[1]Center for Integrated Health Programs, Clinical Services Unit, FCT, Nigeria, [2]Center for Integrated Health Programs, Clinical Services Unit, Abuja, Nigeria, [3]Center for Integrated Health Programs, Quality Improvement, Abuja, Nigeria, [4]Center for Integrated Health Programs, CSU, Benue State, Nigeria, [5]Center for Integrated Health Programs, Strategic Information Unit, Abuja, Nigeria, [6]Center for Integrated Health Programs, CSU, Abuja, Nigeria, [7]CIHP, State Coordination, Benue State, Nigeria, [8]Benue State Ministry of Health, PMTCT Unit, Benue State, Nigeria, [9]CIHP, Strategic Information Unit, Abuja, Nigeria, [10]CIHP, Chief Executive Officer, Abuja, Nigeria

Background: Antenatal care represents a vital component of efforts to prevent mother to child transmission of HIV (PMTCT). Unfortunately, only 61% of pregnant women in Nigeria have a first Antenatal Care (ANC) visit and PMTCT coverage is only 30%. Low uptake of ANC negatively impacts on coverage of PMTCT services accessed in the ante natal setting. In response to this challenge, the Centre for Integrated Health Programs (CIHP), Nigeria with funds from CDC implemented a community program aimed at getting HIV positive pregnant women into the PMTCT program through ANC registration.
Description: The program took place in March and April, 2017 in four Local Government Areas of Benue state, Nigeria. A hot spot analysis was done using program data, and 24 communities were identified to have a HIV prevalence of 4.1% and above. Targeted community mobilization was carried out with participation of 51 health facilities which served these communities. Community volunteers were selected using a set criteria and worked with Local government focal persons and health workers to mobilize pregnant women. Pregnant women were informed of the program and attached incentives. Community structures were used to facilitate mobilization with announcements made through town criers and churches. Women interested in participating were directed to participating health facilities where they were registered for ANC.
Lessons learned: At the end of the four week activity, ANC registration in the 51 facilities increased by 46.9% from 2,203 in the four weeks preceding the intervention to 4,151.A total of 267 (6.4%) pregnant women who booked for ANC through the program were found to be HIV positive. Out of the HIV positive pregnant women, 186 (69.6%) were found to be previously known to be HIV positive and accessing antiretroviral therapy (ART). However, they were not accessing antenatal care and by extension, full package of PMTCT services prior to the program.
Conclusions/Next steps: Pregnant women with known HIV positive status accounted for over 50% of identified positive pregnant women not utilizing antenatal services in this setting. Targeted mobilization at community and ART clinics could improve their utilization of antenatal and PMTCT services.

WEPEC321

Perspectives on social media and technology use for HIV research among young adults in the pediatric HIV/AIDS cohort study

C. Berman[1], D. Kacanek[2], M. Nichamin[1], D. Wilson[1], M. Reznick[3], M. Davtyan[4], K. Tassiopoulos[1], K. Patel[1], S. Allison[5], J. Bauermeister[6], S. Lee[7], M. Paul[8], D. Siddiqui[9], T. Aldape[8], G. Seage III[1]
[1]Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States, [2]Harvard T.H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [3]Westat, Rockville, United States, [4]University of Southern California Los Angeles, Los Angeles, United States, [5]National Institute of Mental Health, Division of AIDS Research, Bethesda, United States, [6]University of Pennsylvania, Philadelphia, United States, [7]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Maternal and Pediatric Infectious Disease Branch, Bethesda, United States, [8]Baylor College of Medicine, Houston, United States, [9]Tulane University School of Medicine, New Orleans, United States

Background: There has been little research regarding the preferences and willingness to use social media and other digital technologies in HIV-related research among young adults who have perinatally-acquired HIV infection (PHIV) or who were perinatally HIV-exposed but uninfected (PHEU).
We investigated these preferences among PHIV and PHEU young adults at clinical sites participating in the Pediatric HIV/AIDS Cohort Study (PHACS) Adolescent Master Protocol (AMP).
Methods: Between 2013 and 2014, we conducted 6 focus group discussions and 6 in-depth interviews (IDIs) with PHIV young adults (n=37) and 7 IDIs with PHEU young adults at 8 clinical sites across the US. Participants were queried about their perceptions and experiences regarding social media and digital technology, adulthood, and participation in a longitudinal HIV study, and completed a brief self-administered survey about their demographic characteristics and technology use. Thematic analysis of coded transcripts was conducted using Atlas.ti, a qualitative data analysis software.
Results: Study participants (ages 18 - 24, 65% female, 63% Black, 38% Hispanic) reported frequent use of various social media and digital technologies in their personal lives. This use depended on a variety of factors, including norms within their social networks, access to technology and the Internet, concerns about online privacy and confidentiality, and HIV stigma.
Some participants also reported reluctance to use digital technologies for communicating about HIV research (Table 1), citing concerns of inadvertent disclosure due to device sharing and/or faulty privacy settings on social media platforms.
Participant motivation to continue in HIV research was partly based on longstanding, close relationships with their pediatric providers; participants were divided in whether their trust in individual providers would increase willingness to use social media and digital technologies, providing important context for considering effective retention strategies.
Conclusions: Although personal use of social media and digital technologies among our study population was high, the willingness to use these media within the context of HIV research varied widely, and this was due primarily to fear of experiencing HIV stigma via inadvertent disclosure of

their status. A flexible approach offering tailored options for communication and privacy among young adults participating in HIV research is essential when considering retention strategies.

WEPEC322

Recruiting and retaining high-risk Black/African-American men who have sex with men (MSM) and transgender women (TW) for HIV testing studies in New York City

G. Ortiz[1], D. Lucy[1], V. Frye[2], M.Q. Paige[1], D. Usher[1], L. Wilton[3], H.V. Tieu[1,4], B. Koblin[1]
[1]New York Blood Center, Project ACHIEVE, New York, United States, [2]City University of New York School of Medicine, Community Health and Social Medicine, New York, United States, [3]Binghamton University, Binghamton, United States, [4]Columbia University Medical Center, Infectious Disease, New York, United States

Background: New HIV cases disproportionately affect Black or African-American gay, bisexual, and other men who have sex with men (MSM) and Transgender Women (TW) in New York City (NYC). In 2016, 71% of new HIV diagnoses among men were MSM; 40% were Black or African-American. Increasing consistent HIV testing is crucial to HIV prevention, but the knowledge base is not well-developed.

Description: Project ACHIEVE of the New York Blood Center recently conducted two studies ("TRUST" and "All About Me") designed to test interventions to increase HIV testing and/or consistent testing among young, Black/African-American, at-risk MSM and TW. TRUST required participants to HIV test with a friend. We describe here methods used to recruit successfully the samples (N=613) and retain >85% of the samples over 6- to 12-month follow-up periods.

Lessons learned: The greatest facilitators of recruitment included: consistent presence of key study team members; making strong, personal connections in the House/Ball and KiKi communities face-to-face and on-line (Facebook) and via ball category sponsorship; transforming the clinic site into a safe and resource-rich space where material and support needs were met; adapting study procedures if enrollments decrease; holding a number of "open houses" at the site and local gay spaces where enthusiasm for research was generated; engaging a simple and remunerated referral system; reimbursing staggered enrollment steps; and offering a range of reimbursement options (cash, gift card, etc.). Barriers to recruitment included difficulty finding "trusted" friends and overly-complicated eligibility criteria and enrollment procedures for TRUST. Retention requires intense staff time and effort. Major barriers include: unstable housing; frequent change in contact information. Facilitators include using social media to stay in close contact. In both recruitment and retention, it was crucial that staff reflected the focal population, which built trust and credibility.

Conclusions/Next steps: Recruiting and retaining at-risk samples is challenging and context-specific. The TRUST and All About Me teams met enrollment and, to date, retention targets by being flexible, sensitive and creative. Most important is treating all participants as individuals and with respect, kindness and patience. Consistency in staff contributes to success, as does constant analysis and adjustment of methods used.

WEPEC323

A large-scale study on the sexual health of young people aged 12 to 25 in the Netherlands: The added value of a participatory action research approach

M. van den Borne[1], S. Meijer[1], I. van der Vlugt[2], H. de Graaf[2]
[1]STI Aids Netherlands, Amsterdam, Netherlands, [2]Rutgers, Utrecht, Netherlands

Background: Participatory action research (PAR) is a powerful strategy to advance both science and practice by conducting the whole research process in partnership with stakeholders. Participation of stakeholders creates shared ownership of knowledge and commitment towards action based on the results. Sex under the age of 25 is a large-scale study on the sexual health of youngsters aged 12 to 25 in the Netherlands based on the principles of PAR.

Description: More than hundred stakeholders from research, practice and policy of sexual health promotion were included throughout the entire research process; from sexologists to youth experts. Stakeholders were involved by means of interviews, surveys, mailings and a work conference. Based on their input the questionnaire was adapted whereby stakeholders needs for specific insights into youngsters sexual health were fulfilled. Moreover, fifteen of the twenty-five Municipal Health Services (MHS) invested in expanding the research within their own region for local representative data. The collaboration with the MHS have led to a total number of 20.500 youngsters participating in Sex under the age of 25. In collaboration with stakeholders the most important outcomes were identified and following actions within their field of sexual health promotion were formulated. These actions were integrated in a national widely supported action plan to improve the sexual health of youngsters.

Lessons learned: The participation of multiple stakeholders made it possible to capture more aspects of sexual health promotion and broadened the perspective of the researchers. The collaboration with the MHS have led to a large scope of results; not only serving the national level but creating local insights as well. Results which enables the regions to adjust sexual health promotion to local needs.

Conclusions/Next steps: In contrast to many other studies is, by use of the PAR-approach, a bridge created between science and practice. Enabling professionals to target their action, by including their needs for specific insights, leads to a more tailored strategy of sexual health promotion for youngsters in the Netherlands. The unique participating role of the MHS created the possibility to further increase the effectiveness of these actions based on local data and by local agents.

WEPEC324

What women want: Branding a new HIV prevention vaginal ring using a user-centric design approach

A. Ismail[1], S. Magni[1], S. Chan[1], B. Dube[1], M. Rampedi[1], L. Solai[2], S. Tenn[2], N. Sutton[2,3]
[1]Genesis Analytics, Health, Johannesburg, South Africa, [2]International Partnership for Microbicides, Silver Spring, United States, [3]Johnson & Johnson Global Public Health, New Brunswick, United States

Background: As an increasing number of HIV prevention medicines are developed, the challenge lies not only in their supply, but ensuring uptake. Uptake is often influenced by the branding of medical products, however, end-users are not always consulted. The International Partnership for Microbicides is submitting the Dapivirine Vaginal Ring (DVR) for regulatory approval. To ensure that the branding is culturally appropriate, acceptable and appealing, we tested potential names and packaging designs with end-users.

Methods: We undertook focus group discussions (FGDs) in high HIV burden countries for both the naming (Malawi, South Africa, Uganda and Zimbabwe) and packaging studies (South Africa and Uganda).

FGDs were conducted in rural and urban areas with women aged 18-45 years. In total, 507 end-users were consulted. Eight names and six packaging designs were tested by participants ranking their top preferences and participating in an open discussion. Results were analysed thematically.
Results: There were names that were found to be culturally inappropriate, had negative connotations or could be misinterpreted for another product and were thus disliked by participants across all countries. Names that were liked across the countries were those that referred to the drug or the ring. A difference in packaging preferences was noted between countries. In South Africa, groups attached importance to the colour and size of the logo, and preferred the bright and bold packaging, whereas participants in Uganda preferred the less colourful, subtle, conservative packaging. The Ugandan participants also stated the importance of a design that would be recognisable and accessible to those with less formal education. In both countries, participants emphasised the need for a smaller box that would fit into their purse
Conclusions: Branding preferences vary between countries due to cultural norms, social context and language differences. Prior to introducing new medical products, consultations with end-users are crucial for uptake. Testing the DVR branding has effectively shown how understanding consumer preferences for product branding could influence its use. We suggested a branding option that resonates with a majority of the end-users across countries. Alternatively, product developers can develop country specific branding.

Harnessing big data for epidemiological research/digital epidemiology

Supervised machine learning to predict HIV outcomes using electronic health record and insurance claims data

J. Semerdjian[1], K. Lykopoulos[2], A. Maas[1], M. Harrell[1], J. Priest[3], P. Eitz-Ferrer[3], C. Wyand[4], A. Zolopa[3]
[1]Roam Analytics, San Francisco, United States, [2]ViiV Healthcare, Global, London, United Kingdom, [3]ViiV Healthcare, US, RTP, United States, [4]Optum Life Sciences, Boston, United States

Background: The HIV care continuum in the US is still short of achieving the UNAIDS target. Learning predictors for HIV outcomes may facilitate interventions that improve patient care. We aimed to learn predictors for viral suppression, retention, linkage to care and antiretroviral therapy (ART) adherence and discuss 1) the application of machine learning methods to predict HIV patient outcomes and 2) opportunities for HIV care improvement derived from HIV outcome predictors.
Methods: We selected HIV patient cohorts from a set of electronic health records (EHR) data and administrative claims data from Optum's de-identified Integrated Claims-EHR dataset (2007-2016). We measured patient viral suppression, retention, linkage to care and adherence and constructed separate models for each. Cohorts for the four outcome measures ranged from 2,062 to 22,649 patients (Table 1).
Outcome measures were determined from medication refills, diagnostic codes, lab results, and patient encounters. We extracted demographic, medical (comorbidity, medications, provider specialty) and encounter features from patient data. We used natural language processing methods to learn clinical text features, which include phrases recorded in provider written patient notes.
To further explore data derived from clinical text, we built a word embedding that visualizes co-occurrence patterns of clinical text (Figure 1). We applied supervised machine learning methods via penalized logistic regression to predict outcome measures.
Results: Our best model predicts HIV suppression with a 0.84 AUC (TABLE-1). We compared model AUC values generated using bootstrapped samples from a held out test set. Models perform best with the complete ensemble of demographic, medical, and encounter features. The most significant features in predicting outcomes are the clinical text features derived with natural language processing of the EHR data. Examples of highly predictive clinical terms for HIV suppression include "migraine", "n/v", "negative anxiety", and "verruca".
Conclusions: This study achieved moderately accurate prediction for HIV outcomes by applying natural language processing and machine learning to EHR and claims data. We suggest that reliable prediction for HIV outcomes may be held in the unstructured patient notes, and can be derived from natural language processing and machine learning. We also demonstrate the validity of using these real world data for secondary use.

Models	Features	AUC	F1 Score	Feature Count	Patient Count
Retained in Care	Demographic-only	0.65	0.66	36	2,062
	Clinical text-only	0.73	0.69	1,230	2,062
	All features	0.75	0.70	1,572	2,062
Engaged in Care	Demographic-only	0.63	0.63	36	22,649
	Clinical text-only	0.73	0.68	1,242	22,649
	All features	0.75	0.69	1,572	22,649
Viral Load Suppression	Demographic-only	0.75	0.78	36	15,552
	Clinical text-only	0.83	0.83	814	15,552
	All features	0.83	0.83	1,126	15,552

Utilising clinical data systems for epidemiological and behavioural research

WEPEC326

A two-stage approach to quantify time with suppressed viral load in resource-constrained settings

J. Edwards[1], S. Hileman[2], S. Zadrozny[2], M. Seamans[3], Y. Donastorg[4], S. Weir[2]
[1]University of North Carolina, Chapel Hill, Epidemiology, Carrboro, United States, [2]University of North Carolina at Chapel Hill, Carolina Population Center, Chapel Hill, United States, [3]Johns Hopkins University, Epidemiology, Baltimore, United States, [4]Instituto Dermatológico y Cirugía del Piel, Santo Domingo, Dominican Republic

Background: Sustained viral suppression is a goal of HIV care and treatment programs. However, in resource-constrained settings, collection of viral load measurements may be logistically challenging and prohibitively expensive. Accordingly, viral load testing is often limited to patients displaying signs of treatment failure, rather than extended to all patients as part of a routine monitoring strategy, and standard methods to estimate measures related to viral suppression may be misleadingly low.

Methods: We present a two-stage design to estimate the average time patients in HIV care and treatment programs spend with a suppressed viral load in the Dominican Republic, where viral load is sometimes available through a national HIV patient monitoring system. The proposed approach uses statistical weighting to combine data available through routinely collected clinical records (stage 1) with data from a validation substudy (stage 2) that measured viral loads on a sample of patients. Under the USAID/PEPFAR-supported, FHI360-led LINKAGES Project, we applied this approach to compare the time suppressed between key populations and others in clinical care in the Dominican Republic.
Results: The target population included 12,113 patients who entered HIV care and treatment in the Dominican Republic between 1 June 2013 and 25 January 2017. The validation study included additional viral load information for 1055 of these patients. Over the 42 months after entry into care, patients spent an average of 23 months on treatment. Using the routinely collected viral load data only, we estimated that 65% of this time (15 months) was spent with a suppressed viral load (< 200 copies/mL). Using the proposed two-stage approach, we estimated that 84% of the time on treatment was spent virally suppressed (19 months). On average, female sex workers spent 1.1 (95% CI: -1.4, 3.7) fewer months suppressed than other women, and men who have sex with men spent 1.7 (95% CI: -0.7, 4.2) fewer months suppressed than other men.
Conclusions: In resource constrained settings, routinely collected viral load data are typically not missing at random. The proposed approach offers a principled and cost efficient means to account for missing viral load data when estimating viral suppression in these settings.

Conceptualizing social and structural factors and their impacts

WEPED327

Sexual objectification as a predictor of willingness to engage in sex with HIV-positive partners

H. Drake, T. Chenneville, L. Rodriguez, T. Peless
University of South Florida Saint Petersburg, Psychology, Saint Petersburg, United States

Background: Existing literature suggests that high levels of HIV-related stigma may serve as a protective factor against HIV transmission by lowering a person's risk tolerance when they encounter potential sexual partners who are HIV positive. In the age of post-exposure prophylaxis (PEP) and pre-exposure prophylaxis (PrEP) in the United States, HIV stigma levels seem to be lowering while engagement in risky sexual behaviors seem to be on the rise (Hess, Crepaz, Rose, Purcell, & Paz-Bailey, 2017). Experiences of being sexually objectified have been implicated in the rise of risky sexual behavior (Watson & Dispenza, 2014). Yet, there is limited research on objectification theory as it applies to men who have sex with men (MSM) and HIV. The present study examines the role of interpersonal sexual objectification on willingness to engage in sex when controlling for HIV-related stigma.
Methods: Data were collected via M-Turk using online survey software. The sample included 294 MSM aged 18 and older from across the United States. Participants completed the AIDS-Related Stigma Scale (ARSS), the Interpersonal Sexual Objectification Scale (ISOS), and questions about sexual behavioral intentions with a potential sexual partner with HIV. Binary logistic regression was used to analyze responses.
Results: Participants included 294 MSM ranging in age from 18-65 (M = 31.5, SD = 9.21). After controlling for HIV-related stigma, results indicated that for every positive unit change in the experience of being objectified, the willingness to have sex with a person living with HIV increased significantly. Comparative analyses showed that experiences of sexual objectification did not significantly increase the willingness to engage in sex with an HIV-negative partner.
Conclusions: These findings have important implications for both researchers and healthcare providers. Future research is needed to further explore the role of sexual objectification as an HIV risk factor for MSM. Healthcare providers should consider sexual objectification when developing interventions to prevent HIV among this high-risk population.

WEPED328

Geographies of risk: Police violence and neighborhood stress among Black men and women in the San Francisco Bay Area

S. Mackenzie[1], A. Martinez[2], M. Cerritos Rivas[3]
[1]Santa Clara University, Santa Clara, United States, [2]San Francisco State University, Department of Sociology and Sexuality Studies, San Francisco, United States, [3]Santa Clara University, Public Health Program, Santa Clara, United States

Background: Police violence and HIV are health crises that disproportionately affect Black men and women in the United States. Little is known about the impacts of environmental stress on these health problems. This study investigates if and how police violence operates as a neighborhood level stressor that impacts the physical health and well-being of Black men and women, including uptake of harm reduction behaviors.
Methods: Quantitative data were collected between October 2015 and February 2017 as part of an HIV prevention study with a mixed HIV status sample of bisexual Black men and Black women in the San Francisco Bay Area (N=231). We developed a Police Perceptions measure to assess experiences of harassment and physical violence by police officers, perceptions of law enforcement, and decision making in daily life. Harm reduction impact was assessed through two questions about intent to carry safer injection materials or condoms due to fear of police violence. We conducted bivariate analyses to assess the relationship between a modified version of the City Stress Inventory, a measure of perceived neighborhood disorder and violence, police violence, and harm reduction practices.
Results: Two thirds (68%) of the men and 40% of the women reported lifetime experiences of police harassment, and 50% of men and 20% of women report experiencing physical abuse by a police officer. Men reported consistently higher levels of police violence as well as city stress than women. Higher levels of neighborhood stress were correlated with higher rates of witnessed and experienced police violence. There is a statistically significant relationship between city stress and fear of carrying paraphernalia (0.000), and a border significant relationship between city stress and fear of carrying condoms (p=0.058).
Conclusions: Police violence and neighborhood stress impact the health and well-being of Black communities. Both witnessing and experiencing police violence in the past six months were significantly related to reducing injection and condom related harm reduction behaviors among Black men and women. Further work on police violence in relation to - and as a form of - neighborhood stress is critical to understand its impacts on harm reduction and public health.

WEPED329

Identifying social vulnerability profiles and their association with risk behaviors and HIV status among MSM in Mexico City

L. Chavira-Razo[1], S.G. Sosa-Rubi[2], L. Alexander[2,3], M. Romero[4], Z. Andrade-Romo[2], J. Segura-Diaz[5], R. Roman-Vergara[6], S. Bautista-Arredondo[1,5]
[1]Instituto Nacional de Salud Publica, Health Economics, Cuernavaca, Mexico, [2]National Institute of Public Health, Mexico, Health Economics, Cuernavaca, Mexico, [3]University of Washington, Department of Global Health, Seattle, United States, [4]National Institute of Public Health, Mexico, Cuernavaca, Mexico, [5]UC Berkeley, School of Public Health, Berkeley, United States, [6]INSPIRA Cambio A.C., Mexico City, Mexico

Background: Men who have sex with men (MSM) are disproportionately affected by the HIV epidemic in Mexico, with a prevalence of 17%, compared to 0.15% in the general population. Of MSM living with HIV, 68% are unaware of their status and responsible for 78% of new infections in this population. Social vulnerability is one of the main factors that prevents MSM from accessing HIV testing and counseling (HTC) services. This study aims to identify the association between social vulnerability profiles and engaging in risk behaviors, getting tested, and acquiring HIV among Mexican MSM.

Methods: From August 2016 to February 2017, 988 MSM were recruited in Mexico City through three community-based recruitment strategies. They completed an electronic, tablet-based survey and were invited to get tested for HIV. We used latent class analysis to identify social vulnerability profiles of MSM based on a combination of socioeconomic status, social support, and self-acceptance of sexual identity. Then, we used a multivariable model to analyze the effect of belonging to each profile on risk behaviors, time since most recent HIV test, and HIV sero-status, while adjusting for the posterior probabilities of belonging to the other profiles.
Results: We identified three profiles of social vulnerability among our sample, with a high level of inter-class differentiation (entropy=0.82). The "Self-stigmatizers" had low acceptance of their sexual orientation and were less likely to get tested for HIV (Adjusted OR [AOR]=2.64, p< 0.01). The "Poorly connected" had a weak social network and low levels of education, and were more likely to have more sexual partners (AOR=1.52, p< 0.01), and test positive for HIV (AOR=1.76, p< 0.05). The "Not vulnerable" had higher education, stronger social networks, and higher self-acceptance of their sexual orientation.
Conclusions: Social vulnerability is known to be a major impediment to seeking HTC services among MSM. Our results suggest that there are heterogeneous types of social vulnerability among the MSM community in Mexico City, and that each profile is associated with specific risk behaviors. Future HTC programs should address these distinct manifestations of social vulnerability in the community in order to more effectively reduce stigma, risky sexual behaviors, and, ultimately, HIV prevalence.

WEPED330

Paths from food insecurity to HIV treatment outcomes in a cohort of women in the us

S.D. Weiser[1], L.A. Sheira[1], K. Palar[1], M. Kushel[1], D. Merenstein[2], T.E. Wilson[3], A. Adedimeji[4], M.H. Cohen[5], A.A. Adimora[6], I. Ofotokun[7,8], L. Metsch[9], J.M. Turan[10], E.L. Wentz[11], P.C. Tien[12,13], E.A. Frongillo[14]
[1]University of California, Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States, [2]Georgetown University Medical Center, Department of Family Medicine, Washington, United States, [3]State University of New York Downstate Medical Center, School of Public Health, Department of Community Health Sciences, Brooklyn, United States, [4]Albert Einstein College of Medicine, Department of Epidemiology and Population Health, Bronx, United States, [5]Stroger Hospital, Department of Medicine, Chicago, United States, [6]University of North Carolina at Chapel Hill, School of Medicine and UNC Gillings School of Global Public Health, Chapel Hill, United States, [7]Emory University, Department of Medicine, Atlanta, United States, [8]Grady Healthcare System, Atlanta, United States, [9]Columbia University, Department of Sociomedical Sciences, Mailman School of Public Health, New York, United States, [10]University of Alabama at Birmingham, Department of Health Care Organization and Policy, School of Public Health, Birmingham, United States, [11]Johns Hopkins University, Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [12]University of California, Department of Medicine, San Francisco, United States, [13]Department of Veteran Affairs Medical Center, San Francisco, United States, [14]University of South Carolina, Department of Health Promotion, Education and Behavior, Columbia, United States

Background: Food insecurity (FI) contributes to HIV-related morbidity and mortality, but no longitudinal research has formally tested the mechanisms through which FI negatively impacts HIV-related health, particularly among women. This study tested the hypothesis that FI leads to poor HIV clinical outcomes through nutritional, mental health, and behavioral paths following our previously published conceptual model.
Methods: We analyzed longitudinal data from the Women's Interagency HIV Study, a multisite prospective cohort study of women with HIV and demographically similar HIV-negative women. Data on 8,225 observations from 1,803 HIV-positive women on antiretroviral therapy (ART) were collected biannually from 2013-2015. FI was measured with the US Household Food Security Survey Module. Outcomes included: 1) viral non-suppression; 2) CD4 cell counts (cells/mm^3); and 3) physical health status (SF-36 scale). We tested the nutritional (BMI or fruit /vegetable intake), mental health (depressive symptoms by CES-D), and behavioral (self-reported ART adherence) paths for all outcomes controlling for covariates using path analysis. We calculated the indirect effects by taking the products of the regression coefficients from adjusted mediation models that included the strongest mediator from each path, after first confirming the assumption of no interaction between FI and the mediators.
Results: Very low food security was associated with unsuppressed viral load, lower CD4 cell counts, and worse physical health (p< 0.05 for all) (Table 1). For viral non-suppression, the nutritional and behavioral paths accounted for 2.1% and 31.8% of the total effect of FI, respectively, with no significant mediation by mental health. For CD4 cell count, the mental health and behavioral paths accounted for 15.2% and 16.4% of the total effect, respectively, with no effect from the nutritional path. For physical health status, the only significant mediator was depression, accounting for 59.8% of the total effect.
Conclusions: FI influences HIV clinical outcomes via different paths depending on the outcome. ART adherence was the strongest mediator of viral non-suppression, while both adherence and depression mediated the path from FI to CD4 count. Nutritional factors played a small role. These results suggest that FI interventions should target FI and its behavioral and mental health mechanisms as a means to improve HIV clinical outcomes.

	Viral non-suppression, Adjusted Odds Ratio, 95% CI		CD4 Cell Count, β (SE)		Physical Health Status, β (SE)

[Table 1: Associations between food insecurity (FI) and HIV clinical health outcomes and test of mediating paths from FI to HIV clinical outcomes]

WEPED331

Increasing severity of food insecurity is longitudinally associated with smoking among women with and at risk for HIV in the United States

L.A. Sheira[1], E.A. Frongillo[2], K. Palar[1], J. Hahn[1], D. Merenstein[3], T.E. Wilson[4], A. Adedimeji[5], M.H. Cohen[6], A.A. Adimora[7], I. Ofotokun[8,9], L. Metsch[10], J.M. Turan[11], E.L. Wentz[12], P.C. Tien[13,14], S.D. Weiser[1]

Background: People living with HIV (PLHIV) in the United States (US), especially women, experience food insecurity at higher rates than the general US population. Furthermore, cigarette smoking among PLHIV is highly prevalent; PLHIV are 6-13 times more likely to die from lung cancer than from AIDS-related causes. Our study tests the hypothesis that 1) concurrent, past, and persistent food insecurity is associated with current cigarette smoking, and that 2) HIV seropositivity would modify this association.

Methods: Food security (FS), measured with the US Household FS Survey Module, was collected biannually from 2013-2015 among participants enrolled in the Women's Interagency HIV Study, a multisite cohort study of US women with HIV and demographically similar women without HIV. Current smoking status was assessed by self-report (non-smoker vs. smoker) at each visit. Longitudinal logistic multiple regressions with random effects were used to model the association between 1) concurrent and
2) persistent (concurrent and past) FS status and smoking status, adjusting for potential confounders.
The odds ratio for persistent FS was calculated by exponentiating the sum of the regression coefficients at the current and past (i.e. one previous) visit.

	Concurrent (1) Adjusted Odds Ratio	Concurrent (1) 95% Confidence Interval	Concurrent+ lag (1,2) Adjusted Odds Ratio	Concurrent+ lag (1,2) 95% Confidence Interval
Concurrent FS (High ref)	Ref.	Ref.	Ref.	Ref.
Marginal FS	1.76**	(1.22 - 2.56)	2.38***	(1.46 - 3.88)
Low FS	2.33***	(1.55 - 3.51)	2.27**	(1.31 - 3.94)
Very Low FS	2.41***	(1.50 - 3.86)	2.58**	(1.31 - 5.10)
Past/Lagged FS (High ref)	--	--	Ref.	Ref.
Marginal FS	--	--	2.43***	(1.52 - 3.88)
Low FS	--	--	1.66	(0.96 - 2.86)
Very Low FS	--	--	2.68**	(1.39 - 5.17)

*** p<0.001, ** p<0.01, * p<0.05; (1) Models also adjusted for HIV status, age, race, income, employment, marital status, education, and child dependents. (2) Persistent FS = e^(ln(AORcurrent) + ln(AORprior)). Estimates and p-values were obtained through post-estimation commands for linear combinations in Stata.

[Table 1: Longitudinal associations between concurrent and past food security status (FS) and current smoking]

Results: Among the 2,553 women, the average age was 47 and most were African-American (72%), HIV-positive (71%), and with annual incomes ≤$12,000 (52%). Over half (58%) reported current smoking, and food insecurity was highly prevalent (44%). In adjusted analyses, current marginal, low, and very low FS were associated with 1.76, 2.33, and 2.41 (all p< 0.01) greater odds of current smoking, respectively, compared to food secure women (Table 1). Persistent marginal, low, and very low FS over the current and previous visit were associated with 5.77, 3.78, and 6.93 greater odds of current smoking compared to persistently food secure women (all p≤0.01). There was no effect modification by HIV status.

Conclusions: Food insecurity over time is associated with cigarette smoking in this sample of predominantly low-income, minority women. Studies to understand whether and what mechanisms by which food insecurity may drive smoking are warranted to develop effective interventions to reduce the prevalence of smoking and the disproportionate rate of lung cancer mortality among PLHIV and other vulnerable populations.

WEPED332

The intersection of disclosure concerns and poverty contributes to loss to HIV care in India: A qualitative study

I. Colocci[1], J. Perlo[1], T. Betancourt[2], A. Pradeep[3], K. Mayer[4], N. Kumarasamy[3], B. Chan[5,6]
[1]Harvard University, Cambridge, United States, [2]Boston College, School of Social Work, Chestnut Hill, United States, [3]Y. R. Gaitonde Centre for AIDS Research and Education, Chennai, India, [4]Fenway Health, Boston, United States, [5]Brigham and Women's Hospital, Infectious Diseases, Boston, United States, [6]Harvard Medical School, Boston, United States

Background: In India, there is little evidence on reasons for high rates of loss to care, which threaten the goal of an AIDS-free generation. We conducted a clinic-based qualitative study on people living with HIV (PLHIV) in Chennai, Tamil Nadu to explore structural and psychosocial conditions that influence loss to care.

Methods: Semi-structured interviews were conducted in 2017 with patients at the Y.R. Gaitonde Centre for AIDS Research (YRG CARE), one of the largest private organizations providing HIV care in India. Using maximum variation sampling, we purposively sampled participants based on lost to care status
(in care vs. previously lost-to-care), sex, and urban vs. rural residence. Interviews were translated from Tamil or Telugu into English and a thematic analysis was conducted using a multistage qualitative data analysis process supported by Dedoose software.

Results: 16 men and 16 women were interviewed; median age was 42 (IQR, 36-48) and median CD4+ was 448 (IQR, 163-609). Almost all participants endorsed positive effects of treatment and care. However, a majority reported disclosure concerns, avoiding nearby health facilities or hiding medications to reduce "questioning" from family and community members. Participants were aware, but often distrustful, of HIV treatment freely available at government facilities. As a result, many rural dwellers travelled long distances, sometimes taking more than twelve hours, to reach YRG CARE. Financial concerns—the cost of medications at YRG CARE, lost wages, and for rural dwellers, transport cost—negatively influenced willingness to attend appointments. Life circumstances causing lost wages or unexpected expenditures therefore prevented participants from attending appointments, resulting in loss to care.

Conclusions: While government facilities provide free treatment, PLHIV were reluctant to access these services because of anticipated stigma and the perception of poor quality. The decision to access the private sector and in many cases to travel long distances to manage disclosure concerns and to obtain better care leaves PLHIV vulnerable to changes in economic status. Improving perceptions of quality of care in the public sector and reducing stigmatizing attitudes in the general population (thereby indirectly reducing anticipated stigma among PLHIV) may be important in reducing loss to HIV care in India.

WEPED333

Social determinants of health and self-rated health status: A comparison between women with HIV and women without HIV from the general population in Canada

M. Shokoohi[1], G. R. Bauer[1], A. Kaida[2], A. Lacombe-Duncan[3], M. Kazemi[4], B. Gagnier[4], A. de Pokomandy[5,6], M. Loutfy[4,7,8], R. Gormley[9], on behalf of the CHIWOS Research Team
[1]University of Western Ontario, Department of Epidemiology & Biostatistics, London, Canada, [2]Faculty of Health Sciences, Simon Fraser University Burnaby, British Columbia, Canada, [3]Factor-Inwentash Faculty of Social Work, University of Toronto, Toronto,Ontario, Canada, [4]Women's College Research Institute, Women's College Hospital, Toronto, Canada, [5]McGill University, Department of Family Medicine, Montreal, Canada, [6]McGill University Health Centre, Montreal, Canada, [7]University of Toronto, Faculty of Medicine, Toronto, Canada, [8]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada, [9]BC Centre for Excellence in HIV/AIDS, Epidemiology and Population Health, Vancouver, Canada

Background: Women with HIV continue to face socio-structural barriers to consistently engage at every step of the HIV care cascade. These barriers have potential to negatively impact the health and wellbeing of women with HIV and undermine attempts to promote HIV care programs. We compared social-structural determinants of health and self-assessed health status between women with HIV and expected general population values.

Methods: We estimated multiple measures of social-structural determinants of health and self-rated health status using the 2013-2015 cross-sectional data from the Canadian HIV Women's Sexual and Reproductive Health (CHIWOS) that enrolled 1,422 women with HIV aged ≥ 16. The prevalence of these determinants were then compared with expected estimates from 46,831 assumed HIV-negative women of the general population from the 2013-2014 Canadian Community Health Survey (CCHS), standardized to the age/ethnoracial group distribution of the CHIWOS sample. Standardized proportion differences (SPD) and 95% confidence intervals (CI) were reported.

Results: A higher proportion of women with HIV compared with estimates expected based on the age/ethnoracial-standardized assumed HIV-negative women reported annual personal income < $20,000 (70.3% vs. 28.1%; SPD 42.2% [95% CI: 39.1, 45.2]), indicating that 42.2% of women with HIV experienced this low income, in excess of what would be expected of Canadian women of similar ages and ethnoracial backgrounds. Additionally, a higher proportion of women with HIV reported severe food insecurity (54.1% vs. 10.2%; SPD 43.9% [95% CI: 40.2, 47.5]), poor perceived social support (30.3% 2.9%; SPD 27.4% [95% CI: 22.2, 33.0]), and frequent racial (46.4% vs. 9.6%; SPD 36.8% [95% CI: 31.9, 41.8]) and gender (53.2% vs. 8.4%; SPD 44.8% [95% CI: 42.6, 51.6]) discrimination. Finally, women with HIV reported a higher proportion of poor/fair health status than the general population of women (24.8% vs. 12.6%; SPD 12.2% [95% CI: 9.4, 15.0]).

Conclusions: Women with HIV experience greater social-structural inequities than in excess of what would be expected. These findings have implications for the development of targeted social service delivery interventions and programming to address basic needs of women with HIV and reduce the magnitude of inequity they frequently experience in their everyday life.

WEPED334

HIV intervention in dangerous times: Examining the impact of the counter-narcotics campaigns in the Philippines - implications for human rights, harm reduction, and blood-borne virus control

R.L. Bona[1], D. Natividad[2], M. Tan[3]
[1]Office of the Chancellor, University of the Philippines - Diliman, Research, Cainta, Philippines, [2]Center for Asian Studies, University of the Philippines Diliman, Research, Quezon City, Philippines, [3]Office of the Chancellor, University of the Philippines - Diliman, Quezon City, Philippines

Background: Starting 2007, the Integrated HIV Behaviour and Serologic Survey of the Health Department of the Philippines started to include numbers for intravenous drug use. The rise in numbers was consistent until the last survey in 2016. This brought attempts to create harm reduction and other HIV intervention programs in areas with high concentration. However, in 2016, Philippine Pres. Rodrigo Duterte introduced war against drugs as a central policy. This war became a threat to identified drug users in the country.

Methods: This medical anthropological study involved a review of the present policies that serve as the circumstances surrounding HIV intervention in the lens of drug use. Done in 2017 to 2018, with interview participants from Metro Manila, the study's methodology is ethnographic in nature, allowing key informant interviewees and group discussants to illustrate their narratives and nuances in depth and within focus through a thematic analysis. Interviewees include persons who use drugs, HIV interventionists, public official who engages in the execution of a localized war on drugs, and non-government and community-based organizations.

Results: All of the interviewed persons who engage in intravenous drug use inject methamphetamine as their primary choice. Their drug initiation is cannabis. All, however, do not consider cannabis as a drug used for sexual activity.

The recurring theme as reason for drug use is "stress". This is further examined to include stresses from unjust work conditions, from a dysfunctional family, from cyclical poverty, from an abusive relationship, from gender-based stigma and discrimination, from an HIV status, and from other social exclusions. These stresses are brought about by systemic political situations perpetuated by flawed policies of the country.

All of the interviewed persons who use drugs agree that the war against drugs does not stop drug use. It only makes healthcare intervention inaccessible to them.

Conclusions: The war against drugs is not stopping drug use. It only pushes persons who use drugs into hiding, making healthcare interventions, including those HIV-related, disconnected and inaccessible. This also leads distrust among the community, and towards their supposed healthcare providers. The war is a barrier and is an obstacle towards achieving zero-stigma and zero-discrimination.

Multilevel exposures and mediators of the relationship between schooling and risk of incident HSV-2 infection in young women enrolled in HPTN 068

M.C.D. Stoner[1], T.B. Neilands[2], K.B. Rucinski[3], A. Selin[3], J.P. Hughes[4,5], F.X. Gómez-Olivé[6,7], C. MacPhail[6,8,9], K. Kahn[6,7,10], A. Pettifor[3], HPTN 068
[1]University of North Carolina, Carolina Population Center, Chapel Hill, United States, [2]University of California, San Fransisco, United States, [3]University of North Carolina, Chapel Hill, United States, [4]University of Washington, Department of Biostatistics, Seattle, United States, [5]Fred Hutchinson Cancer Research Center, Seattle, United States, [6]MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), School of Public Health, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [7]INDEPTH Network, Accra, Ghana, [8]School of Health and Society, University of Wollongong, NSW, Australia, [9]Wits Reproductive Health and HIV Research Institute, University of the Witwatersrand, Johannesburg, South Africa, [10]Umeå University, Umeå, Sweden

Background: Our prior research from South Africa found that partner selection mediates the relationships between school attendance and incident HIV and HSV-2 infection, but little is known about other pathways. This study explores whether certain individual-, household-, and community-level factors account for the protective effect of schooling on incident Herpes Simplex Virus Type 2 (HSV-2) infection in young women.

Methods: We use longitudinal data from a randomized controlled trial of young women in rural South Africa (HPTN 068) collected during the main trial. We used discrete time survival models to estimate the three-year hazard ratio for the effect of distinct measures of schooling on incident HSV-2 infection, overall and through different pathways. Exposures of schooling included low attendance in school (≤ 80% of school days), household SES (quintiles of assets), parental education and mean community years of education. The natural indirect effect and natural direct effect were estimated as measures of mediation. Potential mediators included HIV knowledge, hope for the future, sex in the last 12 months,

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

unprotected sex in the last 3 months and age-disparate relationship (>=5 years). Additionally, we explored interactions between the individual-, household-, and community-level exposures of schooling.
Results: Low attendance in school (≤ 80% of school days) was associated with incident HSV-2 infection (HR 3.45; 95% CI: 1.93, .18) while other household and community exposures of schooling were not. We did not find interactions between any of the multi-level exposures of schooling. The mediators age-disparate relationship, hope for the future and sex in the past 12 months were associated with HSV-2 infection but HIV knowledge and unprotected sex were not. Indirect effects were significant for sex in the last 12 months and age-disparate relationship.
Conclusions: Low attendance in school was associated with a higher hazard of incident HSV-2 infection and partnership level factors were the most important mediators. The relationship between school attendance and HSV-2 was mediated primarily by having an age-disparate relationship, and sex in the past 12 months. Given the protective effect of individual school attendance, focus should be on interventions to keep girls in school and influence behaviors related to exposure to risky partners.

Rural men who have sex with men (MSM) in the United States: Structural stigma and HIV risk

R. Hubach[1], J. Currin[2], A. Durham[3], K. Kavannaugh[3], D. Wheeler[1], J. Croff[3]
[1]Oklahoma State University-Center for Health Sciences, Rural Health, Tulsa, United States, [2]Texas Tech University, Psychology, Lubbuck, United States, [3]Oklahoma State University, Sexual Health Research Lab, Stillwater, United States

Background: The nature of the HIV epidemic in the United States has changed with a shift toward rural areas; where sexual minority populations are dispersed and health care resources are limited. Concurrent socioeconomic factors, geography, and cultural context are coalescing for sexual minorities living in rural communities resulting in individuals at risk for HIV infection. Rural communities are typically more culturally conservative, and therefore may be less welcoming to openly lesbian, gay, bisexual, and transgender individuals. Moreover, the socioeconomic conditions of rural communities mean that most individuals born into these rural communities are unable to move to areas where they would be accepted.
Methods: We recruited 40 gay and bisexual men, ages 22 to 66, residing in rural Oklahoma for in-depth qualitative sexual health interviews. Through this inductive approach, we explored experiences with individual-level and community-level stigma, patterns of sexual health-seeking behaviors, and determinants of sexual risk.
Results: Participants indicated a lack of desire to discuss their sexual behavior or sexual orientation with peers, family, or medical providers due to rejection concerns. Participants discussed how these factors shaped their attitudes towards HIV/AIDS, status disclosure with sexual partners, and their uptake of HIV/STI screening. Participants described a stigmatizing social environment and less access to quality, LGBT-sensitive medical care within rural communities, and perceived these as substantial barriers to enhancing individual-level and community-level sexual health. Finally, structural issues, including lack of comprehensive sexual health education, institutional practices, and state policies within Oklahoma were noted.
Conclusions: Greater attention is needed to build a more comprehensive understanding of the sexual health of marginalized populations living in rural areas of the United States in order to advance the HIV care continuum. Addressing stigma situated across ecological levels in an effort to improve sexual health remains necessary. The combination of both individual-level and environmental/policy -level interventions provide the greatest opportunity to achieve substantial changes in health behaviors and health outcomes. Without this, social determinants may continue to negatively influence health outcomes among this population which remains underserved and under resourced.

