJAF launched innovative harm reduction interventions targeting adolescents who use drugs (AUDs) in 6 Ukrainian cities. The project aimed to engage 6000 AUDs and their sexual partners thus proving feasibility of harm reduction for adolescents.

Description: Services were designed and delivered by non-governmental harm reduction organisations in 2015-2017. The offered combination of services was based on participatory assessment and included a number of harm reduction services complemented by additional services designed to attract and retain clients. The core services included client case definition, HIV counselling and testing, distribution of condoms and sterile injecting instruments, counselling on sexual and injecting risks including risk of transition to injecting, and referrals to youth friendly services. Complementary services included a range of recreational activities designed with participation of clients.

The project has extended tailored harm reduction services to 9,400 AUD and their sexual partners. Out of 4,593 clients who accessed services in 2017, 25% were female and 75% male; 96% were aged 14 to 19. 434 were injecting users and 3,442 - non-injecting users. 8 HIV cases were detected (5 men aged 18-19 and 3 women aged 19-20).

Lessons learned: The project found very low HIV prevalence in the project target group (10-18). This is in line with HIV surveillance and other available data. Chain referral outreach techniques based on Peer Driven Intervention model were more effective than traditional outreach activities. Complementary were crucial in attracting and retaining clients. The most popular complementary services included safe space for relaxed communication with peers, free access to Internet and refreshments. Engagement of 30 AUDs as assistant social workers strengthened outreach and attracted new clients.

Conclusions/Next steps: The project demonstrated feasibility of tailored harm reduction services for adolescents and overcame the long-standing scepticism of both service providers and AUDs. The model can be recommended in countries with high prevalence of drug use, neglected adolescents and underage transactional sex. Expansion of the target group to include young people who use drugs aged 19-24 with particular focus on young women is required for the interventions to increase contribution to HIV detection.



WEPEC292

Utilization of HIV prevention services in the East Africa Cross-Border Integrated Health Study, 2016

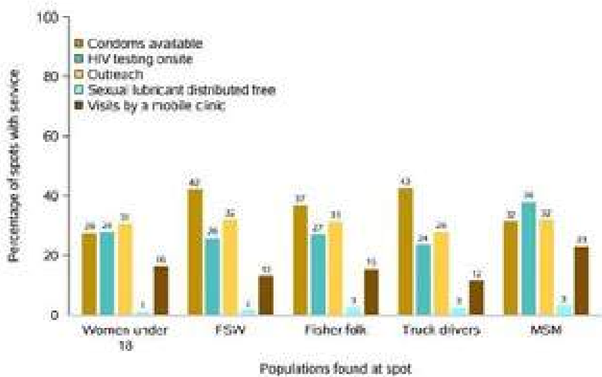
A. Virkud[1], J. Edwards[1], M. Markiewicz[2], G. Mulholland[1], P. Arimi[3]
[1]University of North Carolina in Chapel Hill Gillings School of Public Health, Epidemiology, Chapel Hill, United States, [2]MEASURE Evaluation, Chapel Hill, United States, [3]USAID/East Africa Regional Mission, Nairobi, Kenya

Background: East African cross-border sites are visited by mobile and vulnerable populations, such as female sex workers, men who have sex with men, truck drivers, fisherfolk, and young women who may not benefit from treatment and prevention interventions at their home residence. The goal of this analysis was to use data on cross-border populations in East Africa to explore whether mobile and vulnerable populations were receiving fewer prevention services.

Methods: The USAID- and PEPFAR-funded MEASURE Evaluation project, led by the University of North Carolina at Chapel Hill, collected cross-sectional data using the Priorities for Local AIDS Control Efforts (PLACE) sampling method at 14 cross-border locations near or along the land and lake borders of Kenya, Rwanda, Tanzania, and Uganda from August 2016-January 2017. This bio-behavioral survey captured information from 11,428 individuals at 833 venues (e.g., bars, hotels, guest houses) across all sites. Data were weighted using survey sampling weights and analyzed using methods to account for the complex sampling design.

Results: Across all venues, informants reported offering an average of 2 HIV prevention activities in the six months preceding the survey. The average number of prevention services offered at each venue varied by country, with the highest in Uganda [2.46 (95% CI: 2.14, 2.79)] and lowest in Rwanda [0.95 (95% CI: 2.14, 2.79)]. Only 4.2% (95% CI: 3.2, 5.2) of respondents reported it was easy to access sexual lubricants. Over 40% of venues with sex onsite (48.3% of all sites) or FSWs living at the spot (17.9% of all sites) did not have condoms available. Among respondents reporting vaginal and anal sex, reported use of condom at last sexual encounter were 38.1 (95% CI: 36.3, 39.9) and 62.9 (95% CI: 56.5, 69.2), respectively.

Conclusions: Prevention activities appear to be appropriately targeted towards venues with high prevalence behaviors at the spot (e.g., sex work, sex onsite, or alcohol use). However, gaps remain in access to condoms and sexual lubricants and use of condoms, and there are several opportunities to improve access at sites visited by mobile and vulnerable populations at high risk for HIV.



[Percentage of 833 spots in cross-border sites visited by mobile and vulnerable populations that offered specific HIV prevention services in the past]

WEPEC293

Impact of a community empowerment-based combination HIV prevention model (Project Shikamana) on the HIV continuum of care among female sex workers in Iringa, Tanzania

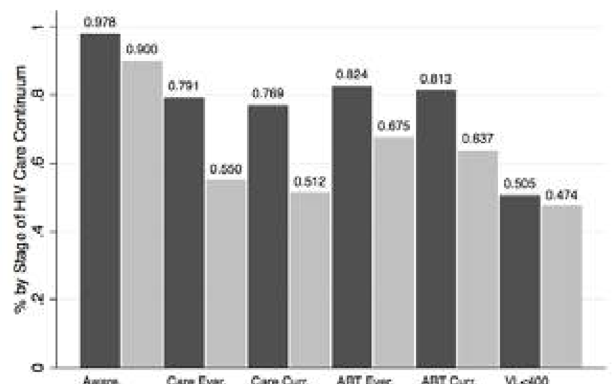
N. Galai[1,2], J. Mbwambo[3], S. Likindikoki[3], S. Beckham[4], C. Shembilu[4], A. Mwampashi[3], A. Mantsios[4], W. Davis[5,6], S. Aboud[7], D. Kerrigan[4,6], Shikamana Study Group
[1]Johns Hopkins University, Epidemiology, Baltimore, United States, [2]University of Haifa, Statistics, Haifa, Israel, [3]Muhimbili University of Health and Allied Sciences, Psychiatry, Dar es Salaam, Tanzania, United Republic of, [4]Johns Hopkins Bloomberg School of Public Health, Health Behavior and Society, Baltimore, United States, [5]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [6]American University, Sociology, Washington, United States, [7]Muhimbili University of Health and Allied Sciences, Department of Microbiology and Immunology, Dar es Salaam, Tanzania, United Republic of

Background: Addressing all steps of the HIV care continuum, particularly among key populations, is critical to reduce the burden of the HIV epidemic in countries with high prevalence and ongoing transmission. A community empowerment-based combination HIV prevention model was implemented among female sex workers (FSW) in Iringa, Tanzania and evaluated in a phase II community randomized trial.

Methods: A cohort of 203 HIV-infected and 293 HIV-uninfected FSW were recruited in two communities randomized into intervention (Ilula) and control (Mafinga) arms. Of HIV-infected women, 171 participated in both baseline (2015-6) and 18-months surveys (2017-8) and provided blood samples for HIV and viral load testing. The community-based, multi-level intervention targeted structural barriers (e.g. stigma and discrimination) to HIV testing and linkage and retention in care via both venue-based and drop-in center services and workshops, support from peer navigators, SMS adherence reminders and sensitivity trainings for clinical providers and police. Robust Poisson and logistic models were used to assess changes over time and the effects on care continuum outcomes.

Results: Among the 171 FSW who were HIV-infected at baseline, only 57 (33.3%) reported being aware of their HIV serostatus and 41 (24.0%) reported being ever linked to care although 74 (43.3%) had laboratory confirmed ART in their blood and 33.3% had viral load < 400 copies/mL. In both communities, there were significant improvement over time along the steps of the care continuum, but women in the intervention community had higher rates of engagement in care and treatment compared to the control community (See graph) including: ever or currently in care (RR=1.44, 95%CI: 1.15-1.81 and RR=1.51, 95%CI: 1.18-1.91, respectively), ART ever or current (RR=1.22, 95%CI: 1.02-1.46 and RR=1.28, 95%CI: 1.05-1.55, respectively), and ART adherence among current users (RR=1.21, 95%CI: 1.00-1.46). However, differences in viral suppression across communities were not statistically significant (RR=1.07, 95%CI: 0.78-1.46).

Conclusions: The community-based model showed a promising impact on all steps of the HIV care continuum among FSW in Iringa, Tanzania. However, improvements did not fully translate into significant changes in viral suppression. Future efforts need to focus more on ART adherence and include assessments of possible HIV resistance to current ART regimens.



[Project Shikamana HIV Care Continuum: Iringa Tanzania, 2015-2018 Ilula - intervention (dark gray) vs. Mafinga - control (light gray) at follow-up]

WEPEC294

Knowledge and Intention to use PrEP among the male-to-female population in Ecuador: Results from a community-based survey (2016)

M. Acosta[1,2], L. Orozco[3], O. Montoya-Herrera[4], M. Cassolato[5], A. Herdoiza[6], C. Acosta[7], L. Riegel[8], R. Delabre[2], D. Rojas Castro[8]
[1]Corporación Kimirina, Investigación, Quito, Ecuador, [2]Coalition PLUS, Community-Based Research Laboratory, Paris, France, [3]Corporación Kimirina, Reserach, Quito, Ecuador, [4]Corporación Kimirina, Community Education-Research, Quito, Ecuador, [5]HIV/AIDS Alliance International, HIV Techinical Treatment, Brighton, United Kingdom, [6]Corporación Kimirina, Executive Direction, Quito, Ecuador, [7]Corporación Kimirina, HIV Program Coordinator, Quito, Ecuador, [8]Coaliton PLUS, Community-Based Research Laboratory, Paris, France

Background: Male-to-Female (MTF) population is particularly affected by HIV in Ecuador, accounting for 32.8% of infections. Participation of Guayaquil in the Iprex study (2007-2011), which showed PrEP efficacy among MSM and MTF, did not lead to PrEP rollout in Ecuador. Information regarding intention to use PrEP among key populations may provide a basis for health policy allowing national access. This study assessed the intention to use PrEP among MTF respondents to a community-based survey in Ecuador.
Methods: A face-to-face survey, conducted by Kimirina in coordination with the Ecuadorian Health Minister, was answered by 335 MTF and 379 MSM in places frequented by key populations in Quito and Guayaquil. Information regarding demographics, sexual behavior, knowledge and intention to use PrEP, and preferred place for PrEP delivery were collected. This analysis was restricted to MTF respondents.
Results: Among 335 MTF, 92.2% (n=309) self-identified as trans women and 98.8% (n=331) as homosexuals. Median age was 27.7 (IQR: 23.5; 32.9), and 39.6% (n=132) reported a good financial situation. Regarding sexual activity, 94.3% (n=316) had occasional partners and 33.6% (n=103) reported unsystematic condom use during anal sex with occasional partners. Transactional sex in the last 12 months was reported by 65.4% (n=212), however one third (36.1%, n=121) were self-declared sex workers. One third (33.4%, n=112) agreed they would likely become HIV-positive in the next 12 months. Prior PrEP knowledge was declared by 9.6% (n=32) of whom 15.6% (n=9) have already used PrEP. Regardless of prior knowledge, 93.1% (n=312) declared the intention to take PrEP when available. Public health units (n=200, 59.7%) were the preferred places for PrEP delivery.
Conclusions: Despite experience with Iprex, PrEP is an unknown prevention tool among MTF. Nevertheless, there is a large proportion of MTF, at high HIV risk, who have the intention to take PrEP if available (mainly in a medical setting). The Ecuadorian public health system and civil society should use these results to provide an adapted response to the HIV.

WEPEC295

Harm reduction for young people in Ukraine: Evaluation results

I. Sazonova[1], V. Kushakov[2], I. Zharuk[2]
[1]Alliance for Public Health, Monitoring and Evaluation, Kyiv, Ukraine, [2]Alliance for Public Health, Kyiv, Ukraine

Background: Despite a large scale and highly developed harm reduction programme serving more than 200,000 PWID each year, Ukraine did not offer harm reduction services tailored to young people. In 2015, Alliance for Public Health with support from EJAF has designed and launched a harm reduction project targeting adolescents who use drugs (AUD) in five cities of the country. The project is based on participatory approach and offers a combination of HIV prevention and care services and complementary activities aimed to attract and retain young people. Here we present the results of evaluation study that accompanied the project implemented in 2015-2017.
Methods: 6,017 AUDs accessed the services over the course of the project. The study employed quasi-experimental design with baseline interviews at service uptake and follow-up interviews at least 6 months after service initiation. Evaluation component was designed to assess changes in AUD behaviour with regards to injection safety and sexual health as well as factors affecting transitions to injecting and increasing the risk of HIV transmission. 74% of all clients were interviewed for the evaluation baseline and 59% of all eligible clients were interviewed during 6 month follow-up (1,188 clients). The data were collected through Syrex cloud, an innovative service monitoring application.
Results: The median age of the clients that participated in evaluation study was 16 years (IQR 15-17). HIV-prevalence in the evaluation group as well as among clients generally was extremely low: 8 HIV cases were detected among all clients and 1 HIV case in the evaluation group over the project lifetime.
Follow-up group reported significantly higher prevalence of condom use (88% vs. 71%, p< 0.001) and low prevalence of casual sexual relationships (0% vs. 26%). 18% of evaluated participants who reported injecting drug use at baseline, has reported only non-injecting use at follow-up, and 27% reported complete cessation of drug use.
Conclusions: The innovative intervention for AUD has shown a significant decrease in high-risk sexual behaviour among regular clients, facilitated transitions from injecting drug use to non-injecting or compete cessation of drug use.

WEPEC296

Access and privacy as barriers to PrEP uptake among young men who have sex with men in two mid-sized U.S. cities

E. Asiago-Reddy[1], A. Braksmajer[2], A. London[3]
[1]SUNY Upstate Medical University, Medicine/Infectious Disease, Syracuse, United States, [2]University of Rochester, School of Nursing, Rochester, United States, [3]Syracuse University, Sociology, Syracuse, United States

Background: PrEP uptake among young men who have sex with men (YMSM) remains low in the U.S. despite disproportionate risk. Understanding barriers to and perceptions of PrEP among non-users is key to engaging at-risk YMSM into PrEP care. We conducted a study that aimed to elicit YMSM´s perceptions of PrEP in their own words, with an eye towards determining optimal means of PrEP delivery among this population.
Methods: YMSM aged 15-30 reporting sex with another man in the last 6 months who had never taken PrEP were recruited in 2 Upstate NY cities. We conducted 2 hour in-depth, semi-structured qualitative interviews. The interview addressed life and sexual histories, PrEP knowledge, and elements of PrEP that would motivate or detract from uptake, including ranking of PrEP characteristics (e.g., cost, access) that participants considered most important. Using both grounded theory and inductive approaches, two researchers independently coded the interviews to identify prominent themes and outlier attitudes.
Results: Of 16 participants, average age was 21 (range 18-26); 6 (37.5%) were black and 5 (31.2%) were Hispanic. Six-month male partners ranged from 1-20 (med. 3.5; mean 4.3). Access, cost and effectiveness were most highly ranked PrEP attributes, and concerns surrounding access were most frequently cited by participants. Four of 7 participants on parental health insurance reported disclosure via insurance as a barrier to PrEP, including 2 who had forgone PrEP due to this factor. YMSM who believed that their health insurance would not cover PrEP tended to report consideration of PrEP as futile, assuming they would not have access.
Conclusions: Among a small sample of at-risk YMSM in Upstate NY, in-depth interviews revealed concerns about access and parental knowledge of PrEP as key barriers to uptake. These results will be used to inform the development of a discrete-choice experiment (DCE) which will specifically address the role of access in the context of decisions surrounding PrEP use. DCEs elicit preferences for specific attributes of a good or service, can evaluate trade-offs in decision making, and may be well-suited to determining PrEP preferences. An adaptive choice based conjoint or two step DCE will be constructed based on these findings.

WEPEC297

Food consumption, food security and coping strategies among PLHIV

M. Josephine Muthoni[1], C. Ouma[2], M. Mumma[3]
[1]UN World Food Programme, VAM, Nairobi, Kenya, [2]UN WFP, Nairobi, Kenya, [3]World Food Program Regional Office, Nutrition, Nairobi, Kenya

Background: With Kenya classified as a UNAIDS fast track country, the HIV response is working towards achieving the global 90-90-90 targets. There remains a paucity of information on the impact of drought-related shocks on HIV response in arid and semi-arid lands which experience cyclical droughts leading to food insecurity and malnutrition both for the general population, but more so for PLHIV and TB clients. During crisis, limited data is available regarding the present status of nutrition as well as food security among PLHIV.
Assessment sought to establish the effects of drought on food consumption, food security and coping strategies among PLHIV and to explore the complex and interacting mechanisms that enhance or impede HIV response in ASAL areas in Kenya.
Methods: A mixed methods research approach was carried out in Kilifi, Kitui and Turkana counties using a composite score of drought severity, poverty index, HIV prevalence and malnutrition. 3 comprehensive care clinics (CCCs) were selected as the entry point. 1272 children aged 2 to 14 years, adult men and women were sampled.
Household Dietary Diversity Score was assessed using one 24-hour recall period. Food insecurity was assessed using the Household Food Insecurity Access Scale. Coping strategies to food insecurity were assessed using the Coping Strategy Index. Descriptive and multivariate analysis was conducted using SPSS v 24.
Results: Mean HDDS and dietary diversity score for Women were both 3.8, and below the minimum recommended threshold. 87% of female participants had low to medium dietary diversity. Prevalence of severe food insecurity was 69.4%. 78.5% of children 2-14 years were from severely food insecure households. 69.2% of adults reported low coping strategies to food insecurity. likelihood of being underweight increased with increasing food insecurity [OR 3.31 (95% CI 1.22-9.02); p=0.019] and low household dietary diversity [OR 2.64 (95% CI 1.48-4.72); p=0.01]. The odds of being underweight were higher in men, substance users, consumers of untreated water and those with high viral load.
Conclusions: PLHIV are exposed to many food security and coping shocks. Family food and livelihoods support in PLHIV households should be planned for and costed as part of HIV programming during drought in ASAL areas.