WEPED337

Female sex work venue characteristics and HIV risk behaviors in two Mexico-US border cities: A latent class analysis

B.S. West[1], N. Agah[1], A. Roth[2], E.E. Conners[3], C. Magis-Rodriguez[4], H. Staines-Orozco[5], G. Martinez[6], K. Brouwer[7]
[1]University of California San Diego, Division of Infectious Diseases and Global Public Health, La Jolla, United States, [2]Drexel University, Community Health and Prevention, Philadelphia, United States, [3]New York City Department of Health and Mental Hygiene, New York, United States, [4]Universidad Autónoma de Ciudad Juárez, Departamento de Ciencias Médicas, Cuidad Juárez, Mexico, [5]Secretaría de Salud, Centro Nacional para la Prevención y el Control del VIH/SIDA (CENSIDA), México City, Mexico, [6]Federación Mexicana de Asociaciones, Salud y Desarrollo Comunitario de Ciudad Juárez, Ciudad Juárez, Mexico, [7]University of California San Diego, Department of Family Medicine and Public Health, San Diego, United States

Background: Research increasingly recognizes the role that the social and built environment play in shaping health. For female sex workers (FSW), the context in which women work is an important predictor of HIV/STI risk behaviors and exposure to violence. This study employs Latent Class Analysis (LCA) to identify profiles of risk associated with FSW venues in Tijuana and Ciudad Juarez, Mexico.
Methods: Data come from a longitudinal cohort of 603 FSW (Tijuana=301, Ciudad Juarez=302) selected through modified time-location sampling within venues. LCA identified patterns of venue characteristics (e.g. torn-down buildings, presence of alcohol or drugs, policing) and multinomial logistic regression was used to identify sociodemographic, behavioral and health indicators associated with belonging to a particular venue class, separately for the two cities (controlling for age and education).
Results: The mean age of the sample was 34. Three classes of FSW venues were identified, corresponding to levels of violence (e.g. violence against FSW, street violence), drug activity (e.g. drug use/sales, presence of cartels), and police activity (e.g. police as clients, FSW arrest, police patrols): low disorder (39%), medium disorder (34%), and high disorder (28%). In multivariable regression, relative to low disorder environments, working in high disorder venues was associated with an increased odds of experiencing abuse by a client (Adjusted Odds Ratio (aOR)=4.29, 95% Confidence Interval (CI)=1.47-12.58), injecting heroin in the past 30 days (aOR=9.77, CI=2.09-45.59), having clients under the influence of drugs (aOR=3.06, CI=1.37-6.83) and using drugs with clients (aOR=1.16, CI=0.58-2.34) in Ciudad Juarez. In Tijuana, working in high disorder venues was associated with an increased odds of having US clients (aOR=5.04, CI=1.52, 16.68), having drunk clients (aOR=9.82, CI=2.77-34.79), drinking alcohol 4+ times per week (aOR=5.22, CI=1.4-19.45), experiencing physical/sexual abuse by a client (aOR=4.81, CI=1.35-17.18), and arrest (aOR=3.45, CI=1.24-9.65).
Conclusions: In two border cities, FSW venues were characterized by different levels of disorder in the social and built environment. Working in venues with higher levels of disorder, as indicated by more violence, drug activity, and police activity, was associated with factors driving HIV/STI risk, suggesting a need for interventions that reshape the HIV risk environment by addressing FSW working conditions.

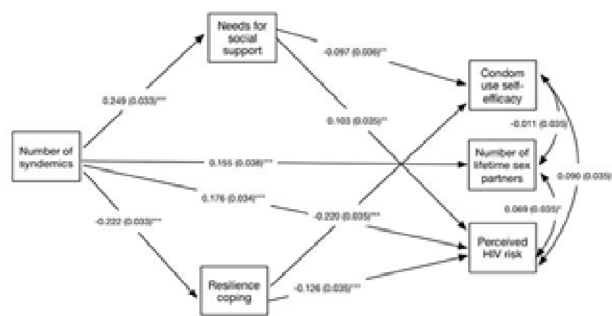
WEPED338

Pathways from multiple syndemic conditions to HIV vulnerabilities and protective factors among transgender, gay, lesbian and bisexual persons in Jamaica

C.H. Logie[1], Y. Wang[1], N. Marcus[1], K. Levermore[2], N. Jones[2], T. Ellis[2]
[1]University of Toronto, Toronto, Canada, [2]Jamaica AIDS Support for Life, Kingston, Jamaica

Background: Transgender, gay, lesbian, and bisexual (TGLB) persons in Jamaica experience pervasive stigma, structurally reinforced by the criminalization of same sex practices and a lack of human rights protections. Syndemics describe the co-occurrence, and potential interaction, of multiple psychosocial and structural factors that may elevate HIV vulnerabilities. We examined pathways from multiple syndemic conditions

to HIV vulnerabilities, and explored social support and resilience as mediators in this relationship, with TGLB persons in Jamaica.
Methods: This community-based study involved a cross-sectional survey with a peer-driven sample of gay and bisexual men (n=569), lesbian and bisexual women (n=205), and transgender women (n=137), in Kingston, Ocho Rios, and Montego Bay, Jamaica. We examined *syndemic conditions* (depressive symptoms, binge drinking, adulthood experiences of violence, childhood sexual abuse), *HIV vulnerabilities* (condom self-efficacy, lifetime sexual partners, perceived HIV risk), and *protective factors* (social support, resilience). We conducted structural equation modelling using maximum likelihood estimation methods to test the direct effects of the number of syndemics on HIV vulnerabilities, and the indirect effects via social support and resilience, adjusting for socio-demographics.
Results: The mean age of participants (n=911) was 26 years (SD=5.42). Most (86.66%, n=786) reported depressive symptoms in the past two weeks. Approximately one-fifth (22.61%; n=205) reported binge drinking in the past three months. One-third (32.45%, n=294) reported childhood sexual abuse and one-fifth (20.77%, n=188) adulthood violence. Most (92.2%) reported at least one syndemic condition; nearly half (47.7%) endorsed two or more. The direct paths from the number of syndemics to lifetime sexual partners (ß=0.155, $p< 0.001$) and perceived HIV risk (ß=0.176, $p< 0.001$) were significant, accounting for the mediation effects of social support and resilience. Social support and resilience mediated the association between the number of syndemics and condom self-efficacy; social support accounted for 28.24% of the total effect of syndemics on condom self-efficacy, and resilience accounted for 57.65% of the total effect.
Conclusions: This research highlights the salience of a syndemics approach to understanding HIV vulnerabilities among TLGB persons in Jamaica. Findings can inform multi-level interventions that address psychosocial (depression, substance use), structural (violence), and protective (resilience, social support) factors, to advance the HIV prevention cascade in Jamaica.



[Figure 1. Final path analysis results for syndemic conditions on HIV vulnerabilities among transgender, gay, lesbian and bisexual persons in Jamaica]

'Yes' to recreational drugs but *'no'* to life-saving medications - unpacking paradoxical attitudes about treatments to improve medication adherence: Key findings

D. Plummer[1], G. Rogers[2], S. Anoopkumar-Dukie[3], M. O'Sullivan[4], A. Mey[3]
[1]*College of Public Health, Medicine and Veterinary Science, James Cook University, Townsville, Australia,* [2]*School of Medicine, Griffith University, Gold Coast, Australia,* [3]*School of Pharmacy and Pharmacology, Griffith University, Gold Coast, Australia,* [4]*Gold Coast Hospital and Health Services, Sexual Health, Gold Coast, Australia*

Background: Despite the well-known life-preserving benefits of antiretroviral therapy (ART), some people living with HIV in Australia are declining treatment while still being prepared to use potentially dangerous recreational drugs (RD). Our research sought to unpack and understand this paradox and to gain insights into the core beliefs regarding HIV, ART, complementary and alternative medicines (CAM) and RD that interplay in people's health management decisions. This knowledge will enable models of care to be developed that recognize and address specific needs, optimise outcomes, and ultimately progress Australia towards eradicating HIV from the domestic landscape.
Methods: In-depth interviews were conducted with adults living with HIV in the Queensland and surrounding regions of Australia between March 2016 and December 2017. Interviews explored knowledge and beliefs about HIV, ART, CAM and RD. Data were audio recorded, transcribed and analysed using a 'grounded theory' approach. Ethical approval: HREC / 15 /QGC / 256.
Results: Forty people aged between 24 and 76 years were recruited to the study. At the time of interview, they had been diagnosed with HIV between 1 month and 31 years. Sixteen reported regular RD use, 16 used CAM regularly, and all 40 reported ART use. Participants' narratives revealed inaccurate knowledge (e.g. transmission of HIV can occur via mosquito bites and sharing razors), alongside stigmatizing and prejudicial beliefs that, for some, became self-directed post-diagnosis. The professed benefits of RD, such as relief from reality, and perceived safety of CAM, were often contrasted by concerns regarding ART toxicity, and financial, emotional and physical burdens believed to be imposed by therapy. The perceived burden of ART appears to be a strong motivator for declining, while positive views towards CAM and RD appear to justify use, particularly to combat health-impairing negative states of mind.
Conclusions: Decisions regarding managing HIV are complex and appear to be influenced by participants' knowledge and beliefs about HIV, ART, CAM, RD and the environment which they live. Optimal models of care for people with HIV must address gaps in knowledge, address stigmatising beliefs and take into account personal circumstances, alongside reservations and desires for managing life with HIV.

WEPED340

"The sky is the limit; I am going there": Exploring hope among young women receiving a conditional cash transfer in rural South Africa

K. Atkins[1], C. MacPhail[2]
[1]*University of North Carolina Gillings School of Global Public Health, Health Behavior, Chapel Hill, United States,* [2]*University of Wollongong School of Health and Society, Faculty of Social Sciences, Wollongong, Australia*

Background: Young women in South Africa face elevated risk of HIV infection compared with male peers. This is exacerbated by structural factors, including poverty, that shape HIV risk behaviours. Conditional cash transfers (CCT) may provide economic strengthening to young women and mitigate their risk for HIV; however, there is limited understanding of the pathways through which this occurs. Hope, which is related to environmental stressors like poverty, motivates future-oriented behaviour and is therefore critical in HIV prevention. This analysis explored hope as a potential pathway through which CCT influences young women's behaviours and HIV risk.
Methods: A qualitative study was embedded in a randomized CCT trial in rural South Africa (HPTN 068). The study enrolled young women aged 13-20 and cash was conditional on school attendance. In-depth interviews were conducted with women every six months. We analysed 53 interview transcripts from participants (n=12) who received CCT and were interviewed three or more times. We used longitudinal qualitative analysis methods to understand how women in the study conceptualized hope over time and how CCT influenced their hope.
Results: This analysis found that CCT instilled in young women a belief that a better life, defined as being educated, independent, and supportive to family, was attainable. Women from financially and emotionally supportive baseline contexts expressed this especially strongly. In addition, CCT influenced women's hope in the present by alleviating daily financial stressors and promoting "good behaviour," including HIV testing, condom use, partner reduction, and, through trial requirements, school attendance. They expressed that, as their hope for a better life increased, their desire to behave well in preparation for that life also increased.
Conclusions: CCT influences hope among young women in rural South Africa by alleviating routine stressors, promoting plans for higher education, and increasing confidence. By increasing women's hope for a better life, CCT also reduces their desire to engage in HIV risk behaviours.

However, these influences are highly reliant on baseline family and financial contexts. This analysis supports the need for additional mixed methods research to better understand hope as a possible mechanism by which CCT influences young women in this and other contexts.

WEPED341

Stigma toward anal sexuality is associated with decreased engagement in HIV services and safer sex practices among MSM in the United States: A mixed-methods study using structural equation modeling

B. Kutner[1], J. Simoni[2], E. Creegan[3], F. Aunon[2], M. Remaiya[2]
[1]New York State Psychiatric Institute and Columbia University, HIV Center for Behavioral and Clinical Studies, New York, United States, [2]University of Washington, Department of Psychology, Seattle, United States, [3]Seattle University, Seattle, United States

Background: HIV incidence remains disproportionately high among men who have sex with men (MSM), and their engagement in efficacious biomedical and behavioral interventions remains low. Social factors, including stigma toward sexual behavior, likely hinder engagement in HIV interventions. After quantifying a specific social factor, *stigma toward anal sexuality,* we tested its effects on both *sexual concerns* and *engagement in HIV interventions* among MSM in the U.S. We hypothesized that elevated *stigma* would be associated with lower *engagement*, mediated by elevated *concerns*.

Methods: We developed two new quantitative measures, an *Anal Sex Stigma Scale* (*ASS-S*) and a measure of *concern*, the *Anal Sex Questions Index* (*ASQx*), from qualitative interviews about cisgender MSM perspectives on anal sexuality (N = 35). We refined these measures in a national online sample (N = 268), then conducted structural equation modeling to test a conceptual model of their effects in another national online sample of sexually active MSM (N = 1263), aged 18 to 72 years (47% men of color, 14% living with HIV, 28% prescribed PrEP, and 36% reporting no consistent prevention strategy during recent penile-anal intercourse).

Results: The final model accounted for 75% of the variance in *engagement*, had good fit (X^2/df = 2.7, RMSEA = .037, CFI = .99, TFI = .99), and found evidence for effects of all factors (p < .005). We did not find evidence of mediation by *ASQx*, but did find evidence that *ASS-S* is associated with less *engagement* (= -.28, p < .001), wholly mediated by men's *comfort* talking about sexual orientation and anal sex practices with health workers (= -.41; = .69; p < .001), controlling for *socioeconomic status* and *social support* specific to anal sex.

Conclusions: The ways MSM cope with stigma and concerns specific to anal sex may not be readily known or easy to disclose within healthcare settings, and their reluctance to discuss anal sexuality with health workers may impede engagement in HIV services and safer sex. Interventions that bolster men's comfort discussing anal sexuality may insulate some men against the concealment effects of anal sex stigma, and thereby improve engagement in HIV interventions.

	β (standardized)						
Model Variables	*Stigma (ASS-S)*	*Concerns (ASQx)*	*Comfort*	*Social Support*	*Socioeconomic Status*	*SE*	R^2
Total effects on:							
Stigma	--			-.39**	-.27**	.03	.25**
Concerns	.54**	--		-.11**		.03	.26**
Comfort	-.41**		--	.41**		.03	.32**
Social Support				--		--	--
Socioeconomic Status					--	--	--
Engagement	-.28**		.69**	.28**	.51**	.09	.75**

Structural covariance with standardized beta coefficients of *engagement* in HIV services and safer sex predicted by anal sex *stigma (ASS-S)*, with *concerns* about anal sexuality (*ASQx*), mediated by *comfort* talking about sexual orientation and specific anal sex practices with a health worker, and controlling for informational and emotional *social support* specific to anal sexuality (*MOS-SSS* adapted), and *socioeconomic status* (*age, income, education, medical coverage*, and *Black/African-American identification*).
* p < .005; ** p < .001. Model fit indices: X^2 (932) = 2542.69, p < .0001, X^2/df = 2.7, *RMSEA* = .037, *90% CI*: .035 - .039, probability of *RMSEA* < .05 = 1, *CFI* = .99, *TFI* = .99, *WRMR* = 1.63.

WEPED342

Applying syndemic theory to understand HIV-related discrimination and sexual risk behavior among people living with HIV (PLHIV) in Hong Kong

R.C.H. Chan[1], A. Restar[2], D. Operario[2], W. Mak[3]
[1]University of Hong Kong, Department of Social Work and Social Administration, Hong Kong, Hong Kong, [2]Brown University School of Public Health, Providence, United States, [3]Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: In the context of HIV-related stigma and discrimination, people living with HIV (PLHIV) might be vulnerable to a "syndemic" of co-occurring psychosocial challenges (i.e., co-occurrence of depression, anxiety, social isolation, and self-stigma) that can affect sexual behavior. The present study examined how HIV-related discrimination contributes to co-occurring psychosocial syndemic problems and results in sexual risk behavior among PLHIV in Hong Kong.

Methods: Two-hundred and ninety-one PLHIV were recruited to complete a self-report questionnaire on their experiences of HIV-related discrimination, psychosocial problems (including depression, anxiety, social isolation, and self-stigma), and condom use patterns during the past three months.

Results: More than one-quarter of the sample (27.1%, N = 79) experienced two or more psychosocial syndemic problems, and 74.1% (N = 80) of the participants who had sex with steady partners reported inconsistent condom use over the past three months. Results of Poisson regression indicated that HIV-related discrimination was positively predictive of the number of psychosocial problems reported by the PLHIV, as well as with inconsistent condom use. In a logistic regression analysis controlling for demographics, HIV-related discrimination and psychosocial syndemics were significantly associated with increased odds of inconsistent condom use with steady partners. Findings from structural equation models further showed that psychosocial syndemics mediated the negative effect of HIV-related discrimination on condom use consistency with steady partners.

Conclusions: PLHIV in Hong Kong suffered from the syndemic effects of stigma, social isolation, and poor mental health, which rendered them vulnerable to condomless sex. In order to curb the rapidly increasing incidence of HIV, multi-level strategies should be adopted to concurrently address structural inequities and psychosocial syndemics faced by PLHIV.

WEPED343

Action for access! Community-lead study finds stigma and discrimination hinder access to sexual health services among men and transgender women who have sex with men in Vietnam and Kenya

S. Arreola[1], T. Đoàn Thanh[2], J. Walimbwa[3], A. Mokabedi[4]
[1]MSMGF, Research, Oakland, United States, [2]Lighthouse, Hanoi, Vietnam, [3]ISHTAR, Nairobi, Kenya, [4]LeGaBiBo, Gaborone, Botswana

Background: Men and transgender women who have sex with men (MTWSM) carry a disproportionately high HIV burden. Compared to general population prevalence of 0.4% in Vietnam and 5.4 in Kenya, among MSM, HIV prevalence is 8.2 % in Vietnam and 18% in Kenya. Data are lacking for transgender women in Kenya, but in Vietnam, existing studies suggest transgender women HIV prevalence is 18%. Despite an urgent need for sexual health services (SHS), few studies have examined the structural factors that impact access to SHS among MTWSM in Vietnam and Kenya. Action for Access! is a community-lead study that explores the relationships between social-structural factors and access to SHS among MTWSM in Vietnam and Kenya.

Methods: Qualitative individual in-depth interviews were conducted between September 2017 and February 2018. 75 Interviews (Table 1.) were recorded, transcribed and Vietnamese and Swahili interviews were translated into English. The research team developed a coding lexicon and coded interviews after reaching 80% inter-rater reliability. For this study, stigma and discrimination (S&D)-coded and SHS-coded quotes were used to analyze patterns of association between them.

Results: Access to SHS was deficient for MTWSM in both countries. S&D further complicated accessing SHS that did exist. All MTWSM reported pervasive experiences of sexual-S&D (Table 2.), and transgender women related transgender-S&D as well. Narratives reveal that, coupled with punitive laws or practices, this highly stigmatizing environment contributed to an internalized fear of being "found out" resulting in their hesitancy to seek SHS. For example, MTWSM described how S&D on the part of health providers often resulted in abandoning access of SHS in favor of, for example:

1) self-care based on internet information or advice from friends or pharmacists,

2) waiting until there is a crisis to seek professional care, or

3) suffering through the indignities of the health care systems because "it is all that is available".

The principal respite noted was accessing SHS from community-lead organizations.

Conclusions: Stigma and discrimination significantly impair MTWSM's access to SHS that are critical for addressing HIV health disparities in Vietnam and Kenya. Strengthening community-lead SHS is recommended.

How are adverse childhood experiences (ACEs) associated with early sexual debut? A contextual analysis of sexual debut among Black women in Baltimore, MD, USA

K. Tsuyuki[1], N.A. Al-Alusi[1], C.J. Catabay[1], D. Murry[2], J.C. Campbell[3], J.K. Stockman[1]
[1]University of California, Medicine, Division of Infectious Diseases and Global Public Health, San Diego, United States, [2]Philander Smith College, Little Rock, United States, [3]Johns Hopkins University, Baltimore, United States

Background: Emerging research suggests that adverse childhood experiences (ACEs) may contribute to HIV risk behaviors, including early sexual debut - a key indicator of HIV infection among women in Sub-Saharan Africa. The effect of ACEs on early sexual debut is not well understood, especially among women in the U.S. This study examines the association between ACEs (individual and cumulative ACE score) and early sexual debut, identifying contextual characteristics at early sexual debut that explain this association.

Methods: Black women (n=140) were recruited from public STD clinics in Baltimore, MD. ACASI surveys collected retrospective data on ACEs and sexual debut. ACEs measured abuse and household dysfunction experienced up to 18 years. Age at earliest initiation of vaginal or anal sex was categorized as very early sexual debut (age 11-12), early sexual debut (age 13-14), or not early sexual debut (age≥15). Multinomial logistic and linear regression models were conducted to examine associations, and contextual variables were entered individually to examine their mediating effects.

Results: Forty-one percent of our sample experienced early sexual debut (11%-very early sexual debut; 30%-early sexual debut); these women reported more ACEs (mean=3.46;std.dev.=0.71) than women without early sexual debut (mean=1.43;std.dev.=0.19). Women with very early sexual debut reported significantly more emotional, physical, and sexual abuse; witnessing maternal abuse; and household substance misuse, than women without early sexual debut. In terms of ACEs, women who experienced very early sexual debut reported significantly more emotional abuse (relative risk ratio-RRR=5.52;95%CI:1.68,18.13), physical abuse (RRR=11.82;95%CI:3.10,45.13), sexual abuse (RRR=6.00;95%CI:1.69,21.26), witnessing maternal abuse (RRR=6.31;95%CI:1.89,21.08), and household substance misuse (RRR=4.20;95%CI:1.38,12.77), than women without early sexual debut. Total ACE score was significantly associated with very early sexual debut (RRR=1.53;95%CI:1.20,1.95), but not early sexual debut (RRR=1.09;95%CI:0.90,1.33). This association was partially mediated by contextual characteristics, such as sexual debut being forced or pressured (RRR=3.52;95%CI:1.14,10.85), with a male partner ≥3 years older (RRR=6.75;95%CI:1.97,23.09), and with condom use (RRR=0.31;95%CI:0.10,0.99). Contextual characteristics exhibited a greater effect size for women who experienced very early sexual debut than early sexual debut.

Conclusions: This study highlights the importance of addressing ACEs in the context of early sexual debut and HIV/STI prevention among women in the U.S.

WEPED345

Maintaining frontline HIV prevention programs in the era of pre-exposure prophylaxis

A.T. Young[1], T. Howard-Howell[2]
[1]Community Education Group, Washington, United States, [2]Rutgers, The State University of New Jersey, School of Social Work, Center for Prevention Science, Rutgers, United States

Background: Pre-exposure prophylaxis (PrEP) has proved promising for medical HIV prevention; however, only 10% of PrEP users in the United States are Black/African-American despite experiencing HIV disparities. PrEP uptake has resulted in shifts eliminating behavior modification approaches without noted consideration of the implications on grassroots leaders at the frontlines of prevention. As a result, Black men who-have-sex-with men (MSM) and cisgender women often engaged in prevention

and care through community-based advocacy have been disproportionately excluded from PrEP trials and under-prioritized for prescriptions. The objective of this project was to increase the research capacity of HIV community-based leaders and support their assessment of the acceptability of PrEP in addition to behavior modification as a comprehensive approach to HIV prevention.
Description: This project was conducted January-September 2017 within a community setting and involved the collaboration of an interdisciplinary community-university team.
Three phases were included:
Phase I—assisting community leaders to develop a survey to evaluate HIV and PrEP knowledge, attitudes, and beliefs;
Phase II—training community leaders as researchers and developing policy-based manuals for community-engagement sessions, and;
Phase III—engaging in data collection and analysis.
Lessons learned: Survey respondents included 156 participants ages 18-60 years. The majority of participants had knowledge of PrEP (n = 107; 68.6%), knew where to access PrEP (n = 97; 62.2%), and felt risks for acquiring HIV would decrease if PrEP was taken as prescribed (n = 90; 59.7%). The overwhelming majority felt PrEP had side effects (n = 113; 72.4%) and were not interested in receiving additional information to access PrEP (n = 79; 50.6%).
Conclusions/Next steps: This project enabled community leaders to maintain a presence in medical HIV prevention research. Survey participants reflected positive beliefs about HIV testing but preferred traditional HIV prevention strategies. An opportunity for community leaders to connect vulnerable populations with the benefits of medical HIV prevention models may increase the likelihood of its acceptability in addition to traditional behavioral change models. Implications suggest HIV community leaders maintain a critical role in HIV prevention education for vulnerable populations.

WEPED346

Challenging criminalisation globally: New directions for un-policing identity, morality, sexuality and bodily autonomy

B.M. Munyati[1], P. Tucker[2], R. Kgositau[1]
[1]*AIDS Accountability International, Cape Town, South Africa,* [2]*AIDS Accountability International, Bruxelles, Belgium*

Background: Across the globe and perhaps more disproportionately in the Global South, courts, parliaments and law enforcement agencies have become avid proponents of using the coercive power of the law to police, control and punish a variety of behaviours which they considered as contributing to 'moral decay'. The activities that come under this rubric include consensual sexual relations between persons of the opposite sex, sodomy, abortion, sex work, adultery, possession or publication of materials considered obscene, pornography, drug use, among others. This criminalisation and moral policing oppresses individuals, societies and reduces space for civil society, as well as hampering the possibility of achieving 90-90-90 and the SDGs.
Description: This project seeks to use create a critical mass globally amongst various stakeholders to ensure that criminalisation is challenged. It asks: what new stakeholders can we bring into this movement? How is criminalisation a cross-cutting issue that can create global solidarity just as HIV and AIDS did? What role is business playing in this movement? How can the media, technology and data experts be effective allies? How can we re-think these issues, such as parallel justice systems?
The project (amongst other activities) is hosting 40 leaders in the field of HIV, media, business, sexuality, human rights, key populations and other sectors to get them to debate, re-think and innovate to challenge criminalisation globally. The meeting will also map the work being done by over 40 individuals and organisations around the globe.
Lessons learned: Pending the April 2018 CCG Dialogue: This global discourse will encourage all stakeholders to engage innovatively with the underlying causes of expanding criminalisation, and especially in the name of public security; and to investigate new and previously untapped partners; and to rethink and undo existing as well as pending punitive, retributive 'solutions'. including with the input of "unusual suspects."
Conclusions/Next steps: The findings and output of this CCG Re-think and mapping meeting forms part of an important step in changing the way activists call for criminalisation, and creating space for civil society, uniting across movements for a larger, longer term goal. The findings should be shared to inform others, and bring them along.

WEPED347

Healthcare supply-related HIV transmission factors in HIV-positive patients participating in the Cameroonian antiretroviral treatment program (ANRS-12288 EVOLCam survey)

P.-J. Coulaud[1,2], K. Ndiaye[1,2], L. Sagaon-Teyssier[1,2], C. Laurent[3], B. Spire[1,2], L. Vidal[1,2], C. Kuaban[4], S. Boyer[1,2], the EVOLCam Study Group
[1]*Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France,* [2]*ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France,* [3]*IRD, INSERM, Univ Montpellier, TransVIHMI, Montpellier, France,* [4]*Faculté de Médecine et de Sciences Biomédicales, Université de Yaoundé, Yaoundé, Cameroon*

Background: Increasing demand for antiretroviral treatment (ART) and reduced international financial support compromise the quality of HIV services in developing countries. We investigated the effects of healthcare supply-related factors on HIV transmission risk (HTR) in patients participating in Cameroon's ART program.
Methods: A cross-sectional survey was conducted among HIV-positive adults attending 19 HIV services in Cameroon (EVOLCam ANRS 12288). Socio-behavioural, psychosocial, medical and facility-related data were collected.
A cluster analysis helped identify HIV-service profiles (HSP) using 22 characteristics, in five domains: (1) General features (2) Number of caregivers, (3) Number of ART-treated patients and services available, (4) Organisation, (5) Technical capacities. HTR was assessed among sexually active patients.
HTR was defined as reporting condomless sexual intercourse in the previous 12 months with HIV-negative partners and having a detectable viral load or non-adherence to ART.
The effect of HSP on HTR after adjustment for individual factors was investigated using a multi-level logistic regression model.
Results: Four HSP were identified. All services in HSP1 (n=4) were district level with a high number of patients. Three provided basic services and specific ART management. HSP2 (n=5) included the largest and best equipped HIV services located at the central level. Three of these had limited CD4 count measurement capabilities due to reagent stock-outs. Facilities in HIV services in HSP3 (n=6) were mainly district level with a lower number of patients. Five reported ART stock-outs. HSP4 (n=4) were all district level, with the lowest capacity in terms of clinical staff. Two reported ART stock-outs.
Among the 1328 sexually active patients studied (women 67%, median age 39 years [Interquartile Range = 33-45]), 24% were at risk of HIV transmission, with large variability according to the specific HIV service profile [min-max: 9%-47%]. After adjustment for individual (age, gender, educational level) and clinical characteristics (CD4 cell count), patients in HSP4 were at greater risk than those in HSP1 (adjusted Odd Ratio (aOR):1.96, 95% Confidence Interval (CI) [1.01-3.80]).
Conclusions: Healthcare supply constraints may affect HIV transmission risk. Strengthening human resources and ART supply chain management is necessary to reach the third target of the 90-90-90 objective.

WEPED348

Preparing community gate keepers to promote the sexual health wellbeing of young people in Uganda

N. Daphynne Olgah[1], T. James[2], N. Priscillah[3], D. Oyom[1]
[1]International Planned Parenthood Federation (IPPF Africa Region), Youth Department, Nairobi, Kenya, [2]Reproductive Health Uganda, Gender and Youth Department, Kampala, Uganda, [3]Sexual and Reproductive Health and Rights Alliance Uganda, Youth Department, Kampala, Uganda

Background: Reproductive Health Uganda is implementing the "*Get up Speak out for Youth Rights*" program, which envisages a world where *Young people realize their SRHR in a society that is positive towards their sexuality. It* is implemented in 4 districts in Eastern Uganda; an area with worst rates of teenage pregnancy in the country.
In March 2017, with support of KIT Institute, a baseline survey for GUSO program was conducted. The survey gave attention to program outcome areas; utilization of SRHR information and education, youth friendly SRHR services, supportive socio-cultural and political environment. Some of the survey findings highlighted in this abstract evaluated the role of community gatekeepers in shaping young people's sexual health.
Methods: The Survey used quantitative and qualitative approaches;1,704 young people(15-24 years) 956 females,748 males were sampled from Iganga, one of four intervention districts.1,500 youth were subjected to a structured questionnaire.qualitative methods employed included,FGDs with 50 young people, 50 Semi-structured interviews and 104 Key informant interviews.Data was analysed using STATA/SPSS and Nvivo.
Results: 70% of the respondents felt able to express their feelings about relationships and their sexuality. They claimed to have adults within their locality with whom they can discuss their feelings and worries. The adults identified were parents, relatives, teachers and religious leaders who can jointly be termed as gate keepers. Still, these gatekeepers leave a lot to be desired in regards to information on young people's sexuality. According to youth, some adults are unapproachable and share information using metaphors making messages unclear. Eventually, youth turn to peers for knowledge and support which compromises the quality of the information shared and received. Additionally, the space for young people to make their own decisions is sometimes not respected.
Conclusions: The community gate keepers of youth have a great role to play in shaping their positive sexual health outcomes through guiding them to make informed reproductive health choices. There is need therefore for programming to target establishing effective youth- adult partnerships as well as building SRHR competency (including basic knowledge, values transformation and communication skills) of gate keepers to work together to address the key challenges Youth face.

WEPED349

Exploring the role of community savings groups in addressing food insecurity and improving healthcare access for HIV-infected and uninfected female sex workers in Iringa, Tanzania

A. Mantsios[1], C. Shembilu[2], J. Mbwambo[2], S. Likindikoki[2], W. Davis[3,4], D. Kerrigan[1,3]
[1]Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States, [2]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of, [3]American University, Sociology, Washington, D.C., United States, [4]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States

Background: Financial insecurity and food insecurity can limit the ability of female sex workers (FSW) to access healthcare and medical treatment and receive proper nutrition. Recent studies reveal that savings groups can play a role in promoting better HIV treatment and care outcomes for people living with HIV. This study sought to qualitatively explore the potential role of community savings groups in facilitating improved HIV outcomes and overall health among FSW in Iringa, Tanzania.
Methods: Between April 2015 and February 2016, 27 in-depth interviews (IDIs) with 15 FSW and 4 focus group discussions with 35 FSW participating in community savings groups were conducted in the Iringa region. Content analysis was conducted to identify salient themes including the dynamic nature of participants' sex work and financial realities and the meaning and importance of community savings groups in their lives, work, and on HIV care seeking behaviors and health.
Results: Inability to afford food came up organically among all study participants in the context of interviews and focus groups. Participants cited food insecurity as a critical element in their decisions to agree to unsafe sex. Women described that the money they received from community savings groups they participated in was often used to purchase food for themselves and their families. Community savings groups also helped FSW afford health care costs including clinic visits, hospital stays and medications they could not pay for otherwise. HIV-infected FSW spoke specifically about money from the groups allowing them to afford to eat a healthy diet and providing them with sufficient money for transport to attend regular HIV clinical care visits.
Conclusions: Findings suggest that participating in a savings group may address issues of food insecurity by ensuring women have adequate financial resources to buy food, alleviating this element of economic vulnerability that places FSW at increased risk of unsafe sex with clients. Furthermore, results indicate that community savings groups may have effects on the overall health and well being of FSW, as well as HIV outcomes for HIV-infected FSW, through improved access to and utilization of healthcare services.

WEPED350

Manufacturing consent: How "public health" constructed an association between HIV/AIDS stigma and gay men in China

Z. Sun
Utrecht University, Department of Interdisciplinary Social Science, Utrecht, Netherlands

Background: Chinese public health agencies, as well as political authorities, are playing a dominant role in its HIV/AIDS policies and programs. One of the major concerns for those policies and programs is removing the stigma among people living with HIV. However, the HIV/AIDS stigma associated with gay men, is not addressed. This study aims to explore why the stigmatizing association between HIV/AIDS and gay men persist. This study in particular explores the manufacturing of consent, structural stigma and internalized stigma to understand why gay men are thought to have HIV/AIDS.
Methods: This qualitative research encompassed 1-year fieldwork in Shanghai, China. Qualitative data was collected through participant observation, which yielded extensive notes (~60,000 words) of observations, and 25 in-depth interviews. Interviews were transcribed verbatim, coded and thematically analysed using NVivo. Interviewees were randomly recruited during participant observations and some were referred by key informants. Interview participants were inclusive of people working in the HIV/AIDS sector, gay men and other men who have sex with men who are seeking an HIV test, and gay men living with HIV/AIDS.
Results: The study found that the association of HIV/AIDS stigma with gay men is the result of actions by public health experts (e.g., clinic doctors, policy makers, academic scholars), reflecting their noting that being gay was equivalent to a high risk of HIV. In addition, it was noted that NGOs working on HIV/AIDS in the gay community indirectly engaged in such stigma production because of their resource-dependence on the public health sector. Also, political authorities often assumed that being a gay man would no doubt also mean they would have HIV/AIDS, which some gay men themselves assumed as well.
Conclusions: In the context of sociocultural and political concern regarding HIV/AIDS and structural stigma regarding homosexuality, the public health response played an importing role in associating HIV/AIDS with gay men. Some gay men also assumed that they were at risk of HIV/AIDS as a result of their identity. This manufactured consent building on internalized stigma indicates that any attempts to remove the assumed relationship between gay men and HIV/AIDS is a challenge in China.

WEPED351

High prevalence of social and structural syndemic conditions associated with poor psychological quality of life among a global sample of gay, bisexual and other men who have sex with men

O. Martinez[1], S. Arreola[2], K. Wilson[1]
[1]Temple University, School of Social Work, College of Public Health, Philadelphia, United States, [2]Global Forum on MSM and HIV, Oakland, United States

Background: Multiple co-occurring social and structural conditions, including sexual and physical violence and discrimination, disproportionally impact gay, bisexual and other men who have sex with men (GBMSM). Most syndemics research has focused exclusively on psychosocial conditions associated with HIV sexual risk behaviors. This study examined the role of social and structural conditions - including socioeconomic status, housing instability, sexual and physical violence and discrimination - on overall psychological quality of life among a global sample of GBMSM.

Methods: We analyzed data from a global sample of 2,417 GBMSM collected between 2014 and 2015 from the MSMGF (the Global Forum on MSM & HIV) third Global Men's Health and Rights Study (GMHR) survey. Participants were recruited through online convenience sampling (e.g. via organizational networks, email listservs and websites). Data were analyzed using SPSS. A linear regression was conducted using count of syndemic conditions (inability to meet basic needs, insecure housing, homophobic discrimination, and sexual and physical violence) as the independent variable to assess the additive effect of the syndemic conditions on Psychological Quality of Life as measured by the World Health Organization. Analyses were also repeated with control variables.

Results: Among 2,417 men, prevalence of syndemic conditions was substantial with 1,594 (66%) of respondents experiencing at least one syndemic factor. In multivariable syndemic analyses, participants with one factor (b=-.22, p< .001), two factors (b=-.33, p< .001), or three or more factors (b=-.62, p< .001) each reported significantly lower levels of Psychological Quality of Life than those with zero syndemic factors. These effects persisted after the introduction of controls.

Conclusions: This study provides initial evidence that intertwined social and structural syndemic conditions are positively associated with poor psychological quality of life among a global sample of GBMSM. Future longitudinal research should further assess the impact of these conditions on overall quality of life and assure the inclusion of other marginalized communities, including transgender men and women. Comprehensive structural interventions that simultaneously address co-occurring social and structural syndemic conditions should be developed and tested.

WEPED352

Structural racism matters: An exploratory study on the gendered-racialized experiences and HIV vulnerabilities of heterosexual young Black men

K. Bryce[1], J.P. Wong[1,2], M. Vahabi[1], A. Bailey[1], D. Miller[1], W. Husbands[3], D.-M. Chuang[1]
[1]Ryerson University, Toronto, Canada, [2]University of Toronto, Toronto, Canada, [3]Ontario HIV Treatment Network, Toronto, Canada

Background: Black communities in Canada are disproportionately affected by HIV. Black people accounted for over 10% of all HIV-related deaths in Ontario, even though they make up only 3.9% of Ontario's population. Existing literature on HIV vulnerabilities tends to focus on individual risky behaviour, without acknowledging how structural conditions, such as racism, gendered expectations and socioeconomic status, contribute to HIV vulnerabilities. This paper reports on the sub-study of a larger study, weSpeak, which examines the social determinants of HIV and collective resilience of self-identified heterosexual Black men in Ontario, Canada. This sub-study focused on the gendered and racialized experiences of heterosexual young Black men (HYBM) in Toronto, their HIV vulnerabilities, and conditions that promote their collective resilience.

Methods: We used purposive sampling to recruit self-identified HYBM. Outreach and recruitment strategies included e-flyers, information sessions and community referrals. Fifteen HYBM, between the ages of 16 to 25, took part in focus groups and individual interviews. Data were analyzed using a narrative approach and guided by analytical lenses of Critical Race Theory and intersectionality.

Results: The study results showed that HIV vulnerabilities and social vulnerabilities are intertwined. Dominant racist stereotypes of Black 'hypersexuality' and 'hyper-masculinity' function in multiple ways to increase HYBM's vulnerabilities to HIV by: (a) imposing psychological pressure for some HYBM to enact these stereotypes; (b) creating obstacles for open dialogue about sex and sexuality between HYBM and their sexual partners; and (3) producing distrust that impedes the negotiation of safer sex practices between HYBM and their sexual partners. Participants identified social support, mentorship, access to equitable opportunities and having a safe space for critical dialogue, as conditions that reduce their HIV vulnerabilities and promote their collective resilience.

Conclusions: The findings of the study suggest that effective HIV prevention responses for HYBM must be underpinned by social justice and address their social vulnerabilities. These responses must incorporate anti-oppression and race-gender-class analyses to engage heterosexual young Black men and women in critical dialogue to challenge racist stereotypes and harmful masculinist expectations that increase young Black people's vulnerability to HIV.

WEPED353

Food insecurity is associated with postpartum stress in Kenyan women of mixed HIV status

P. Murnane[1], J. Miller[2], S. Collins[2], T. Neilands[1], M. Onono[3], C. Cohen[3], S. Weiser[3], M. Laudenslager[4], S. Young[2]
[1]University of California San Francisco, Center for AIDS Prevention Studies, San Francisco, United States, [2]Northwestern University, Department of Anthropology, Evanston, United States, [3]University of California San Francisco, San Francisco, United States, [4]University of Colorado Denver, Aurora, United States

Background: Chronic stress in postpartum women is associated with depression, breastmilk quality, and infant health. Among persons living with HIV, stress is associated with poor drug adherence and disease progression. We hypothesized that food insecurity (FI) increases the risk of stress in postpartum Kenyan women.

Methods: From 08/2014-04/2016, 371 pregnant women were enrolled into a cohort study in western Kenya and followed through 9 months postpartum. Women were purposively sampled to include half HIV-positive, half HIV-negative, and comparable FI levels across HIV strata. Individual FI (range 0-27) in the prior month was assessed at all visits. Hair was collected at 9 months postpartum to measure hair cortisol concentrations (HCC), reflecting adrenal activation during the prior 3 months. We characterized FI in 2 ways: 1) FI at 9 months only, and 2) patterns of FI from pregnancy-6 months postpartum, using group-based trajectory modeling. We used linear regression to predict HCC, adjusting for socio-economic factors, and evaluated HIV status as a potential effect modifier.

Results: Women with HCC results (n=203) were included in the analysis. Mean age was 25.1 years (standard deviation [SD] 4.9) and mean log HCC was 2.0 pg/mg (SD 1.0). The association between 9-month FI and log transformed HCC suggested an inverse-U shape; therefore, we included a linear and quadratic term for FI in the model. Moderate FI (scale=10) compared to low FI (5) was associated with 32% higher HCC (95% CI: 10%-72%, p=0.006); this relationship tapered with when comparing FI scores of 15 vs. 10 and 20 vs. 15 (1% lower HCC [p=0.91] and 29% lower HCC [p=0.08], respectively). We identified 2 FI trajectories from pregnancy-6 months postpartum: 1) chronic FI (moderate-severe at most visits; 58% of women); and 2) mild/no FI (at most visits). Those with chronic FI had marginally elevated HCC (28% higher, 95% CI: -5%-73%, p=0.10) compared to those with mild/no FI. These associations did not differ by HIV-serostatus.

Conclusions: Chronic FI was marginally associated with elevated HCC, while at 9 months, those with moderate FI had the highest HCC. Interventions to mitigate perinatal FI in HIV-positive and negative women could prevent stress-associated poor maternal and infant health outcomes.

WEPED354

Understanding barriers and facilitators to antenatal care services in Cameroon

G. Loni Ekali[1], E. Kiawi[2], A. Abutu[3], J. Sobngwi[4], J. Mosoko[2], P. Ngalame[3], O. Bolu[2], J.B. Elat[1]
[1]National AIDS Control Committee, Yaounde, Cameroon, [2]Centers for Disease Control and Prevention, Yaounde, Cameroon, [3]Centers for Disease Control and Prevention, Atlanta, United States, [4]Catholic University of Central Africa, Yaounde, Cameroon

Background: In Cameroon, HIV prevalence among pregnant women is estimated at 5.7%. Prevention of Mother-to-Child Transmission (PMTCT) services are delivered mainly through the Antenatal Care (ANC) platform. In 2012, ≤ 40% of pregnant women in Cameroon accessed ANC services, implying that only a small proportion had the opportunity to receive HIV testing and PMTCT services if needed. This study was conducted to better understand the factors that affect uptake and retention in ANC and related health services.
Methods: A mixed-method qualitative study was performed between December 2012 and September 2013. Participants were purposively recruited across eight regions of Cameroon. Individual key informant interviews were completed with 40 health providers and community leaders, and 16 focus group discussions were conducted with groups of six to eight people aged 18-60 years in the community. All interviews were audiotaped, transcribed and coded thematically for analysis. Interpretive analyses were performed using ATLAS-ti.
Results: Knowledge of existence of ANC services in the community was universally high. However, rural community participants were less likely to know their HIV status and could not cite specific means by which HIV can be transmitted from mother-to-child. Fear of stigma and discrimination was reported by many participants as leading clients to seek care outside of their community, while high service fees was reported as an obstacle to women's ability to attend ANC. Men's participation in ANC and the need for women to get their spouse's permission to attend ANC were additional concerns. Long distances to and waiting times in ANC, shortage of staff and poor quality of ANC and postnatal care (PNC) services were cited as significant barriers. Pregnant women were attracted to attend community health common initiative groups instead of ANC due to poverty, proximity or misinformation.
Conclusions: Many barriers impact women's ability to access ANC/PMTCT services in Cameroon. Remedial action should focus on health promotion initiatives for women and their partners, provision of ANC supplies, training of nurses and other health facility staff to increase their number and improve service delivery quality, reducing MCH service-associated fees.