WEPEC298

"PrEP tourism" in Bangkok and sexual risk behavior of MSM: A three- and six-month follow up study

M. Van Dijk[1], N. Yaemim[1,2], J.E. Martinez[3], S.E. Stutterheim[1], T. Guadamuz[4], J.B.F. De Wit[5], K.J. Jonas[1]
[1]Maastricht University, Department of Work & Social Psychology, Maastricht, Netherlands, [2]Silom Pulse Clinic, Bangkok, Thailand, [3]Princeton University, Department of Psychology, Princeton, United States, [4]Mahidol University, Department of Society and Health, Bangkok, Thailand, [5]Utrecht University, Department of Interdisciplinary Social Science, Utrecht, Netherlands

Background: The formal availability of Pre-Exposure Prophylaxis (PrEP) in many countries is limited. An important option for men who have sex with men (MSM) to obtain PrEP is abroad, at MSM travel destinations where PrEP is easily available and affordable, such as Thailand. With PrEP sourced in Bangkok, our aim was to assess PrEP use and sexual risk-taking behavior among such MSM. Since some of the clients access PrEP for the first time, we investigated PrEP use and sexual behavior during a three- (T2) and six-month (T3) follow up compared to baseline.
Methods: MSM clients (n=126) of the Silom Pulse Clinic completed a survey on-site about PrEP use and sexual behavior in February-April 2017 (T1). Surveys at T2 (n=65) and T3 (n=48) were completed online. Mean age was 38 years (range: 22-70). The sample was internationally diverse: 97 participants (77.0%) did not live in Thailand and four (3.2%) were born in Thailand.
Results: At T1, 91 participants (72.2%) reported using PrEP informally. At T2, one participant stopped using PrEP, while 11 started using PrEP. At T2, 87.7% (T3: 88.1%) followed a daily regimen. Most reported regular HIV (87.7%) and renal function testing (80.4%). At T1, 56.5% used condoms often or always, while at T2, 67.9% (T3: 72.5%) reported lower condom use since starting PrEP. Between T1 and T2, 8 participants (12.3%) were diagnosed with an STI. At T1, recreational drugs were used by 43 participants (34.1%) during sex. At T2, since starting PrEP use, 82.5% felt less anxious when having sex, and the same proportion reported increased quality of sex life. This remained stable between T2 and T3 (repeated measures F< 1).
Conclusions: Despite not having access to formal PrEP care in their home country, the vast majority of participants managed to follow a daily regimen and to obtain necessary medical checks, and reported increased quality of sex life. Despite their relative distance to local health care provision, this specific group of "PrEP tourists" is well aware of how to use PrEP correctly. A limitation is that high dropout between T1-T2 could have led to an overestimation of daily PrEP regimens.

WEPEC299

Male wellness center: An HIV/STI detection and treatment service model for the MSM community

X. Xiu[1], D. Xiao[2], N. Cao[3], X. Jin[1], Y. Zhang[1], Z. Ding[1], Y. Jie[1], Y. Liao[1], H. Wu[4], B. Shepherd[5], J. Vandenhombergh[5], Y. Bao[1]
[1]AIDS Healthcare Foundation (AHF) China Office, Beijing, China, [2]Tongzhi Welfare, Beijing, China, [3]Hospital of Dermatology, Chinese Academy of Medical Sciences & Peking Union Medical College, Nanjing, China, [4]Beijing Youan Hospital, Beijing, China, [5]AIDS Healthcare Foundation (AHF), Los Angeles, United States

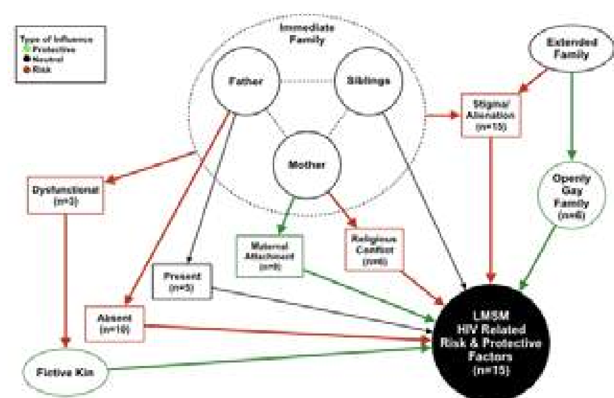
Background: Men who have sex with men (MSM) have elevated risk for contracting HIV and other sexually transmitted infections (STI), thus access to testing and treatment services is vital. MSM often face stigma, discrimination and a general lack of understanding by healthcare providers, which, coupled with inaccurate information sources and gaps in accessible quality healthcare, results in delayed or outright denial of testing and treatment.
Description: The AIDS Healthcare Foundation (AHF)-supported Male Wellness Center was launched in Beijing in December 2016. It links the MSM group into existing hospital services providing integrated counseling, testing, referral and HIV/STI treatment services. Qualified healthcare providers and counselors from the MSM community work closely to deliver services in a private, confidential and discrimination-free setting. Necessary follow-up visits and 24-hour access to specialized professionals for questions and unforeseen difficulties are also available. Instant HIV and syphilis tests are provided free of charge, and HIV positive clients have access to additional counselling, education and referral to free antiretroviral therapy (ART). STI treatment, of which syphilis is free of charge, is provided at wellness center itself.
Lessons learned: From December 1, 2016 to December 31, 2017, 3,513 clients received diagnostic and counseling services. Young, sexually-active MSM showed a greater demand for sexual health services, making up almost three-fourths of those attended; 1,092 (31%) aged 15-24 and 1,519 (43 %) aged 25-49. Of the total, 92 (3%) were newly found HIV positive and all were enrolled into ART. 371(11 %) new and recurrent syphilis cases were diagnosed and treated. Genital warts and urinary tract infection were diagnosed and treated in 241 (7%) and 95 (3%) clients respectively. Notably, 2,207 (63 %) clients accessed and received testing and counseling services twice or more.
Conclusions/Next steps: The Male Wellness Center project effectively addressed current and potential health risks for MSM, as evidenced by rates of first and recurrent utilization of the services provided.
The model should be expanded and replicated, along with promoting services targeting similarly-aged youth through internet and mobile-phone communication methods.

WEPEC300

Family-based HIV risk and protective factors for Latino men who have sex with men in San Juan, PR

M. Garcia[1,2]
[1]Houston Health Department, Houston, United States, [2]Yale University, Center for Interdisciplinary Research on AIDS (CIRA), New Haven, United States

Background: Puerto Rico (PR) is the fifth largest territory throughout the US to have the greatest number of Latinos living with HIV and HIV infection rates for 2016 continue to grow for Latino men who have sex with men (LMSM) ages 25-34. HIV related research among sexual minorities of color has focused on deficiencies and limited research has taken a culturally informed approach regarding identity development and interpersonal family relationships. This study aims to determine if family influences behaviors related to HIV risk and protective factors for LMSM.
Methods: LMSM ages 21 through 30 in San Juan, PR completed semi-structured interviews exploring the influence interpersonal family relationships have on condom use, HIV testing, health seeking behaviors, substance use, and sexual partners. A focus was placed on family as a unit as well as the interpersonal relationships of participants with immediate (e.g., parent, caregiver, sibling) and extended family members (e.g., aunt, uncle, cousin, grandparent). *Fictive kin,* unrelated by birth or marriage, was also explored to understand how LMSM applied family roles to important members within their social network. NVivo was used to conduct a thematic analysis focused on identifying prominent themes based on codes associated with family. All data was analyzed in its original language and direct quotes were translated from Spanish to English.
Results: Fifteen participants (Mean age = 26.2) completed in-depth interviews, 14 in Spanish and 1 in English. Participants reported being HIV negative (80%), gay (93%), household income ≤$19,999 (67%), and some college education or greater (80%). A thematic map illustrates an innovative framework (Figure 1) to conceptualize the influence interpersonal family relationships have on wellbeing for Latino MSM based on the emergent themes:
1) Immediate versus Extended Family;
2) Mother Knows Best;
3) Fractured Paternal Relationships;
4) Siblings Influence; and
5) *Fictive Kin* - Creating My Own Family.
Findings suggest that the mother plays an integral role in enhancing HIV protective factors for LMSM ages 21-30.



[Figure 1. Thematic framework for conceptualizing family-based HIV related risk & protective factors for LMSM (N = 15) in San Juan, PR.]

Conclusions: This study highlights the importance for developing family-based interventions that reinforce cultural beliefs and values through a strengths-based approach towards enhancing HIV protective behaviors for LMSM.

WEPEC301

Serostatus non-disclosure to sexual partners among high-risk drug users living with HIV: Examining the roles of HIV-related stigma and risk behavior

R. Shrestha[1], F. Altice[2], M. Copenhaver[1]
[1]University of Connecticut, Allied Health Sciences, Storrs, United States, [2]Yale University, New Haven, United States

Background: HIV serostatus disclosure among people living with HIV (PLWH) is an important component of preventing HIV transmission to sexual partners. Due to various social, structural, and behavioral challenges, however, many HIV-infected people who use drugs (PWUD) do not disclose their HIV status to all sexual partners. In this analysis, we therefore examined non-disclosure practices and correlates of non-disclosure among high-risk HIV-infected PWUD.
Methods: HIV-infected, methadone-maintained people who reported HIV-risk behaviors were enrolled (n=133). Participants completed an audio-computer assisted self-interview (ACASI) assessing socio-demographic characteristics, HIV disclosure, risk behaviors, health status, ART adherence, HIV stigma, and other characteristics. Multivariable logistic regression was used to identify significant correlates of non-disclosure.
Results: Over 23% of the respondents had sex with someone with whom they had not disclosed their HIV status. HIV risk behaviors were highly prevalent among non-disclosing participants: sharing of injection equipment (70.5%) and inconsistent condom use (93.5%). Non-disclosure of HIV status was significantly associated with not being virally suppressed (aOR=0.189, *p*=0.041), high HIV-related stigma (aOR=2.366, *p*=0.032), and having multiple sex partners (aOR=5.868, *p*=0.040). Furthermore, a significant interaction between HIV-related stigma and living with family/friends suggests that those living with family/friends were more likely to report not disclosing their HIV status when faced with a higher degree of perceived stigma.
Conclusions: Our findings support the need for future interventions to better address the impact of perceived stigma and HIV disclosure as it relates to risk behaviors among PWUD.