WEPED355

The role of HIV-expert clients in extending house-to-house nutrition services for PLHIV in Karamoja region Uganda

M. Mumma[1], E. Twinomujuni[2], C. Ouma[3]
[1]United Nations World Food Programme Regional Bureau Nairobi, Nutrition and HIV, Nairobi, Kenya, [2]UN World Food Programme, Nutrition and HIV, Kampala, Uganda, [3]UN World Food Programme Regional Bureau Nairobi, Nairobi, Kenya

Background: Karamoja region has grappled with high levels of food insecurity and this affects PLHIV more prone to malnutrition because of opportunistic infections. The objective of the Expert Clients (ECs) training was to create a peer-to-peer intervention to offer a viable, creative solutions to areas grappling with human resource challenges that often act as barriers to universally accessible, high quality HIV and Nutrition care and treatment in resource limited settings.
Description: Expert Clients were recruited basing on HIV-status, record of ART adherence, education level, ability to be trained and willingness to volunteer. The HIV expert clients were enrolled through the district health offices in all the seven districts of Karamoja. 75 HIV Expert Clients were selected from the seven districts in this training. These were then trained through a week-long course on nutrition assessment counselling and support for PLHIV. To assist in conducting their work, the ECs were also supported with job aids for nutrition in HIV and basic HIV treatment information. District health focal persons for nutrition and HIV were involved at all levels to enable them to understand the model for easy supervision. The HIV expert clients were voluntarily attached to health facilities near their communities and tasked to follow-up PLHIV on issues of Antiretroviral utilization and nutrition.
Lessons learned: There was improvement in awareness on food and nutrition requirements for PLHIV who are breastfeeding. responsiveness and demand for specific nutrition services for PLHIV increased. health facilities with ECs reported improvement in nutrition education and counselling for PLHIV, 75% of the health facilities reported improvement in patient referrals from the community, 92% indicated continued household reporting by ECs on ART and nutrition for PLHIV follow-up, 72% of the health facilities indicated improvement in appointment keeping.
Conclusions/Next steps: The utilization of expert clients in extending household nutrition services is a promising model .Future evidence building studies will be necessary to inform crucial human resource management and task shifting decision in the provision of health and nutrition services in Karamoja.

Socio-economic differences: poverty, wealth, and income inequalities

WEPED356

Poverty and racial and gender disparities among people living with HIV in Miami-Dade County

C. Bhatt, C. Beck-Sague, J. Devieux, W. Al Khoury
Florida International University, Health Promotion & Disease Prevention, Miami, United States

Background: For over 30 years, Miami-Dade County (MDC), Florida has had among the most challenging epidemics in the country. In 2015, there were over 25,000 people living with HIV/AIDS (PLHIV) in MDC, disproportionately affecting the Black community. Socioeconomic issues associated with poverty may directly or indirectly increase HIV risk factors. We examined association between poverty and HIV prevalence stratifying with gender and race/ethnicity.
Methods: To assess racial trends in HIV infection in MDC, we analyzed 2015 prevalence data from CDC and AIDSVu, and US Census data in the 75 major MDC zip codes. Data were stratified and analyzed by sex and race (Black, White and Hispanic of any race) of PLHIV and socioeconomic status (SES) comparing high (>20% of population living in poverty) to low-poverty zip codes (< 20% of population living in poverty).
Results: In 2015, MDC, FL had the highest HIV prevalence and incidence in the United States (965 and 87 per 100,000, respectively); 43% of PLHIV in 2015 were black, 44% Hispanic/Latino, and 11%. HIV rate in Hispanic/Latino men and women was essentially the same as that of white men and women respectively. Black men were 2.6 times and Black women, 13 times more likely to be HIV-infected than their White counterparts. In 2015, 226 HIV new infections and 143 AIDS cases were reported among adult women. Blacks were overrepresented, accounting for 74% of AIDS and 67% of HIV infection cases reported among women. In 2015, in the MDC zip codes analyzed, median HIV prevalence in Whites was 0.39% compared to 2.71% in blacks. Median HIV prevalence did not differ significantly by residence in poor (vs non-poor) zip codes in whites (0.54% vs. 0.35%; p= 0.308). However, median HIV prevalence in Blacks living in high-poverty zip codes (4.02%) was higher than in Blacks living in low-poverty zip codes (1.85%; p= 0.01). Median number of women with HIV was higher (N=199) in high-poverty zip codes than in low-poverty zip codes (p=0.0001).
Conclusions: These findings suggest that HIV varies by both races, gender, and poverty in Miami, with poverty playing a greater role in Blacks and among women.

WEPED357

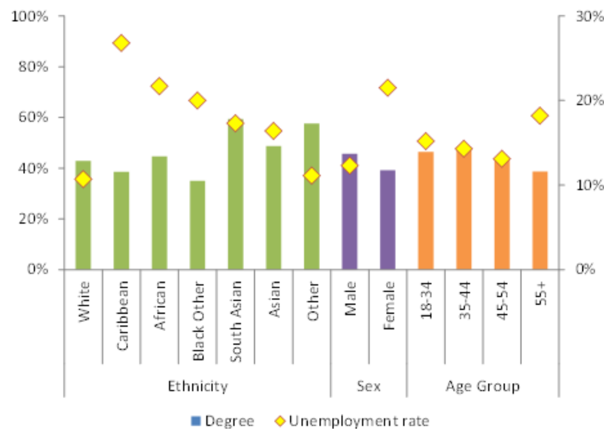
Social and welfare inequities in people living with HIV in England and Wales: Results from Positive Voices 2017

M. Kall[1], M. Auzenbergs[2], V. Delpech[1]
[1]*Public Health England, HIV/STI Department, London, United Kingdom,* [2]*Watipa, London, United Kingdom*

Background: Socioeconomic status is an important predictor of health. In the UK, HIV disproportionately affects socially vulnerable populations such as migrants, gay men and drug users, which may compound social inequity. We describe the social and welfare needs of people living with HIV (PLHIV) in the UK.

Methods: Positive Voices is a cross-sectional, probability survey of PLHIV, conducted between January and September 2017 in 73 HIV clinics in England & Wales. Respondents answered questions on socio-economic status and financial hardship. Participants were also asked about met and unmet social and welfare service needs in the previous 12 months.

Results: Of the 4,416 respondents (51% response rate), 44% were educated to at least undergraduate degree level, compared to 28% in the UK general population. High educational attainment was observed across all age, ethnicity and gender groups. Despite this, 15% of respondents were unemployed, compared to a 4.3% unemployment rate in the UK general population during the same period. The unemployment rate was highest among black Caribbean PLHIV (27%), black African PLHIV (21%) and PLHIV of other black ethnicities (20%) compared to 11% in white British PLHIV. 29% were in receipt of welfare benefits, compared to 8% in the UK general population. Most commonly claimed benefits were Disability Living Allowance (DLA) or Personal Independence Payment (PIP) (15%), Employment and Support Allowance (ESA) or Incapacity benefit (13%), and housing benefits (13%). A quarter (26%) had fallen behind with at least one household bill and 39% did not have enough money to meet their basic needs. The greatest social and welfare service needs were: housing support (22%), financial advice (15%), career skills/training (14%), and employment advice (14%); two-thirds reported these needs had not been met. Reasons for unmet need included not knowing how to access services, not knowing that services existed, or feeling too overwhelmed to seek services.



[Disparity in university degree attainment and unemployment rates by age, sex, and ethnicity among people living with HIV in the UK:]

Conclusions: PLHIV in the UK experience disproportionately high levels of unemployment, financial hardship, and social and welfare service needs despite high education attainment. Access to social and welfare services are an integral part of long-term care and support and should be considered in planning future programming.

WEPED358

Positive finance: Access to insurance for people living with HIV in the UK

K. Smithson, R. Hayes, Y. Azad, D. Gold
NAT (National AIDS Trust), London, United Kingdom

Background: People living with HIV (PLWH) across Europe face barriers to accessing private insurance that requires medical information, with implications for their financial resilience. The research aimed to describe the recent experiences of PLWH in the UK of accessing financial products, and identify how HIV status specifically impacts access to financial products.

Methods: Between February and April 2017, NAT conducted research using a mixed methods approach involving an online survey and focus groups. 215 people responded to the survey, of whom 202 were eligible to take part. Of these 202, 16 participants participated in a focus group in London or Manchester. The only criteria for participating in the survey and focus groups was that the individual must be living with HIV in the UK.

Results:
- 49% thought that life insurance is not available to PLWH, despite it being available in the UK since 2009.
- 60% had avoided applying for a financial product because of their HIV status due to fears of high cost, refusal and stigma.
- Only 28% knew where to look for HIV-inclusive financial products. Mainstream comparison sites often don't work for PLWH and specialist insurers can be difficult to find.
- 25% said they knew or suspected they had been refused a financial product in the last five years because of their HIV status.
- Qualitative data indicated that PLWH are often charged higher premiums, but it is not always clear whether the price fairly reflects the risk of a claim. When they are purchased, insurance products don't always meet the needs of PLWH.

Conclusions: The barriers to access identified from this research can be broadly categorised as follows:
- Self-exclusion from the market
- Difficulty navigating the market
- Ineligibility
- Unsuitable products
- Higher premiums

Some of the causes of these barriers are easily identifiable, such as fear of disclosure due to stigma or the lack of tailored products provided by insurers. Others need further investigation, particularly whether higher premiums fairly reflect the likelihood of PLWH making a claim. Each barrier requires a different response from a range of stakeholders, including the financial services regulator and Government.

WEPED359

Area-level poverty and low willingness to use PrEP among Black individuals in the US South

B. Ojikutu[1], L. Bogart[2], I. Kawachi[3], K. Mayer[4], Y. Ransome[5]
[1]*Brigham and Women's Hospital, Boston, United States,* [2]*RAND Corporation, Santa Monica, United States,* [3]*Harvard School of Public Health, Boston, United States,* [4]*Fenway Institute, Boston, United States,* [5]*Yale School of Public Health, New Haven, United States*

Background: The Southern US, where more than 50% of Black Americans reside, has the highest burden of HIV nationally. Poverty is also highest, and access to health care is lowest. Uptake of pre-exposure prophylaxis (PrEP) has been slow among Black individuals, particularly in the South. We sought to investigate the relationship between geographic factors (area-level HIV diagnoses, socioeconomic status, and access to care) on willingness to use PrEP among Black individuals living in the South.

Methods: We estimated the association between ZIP code-level change in rates of new HIV diagnoses (2014-2015; from AIDSVu.org), sociodemographic factors (percent living below the federal poverty line, percent black population, percent unemployment), percent uninsured (from the 2008-2012 American Community Survey) and willingness to use PrEP among Black adults in the South, drawn from the National Survey on HIV in the Black Community (NSHBC, 2016).

Results: 50.5% (437/865) participants were from the South, and 383 ZIP codes were represented. The mean age was 34 (SD=9) years. 46% were male, 24% had a household income < $25,000, 14% were uninsured and 23% were high risk based upon self-reported behavioral criteria. Only 25% of the high risk individuals reported willingness to use PrEP. Restricting the analysis to ZIP codes with HIV diagnoses data, 142 ZIP codes were included. The median increase in HIV diagnoses was 25 persons per 100,000 population from 2014 to 2015 (Interquartile range [IQR] 14-49). 37% of ZIP codes were in the upper 25th percentile (highest increase in new HIV diagnoses). Examining area-level factors in multivariable regression models, individuals living in ZIP codes within the upper 25th percentile were more willing to use PrEP (Prevalence Ratio (PR)=2.03, 95%CI =1.03-4.00, p=0.041) compared to individuals living in the lower 75th percentile. Higher area-level poverty was associated with lower (PR 0.48, 95%CI 0.25-0.92, p=0.028) willingness to use PrEP. Percent black population, percent unemployment and percent uninsured were not significant in multivariate analysis.
Conclusions: Overall, low numbers of Black individuals in the South are willing to use PrEP. However, individuals in areas with higher numbers of new HIV diagnoses were more willing to use PrEP. To improve uptake, area-level poverty must be addressed.

WEPED360

HIV and poverty vulnerability among women and girls in Abuja Municipal Area Council, Abuja, Nigeria

M. Egemba[1], Y. Falola-Anoemuah[1], O. Onosode[2], O. Onoh[3]
[1]*National Agency for the Control of AIDS, Programme Coordination Department, Abuja, Nigeria,* [2]*International Labour Organization, Abuja, Nigeria,* [3]*Measure Evaluation, Abuja, Nigeria*

Background: Nigerian women bear a disproportionate burden of the HIV epidemic and constitute 59% of HIV positive individuals. Evidence have shown that one of the major drivers of HIV especially amongst females is poverty and financial dependency; thus, contributing to the feminization of poverty and the epidemic. This study interrogates HIV and poverty susceptibility among women and girls in Abuja Municipal Area Council (AMAC), Nigeria.
Methods: In November, 2017, a descriptive study involving 52 females from AMAC was conducted. Respondents who were selected though multistage sampling comprised of female sex workers (FSWs), women and girls among internally displaced persons (IDPs), women living with disabilities (WWD), women from support groups of people infected with and affected by HIV (WSG) and other indigent women. Quantitative data collected with a scaled economic strengthening selection tool were analyzed with descriptive statistics (frequencies and crosstabs).
Results: Median age of respondents was 35years (range:16-54years). 61.54% (number=32) were HIV positive. Fifty percent of the respondents had no source of income, conversely, all of the FSWs interviewed considered themselves employed and 43.75% of them earned above N25,000 monthly. Majority of the respondents (69.23%,n=36) lived in dilapidated and overcrowded shelters with insufficient and irregular food (76.92%,n=40). On a scale of 9-32marks, with 32marks representing the highest score on the poverty vulnerability scale, majority of respondents were "most vulnerable" (55.77%,scores:21-32) and 40.38% were "more vulnerable" (scores:14-20). Amongst categories of women assessed, WSG were "most vulnerable" (37.93%), followed by IDPs (31.03%), FSWs (20.69%), WWD (6.90%) and others (3.45%). Across all groups, HIV positive women(50%) were more indigent than HIV negative women(38.46%) and people of unknown status(11.54%).
Conclusions: There is a strong relationship between positive HIV status and vulnerability to poverty, thus, poverty can be both a cause and effect of HIV infection. Socio-economic data from the respondents revealed the need for economic empowerment initiatives among these categories of women. Building livelihoods through microenterprises for HIV vulnerable women and girls is one of the remarkable ideas for developing financial and economic sustainability, improving household income and creating jobs for increased HIV prevention, care & support and access to treatment for women and their households.

WEPED361

A bridge to employment; AIDS free society

B. Onyango[1], C. Obuya[1], R. Mwende[2]
[1]*African Centre for Women Information Communication and Technology (ACWICT), Programs, Nairobi, Kenya,* [2]*African Centre for Women Information Communication and Technology (ACWICT), Monitoring and Evaluation, Nairobi, Kenya*

Background: Extreme household poverty and lack of economic livelihoods, deprivation of material resources such as housing, food and healthcare coupled with lack of knowledge on HIV transmission and associated risk factors are the main causes to the high HIV prevalence rate among young women in urban slums of Kisumu and Nairobi counties in Kenya.
Description: The *Vusha Girls Employability program,* an innovation of the ACWICT funded by PEPFAR through DREAMS Innovation Challenge and managed by JSI, is a demand-driven workforce development program that aims to improve the employment prospects and income-generating capacities of 1,000 high potential but disadvantaged young women from low-income households. Increasing economic opportunities decreases the likelihood that adolescent girls and young women will engage in transactional sex work. The intervention targets girls at the transition points from high school, vocational education, and tertiary education with the goal of improving employment opportunities, increasing income-generating opportunities, and providing a bridge to employment. The intervention equips the young women with Vocational skills, Life skills, HIV education and Online Work skills.
Lessons learned: To effectively realize the young women transit to employment, the program focused on demand driven skills. In the first 9 months of implementation, 567 young women benefited from the program with 285 getting placement to income generating jobs. Employers have reported positive feedback on the beneficiaries because they possess digital literacy skills and life skills which are important assets in a work environment.
Conclusions/Next steps: The outcome of *Vusha Girls Employability Program* will be useful in national response to reduce new HIV infection amongst adolescents between the ages of 18-24 years old. It recognizes that mitigating on economic and behavioural challenges can significantly reduce new HIV infection associated with transactional sex due to lack of economic empowerment.

Dynamics of social status and power: sex, gender, age, race/ethnicity, sexual orientation, disability

WEPED362

Comparing MSM and transgender women (TW) on socio-demographics and psychosocial constructs relating to the HIV continuum of care and prevention in Lima, Peru

K.A. Konda[1,2], A. Maiorana[3], G.M. Calvo[2], A. Motta[2], E. Lugo[2], A. N[2], A. Silva-Santisteban[2], X. Salazar[2], C.F. Caceres[2], S. Kegeles[3]
[1]*University of California, Division of Infectious Diseases, Department of Medicine, Los Angeles, United States,* [2]*Center for Interdisciplinary Studies in Sexuality, AIDS and Society, Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*University of California, Medicine, San Francisco, United States*

Background: As we approach the 4th decade of HIV prevention and treatment, there is a need for differentiated and nuanced understanding of key populations who are vulnerable to HIV. MSM and transgender women (TW) remain the primary key populations in Peru, and we use information from the baseline of an HIV prevention and engagement in care trial to compare them and provide insight into their needs.
Methods: MSM/TW recruiters and long chain peer recruitment were used to enroll participants in two large, understudied Lima districts. The survey was interviewer-administered to participants using computer-assisted methods.

Results: We enrolled 277 MSM and 136 TW, whose average age was 31. TW reported significantly less formal employment and education than MSM, but similar abilities to cover basic needs. TW were more open about their gender identity than MSM were open about their sexual identity. There was no difference in alcohol abuse, while TW reported more recreational drug use. TW reported more experiences of stigma due to sexual or gender identity and more HIV stigma. There were no significant differences between MSM and TW in depression, experiences of stigma in health care settings, sexual risk, or social support (all p-values >0.05). Although MSM reported more condomless insertive anal sex, there was no difference in condomless receptive sex. But while TW had nearly twice the HIV prevalence of MSM, among those living with HIV there was no difference in linkage-to-care, ART use, or self-reported undetectable viral loads (all p-values >0.05).

	MSM	TW	p-value	Example item (scales only)
Living with HIV	20%	35%	**0.001**	NA
Undetectable viral load (among HIV positives)	46%	49%	0.725	NA
Condomless receptive anal sex, last 3 months	36%	41%	0.348	NA
Condomless insertive anal sex, last 3 months	22%	7%	**<0.001**	NA
Recreational drug use, last 2 months	16%	25%	**0.032**	NA
General self-efficacy	24.3	23.1	0.058	It's easy for me to stick to my aims and accomplish my goals.
Open with almost everyone about sexual/gender identity	35%	60%	**<0.001**	
Experiences of stigma due to: a)Sexual or gender identity	a) 5.9	a) 9.1	a) **<0.001**	a) Have you felt excluded from family gatherings because you are gay/trans?
b) Normative HIV stigma	b) 25.8	b) 9.8	b)**0.014**	b) People with HIV lose jobs when their employers learn they have it.
c) Stigma in health care	c) 1.6	c) 27.6	c) 0.636	c) Have you ever felt that you were not treated well in a health center because someone knew that you are gay or trans?
*All scales use t-tests to compare means. All categorical variables are compared using chi-square tests.				

[Characteristics Comparing MSM and TW Vulnerabilities in Large Districts in Lima, Peru]

Conclusions: MSM and TW have both similar and different experiences, influencing their risk profile for HIV and care engagement. TW had more socioeconomic vulnerabilities. The more frequent experiences of stigma among TW is explicable given more societal rejection of TW and the inability to hide their gender identity. MSM were more able to hide their sexual identity and, perhaps consequently, reported less stigma. That health care related stigma was similar may be related to self-selection into facilities accustomed to working with these populations. HIV prevalence reflects those found in similar populations elsewhere, but viral suppression remains low for both groups.

WEPED363

Influences of gender norms and gender roles on HIV treatment engagement in Vietnam

M. Do[1], H. Le H.[2], H. Ho T.[2], H. Dinh T.[2], T. Truong Q.[2], T. Dang V.[3], D. Nguyen D.[3], K. Andrinopoulos[4]
[1]Tulane University School of Public Health and TM, Global Community Health and Behavioral Sciences, New Orleans, United States, [2]Hanoi University of Public Health, Hanoi, Vietnam, [3]USAID/Vietnam, Hanoi, Vietnam, [4]Tulane University School of Public Health and TM, New Orleans, United States

Background: HIV-positive people who use injection drugs (PWID) face significant challenges that influence their engagement in HIV treatment, particularly in meeting normative expectations related to gender and drug use behavior. In contexts, like Vietnam, where heterosexual transmission of HIV is substantial, PWIDs' female sexual partners (FSPs) are at risk of drug use and HIV infection. Understanding more about the relationship between gender expectations for PWID and FSPs with drug use and HIV treatment would help inform retention programs.

Methods: We describe how expected gender roles may contribute to HIV treatment engagement among HIV-positive male PWIDs and FSPs. In-depth interviews were conducted with 30 male PWIDs and 21 FSPs in September 2017. The interviews were in Vietnamese, translated into English, and analyzed using NVivo 11 software.

Results: Male PWIDs often presented later to treatment and were less likely to consistently stay in treatment than FSPs for several reasons. The perceived criminalization of drug use led to a higher level of discrimination reported by male PWIDs, compared to FSPs who were often perceived as victims of their partner's behavior. FSPs who also inject drugs were also highly stigmatized. Perceived norms around the roles of men as the head of the household economically, in maintaining the family lineage and ancestor worship practices may negatively influence PWIDs' retention, either because they had to travel for work, or had to hide their HIV status and treatment due to family's expectations. FSPs, on the other hand, were more likely to stay in treatment because of their expected roles in taking care of their family and in-laws, although it could also be challenging as FSPs reported reluctance to seek support from their in-laws or their own family.

Conclusions: While the couple approach is important for HIV treatment retention, specific interventions need to be tailored to assist male PWIDs and FSPs overcome the challenges. The sharp differential treatment of male PWIDs vs. FSPs by families and communities imply that:
1) more focused support for FSPs is needed for their long-term treatment, and;
2) an increasing number of FSPs who inject drugs could remain hidden, posing an additional challenge to HIV programs.

WEPED364

Understanding HIV medication adherence amid multi-level, intersecting, and shifting challenges: Listening to the needs of the most vulnerable PLWH in the U.S.

M. Teti[1], E. Koegler[1], M. Enriquez[2], L. Bowleg[3]
[1]University of Missouri, Health Sciences, Columbia, United States, [2]University of Missouri, Nursing, Columbia, United States, [3]George Washington University, Washington DC, United States

Background: One-third of PLWH in the U.S. are insufficiently adherent for viral load suppression. PLWH who experience health inequities report worse viral load outcomes and less support from adherence interventions. The purpose of this study is to explore the nexus of daily challenges and adherence among PLWH without viral load suppression, who face multiple and intersecting inequities, such as those that stem from racial/ethnic minority status and/or poverty and/or HIV stigma and/or sexual or gender minority status.

Methods: Participants included 50 PLWH without viral suppression who took part in two peer-led HIV medication adherence intervention studies. Participants experienced multiple inequities: most were individuals of color; all were low-income; many were sexual minorities. HIV positive peer interventionists documented 6 weekly meetings describing participants' adherence experiences using detailed field notes. Participants chose notes for data collection, versus recordings, to promote open peer-to-peer dialogue. Content and narrative analyses of 300 field notes were used to identify adherence challenges.

Results: Challenges to adherence were characterized by four descriptive themes - severe, multileveled, intersecting, and variable. Participants experienced an average of 27.8 (range 8-52) major stressors over the course of six weeks. Average stressors reported in a single week were 4.6 (range 1.6-6.5). Common stressors were physical illness, mental health, isolation, poverty, homelessness, substance abuse, and hunger. Most participants reported barriers at the individual (e.g., depression) relational (e.g., isolation) and community/social (e.g., homelessness) levels. All participants described how barriers intersected and escalated (e.g., homelessness worsened drug use and hunger). PLWH experienced barriers that shifted over time and affected adherence (e.g., depression in control one week, poor the next due to an unexpected event).

Conclusions: Peer conversations allowed honest documentation of dialogue from vulnerable patients with compounding challenges and health inequities. Gathering insights from this subgroup of PLWH can

inform flexible solutions that respond to patient priorities. Interventions (medical and behavioral) need to be ongoing and sustainable, addressing multi-level challenges in the context of patient's lives, also accounting for instability. Improving adherence among PLWH without a suppressed viral load who face multiple health inequities is essential to meeting national adherence goals, protecting the health of PLH, and curbing HIV transmission.

WEPED365

Sociocultural contexts of HIV risk behaviors among Mak Nyah (Transwomen) in Kuala Lumpur, Malaysia

T. Nemoto[1], M. Iwamoto[1], V. Stanislaus[1], Y.K. Teh[2]
[1]Public Health Institute, Oakland, United States, [2]National Defense University of Malaysia, Defence and Management Studies, Sungai Besi Camp, Malaysia

Background: Very limited data on HIV/AIDS among mak nyah are available because civil and religious (Syariah) laws criminalize mak nayh in Malaysia where the national religion is Islam. Few studies reported the substantial increase in HIV prevalence, gender-based discrimination, violence, and human rights abuses against mak nayh. This study aimed to describe sociocultural contexts of HIV-related risk behaviors among mak nayh in Kuala Lumpur.
Methods: After completing qualitative interviews, a total of 150 mak nyah were recruited for survey interviews. Participants were recruited based on purposive sampling through direct outreach and referrals from local ASOs that provided services for mak nayh.
Results: Mak nyah study participants (N=150) were: mean age=38.0 years (SD=10.1); 72.0% Malay, 14.0 % Indian, 8.7% Chinese, and 5.3% other; 62.0% single and 33.3 % having a partner; 58.0% identified as mak nyah and 35.3 % female; 8.7 % had sex reassignment surgery; 82.0% heterosexual, 13.4% homosexual, and 4.0% bisexual. Most of the participants (88%) had tested for HIV and 12.7% reported living with HIV. About 2/3 reported currently engaging in sex work and 56.7% reported having engaged in oral sex with customers and 35.3% had not used a condom all the time; 48.0% engaged in anal sex with customers and 16.7% had not used a condom all the time. Only 1/3 correctly answered all HIV knowledge questions and 27.9% had engaged in condom-less sex when customers offered extra money. More than one third (37.6%) reported ever being physically assaulted; 28.2% and 18.7% being raped or sexually assaulted when under 18 years old and 18 years and over, respectively; 51.8% were depressed (CES-D).
Conclusions: The study provided important descriptions of risk behaviors and sociocultural factors among mak nayh that confirmed qualitative results from previous studies. It is alarming that a high prevalence of sexual and physical violence and depression among mak nayh. System level changes to eliminate discrimination and human rights abuses against mak nyah could take time, but direct health and social services and social media campaigns from CBOs could be implemented not only to address HIV prevention, but also health and human rights for mak nayh in Malaysia.

Ashamed, afraid and proud: Masculinities as key barriers to the attainment of the 90-90-90 targets in two rural districts in Zimbabwe

T.B. Masvawure[1,2], J.E. Mantell[1,3], M. Mapingure[4], T. Apollo[5], C. Gwanzura[6], L. Block[1], E. Bennett[3], P. Preko[7], G. Musuka[4], M. Rabkin[1]
[1]ICAP, Mailman School of Public Health, Columbia University, New York, United States, [2]College of the Holy Cross, Sociology and Anthropology, Worcester, MA, United States, [3]New York State Psychiatric Institute and Columbia University, Division of Gender, Sexuality and Health, New York, United States, [4]ICAP, Mailman School of Public Health, Columbia University, Harare, Zimbabwe, [5]Ministry of Health and Child Care, HIV/AIDS and STIs Unit, Harare, Zimbabwe, [6]Ministry of Health and Child Care, AIDS and TB Unit, Harare, Zimbabwe, [7]ICAP, Mailman School of Public Health, Columbia University, Mbabane, Swaziland

Background: Despite dramatic improvements in access to antiretroviral treatment (ART) in sub-Saharan Africa, men are less likely than women to test for HIV and to link to ART when they test positive. This poses an important challenge to the attainment of the 90-90-90 targets.
Methods: We explored HIV+ men's challenges to HIV testing and care at three purposively-selected high-volume ART clinics in rural Zimbabwe. We conducted twenty focus group discussions with 57 HIV+ men in Community Antiretroviral Refill Groups (CARGs), 61 HIV+ men not in CARGs and 29 HIV+ women in CARGs, and 46 in-depth interviews with policy makers, implementers, community members and health care workers. Data were analyzed using deductive and inductive approaches.
Results: Masculinities and concerns about social status—expressed through the idioms of "shame", "fear" and "pride"—were prominent themes for why few men get tested for HIV or initiate ART. Men were "ashamed" to be seen testing for HIV by community and family members because it implied "promiscuity", whereas collecting medications at health facilities (HF) publicly revealed one´s HIV status. HIV testing and HIV care were thus seen as potentially damaging to men´s reputations. "Fear" of marital conflict was another barrier as wives accused husbands who tested HIV+ of infidelity. Consequently, many men preferred to wait for wives to get tested first or for wives to suggest testing together. The last idiom—men´s "pride" - is deeply tied to notions of masculinities. Men believed they were invincible, and thus downplayed the importance of getting tested, denied an HIV+ result, refused to initiate ART, or stopped taking medications when their health improved or they started new relationships. Other men avoided HIV testing because they did not want to use condoms with wives if found positive, while others did not want an HIV+ diagnosis to affect their ability to attract new sexual partners. Some men considered HF to be "female spaces" and did not want to be seen there. Finally, only economically unproductive men were believed to spend hours at HF.
Conclusions: Men's needs and lived realities continue to be a "blind spot" in HIV programming (UNAIDS 2017). Innovative men-focused strategies are urgently needed.

WEPED367

Disability predicts violence against women over 12 months: A prospective cohort analysis amongst young women in urban informal settlements in South Africa

A. Gibbs[1,2], K. Dunkle[3], I. van der Heijden[3], L. Washington[4], N. Shai[3], S. Willan[1], R. Jewkes[3,5]
[1]South African Medical Research Council, Gender and Health Research Unit, Durban, South Africa, [2]University of KwaZulu-Natal, Health Economics and HIV/AIDS Research Division, Durban, South Africa, [3]South African Medical Research Council, Gender and Health Research Unit, Pretoria, South Africa, [4]Project Empower, Durban, South Africa, [5]University of Witwatersrand, School of Public Health, Johannesburg, South Africa

Background: Women living with disabilities are more vulnerable to intimate partner violence (IPV), and women who experience IPV more likely to acquire HIV. Yet, the majority of studies on the associations between disability and IPV are cross-sectional and cannot therefore account for the temporality of associations. Here we assess whether disability sta-

Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

tus at baseline predicted IPV incidence over 12months of follow-up in a cohort sample, in urban informal settlements in eThekwini Municipality, South Africa.

Methods: We analyzed preliminary data from young South African women participating in the Stepping Stones and Creating Futures randomized control trial. Disability at baseline was assessed using a modified version of the Washington Group Short Set of Questions on Disability, categorized into three levels of disability, none, moderate and severe, and used to model physical, sexual, economic, and emotional IPV, and non-partner sexual violence at one year follow-up. For each outcome, we built separate Gaussian random effects models, reporting adjusted odds ratios, controlling for socio-demographics at baseline, time, baseline IPV, and study arm.

Results: At baseline 50.2% reported no disability, 30.4% moderate disability, and 19.4% severe disability. 417/680 women were followed up, with no differences by baseline disability status. Past year IPV incidence at follow up was highly prevalent: physical IPV 47.9%, sexual IPV 32.3%, emotional IPV 67.7%, and economic IPV 54.4%. 30.0% of participants also reported non-partner sexual violence. Women reporting moderate disability at baseline were more likely to report emotional IPV aOR1.64(1.00-2.68), and women reporting severe disability at baseline were more likely to experience physical IPV aOR2.94(1.66-5.22), sexual IPV aOR2.04(1.16-3.59), emotional IPV aOR2.71(1.42-5.18), and non-partner sexual violence aOR2.58(1.41-4.74) at follow-up, than women not reporting a disability at baseline (table 1).

Conclusions: Severity of disability predicted women's incident experience of physical, sexual, and emotional IPV, and non-partner violence. Interventions working to prevent HIV-acquisition through preventing violence need to ensure that women and girls with disabilities are included, and that intervention materials and activities are accessible. Effectiveness of programs for participants with disabilities should be explicitly assessed.

Disability status	Physical IPV past 12m: aOR (95%CI)	Sexual IPV past 12m: aOR (95%CI)	Emotional IPV past 12m: aOR (95%CI)	Economic IPV past 12m: aOR (95%CI)	Non-partner sexual violence past 12m: aOR(95%CI)
No reported disability	base	base	base	base	base

Women´s decision-making and agency in the context of Option B+ in Malawi: An in-depth longitudinal qualitative study

F. Cataldo[1,2], F. Kasende[1], P.M. Nkhoma[1], M. van Lettow[1,2], R. Nyirenda[3], J.J. van Oosterhout[1,4], E. Schouten[5], M. Nyangulu[6], B.A. Tippett Barr[6]
[1]Dignitas International, Medical and Research Department, Zomba, Malawi, [2]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [3]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi, [4]College of Medicine - University of Malawi, Department of Medicine, Blantyre, Malawi, [5]Management Sciences for Health, Lilongwe, Malawi, [6]Centers for Disease Control and Prevention, Lilongwe, Malawi

Background: Although lifelong antiretroviral therapy (ART) for HIV-positive pregnant and breastfeeding women ('Option B+') has dramatically expanded in Malawi since 2011, challenges with rapid ART initiation and sub-optimal retention in care have been reported. We explored women´s individual decision-making and agency in relation to treatment uptake, long-term retention in care, breast-feeding practices, and reproductive intentions.

Methods: We report on a longitudinal multi-site ethnographic study (July 2016-September 2017), nested in a broader PMTCT impact evaluation, conducted in 13 sites (Southern/Central regions). In-depth interviews, focus group discussions and observations were conducted with women retained in cared in Option B+ (n=53) and their male partners (n=19), adolescents (n=13), lost-to-follow-up women (n=23), community and PMTCT leaders (n=23), and healthcare workers (n=154). Data were analyzed through interpretive open-ended coding (Nvivo11) and a comparative thematic framework approach.

Results: Median age of women retained in care was 32 years; they had 3 children on average. Although most women reported that starting ART was the ´healthy´ option, male partner disclosure and participation treatment uptake/continuation was central to decision-making processes. Women who felt unable to discuss test results and treatment uptake with male partners reported delaying ART initiation and having challenges continuing ART due to difficulties hiding treatment. Similar opinions were presented across other groups of research participants: complex decision-making dynamics between women newly identified as HIV-positive and male partners of unknown HIV status hindered long-term retention in care. Fears about possible breach of confidentiality while visiting health facilities led some women to decide to stop ART. Breastfeeding decisions and reproductive intentions were perceived by community leaders as ´the responsibility of the man´. Living with HIV and perceptions of risk for themselves and their infants were central to women´s reproductive intentions.

Conclusions: Despite an increased optimism around Option B+, decisions around starting and remaining on lifelong treatment, breastfeeding, and reproductive intentions remain deeply entrenched within gender and cultural norms that affect women´s care trajectories. Additional efforts at balancing joint decision-making between women and their partners, and involving male partners at every step of the testing and care continuum are essential to improving long-term retention in Option B+ and other Test-and-Treat programs.

Economic transitions and social and cultural changes affecting HIV and the HIV response

WEPED369

Traditional leaders play a key role in the roll out of early ART at community level

M. Zwane-Machakata[1], J. Manana[1], L. Chingandu[2], R. Eghtessadi[2]
[1]SAfAIDS, Swaziland Country Office, Manzini, Swaziland, [2]SAfAIDS, Regional Office, Harare, Zimbabwe

Background: The MaxART consortium, led by the Swaziland Ministry of Health conducted the MaxART Early Access to ART for All (EAAA) study in Swaziland from 2014 - 2017. The study sought to answer questions on clinical outcomes, acceptability, feasibility, affordability and scalability of an Early ART programme in Swaziland. The study also included a component of engaging existing traditional structures to inform communities about the EAAA study and mobilize HIV positive individuals to access early ART.

Methods: To promote better understanding of the role and contribution of traditional leaders in the roll out of early ART study in study communities, data was collected through 96 semi-structured interviews and 9 focus group discussions with key community actors including support group members, community-based volunteers, traditional healers, religious leaders and traditional leaders.

Results: The active role of traditional leaders in informing communities about the Early ART programme and mobilizing communities take up HIV testing and early treatment was recognized across all the key actors. Two main mechanisms used by traditional leaders for community mobilization emerged from the interviews namely: using community meetings, either individually or in collaboration with community-based volunteers and being role models, which constituted taking public HIV tests and thus reducing stigma around HIV testing. 90% of respondents agreed that traditional leaders play a key role in mobilisation of communities for uptake of services. 80% of TL interviewed reported they took public HIV tests to set a good example to their communities. 34% of

TLs who were tested have publicly shared their HIV status. 92% of CBVs interviewed testified that they worked with TLs Leaders through community meetings to share information on HIV and EAAA. **87%** of Support Group members confirmed that TLs help them in discharging their duties under EAAA programme.
Conclusions: Traditional authorities play a major role in implementing HIV programmes at community level. With appropriate and accurate engagement they can meaningfully support health programmes to access communities. They can further model good health seeking behaviour thus encouraging uptake of services. They can improve acceptability of HIV programmes and support stigma reduction efforts as well as support treatment retention and adherence.

WEPED370

ART adherence among patients cared in the community client-led ART delivery (CCLAD) - TASO, Uganda experience

A. Okiror
The Aids Support Organisation (TASO), Finance, Kampala, Uganda

Background: TASO Uganda is one of the largest organizations implementing HIV care and treatment institutions in Sub Saharan Africa, caring for over 100,000 people living with HIV. TASO introduced Community drug distribution points model (CDDP) and recently the, Community client led ART delivery model (CCLAD) for stable patients on ART. The main aim of this study is determine adherence outcome among patients on CCLAD.
Description: TASO developed eligibility and exclusion criteria. The CCLAD eligibility criteria were: adherence, poor response to ART (CD4 count consistently below 350 for more than six months), TB co-infection or presence of any malignancies. A data tool tracking client indicators was developed with the help of Peer Leaders. data is captured in one main system to the national data reporting tool. Pre-packaging of drugs, labeled and packed separately, makes distribution of refills to individual clients easier for each client in preparation for delivery. Transport costs: a group of seven to ten clients contributed a nominal user fee to cover the cost of transportation for the leader to collect the drugs each time.
Lessons learned: A total of 62,129 patients were on ART were enrolled in 2015 for this study, 23,113 (37%) were in facility arm, 36,777 (59%) were in CDDP arm, 2799 (14%) were on CLAD arm. The adherence outcome for facility above 95% was 88%, 89% for CCLAD and 89% for CDDP. We learnt that a simple data collection tool facilitated the peers to collect information which is then transcribed to national ART registers. Pre packing of drugs with clear labeling by pharmacy staff enable accurate distribution of ART refills, patients were empowered to take care of the challenging transport cost by jointly contributing to costs for peer leaders to pick group medications
Conclusions/Next steps: CCLAD models achieved similar adherence outcomes compared to facility-based models and community-based drug delivery by facility staff. Peer leaders, as lay ART providers facilitated the smooth implementation of the CCLAD model. CCLAD model should be scaled up for stable patients on ART

Intergenerational and/or transactional sex

Understanding HIV risk in the postpartum period: Being in an age-disparate relationship increases postpartum inconsistent condom use for socially isolated South African women

A.K. Groves[1], L. McNaughton Reyes[2], S. Maman[2], L.T. Gebrekristos[1], D. Moodley[3]
[1]Drexel, Community Health and Prevention, Philadelphia, United States, [2]UNC Chapel Hill, Health Behavior, Chapel Hill, United States, [3]Nelson Mandela Medical School University of KwaZulu Natal, Obstetrics and Gynaecology, Durban, South Africa

Background: Age-disparate relationships are considered a key driver of the HIV epidemic; however, the evidence supporting the association has been mixed. This heterogeneity may be explained by the fact that other social-contextual factors, such as social isolation, work synergistically with age-disparate relationships to increase women's vulnerability to HIV infection. In this longitudinal study, we hypothesize that the association between being in an age-disparate relationship and inconsistent condom use postpartum will be stronger for women who are socially isolated compared to those who are not.
Methods: Data come from 605 HIV-negative participants who completed a baseline antenatal visit and 14-week postpartum follow up as part of a larger longitudinal RCT. We used logistic regression to test our hypothesis. Specifically, we examined whether the relationship between baseline age disparity and postpartum inconsistent condom use varied as a function of baseline social isolation, controlling for relevant covariates.
Results: Nearly 25% of women were in an age-disparate relationship with a partner who was 5 years or older; significantly more women in age-disparate relationships reported inconsistent condom use postpartum (26.61% vs. 17.30%, p=.02). Just over 10% reported social isolation during pregnancy such that they saw no people in their network in the past week; socially isolated women also reported significantly more inconsistent condom use postpartum (30.00% vs. 17.54%, p=.01). As hypothesized, there was a significant interaction between being in an age-disparate relationship and reported social isolation after adjustment for covariates. Specifically, women in an age-disparate relationship were 9.21 times more likely to report inconsistent condom use postpartum if they were also socially isolated (95% CI: 2.41, 35.22); there was no effect for those who were not socially isolated.
Conclusions: The findings suggest that being in an age-disparate relationship affects HIV risk, particularly for women who are socially isolated from their friends and family in the early postpartum period. Further research is needed to determine if there are other ways in which one's existing social networks affect power differentials in age-disparate relationships. Interventions that reduce women's social isolation during the postpartum period, particularly for those with older sexual partners, may reduce South African women's vulnerability to HIV during this time.

WEPED372

Measuring gender norms associated with transactional sex for adolescent girls and young women in Central Uganda - implications for structural interventions

K. Stoebenau[1], J.B. Bingenheimer[2], I.N. Ddumba[3], N. Kyegombe[4], S. Namakula[5], J. Mulindwa[5]
[1]University of Maryland, College Park, United States, [2]George Washington University, Prevention and Community Health, Washington, DC, United States, [3]Makerere University, Kampala, Uganda, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Independent Consultant, Kampala, Uganda

Background: Transactional sex, or informal sexual exchange relationships, are an important determinant of adolescent girls' and young women's (AGYWs) disproportionate HIV risk in sub-Saharan Africa. Transactional sex relationships are structured by both social and economic gender inequalities, suggesting economic intervention strategies

alone may not be adequate. In this study we explored the less examined social norm influences on transactional sex. We describe findings from a pilot study that developed innovative experimental vignettes to identify and assess gender norms stemming from the shared expectation that men should provide financial support to their partners.

Methods: We developed vignettes in the Kampala and Masaka districts of Uganda with 15 to 24 year old women between February, 2017 and January, 2018. The three phases of primary data collection included
1) 10 focus-group discussions (FGDs) to identify gender norms,
2) two rounds of 16 cognitive interviews to refine vignettes, and
3) the administration of a pilot survey experiment to 108 sexually-active unmarried AGYW (general population (n=78) and high-risk venues (n=30)).
Respondents were randomly assigned to one of two versions of each of three vignettes (short stories) which presented different levels of male provision.

Results: The vignettes examined whether the amount a man provided changed perceived approval of men's authority in relationships, men's sexual decision-making power, and women having multiple partners. We find an increase in the value a man provides significantly raises perceived levels of community approval for his sexual decision-making power (p< .001), and significantly lowers perceived peer approval of AGYW's seeking a second partner (p< .05). Finally, we find women who practiced transactional sex in the last 12 months (51%) were more likely to approve of women who sought multiple partners when their primary partner did not provide.

Conclusions: Our findings suggest that approval of men's sexual decision-making power increases when they provide more and that women are less socially sanctioned, or more approved of by their friends, when they seek a second partner in the event their first cannot provide. These findings highlight normative drivers of HIV risk associated with transactional sex that should be addressed by HIV intervention efforts working with AGYW.

WEPED373

Gender disparities in lifetime and recent transactional sex among high-risk youth

A.E. Fehrenbacher[1], D. Swendeman[1], S.-J. Lee[1], L. Kozina[2], M. Koussa[1], C. Reback[3], Adolescent Medicine Trials (ATN): Project CARES
[1]University of California, Center for HIV Identification, Prevention, and Treatment Services (CHIPTS), Los Angeles, United States, [2]Tulane University, New Orleans, United States, [3]Friends Research Institute, Los Angeles, United States

Background: Transgender and gender non-conforming (T/GNC) sex workers are severely marginalized and understudied despite having the highest HIV prevalence of all key populations globally, estimated at 27-40%. HIV prevalence among T/GNC sex workers is nine times higher than cisgender women sex workers and four times higher than cisgender men sex workers. T/GNC refers to gender identity that differs from assigned sex at birth. Cisgender refers to gender identity that corresponds with assigned sex at birth.

Methods: This analysis examined gender disparities in transactional sex among a cohort of high-risk 12-24 year olds (n=546) in Los Angeles and New Orleans in the Adolescent Medicine Trials (ATN): Project CARES from 2017-2018. Participants were recruited from homeless youth shelters, LGBT centers, clinics, and social media. Logistic regression was used to test the relationship between gender and prevalence of transactional sex (lifetime and last 12 months). Zero-inflated negative binomial regression was used to test the relationship between gender and frequency of transactional sex (last four months). The sample was 58% cisgender men, 35% cisgender women, and 7% T/GNC. Among T/GNC respondents, 71% were transgender women, 10% transgender men, and 19% non-binary.

Results: Lifetime prevalence of transactional sex was nearly three times higher among T/GNC respondents than cisgender respondents (63% T/GNC, 25% cisgender men, 23% cisgender women) and twice as high in the last 12 months (51% T/GNC, 24% cisgender men, 22% cisgender women). In addition to gender, lifetime transactional sex was significantly associated with being lesbian/gay, bisexual, or queer; lifetime history of homelessness, incarceration, mental health hospitalization, and substance abuse treatment; and recent (last 12 months) illicit drug use, testing positive for a sexually transmitted infection, sex with an HIV-positive partner, and condomless anal sex. There were no significant gender differences in frequency of transactional sex in the last four months.

Conclusions: T/GNC youth are significantly more likely to report transactional sex than cisgender youth. Structural risks of incarceration and homelessness contribute to substance use and mental health conditions, which cumulatively exacerbate HIV risk for T/GNC youth. Interventions for T/GNC youth must address multiple, intersecting forms of marginalization that limit their access to supportive risk reduction environments.

WEPED374

Self-esteem as an indicator of transactional sex among young women in rural South Africa (HPTN 068)

D. Giovenco[1], A. Pettifor[1], J. Hughes[2], C. MacPhail[3], R. Wagner[4], K. Kahn[4]
[1]University of North Carolina, Chapel Hill, Epidemiology, Chapel Hill, United States, [2]University of Washington, Biostatistics, Seattle, United States, [3]University of Wollongong, School of Health and Society, Wollongong, Australia, [4]MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Parktown, South Africa

Background: Transactional sex (TS), or the exchange of sex for financial or material gain, has been well documented as a contributor to the HIV epidemic in sub-Saharan Africa. Studies conducted among young women in South Africa have found that approximately 20% of participants reported engaging in TS. Previous research has yet to identify psychosocial factors that make young women vulnerable to TS. Self-esteem has been associated with the adoption of risk behaviors among young people. The objective of this analysis was to determine if self-esteem is associated with TS among young women in South Africa.

Methods: HPTN-068 was a 3-year randomized controlled trial to assess the impact of a conditional cash transfer on HIV incidence among young women in rural South Africa that enrolled 2,533 participants from 2011-2012. In 2015-2017, a cross-sectional survey was offered to all participants from the main trial who had not died or been withdrawn. The current analysis utilized this post-intervention visit survey. Self-esteem was derived from the Rosenberg self-esteem scale and dichotomized at the median. TS was derived from 8-yes/no items that inquired if a participant had exchanged sex for food, money, material goods, or social status since their last visit in the main trial. Participants who responded "yes" to one or more items were categorized as having TS. Log-binomial regression was used to compute a prevalence ratio (PR). Additional covariates were specified to minimize confounding bias.

Results: 1,942 young women ages 17-26 years (M=20 years) were included. Approximately half (49%) were categorized as having high self-esteem and 15% reported having engaged in TS since their last visit. The prevalence of TS among those with low self-esteem (23.79%) was 5.05 times the prevalence of TS among those with high self-esteem (4.71%), 95% CI: 3.61-7.08, *p*< 0.001. The effect remained significant after adjusting for age, education, financial security, intimate partner violence, gender attitudes, and adverse childhood experiences (PR=4.10, 95% CI: 2.91-5.78, *p*< 0.001).

Conclusions: Findings provide support for the association between low self-esteem and TS in this context. Future research should examine self-esteem and incident TS to establish causality. Psychosocial factors, including self-esteem, should be considered when designing intervention programs.

WEPED375

Beyond money and gifts: Identifying the strategies men use to establish and maintain relationships with adolescent girls and young women in Uganda

G. Siu[1], A. Gottert[2], P. Keilig[2], A. Katahoire[1], F. Ayebare[1], N. Jani[2], S. Mathur[2], J. Pulerwitz[2]
[1]*Makerere University, Child Health and Development Centre, Kampala, Uganda,* [2]*Population Council, HIV and AIDS Program, Washington, United States*

Background: While much research has focused on men's use of money/gifts as a strategy for establishing relationships with adolescent girls and young women (AGYW), including implications for HIV risk, little is known about other tactics employed. We explored men's perspectives on these issues in Uganda.
Methods: We conducted in-depth interviews with 94 male partners of AGYW (ages 19-45) in three districts of Uganda, from March-May 2017. Respondents were recruited at community 'hot spot' venues (n=54) and via AGYW participating in DREAMS interventions (n=40).
Results: Most respondents (80%) were married (with mean age 28). Half reported recent multiple concurrent partnerships, mainly with AGYW. Nearly all men described using money/gifts as a strategy for starting and/or maintaining these relationships-from a meal to school fees or luxury items. However, participants reported other strategies as well. Some men used the nature of their occupation to engage girls, such as ready access to transport from a boda-boda motorcycle-taxi driver, or a man's bar or shop as a social hang-out space. Many men described using 'go-betweens', his own or the girl's friends or relatives, to establish familiarity before approaching her himself - often in return for bribes. Finally, men used regular phone contact to emphasize their interest in a young woman, with some men buying her a phone to make sure he can "keep her close." Men saw these strategies as necessary to "get the girl," grounded in the belief that he is only valuable based on the material wealth and lifestyle he can provide.
Conclusions: Men in Uganda use a range of strategies to establish relationships with AGYW, including money/gifts, the nature of their occupation, go-betweens, and regular phone contact. Such strategies generally demonstrate controlling behaviors and may heighten AGYW's vulnerability to HIV (and violence). Community-based interventions are needed to engage both men and women in critical reflection about the risks and emotional impacts of such strategies on both genders.

Migration and HIV

WEPED376

Sexual partnership patterns and HIV risks among male migrant market workers from Central Asian countries in Kazakhstan

G. Mergenova[1], A. Terlikbayeva[1], L. Gilbert[1,2], S. Shaw[3], S. Primbetova[1], N. El-Bassel[1,2]
[1]*Columbia University, Global Health Research Center of Central Asia, Almaty, Kazakhstan,* [2]*Columbia University, School of Social Work, New York, United States,* [3]*Brigham Young University, Social Work, Provo, United States*

Background: Globally, risky sexual behavior found to be associated with migration and mobility and contributes to HIV/STIs transmission.
We hypothesized that sexual partnership patterns, including:
1) monogamous partnership (MP) - both partners report only one partner;
2) indirect multiple partnerships (IMP) - a person reports one partner, while his partner has many partners;
3) simple multiple partnership (SMP) - a person reports many partners, the later reports one partner;
4) complex multiple partnerships (CMP) - a person reports many partners, who also have multiple partners, would be associated with mobility and HIV/STIs sexual risk (unprotected sex, sex under influence of alcohol, sex with a sex worker) among male migrant workers from the biggest market in Central Asia (CA), Almaty, Kazakhstan.
Methods: We used data of sub-sample (n=830) of sexually active men from a cross-sectional survey with biological data on HIV/STIs (syphilis, chlamydia, gonorrhea) from the Silk Road Health study among 1,342 male market workers. We used regression analysis (adjusting for age, marital status, income, migration status) to examine the association between sexual partnership patterns, mobility, HIV/STIs sexual risk and prevalence of STIs.
Results: Of the sample, 44.9 % reported being in MP, 1.2% - IMP, 26 % - SMP, 7.11 % - CMP. Mobility was associated with higher likelihood of being in CMP (RR=1.68, 95%CI: 1.04, 2.72, p< 0.05) and with lower probability of being in MP (RR=0.70, 95%CI: 0.59, 0.83, p< 0.001). Being in CMP was associated with higher likelihood of having unprotected sex with a female partner (RR=1.43, 95%CI: 1.17, 1.74, p< 0.001). Commercial sex was associated with higher likelihood of being in CMP (RR=2.25, 95%CI: 1.46, 3.45, p< 0.001) and in SMP (RR=1.88, 95%CI: 1.32, 2.69, p< 0.001). Likelihood of having sex under influence of alcohol was higher among men in CMP (RR=2.19, 95%CI: 1.45, 3.29, p< 0.001) and in SMP (RR=1.88, 95%CI: 1.32, 2.69, p< 0.001), whereas for men in MP, it was lower (RR=0.28, 95%CI: 0.18, 0.43, p< 0.001).
Conclusions: Sexual partnership patterns are characteristics of mobile population that may increase heterosexual transmission of HIV/STIs and must be considered in HIV/STIs prevention approaches among mobile populations in CA.

WEPED377

Antiretroviral treatment outcome in migrant workers living with HIV in Northern Thailand

L. Aurpibul[1], A. Tangmunkongvorakul[1], P.M. Musumari[2,3], A. Jirattikorn[4], A. Ayuttacorn[4], K. Srithanaviboonchai[1,5]
[1]*Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand,* [2]*Kyoto University School of Public Health, Department of Global Health and Socio-Epidemiology, Kyoto, Japan,* [3]*Japan Foundation for AIDS Prevention, Tokyo, Japan,* [4]*Faculty of Social Sciences, Chiang Mai University, Chiang Mai, Thailand,* [5]*Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand*

Background: Migrant workers living with HIV in Thailand have access to ART through various publicly supported health care programs. However, there has been concern that being minorities plus potential socioeconomic barriers would impact the effectiveness of treatment in this population. We determined HIV treatment outcomes among migrant workers in northern Thailand.
Methods: A cross-sectional study was conducted at 12 community hospitals in Chiang Mai, Northern Thailand. Inclusion criteria were:
1) working in Thailand with history of birth outside Thailand; and
2) having HIV infection and on ART for ≥ 1 year.
The study complied with local IRB; all eligible patients were invited to join, written inform consent was obtained prior to a face-to-face interview. Laboratory results and ART regimens were reviewed from hospital record. HIV treatment outcomes were determined from immunologic and virologic measurement.
Results: Two hundred and fifty-seven patients were enrolled; 65% were female. The mean age was 39.8 ±8.8 years. Seventy-eight percent identified themselves as Shan ethnicity, and 99% of all were from Myanmar. Half (54%) never attended formal education. Ninety-one percent were employed; 23% in construction, 21% in agricultural/farm, and 21% were general laborers. Their median monthly income was 6,000 baht (185 USD) (IQR 3,500-8,000). Sixty-two percent were living with husband/wife or partner.
The median duration on ART was five years (IQR 3-7) with a majority (91%) on the first-line NNRTI-based (49% efavirenz, 42% nevirapine), and 9% receiving PI-based regimens. Eighty-eight percent self-reported >95% adherence. Their mean current CD4+ lymphocyte count was 450 ± 279 cells/mm^3; 178 (69%) had CD4+ lymphocyte count ≥ 350 cells/mm^3, and 94% were virologic-suppressed (having HIV RNA level < 400 copies/mL). No difference was seen in characteristics between those virologically suppressed or not. In multivariate logistic regression analysis, factors associated with CD4+ lymphocyte count ≥ 350 cells/mm^3 included female sex, received HIV testing due to reasons other than illnesses, and duration on ART ≥ 5 years.

Conclusions: Favorable ART outcomes were seen among migrant workers in northern Thailand. Screening for HIV prior to other illnesses and subsequent linkage to HIV care should be continuously encouraged to preserve immune function and minimize time for HIV transmission.

Variables	Total	Female	Male	p-value
Number of participants	257	166 (65)	91 (35)	
Age (years)	39.8 ± 8.8	39.7 ± 9.0	40.1 ± 8.6	0.73
18-<25 years	9 (4)	8 (5)	1 (1)	0.30
25-< 50 years	214 (83)	135 (81)	79 (87)	
≥ 50 years	34 (13)	23 (14)	11 (12)	
Duration form HIV diagnosis	6 (2-10)	6 (3-11)	5 (2-10)	0.34
Duration from ART initiation	5 (3-7)	5 (3-8)	4 (2-7)	0.09
Current ART regimens				
PI-based regimens	22 (9)	16 (10)	6 97)	0.40

Internal migration, changes in household composition and engagement in HIV care and treatment in rural South Africa

M.-S. Kang Dufour[1], S. Lippman[2], A. Pettifor[3], C. Kabudula[4], R.G. Wagner[4], A. Leddy[2], A. Julian[4], N. Masilela[4], S. Tollman[4], M. Collinson[4], C. Ginsburg[4], K. Kahn[4]
[1]University of California, San Francisco, San Francisco, United States, [2]University of California San Francisco, Division of Prevention Science, San Francisco, United States, [3]University of North Carolina, Raleigh, United States, [4]MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Agincourt, South Africa

Background: Within South Africa, where national HIV prevalence is 12.2%, evidence suggests that rural areas characterized by high levels of temporary and internal migration and changes to household composition are most impacted by the epidemic. Understanding and tracking engagement in care in communities with highly mobile populations is complicated as individuals access care at more than one location. We utilized data from a health and socio-demographic surveillance site (HDSS) in Agincourt, Mpumalanga to assess the impact of population movement on HIV care engagement.
Methods: We merged data for all adults aged 18 to 49 captured within the annual HDSS census with electronic medical record data captured between 1 August 2015 and 31 December 2016 at the ten clinics serving the HDSS catchment area. Linking clinical data to the census records allowed us to track HIV care and treatment for individuals who accessed care at multiple sites, as well as to assess both migration (within and away from the region) and changes in household composition for each individual.
Results: Overall 32,481 women and 30,278 men aged 18 to 49 were resident in the HDSS between August 2015 and December 2016. Among residents, 50% had experienced some type of migration and 40.5% experienced a change in the number of adults living in the household. Being identified as HIV-positive on clinic records was associated with recent birth (OR 1.5 ;95% CI 1.4-1.7) or death in the household (OR 1.6 ;95% CI 1.2-2.2). Those who had migrated within the HDSS or experienced temporary migration were less likely to be identified as HIV-positive (OR 0.72; 95% CI 0.62-0.83 and OR 0.36 ;95% CI 0.34-0.39, respectively). Internal migration (OR 0.71; 95% CI 0.53-0.94) and having given birth (OR 0.67; 95% CI 0.56 - 0.81) were associated with defaulting from care.
Conclusions: In a high prevalence area with both a high degree of temporary and permanent migration, migration was associated with both lower probability of being identified as HIV-positive and increased probability of default from care. Our findings highlight the need for innovative care strategies to improve HIV diagnosis and engagement in care and treatment for migrant populations.

Qualitative study on the providers' perspectives regarding access to HIV care and treatment of migrants between Lesotho and South Africa

I.O. Faturiyele[1], K. Ntene-Sealiete[2], D. Karletsos[3], A. Musekiwa[4], M. Khabo[3], N. Sigwebela[4], S. Mndaweni[4], B.M. Mpila[4], P.T. Pisa[5], K. Maile[6]
[1]EQUIP Innovation for Health, Country Director, Maseru, Lesotho, [2]Ministry of Health, Maseru, Lesotho, [3]EQUIP Innovation for Health, Maseru, Lesotho, [4]EQUIP Innovation for Health, Centurion, South Africa, [5]EQUIP Innovation for Health, Centurion, Lesotho, [6]EQUIP-Innovation for Health, Maseru, Lesotho

Background: The HIV treatment and care cascade aims to diagnose and provide treatment and care to HIV infected individuals. However, HIV treatment and care for migrants is affected by their mobility and interaction with HIV treatment programs and the health care systems in different countries.
Objective: To assess service providers' knowledge around healthcare services provision to migrant HIV patient populations and continuity of care in both rural and urban facilities situated in high HIV burden districts of Lesotho.
Methods: The study setting included three borderland districts of Lesotho where migration flows are known to be high. A total of 15 health facilities accessed by high patient volumes were selected in Maseru, Leribe and Mafeteng. Purposive sampling was used to recruit health care providers for qualitative in-depth interviews across facilities. Two service providers at each facility were identified among those with highest interaction with HIV-infected patients on ART (clinicians, physicians, nurses, pharmacists, or counsellors). Data were analysed using the grouping of themes approach.
Results: Service providers indicated that the current referral system for HIV-positive patients on ART lacks flexibility: most migrants do not know their precise destination before leaving their country; yet, a transfer letter is accepted in South Africa only if addressed to a specific health facility. They also identified discrimination based on nationality or language as another barrier to access. Service providers indicated that most migrant patients preferred all HIV treatment services to be rendered in Lesotho, as they perceive the treatment provided in South Africa to be less effective and having more serious side effects. A need for mHealth systems or telephone tracking to track patients outside the country was suggested in combination with multi-month dispensing of antiretroviral treatment (ART) and harmonizing documentation among neighbouring states thus making referral processes easier.
Conclusions: Service providers' perspectives indicate the need to modify and re-structure HIV care among migrants. Specifically, in relation to differentiated care model that will support multi-month supply of treatment, tracing and mHealth platforms to improve various HIV outcomes including retention, adherence, virologic suppression and mortality.

WEPED380

Access to HIV care and treatment for migrants between Lesotho and South Africa

I.O. Faturiyele[1], K. Ntene-Sealiete[2], D. Karletsos[1], A. Musekiwa[3], M. Khabo[1], N. Sigwebela[3], S. Mndaweni[3], B.M. Mpila[3], P. Mahasha[3], P.T. Pisa[3], K. Maile[1]
[1]EQUIP Innovation for Health, Maseru, Lesotho, [2]Ministry of Health, Maseru, Lesotho, [3]EQUIP Innovation for Health, Centurion, South Africa

Background: The HIV treatment and care cascade aims to diagnose and provide treatment and care to HIV infected individuals. However, HIV treatment and care for migrants is affected by their mobility and interaction with HIV treatment programs and health care systems in different countries.
Objective: To assess healthcare needs, preferences and accessibility barriers of HIV-infected migrant populations in high HIV burden, borderland districts of Lesotho.

Methods: We selected 15 health facilities accessed by high patient volumes in Maseru, Leribe and Mafeteng. We then administered a survey questionnaire to consenting HIV infected individuals on anti-retroviral therapy (ART).
We defined a migrant as a Lesotho national who is currently living or has been living in South Africa for at least three consecutive weeks in the past six months.
Results: We enrolled a total of 2,784 HIV-infected migrants: 57.0% from urban sites and the remainder from rural sites; majority were aged between 36-45 years (37.6%); and almost half (49.7%) were domestic workers followed by construction workers (18.0%).
More than 95.0% preferred and collected their medications primarily in Lesotho. In terms of preferred dispensing intervals, less than 7.0% opted for a 1-2 month anti-retroviral (ARV) refills whereas 30.2% and 63.0% indicated a preference for 3-4 month and 5-6 month refills respectively. More than 65.0% encountered barriers to receiving their antiretroviral treatment (ART) and about 25.0% defaulted while in South Africa.
Treatment default rate for domestic workers and textile industry workers was significantly higher than that of other professional categories ($p<0.02$); however, we did not observe significant differences in defaulting with respect to gender ($p=0.11$). The primary reason for defaulting was failure to afford travelling costs to collect medication.
Conclusions: Existing healthcare systems in both South Africa and Lesotho experience challenges in providing proper care and treatment for HIV infected migrants. There is need for targeted interventions and a differentiated care model specific to HIV infected migrants such as a multi-month supply of treatment.

WEPED381

The intersections of transnationalism, sexuality and HIV risk: The case of Chinese immigrants to Canada

Y.R. Zhou[1], W.D. Coleman[2], Y. Huang[3], C. Sinding[4], W. Wei[5], R. Cain[6], J. Gahagan[7], E. Micollier[8]
[1]McMaster University, School of Social Work, Hamilton, Canada, [2]University of Waterloo, Waterloo, Canada, [3]Remin University of China, Beijing, China, [4]McMaster University, Hamilton, Canada, [5]East China Normal Univserity, Shanghai, China, [6]McMaster Univserity, Hamilton, Canada, [7]Dalhousie University, Halifax, Canada, [8]The French Research Institute for Development, Paris, France

Background: Immigrants studies in recent decades widely document international migrants' dual, simultaneous engagement in sending and receiving countries. The notion of transnationalism - in such forms as cross-country mobility and connections - and its implications for research into HIV risk have been largely overlooked, however. Based on a study of the new wave of Chinese immigrants to Canada, this paper explores the effects of transnationalism on those individuals' risk perceptions, risk exposure and risk responses.
Methods: Informed by multi-sited ethnography, the data were collected through individual, semi-structured, in-depth interviews carried out from 2012 to 2015 with 66 Chinese adult immigrants - 31 women and 35 men - in Canada and China. Guided by the coding scheme that was collectively developed by the research team, the transcribed interviews were coded by using NVivo (9.2).
Results: First, the settlement processes and subsequent challenges in Canada - such as economic downward mobility, geographic separation of marries spouses, and social marginalization and isolation - have made Chinese immigrants under study vulnerable to sexual health (including HIV) risks that they may not face back home.
Second, despite the changing dynamics of HIV risk in a in a post-immigration context., their risk perceptions and attitudes toward HIV are largely influenced by the values and beliefs they developed in China.
Third, although living in Canada means a bigger space for individual freedom, their simultaneous awareness of the desired gender roles and relations in the two, quite different, societies in turn generates various contradictions and conflicts that compromise their capacity to respond to the risk.
Conclusions: In a globalizing world, risks to international migrants' health involve complex, multi-faceted interactions between host and home country values, practices and norms. Taking into account Chinese immigrants' sustained linkages with their home country, we argue that researchers should go beyond a nation-bound concept of society (i.e., the host society), and take into account the simultaneous influence of both Canada and China on their HIV vulnerability.

Violence and conflict: political, social, structural, interpersonal, and family-based

WEPED382

Quantifying the levels of violence towards men who have sex with men (MSM) in three cities of Honduras

N. Gallardo[1], J. Wheeler[2], P. Letona[1], F. Alvarenga[1], S. Lungo[1]
[1]Pan American Social Marketing Organization (PASMO), Guatemala, Guatemala, [2]Population Services International (PSI), Washington, DC., United States

Background: High rates of drug and gang violence, makes Honduras a violent country. A social context of traditional values, homophobia and machismo create an environment that makes MSM vulnerable. There has been no recent quantification of violence towards them. The Pan American Social Marketing Organization conducted a population-based study to assess the USAID Combination Prevention Program for HIV and quantify the proportion of this population experiencing violence.
Methods: Between May-August 2017, a respondent driven sampling (RDS) cross-sectional survey was conducted in three Honduran cities with 1922 MSM (47% from Tegucigalpa, 31% from San Pedro Sula, 22% from La Ceiba), aged 18-40 years old. Four types of violence were measured (psychological, verbal, physical and sexual), by asking participants if they have felt threatened, insulted, punched of forced to have sex during the last 12 months, and if they perceived it was due to their sexual preference.
Results: Overall, 19% of the participants self-identified as heterosexual, 39% as bisexual, 33% as gay, and 9% as transgender. In addition, 50% was of low socioeconomic status (SES), 30% of middle SES, and 20% of high SES. In Tegucigalpa, 29% of the participants suffered some type of violence, 21% suffered psychological violence, 34% verbal violence, 11% physical violence; and 7% sexual violence perceived to be related to their sexual orientation. In San Pedro Sula, 18% suffered some type of violence, 17% suffered psychological violence; 26% verbal violence; 10% physical violence; and 5% sexual violence. Finally, in La Ceiba, 29% suffered some type of violence, 25% suffered psychological violence; 34% suffered verbal violence; 15% physical violence; and 5% sexual violence. Results show that suffering some type of violence may reduce the chances of using condom at last sex (OR 0.694 [0.511-0.943], $p < 0.05$), and increase the probability of conducting an HIV test (OR 1.536 [1.214-1.942], $p < 0.001$).
Conclusions: The study shows considerable levels of violence towards MSM due to their sexual preferences, and how it can influence healthy behaviors. Therefore, it is important for HIV prevention programs to promote violence prevention activities and offer psychological support at clinic level.

Prevalence of intimate partner violence among HIV positive depressed perinatal PMTCT-plus clinic attendees in urban Tanzania: A baseline study

Z. Aloyce[1], E. Larson[2], A. Komba[1], A. Mwimba[1], A. Kaale[1], A. Minja[1], H. Siril[3], J. Kamala[1], M. Somba[1], S.F. Kaaya[4], M.C. Smith Fawzi[5]

[1]Africa Academy for Public Health, Program, Dar es Salaam, Tanzania, United Republic of, [2]Harvard T.H Chan School of Public Health, Department of Global Health and Population, Boston, United States, [3]Management and Developments for Health, Program, Dar es Salaam, Tanzania, United Republic of, [4]Muhimbili University of Health and Allied Sciences, Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of, [5]Harvard Medical School, Global Health and Social Medicine, Boston, United States

Background: Intimate partner violence (IPV) among women with HIV and depression in Tanzania is a social problem that may occur following partner disclosure of a woman's positive HIV status. The main objectives of this study were: to estimate the prevalence and types of IPV among HIV positive and depressed perinatal women attending antenatal clinics in 16 health facilities in Dar es salaam, Tanzania; and to examine associations between IPV and disclosure of HIV status in this sub-population.

Methods: The baseline survey of a cluster randomized controlled trial that enrolled 742 attendees of antenatal clinics in Dar es Salaam contributed data for this analysis. Participants attending clinics for prevention of mother-to-child transmission of HIV and on antiretroviral therapy (ART) were enrolled if they provided informed consent to participate and screened at or above the threshold of 9 on the PHQ-9, a depression screening tool. Data were collected using interviewer administered questionnaires to obtain sociodemographic measures, experience with physical or sexual IPV in the past six months, self-disclosure of their HIV status, and experience of emotional violence from their partner after disclosure of status.

Results: The mean age of participants was 29.6 years old (SD=5.4; range of 18-43). Among 725 women who responded to the question, 659 (90.9%) had been in an intimate relationship over the last six months, among whom 67 (10.2%) had experienced physical violence and 76 (11.6%) sexual violence. Nearly 75% disclosed their HIV status to anyone outside health facility staff of whom 63.5% had disclosed their HIV positive status to their partners. The risk of experiencing any physical or sexual violence was not different between women who disclosed their HIV status to their partners and women who did not disclose (RR: 0.98, 95% CI: 0.75, 1.28). After disclosing their HIV status to partners, 60 (17.3%) women experienced emotional violence.

Conclusions: Reports of both physical and sexual IPV were high in this population of HIV-infected, depressed pregnant women. Although there was no association between physical and sexual IPV and disclosure, increased programmatic efforts need to be made regarding the risk of emotional abuse following disclosure of HIV status.

WEPED384

Coerced first sex among adolescents living with HIV in the Copperbelt, Zambia: Cross-sectional analyses of prevalence and associations with ART adherence, depression and alcohol use

K. Merrill[1], D. McCarraher[2], C. Packer[2], N. Nyambe[3], S. Mercer[2], J. Mwansa[4], J. Denison[1]

[1]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States, [2]FHI 360, Social and Behavioral Health Sciences, Durham, United States, [3]FHI 360, Lusaka, Zambia, [4]Arthur Davison Children's Hospital, Ndola, Zambia

Background: Experience of sexual violence is linked with poor antiretroviral therapy (ART) adherence, poor mental health, and alcohol abuse among HIV-positive adults. However, we lack data on sexual violence and associated outcomes among adolescents living with HIV (ALHIV) in sub-Saharan Africa (SSA). This secondary analysis aimed to estimate prevalence of one form of sexual violence—coerced first sex—and its associations with ART adherence, depression, and alcohol use among ALHIV ages 15-19 in Zambia.

Methods: A cross-sectional study was conducted (December 2012-May 2013) in three HIV clinics in urban areas of the Copperbelt Province to examine ART adherence and sexual behaviors. We interviewed 309 of the estimated 365 ALHIV receiving care at these clinics. Prevalence and descriptors of coerced first sex, a binary measure, were tabulated. Exact logistic regression was used to estimate crude and adjusted associations between experience of coerced first sex and: a ≥48-hour consecutive treatment gap in ART in the past three months, a positive screen for depression based on the Hopkins Symptoms Checklist depression subscale (HSCL-15), and past-month alcohol use.

Results: 64 ALHIV (21% of the sample, 55% female, 65% perinatally infected) who reported having ever had sex were included. Over one-third of males (9/29, 31%) and two-thirds of females (22/35, 63%) reported their first sexual experience was forced. Of these, 16% (n=5) reported they acquired HIV through rape or forced sex. In analyses adjusted for age and sex, adolescents who experienced coerced first sex showed higher odds of having a ≥48-hour treatment gap in ART adherence in the past three months (OR: 1.53, 95%CI: 0.35-6.89), but this association did not reach significance. No evidence was found on associations between coerced first sex and depression or alcohol use.

Conclusions: The high prevalence of forced sexual debut in our study, particularly among females, highlights the need for clinicians to ask about experiences of sexual violence on enrollment in ART and to tailor services appropriately. Our study was not powered for these analyses, and additional research is needed on experience of sexual violence and its effects with HIV-related outcomes, including ART adherence, among ALHIV in SSA.

WEPED385

The relationship between intimate partner violence and HIV risk behaviors in Black and White young men who have sex with men

D. Gerke[1], W. Auslander[1], W. Sewell[2]

[1]Washington University in St. Louis, George Warren Brown School of Social Work, Saint Louis, United States, [2]Washington University in St Louis, Social Work, Saint Louis, United States

Background: Young men who have sex with men (YMSM) are the group at highest risk for HIV infection in the US. Previous research demonstrated that experiencing intimate partner violence victimization (IPV) was associated with increased risk for HIV in minority women. Although data indicates that men are also victims of IPV, few studies have examined IPV experiences of YMSM, and the relationship between IPV and HIV risk in this high-risk population. Accordingly, the following research questions were asked:

1) What is the extent of IPV experienced by YMSM;

2) Is IPV significantly associated with HIV-risk behaviors, accounting for demographics?

Methods: Participants were 168 YMSM ages 18-34 (M=25.01, SD=3.58) recruited from AIDS service organizations (ASOs) in two mid-sized midwestern cities, who were 57.7% Black and 42.3% White. Data were collected through computer-assisted personal interviews assessing HIV risk behaviors in last 12 months: number of unprotected anal intercourse (UAI) occasions; number of male sexual partners (MSEXP); PrEP use. Independent variables were: types of IPV: physical, controlling, monitoring, HIV-related, emotional. Demographic variables were: ethnicity, education, income. Data analyses included descriptive statistics, nonparametric correlations, logistic and negative binomial regressions.

Results: More than half (57.7%) reported experiencing at least one type of IPV in the last year. Logistic regression results showed that those who experienced higher levels of HIV-related IPV (OR=1.44, p< .01) and higher income levels (OR=1.30, p< .05) were more likely to use PrEP than their counterparts. Bivariate analyses indicated that monitoring IPV was significantly associated with more UAI, and controlling and HIV-related IPV were significantly associated with more MSEXP. However, results of negative binomial regressions showed these relationships were not significant with demographics in the models. Analyses examining demographic differences in HIV-risk behaviors indicated that White and more highly educated YMSM reported significantly more MSEXP than their counterparts.

Conclusions: Findings suggest that HIV-related IPV (e.g. partner lying about or not disclosing HIV status) may act as a motivator to using PrEP for YMSM because of their increased perceptions of susceptibility. Other forms of IPV may not be directly associated with increased UAI or MSEXP. Results may be specific to YMSM using ASO services in midsized cities.

WEPED386

"Neither safe nor secure": Systematically addressing safety and security in HIV programs for key populations to protect implementers and facilitate effective programming

R. Chawla[1], R. Dayton[2], S. Middleton-Lee[3], S. Mellors[1]
[1]The International HIV/AIDS Alliance, Brighton, United Kingdom, [2]FHI 360, Durham, United States, [3]Independent Consultant, Brighton, United Kingdom

Background: Community-based organizations (CBOs) are the heart of HIV programs for and with key populations (KPs) - men who have sex with men, sex workers, transgender women, and people who inject drugs. Implementers of KP programs working in hostile environments—for example, where KP members are criminalized—face safety and security challenges ranging from eviction and blackmail to torture and death. These human rights violations also limit the impact of HIV programs. More needs to be done to protect implementers and limit programming interruptions.
Description: To address this gap, in 2017 the International HIV/AIDS Alliance and FHI 360 - through the USAID- and PEPFAR-supported LINKAGES project - conducted a desk review and convened a workshop in East Africa of 48 CBOs, nongovernmental organizations (NGOs), UN agencies, donors, and security experts working in hostile environments to develop a safety and security toolkit. The toolkit includes: 1) a review of safety and security challenges, their impacts on HIV programming, and promising practices to address them; 2) practical checklists to help program implementers systematically identify safety and security gaps affecting organizations, individuals, and implementation sites; and 3) an annotated bibliography of safety and security resources. Workshop attendees used and added to the toolkit, making observations about its utility in their contexts.
Lessons learned: Workshop participants confirmed that very few organizations implementing programs for and with KPs feel that they are adequately equipped to keep their implementers safe. At the same time, many CBOs have developed strategies and resources to address safety and security challenges that they believe could also help others. Helping CBOs identify their gaps and linking them to existing resources, through the toolkit, is an effective way to increase awareness of both safety and security gaps and resources.
Conclusions/Next steps: Integration of this toolkit, including completing the checklists and developing a safety and security plan to address any identified gaps, should be a resourced part of HIV programs for KPs. Donors and NGO partners must work together to ensure that local organizations taking on risks as part of implementing HIV programs also receive support to mitigate and respond to those risks.

WEPED387

Preventive strategies for sex workers to reduce risk of violence and HIV

S. Hendriks[1,2], L. Woensdregt[2], I. van Beekum[3], Sex Work Study Group Consisting of Research Assistants and Coordinators from the Sex Worker-Led Organisations
[1]Aids Fonds, Sex Work Programme, Amsterdam, Netherlands, [2]VU University Amsterdam, Social Sciences, Amsterdam, Netherlands, [3]Aidsfonds, Amsterdam, Netherlands

Background: Violence is one of the most important factors affecting the vulnerability of sex workers to HIV/AIDS. Sex workers experience physical, sexual, economical and emotional violence from clients, police and the community. This often causes inconsistent condom use and prevents sex workers from accessing necessary support and health care. To avoid and mitigate the risk of violence and HIV they adhere to a variety of strategies and techniques. This study describes prevention and mitigating strategies used by sex workers in Southern Africa to reduce risk of violence and HIV.
Methods: Participatory mixed methods were used. In total 2227 sex workers participated in the study (N= 1895 for survey, N= 79 for in-depth interviews, N= 253 for FGDs) in Botswana, Mozambique, Namibia, South Africa and Zimbabwe. Sex workers were part of the design and roll-out of the study. Additionally they were trained as research assistants and distributed the survey among peers. The survey and in-depth interviews focused on violence; social capital; law enforcement; and risk and mitigation factors.
Results: Sex workers who experience violence adhere to a variety of strategies and techniques to avoid and mitigate risks. Most used strategies are negotiating and receiving payment before having sex (97%), avoiding known dangerous places (96%) and adapting their behavior (92%). Sex workers who use preventative measures see no significant decrease in the amount of violence they face. Regression analysis shows that the only effective strategy is giving money to another sex worker to protect earnings, which decreases the amount of economical violence. Furthermore, sex workers who refuse clients more frequently, experience more violence.
Conclusions: Preventative measures used by sex workers are not sufficient to reduce violence and increase their safety and security. To prevent violence and HIV sex workers' human rights need to be respected by society and protected by law enforcement and the judicial system. Furthermore, decriminalization of sex work is necessary, since it promotes safe working conditions for sex workers, reduced police violence and abuse, and better client negotiation capacity.

WEPED388

Effects of a community empowerment intervention on physical violence among female sex workers in Tanzania

A.M. Leddy[1], N. Galai[2,3], S. Beckham[2], C. Shembilu[4], A. Mwampashi[4], A. Mantsios[2], W. Davis[5], S. Likindikoki[4], J. Mbwambo[4], D. Kerrigan[2,5]
[1]University of California, San Francisco, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [3]University of Haifa, Haifa, Israel, [4]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of, [5]American University, Washington, United States

Background: Female sex workers (FSWs) in Tanzania experience high rates of gender-based violence (GBV), which is associated with increased risk for HIV. We assessed whether a community empowerment-based approach for combination HIV and violence prevention was associated with reduced physical violence among FSWs in Iringa, Tanzania. We also sought to determine the predictors of physical violence among this population.
Methods: A phase II community randomized controlled trial of a community empowerment-based combination HIV prevention approach, Project Shikamana, was conducted in Iringa, Tanzania. Intervention components included workshops to raise awareness about violence and sex worker rights, and provide opportunities for FSWs to strategize ways to prevent and address violence perpetrated against FSWs. We used logistic regression models for repeated measurements at baseline and 18 months follow-up to explore changes in physical violence in the past 6 months by intervention community, and assess the determinants of physical violence among FSWs.
Results: A total of 387 FSWs were enrolled in the Project Shikamana cohort at baseline and completed the follow-up survey. Baseline prevalence of HIV was 41% and 35% reported physical violence in the past 6 months. Stratified analysis by study community revealed that FSWs in the intervention community had significantly decreased odds of physical violence at follow up (OR: 0.51, 95% CI: 0.29-0.88).
There were no significant differences in the control arm. In unadjusted analyses, intoxication during sex work, work mobility, clients expecting FSWs to use substances during sex work, having four or more clients per week, and denial payment for sex work were associated with increased odds of physical violence. Clients' expectations of FSW substance use

and denial of payment for sex work remained significantly associated with increased odds of physical violence, after adjusting for age, income, marital status, HIV status, and significant variables in the bivariate analysis.

Conclusions: Project Shikamana was associated with reductions in physical violence among FSWs in the intervention community. Findings suggest the potential role community-empowerment interventions can play in violence prevention among FSWs and highlight the need for future interventions among this population to address client expectations of substance use during sex work and denial of payment for sex work.

Community collective efficacy is associated with reduced intimate partner violence (IPV) incidence in the HPTN 068 cohort

A.M. Leddy[1,2], T.B. Neilands[1], J. Ahern[3], S.M. Delong[4], F.X. Gómez-Olivé[5], C. MacPhail[5,6], K. Kahn[5,7], A. Pettifor[4,5], S.A. Lippman[1]
[1]University of California, Division of Prevention Sciences, Department of Medicine, Center for AIDS Prevention Studies, San Francisco, United States, [2]University of California, Division of HIV, ID and Global Medicine, San Francisco, United States, [3]School of Public Health, University of California, Department of Epidemiology, Berkeley, United States, [4]Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [5]University of the Witwatersrand, MRC/Wits Rural Public Health and Health Transitions Research Unit (Agincourt), Johannesburg, South Africa, [6]School of Health and Society, University of Wollongong, Wollongong, Australia, [7]Umeå Centre for Global Health Research, Umeå University, Division of Epidemiology and Global Health, Department of Public Health and Clinical Medicine, Umeå, Sweden

Background: Intimate partner violence (IPV) is associated with increased risk for HIV and reduced engagement along the HIV care continuum. Collective efficacy (CE), defined as mutual trust among community members and willingness to intervene on the behalf of the common good, has been found to be associated with reduced neighborhood violence. Limited research has explored whether CE is associated with reduced incidence of IPV. This is of particular interest among adolescent girls and young women (AGYW) in sub-Saharan Africa, where the burden of HIV is greatest and IPV is common.

Methods: We conducted longitudinal analysis among 2,533 AGYW (ages 13-20) enrolled in the HPTN 068 cohort in the Agincourt Health and Demographic Surveillance System. We included participants from the 28 villages where community surveys and annual census data were collected during the 068 study. HPTN 068 participants completed up to five annual survey visits (2011-2016). Household-level data were collected from the parent/guardian of each participant at all visits. CE was measured at the village-level in 28 communities in Agincourt via two population-based cross-sectional surveys among 18-35 year old residents in 2012 and 2014. The CE score represents a summary village score created by combining validated measures of community social cohesion and social control. We used Agincourt census data to adjust for village-level covariates. Multivariable Poisson generalized estimating equation regression models assessed the relative risk (RR) between village mean CE scores and subsequent physical IPV 12-month incidence, adjusting for age at baseline, HIV status, education, baseline reports of physical IPV, household assets, and community characteristics.

Results: Thirty-eight percent of the cohort (N=950) reported at least one episode of physical IPV after baseline. For every standard deviation increase in village-level CE, there was a 6% reduction in physical IPV incidence in the past 12 months (RR: 0.94; 95% CI: 0.90, 0.98; p< 0.01) among AGYW after adjusting for covariates.

Conclusions: Increased community-level CE was associated with reduced physical IPV incidence among AGYW in South Africa. These results support interventions that foster the development of CE at the community level to prevent IPV among AGYW and potentially improve HIV outcomes among this priority population.

WEPED390

Experiences of traumatic events increases men's HIV-risk behaviours: A cross-sectional study and structural equation model (SEM) amongst young (18-30) men in urban informal settlements in South Africa

A. Gibbs[1,2], A. Hatcher[3,4], R. Jewkes[3,5], L. Washington[6], Y. Sikweyiya[5], D. Peacock[7], M. Khumalo[7], T. Ngoma[7], N. Christofides[3]
[1]South African Medical Research Council, Gender and Health Research Unit, Durban, South Africa, [2]University of KwaZulu-Natal, Health Economics and HIV/AIDS Research Division, Durban, South Africa, [3]University of Witwatersrand, School of Public Health, Johannesburg, South Africa, [4]University of California, San Francisco, United States, [5]South African Medical Research Council, Gender and Health Research Unit, Pretoria, South Africa, [6]Project Empower, Durban, South Africa, [7]Sonke Gender Justice, Cape Town, South Africa

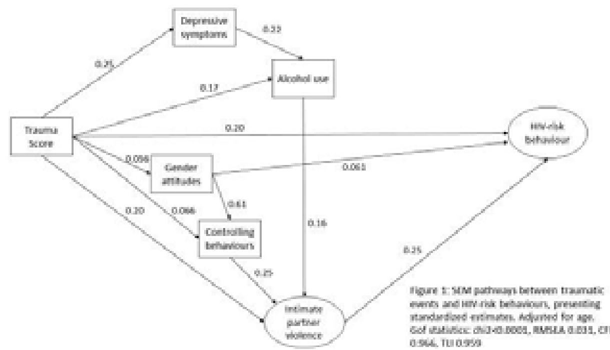
Background: Qualitative research on men's HIV-risk behaviours has emphasized how men's experiences of traumatic events, such as witnessing violence, being attacked, and so forth may lead to increased HIV-risk behaviours. Little quantitative research has sought to operationalize these ideas. We seek to understand the associations between experience of traumatic events and HIV-risk behaviours amongst heterosexual men in urban informal settlements in South Africa.

Methods: We conducted a cross-sectional survey among 2517 men living in urban informal settlements in Johannesburg and Durban, South Africa, enrolled in two intervention trials. We modelled associations in two ways, first through adjusted regression models, and secondly structural equation modelling (SEM) to assess whether men's experiences of traumatic events were independently associated with increased HIV-risk behaviours, and whether there were mediated pathways via mental health, gender attitudes, and intimate partner violence (IPV).