Male and female condom use

WEPEC302

Contextualizing condoms: Location, partner type, and substance use as contexts for sexual risk behavior with transactional and non-transactional partners of men who have sex with men in Peru

A. Castañeda-Huaripata[1], R.C. Passaro[2,3], W. Gonzales-Saavedra[1], E.R. Segura[2], S. Chavez-Gomez[1], R. Lama[1], R. Bobadilla[1], M. Reyes[1], R. Cabello[1,2], J.L. Clark[2]
[1]Asociación Civil Via Libre, Lima, Peru, [2]South American Program in HIV Prevention Research, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, United States, [3]College of Medicine, University of Tennessee Health Science Center, Memphis, United States

Background: Men who have sex with men (MSM) in Peru consistently report low frequencies of condom use. To improve understanding of the evolving context of condomless intercourse in same-sex male partnerships, we studied associations between partner type, substance use, and condomless receptive anal intercourse (cRAI) in common MSM sex venues.
Methods: In a 2017 cross-sectional study of rectal STI screening and HIV prevention, MSM reporting recent cRAI completed a survey of demographic characteristics and sexual risk behavior with their three most recent partners. Generalized estimating equations, stratified between transactional sex (TS) and non-TS partners, estimated correlations of cRAI with venue of last sexual contact, participant alcohol use prior to sex, and negotiation of condom use before or during sex.
Results: Among 1,428 sexual encounters of 450 MSM (median age 27 years), 160 were transactional (11.2%) and 1,268 were non-transactional (88.8%). The most commonly reported venue for TS and non-TS en-

counters was a hotel (51.5% of TS & 32.6% of non-TS). Sexual encounters with transactional partners at sauna venues often included alcohol (75.0%) and drug use (75.0%) before sex, and none of these encounters involved condom use negotiations before or during sex. Transactional sex encounters in public venues frequently included discussions about condom use (71.4%), but were also associated with cRAI (aPR, 95% CI: 1.94, 1.11-3.36), likely due to negotiations for higher compensation with condomless sex. In all encounters with transactional partners, cRAI was associated with alcohol use (1.35, 1.03-1.77). Among non-transactional partners, cRAI was associated with encounters that occurred at the participant's home (1.25, 1.05-1.49) and in the context of alcohol use (1.19, 1.09-1.31). Alcohol use before sex occurred most commonly at hotels (31.7%), while drug use occurred most often at public sex venues (13.5%). Encounters with non-transactional partners rarely included discussions of condom use and HIV serostatus before or during sex (< 15% of all encounters), regardless of venue.

Conclusions: We observed different patterns and implications of substance use, condom negotiation, and cRAI with transactional and non-transactional partners of MSM at diverse sex venues. Additional studies are needed to explore how venue, substance use, and partner type differentially structure HIV/STI risk contexts.

WEPEC303

Community condom preferences in Zambia from the HPTN 071 (PopART) trial

M.M. Phiri[1], R. Kumar[1,2], A. Schaap[1,2], K. Shanaube[1], R. Hayes[3], S. Fidler[4], H. Ayles[1,2]

[1]Zambia AIDS-Related Tuberculosis (Zambart), University of Zambia, Lusaka, Zambia, [2]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [3]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [4]London School of Hygiene and Tropical Medicine, Department of Medicine, London, United Kingdom

Background: Condom use is a very effective HIV/STI prevention strategy, yet usage remains low. In Sub-Saharan Africa, standard condoms are available at health facilities, but uptake is low and community members perceive their quality to be inferior compared to branded condoms. HPTN071(PopART) is a 3-arm community-randomized trial of a combination HIV prevention package in 21 communities in Zambia and South Africa. The intervention includes condom distribution delivered door-to-door by community health workers. Our objective was to understand condom preferences of participants in 8 intervention communities in Zambia.

Methods: Standard government-provided male (Giulin Zizhu Latex Co Ltd) and female (fc2®) condoms were provided to participants from December 2013 - September 2017. Alternative branded condoms (Moods®) and lubricants (Optilube®) were provided from June 2015 - September 2017. Electronic data on numbers of condoms requested and received during household visits, and condom preferences were collected from 8 intervention communities in Zambia from July 2016 - August 2017, and analysed using STATA 13.1. Semi-structured interviews were conducted to find participants' preferred type of condom, and reason for the preference.

Results: Overall, 292,552 people consented to participate in the main PopART intervention, 97.8% had data recorded. Excluding those <15 years, 165,873 participants remained: 37.5% male, 62.5% female (Figure 1). Of the males, 7% requested and received lubricant, 6.7% female condoms, and 32% male condoms (branded and government).

Of men receiving condoms, 65.6% expressed interest in receiving branded condoms compared to 17.2% in those who didn't receive condoms.

For females, 6.5% requested and received lubricant, 7.5% female condoms and 18.6% male condoms (branded and government).

Of women receiving male condoms 63.6% expressed interest in receiving more branded condoms compared to 10.7% who didn't receive condoms.

Overall, flavoured and scented condoms were the most preferred across all age groups because they "felt like skin to skin"; were "light and strong"; and "had a good smell." More women (20.4%) than men (7.4%) self-reported preference in receiving female condoms.

Conclusions: Future programs and governments should consider adding flavoured, scented and female condoms to encourage condom use. Research should be conducted on whether receiving branded male condoms and lubricant has an impact on condom usage among community members.

		Total N(%)	Flavoured N(%)	Scented N(%)	Ribbed N(%)	Studded N(%)	Female N(%)	Other brand-specific type N(%)

WEPEC304

Acceptability and availability of co-packed condom and lubricant among key populations in Nigeria

O. Fajemisin[1], A. Oluwayinka[2], G. Omoregie[3]

[1]Society for Family Health, Research, Measurement and Results, Abuja, Nigeria, [2]Society for Family Health, Research and Evaluation Department, Abuja, Nigeria, [3]Society for Family Health, Global Fund HIV Programme, Abuja, Nigeria

Background: Consistent use of condoms remains effective in preventing HIV transmission amongst key populations (KPs) while the use of water-based lubricants reduces the chances of condom failure. In Nigeria, reduced access to appropriate lubricants has been linked to use of oiled-based types with increased condom failure. To increase use of appropriate, lubricants, the Society for Family Health introduced a Co-packed Condom and Lubricant (CCL) under the Global Fund (GF) grant, which was made available to all key populations (KPs). After six months of its introduction, the program assessed the performance of the CCL for availability, use and desirability.

Methods: The study adopted mixed-method approach of quantitative and qualitative data collection. The quantitative method involved the use of interviewer-administered structured questionnaire to KPs, while focus-group discussions with KPs who had been exposed and used to obtain perceptions. The study population included all KPs from focal states of the GF program.

Results: The respondents (2351) included 787 men who have sex with men (MSM), 789 female sex workers (FSW) and 775 People who inject drugs (PWID), About 87% of respondents were aware of CCL; 77% of these were still using the CCL; and 52% of respondents reported constant use of CCL. The commonest (26%) reason given for using CCL was the fact that CCL is better than using condoms alone. However, about 35% stated that other condoms were more readily available than the CCL The advantages of CCL include that dual-use had sex more pleasurable and CCL were convenient to use. However, FSWs want a lesser volume of lubricants while the MSM preferred increased amount and both preferred an increase in the number of condoms per pack.

Conclusions: The newly introduced CCL was well known, accepted and used among the KPs. CCL should be made more available, accessible to KPs. There is need to develop different packages of CCL to meet the needs of FSW and the MSM. Sustaining its availability will include developing a cost that can be afforded by all groups.

WEPEC305

A functional performance study of the "Wondaleaf" female condom

M.E. Beksinska, N. Mphili, R. Greener
University of The Witwatersrand, MRU- Match Research Unit, Durban, South Africa

Background: New female condoms (FCs) are in development that have innovative designs to introduce the FC into the vagina. One of these new designs is the "Wondaleaf" female condom, which has an adhesive shield replacing the outer ring/frame of a typical FC. As the shield covers both internal and external genitalia, it aims to provide better protection against unintended pregnancies and sexually transmitted infections. The primary objective of this research was to compare the functional performance of two FC types- the Wondaleaf FC and FC2, where the FC2 served as the control device.
Methods: This was a two-period, cross-over randomized controlled trial to determine the functional performance, safety and acceptability of Wondaleaf FC and FC2. This study enrolled 55 women in Durban, South Africa in 2017. Primary analyses centered on total clinical failure and total female condom failure. Rates of clinical breakage, total breakage, slippage, misdirection, and invagination were also calculated.
Results: Fifty three of the 55 women enrolled (96%) completed both study follow-up visits. Participants were of a mean age of 28 years with 10 years or more of schooling. All participants had ever used male condoms, and 45.4% had ever used FCs. Total clinical failure was 5.3% for the Wondaleaf FC and 7.5% for FC2. A small number of women had difficulties applying the Wondaleaf shield however once fitted, the shield of the Wondaleaf FC remained adherent in all uses. In three cases some of the shield material was pushed into the vagina, however this did not present an exposure risk. Acceptability was generally higher for the Wondaleaf compared to the FC2. Two-thirds of women (69.8%), and over a half of men (58.4%) stated a preference for Wondaleaf over FC2.
Conclusions: This new design performed well compared to FC2 with lower condom clinical failure and higher acceptability and preference. The design is more complex than a typical FC and requires good instruction for users to fit the adhesive shield.

Access to harm reduction interventions

WEPEC306

Harm reduction program intervention and behavioral factors correlation with anti-hepatitis C positivity among people who inject drugs in Georgia

N. Shengelia[1], I. Chikovani[2], L. Sulaberidze[1]
[1]*Curatio International Foundation, Research Unit, Tbilisi, Georgia,* [2]*Curatio International Foundation, Tbilisi, Georgia*

Background: Georgia is implementing HCV elimination program and People Who Inject drugs (PWID) represent one of the severely affected population with Hepatitis C virus (HCV) infection. Harm reduction programs (HRP) aim to reduce the risk of HIV and transmission among this key population. We assessed correlation of HRP intervention, behavioral factors and anti-HCV positivity among PWID in Georgia.
Methods: A Cross-sectional bio-behavioral study using respondent-driven sampling (RDS) was conducted among 2,049 PWID in 7 cities of Georgia during 2016-2017. RDS-weighted estimates were used and bivariate and multivariate logistic regression analyses were conducted to identify correlates of anti-HCV positivity and harm reduction program coverage along with behavioral factors.
Results: Prevalence of Hepatitis-C was 63.2% among study population. Awareness about HIV testing possibilities and receiving sterile injecting equipment and condom from HRP during the last 12 months- "Program general coverage" reported 14.2% and "program full coverage "- receiving brochures and qualified educational information in addition to "general coverage" reported 11.5% of PWID. Significant association was found between anti-HCV positivity and HRP service reach. PWID, who were not covered with "general coverage" had lower odds (OR 0.3, $p < 0.05$) while those without "full coverage" had higher odds (OR 5.1 $p< 0.01$) of anti-HCV positivity. Those who were tested on anti-HCV during last 2 years or more than 2 years were more likely to be infected, (OR 2.93 $p< 0.01$) and (OR 1.67 $p=0.01$) respectively. PWID, who used condom at their last intercourse were less likely to be positive, compare to those, who did not have sex last year OR 2.02, $p< 0.01$. A one-year increase of drug use practice increases risk at 8.5% of anti-HCV positivity $p< 0.01$. Use of non-sterile injecting equipment at their last injection was associated with lower risk of anti-HCV positivity (0.65 $p< 0.05$).
Conclusions: HCV positive PWID benefit from HRP mostly due to access to sterile injecting equipment and condoms. On the other hand, HCV positive PWID have lower risky behavior, possibly because of HRP influence. To scale-up access to the HRP will reduce HCV transmission risks on the way to eliminate HCV infection in the country.

WEPEC307

Impact of health behavior campaigns on HIV-risk behaviors in Swaziland

I. Mushamiri[1], Z. Mnisi[2], M. Nkambule[3], G. Bicego[4], J. Justman[5]
[1]*Columbia University Mailman School of Public Health, Epidemiology, New York, United States,* [2]*Swaziland Ministry of Health, Mbabane, Swaziland,* [3]*Swaziland National Emergency Response Council on HIV/AIDS, Mbabane, Swaziland,* [4]*US Centers for Disease Control and Prevention, Atlanta, United States,* [5]*ICAP at Columbia, Mailman School of Public Health, Columbia University, New York, United States*

Background: Several mass media health behavior campaigns (HBCs) were conducted in Swaziland between 2010-2015 to avert new HIV infections. We describe the association between HBCs and specific behaviors among a prospectively followed, nationally representative, HIV-negative cohort from the 2011 Swaziland HIV Incidence Measurement Survey (SHIMS).
Methods: Survey staff conducted household-based HIV testing and collected information from adults, 18-49 y, about risk behaviors and exposure to HBCs in the previous 6 months. HIV-negative participants repeated the questionnaire and HIV testing 6 months later. Survey data were weighted for sampling design and multivariable logistic regression analysis assessed associations between HBC exposure and risk behaviors among those reporting sexual activity at both baseline and follow-up. Assessed behaviors were ever HIV testing (at baseline); number of sexual partners; condom use; and male circumcision (MC) or having a circumcised primary partner.
Results: Among 18,172 adults, 12,368 tested HIV-negative at baseline; of these, 11,232 (91%) completed a 6-month follow-up visit and 121 incident infections were observed. Among women, there was a baseline association between reporting ever HIV testing and exposure to HIV testing HBC messages (adjusted OR [aOR] 3.84, 95% CI [1.18-12.55]); and reporting fewer (i.e., 1 versus 2, or 2 versus ≥3) sexual partners and exposure to partner reduction HBC messages (aOR = 3.02, 95% CI [1.38-6.62]). Among men, there was a baseline association between reporting fewer partners and exposure to partner reduction messages (aOR = 2.26, 95% CI [1.49-3.44]). In the longitudinal assessment, men who reported baseline exposure to partner reduction HBCs were more likely to report fewer sexual partners 6 months later (aOR = 1.95, 95% CI [1.26-3.00]). No significant association was found for men or women between exposure to HBCs about condoms and condom use, nor about MC and the MC outcome [Table]. Exposure to HBCs did not predict incident HIV infections.
Conclusions: These findings suggest a minimal impact of mass media HBCs on promoting low-risk behaviors among adults in Swaziland, the country with the highest global national HIV prevalence. Although both men and women appeared to respond positively to partner reduction HBC messages, averting risky behaviors at a population level appears to require additional interventions.

WEPEC308

Factors associated with never accessing North America´s first and largest supervised injection facility among people who inject drugs in Vancouver, Canada

M.C. Kennedy[1,2], K. Hayashi[1,3], M.-J. Milloy[1,4], R. McNeil[1,4], E. Wood[1,4], T. Kerr[1,4]
[1]British Columbia Centre on Substance Use, Vancouver, Canada, [2]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada, [4]University of British Columbia, Department of Medicine, Vancouver, Canada

Background: Supervised injection facilities (SIFs) have increasingly been established in various settings worldwide. Previous studies have demonstrated the role of SIFs in reducing potential for HIV infection and other harms stemming from injection drug use. However, little is known about potential barriers to utilization of this form of health service. We therefore sought to characterize factors associated with never using Insite, North America's first and largest SIF, among people who inject drugs (PWID) in Vancouver, Canada.

Methods: Data from two ongoing prospective cohort studies of PWID were collected between June 2006 and December 2012. Multivariable logistic regression was used to identify factors associated with reporting having never used the SIF at baseline and in all subsequent study follow-up visits.

Results: Of 1514 PWID included in the study, 496 (32.8%) were women, 920 (60.8%) were White and the median age was 46 years (interquartile range [IQR] = 39-52). The median follow up duration was 46 months (IQR = 18-71). A total of 267 (17.7%) participants reported having never used the SIF at baseline and in all subsequent study follow-up visits. In multivariable analyses, requiring manual assistance with injections (adjusted odds ratio [AOR] = 1.54; 95% confidence interval [CI]: 1.05-2.27), non-injection crystal methamphetamine use (AOR = 2.07; 95% CI: 1.16-3.70), and HIV seropositivity (AOR] = 1.52; 95% CI: 1.13-2.05) were positively associated with never using the SIF. Variables independently and negatively associated with never using the SIF included unstable housing (AOR = 0.67; 95% CI: 0.45-0.99), residence in the neighbourhood of the SIF (AOR = 0.61; 95% CI: 0.42-0.89), participation in methadone maintenance therapy (AOR = 0.55; 95% CI: 0.41-0.73), daily heroin injection (AOR = 0.32; 95% CI: 0.19-0.54), public injection (AOR = 0.28; 95% CI: 0.18-0.43), and binge injection (AOR = 0.49; 95% CI: 0.31-0.77).

Conclusions: Most PWID reported having ever used the SIF. However, PWID who required manual assistance with injections or used non-injection crystal methamphetamine were more likely to report having never used this service. These findings point to the need to consider amending SIF operational regulations that may create barriers to SIF service engagement for these subpopulations of PWID.

Characteristic	Unadjusted Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)

Methadone maintenance therapy participation (yes vs. no)*	0.60 (0.46 – 0.78)	0.55 (0.41 – 0.73)
Sex work involvement (yes vs. no)*	0.58 (0.36 – 0.94)	0.68 (0.40 – 1.16)
Ever treated poorly by healthcare professionals (yes vs. no)	0.51 (0.35 – 0.74)	0.74 (0.49 – 1.11)

* Refers to the cumulative proportion of activities or experiences in the previous 6 months during follow up, dichotomized as 50% vs. <50% of the time.
‡ DTES = Downtown Eastside neighbourhood (where the SIF is located).

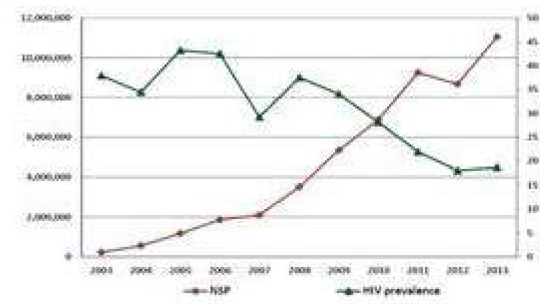
[Table 1: Logistic regression analysis of factors associated with having never used the Insite supervised injection facility (SIF) among people who inject drugs in Vancouver, Canada (n = 1514).]

WEPEC309

No wall in Myanmar: Needle and syringe automatic taking machines (NSATM) are breaking down barriers in HIV prevention for people who inject drugs in remote rural villages

H. Phyo Aye[1], T. Linn[2], W. Toe Wai[3]
[1]Asian Harm Reduction Network-Myanmar, Harm Reduction, Myitkyina, Myanmar, [2]Asian Harm Reduction Network-Myanmar, Harm Reduction, Yangon, Myanmar, [3]Asian Harm Reduction Network-Myanmar, Harm Reduction, Bhamo, Myanmar

Background: Myanmar is confronted with a dual epidemic of drugs and HIV. HIV prevalence is 28.5% (IBBS 2014) among PWID driven by sharing injecting equipment. Needle Syringe Programs (NSP) have proven to reduce HIV incidence and are the vital part of HIV prevention, but are also most sensitive and misunderstood among the community and need strong local advocates. Frequent crack-downs by law enforcement and anti-drug faith-based vigilante forces more PWID 'underground' and exacerbates access difficulties for the traditional way of NSP through outreach. Furthermore, drug use is mainly a rural phenomenon in Myanmar with a wide geographical area to cover. To address some of these issues and increase the access to clean needles and syringes (N/S), AHRN initiated community-based Needle and Syringe Automatic Taking Machine (NSATM) whereby owners of participating shops are also nurtured as community advocates.



[Needle and syringe distribution and HIV prevalence among PWID (2003-2013)]

Description: AHRN started to implement the free distribution of clean needles and syringes through NSATM through grocery-shops, snack shops etc in its project sites in Kachin Shan and Sagaing Regions in the

last quarter of 2015. PWID can access clean injection equipment in the NSATM shops from early morning till night time, in most cases 7 days/week and in some shops even for 24 hours. Participating owners are provided with training, official recognition as HIV prevention service and incentives. Outreach, needle patrolling by peers and NSATM shops are collecting used N/S.