Results: Of 2517 men, 87.7% reported any past year risky sexual behaviour and 63.8% reported any traumatic event in their life. In adjusted regressions witnessing of a murder of a family member, witnessing a murder of a stranger, witnessing an armed attack, experiencing excessive harm, being kidnapped, being or feeling close to death or witnessing a rape were all significantly (p< 0.05) and independently associated with an increase in risky HIV-behaviours. The SEM indicated a direct pathway between increasing traumatic experiences and HIV-risk behaviours (Figure 1). Three other sets of paths provided mediated relationships. First, trauma increased gender inequitable attitudes and then HIV-risk. A second pathway was mediated by IPV, in turn increasing HIV-risk. Third, trauma increased depression and alcohol use, which increased IPV. SEM had satisfactory goodness of fit statistics.

Conclusions: Traumatic experiences were independently associated with HIV-risk behaviors in the regression and SEM. Traumatic experiences also increased HIV-risk through worsening mental health, creat-

ing more gender inequitable attitudes, and through increasing men's use of IPV. Reducing men's experiences of traumatic events may reduce risky sexual behaviour, but these need to be accompanied by working on men's mental health, transforming gender attitudes, and reducing IPV perpetration.



[Figure 1: SEM showing associations between trauma and HIV-risk]

WEPED391

Hidden and covered - underreporting of violence in transgender project even after empowerment processes

S. Kandaswamy[1], S. Shaikh[2], E. Restoy[3], A. Aher[2], V. Arumugam[1], H. Singh[4], U. Chawla[2], S. Mehta[5]
[1]India HIV/AIDS Alliance, Strategic Information, New Delhi, India, [2]India HIV/AIDS Alliance, Program & Policy, New Delhi, India, [3]International HIV/AIDS Alliance, Head: Knowledge, Brighton, United Kingdom, [4]India HIV/AIDS Alliance, Grants Management, New Delhi, India, [5]India HIV/AIDS Alliance, Chief Executive, New Delhi, India

Background: Gender inequality, stigma and discrimination, punitive laws, lack of sensitized government testing centres, service accessibility, providers' attitude, and violence, remains some of the barriers faced by the TGH population in India. India HIV/AIDS Alliance implemented Wajood programme for empowering the TGH to increase their access the health services by creating an enabling environment. Under this, one of the major objective is documenting the human rights violence faced by TGH.

Methods: A cohort of 385 client's crisis cases were documented in two years under the programme intervention. Client data were collected using structured software called ReACT excel tool. Descriptive analysis were carried out using the SPSS 20.0. As an intervention, individuals facing any kind of crisis will be intimated to the Wajood programnme. Community mobilisers, advocacy officers and crisis response team will support the individuals to overcome the crisis within 48 hours.

Results: Among 2,925 TGH only 385 (13%) TGH self-reported the crisis. 53% of crisis reported was of physical violence, 26% on harassment,19% on discrimination and remaining on trauma. Under the self-reporting population, 61% of crisis were faced by transwoman, 29% by Hijra (subgroup of TGs with strict community norms) and 10% by Jogappa (subgroup of TGs with strict community and religious norms, exclusively in Bijapur, so far not reached by any national programme).

Among these individuals, 42% of crisis were faced by people belonging to the age group of 26-30 years and 31% were from 18-25 years. 51% of population were engaged in sex work and 22% begs for livelihood.

88% of crisis were triggered by non-state authorities (family members, local goons, auto drivers, education institutes etc.) and 12% of crisis were triggered by state authority (police, health care providers and other government officials).

Conclusions: The crisis which is self-reported here, many TGH were facing issues and struggling with barriers and has not reported yet, in the programme itself only 13% of TGH reported about the crisis, in this scenario enhanced awareness and empowerment is required for the TGH community and sustained interventions to solve their crisis by themselves, otherwise HIV programme will never be able to fully attain its goals.

WEPED392

Effects of intimate partner violence on engagement in HIV care among women living with HIV in Rakai, Uganda

A. Wirtz[1], N. Nakyanjo[2], J. Wagman[3], R. Gray[1], J. Ssekasanvu[1], D. Serwada[2], J. Kagaayi[2], M. Wawer[1]
[1]Johns Hopkins School of Public Health, Epidemiology, Baltimore, United States, [2]Rakai Health Science Program, Rakai, Uganda, [3]University of California, San Diego, United States

Background: There is an association between intimate partner violence (IPV) and HIV acquisition, but less is known about the effect of IPV on engagement in HIV care. We estimated the effects of IPV on engagement in HIV care among women in Rakai, Uganda.

Methods: This mixed-methods study employed quantitative analysis of women living with HIV (N=2,016) in the Rakai Community Cohort Study from 2008-2013, during which the Conflicts Tactics Scale was included in the survey. Measures included recent (last 12 months) forms of psychological, sexual, and physical IPV. Generalized estimation equations estimated population-averaged association of recent IPV and engagement in HIV care. Interaction terms assessed effect modification by age. Qualitative research included in-depth interviews with women who had reported IPV (N=25) and with service providers who provide HIV care and/or services for IPV (N=15). Interviews/discussions explored the behavioral mechanisms by which IPV impacts engagement in HIV care.

Results: 53% of participants were engaged in care and 29% reported recent IPV. The odds of engagement in care were 55% lower for women who reported any IPV in the same survey interval compared to those without recent IPV (Table 1, Model 1). Among participants with a recent HIV diagnosis, IPV reduced the odds of engagement in care by 69%, which was marginally significant (Model 2). Recent IPV was marginally associated with a 59% reduced odds of engagement in care in the subsequent survey interval (Model 3). Models 1-3 demonstrated significant modification by age, in which the youngest age group (15-30 years) who experienced IPV have the lowest odds of engagement in care in the same and subsequent survey intervals. Qualitative research recounted direct effects of IPV on care and ART use, including partner destruction of medication. Multiple indirect effects of IPV on engagement in care were reported; these were often related to psychological violence that reduced women's HIV service use to avoid IPV victimization.

	Model 1	Model 2	Model 3	Model 4
	Association between IPV & HIV care in same survey interval (N=2,016)	Model 1 restricted to all recent diagnoses in the same survey interval (N=968)	Effect of IPV on HIV care in the next survey interval (N=1,048)	Model 3 restricted to all recent diagnoses in the next survey interval (N=304)
	aOR (95%CI, p-value)	aOR (95%CI, p-value)	aOR (95%CI, p-value)	OR (95%CI, p-value)
Any IPV (ref: No)	0.45 (0.24-0.82; 0.01)	0.31 (0.09-1.09; 0.07)	0.41 (0.14-1.12; 0.08)	0.29 (0.03-2.84; 0.29)
Age (ref: 41yrs +)				
15-30 years	0.27 (0.21-0.35; <0.01)	0.45 (0.28-0.70; <0.01)	0.30 (0.20-0.46; <0.01)	0.27 (0.10-0.72; 0.01)
31-40 years	0.88 (0.69-1.12; 0.30)	0.77 (0.48-1.23; 0.28)	0.88 (0.59-1.33; 0.55)	0.47 (0.17-1.29; 0.14)
IPV x Age interaction	1.32 (1.04-1.68; 0.02)	1.58 (0.99-2.50; 0.05)	1.48 (0.99-2.2; 0.06)	1.69 (0.74-3.86; 0.22)

Note: aOR: adjusted odds ratio; ; IPV: intimate partner violence (includes any psychological, sexual or physical violence in the last 12 months); ref: reference category; models also control for education and community

[Table 1. Relationship between IPV and engagement in HIV care among women living with HIV in Rakai, Uganda (2008-2013)]

Conclusions: IPV negatively impacts engagement in HIV care. As treatment is expanded globally, combination approaches in HIV care that include identification and response to IPV, including psychological IPV, may improve individual health and support national care continuum targets for population health.

WEPED393

Why suffer in silence? The violence within!

S.A. Thompson[1], Y.A. Abdul Rahman[1], E.K. Bruce[1], M. Levy[2], H. Adrian[3], H. Nagai[1], D. Nartey[4]
[1]*JSI Research & Training Inst., Inc., Accra, Ghana,* [2]*JSI Research & Training Inst., Inc., Washington, United States,* [3]*JSI Research & Training Inst., Inc., Boston, United States,* [4]*JSI Research & Training Institute, Inc. (JSI), Monitoring and Evaluation, Accra, Ghana*

Background: The USAID Strengthening the Care Continuum project, implemented by JSI, improves civil society and the Government of Ghana's capacity to provide quality and comprehensive HIV services for key populations and people living with HIV.
Intimate partner violence (IPV) among men who have sex with men (MSM) in Ghana, specifically Takoradi, has brought to the fore disturbing concerns to practitioners in the public health community due to its devastating health effect on victims. Anecdotal evidence suggests that KPs suffer IPV, most of which go unreported largely because potential victims perceive their sexual behavior as criminal, against heterosexual norms of sexual practice and the economic power dynamics within the MSMs sexual relationship.
In 2015, we found out that 41 MSMs out of 1163 MSMs screened for SGBV suffered intimate partner violence within their relationships but did not officially report to the police for action due to fear of being arrested. All the 1163 MSMs were provided SGBV services. This informed the study which sought to:
"Reduce the effect of intimate partner violence within MSM relationships in the Western region of Ghana".
Description: To address the challenge of IPV within MSM community, the project conducted advocacy against intimate partner violence among MSMs and in the process, key IPV messages were disseminated in the KP communities. Programs to educate MSMs on the safety and healthy living was done. Meetings with key partners such as Commission for Human Rights and Administrative Justice (CHRAJ) and Police, to advocate against SGBV to ensure access to SGBV services by KPs. A help desk was set up to provide emotional support, counseling and information to empower MSMs who have suffered violence.
Lessons learned: Reported cases of IPV has started showing a downward trend; 41 in 2015, 13 in 2016 and 9 in 2017 after the intervention. This data suggests that when programming for MSM exists to inform against IPV, violence and abuse among this population could be reduced.
Conclusions/Next steps: The findings suggest the usefulness of this approach and the potential for expansion. Intimate Violence among MSMs also reduced indicating that advocacy among KPs needs to be increased.

WEPED394

Men's vulnerabilities are compromising their own health and well-being, and are strongly linked to HIV risk in Durban, South Africa

A. Gottert[1], S. Mathur[1], C. Cawood[2], J. Pulerwitz[1]
[1]*Population Council, HIV and AIDS Program, Washington, United States,* [2]*Epicentre AIDS Risk Management, Paarl, South Africa*

Background: There is often limited focus on the vulnerabilities men face in their lives - either as key public health issues or as they link to HIV transmission. We examined such vulnerabilities and their association with HIV risk behaviors among men in Durban, South Africa.
Methods: We surveyed 962 men ages 20-40 recruited at community 'hot spot' venues (n=649) and at HIV service sites (n=313) in two informal settlements in Durban, from May-September 2017. Adult experiences of violence and of deprivation, and childhood experiences of abuse and of parental absence, were each measured with sets of 2-4 items. Alcohol abuse was measured by the AUDIT-C; depression by the PHQ4 scale (alpha=0.81).
Results: Respondents' average age was 28; 15% were married/cohabiting. On average respondents had 3.7 sexual partners in the last year, and 14% used condoms consistently with their last three non-marital partners. About 40% had ever witnessed an armed attack, been robbed at knifepoint/gunpoint, and had felt close to death. Before age 18, 77% had been beaten physically at home (14% 'very often'), 21% had seen/heard their mother being beaten by her husband/boyfriend, 42% were not raised by at least one biological parent, and 37% had lost a parent. Half (52%) abuse alcohol, and 30% were moderately or severely depressed. In multivariate analyses, adult experiences of violence ($p=0.001$) and of deprivation ($p=0.001$), and childhood experiences of abuse ($p< 0.05$), were each associated with having multiple sexual partners in the last year. Childhood experiences of abuse and of parental absence were associated with less consistent condom use ($p< 0.05$ and $p< 0.01$, respectively). Parental absence was also associated with having more age-disparate partners ($p< 0.05$). Men who abused alcohol had more partners in the last year ($p< 0.001$) and more highly age-disparate partners ($p< 0.01$). Depression was also associated with having more partners ($p< 0.05$).
Conclusions: Men in Durban are experiencing serious vulnerabilities including depression, alcohol abuse, and childhood and adult experiences of deprivation and violence. Each of these factors had direct effects on key HIV risk behaviors. Interventions should focus on reducing such vulnerabilities, to promote wellbeing and to curtail the HIV epidemic.

Humanitarian crises and HIV

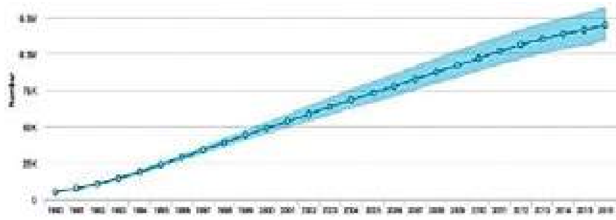
WEPED395

Triple threat: Resurging epidemics, a broken health system, and global indifference to Venezuela's crisis

M.A. Torres[1], A. Nieves[2,3]
[1]*ICASO, Toronto, Canada,* [2]*Accion Ciudadana contra el SIDA, Caracas, Venezuela,* [3]*Red Venezolana de Gente Positiva (RVG+), Caracas, Venezuela*

Background: There is an unprecedented humanitarian emergency in Venezuela. In 2017, gross domestic product plum-meted by 12% and inflation rates soared to 1,600%. Economic collapse has made accessing food and life-saving medicines difficult or impossible for most. The global response has been stunning indifference. The political nature of the crisis means that information is also limited, hindering efforts for effective relief. Greater transparency is needed to compel urgent global action.
Methods: To document the health emergency in Venezuela, ICASO and Acción Ciudadana contra el SIDA (ACCSI) performed a rapid assessment during September 2017. A desk review was performed along with a series of targeted key informant interviews with people living with HIV, doctors, advocates, academics and United Nations representatives. The approach also included synthesis of information from an emergency consultation, convened by affected communities in Caracas, Venezuela.
Results: Venezuela is undoubtedly experiencing an acute public health emergency: There has been a 205% increase in new malaria cases after the country declared elimination; there is almost a complete lack of access to tuberculosis screening for vulnerable populations such as prisoners and indigenous communities; the number of AIDS-related deaths in the country has risen by nearly three quarters since 2011. Food is scarce and malnutrition and starvation are spreading. People on the ground describe frequent stock-outs of medicines, including antirretrovirals, and fear of imminent death.
Conclusions: Venezuela is a case study of the many ways in which international policies, based on numerical indicators and data, have failed to address a burgeoning crisis for the country and the region. Venezuela's crisis is the result of a long process of political unrest and bad economic decisions. While it is in many ways unique, the case also is an indication of things to come. Many current high-income countries

are more vulnerable than they appear, and could experience shocks - whether due to conflict or natural disasters - that rapidly move them from one spot on the development spectrum to another.



[Figure. People living with HIV (all ages) in Venezuela (UNAIDS)]

Comprehensive services for Internally Displaced Persons (IDPs) and IDPs with chronic diseases affected by the war in Eastern Ukraine

M. Volovod[1], O. Bryzhovata[2], E. Sokolyuk[3], L. Sydorenko[3], N. Moskovchenko[1]

[1]All-Ukrainian Network of People Living with HIV, Innovation Programmes, Kyiv, Ukraine, [2]All-Ukrainian Network of PLWH, Kyiv, Ukraine, [3]Regional Branch of the All-Ukrainian Netwrok of PLWH, Kryvyi Rih, Ukraine

Background: The Humanitarian Needs Overview[1] estimates that 3.1 million people are in need of humanitarian assistance in Ukraine. Many IDPs stated that continuous stress and numerous obstacles interfere with seeking humanitarian assistance therefore they are reluctant to do so. It can make a direct threat to health and life for IDPs with chronic diseases like HIV infection, hepatitis, etc. [1] Ukraine: Humanitarian Crises Analysis, 2016. SIDA

Methods: In January 2016, the All-Ukrainian Network of PLWH has launched the 2-year project aimed at improving access to comprehensive services for IDPs (including the HIV-services) and adopting of the regional programme for IDPs which is to be financed from the budgets of the Donetsk and Dnipropetrovsk regions of Ukraine. The project envisages outreach activities and the work of the Centers for Comprehensive Services; legal component ensures collecting violations and protecting human rights. At the regional level, the project has taken over coordinating efforts between humanitarian actors, NGOs, and public institutions involved in IDP support.

Results: The feedback from project clients is approbatory but also stimulates project to remain flexible as lots of external factors have been constantly affecting it. Overly strict regulation hinders adopting of the regional programme for IDPs. Numerous cases of mental health issues among IDPs (which reportedly lead to cessation of treatment by people with chronic diseases) require remedial actions to be done by either project itself or its partners.

Conclusions: Although the project is still in progress, the following conclusions can be already made:

- While majority of the international humanitarian missions work mainly in the 'grey zone', it remains vital to keep supporting those IDPs who seek asylum at the government-controlled areas.
- The natural migration makes the continued client retention in the project almost impossible. Scaling up the initiative to other regions can contribute to this.
- Legal amendments should be advocated to ensure that all the required civil procedures and services are accessible and non-discriminatory toward IDPs.

WEPED397

Model of gender-sensitive services for internally displaced HIV positive women in Donetsk and Lugansk oblasts

N. Lukyanova[1], O. Stryzhak[2], V. Variga[2], I. Yeleneva[3]

[1]UNDP Ukraine, Kyiv, Ukraine, [2]NGO 'Positive Women', Kyiv, Ukraine, [3]UNDP Ukraine, Kramatorsk, Ukraine

Background: Ukraine continues to have a concentrated HIV epidemic among key populations at higher risk of HIV. The armed conflict in the East of Ukraine affected Donetsk and Lugansk oblast and caused numerous internal displacement. Recent study showed that there are more internally displaced women than men, and they are more vulnerable to rights violation (as a cause and result of HIV and other sexually transmitted diseases) as well as to violence, requiring special legal support and services at the host communities.

Description: UNDP's two years initiatives aimed to assess the ability of local public and civil society sector institutions to effectively respond to the growing HIV epidemic and ensure equal access to various local services for HIV positive women and girls affected by the conflict in the Eastern Ukraine.

In 2017 the mapping of gender-sensitive services for HIV positive was conducted followed by piloting Crisis Response Points for women and girls living with or affected by HIV at Donetsk and Lugansk oblasts.

Lessons learned: Absence of gender-sensitive services for internally displaced HIV positive women or women affected by the epidemic in the conflict areas. The piloted model of crisis response helped 30 women at risk of HIV or living with HIV applied to crisis response points for assistance, out of them almost 1/3 discovered rough violation of their rights;

The developed awareness raising campaign "Be aware=be protected" targeting key populations has to support local level initiatives to motivate women and girls victims of sexual violence to refer for help and test for HIV.

Piloted crisis response models have to be presented at round tables or stakeholders meetings where all collected practices and challenges should be discussed

Conclusions/Next steps:

· Local stakeholders have to be mobilized to pay more attention to address GBV and HIV/AIDS in the conflict regions;

· The New National HIV/AIDS Program and local HIV-related policies have to plan a specific gender-sensitive services for IDPs and HIV-positive women and girls faced GBV;

· Advocacy efforts and community mobilization should be taken over by local HIV services NGOs and local activists.

WEPED398

HIV response in the midst of natural disasters and a humanitarian crisis: The case of Puerto Rico

M. Marzán-Rodríguez, E.I. Santiago-Rodríguez, S.M. Malavé-Rivera, R.L. Vargas-Molina, C.E. Rodríguez-Díaz

University of Puerto Rico, School of Public Health, San Juan, Puerto Rico

Background: Hurricanes Irma & Maria made landfall in Puerto Rico (PR) on September 2017. The aftermath of both Hurricanes has been devastating, with detrimental impact on public health issues. PR has been in a state of political-economic emergency for years. The colonial relationship with the United States serves as a main constraint for local authorities and communities, due to an existing cap on congressional spending for health services. Social conditions prior to the natural disaster heightened the vulnerability of specific populations, particularly people living with HIV (PLWH).

Description: With a collapsing economy and a weakened infrastructure, the impact of the hurricanes, 2 weeks apart from each other, created a deeper humanitarian crisis. Basic goods including water, power, food and gas, were scarce if not absent for a long period of time. Communication networks were severely affected. Roads and transportation systems were paralyzed, making it impossible for PLWH to get to the clinics. Some HIV clinics suffered damages to their infrastructure, limiting service provision leaving PLWH without access to treatment and care.

Author Index

Lessons learned: To address future emergency situations we recommend: 1) establishing an emergency plan for HIV providers & healthcare settings at the private, public and community levels, to guarantee access to clinical services; 2) designing an HIV medication distribution plan by regions to ensure access to medication; 3) maintaining a local emergency stock of HIV medication for at least one month per patient; 4) enhancing HIV surveillance to identify location and track migration patterns of patients and; 5) developing and implementing public health policies to mitigate vulnerabilization of HIV patients.
Conclusions/Next steps: The impact of natural disasters on the HIV epidemic depends on the capacity of the government, agencies and communities to respond. Lack of economic and political autonomy in decision-making processes, governmental bureaucracy of public agencies at federal, state and local levels, and an inadequate response further unmask inequalities and disparities for the HIV population in PR.

Sexuality- and/or gender-based violence and exploitation, including in conflict settings

WEPED399
Experiences of gender-based violence among FSWs, MSM, and transgender women in Latin America and the Caribbean: A mixed methods analysis to inform HIV programming

E. Evens[1], M. Lanham[2], K. Santi[3], J. Cooke[3], K. Ridgeway[1], G. Morales[2], C. Parker[4], C. Brennan[1], D. Davis[5], R. McLean[6], M. de Bruin[7], Y. Paul[7], R. Dayton[2]
[1]FHI 360, Health Services Research, Durham, United States, [2]FHI 360, Research Utilization, Durham, United States, [3]UNDP, HIV, Health and Development, Panama City, Panama, [4]FHI 360, Behavioral, Epidemiological and Clincal Research, Durham, United States, [5]FHI 360, Health Services Research +, Durham, United States, [6]University of the West Indies, Department of Economics, St. Augustine, Trinidad and Tobago, [7]University of the West Indies, HIV/AIDS Response Program, Kingston, Jamaica

Background: Female sex workers, men who have sex with men, and transgender women are disproportionately affected by gender-based violence (GBV) and HIV, yet little is known about the impact of GBV and the services key population (KP) members want after experiencing violence. This study explored the nature and consequences of GBV and the needs of victims to inform HIV programming.
Methods: Using a participatory approach, FSWs, MSM, and transgender women in Barbados, El Salvador, Trinidad and Tobago, and Haiti worked with the PEPFAR-supported LINKAGES project, UNDP, and The University of the West Indies to conduct a mixed-methods study. KPs trained in qualitative methods conducted 278 structured interviews with peers to understand GBV experiences and linkages between violence and HIV risk. Responses to open-ended questions were coded in NVivo and analyzed using applied thematic analysis; responses to closed-ended questions were entered into EpiData and analyzed descriptively.
Results: Nearly all participants (98 percent) experienced some form of GBV. Emotional and economic violence were most common (99 percent and 80 percent, respectively). More than 70 percent also reported sexual and physical violence and other human rights violations. Over 70 percent reported violence under age 18, during sex work, from intimate partners, in public places, health care, and from police. Impacts included trauma; lack of legal and health services; and loss of employment, housing, and education. Only 23 percent believed GBV put them at risk for HIV. While many disclosed violence to friends and family, few sought services for fear of further abuse. Participants wanted KP-friendly mental and physical health care and improved support from law enforcement.
Conclusions: GBV was pervasive, but victims had limited access to services and lacked recognition of the link between HIV and GBV. We recommend that HIV programs: educate KPs on connections between HIV and GBV; implement GBV detection and care; sensitize and expand GBV programs traditionally targeting cisgender women and work with law enforcement to limit violence and create an environment where HIV programs can effectively operate. Integrated interventions addressing both HIV and GBV could help reduce KPs' burden of HIV, increase service utilization, and respect, promote and fulfill their human rights.

WEPED400
Increasing access to HIV prevention and treatment prevalence gender-based violence screening in Lubombo region of Swaziland

S.M. Haumba[1], B. Simelane-Vilane[2]
[1]University Research Co., LLC, Senior Management, Mbabane, Swaziland, [2]University Research Co., LLC, Mbabane, Swaziland

Background: Despite linkage between HIV/STI and gender based violence (GBV), services for GBV survivors are limited. In 2016, the PEPFAR funded project in Lubombo region started developing regional capacity for provision of medical and therapeutic counselling care to survivors GBV. The objective is to share lessons learned from establishing a GBV screening program in Lubombo for HIV care and treatment programs.
Description: Between September 2016 and September 2017, GBV services were established in 9 health facilities in Lubombo, and later expanded to 29 health facilities. A reporting network established for social, health, legal, police and community linkages and tools were developed. GBV Peer navigators routinely screened for GBV, provided health education, medical, therapeutic counselling and referral services. Data were de-identified and analysis done for routine patient care, quality improvement and program purposes.
Lessons learned: (1) the burden of HIV among GBV cases was high,
(2) as GBV screening program identifies links HIV positive cases to HIV care and treatment,
(3) referral network for GBV screening, and services increases GBV reporting, and
(4) GBV survivor's empowerment is critical for post GBV HIV prevention services. From inception, GBV case reporting increased from 1 GBV case per health facility per month to 12 cases. A total of 584 cases with mean age of 25 years were reported: 478 (75%) females; < 10 years (63), 10-14 (24), 15-24 (79), 20-24 (91), and 25+ (321). Emotional and psychological constituted (42%) neglect and economic abuse (29%), physical abuse (19%) and sexual abuse (10%). 100% of cases received psychosocial package. 67% Sexual abuse cases who reported within 72 hours were eligible and received post HIV/ FP post exposure prophylaxis (PEP). 66 GBV cases came with HIV known status, 139 tested on site were HIV positive. All HIV positive cases were linked to treatment and care. 70% of GBV cases reported to health care facility/peer navigator and 30% to police then referred to health facility.
Conclusions/Next steps: National scale of GBV screening in health facilities, the network for GBV referrals and empowerment of GBV survivors should strengthened as an entry into care and for HIV prevention services.

Child labour in Tanzanian small-scale gold mines: High HIV and violence risk

R. Abdul[1], E. Metta[1], J. Charles[2], L. Kikoyo[2], A. Koler[2], N. Toroka[2], J. Tarimo[3], E. Geubbels[1]
[1]Ifakara Health Institute, Health Systems, Impact Evaluation and Policy Department, Dar es Salaam, Tanzania, United Republic of, [2]Pact Tanzania, Dar es Salaam, Tanzania, United Republic of, [3]Ministry of Health, Community Development, Gender, Elderly and Children, Department of Social Welfare, Dar es Salaam, Tanzania, United Republic of

Background: Tanzania is among the world's leading gold producers, partly through artisanal and small-scale mining (ASM). Though illegal, child labour in ASM is common and is considered one of the worst forms of child labour. Formative research in Tanzania suggests ASM communities are a high HIV-risk environment. Under the USAID Kizazi Kipya (K2) program, we assessed the association of child labour in ASM with experience of violence, sexual risk behavior and HIV in three councils with ASM activities in Tanzania.

Methods: In 2017, we conducted a baseline survey in ASM communities among 786 children (0-19 years) and their caregivers who had been identified to enroll in the K2 program. We also offered children voluntary HIV testing and counseling. K2 aims to reduce social and health (including HIV) risks of vulnerable children. K2-ASM beneficiaries were divided into children 'working in mining' (i.e. digging, crushing, washing ore, amalgamation and/or food preparation, bar work and sex work catering to miners) and children 'not in mining' living in the ASM communities but not working in mining. Respondents age 6 and older who answered the violence questions themselves were included in this descriptive and multivariable logistic regression analysis (n=371).

Results: Sexual, physical and emotional violence had been experienced by 12.6% of boys and 11.2% of girls (p=0.68), 76.1% of girls and 80.3% of boys (p=.32), 47.0% of boys and 33.0% of girls ($p < .05$) respectively. Working in mining was associated with increased experience of sexual or physical abuse (table). Children working in mining were slightly more likely to have ever had sex, used alcohol, have had transactional sex, have had more than one sexual partner and have used a condom ($p > .05$). HIV prevalence was statistically significantly higher among children working in mining than among those in the general population (graph).

Conclusions: ASM communities are a structurally high HIV-risk environment for children. Direct involvement in mining work puts both girls and boys at higher risk of experiencing sexual and physical violence. Child protection and HIV programs need to target children in ASM communities. These findings will inform service delivery to these beneficiaries through the K2 program.

		Odds ratio (95% confidence interval)		
	n	Sexual violence	Physical violence	Emotional violence
Not in mining	121	1	1	1
Working in mining	250	**2.6 (1.1-6.0)**	**2.4 (1.4-4.1)**	1.2 (0.7-1.8)

Intimate partner violence and associated factors in HPTN 071 (PopART) study communities - a comparison by HIV status

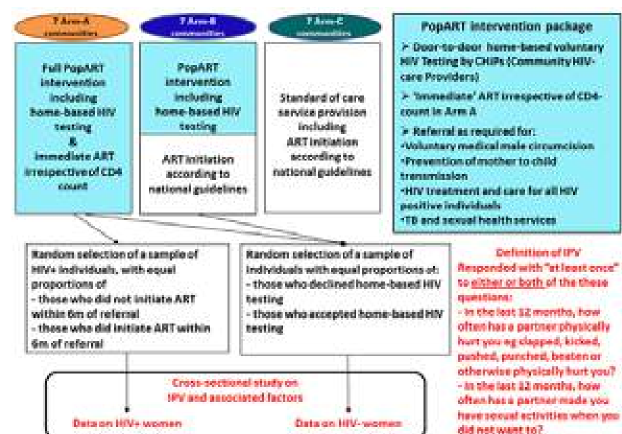
K. Sabapathy[1], C. Mulubwa[2], C. Mubekapi-Musadaidzwa[3], V. Bond[1,2], G. Hoddinott[3], H. Stockl[1], S. Floyd[1], P. Bock[3], J. Seeley[1], H. Ayles[1,2], S. Fidler[4], R. Hayes[1], HPTN 071 (PopART) Study Group
[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Zambart, Lusaka, Zambia, [3]Stellenbosch University, Cape Town, South Africa, [4]Imperial College, London, United Kingdom

Background: The HPTN 071(PopART) study is a community-randomised trial in Zambia and South Africa, examining the impact of combination-prevention including universal test and treat (UTT), on HIV-incidence (Figure-1). Intimate partner violence (IPV) is known to adversely affect women's health. We evaluated factors associated with IPV (physical and/or sexual) in PopART intervention communities.

Methods: During 2015-16, a random subset of adults who participated in the first year of the PopART intervention were recruited. Data on 300 HIV-negative women from Arm-A and Arm-B communities being offered HB-HTC, and 422 HIV-positive women from Arm-A communities who had been referred for ART were included (Figure-1). Demographic, socio-economic, behavioural factors and perceptions/opinions about HIV/HIV service factors were surveyed using standardised questionnaires and associations with IPV were examined. Logistic regression was performed to estimate odds ratios.

	HIV- [N=300, median age:31y(IQR:23-40)]			HIV+ [N=422, median age 34y(IQR:28-42)]		
	IPV n/N (%)	aOR*	95% CI	IPV n/N (%)	aOR*	95% CI
IPV (sexual &/or physical)	64/300 (21)	-	-	98/422 (23)	-	-
Sexual violence	42/300 (14)	-	-	60/422 (14)	-	-
Physical violence	33/300 (11)	-	-	68/422 (16)	-	-
Both	11/300 (4)	-	-	30/422 (7)	-	-
Accepted HB-HTC	34/165 (21)	1	p=0.30	-	-	-
Declined HB-HTC	30/135 (22)	1.47	0.71-3.06	-	-	-
Started ART within 6m	-	-	-	53/221 (24)	1	p=0.78
Did not start ART within 6m	-	-	-	45/201 (23)	0.92	0.53-1.62

[Table 1. IPV and selected associated factors, stratified by HIV-status]



[Figure. Overview of PopART trial during the first year of the intervention and sampling frame of current study]

Results: Among >700 women studied, ~20% of both HIV-negative and HIV-positive women reported experiencing physical and/or sexual violence in the last 12-months (Table 1). The proportion of women reporting sexual violence was similar by HIV status, but HIV-positive women were more likely to report physical violence and both sexual

and physical violence. Among HIV-negative women, transactional sex (aOR:4.30, 95%CI:1.20-15.44, p=0.03) and not knowing partner's HIV status (aOR:3.01, 95%CI:1.24-7.29, p=0.02) were associated with increased odds of IPV. Having control of household finances was associated with reduced odds, and women with AUDIT scores ≥8 (increased risk of alcohol dependence) were at increased odds of IPV in both groups in crude analyses, but statistical evidence of association only remained in the multivariable model for HIV-positive women (aOR:0.39, 95%CI:0.21-0.74, p=0.004 and aOR:1.96, 95%CI:1.02-3.77, p=0.02, respectively). For HIV-positive women, IPV was associated with disclosure of HIV status to their sexual partner in the crude analysis but not after adjusting for confounding factors (aOR:1.54, 95%CI:0.87-2.72, p=0.14). IPV was not associated with declining HB-HTC or failure to initiate ART within 6-months of referral (aOR:1.47, 95%CI:0.71-3.06, p=0.30 and aOR:0.92, 95%CI:0.53-1.62, p=0.78, respectively).
Conclusions: We identified factors associated with IPV which differed by HIV status. Our findings could help the development of interventions against IPV. Promisingly, our evidence suggests that acceptance of PopART UTT interventions was not affected by IPV.

WEPED403

Spreading WINGS (Women Initiating New Goals of Safety): Cross-cultural adaptation, feasibility and preliminary effects of an intervention to address gender-based violence among women who use drugs in India

P. Bhutia[1], M. Pantelic[2], L. Gilbert[3], S. Mehta[4]
[1]India HIV/AIDS Alliance, Technical Support, Drug Use and Harm Reduction, New Delhi, India, [2]International HIV/AIDS Alliance, Research and Evaluation, Hove, United Kingdom, [3]Columbia University School of Social Work, Social Intervention Group, New York City, United States, [4]India HIV/AIDS Alliance, Program and Policy, New Delhi, India

Background: Rates of gender-based violence (GBV) against women who use drugs (WUDs) are 3-5 times higher than among other women, elevating their HIV risks. Asia is home to the largest population of WUDs but has no well-established programs to address GBV in this population. We aimed to address this gap by implementing and testing an intervention to address GBV among WUDs in India.
Methods: We cross-culturally adapted WINGS, a Columbia University-licensed evidence-based GBV screening, brief Intervention and referral to treatment model for WUDs. 48 WUDs were recruited from Sahara Aalhad, an NGO in Pune and 36 completed a 3-month post-intervention follow-up. Between baseline and follow-up, WUDs received two one-on-one psycho-educational sessions on safety planning skills to reduce their risks for GBV. WUDs were also linked to HIV testing and treatment and GBV-related services as needed. Generalised linear models estimated changes in study outcomes between baseline and 3-month post-intervention assessment. Random-effect Poisson and logistic regressions were used for continuous and dichotomous measures, respectively.
Results: At baseline, the mean age of WUDs was 30, 45.8% were married and 75% had children. 25% had an education higher than primary school. 22.9% had been employed in the past year and 20.8% had experienced homelessness in the past 3 months. 54.2% had engaged in sex work, 20.1% had been arrested and 31.3% used heroin in the past 90 days. Prevalence of any GBV was 97.7%, of which 85.4% was verbal, 83.3% was injurious physical violence and 79.2% was sexual violence. Effects of WINGS on incidents of GBV are presented in Table 1. WUDs reported significantly fewer incidents of verbal and physical GBV post intervention, both from intimate partners and others. There were also significant increases in linkages to GBV services over the 3-month follow-up period. No significant differences were observed on sexual violence. 39.5% were provided referrals for HIV testing. 10% registered for ART at Government health cares.

Conclusions:

	Sample No.(%) or mean, SD		Relative Risk ratio or odds ratio- change from baseline to 3-months follow-up	
	Baseline	3 months	Unadjusted	Adjusted
Intimate Partner Violence				
No. of verbal incidents: IRR	43.4, 39.5	40.1, 40.8	0.93 [0.86-0.99] p = 0.032 *	0.93 [0.86-0.99] p = 0.032 *
No. of physical incidents: IRR	81.6, 74.0	54.75, 61.7	0.67 [0.63-0.71] p < 0.001 ***	0.67 [0.63-0.71] p < 0.001 ***
No. of sexual incidents: IRR	98.5, 100.1	96.6, 94.5	0.98 [0.94-1.03] p = 0.423	0.98 [0.94-1.03] p = 0.423
Non intimate partner gender-based violence				
No. of verbal incidents: IRR	22.3, 32.9	14.8, 25.4	0.66 [0.59-0.74] p < 0.001***	0.66 [0.59-0.74] p < 0.001 ***
No. of physical incidents: IRR	28.1, 45.8	14.0, 28.1	0.50 [0.45-0.56] p < 0.001 ***	0.50 [0.45-0.56] p < 0.001 ***
No. of sexual incidents: IRR	11.6, 25.2	11.5, 35.1	0.99 [0.86-1.13] p = 0.203	0.99 [0.86-1.13] p = 0.203

[Effects of WINGS on incidents of IPV, GBV, substance use and linkage to services in the past 90 days (n = 36 women who completed 3-month follow-up)]

Study findings suggest the feasibility and promise for community-based implementation of a peer-delivered intervention for addressing GBV among WUDs in resource-constrained settings. Evidence on larger samples and across cultural contexts is urgently needed to meet needs of WUDs in Asia.

WEPED404

Assessing the safety of Zambian female sex workers amidst violence from their male clients

K. Malama[1], B. Spire[1], A. Gosset[1], M. Nishimwe[1], P.-J. Coulaud[1], L. Sagaon-Teyssler[1], R. Parker[2], A. Tichacek[2], M. Inambao[3], W. Kilembe[4], S. Allen[2]
[1]Aix-Marseille University, Marseille, France, [2]Rwanda Zambia HIV Research Group, Atlanta, United States, [3]Zambia-Emory HIV Research Project, Ndola, Zambia, [4]Zambia-Emory HIV Research Project, Lusaka, Zambia

Background: Zambian female sex workers (FSW) are vulnerable to violence from their male clients, which places them at risk for HIV. FSW experiencing violence may find themselves isolated as the police represent the major violence response service and sex work remains illegal. Community-based support programmes can mediate between FSW and violence response services in addition to providing risk reduction education and HIV testing services. We investigated FSW response to violence from male clients and their knowledge of support programmes.
Methods: Between September 2012 and March 2015, the Zambia-Emory HIV Research Project (ZEHRP) recruited 555 HIV-negative FSW aged 18-45 from Lusaka and Ndola into a cohort study. FSW completed a face-to-face baseline questionnaire, in which they were asked if they had ever experienced violence from their male clients (y/n). FSW were also posed multiple response questions on what they did in the event of such violence, measures they generally took to ensure their safety around clients and if they knew of any programs to support FSW.
Results: Of 498 respondents, 37% (n=185) reported having experienced violence from their male clients. When faced with violence, the majority of women reported running away (72%), while 30% attempted to negotiate with clients, some called their friends (32%) and only a minority of 13% chose to call the police. To ensure their safety with clients, FSW (n=425) mostly reported staying calm during negotiations (63%), asking for money before sex (62%), being honest during interactions (51%) and avoiding alcohol and drugs (40%). Out of 425 respondents, a mere 3% of women (n=13) stated that they were aware of any support programmes for FSW other than ZEHRP, with the vast majority (97%, n=412) indicating no such knowledge.
Conclusions: FSW were reluctant to report violence to the police, despite being highly susceptible to it, suggesting a lack of trust in the authorities for fear of prosecution. Support programmes, which FSW were largely unaware of, could help tackle HIV prevention, gender based

violence and FSW empowerment. HIV prevention efforts should look to raise awareness of existing support programmes in order to better meet the health and safety needs of FSW.

WEPED405

Young Jamaican men who have sex with men experiences with childhood sexual abuse and sexual assault

O. Harris[1], L. Dunn[2]
[1]University California, Center for AIDS Prevention Studies, Alameda, United States, [2]University of the West Indies, Mona Campus, Gender Development Studies, Kingston, Jamaica

Background: The prevalence of HIV is exceptionally high among Jamaican men who have sex with men (MSM). Researchers have theorized that the high prevalence of HIV among Jamaican MSM may be due to social vulnerabilities, such as high unemployment, homelessness, limited education, coupled with the criminalization of same-sex sexual behaviors. A noticeable gap in the literature is the impact of childhood sexual abuse (CSA) and sexual assault on the state of the epidemic among this population. This study focuses on Jamaican MSM's experiences with CSA and sexual assault and how these domains relate to HIV risk and prevention.
Methods: In this qualitative descriptive study, we used semi-structured in-depth interviews with 20 MSM and a focus group discussion with 10 MSM as the primary data sources. Participants were recruited from five urban and peri-urban parishes in Jamaica. Data were recorded, transcribed verbatim, and analyzed using thematic content analysis.
Results: Participants were aged 18-29 years and self-identified as gay or bisexual. More than one third of the sample disclosed a history of childhood sexual abuse or sexual assault. Participants who manifested a feminine presentation as a child reported experiencing significant sexual violence, which often starts with unwanted touching, exposure of genitalia, and end with nonconsensual sexual acts. The predominant characteristics of the perpetrators include male family member (i.e., cousin, uncle), pastor, or family friend. Agency and resiliency was achieved through reporting the abuse to family and friends; however, the decision to disclose the abuse was weighed against whether or not they would be believed. Participants have also described how these experiences have led to continued psychosexual trauma extending into adulthood and acted as triggers and barriers to engaging in HIV prevention and care.
Conclusions: Our findings serve as a catalyst for understanding how CSA and sexual assault affect young Jamaican MSM and how such experiences may in turn affect attitudes and behaviors regarding HIV testing and engagement in care. Findings also highlight the need for incorporating CSA and sexual assault questions into health and sexual history screening materials for Jamaican MSM and call for the strengthening of mental health services for survivors of abuse.

Myanmar prison health: Opening closed doors for the prevention, care and treatment of inmates living with HIV, TB and other infections - lessons learned

W. Zaw[1], H. Piang[2], T. Lin[3]
[1]Asian Harm Reduction Network-Myanmar, Program, Kale, Myanmar, [2]Asian Harm Reduction Network-Myanmar, Treatment Unit, Kale, Myanmar, [3]Asian Harm Reduction Network-Myanmar, Program, Yangon, Myanmar

Background: The Myanmar prison population is estimated at 60,000 in 45 prisons, anecdotal reports indicate that overcrowding of prisons in Myanmar creates an environment which heightens the risk of vulnerability to HIV, TB, hepatitis and other infectious diseases. The Prison authorities took the leadership allowing AHRN as NGO to enter the prison and in two labour camps in Kalay, to pilot the implementation of health care service for inmates and staff.
Description: Kalay is located along the remote transport route to Myanmar's border with Northeast India, which runs through the Chin Mountains and connects to the border town of Tamu, 80 km north. There are more than 1800 inmates in Kalay Prison and more than 200 prisoners in each labour camp. The health care service for the inmates is limited due to lack of (human) resources and infrastructure.
AHRN staff was trained on prison contexts, occupational health, security regulations and social peculates. In July 2017 the prison health intervention commenced in Kalay prison and two labour camps, including HIV testing, counseling and care, Hepatitis B screening and vaccination, Health Education, TB screening and Treatment, Basic Health Care in order to assist the prison health department in addressing pressing health concerns.
Lessons learned: Within six months, 1006 inmates and staff were vaccinated for HBV, 180 inmates received HIV testing and counseling, 140 PLHIV received HIV care, 233 inmates have been screened for TB and 6 are under TB treatment, and 1137 received BHC. Training of AHRN staff on specifics of working in prison proved important for mutual appreciation and understanding and increased access. A through-care has been drafted to ensure patient follow-up after release.
Conclusions/Next steps: Regular briefing with prison authorities to stem expectations were important to build trust and confidence that AHRN as 'outside' group respect the security considerations. Resource constrains limit full ART coverage, infection control measures can expand, through-care and referral of inmates has not been formalized yet. There is the opportunity to implement further health standard operation procedures, training of staff, increase and systemize voluntary HTC and screening on TB coverage.

WEPED407

HIV risk perceptions and risk reduction strategies among prisoners in Kyrgyzstan: A qualitative study

J. Rozanova[1], L. Azbel[2], A. Kurmanalieva[3], N. Shumskaya[3], R. Marcus[1], K. Lamonaca[1], T. Rhodes[2], G. Culbert[4], F.L. Altice[1], J.P. Meyer[1]
[1]Yale University School of Medicine, Internal Medicine, New Haven, United States, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]AIDS Foundation East - West in the Kyrgyz Republic, Bishkek, Kyrgyzstan, [4]University of Illinois at Chicago, Chicago, United States

Background: In Kyrgyzstan, both methadone maintenance therapy (MMT) and needle-syringe programs (NSP) have been introduced in prisons as measures to reduce HIV transmission. To investigate their delivery and effects, we undertook qualitative research to explore how prisoners with a history of drug injection conceptualize and reduce their HIV risk during incarceration.
Methods: Prisoners were purposively sampled ensuring addiction treatment experience diversity from one male and one female prison near Bishkek, Kyrgyzstan from 2016-2017. We conducted in depth qualitative interviews in Russian or Kyrgyz with 15 male and 10 female prisoners with a history of drug injection to examine HIV risk perceptions. Using an inductive analytic approach, 3 researchers independently coded translated interview transcripts using Dedoose qualitative research software with 85% inter-coder agreement; discrepancies were resolved through discussion. We assessed five codes related to HIV risk, which encompassed perspectives on drug use, addiction, personal health, harm reduction including MMT and NSP, and the prison risk environment.
Results: From participants' interview accounts on managing their HIV risk during incarceration, three overarching themes emerged:
1) rationality of safety, whereby avoiding HIV infection was perceived as both an individual and collective responsibility;
2) peer HIV risk governance that included tactics for ensuring safety, whereby prisoners encouraged one another into curbing risky injection practices to avoid harming themselves and others and disciplined prisoners who failed to disclose their HIV status; and
3) relationships with prison healthcare providers, whereby prisoners' ongoing patient-clinician relationships supported their efforts to reduce their HIV risk during incarceration. Women prisoners tended to discuss HIV risk reduction strategies in terms of compassion and male prisoners in terms of coercion.

Conclusions: Among prisoners in Kyrgyzstan with a history of drug injection, we found that peers influence HIV risk perception and reduction strategies. As prisons across EECA are characterized by a paucity of government resources for healthcare, making way for informal governance by prisoners themselves, within-prison peer-driven HIV prevention interventions can potentially harness these peer influences to reduce HIV risk.

WEPED408

A systematic review of HIV outcomes and engagement in care across incarceration trajectories among women living with HIV

M. Erickson[1], A. Sernick[1], N. Pick[2,3], F. Ranville[1], R. Elwood Martin[4], K. Shannon[1,3], A. Krusi[1,4]

[1]BC Centre for Excellence in HIV/AIDS, Gender and Sexual Health Initiative, Vancouver, Canada, [2]BC Women's Hospital and Health Centre, Oak Tree Clinic, Vancouver, Canada, [3]University of British Columbia, Department of Medicine, Vancouver, Canada, [4]University of British Columbia, School of Population and Public Health, Vancouver, Canada

Background: Despite increased rates of incarceration among Women living with HIV (WLWH) globally, and the over-representation of WLWH in correctional settings, there is limited data concerning the gender-specific impacts of incarceration on HIV outcomes and engagement in care for WLWH.

Methods: We systematically searched OVID Medline, Web Of Science, PsycINFO, CINAHL, Sociological abstracts, Cochrane Library, and EMBASE, for peer-reviewed English-language studies, published between January 2007 and February 2017, reflecting: Incarceration, Women (trans inclusive), and HIV. Articles were included for evaluation if they presented sex/gender specific outcomes for WLWH, prior-to, during or following incarceration including at least one of three endpoints of interest: Viral Load (VL), ART adherence, or engagement in care. Studies were identified, screened and selected using systematic methods.

Results: Of 1119 studies matching the search criteria, 24 (2%) met the final inclusion criteria. Of the included studies, 19 contained samples of women and men, 6 of which were trans inclusive. Five studies were conducted exclusively among women, including one study focused solely on trans women. The majority (n=23) were conducted in the United States. For periods prior-to and during incarceration, our review did not reveal clear gender differences with regards to VL suppression, medication adherence or engagement in care for WLWH. However, studies reporting post-incarceration outcomes demonstrated significant gender disparities in all three of outcomes of interest. The majority (86%) of studies that reported on post-incarceration periods, conducted among both women and men, demonstrated that women were less likely to be engaged in care, less likely to be virally suppressed, and less likely to achieve optimal ART adherence in the months following release from correctional facilities.

Conclusions: Our literature review shows significant gender disparities in HIV outcomes for WLWH following release from correctional settings. Despite growing numbers of incarcerated WLWH globally, there remains a substantial gap in research examining the impact of incarceration on HIV health outcomes for WLWH. This review highlights the critical need for further studies examining the experiences of WLWH throughout incarceration trajectories, and the need to develop specific gender-informed interventions aimed at improving post release engagement in care for WLWH, alongside efforts to prevent the incarceration/re-incarceration of WLWH.

WEPED409

The role of civil society organizations (CSOs) in improving early HIV detection and continuity of ART in Tajikistan prisons

Z. Davlyatova

AFEW-Tajikistan, Dushanbe, Tajikistan

Background: In 2014, the prevalence of HIV in the Tajikistan penitentiary system was 7 times higher than the prevalence level in general society. Prisons authorities report that the penal system faces difficulties in organizing regular HIV testing among prisoners and that inmates lack basic knowledge about HIV, are ashamed to apply for assistance and are afraid disclose their health status. This discourages timely detection of HIV, and leads to interruption of ART and HIV transmission among inmates.

Description: In accordance with the START Plus model (officially approved and introduced by the penitentiary system) and in cooperation with prison administrations and civilian AIDS centers, AFEW-Tajikistan delivered voluntary HIV testing and counseling (HTC) and regularly organized HIV prevention mini-trainings for prisoners. Each HIV-positive prisoner received the necessary counseling, as well as social and adherence support to ensure continuity of ART during the transitional period before and after release.

Lessons learned: In 2017, 1586 (72%) prisoners of three colonies situated in Norak, Yovon and Khujand were reached by the HTC campaign. As result, 14 new cases of HIV were detected, equivalent to 21% of all 67 new cases detected in all Tajikistan prisons in 2017. 100% of inmates with newly-detected HIV initiated ART and received counseling and adherence support from AFEW-Tajikistan and partner CSOs social workers. 100% of HIV-positive prisoners released from these prisons were also assisted in health specialist appointments, timely registration at an AIDS center in their hometown, continuation of ART, and TB testing. To support continued adherence to ART, CSO social workers regularly visited ex-prisoners and assisted them in resolving social problems, acquiring the necessary vocational education and seeking employment. As result, there were 0 cases of ART interruption among the HIV-positive START Plus participants.

Conclusions/Next steps: With the official support of the prison authorities and based on evidence of its effectiveness, the START Plus model provides CSOs with opportunities to deliver services for prisoners and ex-prisoners in the transitional period before and after release, and initiate dialogue with donors to attract funds for supporting community-driven initiatives on HIV prevention and health promotion in prisons.

WEPED410

Peer Navigation System in Central Asian prisons as the most effective approach for HTS, ARV treatment initiation and adherence support

R. Dudnik

AIDS Foundation East-West in Kazakhstan, Almaty, Kazakhstan

Background: The majority of inmates (over 60%) in Central Asia inject drugs or was imprisoned for drug-related crimes. Due to unsafe practices inmates are at high risk of becoming infected with HIV and transmitting it to others. Historically, in post-Soviet countries, prison staff and doctors of governmental health system are perceived by inmates as "enemies" that cannot be trusted. Inmates PWID and PLHIV perceive all initiatives coming from them as a means of controlling or conducting experiments on people. That's why most of them refuse testing and treatment, and the ART coverage, adherence to treatment are still on the very low level.

Description: USAID HIV React Project (2014-2019) implemented by „AIDS Foundation East-West in Kazakhstan" in 18 prisons of Central Asia (Kazakhstan, Kyrgyz Republic, Tajikistan) consisting 16600 inmates including more than 700 PLHIV (data for October 2016). There are 56 peer navigators among current inmates in all project prisons are involved in the project implementation by actively promoting HTS among prisoners who inject drugs, putting their efforts into motivating and escorting PWID prisoners into testing points inside the prisons and motivate PLHIV to start ART and adhere to treatment.

Lessons learned: Inmates trust Peer Navigators because they are also inmates with drug use experience and/or positive HIV status. This significantly increases the effectiveness of the work aimed to achieve the 90-90-90 goals among inmates. Peer Navigators are motivated to work by incentives (additional food and hygienic packages) and by opportunity to increase its authority in their community. The main factors for the success of the approach is the proper initial selection and regular trainings for peer navigators. Personal experience is the key, therefore they should be well trained and free from any prejudice, myths and misconseptions.
Conclusions/Next steps: During the recent Project year (October 2016 - September 2017) 4690 PWID and 1049 PLHIV inmates (including recently released covered by Peer ex-inmates) were covered by the trained Peer Navigators. 3690 PWID received HTS, 574 PLHIV on ART received support in adherence to treatment, 121 newly identified PLHIV started ART. Peer Navigation System is the most effective approach to achieve 90-90-90 goals among inmates in Central Asia.

WEPED411

Harm reduction friend or foe? Correctional officers and prison-based needle and syringe programs

E. van der Meulen[1], S.K.H. Chu[2], R. Reece[3], R. Elliott[2]
[1]Ryerson University, Department of Criminology, Toronto, Canada, [2]Canadian HIV/AIDS Legal Network, Toronto, Canada, [3]Humber College, Toronto, Canada

Background: In Canada, federal prisoners comprise a marginalized population, many of whom are dependent on drugs. 80% of federally incarcerated men were identified as having a substance use problem upon admission and one-quarter of federally incarcerated women are serving time for a drug offence. Yet the past decade of tough-on-crime legislation has further eroded prisoners' health and safety and contributed to overcrowding, violence and exceedingly high rates of HIV and HCV, especially among Indigenous prisoners.
Description: Although injection drug use is a major factor contributing to HIV and HCV transmission behind bars, the Canadian government has refused to implement prison-based needle and syringe programs (PNSPs), citing unfounded threats to prison security, among other reasons. In a qualitative study with former prisoners and medical and community professionals who provide support to incarcerated populations, we sought to elucidate the main barriers to PNSPs and in particular, those posed by correctional officers.
Lessons learned: As the primary frontline workers in prisons, correctional officers play a significant role in PNSP success or failure. However, respondents overwhelmingly saw correctional officers as a key obstacle to PNSP implementation and perceived many officers as having little compassion for prisoners' health and wellbeing. A narrow focus on prison security has led many officers to believe that the provision of sterile injection equipment undermines their responsibility to maintain security or could be seen as condoning drug use, while overlooking the fact that PNSPs improve workplace safety by reducing accidental needle-stick incidents.
Conclusions/Next steps: As respondents emphasized, it is essential for correctional officers to be educated on drug use and drug dependence if PNSPs are to be effective. A peer knowledge exchange between correctional officers in Canada and those working in international PNSP settings would be immensely helpful. The challenges to PNSP implementation are considerable, but they are not insurmountable. Where PNSPs exist, there is a high level of staff support for the programs. With education about the manifold benefits of PNSPs, including for workplace health and safety, misconceptions about PNSPs can be addressed, concerns can be eased, and a seemingly intransigent workforce could emerge as PNSP champions.

WEPED412

Organization of medical care for HIV-infected inmates in institutions of the State penitentiary service of Ukraine

O. Klymova[1], L. Getman[1], S. Vasyliev[2], T. Gaborets[2], S. Klymov[2]
[1]Public Health Center of the Ministry of Health of Ukraine, Kyiv, Ukraine, [2]Ministry of Justice of Ukraine, Kyiv, Ukraine

Background: HIV and AIDS prevalence among prison inmates and pre-trial detainees is about 15 and 14 times respectively higher than among adults of general population in Ukraine. The delivery of medical care should be closely cooperated with civil health. We aimed to analyze the providing of the timely access of HIV-infected prisoners and detainees to antiretroviral therapy (ART) in accordance with international standards).
Methods: We analyzed the ART coverage of HIV-infected convicts and detainees in the institutions of the State Penitentiary Service of Ukraine (SPSU) over the period of 2016-2017, according to the reporting form No. 56 „Report on the antiretroviral therapy delivery for HIV-infected persons in the ___ month of the 20__ year", approved by Order of the Ministry of Health of Ukraine dated March 23, 2012 Nº 182.
Results: Based on the results of the analysis of official statistics data, 4,129 HIV-infected inmates were identified and 1995 patients among them were treated with ART by the beginning of 2016. As of January 1, 2018 there were identified 3,830 HIV-infected inmates and 2543 patients among them were treated with ART. Thus, the rate of coverage of ART among prisoners and detainees has been increased from 48.3% to 66.4% during 2016-2017 years. However, taking into account the goals of the Fast Track "90-90-90" strategy, the rate of ART coverage of HIV-infected prisoners and detainees remains low caused by the lack of medical staff in SPSU and insufficient social work with the HIV-infected inmates.
Conclusions: Increased but low ART coverage of HIV-infected prisoners and detainees does not meet the requirements of international standards. In order to improve the quality of medical services in the SPSU there was established the state institution „Center of Health of SPSU". One of the expected results is to provide continuous medical care to the prison inmates with HIV-infection, tuberculosis, drug addiction in accordance with current legislation and international recommendations.

WEPED413

Law and practice that inhibit HIV treatment adherence for pre-trial detainees in Malawi

A. Raw[1], V. Mhango[2], I. Maluza[2]
[1]Southern Africa Litigation Centre, Health Rights Programme, Johannesburg, South Africa, [2]Centre for Human Rights Education, Advice and Assistance, Blantyre, Malawi

Background: In Malawi, people living with HIV in police custody and remand detention in prisons face barriers to adhering to antiretroviral treatment (ART). This paper analyses the legal and regulatory framework governing access to healthcare for pre-trial detainees in order to determine barriers to treatment adherence.
Description: It is a common for arrested persons to spend unlawfully prolonged periods in police and remand detention. People living with HIV in police custody are often refused requests to facilitate access to medications, including ART. Once transferred to remand sections in prisons, detainees may face further delays before consulting a healthcare worker to re-establish access to treatment. These treatment disruptions have direct effects on prisoners' health and rights.
Lessons learned: While having a broadly supportive consitutional and common-law framework on the rights of all persons in detention, nothing in legislation governing arrest and powers of police specify rights or duties on access to healthcare or medicines when a person is held in police custody. Furthermore, there is no domestic regulatory guidance to ensure that detainees' access to treatment is sustained in transfer periods between police custody and remand sections in prisons. Finally, despite that the Prisons Act does not distinguish between convicted offenders and remand detainees in relevent sections, in practice, prisoners on remand are considered the responsibility of the Police, which has limited capacity to facilitate access to care.

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

Conclusions/Next steps: In the absence of an adequate legislative or regulatory framework, police officers do not assume responsibility for ensuring access to treatment for persons in police custody, nor are they enabled to do so with appropriate budgetary allocations. In addition, these legal and policy gaps, result in violations of privacy and confidentiality of HIV status for people in police custody who are forced to disclose their status to arresting officers in the presence of other detainees in order to request to access treatment. Once in prison facilities, the distinction between the law and practice creates disputes over mandate and constrains access to emergency medical care in particular. Legal and policy development is critical to enable treatment adherence in pre-trial detention.

WEPED414

Training family physicians to care for HIV infected men in very a short-term jail setting

J. Gates, J. Ryu, S. Livermore
University of Southern California School of Medicine, Family Medicine, Alhambra, United States

Background: HIV screening, treatment, and linkage to care upon release is extremely difficult in jails given that some are incarcerated for as short as 24/48 hours. Even with an average length of incarceration of 30 to 40 days infected patients often don´t see an HIV specialist provider before they are release.

Description: The Los Angeles County Jail (LACJ) is the largest in the world averaging 18,000 to 20,000 incarcerated persons any given day. The LACJ averages about 500 known persons with HIV daily. Before intervention, most HIV infected men were not seen by an HIV specialist before release. The result was many were off their medications or put on a different regimen. To meet the challenge of the lack of HIV care while incarcerated in in the jail we began a HIV fellowship to train family physicians to provide care in the LCJ with the idea that these physicians would become experts in HIV treatment, learn how to provide care within a jail setting, and serve as agents to implement system changes to improve the overall HV care. To learn HIV medicine these family physicians trained for a year at the major HIV clinic at the Los County+USC Medical Center and at selected community based HIV clinics (where incarcerated seek care). To learn to provide care in the jail, fellows spent 20-30% time working under the supervision of the fellowship director who provided HIV care both within the jail and at the medical center.

Lessons learned: All 7 of the family physicians have successfully completed this corrections HIV fellowship with 3 taking potions at various jails and the other work in HIV setting where formally incarcerated are receiving HIV care. Beyond increasing the HIV workforce in jails this program has fundamentally improved the HIV care with the LACJ. HIV patients are now routinely screened upon booking, see an HIV expert before release, are maintained on current ARTs (when known).

Conclusions/Next steps: Increase the number of family medicine physicians to provide HIV treatment, develop a system that links patients to care in the community upon release. Co-locate HIV providers both in the jails and the community.

Media, cultural and religious representations of HIV and of key populations

WEPED415

The advertisers activists collective: #EqualityChallenge guidelines to improve accountability to LGBT in South African advertising

C. Patel[1], L. van den Heever[2], P.D. Tucker[3]
[1]AIDS Accountability International, Cape Town, South Africa, [2]AIDS Accountability International, Research, Cape Town, South Africa, [3]AIDS Accountability International, Research, Bruxelles, Belgium

Background: Advertisements (and those who create them and commission them) have the power to change norms and either reinforce or reverse stigma and discrimination. Whether advertisements feature women, mentally ill people, the disabled, LGBTIQ (Lesbian, Gay Bisexual, Transgender, Intersex or Queer people), or certain race groups, they can perpetuate harmful stereotypes or break them down. But the problem is that many advertisers, marketers and business do not know these commitments nor care to be leaders in human rights.

Description: The #EqualityChallenge advertisers' guidelines are meant as a framework to help advertisers, marketers, businesses and SOGIE (sexual orientation and gender identity and expression) activists work together to make equality, dignity, freedom and security a reality for the millions of LGBT people living in South Africa and the rest of Africa. AAI offers trainings on the guidelines and they are being well received by staff at ad firms.

Lessons learned: The advertising industry has been very welcoming of our message and keen to use their influence for human rights.
Marketers are more hesitant and less accessible due to fear of damaging their brand by association with stigmatised groups.
The peer influence effect and competitive spirit to be the leader is a powerful on in this industry.
In 18 months we have 3 adverts with trans people in them that are ethically setting a new standard.
Other media, such as print and radio have shown great interest in supporting this work.
If civil society can create positive feedback on inclusive adverts and drown out any phobic response, we have permanent allies in the advertisers and marketers.

Conclusions/Next steps: The project wants every advertising agency in Africa to take the #EqualityChallenge pledge, to embrace and endorse these guidelines, and to work to further LGBTIQ equality. With the support of inspirational, committed, justice-oriented and talented creatives like our current ambassadors and the agencies they represent, this ambitious goal is reachable.

WEPED416

Ambitious goals, restrictive environments: Accelerating HIV testing uptake among men who have sex with men in Jakarta's Fast-Track response

R. Ningsih[1], C. Francis[2], J. Macom[3], A. Human[2], M. Setyawan[2]
[1]Pact Inc., Jakarta, Indonesia, [2]FHI 360, Jakarta, Indonesia, [3]FHI 360, Bangkok, Thailand

Background: Jakarta's Provincial Health Office (PHO) articulated 2017 testing targets to reach an annual epidemic control goal of diagnosing 9,292 people living with HIV. Focus was placed on testing key populations (KPs), particularly men who have sex with men (MSM), for whom epidemiological and programmatic data indicated low testing coverage and rising HIV prevalence. Enhanced outreach approaches, amplified mobile and static testing services, and new HIV testing campaigns targeting MSM were among interventions introduced to accelerate HIV testing uptake. However, 2017 was also characterized by a deteriorating environment for MSM human rights, with attempts made to ban online gay social network applications and high-profile raids and arrests of gay and bisexual men taking place under the auspices of enforcing pornography laws.

Description: The USAID- and PEPFAR-supported LINKAGES Indonesia project reviewed 2017 HIV testing data among 88 HIV testing services in Jakarta. Testing uptake among MSM was charted across 12 months. Initiation dates for three important Fast-Track programmatic interventions — USAID/LINKAGES' key population mobile testing initiative (DOKLING); PHO's sub-district testing target guidance; and APCOM's TestJKT campaign — were plotted against monthly MSM testing uptake data. Dates of two high-profile sauna raids and mass arrests of MSM were also incorporated into the 12-month analysis.
Lessons learned: While MSM testing uptake has increased by 35 percent over 2017, erratic monthly totals suggest that uptake is affected by both enabling and restrictive measures. An 18 percent increase in testing followed the intensification of mobile testing services between April and May, although testing figures dropped by 12 percent from May to July, corresponding with the raid of Atlantis Spa when 141 persons were detained and mobile testing services were disrupted. Testing rates subsequently rose by 28 percent in July, as the PHO announced sub-district testing targets that increased testing frequency. Thereafter, testing rates declined by 16 percent. An October 6 raid and detention of 58 men did not appear to immediately affect MSM testing uptake, which increased by 19 percent in November as the TestJKT campaign intensified.
Conclusions/Next steps: Close monitoring of enabling environment measures and HIV service uptake among highest-risk KPs is critical in Fast-Track programming environments.

WEPED417

HIV/AIDS as a latent discourse. Practices of fragmentation, historicization and othernisation in Switzerland

D. Knuchel
University of Zurich, Zurich, Switzerland

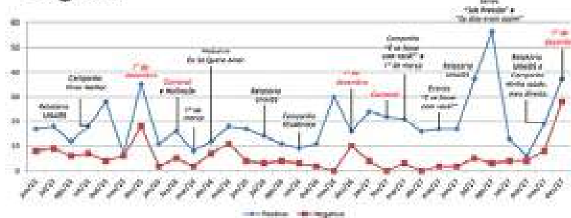
Background: In Switzerland HIV/AIDS is rather a chronic than a fatal infection nowadays due to effective treatment possibilities. This so-called ´normalisation´ has an impact on media discourse and it appears as if HIV/AIDS is no longer of public interest. The same can be said for cultural studies dealing with HIV/AIDS in Switzerland, with the literature focusing in particular on the 80es and 90es. This paper aims to fill this gap and sheds light on developments in media discourse among HIV/AIDS in Switzerland between 2006 and 2016.
Methods: The study is situated in the broader field of cultural language studies and is drawing on tools from (German) discourse linguistics and corpus pragmatics (e.g. text mining). The analysis is based on a thematic digital corpus consisting of 6000 texts published in the German-speaking part of Switzerland between 2006 and 2016. All texts containing the character strings *HIV* or *AIDS* from eight different press products (newspapers and magazines) have been included and processed accordingly to corpus linguistic standards (metadata, lemmatisation, part of speech tagging). The analysis has been carried out in three steps. Firstly, text distribution accordingly to different metadata such as year, source, topic have been computed and compared. Secondly, a combination of a keyword and collocation analysis has been conducted and thirdly concordance lines have been examined.
Results: The quantitative distribution analysis shows a steady decline in media attention. Furthermore, only 20 percent of all articles deal with HIV/AIDS as a maintopic. The keyword and collocation analyses show six different topical framings: science, Africa, development cooperation, 80es/90es, minorities ,events. In addition, a more detailed breakdown of the results shows that conceptualisations of HIV/AIDS such as *>HIV/AIDS as infectious disease<* , *>HIV/AIDS as historic phenomenon<* , *>HIV/AIDS as African disease<* and *>HIV/AIDS as a consequence of immoral conduct<* are unconnected and can be understood as different phenomena with the same term.
Conclusions: The corpus linguistic analysis shows that HIV/AIDS in media is a latent discourse which is defined through practices of fragmentation, historicization and othernisation. This findings emphasize that collective knowledge about HIV/AIDS is blurring and sterotypes and prejudice are still part of public representations.

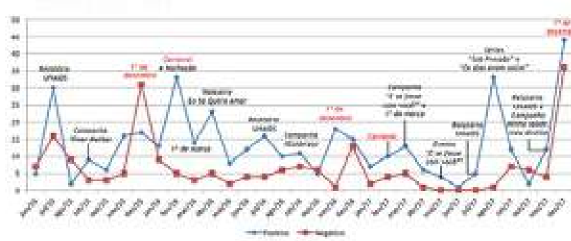
WEPED418

Signs of hope on ending stigma and discrimination in Brazil: Analyzing the impact of HIV outreach campaigns and initiatives on the news coverage of Brazilian media

D. De Castro[1], G. Braga-Orillard[2]
[1]UNAIDS, Communications, Brasilia, Brazil, [2]UNAIDS, Brasilia, Brazil

Background: Brazilian press has only recently started to recover from its almost decade-long silence on AIDS. Studies show that from 2007 to 2013, major media outlets have very rarely dedicated headlines and front pages to this subject, including on World AIDS Day. Stories on HIV and AIDS were almost always shoved in the middle of generic news desks, and stories had mostly scientific and medical approaches, focusing, at times, on tabloid-like stories, fuelling stigma and discrimination. In 2015, UNAIDS office in Brazil started a daily monitoring of the national news on HIV and AIDS in Portuguese as part of its internal communications strategy to build messages and campaigns on prevention, treatment and zero discrimination.
Methods: Stories were systematically collected every morning from an average of 30 different credible news providers (TV/radio, digital and traditional print). Content analysis classified news either as negative (when discriminatory, pejorative, or disruptive) or as positive (when they contributed directly or indirectly to the HIV response, providing important service, information and/or adequate terminology, or provided they were neutral and impartial). UNAIDS main outreach activities and campaigns were cross-checked with the Excel line graphics generated for the June 2015-December 2017 period to better understand its impacts on the media coverage of HIV in Brazil. Graphics for TV/radio, digital and traditional print results were compiled separately.





[Media Monitoring UNAIDS Brazil - June 2015 to December 2017]

Results: Out of 1,939 pieces analyzed from June 2015 to December 2017, 1,442 were classified as positive and 497 as negative, with negative peaks occurring mostly around key local dates for HIV awareness, December 1 and Carnival.
Conclusions: i) Digital and traditional print media respond better to campaigns and key messages, producing more positive content on HIV and AIDS, even during key dates, such as WAD and Carnival, whereas TV/

radio outlets deliver peaks of negative news on key dates; ii) overall improvement of coverage, especially on digital and print, with a positive-negative ratio of 3.7 to 1 in print; 3.4 to 1 in digital; and 1.3 to 1 in TV/radio; iii) targeted media training for TV/radio before key dates could mitigate negative coverage.

WEPED419

Capacity building of media personnel for positive and unbiased portrayal of communities at-risk for HIV: Towards creation of an enabling social environment through media

S. Ramasamy Kandasamy[1,2], G. Kumar[3], V. A[3], P. Krishnasamy[3], B. Veeraragavan[4]
[1]Voluntary Health Services, Projects, Chennai, India, [2]APCOM, MSA DIVA Project, Bangkok, Thailand, [3]Voluntary Health Services, MSA DIVA Project, Chennai, India, [4]The Voluntary Health Services - VHS, MSA DIVA Project, chennai, India

Background: Media plays an important role in addressing stigma and discrimination faced by marginalized communities in India. Although there has been an increase in the media coverage of HIV over the years, due to lack of understanding on issues faced by hijras/transgender women, adequate and good coverage are sub optimal. Enhancing/building the capacities of media/media personnel on issues faced by hijras/transgender women will not only correct misconceptions but also result in unbiased portrayal, stigma reduction and creation of supportive policies and programmes.
Description: Voluntary Health Services (VHS), with support from the Global Fund, is implementing a four-year project (2014-18) titled *'Diversity in Action'* in India to reduce the impact of HIV on hijras/transgender women. One of the focus areas of the project is to sensitize and capacitate various stakeholders including media personnel on issues faced by hijras/transgender women. Through the project, one national and 4 sub regional level media sensitization workshops were organized for media personnel. More than 300 print and electronic media personnel were sensitized through these workshops. Some major outcomes from these workshops are increased knowledge and understanding among the media personnel on trans issues, which resulted in producing unbiased, clear, accurate and respectful materials. These workshops have also paved way for further strengthening partnerships between media professionals and trans community. Face-to-face interactions with trans people greatly helped media personnel in better understanding about trans communities and their issues.
Lessons learned: Sensitizing media on issues of hijras/transgender women will not only help in producing unbiased, non judgmental and respectful materials about communities but also help in promoting acceptance, and contributing to supportive policies and programmes. Involvement of trans communities in media sensitisation programs is of great importance as face-to-face interactions provide better understanding and human touch.
Conclusions/Next steps: The trainings for media personnel need to be scaled up in different states of India, especially where stigma and discrimination against hijras/transgender women are still rampant. Advocacy with the associations of media personnel is also a potentially high impactful activity that could be pursued.

Gay, bisexual, and other men who have sex with men

WEPED420

Sexual sensation seeking and transmission risk in the era of HIV treatment as prevention

W. Gómez[1], C. Grov[2], A. Batchelder[3], P. Chai[3], E. Boyer[3], S. Dilworth[4], A. Carrico[5]
[1]University of California, School of Social Welfare, Berkeley, United States, [2]City University of New York, New York, United States, [3]Harvard University, Boston, United States, [4]University of California, San Francisco, United States, [5]University of Miami, Miami, United States

Background: Sexual sensation seeking is associated with multiple, co-occurring syndemic conditions such as methamphetamine use that could synergistically increase risk of onward HIV transmission. However, relatively little is known about how sexual sensation seeking may contribute to transmission risk in the era of HIV treatment as prevention.
Methods: HIV-positive, methamphetamine-using sexual minority men completed the baseline visit for a trial that included self-report measures and a blood draw for HIV viral load. We examined sexual sensation seeking as a correlate of:
1) serodiscordant condomless anal intercourse (SCAI) on methamphetamine (insertive and receptive) in the past three months; and
2) a composite index of difficulties with the HIV care continuum (i.e., any missed HIV primary care appointments, indices of anti-retroviral medication non-adherence, and HIV viral load > 200 copies/mL). Logistic and linear regression analyses adjusted for age, ethnicity, and addiction severity.
Results: The sample of 123 HIV-positive, methamphetamine-using sexual minority men was predominantly Caucasian (43%), middle-aged (Median = 45.1), and 16% had a potentially transmittable HIV viral load (> 200 copies/mL). Seven percent of participants with a potentially transmittable HIV viral load reported engaging in SCAI. Greater sexual sensation seeking was independently associated with receptive SCAI (Adjusted Odd Ratio [AOR] = 1.97; 95% CI = 1.09 - 3.55; p = 0.03) but not insertive SCAI (AOR = 1.72; 95% CI = 0.87 - 3.39; p = 0.12). Greater sexual sensation seeking was also independently associated with fewer HIV care continuum difficulties (standardized Beta = -0.23, p = 0.03).
Conclusions: Sexual sensation seeking was associated with greater odds of receptive SCAI on methamphetamine, but also fewer HIV care continuum difficulties. Further research with HIV-positive sexual minority men should examine if those with higher levels of sexual sensation seeking are more motivated to engage in the HIV care continuum to mitigate risk of onward HIV transmission.

WEPED421

Innovative HIV prevention and testing campaigns for maximized regional reach in conservative settings

E. Ballan
M-Coalition, Beirut, Lebanon

Background: HIV testing and Prevention awareness campaigns through social media are the new age method to reaching larger key populations to motivate MSM around sexual health. Yet in contexts such as the MENA region where homosexuality is criminalized by law, the challenge remains in reaching large number and familiarizing populations around HIV, testing, prevention and communication.
Description: In 2017, M-Coalition took on a new scope towards HIV related messages to achieve increased HIV testing rates, reduce fear and stigma around HIV screening, educate around safer sex practices and debunk myths around HIV. The campaign consisted of 5 short videos each targeting only one message at a time to make learning easier, the themes were: Fear, Confidentiality, Safer Sex, Living with HIV and encouraging communication among peers. In a bold move the videos featured MSM in different settings, involved different physical features of gay and bisexual men and used humor as a way to encourage individuals to share social media content.

Lessons learned: In our findings more MSM related to the videos than previous video campaigns which have occurred in the region. Humor meant a broader audience watching the videos until the end, it also gave more way to individuals sharing the videos on their personal profiles and pages as humor content is shared more frequently than other types of content. Interaction with viewers also increased as more people were reaching out to ask questions. A call to action at the end of each video linked viewers to the official website where they were able to locate MSM friendly HIV services in their countries. The use of single and simple messages made sure that viewers would watch the video only once and understand the content easily. The campaign also allowed MSM in conservative settings to view the videos through social media and receive information where outreach programs failed.

Conclusions/Next steps: The challenge represented itself in follow up on the scale of testing rates post campaign. Humor and simple messages seemed more effective which encourages national NGOs in adapting similar methods. Simplicity of HIV messages helped reduce stigma around HIV within MSM communities identified through success stories.

WEPED422

My disclosure, our test: An egocentric network analysis examining disclosure of MSM behavior networks and their relationship to HIV testing in China

B. Cao[1,2,3], A.J. Saffer[4], C. Yang[5], H. Chen[6], K. Peng[6], S.W. Pan[2,3,7], M. Durvasula[8], C. Liu[2,3,9], H. Fu[10], J. Ong[3,11], W. Tang[2,3,12], J.D. Tucker[2,3,4]
[1]Shenzhen University, Shenzhen, China, [2]University of North Carolina Project - China, Guangzhou, China, [3]SESH (Social Entrepreneurship to Spur Health), Guangzhou, China, [4]University of North Carolina at Chapel Hill, Chapel Hill, United States, [5]Johns Hopkins University, Baltimore, United States, [6]City University of Hong Kong, Hong Kong, Hong Kong, [7]Xi'an Jiaotong-Liverpool University, Suzhou, China, [8]Duke University, North Carolina, United States, [9]University of California, San Diego, United States, [10]Eastern Virginia Medical University, Virginia, United States, [11]London School of Hygiene and Tropical Medicine, London, United Kingdom, [12]Guangdong Provincial Centre for Skin Diseases and STI Control, Guangzhou, China

Background: As men who have sex with men (MSM) disclose their same-sex behaviors, they create disclosure networks. Disclosure networks can provide peer support, promote care seeking, and spur HIV testing. However, some environments have greater homophobia and stigma, contributing to less disclosure and HIV testing. This study examined the characteristics of disclosure networks that are associated with HIV testing among MSM in China.

Methods: An online nationwide survey was conducted in January 2017 among Chinese MSM. We collected information on participants' sociodemographic characteristics, MSM behavior disclosure to anyone, and HIV testing behavior. Name-generator questions were used to ask each participant ("ego") to nominate up to five social network members ("alters") with whom the ego had disclosed his MSM behaviors. We also asked the ego to report his relationship with the alters and the alters' HIV testing behaviors.

Egocentric network analysis was used to examine the association between disclosure network characteristics and the ego's HIV testing behaviors. Dyadic network analysis was used to examine the relationship between the ego and each alter's HIV testing behaviors controlling for clustering of observations within an individual.

Results: Overall, 836 men completed the survey, and 806 (96.4%) who reported at least one alter were included in this analysis. Among these 806 men, 72.2%(582) had been tested for HIV. The average disclosure network size was 4.05 (SD=1.47), and 66.6% (537) named five alters to whom they disclosed their MSM behavior. Friends represented 45.1% of all alters in participants' disclosure networks, 18.7% were sex partners and 2.5% of alters in the disclosure network were healthcare professionals. MSM who reported larger disclosure networks were more likely to have been tested for HIV (aOR =1.21, 95%CI: 1.08-1.34). The dyadic analysis showed that men with alters who tested for HIV were more likely to have tested for HIV (aOR = 6.07, 95% CI: 4.28-8.59). Disclosure to healthcare professionals was associated with HIV testing (aOR =5.43, 95%CI: 2.11-14.04).

Conclusions: The composition of MSM disclosure networks suggests that a larger disclosure network size may improve HIV testing among MSM. Our findings may help inform disclosure network-based interventions to promote MSM HIV testing.

WEPED423

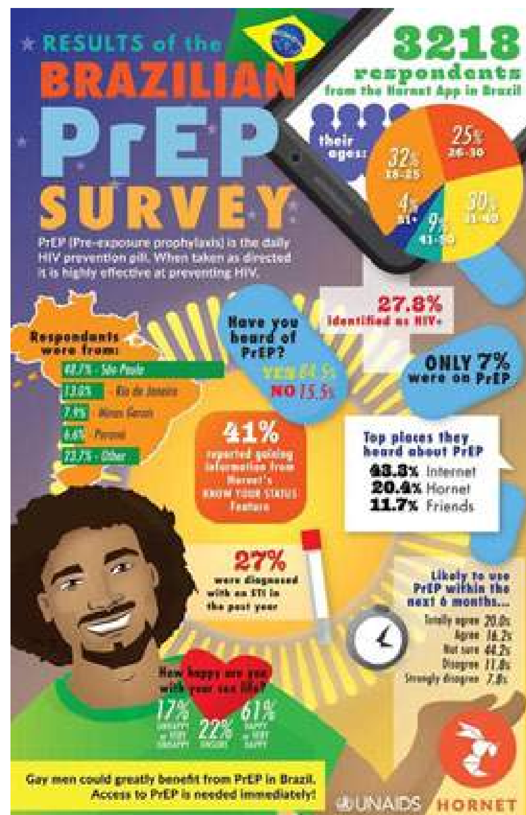
Brazil, PrEP, & gay dating apps. A survey about knowledge, access and future use of PrEP among users of dating app Hornet

C. Euzebio de Lima[1], A. Garner[2], G. Braga-Orillard[1]
[1]UNAIDS, Brazil Country Office, Brasilia, Brazil, [2]Hornet, Los Angeles, United States

Background: The objective of the survey was to examine PrEP knowledge, access and likelihood of future use, to provide evidence for advocacy and for the implementation of PrEP in Brazil. HIV epidemic has increased substantially during the last decade among MSM, especially young men - prevalence is estimated 19.8% among MSM 25 years and older, and 9.4% among those aged 18-24. In January 2018, Ministry of Health started offering PrEP free of charge through the public health system.

Methods: A questionnaire, adapted from the one implemented by Hornet in 2016 in partnership with ECDC, was distributed through the gay social networking app platform. Over three weeks (Sept/Oct 2017) app users were asked to participate in an anonymous survey about HIV prevention — 3,218 responses were collected.

Results: Previous knowledge about PrEP was high in general (85%). Meanwhile, 90% of respondents in the 31-40 age group said they had heard about PrEP, 24% in the 18-25 age group had never heard about it. 27.8% reported being HIV positive. Only 7% of HIV negative respondents were currently taking PrEP (through clinical trials/ordering online). 40% of respondents learned about PrEP via the internet, 20.4% from Hornet app, and 11.7% from friends. 20% reported not having tested for an STI in the last twelve months, and among those tested, 27% reported being diagnosed with an STI. 36.2% were likely to use PrEP in the following six months. 60% of respondents said they were happy with their sex lives, 22% were unsure, and 17% were unhappy.



[Results of the survey about knowledge, access and future use of PrEP among users of dating app Hornet in Brazil.]

Conclusions: MSM in Brazil are highly vulnerable to HIV and STI. Young MSM have less knowledge about PrEP than adults. A tailored communication strategy should be designed for them. Internet, including especially gay dating apps are an important source of health information for MSM and should be included in HIV prevention strategies. Willingness to use PrEP is high, so government and community should work together to ensure that MSM have the information they need to access PrEP.
Gay dating apps can represent a fruitful space for the implementation of strategies of positive prevention for MSM living with HIV.

WEPED424

Social media intervention exposure and its association with HIV testing: Secondary analyses from a randomized controlled trial in China

B. Cao[1,2,3], W. Tang[2,3,4], H. Lu[4], S. Leuba[4], D. Wu[2,3], J. Ong[3,5], C. Liu[6], R. Fu[7], P.T. Saha[4], C. Wei[8], J.D. Tucker[2,3,4]
[1]Shenzhen University, Shenzhen, China, [2]University of North Carolina Project - China, Guangzhou, China, [3]SESH(Social Entrepreneurship to Spur Health), Guangzhou, China, [4]University of North Carolina at Chapel Hill, Chapel Hill, United States, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]University of California, San Diego, United States, [7]Guangzhou Center of Disease Control and Prevention, Guangzhou, China, [8]Rutgers University, Piscataway, United States

Background: Social media interventions are known to be effective in promoting HIV testing among key populations. However, it is unclear how intervention materials distributed through social media are recognized and acknowledged by men who have sex with men (MSM).
This study examined the effect of exposure to different social media intervention components on HIV testing.
Methods: We conducted a stepped-wedge cluster randomized controlled trial from July 2016 to July 2017 in eight Chinese cities. Participants were recruited from a popular gay app (Blued). The social media interventions were implemented biweekly for three months, and included six different images or texts, information on local HIV testing sites, and information on a community contest to promote testing.
We collected data on socio-demographics, facility-based HIV testing behaviors, exposure to different intervention components (i.e., recalled different messages), and further propagation of intervention components (e.g., shared with others, forwarded to others) or engagement (e.g., participated in local community contest).
Multilevel logistic regression was conducted to examine the relationship between social media intervention exposure and HIV testing behaviors.
Results: Of the 1381 men who participated, 1069 men completed the entire survey and were included in this study. Among the six images or texts sent during the intervention, study participants recalled an average of 2.7 (SD = 1.6) images/texts and forwarded 1.2 (SD = 1.4) images/texts. 85.3% (n = 912) of men remembered receiving information on HIV testing sites and 46.9% (n = 428) of them forwarded HIV testing site information. 34.2% (n = 366) of men recalled information on the community contest and engaged in an average of 1.2 (SD = 1.5) contest-related activities.
Recalling images or texts (aOR = 1.13, 95%CI: 1.02-1.25) and community contest information (aOR = 1.59, 95%CI: 1.13-1.24) were associated with HIV testing uptake.
Conclusions: This secondary analysis suggests that cognitive response to social media intervention messages can facilitate HIV testing. Our study disentangles different intervention components and may help specify effective social media intervention contents to promote HIV testing.

	Descriptive data		Multilevel analysis	
	N	%	Adjust odds ratio (95% CI)	p-value

WEPED425

Marijuana use predicts newly diagnosed HIV among Black men and transgender women who have male sex partners

L. Eaton[1], R. Baldwin[1], L. Zohren[1], J. Maksut[1], A. Carrico[2]
[1]University of Connecticut, Storrs, United States, [2]University of Miami, Miami, United States

Background: Black men and transgender women who have male sex partners (BMTW) experience alarmingly high rates of HIV. In Atlanta, GA, USA, approximately one-third of BMTW are living with HIV and current estimates project that 60% of BMTW will be living with HIV by age 40 if incidence remains unchanged. Use of sex-drugs such as stimulants, amyl nitrites, and erectile dysfunction medications (EDM) predicts 3-6 fold faster rates of HIV seroconversion in predominantly White cohorts of sexual minority men. However, it is unclear whether and how substance use fuels the HIV epidemic in BMTW.
Methods: We enrolled 449 BMTW who tested HIV-negative into a cohort that included HIV testing at the 12-month follow-up. Multivariable logistic regression analyses examined if any use of marijuana, stimulants (*i.e.,* powder cocaine, crack-cocaine, or methamphetamine), EDM, and amyl nitrites at baseline predicted greater odds of being newly diagnosed for HIV at 12 months.
Analyses adjusted for depressive symptoms, alcohol use, and sexual risk taking as possible confounders at baseline.
Results: At 12 months, 5.3% (*N*=24) of BMTW were newly diagnosed with HIV. Marijuana use independently predicted 2.5-fold greater odds of newly diagnosed HIV (OR=2.49, 95%CI=1.01-6.18), but other sex-drugs and alcohol use were not significantly associated with newly diagnosed HIV. Compared to marijuana non-users, marijuana users reported equal numbers of male sex partners and condomless sex acts, but had substantially higher odds of reporting any substance use during sex (OR=7.49, 95%CI=5.99-9.37), any alcohol use during sex (OR=2.23, 95%CI=1.85-2.80), and any sex in exchange for goods (OR=1.65, 95%CI=1.16-2.34).

Conclusions: Among our community-based sample, HIV annual incidence is alarmingly high. Further, in contrast to prior clinical research, marijuana use independently predicts greater odds of undiagnosed HIV and concomitant sexual risk taking in BMTW. Expanded efforts to promote HIV testing in BMTW who use marijuana could support the timely identification of new HIV infections to optimize the benefits of HIV treatment as prevention. Further research is warranted to determine the underlying mechanisms linking marijuana use and HIV seroconversion.