Lessons learned: From 20 NSATM shops in 2016, the number rose to 34 in 2017. The number of N/S distributed through NSATM increased from 1.2 to 2.25 million, a quarter of AHRN total N/S yearly turnover. The return rate remains low, albeit improving. The shop owners, as influential persons in their neighbourhood, are facilitating the advocacy process.

Conclusions/Next steps: NSATM in the community works, is good advocacy, changes positively the perception of NSP and is instrumental in enhancing access to sterile equipment. Moreover, focus group discussions with clients, indicates that easier access decreases sharing of injecting equipment significant. As next steps, AHRN will further expand its NSATM activities and is conduct an in-depth survey how to address low return rate.

Novel research designs for epidemiology and surveillance

WEPEC310

Correcting mortality for loss to follow-up in African ART programmes: Comparison of methods

N. Anderegg[1], F. Chammartin[1], M. Schomaker[2], H. Tweya[3], B.D. Rice[4], J.R. Hargreaves[4], M. Egger[1,2], on behalf of the MeSH Consortium
[1]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [2]University of Cape Town, Centre for Infectious Disease Epidemiology and Research (CIDER), Cape Town, South Africa, [3]The Lighthouse Trust, Lilongwe, Malawi, [4]London School of Hygiene & Tropical Medicine, Department of Social and Environmental Health Research, Faculty of Public Health and Policy, London, United Kingdom

Background: Loss to follow-up (LTFU) makes mortality estimation in HIV-positive patients on ART challenging. Mortality among patients LTFU is typically higher than among those in care, biasing program-level estimates of mortality downwards if LTFU is ignored. Existing methods to address this problem can be classified as «ad-hoc» methods (if LTFU-outcomes are unknown) or «ascertainment» methods (if some LTFU-outcomes are ascertained). Ascertainment of LTFU-outcomes through tracing of patients or record linkage is not always feasible: «ad-hoc» methods are the only choice in many settings. We compared an «ad-hoc» method with an «ascertainment» method, and examined the influence of the proportion of outcomes ascertained.

Methods: The «ascertainment» method (Schomaker et al, Stat Med 2014) uses multiple imputation to estimate survival times in patients LTFU after a sample of outcomes was ascertained. The «ad-hoc» method (Brinkhof et al, PLoS ONE 2010) uses a pattern-mixture model, assuming a k-fold increase in the hazard of death after being lost. We calculated 3 different estimates of k based on findings from literature. We used simulated data (500 runs) and empirical data from patients starting ART 2001-2010 in Lilongwe, Malawi.

For the simulated data we studied differences between true and predicted median survival times via root-mean-squared-deviation (RMSD).

For empirical data we compared predicted 1-, 2-, and 3-year mortalities.

In addition, we assessed the performance of the naive approach (ignoring LTFU) and the impact of the proportion of outcome ascertainment on RMSD and mortality.

Results: Our simulated datasets included 1000 patients, 29% were LTFU on average. Malawi data included 7084 adult patients; 1864 were LTFU. 72.3% of LTFU-outcomes could be ascertained through tracing. RMSD was largest for the naive approach, smallest for the «ascertainment» method and varied substantially dependent on the choice of k in the «ad-hoc» method (Table). Estimated mortality was lowest with the naive and highest with the «ascertainment» method (Table). The «ascertainment» method consistently outperformed the «ad-hoc» approach, even if the proportion of outcomes ascertained was as low as 1%.

Conclusions: Ad-hoc methods will give more reliable results than naive estimates. Methods based on ascertainment of LTFU-outcomes will, however, be more accurate, even for low proportions of ascertained outcomes.

Method	Simulated data RMSD(pT_{50})†	Malawi data Mortality (95%-CI) 1-year‡	2-year‡	3-year‡
Naive	12.80 years	2.9% (2.5-3.4)	3.3% (2.8-3.8)	3.5% (3.0-4.0)
«Ascertainment»				
1% ascertained	4.13 years	8.0% (7.3-8.6)	13.9% (12.9-14.3)	16.8% (15.7-17.9)
5% ascertained	3.74 years	7.9% (7.2-8.6)	13.7% (12.8-14.7)	16.5% (15.4-17.6)
20% ascertained	3.38 years	8.4% (7.7-9.1)	13.7% (12.8-14.6)	16.2% (15.2-17.3)
50% ascertained	2.31 years	9.3% (8.6-10.1)	13.4% (12.5-14.3)	15.4% (14.4-16.4)
72.3% ascertained	1.56 years	10.1% (9.4-10.9)	13.3% (12.4-14.2)	14.9% (13.9-15.9)
100% ascertained	0.00 years	unknown	unknown	unknown
«Ad-hoc»				
k_1*	8.40 years	5.9% (5.4-6.5)	8.9% (8.1-9.6)	11.5% (10.7-12.4)
k_2*	8.86 years	6.3% (5.7-6.9)	9.4% (8.7-10.2)	12.3% (11.4-13.2)
k_3*	3.46 years	6.7% (6.0-7.3)	10.1% (9.3-10.8)	13.2% (12.2-14.1)

†The lower the better.
‡post ART initiation.
*Simulated data $(\bar{k}_1, \bar{k}_2, \bar{k}_3) = (9.98, 12.16, 12.59)$; Malawi data $(k_1, k_2, k_3) = (12.56, 14.07, 15.98)$.

WEPEC311

Mapping and size estimation of hidden key populations in low-income setting

K. Deuba[1], U. Shrestha[1], B. Rawal[2], R. Khanal[1], B.D. Pandey[2], T. Paudel[3], R.K. Bhattarai[4], A.M. Ekstrom[5]
[1]National Centre for AIDS and STD Control/ Global Fund Programs, Kathmandu, Nepal, [2]National Centre for AIDS and STD Control, Ministry of Health, Kathmandu, Nepal, [3]Former Chief Specialist, Ministry of Health, Kathmandu, Nepal, [4]Save the Children, Kathmandu, Nepal, [5]Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden

Background: Most of the low-income countries experiencing concentrated HIV epidemic lack information about key populations (KP), including people who inject drugs (PWID), men who have sex with men (MSM), transgender (TG) and female sex workers (FSW) because they are hidden and marginalised in society and remain undocumented. There are many approaches to size estimation. Among them, mapping or census is particularly useful when local estimates are needed for planning and monitoring of programmes.

Methods: The mapping exercise among MSM, TG, PWID and FSW was carried out in 44 districts of Nepal between July and November 2016. Then mapping exercise was done collecting relevant information directly from hotspots where the key population members congregate. Key informant interviews were carried out among KP members as well as non-key population key informants who were familiar with the local situation in and around the hotspots. The key informants associated with each hotspot were interviewed to obtain the estimated number of KP who visit that hotspot on a weekly basis and to learn about the frequency of their visit to hotspots and patterns of mobility to other hotspots in the same district. The data collection was carried out. Adjustment factors (mobility adjustment, frequency adjustment and invisibility adjustment) were sequentially applied.

The data analysis procedures were based on stratification and extrapolation, to estimate the number of KP in mapped and unmapped districts and the entire country.

Results: The national estimate of FSW is minimum 43,829 and maximum 54,207. The national estimates of MSM/TG are minimum 88,009 and maximum 112,150 of which minimum 18,704 and maximum 24,216 are TG, and minimum 53,373 and maximum 67,292 are MSM. The national estimate of PWID is minimum 27,248 and maximum 34,487. Among them, minimum 24,572 and maximum 30,561 are men, and minimum 2,676 and maximum 3,926 are women.

Conclusions: The size of KP provided through mapping exercise can be utilised for target setting and a measure of program coverage. Major limitation is that mapping may count the majority of KP who visit hotspots on a very regular basis and miss to count another subset who did not visit or less frequently visit the hotspots.

WEPEC312

Maternal HIV does not affect children's resiliency from birth to 5 years: Moving to a rural setting is protective

M.J. Rotheram-Borus[1], J. Christodoulou[1], P. Hayati Rezvan[1], W.S. Comulada[1], E. Almirol[1], M. Tomlinson[2]
[1]*University of California, Department of Psychiatry and Biobehavioral Sciences, Semel Institute, Los Angeles, United States,* [2]*Stellenbosch University, Department of Psychology, Stellenbosch, South Africa*

Background: "Resiliency" is often assessed in high-income countries using cross-sectional samples based solely on children's behavior. Using a multidimensional definition over time, this study follows a population of South African children over the first five years of life to determine the impact of Mothers Living with HIV (MLH) and a home visiting intervention on resiliency.

Methods: Almost all pregnant women (98%; N=1238; n=354 MLH) in 24 matched neighborhoods in Cape Town townships were recruited and randomized by matched neighborhood clusters to:
(1) standard care; or
(2) paraprofessional home-visiting.
Six assessments were conducted during pregnancy, at 2 weeks, 6, 18, 36, and 60 months post-birth with 83%-94% follow-up rates. Over time, 36% of households migrated to rural settings. At each assessment, resilient children were: within 2 SD on each WHO growth measure; within 1 SD on each measure of cognitive functioning; and not deviant on the Achenbach Child Behavior Checklist scales. Sociodemographic, maternal stressors, child protective factors, neighborhood, and intervention condition were examined as predictors of child resiliency over time using t-test for continuous variables and chi-square for categorical variables.

Results: Seventeen percent of children were resilient over time, similar across children of MLH (19% resilient) and non-MLH (16% resilient) and intervention conditions. Food insecurity was associated with reduced resilience. Mothers with higher income, less depression, alcohol use, and intimate partner violence, and without a live-in partner, were significantly more likely to have resilient children. Breastfeeding and attending a preschool crèche were unrelated to resiliency. Three neighborhood clusters (n=6 neighborhoods) had unusually low percentages of resilient children (11%), and one cluster (n=2 neighborhoods) had a higher percentage (27%). Children from resilient neighborhoods were more likely to migrate and be raised by their mothers in the rural Eastern Cape.