WEPED426

Structures of sexuality: Bisexual stigma and HIV risk with primary female partners among behaviorally bisexual Black men

S. Mackenzie[1], C. Michels[2], J. Chang[3]
[1]Santa Clara University, Public Health Program, Berkeley, United States, [2]San Francisco State University, Center for Research and Education on Gender and Sexuality, San Francisco, United States, [3]San Francisco State University, Health Equity Institute, San Francisco, United States

Background: Behaviorally bisexual Black men have been cast as the cause of HIV's disproportionate presence among Blacks, yet their relationships remain understudied. This analysis explores the relationship between bisexual stigma and HIV risk among a sample of behaviorally bisexual Black men of mixed HIV status in the San Francisco Bay Area in the United States.

Methods: Quantitative data were collected between October 2015 and June 2017 as part of a mixed methods HIV prevention study with bisexual Black men their female partners in the San Francisco Bay Area (N=231). Three separate multivariate analyses of men's data (N=121) assessed the indirect effects of stigma on unprotected sex, utilizing discrete stigma measures of bisexual stigma, internalized homophobia, and bisexual identity. The controlling measures were education, age, participant's HIV status, and partner's HIV status. The mediator was difficulty of disclosure of sexual activity with men to their female partner, and the outcome was condom use when having vaginal sex with a primary female partner in the past six months.

Results: Men with higher levels of stigma had a higher level of difficulty with disclosure (, *p*: 0.279, 0.003; 0.234, 0.011; 0.311, 0.001; respectively). When controlling for effects of each stigma measure along with the four covariates, higher levels of difficulty of disclosure had a negative effect on condom use (, *p*:-0.223, 0.027; -0.283, 0.004;-0.227, 0.023; respectively). More importantly, bisexual stigma, internalized homophobia and difficulty with bisexual identity also had a negative impact on condom use when mediated by disclosure (Indirect Effect, 95% CI:-0.073, -0.191 to -0.012; -0.094, -0.245 to -0.022; -0.081, -0.193 to -0,006; respectively).

Conclusions: These findings indicate that bisexual stigma and internalized homophobia experienced by behaviorally bisexual Black men presents a barrier to condom use through constraining disclosure to female partners. Men who reported higher levels of bisexual stigma and internalized homophobia reported that it was harder to disclose having sex with men with their primary female partner, which was significantly related to lower levels of condom use. Structural barriers to HIV prevention must be addressed through developing anti-stigma prevention campaigns targeting both men and women to reduce bisexual stigma.

WEPED427

Digital media and sexual health promotion among MSM and transgender women in India: Exploring the contours of online interventions

P. Dhall[1], R.K. Dasgupta[2], J. Harrison-Quintana[3]
[1]Varta Trust, Leadership and Management of the Organization, Kolkata, India, [2]Loughborough University, Institute of Media and Creative Industries, Loughborough, United Kingdom, [3]Grindr for Equality, Washington, United States

Background: The digital sphere now plays a major role in sexual networking, norms and practices among queer people in India. Digital media have become a significant means of information dissemination and community mobilization around queer health and rights concerns in the last two decades. But systematic and sustained sexual health interventions are largely absent from the digital sphere in India.

Description: Varta participated in a qualitative study to understand what digital sexual health interventions for MSM and transgender women could look like. The study was conducted in Kolkata with support from Wellcome Trust. Guided by digital ethnography and HIV intervention experience of the researchers, and learning from sexual health related content and interaction on Varta's website, the study included literature review, participant observations, four focus groups (n = 10) and 10 semi-structured interviews with outreach workers, counsellors, activists and media persons. Preliminary findings were fine-tuned through discussions in a symposium on digital media and health at Jadavpur University.

Lessons learned: The study was published as "Social Media, Sexuality and Sexual Health Advocacy in Kolkata, India - A Working Report". It explained how digital media had transformed and speeded up sexual networking (including sex work operations) among MSM and transgender women in Kolkata, often eliminating need for physical cruising or soliciting. Respondents recommended digital interventions that addressed hitherto neglected mental health, social exclusion and violence related drivers of HIV vulnerability. The study inspired two pilot interventions around respondent felt needs on Varta website with hyperlinks on Grindr app. A guide to tackle both online and offline gay blackmail, and a searchable database on queer-friendly sexual health, mental health and legal aid services were developed.

Conclusions/Next steps: Comprehensive digital interventions to match changes in sexual networking among MSM and transgender women are urgently need. Additionally, digital interventions may help reach population sub-sections otherwise inaccessible through traditional physical outreach for sexual health promotion. Immediate reader responses to online pilots with diverse queries on tackling sexual abuse, blackmail and health concerns further underlined the potential for digital interventions. But these interventions may have their own set of challenges around digital literacy, smart phone ownership and trust in online information sources.

WEPED428

Latent classes of sexual positioning practices and sexual risk among men who have sex with men in Paris, France

D. Dangerfield II[1], C. Carmack[2], T. Gilreath[3], D. Duncan[4]
[1]Johns Hopkins School of Nursing, Baltimore, United States, [2]University of Houston, Houston, United States, [3]Texas A & M University, College Station, United States, [4]New York University, New York, United States

Background: In France, HIV incidence has declined among all groups except men who have sex with men (MSM). HIV/STI risk varies by sexual positioning practices; however, limited data have characterized the sexual risk profiles of this population. To fill this gap, this study utilized latent class analysis (LCA) to explore profiles regarding condomless sexual positioning and seroadaptive behaviors.

Methods: MSM were recruited on a geosocial networking smartphone application in Paris, France in October 2016 (n=566). LCA was used to classify sexual positioning, seropositioning, and serosorting profiles. Age, HIV status, relationship status, substance use, group sex, and PrEP history were used in a multinomial regression model predicting the likelihood of class membership.

Results: Three latent classes were identified: Majority Top Serosorters, Versatile Low Partners, and Majority Bottom Some Serosorters. Majority Top Serosorters had the highest mean number of partners for condomless insertive anal intercourse and the highest probability of serosorting; Majority Bottom Some Serosorters had the highest mean number of partners for condomless receptive anal intercourse (~13 partners). MSM classified as Majority Bottom Some Serosorters were 7% more likely to be classified as such than Class 2 with each year increase in age (AOR 1.07; 95% CI=1.02, 1.21). Compared to HIV-negative/status unknown MSM, HIV-positive MSM were more likely to be classified as Majority Bottom Some Serosorters than Versatile Low Partners (AOR 7.04; 95% CI= 2.38, 20.8). MSM who reported substance use before or during sex were more likely to be classified as Majority Bottom Some Serosorters than Versatile

Low Partners (AOR 3.00; 95% CI=1.04, 8.67). MSM who reported PrEP history had 6.21 times the odds of being classified as Majority Bottom Some Serosorters than Versatile Low Partners.
Conclusions: Highlighting sexual risk profiles among MSM in France supports tailored and targeted interventions for highest risk individuals. Future research should incorporate qualitative methods to understand motivations for behaviors among high-risk MSM.

WEPED429

Suicidal ideation and suicidal behaviour among men who have sex with men in Malaysia

M.A. Ab Halim[1], J.A. Wickersham[2], A. Kamarulzaman[3], L. Sin How[4]
[1]Centre of Excellence for Research in AIDS, Faculty of Medicine, University Malaya, Kuala Lumpur, Malaysia, [2]Section of Infectious Diseases, Department of Internal Medicine, Yale School of Medicine, New Haven, United States, [3]University Malaya, Faculty of Medicine, Kuala Lumpur, Malaysia, [4]University Malaya, Kuala Lumpur, Malaysia

Background: Previous studies have shown that MSM tend to have higher suicidal ideation and attempt rates compared to the general population. The reported prevalence of suicidal ideation among MSM ranges from 13.18% to 55.80%. The prevalence of suicidal behaviour and ideation in Malaysia where MSM is highly stigmatised is unknown. We sought to estimate the prevalence of suicide ideation and attempt rates in a cohort of MSM in Malaysia setting.
Methods: Men who had anal sex in the past 12 months were invited to an online survey which was advertised on social media and Grindr. The 4-item, suicidal behaviours questionnaire-revised (SBQ-R) was used to examine suicidality, including suicidal thoughts, disclosure of such thoughts, and suicide attempt. Univariable and multivariable logistic regressions were conducted to determine demographic and psychosocial factors associated with suicidal behaviours.
Results: Of 539 participants who completed the survey, 32.1% reported suicidal behaviours. Specifically, 41% reported lifetime suicidal ideation and 8.2% 'will attempt suicide in the future'. The sample also reported rates of depression (CESD-20 > 16), intimate partner violence (IPV), and childhood sexual abuse (CSA) at 60.9%, 23.7%, and 21.9%, respectively. About 40% of self-reported HIV-positive MSM endorsed suicidal behaviours while the prevalence of suicidal behaviours was 30.3% among HIV-negative and 30.9% among who never tested for HIV. Chinese ethnicity (unadjusted odds ratio (UOR)=1.78 95% CI=1.17-2.72, *p*=0.007), Malay ethnicity (UOR=0.62 95% CI=0.43-0.89, *p*=0.010), unemployment (UOR=1.57 95% CI=1.04-2.37, *p*=0.032), and involved in commercial sex (UOR=1.58 95% CI=1.04-2.39, *p*=0.03) were associated with suicidal behaviours. Consistent condom use was not associated with suicidal behaviours (UOR-0.97, 95%CI=0.66-1.43, *p*=0.36). In the multivariable analysis, MSM who were depressed (adjusted odds ratio (AOR)=5.17, 95% CI=3.17-8.42, *p*=< 0.001), victims of IPV (AOR=2.07, 95% CI=1.32-3.23, *p*=0.001) and, who experienced CSA (AOR=1.80, 95% CI=1.12-2.91, *p*=0.015) were more likely to report suicidal behaviours.

Variables	Regression coefficient (b)	Adjusted Odd Ratio (95% CI)	Wald Statistic	p-value
Depressive symptoms	1.642	5.17 (3.17, 8.42)	43.375	<0.001
Victim of Intimate Partner Violence	0.725	2.07 (1.32, 3.23)	10.081	0.001
Experienced Childhood Sexual Abuse	0.590	1.80 (1.12, 2.91)	5.869	0.015

[Associated factors of men who have sex with men who have suicidal behaviour]

Conclusions: This was the first study to document high level of suicidal behaviours among MSM in Malaysia. A specific intervention and prevention program focusing on mental health in the MSM community should be integrated into the comprehensive HIV prevention programme and National Suicide Prevention Strategic Action Plan. Further qualitative studies are needed to understand the causes of suicidal behaviours.

WEPED430

Eliminating homophobia among healthcare providers to increase access to HIV-related services targeting men who have sex with men (MSM) and women who have sex with women (WSW) in Zimbabwe

J. Chirunga
GALZ, Project, Harare, Zimbabwe

Background: Men who have Sex with Men (MSM) have always had a key role in the global HIV epidemic. Recent studies from Zimbabwe indicate disproportionately high HIV prevalence rates among MSM (23.5%) and WSW (32.6%) when compared to adults in the general population. Despite these high rates, MSM and WSW have been consistently excluded from national AIDS programming. They further report stigma, discrimination and denial of services as common experiences while accessing HIV-related services from health settings. In order to address this barrier and to increase healthcare access for MSM and WSW.
Description: GALZ implemented a two prong approach: One targeting Healthcare Professionals, Service Providers, and Workers (HCW), and one targeting MSM & WSW. HCWs were mobilised through forming strategic partnerships with HCW associations e.g. Doctors for Human Rights (Zimbabwe). HCWs were trained by GALZ and Anova Health staff using the John Hopkins and MSMGF curriculum.
MSM and WSW were mobilised to make use of these services through direct service provision by GALZ, as well as through peer and referral programming. GALZ provided a minimum service package targeting HIV-SRH health needs, as developed through community level research. The peer programming provided for peer-to-peer basic counselling and referral services around SRH using a voucher-based referral system.
Lessons learned: Through these two approaches, GALZ established a pool of 182 HCWs (Doctors, RGNS, Pharmacists, Radiologists, Midwives etc) competent to provide MSM- and WSW- friendly services. The intervention also reached 2400 MSM and 160 WSW in uptake of HIV-SRH related services through the network of competent HCWs.
The peer programme precipitated the formation of a peer-support group around treatment/ ART Adherance
Affiliated processes under the peer programme such as SMS and social media messaging, and group discussions have further served to promote prevention and treatment adherence and behaviours within the target MSM and WSW population.
Conclusions/Next steps: Continuous engagement with government to increase buy-in of HCW trainings and sensitization on Key Populations. Continuous monitoring and intensifying linkages of MSM and WSW needs. Demand creation and accessibility to be increased through public awareness within media and amongst the target group. Need to increase research and reach in WSW HIV-SRH service mobilisation.

WEPED431

How do gay serodiscordant couples in Sydney, Australia apply treatment as prevention to their relationships?

S. Philpot, G. Prestage, J. Ellard, A.E. Grulich, B.R. Bavinton, The Opposites Attract Study Group
Kirby Institute, UNSW, Kensington, Australia

Background: Treatment as Prevention (TasP) as safe sex holds considerable appeal for gay Australian serodiscordant couples, providing the enjoyment of condomless sex without the fear of HIV-transmission. Most Australian gay serodiscordant couples currently practise condomless sex, and often adopt a relational approach towards managing HIV, thus signifying the importance of 'the couple' in HIV prevention. However, they lack a formal strategy that helps them navigate TasP. We explored the importance of 'the couple' within such relationships with the aim of developing a serodiscordant-specific HIV prevention strategy based on TasP.
Methods: Semi-structured interviews were conducted in 2015 and 2016 with 10 HIV-positive and 11 HIV-negative gay men representing 15 serodiscordant couples in Sydney, Australia. Participants were recruited through the Opposites Attract study. Using thematic analysis, key themes were identified and a coding schedule was developed.

Results: Most couples relied on TasP as their primary prevention strategy, a few used condoms, and a few rarely practised anal sex. When relationships were new, couples often used condoms and were cautious during sex. As time passed, they decided to forego condoms and trial TasP, though they did this with trepidation initially. Most apprehensions about TasP faded as it was increasingly practised. Confidence in TasP was facilitated by repeated condomless sex, consistent test results, and being in a couple framed by trust, commitment, and familiarity. HIV-negative participants who preferred condoms referred to their partner's HIV as infectious and thought of condoms as the right way to protect their own sexual health.
Conclusions: 'The couple' is a crucial component of gay serodiscordant HIV prevention. We recommend that 'Viral Load Agreements' (VLAs) be endorsed for serodiscordant couples who want to rely on TasP. Such agreements would include discussions about monogamy or otherwise, dispensing with condoms, regular viral load and HIV testing, excellent adherence to medication over time, and ongoing communication about these conditions. VLAs offer couples who have never used TasP a formal strategy to follow, and provide effective strategies for the maintenance of TasP for couples who already use it. However, condoms continue to play an important role for some couples and should continue to be promoted.

Sexual practices of men who have sex with men (MSM) in Madagascar

B.N. Rahaivondrafahitra[1], F.J. Park[2], P.-L. Lesage[3], N. Taruberekera[2], T.M. Raoelison[4], E. Enkurunziza[3]
[1]Population Services International, Research, Antananarivo, Madagascar, [2]Population Services International, Research Monitoring and Evaluation, Johannesburg, South Africa, [3]Population Services International, Representation, Antananarivo, Madagascar, [4]Population Services International, VIH, Antananarivo, Madagascar

Background: MSM are a vulnerable population with a high prevalence of HIV (14.8%) and low HIV testing coverage (16.5%) in Madagascar. This study aims to examine barriers and motivation to HIV prevention, specifically on HIV testing, and condom and lubricant use among MSM in order to refine behavior change communication and programmatic strategies.
Methods: We conducted semi-structured in-depth interviews with 81 MSM ages 15-57 in July, 2017 in 6 urban areas with the largest populations of MSM. Study participants were purposely sampled with the assistance of MSM association leaders, who were asked to target individuals meeting the eligibility criteria. Respondents were eligible to participate if they self-identified as MSM, or were MSM who hide their sexual identity, and were between the ages of 15-23 or 24-57. All participants provided written consent. Discussions were audio-recorded, transcribed in Malagasy, and analyzed using thematic content analysis method.
Results: We interviewed 27 men who self-identify as MSM and 54 men who do not openly disclose their sexual identity (27 young people and 27 adults). The study found that there were no notable differences in their barriers and motivation to HIV prevention. Some participants did not use condoms because they had confidence in their partners' health, or because their partners refused (typically due to lack of pleasure), or they used lubricant as a condom substitute. Although some participants indicated using condoms with lubricants for protection and easy penetration, others had no knowledge of lubricants. Some did not use lubricants because some condoms were already lubricated, or they used saliva as an alternative. Although the majority of participants have been tested previously, many dealt with a variety of barriers to HIV testing including fear of doctors, injections, positive results, or stigmatization, and lack of time.
Conclusions: Our findings reveal that adopting healthy behaviors for HIV prevention still presents challenges. HIV prevention efforts for MSM should focus on providing MSM friendly services that provide privacy for MSM such as home and mobile testing and testing during MSM events. These can promote increased perception of risk, regular testing, and safer sex practices of condom and lubricant use.

WEPED433

Exploring alcohol and other drug use among men who have sex with men (MSM) in Nairobi, Kenya: Implications for HIV and health promotion interventions

A. Tukai[1], H. Babu[1], A. Mugambi[1], C. Nyamweya[1], M. Kung'U[1], P. Ngurukiri[1], R. Kabuti[1], J. Liku[1], W. Nutland[2], P. Weatherburn[2], E. Fearon[2], A. Smith[3], J. Kimani[1,4], A. Bourne[5], The TRANSFORM Group
[1]Partners for Health & Development in Africa, Nairobi, Kenya, [2]London School of Hygiene & Tropical Medicine, Department of Social & Environmental Health Research, London, United Kingdom, [3]University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom, [4]University of Manitoba, Nairobi, Kenya, [5]La Trobe University, Australian Research Centre in Sex, Health & Society, Melbourne, Australia

Background: High levels of risky behavior and HIV prevalence have been reported among MSM in Kenya. Research in other contexts has documented an association between alcohol and other substance use and sexual risk behavior among MSM, however there is extremely limited data relating to this population anywhere in Africa. With a view to informing HIV prevention/care and harm reduction programs, this paper examines the social and sexual contexts of alcohol and drug use among (MSM) from Nairobi, Kenya.
Methods: Between April and July 2017, in-depth interviews were carried out with 30 MSM (aged 19-56) recruited via purposive sampling. Semi-structured interviews examined the contexts and motivations for alcohol and other drug use generally, as well as the role and impact of substance use during sex. Data were subject to thematic analysis.
Results: Five men were living with diagnosed HIV and 13 had not tested within the previous 6 months. All but two participants reported use of alcohol or other drugs during sex with other men. A common narrative of alcohol facilitating social and sexual confidence was perpetuated, all the more significant in this context given significant societal pressures and internalized homophobia that they often had to overcome to engage with other MSM.
However, at the same time, many men expressed fear that when drunk they may be less attentive to their surroundings and risk exposing themselves as MSM to other community members.
Around a third of men engaged in sex work and alcohol helped them mitigate fears of meeting clients, but this also presented challenges in the negotiation of safe sex. Consuming alcohol or other substances also enabled more adventurous sexual activity, such as group sex or attempting different sex roles with other men.
Conclusions: Consuming alcohol or other substances is often considered necessary to have sufficient courage to meet other men for sex, particularly in the context of sex work. Excessive alcohol use can inhibit sexual negotiation and put men at risk for HIV/STIs and expose MSM to abuse or assault. Substance use harm reduction interventions operating in tandem with HIV prevention and care activities are required to mitigate such risks.

WEPED434

Quality of life among HIV-infected and HIV-uninfected men who have sex with men in Nigeria: A cross-sectional study

B.O. Kayode[1], H. Ramadhani[2], U. Ononaku[1], T.A. Crowell[3,4], R. Nowak[2], H. Liu[5], S. Baral[6], N. Ndembi[1], M. Charurat[2]
[1]Institute of Human Virology, FCT, Nigeria, [2]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States, [3]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [4]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [5]University of Maryland School of Public Health, Department of Epidemiology, College Park, United States, [6]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States

Background: Being gay/bisexual and HIV positive in a culture where these are highly stigmatized may impact quality of life (QOL). This study assessed QOL measures among HIV positive and negative men who have Sex with Men (MSM) in Abuja, Nigeria.

Methods: Between June 2017 and January 2018, a cross-sectional study of 300 MSM recruited from the ongoing TRUST cohort in Abuja was conducted. Face-to-face interviews were done using the validated WHOQOL-BREF tool to assess QOL at four domains: physical, psychological, social relationship, environmental, and 2 stand-alone questions of respondent rated QOL and health satisfaction. Raw scores from each domain were transformed to 0 and 100 accordingly. A t-test was used to compare mean QOL scores between HIV negative and positive participants and, among HIV positive participants, to compare those on treatment ≥1 year to those on treatment < 1 year.
Results: A total of 300 MSM enrolled with median age 25 [interquartile range 22-29] years and 164 (54.7%) were HIV positive. Compared to HIV positive participants, QOL was significantly higher among HIV negative participants in physical, psychological, and social relationship domains as well as respondent-rated QOL and health satisfaction (Table). There was no statistically significant difference between HIV positive and negative participants in relation to the environmental domain. Among HIV positive participants, QOL was significantly higher among those on treatment for ≥1 year compared to those on treatment for < 1 year for physical and psychological domains (p< 0.01).

	HIV Positive		HIV Negative		p-value
	Mean (SD)	CI	Mean (SD)	CI	
Physical Domain	72.9 (12.9)	(71.0 -74.9)	78.0 (11.3)	(76.1 -79.9)	< 0.01
Psychological Domain	67.4 (15.1)	(65.1 -69.7)	72.3 (12.1)	(70.2 -74.3)	< 0.01
Social relationship Domain	59.5 (19.4)	(56.5 -62.5)	66.0 (18.6)	(62.8 -69.1)	< 0.01
Environmental Domain	58.9 (12.8)	(56.9 -60.9)	57.3 (13.3)	(55.0 -59.5)	0.28
General QOL	57.9 (19.7)	(54.9-65.3)	67.4(23.6)	(63.6-71.5)	< 0.01
Health Satisfaction	60.9(26.7)	(56.9-65.3)	72.7(22.0)	69.2-76.6)	< 0.01

[Mean Quality of Life Scores Among HIV Positive and HIV Negative MSM in Nigeria]

Conclusions: These findings show that provision of HIV care within short term improves QOL of infected persons and other interventions should be emphasized in the assessment and management of HIV.

WEPED435

Unreached group / risk of HIV and STI / spouse and partners of MSM/MSW/TG community / Far-western Region, Nepal

R. Lama
Sudur Paschim Samaj, Adminstration, Dhangadhi, Nepal

Background: Nepal has concentrated epidemic. First-time IBBS study on HIV prevalence for MSM/TGs in Farwestern region. Nepal also accepted the 90-90-90 goal. In the Far-western Region, 5.7% HIV prevalence and 13% STI prevalence has been revealed during IBBS study in 2016. Most of the program is focused on prevention for MSM/TG only. But there is lacking program for Spouse, partners, and children of MSM/Tgs. But in a scenario of spouse and Children, we are unknown about the infection on their spouses, partners, and children. Our programs are focused for MSM/MSW/TGs only. and we had difficult to reached there spouses and partner. So it is very difficult to engage their partners, wives, and children in our program. Nepal is a male-dominated society so many of the MSM/TG were didn't show there female partners and spouses and they never expose their behavior. Because of Self stigma and Social stigma and discrimination.
Methods: A cross-sectional research design and Respondent Driven Sampling (RDS) method was applied for sample selection. The total sample size was 100. Respondents were interviewed after obtaining witnessed oral consent followed by pre-test counseling and blood, urine and anal swab sample collection. A structured questionnaire was used to collect background characteristics, knowledge on HIV and AIDS and STIs, sexual behavior, exposure and access to HIV services and stigma and discrimination. During the questioner with 100 respondents 71 MSM/TG was accepted they were married with women.
Results: As we have no program for Spouse, partners, and children, infection rate might be high. National Guideline also not to accept the spouse of MSM/MSW and TG in High-risk population. But we are unaware of these problems as we do not have any study till date. So infection is spreading unknowingly.
Conclusions: We should have focus prevention program for partners, spouses and children in our regular program. As we do not have any baseline for prevalence rate for them we should conduct research for HIV prevalence for partners and spouses, of MSM/TGs. If we didn't focus on programme spouse of MSM/ TG, 90-90-90 goal will be not reached

WEPED436

Substance use and psychosocial problems among Nigerian men who have sex with men (MSM): A qualitative study of motivation and consequences

A. Ogunbajo[1], S. Iwuagwu[2], W. Rashidi[3], N. Nwosu[2], T. Eyohwo[2], T. Oke[4], G. Harper[5]
[1]Brown School of Public Health, Behavioral & Social Sciences, Providence, United States, [2]Centre for Right to Health, Lagos, Nigeria, [3]Queer Alliance Nigeria, Lagos, Nigeria, [4]University of Buffalo School of Social Work, Buffalo, United States, [5]University of Michigan School of Public Health, Ann Arbor, United States

Background: Nigerian men who have sex with men (MSM) are disproportionately affected by the HIV epidemic. Various studies have found that substance use and psychosocial problems interact synergistically to potentiate sexual risk behavior and HIV psychosocial problems in Nigerian MSM remains unknown. Consequently, we carried out a qualitative study to explore the context of substance use and consequences of psychosocial problems among Nigerian MSM.
Methods: Semi-structured, in-depth qualitative interviews were conducted with 30 MSM in Lagos, Nigeria between June and August 2017. Participants were recruited through referral from key informants and snowball sampling. The interviews were conducted in a private office at a local NGO that provides HIV prevention services to vulnerable populations. Using qualitative software (NVIVO 10), an inductive content analysis approach was used to identify context and function of substance use and consequences of psychosocial problems among Nigerian MSM.
Results: The average age of participants was 27.9 years (S.D. = 4.9) and More than half (N=20, 73.3%) of participants self-identified as gay/homosexual. Salient findings included:
(A) motivations for substance use include:
i) lack of economic opportunities such as jobs,
ii) coping with negative attitudes from friends, family, and larger society due to sexual orientation, and
iii) social pressures from casual friends and sexual partners;
(B) some common consequences of substance use were engaging in unplanned and/or unprotected sexual experiences and inability to maintain sexual autonomy during experience;
(C) most participants described chronic substance use behaviors and mental health problems but lacked agency to seek treatment due to:
(i) limited financial resources,
(ii) lack of knowledge of substance use treatment facilities and mental health services in local area, and
(iii) fear of stigmatization of substance use habits or mental health problems;
(D) co-occurrence of substance use and mental health, where participants described using substances to deal with mental health issues and developing mental health issues as a result of substance-using habits.
Conclusions: Our findings highlight the need for substance use cessation and mental health services tailored to the unique needs of Nigerian MSM. Additionally, healthcare providers should undergo sensitization trainings to better serve the MSM community.

WEPED437

A serial, cross-sectional comparison of condomless anal sex and HIV testing among young men who have sex with men (MSM) in Beirut, Lebanon

G. Wagner[1], B. Ghosh-Dastidar[2], C. El Khoury[3], E. Balan[3], J. Tohme[3], M.G. Mutchler[4,5], J. Mokhbat[6], K. Goshn[3], M. Hojiej[3], C. Abi Ghanem[3], S. Tebbetts[7], S. Kegeles[7]
[1]RAND Corporation, Health, Santa Monica, United States, [2]RAND Corporation, Santa Monica, United States, [3]AFE, Beirut, Lebanon, [4]California State University, Dominguez Hills, Carson, United States, [5]APLA, Los Angeles, United States, [6]Lebanese AIDS Society, Beirut, Lebanon, [7]UCSF, San Francisco, United States

Background: In 2012, our research in Beirut with young men who have sex with men (YMSM) showed high rates of recent condomless anal sex, and low rates of recent HIV testing. In 2017 we used the same methods to collect data from YMSM, enabling us to assess for temporal changes in these behaviors, in addition to sociodemographic correlates.
Methods: Long-chain referral sampling was used to recruit 164 YMSM (age 18-29) in 2012 and 226 in 2017, with most having some university education and being gay-identified. Multivariate regression analysis was used to examine sociodemographic correlates of any condomless anal sex in the past 3 months and HIV testing in the past 6 months using the 2017 sample, and whether these behaviors differed between the two study samples. Propensity score weighting was used to eliminate any differences between the samples on all sociodemographics, increasing the likelihood that observed differences were due to temporal changes in the environment.
Results: Compared to the 2017 sample, the 2012 sample had significantly higher levels of any condomless anal sex in the past 3 months [68% vs. 51%; OR (95% CI) = 2.11 (1.30, 3.41)] and in last anal sex encounter [63% vs. 37%; OR (95% CI) = 2.93 (1.72, 4.98)], and lower levels of HIV testing in the past 6 months [27% vs. 52%; OR (95% CI) = 0.35 (0.21, 0.57)]. In the 2017 sample, employment, any university education, low monthly income and being in a committed relationship, were all independent correlates of having any recent condomless anal sex, regardless of partner HIV status; any recent condomless anal sex with partners whose HIV status was positive or unknown was associated with employment and any history of having an STI. There were no correlates of HIV testing in the regression analysis.
Conclusions: These findings suggest a temporal trend towards increased HIV protective behaviors (condom use; HIV testing) among YMSM in Beirut over the past 5 years, implying that increased grass roots, community-based efforts to combat HIV are working. Further inroads could be secured if HIV prevention programming target relational and economic influences.

WEPED438

LINX LA: Developing a web-based mobile app to improve treatment outcomes among HIV-positive sexual minority-identified young Black men

A. Miyashita Ochoa[1], I.W. Holloway[1], B.D.M. Wilson[2], E.S.C. Wu[1], T.L. Smith[3]
[1]UCLA Luskin School of Public Affairs, Social Welfare, Los Angeles, United States, [2]UCLA School of Law, Williams Institute, Los Angeles, United States, [3]APLA Health, HIV Prevention Services, Los Angeles, United States

Background: Young Black men who have sex with men (BYMSM) living with HIV experience disparities in treatment outcomes across the HIV Care Continuum (CC) in the U.S. While mobile application (app) interventions to improve HIV treatment outcomes exist, few have been culturally tailored for and designed by BYMSM to address social determinants of health. We sought to develop and test an app (LINX LA) to improve HIV treatment outcomes among BYMSM by addressing their social work and legal needs.
Methods: In partnership with community partners and BYMSM themselves, we sought to
(1) identify social service and legal barriers to engagement in care for BYMSM, and;
(2) iteratively develop and test an app to address those barriers.
Phase 1 consisted of interviews with BYMSM (N=13) to identify technology use patterns, experiences of HIV diagnosis and engagement in care, and social service/ legal needs to create a user persona and app prototype.
Phase 2 consisted of moderated interviews with BYMSM (N=20) and providers (N=11) to refine the Phase 1 prototype. Phase 3 consisted of a one week test of LINX LA with BYMSM (N=14).
Results: Social service and legal needs identified included homelessness, debt, and HIV-based discrimination. Lack of social support and HIV stigma were also major barriers to engagement in care. Three core app functions were developed:
(1) Community forum;
(2) Informational posting; and
(3) Text-based peer health navigation.
Key adjectives used to describe the app were "engaging" "private" and "useful." In Phase 3, participants initiated 31 distinct chats, posted 76 comments and 20 "likes". Participants agreed that the app was a "safe setting" where they could get "social support".
Conclusions: Mobile apps have the potential to engage BYMSM and improve treatment outcomes across the HIV CC. Iterative user-centered mobile app development resulted in the app LINX LA which will undergo efficacy testing in a randomized controlled trial. Open-source technology will enable LINX LA to be adapted for other practice settings and populations. We attribute positive feedback regarding LINX LA to our community-based participatory design process. Mobile health interventions to address HIV CC outcomes must be developed in partnership with end-users and key community stakeholders.

WEPED439

Sexual initiation and quality of life among gay, bisexual and other men who have sex with men worldwide

S. Arreola[1], O. Martinez[2], K. Wilson[2], G. Ayala[1], K. Makofane[3]
[1]MSMGF, Research, Oakland, United States, [2]Temple University, School of Social Work, Philadelphia, United States, [3]Harvard, Social Epidemiology, Boston, United States

Background: Gay, bisexual and other men who have sex with men (GBMSM) have a high prevalence of childhood sexual abuse (CSA) associated with negative health outcomes linked to HIV-risk. However, it is unclear how different categories of sexual initiation, including CSA (forced sex before 16 with someone >5 years older), relate to a broader range of quality of life (QoL) domains. This study examined the differential associations between sexual initiation (None < age 16; Consensual < age 16; Forced < age 16; and Forced ≥ age 16) and QoL.
Methods: We analyzed data from a global sample of 2,481 GBMSM, in 7 languages, collected between 2014 and 2015 from the Global Men's Health and Rights Survey. Participants were recruited through online convenience sampling (e.g. via organizational networks, email listservs and websites). We used World Health Organization´s (WHO) standardized QoL measures (Physical, Psychological, Social and Environmental); T-tests and Chi Squared tests to assess associations between four sexual initiation categories and all Quality of Life domains.
Results: Table 1. shows consensual sex before age 16 had higher psychological, social, environmental and overall QoL and lower suicidality than men who initiated sex at/after age 16; whereas before age 16, men who had forced-sex had worse QoL and suicidality than either those who had none (physical, psychological, environmental and overall) or consensual sex (all domains). This pattern held comparing forced and consensual sex at/after age 16: forced had poorer physical, psychological (marginally significant), environmental, overall QoL, and suicidality than consensual.
Conclusions: This study is the first to differentiate the impact of four categories of sexual initiation on four QoL domains among a global sample of GBMSM. Consistent with previous findings, forced sexual initiation had the most negative QoL outcomes. Results also indicate that consensual sexual initiation before age 16 was not necessarily associated with negative QoL, suggesting that subjective experience of sexual initiation is as important as age of initiation when assessing for CSA. Therefore, it is important to differentiate both childhood and adult sexual initiation deferentially for forced versus consensual experiences so that interventions may be tailored to specific trajectories related to each.

WEPED440

Correlates of stages in the HIV care continuum among HIV-positive young men who have sex with men

D. Bruce[1], J. Flores[1], W. Love[1], M.I. Fernandez[2], ATN
[1]*DePaul University, Health Sciences, Chicago, United States,* [2]*Nova Southeastern University, College of Osteopathic Medicine, Davie, United States*

Background: Young men who have sex with men (YMSM) continue to be overrepresented in the HIV epidemic. Compared to adult populations, YMSM living with HIV (HIV+ YMSM) experience significant disparities at each stage of the HIV care continuum. The current study aimed to identify demographic and behavioral characteristics associated with care continuum stages among HIV+ YMSM.

Methods: We examined demographic, behavioral, and clinical data of 991 HIV+ YMSM enrolled in ATN086-106, a multisite cross-sectional study within the Adolescent Trials Network for HIV/AIDS Interventions (ATN). Demographic and behavioral variables that demonstrated significance in bivariate analyses were entered into multivariate logistic regression models to assess correlates of a range of care continuum markers.

Results: Prevalence of care continuum markers across the sample were: 63.8% reported consistent HIV care, defined as missing < 1 appointment in past 12 months; 52.3% were currently on antiretroviral therapy (ART); 36.8% were on ART >6 months; 33.2% reported >90% adherence; and 28.9% were virally suppressed. Multivariate results indicated that methamphetamine use during the past 90 days was negatively associated with consistent HIV care (OR=0.59, 95%CI: 0.42, 0.84), being on ART (0.68, 95%CI: 0.48, 0.95), and ≥90% adherence among those on ART (OR=0.47, 95%CI: 0.28, 0.81); post-high school education was positively associated with consistent HIV care (OR=1.38, 95%CI: 1.02, 1.85) and being on ART (OR=1.48, 95%CI: 1.12, 1.95); African American race (OR=0.51, 95%CI: 0.33, 0.81) and mental health symptomology (OR=0.67, 95%CI: 0.56, 0.80) were negatively associated with consistent HIV care but demonstrated no associations with other stages of the continuum. Daily marijuana use was negatively associated with consistent HIV care (OR=0.65, 95%CI: 0.48, 0.89), and any marijuana use in the past 90 days was negatively associated with adherence (OR=0.54, 95%CI: 0.36, 0.82). No demographic or other behavioral correlates were associated with viral suppression after controlling for adherence and being on ART ≥6 months.

Conclusions: Methamphetamine use appears to have negative effects on HIV care among HIV+ YMSM across the care continuum, while marijuana use frequency may have differential effects. Efforts to improve treatment as prevention approaches and the HIV care continuum among HIV+ YMSM should emphasize substance use assessment and intervention.

WEPED441

'How come you are a refugee, yet in Uganda there is no war?' Social, sexual and psychological wellbeing of East African MSM and transgender (MSM/TG) migrants in Nairobi

A.D. Smith[1], M.B. Clark[2], A. Bourne[3], R. Kabuti[4], M. Kung'u[4], H. Babu[4], P. Weatherburn[5], E. Fearon[5], J. Kimani[4,6], TRANSFORM
[1]*University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom,* [2]*City University of New York, CNUY Baccalaureate for Unique and Interdisciplinary Studies, New York, United States,* [3]*La Trobe University, Australian Research Centre in Sex, Health & Society, Melbourne, Australia,* [4]*Partners for Health and Development, Nairobi, Kenya,* [5]*London School of Hygiene and Tropical Medicine, Department of Public Health, London, United Kingdom,* [6]*University of Manitoba, Department of Medical Microbiology and Infectious Diseases, Winnipeg, Canada*

Background: East African LGBT migrants seeking asylum in Kenya report harrowing accounts of sexuality-related discrimination precipitating migration. UNHCR estimates over 400 LGBTI migrants have registered for refugee status in Nairobi - the number of illegal migrants is unknown. We explored sexual, social and psychological wellbeing of non-Kenyans enrolling in a study of MSM/TG resident in Nairobi.

Methods: 618 MSM/TG enrolled via respondent-driven sampling in 2017. Eligibility criteria were age 18+, male gender at birth/currently, Nairobi residence and consensual oral or anal intercourse with a man during the last year. Participants completed a computer-assisted survey including knowledge and access to HIV prevention/care resources, experience of discrimination and violence, and measures of social support [MSPSS] and depression [PHQ-9]. MSM/TG born outside and arriving in Nairobi since 2012 were considered international migrants (asylum or refugee status was not assessed directly). Analysis was RDS-II weighted.

Results: 100/618(17.3%) MSM/TG were born outside Kenya of whom 43(44.5%) arrived in Nairobi in the last year (recent migrants) and 56(55.5%) 1-5 years ago (established migrants). Migrants originated from Uganda 83.0%(n=86), DR Congo 11.5%(n=9), Rwanda 4.6%(n=4) and Tanzania 0.8%(n=1).

HIV prevalence was lower among migrants than Kenyan MSM (9.0 vs 30.1% p< 0.001). Recent migrants more often reported problems accessing condoms (OR 2.72[1.43-5.16] p=0.002), and lubricants (OR 1.65[0.88-3.10] p=0.117), and were less likely to have HIV tested in the past 12 months (OR 0.48[0.22-1.02] p=0.056).

31.8% recent and 25.3% established migrants had moderate to severe depression (>PHQ9) versus 15.5% Kenyan MSM/TG (p=0.025). Perceived social support was also lower (mean MSPSS: recent: 4.1; established 4.0; Kenyan MSM/TG 5.0; p< 0.001). Violence and discrimination from family, police and health care were more frequently reported by both recent and established migrants (table).

	Recent migrants (up to 1 year)		Established migrants (1-5 years)		Other study participants		p

Sexual assault	11	*26.0*	18	*28.5*	58	*10.2*	<0.001

[Stigma, discrimination and violence attributed to sexual orientation reported by recent and established international migrants to Nairobi, Kenya (2017)]

Conclusions: MSM/TG migrants experience alarming levels of discrimination, assault, depression and poor social support in Nairobi. There is no coordinated response at a time when financial support for LGBT migrants has been withdrawn. Provisions for security and wellbeing of registered migrants should be urgently reviewed and addressed. Access to and information about Kenyan HIV prevention services should be made available to migrants on entry. Measurement of refugee/migrant status in future research is recommended.

WEPED442

Stigma/discrimination faced by men who have sex with men in India: Correlates and association with risk behaviours (alcohol/drug use and inconsistent condom use), and access to HIV services

V.M.L. Pinnaka[1], V. Chakrapani[1], T. Sirari[1], P. Dhadwal[1], P. Kumar[2], V. Srinivas[2]
[1]Post Graduate Institute of Medical Education and Research, School of Public Health, Chandigarh, India, [2]National AIDS Control Orgainisation, New Delhi, India

Background: The high prevalence of stigma and discrimination faced by MSM, globally and in India, has been well documented. However, from India, limited information is available on the correlates of stigma/discrimination faced by MSM and its effect on various risk behaviours and uptake of HIV prevention-related services.
Hence, this analysis aims:
1) to identify correlates of factors associated with stigma/discrimination; and
2) examine whether stigma is associated with alcohol and drug use, sexual risk, and access to HIV prevention services.
Methods: We used data from a probability-based sample of 23,081 MSM who participated in Integrated Bio-Behavioural Surveillance (IBBS) conducted in 24 states in India. Stigma/discrimination composite score was computed using 4 items:
1) physical violence;
2) sexual violence;
3) disrespectful treatment by friends, family or neighbours;
4) disrespectful treatment in health facilities.
Negative binomial regression was used with stigma composite score as the outcome variable. Multivariate logistic regression was used to examine whether stigma composite score predicts alcohol use, drug use, inconsistent condom use and exposure to HIV prevention programme (i.e., access to HIV services).

Factors associated with stigma/discrimination			
Variables	**Risk Ratio**	**p value**	**95% CI**
Age			
15 - 24 years	1		
25 - 39 years	1.10	< .01	1.03 - 1.18
≥ 40 years	0.95	.45	0.84 - 1.08
Years of Education			
Illiterate	1		
1-5 years	0.71	< .001	0.62 - 0.82
6 -12 years	0.71	< .001	0.64 - 0.80
13 and above	0.69	< .001	0.60 - 0.79
Marital Status			
Married	1		
Single	1.17	< .001	1.09 - 1.26
Identity			
Kothi	1		
Double-decker	0.90	< .01	0.84 - 0.96
Panthi	0.91	< .05	0.84 - 0.99
HIV Status			
Negative	1		
Positive	1.14	< .05	0.99 - 1.31

No	1		
Yes	0.91	< .05	0.85 - 0.98
Health-related outcomes associated with stigma/discrimination*			
Variables	**aOR**	**p value**	**95% CI**
Alcohol Use	1.19	< .001	1.15 - 1.23
Drug Use	1.80	< .001	1.73 - 1.88
Inconsistent Condom Use	1.12	< .01	1.04 - 1.21
No exposure to HIV Prevention Programmes	1.08	< .01	1.03 - 1.13
* Adjusted for age, years of education, marital status, identity, sex work and HIV status			

[Table 1: Factors associated with stigma and discrimination and Its association with various health outcomes among men having sex with men in India]

Results: The mean age of the participants was 27.6 years (SD 7.4 years). About two-thirds were single, reported having about 6-12 years of education and had diverse sexual identities: kothis (feminine/receptive) - 44%, double-deckers (insertive/receptive) - 31% and panthis (masculine/insertive) - 25%. MSM who were in the age group of 25-39 years (vs. 15-24 years age group), single, and relatively less educated and kothi-identified persons had higher levels of stigma scores. HIV knowledge or HIV status did not significantly predict stigma. Stigma/discrimination scores significantly predicted alcohol use (aOR=1.19, < .001), drug use (aOR=1.80, p < .001) and inconsistent condom use (aOR=1.12, p < .01) (Table-1). Those who had experienced high levels of stigma had lower odds of exposure to HIV programme, and thus less access to HIV prevention services.
Conclusions: Experiencing high levels of stigma is associated with HIV-related risk behaviours (alcohol/drug use and inconsistent condom use), and decreased access to HIV prevention services. Stigma reduction and mitigation programmes could help in decreasing HIV risk among MSM and improve their access to HIV-related services.