Conclusions: The children of MLH were equally likely to be resilient and their predictors similar to their peers without HIV. Moving to the Eastern Cape and being raised by one's mother are protective. Examining children's resiliency over time based on measures from multiple domains is an important methodological advance, especially in lower and middle income countries.

WEPEC313

Estimating the population size of female sex workers in Kampala, Uganda, using three-source capture-recapture

K. Apodaca[1], R. Doshi[1], M. Ogwal[2], R. Bain[1], E. Amene[1], H. Kiyingi[3], A. McIntyre[1], W. Hladik[1]
[1]*Centers for Disease Control and Prevention, Atlanta, United States,* [2]*School of Public Health, Makere University, Kampala, Uganda,* [3]*Centers for Disease Control and Prevention, Kampala, Uganda*

Background: Understanding the HIV epidemic among female sex workers (FSW) is dependent on reliable population size estimates; however, no gold standard size estimation method for 'hidden' populations exists. Two-source capture recapture is a commonly used method, but is subject to stringent assumptions. This method utilizes a capture stage where individuals are sampled, tagged and then resampled. We piloted three-source capture-recapture (3S-CRC), which relaxes the assumption of independence of captures, to estimate the number of FSW in Kampala, Uganda.

Methods: In October 2017, FSW were sampled during three captures and "tagged" by offering them a bracelet for capture 1, and a mirror for capture 2. No items were distributed for the third capture. FSW were defined as women, 15 years or older, and selling sex to men. All captures were completed one week apart to minimize the impact of migration in and out of Kampala. FSW sampled during captures 2 and 3 were asked if they had received the distributed object(s). The proportions of FSW receiving a bracelet, mirror, or both were calculated. Total FSW estimates were produced by fitting different log-linear models to 2^k contingency tables, Statistical analyses were conducted using the package Rcapture in R version 3.4.3 which fits multiple models at the same time.

Results: We sampled 962, 965, and 1417 FSW in captures 1, 2, and 3, respectively. There were 316 recaptures between captures 1 and 2, 214 recaptures between captures 2 and 3, and 235 recaptures between captures 1 and 3. There were 109 FSW captured in all three rounds. Estimates of FSW vary based on model selection shown in Table 1. The base model (M_0), which did not account for time of capture or heterogeneity among FSW, was 5,282 (5000, 5591). Chao, Poisson, and Darroch model estimates were 6063(5644,6532), 9212 (7832, 10941) and 15298 (11448, 20760), respectively.

Conclusions: The most conservative estimate is the M_{th} Chao which provides a lower bound for the FSW population in Kampala. Adding additional captures could improve model stability. We employed 3S-CRC to estimate FSW size in Kampala and provided critical denominator data for planning HIV prevention, care, and treatment programs.

WEPEC314

Probabilistic recorded linkage as a tool to improve TB-HIV coinfection surveillance in Brazil

K. Andrade[1], C.O. Dantas[2], D.M. Pelissari[2], M.S. Rocha[2], L.A. Nascimento Júnior[2], P.O. Bartholomay[2], D. Arakaki[2], R.A. Ribeiro[3], R. Coelho[3], A.R.C.d. Cunha[3], G.F.M. Pereira[3]
[1]*Ministry of Health, National Tuberculosis Programme, Brasilia, Brazil,* [2]*National Tuberculosis Programme / Ministry of Health, Department of Communicable Disease Surveillance, Brasilia, Brazil,* [3]*Ministry of Health, National Aids Department, Brasília, Brazil*

Background: Brazil is in two of the three high burden countries list from WHO - tuberculosis (TB) and TB-HIV coinfection. Underreporting of diseases that are relevant to public health is a major challenge for health surveillance since it compromises the evaluation of the magnitude of these diseases. This study aims to analyze the underreporting of HIV/AIDS cases in the National Information Systems in Brazil, as well as qualify the surveillance of TB-HIV coinfection.

Methods: It is a descriptive cross-sectional study. A probabilistic recorded linkage was performed between the databases of the Notifiable Disease Information System (Sinan) to TB (2011-2014) and the database from the Department of Sexually Transmitted Disease, AIDS and Viral Hepatitis (DIAHV) with all HIV/AIDS cases reported to Sinan-AIDS, Mortality Information System, Laboratory Exams Control System, and Logistic Control System for Medications. It is an operational research conducted using routine data which waives the Ethical Committee review.

Results: 29,490 new cases coinfected with HIV were reported in Sinan-TB. Of These, 19,243 linked to the consolidated database of DIAHV. To qualify information on TB dataset, those patients reported in the Sinan-TB with information about HIV filled as "negative", "being processed" and "not performed" but linked to DIAHV dataset as having a known HIV/AIDS positive status had their information updated. 1,449 TB patients had their information updated. According to Sinan-TB, for the years of 2011, 2012, 2013 and 2014, the coinfection rates were 9.8%, 9.8%, 9.9% and 10.1%, respectively. After the linkage, these percentages increased to 10.3%, 10.4%, 10.5% and 10.6%, respectively. About underreporting, 10,247 TB cases had a positive HIV test, but were not linked to the consolidated database from DIAHV. According to year of TB diagnosis, in 2011, 2012, 2013 and 2014, there was 3,198; 2,413; 2,398; and 2,238 HIV underreported cases.

Conclusions: These expressive numbers of underreported HIV/AIDS cases are people who are constantly in health facilities without being notified in the HIV/AIDS systems, and consequently, without starting their HIV/AIDS care. These findings are being used by the National Tuberculosis Programme and the DIAHV to discuss and delineate joint actions and recommendations to tackle both diseases.

WEPEC315

On estimating the number of people with known HIV positive status for the UNAIDS 90-90-90 targets

G. Nguefack-Tsague[1], S.C. Billong[2], O.W. Tiemtore[3], A. Zeh[2], A. Wade[3], I. Diallo[4], E. Mvilongo[2], R. Fodjo[2], B. Bongwong[1], M.N. Ngoufack[5], Y. Ndowa[6], H. Diallo[6], B. Clary[6], J. Ze Minkande[1], L. Zekeng[7], J.B. Guiard-Schmid[3], J. Zhao[6], J.B. Elat-Nfetam[2]

[1]University of Yaounde 1, Faculty of Medicine and Biomedical Sciences, Department of Public Health, Yaounde, Cameroon, [2]Ministry of Public Health, National AIDS Control Committee, Yaounde, Cameroon, [3]Dispositif d'Appui Technique - Afrique (DAT-Afrique), Initiatives Conseil International-Santé (ICI-Santé), Ouagadougou, Burkina Faso, [4]CHU-Yalgado, Hôpital de Jour, Ouédraogo, Burkina Faso, [5]Centre International de Reference Chantal Biya, Yaounde, Cameroon, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland, [7]UNAIDS, Dar es Salaam, Tanzania, United Republic of

Background: In 2014, the Joint United Nations Program on HIV and AIDS (UNAIDS) and partners set the '90-90-90' targets by 2020. While UNAIDS SPECTRUM Software estimates the number of people living with HIV/AIDS (PLHIV), many countries including sub-Saharan countries are facing the challenge of estimating the 1st 90. Many methods have been proposed for this purpose, some of them using cumulative number of people tested HIV+; with difficulties to account for duplication as a major setback. Our objective was to propose an alternative modelling procedure, and to discuss its appropriateness to account for duplication, especially in the absence of a unique identifier code.

Methods: Starting from a base year, the number of HIV+ tests per year was obtained by summing all positive tests for each entry point. The cumulative crude number of positive tests for a year was obtained by summing up positive tests of current and preceding years. In addition to adjusted parameters such as *the false positive rate*; the *probability of death and the permanent emigration of a tested HIV+*; we proposed two additional parameters: *the probability for an HIV+ person being re-tested positive* and *the average number of HIV+ tests*. The uncertainty of the adjusted estimate was assessed using the plausibility bounds under Poisson distribution. Sensitivity analyses were performed and a representative national survey carried out to estimate model parameters.

Results: Sensitivity analysis showed that the *average number of HIV+ tests* was the most important parameter that accounted for duplication. In Cameroon, SPECTRUM in 2016 estimated 560 000 PLHIV. From the '90-90-90' targets, 90% (504 000) of PLHIV had to know their status. Applying this model from 1987 to 2016, we estimated that the first 90 was 75.5% (380 540/504 000) i.e. 380 540 (95%CI: 379 100-381 517) PLVIH knew their status, thus a gap of 123 460 (95%CI: 122 773-124 150) PLHIV.

Conclusions: Our analysis proved that the model appropriately accounted for duplication and can be applied to countries facing similar challenges. In addition to determining the gap, efforts should be made to understand its associated factors and to implement correct measures to create HIV testing demand.

WEPEC316

Development of a nationally representative HIV patient survey: Experiences from the Positive Voices survey in the United Kingdom

M. Kall, V. Delpech, Positive Voices Study Group

Public Health England, HIV/STI Department, London, United Kingdom

Background: As the paradigm of HIV service models increasingly shifts toward patient-centred care, the continual collection of the patient-reported outcome and experience data required to inform and evaluate these services poses a unique challenge to those responsible for routine HIV surveillance. We present the methods of a new national HIV patient survey designed to be routinely implemented as part of routine national surveillance, yielding good response rates while requiring minimal resources to run.

Description: The concept of using surveillance records as a national sampling frame was tested and proven effective through statistical sampling tests. The survey method and questionnaire was developed through iterative, participatory methods under the guidance of an Advisory Group including patient representatives, clinicians, academics, commissioners and civil society. A phase of formative research of qualitative interviews with HIV patients and HIV clinic staff was used to identify the most feasible and acceptable methods to deliver the survey. Following this, in 2014 a pilot study was run in 30 clinics, whereby a random sample of patients attending for HIV care were recruited in clinic to complete a questionnaire. Findings from the pilot informed the national scale-up of the survey in January - September 2017, which achieved a sample of 4,416 (51% response rate) included the following key methods: - Unconditional £5 high street voucher - Choice of online or paper response formats - Research approvals which gave access to flexible workforce, particularly useful for large clinics - 6 month recruitment period - Email and post options.

Lessons learned: With sufficient investment of time, funding and synergistic working with multiple stakeholders, a good response rate is achievable for clinic-based recruitment of HIV patients to achieve generalisable national estimates of key patient health and outcome data using national surveillance records as a sampling frame. Low denomination, unconditional monetary vouchers are cost-effective to boost response rates particularly in traditionally underrepresented groups.

Conclusions/Next steps: The survey data will be cleaned, weighted and top-line findings reported in Spring 2018. Funding has been secured for a community led analysis which will explore in-depth issues relevant to people living with HIV through a series of workshops, culminating in a Community Report.

Novel research designs for HIV prevention in the era of PrEP/PEP

WEPEC317

The use and likelihood of using, PrEP among men who have sex with men (MSM) in Europe and Central Asia: Findings from a large Hornet/ECDC survey

A. Bourne[1], A. Pharris[2], A. Garner[3], G. Spiteri[2], B. Alba[1], T. Noori[2]
[1]Australian Research Centre in Sex, Health & Society, La Trobe University, Melbourne, Australia, [2]European Centre for Disease Prevention and Control, Stockholm, Sweden, [3]Hornet Gay Social Network, California, United States

Background: Currently, seven European countries provide HIV pre-exposure prophylaxis (PrEP) through public health services, although there are numerous reports of off-licence use. The objectives of this study were to examine current use of PrEP, likelihood of future use, and indicators of potential PrEP candidacy in an opportunistic sample of European MSM.

Methods: The European Centre for Disease Prevention and Control and Hornet Gay Social Network sent out a questionnaire in eight languages to users of the Hornet application between 17 June and 16 August 2017. Descriptive statistics present proportions and Chi-square analysis to determine factors associated with PrEP use.

Results: Of the 12,053 responses received from 55 countries in Europe and Central Asia, 10.7% had diagnosed HIV. Among HIV negative/untested men, 10.1% (n=1,071) were currently taking PrEP, or had done so within the previous three months. Current or recent PrEP users were significantly more likely to have taken post-exposure prophylaxis (PEP) (OR=15.66, 95%CI [13.17, 18.62]) or received an STI diagnosis (OR=4.56, 95%CI [3.82, 5.44]) in the previous 12 months, or engaged in chemsex within the previous 3 months (OR=7.27, 95%CI [5.99. 8.82]) than those who had not. Most commonly, men obtained PrEP from a physician (34.0%), the internet (30.3%) or friends (12.1%); 33.8% had not disclosed PrEP use to their doctor. Men reporting happiness with their sex life were more likely to have taken PrEP (OR=1.77, 95%CI [1.63, 1.93]). Nearly a quarter (22.0%) of those not on PrEP said they were likely to use it in the next six months, particularly if they had taken PEP or been diagnosed with an STI in the last 12 months, or engaged in chemsex in the last 3 months

Conclusions: These findings indicate that the majority of men using PrEP are appropriately assessing their sexual risk. Similarly, men expressing a likelihood of using PrEP in the future report sexual behaviours in line with common PrEP prescribing guidance, indicating accurate risk perception. A large proportion of men are accessing PrEP outside of traditional healthcare settings, posing a challenge for routine monitoring. A clear association between PrEP use and sexual happiness suggests a promising route for demand creation interventions.

WEPEC318

Is prevalence of early HIV-infection at baseline correlated with HIV incidence: An analysis of 10 PrEP trials

G. Antoni[1], C. Pintado[2], C. Delaugerre[3,4], L. Meyer[1,5,6], J.-M. Molina[2,7]
[1]INSERM, SC10-US19, Essais thérapeutiques et Maladies Infectieuses, Villejuif, France, [2]Assistance Publique des Hôpitaux de Paris, Hôpital Saint Louis, Maladies Infectieuses, Paris, France, [3]Assistance Publique des Hôpitaux de Paris, Hôpital Saint Louis, Virologie, Paris, France, [4]Université Paris Diderot, INSERM U 941, Paris, France, [5]Assistance Publique des Hôpitaux de Paris, Hôpital Bicêtre, Le Kremin Bicêtre, France, [6]University Paris Sud, INSERM, U 1018, Le Kremin Bicêtre, France, [7]Université Paris Diderot, INSERM U941, Paris, France

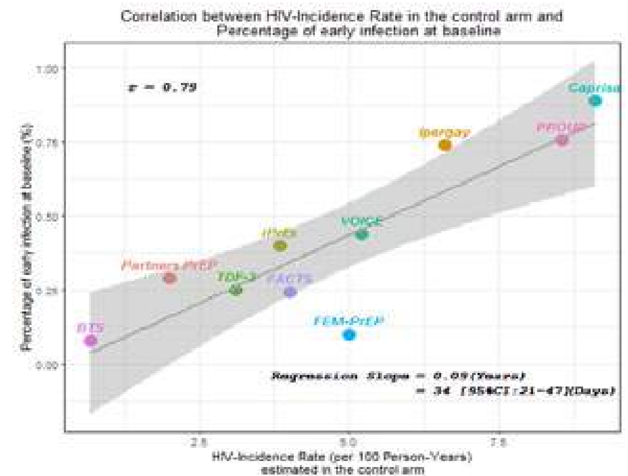
Background: Due to the high efficacy of PrEP with TDF/FTC in high risk individuals, the assessment of new preventive interventions is challenging since a control arm without PrEP would be unethical. Therefore, it would be critical to have a good estimate of HIV incidence in the population. We wished to assess in an exploratory analysis using data from previous PrEP trials, whether the prevalence of early HIV infection at baseline would correlate with HIV incidence in the control arm. The goal would be to establish a surrogate of the "natural" HIV infection risk in a population enrolled in a prevention trial.

Methods: We reviewed data from 10 PrEP trials conducted among high risk MSM, young women, heterosexual men and IVDUs in high and low income countries. We used HIV incidence in each trial estimated in the placebo or the deferred arm. The prevalence of early HIV infection at baseline was measured by the percentage of subjects with both a negative rapid point of care antibody HIV test and a positive plasma HIV-RNA . Data from each trial were plotted to assess the Spearman correlation coefficient (r); the regression slope was used to estimate the mean duration of early HIV infection, according to the relationship:

$Prevalence_{\text{early infection}} \approx Duration_{\text{early infection}} * Incidence\ Rate_{\text{infection.}}$

Results: Data from the following placebo-controlled (Caprisa 004, Iprex, Partners PrEP, TDF-2, FACTS, Fem-PrEP, VOICE, BTS, IPERGAY) and immediate vs deferred (PROUD) PrEP trials were used (Figure 1). Correlation between HIV incidence without PrEP and the prevalence of early HIV-infection at baseline yielded an r coefficient of 0.79 (p=0.01). Mean duration of early HIV infection was estimated at 34 days (95% CI: 21-47).

Conclusions: In this exploratory analysis, a strong quantitative relationship was found between the prevalence of early HIV-infection at baseline and HIV incidence without PrEP during follow-up. In addition, this analysis provided a good estimate of the duration of early HIV-infection. These results could be valuable for future prevention trials to evaluate natural HIV incidence and to better interpret the efficacy of the intervention tested.



[Figure. Correlation between HIV-Incidence Rate in the control arm and Percentage of early infection at baseline]

Capacity building for epidemiological and prevention research

WEPEC319

Religion a structural platform for HIV intervention in Abia State Nigeria

K.N. Igbojionu[1], D.E.O. Igbojionu[1], E. Okey-Uchendu[2]
[1]Zinnok Initiative for Women and Children, Umuahia, Nigeria, [2]National Agency for the Control of Aids, Programme, Abuja, Nigeria

Background: With an estimated 3.4 million people living with HIV/AIDS, Nigeria ranks second in terms of HIV/AIDS disease burden in Africa. Although Nigeria's epidemic is generalised, it experiences concentrated epidemics among key populations. Religious leaders are key gatekeepers in the HIV programming in Nigeria. Most Nigerians are very religious and belief greatly in the pronouncements of their religious leaders. They are either Muslims or Christians and only few Nigerians are neutral about their religions. Zinnok Initiative for women and children therefore saw religion as a structural platform for HIV interventions in Abia State.

Description: Zinnok advocates to religious leaders in the state to include brief messages on HIV during their sermons. HIV testing services are also carried out during big festivities and positive clients are linked to HIV services sites within the state. Abia state is a predominately Christian state but there are few Muslims as well. Zinnok advocacies are carried out to both Muslims and Christian bodies. Zinnok get permission from these religious bodies to have talks on HIV, prevention, treatment and care. Mothers are also educated out PMTCT services and are encouraged to register for anti-natal care. Issues about stigma and discrimination are also addressed during these programme. It also services as an opportunity to reach the Adolescent and Young person (AYP) with effective HIV prevention strategies.
Lessons learned: Most religious leaders misguide the members due to ignorance on HIV/AIDS issues. The engagement of religious leaders by Zinnok Initiative for women and children served as an opportunity to reach the religious leaders with effective HIV awareness messages on HIV prevention, treatment and care. The religious leaders are now able to make informed decisions and guide their members rightly. They also know about the available HIV service centers. They have served as effective stakeholders in Zinnok HIV programming with the state.
Conclusions/Next steps: The religious leaders help in ensuring messages on HIV gets to the individuals, family&community members. Organisations should see them as partners in achieving the 90:90:90 target. There should therefore be opportunities to intentionally carry them along in order to reduce new infections&ensure more people are on treatment.

Community involvement and good participatory practice in epidemiological and prevention research