WEPED443

PrEP Uptake and Persistence in a Sample of Trans MSM in the United States

K. Mayer[1], S. Reisner[2], D. Pardee[3], A. Asquith[3], G. Mayer[4]
[1]The Fenway institute/Harvard/Beth Israel Deaconess Medical Center, Infectious Diseases, Boston, MA, United States, [2]Harvard Medical School/Harvard T.H. Chan School of Public Health/Fenway Health, Boston, United States, [3]The Fenway Institute, Fenway Health, Boston, United States, [4]Gilead Sciences, Inc., Foster City, United States

Background: Transgender people are highly burdened by HIV infection, and trans masculine adults who have sex with cisgender males (trans MSM) may be at particularly high risks for HIV. Despite documented HIV acquisition risk, data on PrEP uptake and persistence in trans MSM are scarce to guide HIV prevention.
Methods: A national sample of U.S. trans MSM recruited via peer referral, dating apps and other social media completed an online survey between November-December 2017. Trans MSM self-reporting receptive anal or frontal/vaginal sex with a cisgender male sex partner in the past 6 months were eligible: HIV-uninfected TMSM who had heard of PrEP and reported on PrEP use were included in this data analysis (n=622). A multivariable logistic regression model was fit analyzing PrEP uptake (yes/no) on statistical predictors derived from transgender/MSM/PrEP research literature.
Results: Sociodemographic and clinical data from all the respondents found that mean age was 28; 10% were Black; 22% Latinx; 68% endorsed masculine identity; 33% identified as gay; 78% used testosterone. Over the prior 6 months, 68% reported anal, and 64% frontal/vaginal, condomless receptive sex (CRS) with a cisgender male; 23% were currently on PrEP and 12% had previously taken PrEP. Adjusting for age, race, education, health insurance, HIV testing, testosterone use, and stigma, factors significantly associated with PrEP uptake were: identifying as Latinx (aOR=2.55; 95%CI=1.29-5.03), binary gender identity (aOR=2.03; 95%CI=1.10-3.56), gay sexual orientation (aOR=2.71; 95% CI=1.54-4.78), polyamorous relationship (aOR=1.98; 95% CI=1.14-3.44), higher number of sexual partners (aOR=1.11, 95%CI=1.05-1.17), social media as preferred health information source (aOR=1.99, 95%CI=1.17-3.39), and higher perceived HIV risk (aOR=1.17; 95%CI=1.04-1.31), and CRS (aOR=2.19; 95% CI=1.17-4.12). PrEP was most commonly obtained via primary care providers (60%), sexual partners (21%), STI clinics (11%), or OBGYN providers (11%).
Conclusions: PrEP use was common in this trans MSM sample, which may partly be a function of recruitment methods (e.g., included outreach to HIV prevention listservs). PrEP uptake was modest, given their prevalence of HIV risk behaviors. Although 68% of the trans MSM reported sexual risk, the majority were not using PrEP, suggesting further study and community education are needed to enhance uptake among trans MSM.

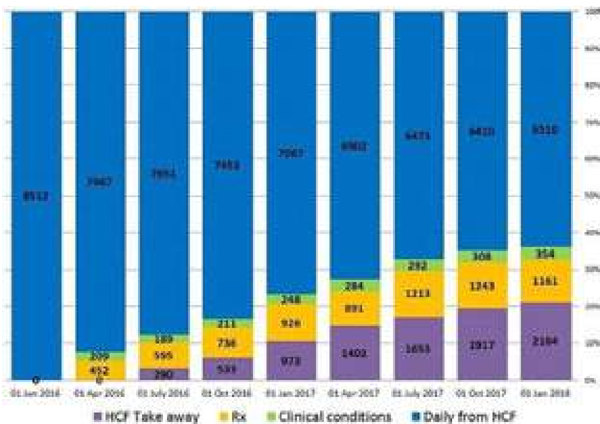
People who use drugs (including by injection)

WEPED444

Rapid scale up of takeaway practices for opioid substitution therapy in Ukraine: Exploring possibilities of new legislation

T. Grytsenko[1], I. Ivanchuk[2], O. Bidovanets[1]
[1]Public Health Center of the Ministry of Health of Ukraine, HIV, VH and STIs Prevention and Control Department, Kyiv, Ukraine, [2]Public Health Center of the Ministry of Health of Ukraine, Project Management and International Cooperation Department, Kyiv, Ukraine

Background: In order to improve retention, patients resocialization, decrease financial and HR burden on healthcare facilities, providing OST, regulatory framework, allowing patients, falling under certain criteria («patient stability») to receive up to 10 days takeaway dose, which was previously only available due to clinical conditions, has been introduced.
Description: Legislation came into force in early 2016, setting common regulations for all facilities and regions of Ukraine. As of 01.01.2018, share of OST patients receiving takeaway dosage for further self-administration has grown up to 32,6% (3325 out of 10189) (not including 354, receiving takeaway dosage due to the clinical conditions). 65,1% of them (2164) receive drugs directly from the clinic, keeping patients tied to the single facility, while 34,9% (1161) receive prescription blank, which can be presented at any eligible pharmacy. Since, regions have shown their own approach, from total disregard to the practice (0%, 0 out of 174 patients) to rapid implementation on all levels (86,4%, 146 out of 169 patients) with no specific interventions from the national level, excluding providing explanations on new legislation. Takeaway share is different in terms of drugs as well, varying from 26% for methadone tablets (2648 out of 8901 patients) to 63% for buprenorphine (677 out of 1075).



[Share of OST patients receiving takeaway drugs in Ukraine]

Lessons learned: Given the differences in implementation of new model, it`s important to provide additional tailored recommendations, depending on drug misuse and overdose risks. Assessment on recommended ratio of patients receiving OST on a daily basis under direct supervision and those, receiving takeaway dosage, based on existing evidence and considering country context, should be carried out. Implementation of the takeaway practice has significantly increased attractiveness of the program for the clients (scale up for 1677 patients within 2 years), though long-term impact on HIV epidemic, as well as illicit drug use and additional risks for the patient and PWID population remains unclear.
Conclusions/Next steps: Though takeaway model is crucial both for sustainability of OST programs in terms of limited resources and as a approach of patients encouragement, additional regulations and recommendations to mitigate possible risks and balance out with benefits is needed throughout of program scale up.

WEPED445

Will gay and bisexual men who use methamphetamine participate in PrEP services?

P. Saxton[1], S. Azariah[2], R. Franklin[2], R. Forster[2], S. Werder[2], R. Jenkins[2], J. Myers[3], J. Rich[3], M. Fisher[4]
[1]University of Auckland, Gay Men's Sexual Health research group, Dept of Social and Community Health, Auckland, New Zealand, [2]Auckland Regional Sexual Health Service, Auckland, New Zealand, [3]New Zealand AIDS Foundation, Auckland, New Zealand, [4]Body Positive, Auckland, New Zealand

Background: New Zealand is launching a fully funded and targeted PrEP programme in March 2018. Methamphetamine use by gay and bisexual men (GBM) is listed as an eligibility criterium for PrEP, but we don't know whether GBM who use methamphetamine will disclose their use to physicians or engage with PrEP services. We aim to examine methamphetamine use among GBM in the NZPrEP demonstration project.
Methods: We used an open-label single-arm treatment evaluation study design in 2017 ("NZPrEP"). The settings were four publicly-funded sexual health clinics in Auckland. The study population was 150 GBM at elevated HIV risk recruited from clinics, community sources and social media. The study medication emtricitabine/tenofovir was fully funded. At baseline, participants self-completed an online questionnaire about PrEP motivations, sexual and risk behaviours. We examined drug use (cannabis, amyl, GHB, ecstasy, amphetamine, methamphetamine, cocaine, ketamine, LSD and mephedrone) and alcohol use in conjunction with sex in the previous three months. We defined "heavy users" as participants using
(i) any of these drugs; or
(ii) alcohol "most of the time" or "always" before sex respectively.
We compared participants using substances against non-users on the following outcomes:
(a) self-reported STI in the last 12 months;
(b) self-reported rectal STI in the last 12 months;
(c) diagnosed prevalent rectal chlamydia or gonorrhoea;
(d) 10 or more receptive condomless anal intercourse partners in the last three months.
Results: We enrolled 150 GBM with a median age of 32 (range 19-51). One in 20 (5%) reported injecting drugs in the previous year. 61%, 48% and 8% reported any alcohol, drug and methamphetamine use respectively in the previous three months, and 13% and 10% engaged in heavy alcohol and drug use respectively. Participants reporting any alcohol use before sex were more likely than non-drinkers to report 10 or more receptive condomless anal intercourse partners (14.1% vs 3.5%, p=0.034), but were less likely to be diagnosed with a rectal bacterial STI at baseline (13.2% vs 26.3%, p=0.044). No other significant differences between users and non-users were detected.
Conclusions: HIV-negative GBM using methamphetamine are engaging in PrEP demonstration projects. Their HIV acquisition risk is similar to other GBM participating.

WEPED446

Prevalence of HIV, HCV and syphilis among PWUD - data from the first mobile testing and harm reduction service point in Poland

A. Kwiatkowska[1], M. Ankiersztejn-Bartczak[1], A. Świderska[2]
[1]Warsaw University, Warsaw, Poland, [2]Medical University of Warsaw, Warsaw, Poland

Background: In 2017 The Foundation of Social Education executed the pilot version of Mobile
Testing Point and Harm Reduction dedicated to the most exposed populations which are psychoactive substances users and sex workers. Professionaly full-equipment camper proffers quick tests for HIV, HCV and syphilis, the injection equipment, condoms and lubricants. Users could benefit of gratuitous medical and therapeutical guidance. The Mobile Testing Point is the first one in Poland which reached to users who never before were in public point of testing. Therefore these people examined for HIV, HCV and syphilis and get support in starting and proceed suitable treatment.

Methods: The quantitative survey was conducted using the PAPI method (the original questionnaire) from 17th August do 15th December 2017. The amount of clients of the Mobile Testing Point and Harm Reduction service was 234 in Warsaw and the surrounding areas.
Results: The percentage of HIV infections and HCV among those who performed the test is 14.6% for HIV and 56.5% for HCV. 93.1% of people infected with HIV were also infected with HCV. In 3% of people performing the test, syphilis was detected. Only 9% of people infected with HIV and 29% of people infected with HCV knew about the infection earlier. 58.6% of people with HIV and 61.5% with HCV had sexual contact without any protection . 68.4% of all respondents and 87.4% of people with a positive test received psychoactive substances in the last 30 days. Among those receiving psychoactive substances in the last 30 days the most popular were mephedrone (33.2%), heroin (23.8%) and amphetamine (9.8%). 86.2% of people infected with HIV and 74.3% of people infected with HCV reported having knowledge about the ways of infection.
Conclusions: People with addiction of drugs are particularly vulnerable to HIV and HICV. These people are willing to use the Mobile Harm Reduction Service offer. The activity of the Mobile Testing Point service contributes to limiting the pread of HIV and HCV infections. Moreover increases the level of knowledge about the ways of infection, and also allows to estimate the scale of occurrence of the problem among the most exposed groups.

WEPED447

High burden of psychosocial stress among opioid-dependent persons on medically assisted therapy in Kwale County, Kenya

S. Abdallah[1], B. Gakurya[2], F. Mdune[2], M. Swaleh[2], B. Makenzi[3], H. Albusaidy[3], A. Said[4]
[1]UNODC ROEA, Health, Mombasa, Kenya, [2]Kombani MAT Clinic, Kwale, Kenya, [3]Kwale County, Health, Kwale, Kenya, [4]Teens Watch Centre, Kwale, Kenya

Background: While it is widely acknowledged that illicit substance use is associated with numerous psychosocial problems, knowledge of the magnitude of this problem among people who use drugs in Kenya is limited. Since psychosocial interventions comprise 70% of recovery process from drug use, Kwale County introduced Medically Assisted Therapy (MAT) in October 2017 to increase access to clinical, behavioural and structural interventions for over 3,000 estimated opioid dependent persons. We conducted a simple study to assess the psychosocial well-being of clients on MAT in order to better address prevailing gaps in psychosocial interventions.
Methods: Retrospective review of psychosocial interventions register. Eligible client: all enrolled between October -December 2017, with documented indepth assessment by medical social worker, an individualized treatment plan, and brief follow up consultations. Key study variables abstracted include: socio-demographic characteristics, drug use history, self-reported psychosocial issues and interventions.
Results: Of 213 MAT clients enrolled, females comprised 8%. Due to economic constraints compounded by family breakdown,< 40.0% attained secondary level education or higher (27.8% for females): This limited their employment opportunities, with 40% of females unemployed versus 27.6% males, and 28% of all clients engaging in unskilled labour.
At baseline, over 70% clients used heroin concurrently with cannabis, benzodiazepines or alcohol. Several clients complained of low self-esteem and stress at baseline, with one harboring suicidal thoughts. Despite agonizing over relationship issues with sexual partner or other family members, many clients maintain contact with at least one family for emotional or financial support, with mother as chief supporter for 45% clients, followed by siblings. Common treatment goals: reduce/stop illicit drug use, family reunification and secure jobs.
Conclusions: Findings confirm major psychosocial problems among Kwale's MAT clients, especially females. Neglect of these issues may compromise MAT service uptake and effectiveness of methadone treatment. Underlying psychosocial issues may have either triggered or aggravated illicit substance use behaviour. In addition to more client and family-centered approach to psychosocial interventions, further implementation science research urgently needed to determine which interventions work, in order to enhance MAT treatment outcomes, reduce HIV-related risks and assure durable recovery from drug use among male and female clients.

WEPED448

Mapping and behavioral study of the population of drugs users (DUs)/people who inject drugs (PWID) along the Abidjan-Lagos corridor

A.-A. Fagbemi[1], L. Tchobo[1], I. Kone[1], A. Paul[1], A. Imorou Bah Chabi[1], M. Ndi Berinyuy[1], P. Zekeng[2]
[1]Abidjan-Lagos Corridor Organisation, Health, Cotonou, Benin, [2]Africa Synergie, Cotonou, Benin

Background: In order to effectively implement a harm reduction project for DUs and PWID, the Abidjan-Lagos Corridor Organization (ALCO) conducted mapping and behavioural study of DUs/PWID.
The objective was to identify the sites and the hotspots used by Dus and PWIDs at eight (8) border sites along Abidjan-Lagos corridor and Study their behavioral characteristics.
Methods: It was a cross-sectional survey with a programmatic focus. Qualitative data for structural component were collected using the Rapid Assessment and Response (RAR) methodology and map data using the principles of PLACE method (Priorities for Local AIDS Control Effort). Three questionnaires were administered. After the interviews, GPS coordinates were taken during site visits.
This study covered the eight border sites along the Abidjan-Lagos corridor: Noé (Côte d´Ivoire-Ghana), Elubo (Ghana-Côte d´Ivoire), Aflao (Ghana-Togo), Kodjoviakopé (Togo-Ghana), Sanvee Condji (Togo -Benin), Hillacondji (Benin-Togo), Kraké Plage (Benin-Nigeria) and Sèmè (Nigeria-Benin). It was conducted during the last quarter of 2017
The final size of the sample was 1949 (6.1% of women).
Results: Thirty-nine (39) drug use sites have been identified: 6 are in Noe, 5 in Elubo, 5 in Aflao, 2 in Kodjoviakope, 1 in Sanvee Condji, 9 in Hillacondji, 4 in Kraké and 7 in Sèmè. These sites are either bars, beaches, wasteland, ghettos, houses etc. Medication use (smoked / inhaled and oral route) was reported by 43.1% of participants while 38.5% reported using cocaine, 28% of heroin. Among cocaine users, the smoked / inhaled route was predominant with 26.7% of cases, followed by the smoked pathway in the form of crack (16.5%) and the injectable route (14.7%). Among heroin users, the smoked / inhaled route was also predominant with 23.5% of cases, followed by the injectable route (12.7%). 71% of participants of the study reported never injecting drugs. The average age for the first use was of 20 years and 22.7 years at the first injection.
Sharing of syringes with others over the past 30 days was reported in 11.8% of cases.
Conclusions: This study made it possible to have the precise list of the sites of drug use, to know the habits of consumption in order to better plan the harm reduction project.

WEPED449

Integrating harm reduction principles into HIV/AIDS healthcare delivery in the Philippines: Readiness of HIV care providers and drug rehabilitation care providers

C. O'Connor, K. Leyritana, R. Olete
Sustained Health Initiatives of the Philippines (SHIP), Madaluyong City, Philippines

Background: The Philippines' HIV epidemic is one of the fastest-growing globally. Drug use is one driver of growing infection rates. With government's "war on drugs" launched in 2016, physicians caring for PLHIV who use drugs lack clear guidelines on the legal and clinical protocols for these patients.
This study measures attitudes and practices of HIV care and drug rehabilitation providers from across the Philippines.
Methods: Our organization developed a program to improve care for PLHIV who use drugs through training, referral, and appropriate clinical protocols for HIV care and drug rehabilitation. A training/networking

event was held and a pre-training questionnaire was administered to 35 respondents (16 HIV care and 17 drug rehabilitation providers).
Results: Practices: 61% of the respondents from drug rehabilitation facilities reported having a protocol in place for HIV screening. 33% of respondents from HIV care facilities had a protocol in place for substance use screening. One rehab and no HIV care facilities had a policy for management of PLHIV who use drugs.
Attitudes: 36% of respondents disagreed with the statement "People who use drugs are dangerous." 91% of respondents disagreed with the statement "People who use drugs should be killed." 57% of respondents disagreed with "Healthcare providers should report clients' illicit drug use to law enforcement authorities." 69% agreed with "Healthcare providers should inform people who use drugs about safer practices for the use and administration of drugs." There was variation in attitudes between HIV and drug rehabilitation providers.
Conclusions: The pre-training survey showed that some providers have positive regard toward people who use drugs and harm reduction. Following training we anticipate there may be a shift in attitudes; we will conduct a follow-up. A sustained effort would be required for harm reduction practices to be acceptable to HIV care and drug rehabilitation providers in the Philippines.

WEPED450

Barriers to accessing quality care for HIV and substance use in the Philippines: In-depth interviews with PLHIV who use drugs

R. Olete[1], C. O'Connor[1], K. Leyritana[1], J. Salisi[1], R. Bona[1], G. Binay[2]
[1]Sustained Health Initiatives of the Philippines, Mandaluyong City, Philippines, [2]NoBox Philippines, Quezon City, Philippines

Background: The Philippines' HIV epidemic is one of the fastest-growing globally. Drug use is one driver of growing infection rates. Among people who inject drugs in Cebu city in 2015, HIV prevalence was 43%. With government's "war on drugs" launched in 2016, accessing care has become more challenging because of fear of legal implications, stigma/discrimination, and at worst, being killed. This study explores the underlying personal and structural factors affecting access to healthcare for PLHIVs who use drugs.
Methods: Key informant interviews were conducted with 13 respondents from 4 provinces/regions. Respondents were 11 males, 2 females, HIV+, used recreational drugs, and were recruited via local NGOs. The interview guide asked about drug use history, healthcare seeking behavior, and access to care. The interviews were recorded, transcribed, translated to English, and a qualitative thematic analysis was done.
Results: Shabu (methampethamine) is the most common drug used by the informants. Among those injecting, 100% reported sharing needles.
Eight informants did not disclose their drug use to their HIV doctors and did not plan to due to fear of being judged, scolded or taken to rehabilitation centers. This reluctance to disclose impacts ART adherence - only 4 informants reported good adherence, other informants missed doses regularly, one reported stopping ART for six months, and another for three years.
Fear of the war on drugs is a barrier to healthcare, especially for overdose. The majority of respondents had experienced overdose, and most stated that they were reluctant to or certainly did not want to be brought to hospital if they overdosed.
Conclusions: Lack of trust in healthcare providers is a key barrier for PLHIVs who use drugs in accessing quality care. Therefore, it is important to build capacity and create policies in healthcare settings to ensure that they are safe, stigma-free spaces for PLHIV who use drugs.

WEPED451

Prevalence and correlates of knowledge of hepatitis B and C virus among people who inject drugs (PWIDs) in Lagos, Nigeria

S. Iwuagwu[1], T. Eyohwo[1], N. Nwosu[1], A. Ogunbajo[2], C. Onyekatu[1], C. Ekerete-Udofia[1]
[1]Centre for Right to Health, Lagos, Nigeria, [2]Brown School of Public Health, Providence, United States

Background: In Nigeria, people who inject drugs (PWIDs) are at increased risk for infections such as human immunodeficiency virus (HIV), hepatitis B virus (HBV), and hepatitis C virus (HCV). Knowledge about HBV and HCV may facilitate testing and treatment behavior among PWIDs. No known study has explored the knowledge of HBV and HCV among PWIDs in Nigeria. To fill this gap, the current study assessed knowledge of HBV and HCV among Akala community dwellers in Lagos, Nigeria and explored the association between knowledge of HBV and HCV and self-reported risk assessment.
Methods: The study conducted cross-sectional, snowball sampling, of PWID and non-PWID dwellers in the Akala community in Mushin, Lagos, (where local NGO, Centre for the Right to Health is implementing a UNODC-supported community-based drug rehabilitation project). Data collection was conducted between October and December 2016. Participants were asked about whether they had heard of HBV and HCV and screening for both. Risk assessment included measures of illicit drug use, history of HBV/HCV vaccination, HIV status, and self-reported HBV and HCV status. Descriptive statistics and unadjusted bivariate analysis using chi square with HBV/HCV knowledge as the primary outcome was conducted.
Results: Majority of participants (81.1%) had never heard about either HBV or HCV. Most participants had no knowledge of how HBV/HCV was transmitted (79.6%) and that HBV/HCV can be asymptomatic (84.2%). Only about a third (34.8%) of participants knew HBV/HCV was treatable. Knowledge of HBV/HCV was significantly associated with sharing of needles($p< 0.000$) and injection drug use ($p< 0.000$). Knowledge of HBV/HCV was not significantly associated with gender ($p=0.57$).
Conclusions: Lack of knowledge of HBV/HCV, how it is transmitted and the availability of treatment was high among PWID and non-PWID dwellers in the Mushin area of Lagos, Nigeria. Increased knowledge and awareness of HBV/HCV, especially among PWIDS, is pertinent to reducing hepatitis transmissions in this key population. While injection drug use and sharing of needles were associated with increased knowledge of HBV/HCV, more programs providing evidence-based information about HBV/HCV and local screening resources are needed.

WEPED452

Differentiated service delivery for harm reduction strategies for people who inject drugs_learnings from the Mauritian context

R. Petlele[1], L. Malaka[1], C. Kganakga[2]
[1]South African National AIDS Council, Johannesburg, South Africa, [2]South African National AIDS Council, Pretoria, South Africa

Background: A recent study concluded that HIV prevalence among male PWID is at 14% and 17% among female People who use drugs (PWUD) in South Africa. The 2017-2022 National Strategic Plan for HIV, TB and STIs identifies people who inject drugs (PWIDs) as one of the five key populations at high-risk of HIV infection. The NSP further stipulates the need for strategies to reach key populations with tailored packages to meet their needs.
Description: The South African National AIDS Council Secretariat, civil society and government representatives embarked on a PWID study tour to learn from Mauritius' successful harm reduction strategy to increase the South African coordination and implementation structure's understanding of the processes involved in planning, coordinating and monitoring programmes to provide HIV prevention and harm reduction services. The South African delegation was privy to learnings from the national Drug Observatory led by the Ministry of Health, site visits to facilities and outreach activities PWIDs.

Lessons learned: The successful implementation of the Mauritian HIV prevention and harm reduction strategies is the differentiated service delivery model. Doses of methadone are dispensed from caravans. PWIDs know the location and times when the caravan will be dispensing the medication. PWIDs have access to clinicians at centres around the community. Another outreach strategy used is the distribution of clean needles and syringes to PWID; a combi makes trips to designated spots around the community; here used needles and syringes are collected and new ones dispensed.

Conclusions/Next steps: Differentiated model of service delivery in Mauritius has worked very well; services are provided in the community, delivered to the users where it is accessible. With the high burden on South Africa's public health facilities, provision of PWID harm reduction HIV prevention services would be best provided outside the formal health system. PWID face discrimination, harassment from law enforcement and generally ostracised from social structures, including health facilities. The feasibility of differentiated models of service delivery is pertinent in the South African context where a safe space for service delivery will be important for increased access and uptake.

WEPED453

Barriers to effective HIV prevention and Service delivery among people who inject drugs in Nigeria

A. Ogunrombi[1], E. Godwin[2]
[1]YouthRISE Nigeria, Policy/Programs, Abuja, Nigeria, [2]Heartland Alliance Nigeria, Abuja, Nigeria

Background: According to the Nigeria 2014 Integrated Bio-behavioral Surveillance Survey (IBBSS), the HIV prevalence among people who inject drugs(PWID) is 3.4%. The HIV prevalence however varies from state to state with some as high as 7%. Female injecting drug users have also recorded higher prevalence rate than their male counterparts - seven times higher. Despite the HIV prevalence and increasing report of injecting drug use in the country, core harm reduction programs such as Opioid substitution therapy and Needle and Syringe programs are still lacking. However, HIV testing and antiretroviral services are provided for the group alongside the general population. This study examines the barriers to HIV prevention and service delivery among PWID in Nigeria from the service recipient perspectives.

Methods: Series of focus group discussions and key informant interviews involving PWID, gatekeepers
at drug using locations and community outreach workers in the Federal Capital territory were conducted. A total of 40 interviews were documented.

Results: The study showed a critical interplay of how behavioral and structural barriers affect uptake of services and availability of evidence-based HIV prevention tools for PWIDs in Nigeria. Behavioral factors such as low risk perception, HIV-related stigma and confidentiality of HIV test result are key barriers to uptake of available services. Structural barriers such as non-implementation of NSP and criminalization of drug users increases the risk of HIV acquisition with many HIV positive PWID reporting needle & syringe sharing. Also identified are gender related issues that increases the HIV risk among females who inject drugs. In relation to service delivery, peer-driven HIV testing services and community-based ART model
of care were identified as critical strategy to improve service uptake.

Conclusions: Effectiveness of HIV prevention services among PWID is not limited to just availability of the services but also how the services are delivered in ensuring utilization. Addressing structural barriers are key in reducing the HIV burden among PWIDs.

WEPED454

Patterns of substance use and substance use treatment predict viral suppression over time among HIV-positive women in the Women's Inter-agency HIV Study (WIHS): A cross-classified repeated measures latent-class analysis

D. Feaster[1], M. Philbin[2], C. Parish[1], T.K. Lee[1], E. Golub[3], T. Wilson[4], A. Sharma[5], S. Kassaye[6], J. Cohen[7], A. Adimora[8], I. Ofotokun[9], D. Konkle-Parker[10], J. Cook[11], R. Cook[12], L. Metsch[2]
[1]University of Miami, School of Medicine, Miami, United States, [2]Columbia University Mailman School of Public Health, Sociomedical Sciences, New York, United States, [3]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [4]SUNY Downstate Medical Center, Public Health, Brooklyn, United States, [5]Albert Einstein College of Medicine, Medicine, Bronx, United States, [6]Georgetown University Medical Center, Medicine, Washington, United States, [7]University of California San Francisco, San Francisco, United States, [8]University of North Carolina Chapel Hill, School of Medicine, Chapel Hill, United States, [9]Emory University Department of Medicine, Infectious Diseases, Atlanta, United States, [10]University of Mississippi Medical Center, Infectious Diseases, Jackson, United States, [11]University of Illinois at Chicago, Psychiatry, Chicago, United States, [12]University of Florida, Epidemiology, Gainesville, United States

Background: HIV viral suppression is an important indicator of effective HIV treatment, and decreases the likelihood of transmission. Substance use (SU) can negatively impact HIV-positive individuals' care engagement, including a higher likelihood of viremia and transmission. Therefore, it is important to understand the relationship between SU, SU treatment, and viral suppression.

Methods: Data from 2512 women were collected during six semiannual visits (10/2013-09/2016) at nine Women's Interagency HIV Study (WIHS) sites-WIHS is the largest U.S. cohort study of HIV-positive and HIV-negative women. We compared the use of single substances and SU treatment indicators to viral suppression, and then used latent class analyses of these domains to predict viral suppression.

Results: Substance use patterns were similar across HIV-positive and HIV-negative women. Among HIV-positive women, bivariate models by substance type found that stimulant users had the largest difference in viral suppression between users and non-users (74% versus 82%). In latent class analysis, individuals with consistent use of stimulants, marijuana and binge drinking had the lowest percentage of suppression (62%), with those consistently using all substances with the next lowest percentage (69%). The class that predominately used marijuana (82% virally suppressed) and the class with very low use of any substance (85% virally suppressed) had the highest rates. The interaction of SU and SU treatment classes showed that the rate of virally suppressed individuals in the Low-SU and No-SU-Treatment classes increased from 81% to 88% (baseline to 30 months), whereas the Declining-Use class and all classes including stimulants who were also in the No-SU treatment class had a decreased likelihood of viral suppression from baseline to 30 months. Individuals in Increasing-Professional-Treatment who used stimulants and other substances had the lowest viral suppression at baseline (36%) but also greater increases (13%) than the Low-Use/No-SU-Treatment individuals. Consistent Alcoholics/Narcotics Anonymous (AA/NA) attendance was associated with higher rates of viral suppression across all substance use classes.

Percent Virally Suppressed	Substance Use Treatment Classes							
	Increasing Professional Treatment/ No AA/NA		Decreasing Treatment		Low Professional Treatment/ High AA/NA		No SU Treatment	
Substance Use Classes	Baseline	30 Months	Baseline	30 Months	Baseline	30 Months	Baseline	30 Months
Declining Use	55%	69%	70%	82%	68%	96%	73%	69%
Mostly Marijuana + Marijuana & Binge + Binge Drinkers	89%	83%	50%	77%	98%	99%	75%	84%
Stimulants, Marijuana & Binge Drinking + Uses All Substances	36%	49%	70%	68%	24%	88%	68%	64%
Low Use	64%	78%	80%	78%	90%	95%	81%	88%

[Percent viral suppression by substance use classes and substance use treatment classes]

Conclusions: Substance using women who attended treatment showed improvement in HIV viral suppression rates relative to those not in treatment. Latent class analysis provides a sharper picture of how specific patterns of SU and SU treatment affect HIV-positive women's maintenance of viral suppression.

WEPED455

Rapid assessment of the quantity, quality and effectiveness of services for the young women using drugs in the Kyrgyz Republic

R. Baiazitova
Public Foundation 'Ganesha', Bishkek, Kyrgyzstan

Background: Young women using drugs (YWUD) are often „invisible" to harm reduction and HIV prevention programs. YWUD often face violence, stigma, and discrimination. Discrimination and violence from close associates, older people using drugs, and police make the group more closed. YWUD often feel that they cannot seek help and therefore remain exposed to risk of HIV infection and without adequate protection of their human rights. YWUD continue to be underserved, with little information and few services targeted to them. In this regard Community based organization "Ganesha" conducted an express assessment of the quantity, quality and efficiency of services provided by state and non-governmental institutions for YWUD.
Methods: The rapid assessment conducted January -April 2017 in the city of Bishkek and Chui oblast. The evaluation methods were selected in accordance with objectives of the rapid assessment - quantitative data collection and analysis. Two questionnaires were developed for service providers and clients. Data collection and analysis was carried out by the community, individually with each respondent.
Results: 50 YWUD (18-32 years) participated in rapid assessment. Rapid assessment showed that Harm Reduction programs are not gender sensitive and are not designed to provide services to YWUD. The rapid assessment showed that YWUD do not know about the services provided in Harm Reduction and Guaranteed State Assistance programs. Low involvement in prevention programs is also resulted from a general lack of services targeting YWUD. Medical services in the field of HIV, SRHR are only available for adolescents with consent of official representatives, which is the main barrier to receiving medical services. A rapid assessment among service providers has shown that separate programs are needed to provide services targeted at the needs of YWUD. The country lacks interest and funding from donors and the state for HIV prevention among YWUD.
Conclusions: Implementing effective HIV prevention among YWUD requires the development and official approval of comprehensive package of services oriented to needs of YWUD that take gender into account. The Ministries of Education and Health should develop program with a non-discriminatory approach to SRHR, and reduce demand and harm from psychoactive substances with full community participation.

WEPED456

Engaging community-based model of care for differentiated anti-retroviral therapy (ART) service delivery for people who inject drugs (PWIDS) in Nigeria: Lessons and challenges

O. Alao[1], A. Adebiyi[2], O. Osisami[3], A. Kalaiwo[4], O. Tewobola[3]
[1]Youth Initiative for Drugs Research Information Support and Education, Abuja, Nigeria, [2]Youth Initiative for Drugs Research Information Support, Abuja, Nigeria, [3]Heartland Alliance International Nigeria, Abuja, Nigeria, [4]United States Agency for International Development, Abuja, Nigeria

Background: Current models of providing HIV services for prevention, testing, care and treatment are being stretched to the limit.
To reach the UNAIDS 90-90-90 targets, there is call for new and differentiated approaches needed to meet the diverse needs and expectations of all people living with HIV (PLHIV**).** The purpose of this study is to show the effectiveness of a community-based model in ART service uptake for People Who Inject Drugs (PWIDs).
Description: Between January to December of 2017, YouthRISE piloted a Mobile Community-based ART (MCA) program that provided real time service enrollment for PWIDs, from the point of HIV testing through to linkage to holistic care. Services are provided by a mobile team of social and health workers and include HIV testing, ART initiation, ARV refill, adherence counselling, nutritional support and home-based care.
Clients who are willing to go to the facility are encouraged to do so for continuation of services but those who are unable are counselled and still provided treatment services by the mobile team till a point they could go to the facility on their own.
Lessons learned: The use of the community-based model has contributed to high a rate in ART enrollment for PWIDs within the facility. Before January 2017, the ART enrollment rate for PWIDs who were HIV-positive was 18%.
Between January to December 2017, after the MCA was introduced, 1592 (1021 Males, 571 Females) PWIDs were tested for HIV out of which 102(36 Males, 66 Females) tested positive. Of these, 72 were initiated into ART representing 70.5% enrollment rate.
After 12 months, 87% were retained in care with only 13% dropping out after staying on treatment for an average of 6 months. The establishment of HIV support group for the PWID community has also improved retention in care.
Using this model of care in YouthRISE has facilitated ART initiation, provide access to proximate HIV care and minimizing structural barriers to retention.
Conclusions/Next steps: Adaptation of ART service delivery model for PWIDs is critical to ensuring PWIDs are reached with HIV testing services, enrolled and retained in treatment and care services.

WEPED457

Social-structural influences on access and adherence to antiretroviral therapy among people living with HIV/AIDS who use drugs: A qualitative meta-synthesis

T. Fleming[1], W. Damon[1], W. Small[1,2], R. McNeil[1,3]
[1]British Columbia Centre on Substance Use, Vancouver, Canada, [2]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [3]University of British Columbia, Department of Medicine, Vancouver, Canada

Background: Although social and structural forces, such as drug law enforcement and economic marginalization**,** have been identified as critical determinants of access and adherence to highly active antiretroviral therapy (HAART) among people living with HIV (PLWHIV) who use drugs, there remain significant knowledge gaps in relation to how these forces intersect to produce sub-optimal HAART outcomes across settings. This qualitative meta-synthesis was undertaken to address this research gap and examine the social-structural contexts of HAART access and adherence globally to inform structural and programmatic interventions to improve HAART outcomes.

Methods: A systematic literature search of the English-language peer-reviewed qualitative literature on HAART access and adherence among PLHIV who use drugs yielded 33 articles meeting the eligibility criteria for this analysis. Eligibility criteria included articles published since 1998 focusing on HAART access and adherence in which ³50% of their sample identifying as PLHIV who use drugs. Three team members analyzed the articles in NVivo using a qualitative meta-synthesis approach.
Results: Studies included in this meta-synthesis represented an aggregate of more than 1200 HIV-positive PWUD across 15 countries. This analysis of the included articles revealed how social-structural conditions stemming from drug criminalization and socio-economic marginalization produced sub-optimal HAART outcomes. Specifically, this analysis found that: (1) drug criminalization resulted in law enforcement strategies (e.g., policing near clinics) that interrupted access to HAART and disrupted adherence routines; (2) structural and interpersonal stigma associated with drug use constrained access to HAART and undermined patient-provider relationships; and (3) structural vulnerabilities (e.g., residential instability, incarceration) were barriers to HAART initiation and produced HAART interruptions.
Conclusions: The findings of this meta-synthesis shed light on the ways in which social-structural forces converge to undermine HAART access and adherence among PLHIV who use drugs. Findings demonstrate that complementary drug policy reforms (e.g., drug decriminalization) and structural interventions (e.g., expansion of social housing) will be necessary to optimize HAART-related outcomes among this population. These complementary approaches may prove necessary to achieve 90-90-90 targets among PLHIV who use drugs.

WEPED458

Norms on drug injection in Athens, Greece (2013-2015)

A. Hadjikou[1,2], K. Pantavou[1], G. Giallouros[1], E. Pavlitina[3], L. Williams[4], G. Lavranos[2], D. Lamnisos[2], M. Talias[5], D. Paraskevis[6], S. Friedman[4], G. Nikolopoulos[1]
[1]Medical School, University of Cyprus, Nicosia, Cyprus, [2]European University of Cyprus, Nicosia, Cyprus, [3]Transmission Reduction Intervention Project, Athens, Greece, [4]National Development and Research Institutes, New York City, United States, [5]Open University of Cyprus, Nicosia, Cyprus, [6]National and Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Medical School, Athens, Greece

Background: Norms on injection practices can influence drug injection-related behavior and therefore HIV outcomes. This work describes norms among people who inject drugs (PWID) in Athens, Greece in the context of an HIV outbreak during years of serious economic crisis.
Methods: The Transmission Reduction Intervention Project (TRIP) used a social network-based contact tracing approach to detect recent HIV infections (June 2013-July 2015). TRIP also collected data on injection norms, using a structured questionnaire, from 310 PWID (females 19%). Of these, 21 served as recently HIV-infected seeds to recruit 140 people from their social networks; 16 were longer-term HIV-infected seeds who recruited 59 people from their networks; and 74 people served as HIV negative controls.
Results: Around a third of the participants (35%) reported that people they use drugs with encouraged them to share syringes and more than half (52%) said that they were encouraged by those people to share other injecting equipment. The proportions were much higher for unsafe injection norms at drug-using venues. Between 60% and 70% of the participants said that they saw people at drug-using venues encouraging others to share either syringes/needles or cookers, rinse water, and other injecting equipment. The results did not significantly differ by gender or HIV status or across groups of seeds (recent vs. long-term-infected) and their networks.
Conclusions: Norms on drug injection in Athens, Greece in the months following the peak of the outbreak favored risky behaviors. These findings raise concerns. Future work should seek to understand whether these norms are a potential pathway through which macro-level processes, such as economic crises, affect HIV risk and result in HIV transmission.

WEPED459

Young and High - a rising reality: A qualitative analysis of drug use among young gay, bisexual and MSM in sexualized settings in Bangkok, Hanoi and Jakarta

N. Perera[1], A. Valeriano[2]
[1]Youth Voices Count, Mt. Lavinia, Sri Lanka, [2]UNAIDS RST Asia Pacific, Bangkok, Thailand

Background: Methamphetamine drug use among gay, bisexual and MSM in sexualized settings is increasing in the ASEAN region. Young gay, bisexual and MSM are more engaged in this behavior as per anecdotal data. There is very less information in this region about drug use in sexualized settings which hampers targeted interventions.
Methods: For the first time in ASEAN region, Youth Voices Count launched an online survey in Bangkok, Jakarta and Ho Chi Min targeting young gay, bisexual and MSM who use drugs in sexualized settings. The survey was launched in 4 languages and aimed to collect information on types of drugs used, motivation for drug-use initiation and continuation, safer sex practices, access to HIV services and harm reduction services. The data was collected between October- November 2017. 3 KIIs with young gay, bisexual and MSM were conducted in each country with a total of 9 KIIs.
Results: The initiation of drug use among young gay, bisexual and MSM has taken place as a result of psycho social issues such as anxiety with "coming out", need to be in relationships or to engage in sex work for a higher pay. Majority of respondents who have used drugs in last sexual contact have also not used condoms or visited and sexual health service during past 6 months. Majority of respondents who used drugs in sexualized settings were unaware of any harm reduction services that they could access in their cities. They are also unaware of PrEP and PeP and due to stigma and discrimination are unwilling to access sexual health services.
Conclusions: Comprehensive interventions should be implemented to address the psychosocial issues of young gay, bisexual MSM in general. More effective partnerships should be developed between organizations working on gay, bisexual, MSM communities and communities of people who use drugs to create service provision, care and harm reduction service linkages. More research needs to be done to gather strategic information to develop targeted interventions for young gay, bisexual, MSM who use drugs in sexualized settings.

WEPED460

Chemsex among men who have sex with men in Singapore and the challenges ahead: A qualitative study

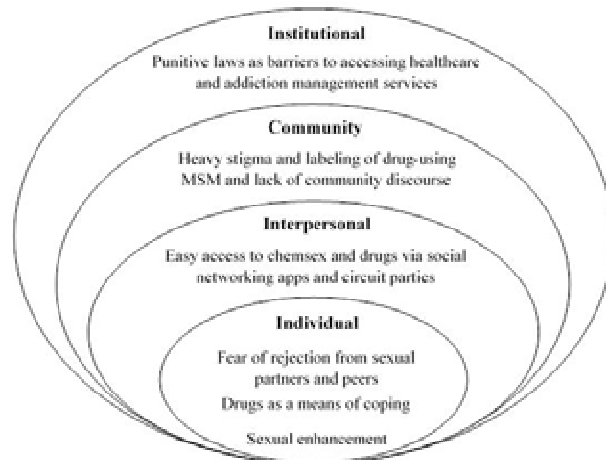
R.K.J. Tan[1], C.M. Wong[2], M.I.-C. Chen[1,3], Y.Y. Chan[3], M.A. Ibrahim[3], O.Z. Lim[3], M.T.-W. Chio[4], C.S. Wong[3], R.K.W. Chan[4], L.J. Chua[5], B.C.H. Choong[3]
[1]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [2]Family Health International 360, Durham, United States, [3]Tan Tock Seng Hospital, Institute of Infectious Diseases and Epidemiology, Singapore, Singapore, [4]National Skin Centre, Department of STI Control (DSC) Clinic, Singapore, Singapore, [5]National University of Singapore, Faculty of Law, Singapore, Singapore

Background: Sexualized substance use, or 'chemsex' has been shown to be a major factor driving the syndemic of HIV/AIDS in communities of gay and bisexual men around the world. However, there is a paucity of research on chemsex among men who have sex with men (MSM) in Singapore due to punitive drug laws and the criminalization of sexual behavior between men. This qualitative descriptive study is the first to explore perceptions towards, motivators to engaging in, and the barriers to addressing chemsex among MSM in Singapore.
Methods: We conducted 30 semi-structured in-depth interviews with a purposively recruited sample of self-identified MSM between the ages of 18 to 39 in Singapore. Maximum variation sampling was employed to ensure a diversity of responses from MSM of varying socioeconomic backgrounds, relationship status, and HIV/STI status. Topics included participants' perceptions of drug use in the community, perceptions towards chemsex, reasons for drug use and chemsex, the impact of drug

use on the MSM community, and recommendations to help address chemsex among MSM in Singapore. Interviews were audio-recorded, transcribed, coded, and analyzed through an inductive analytical approach.

Results: Participants reported that it was common to encounter chemsex within the Singaporean gay scene as it could be easily accessed or initiated using social networking phone apps, but is often a surreptitious act that takes place overseas or away from the community's view. Enhancement and prolongation of sexual experiences, fear of rejection from sexual partners and peers, and its use as a coping mechanism were three main reasons cited for engaging in chemsex, while the impact of punitive drug laws on disclosure and stigmatization of drug users within the community were thought to be key barriers towards addressing chemsex. Participants suggested using MSM-specific commercial venues as avenues for awareness and educational campaigns, and social media to reach out to younger MSM.

Conclusions: This study highlights the complexities behind chemsex use in the MSM community, and the range of individual to institutional factors to be addressed. We recommend that community-based organizations and policy-makers find ways to destigmatize discussion of chemsex and provide safe spaces to seek help for drug use.



[Socio-ecological framework of factors driving chemsex among MSM]

WEPED461

A community health worker intervention for HIV-infected drug users in Vietnam

L. Li[1], J. Hsieh[2], C. Lin[1], S.-J. Lee[1], C.-W. Lan[2], A.T. Le[3], A.T. Nguyen[3]
[1]Semel Institute/University of California Los Angeles, Department of Psychiatry and Biobehavioral Sciences, Los Angeles, United States, [2]UCLA Center for Community Health, Los Angeles, United States, [3]National Institute of Hygiene and Epidemiology, Hanoi, Vietnam

Background: Countries with limited resources, such as Vietnam, need interventions that target not only key populations but also community health workers (CHW). Our intervention program aims to enhance CHW's capacities to effectively interact with people living with HIV and using drugs (PLHUD) to achieve optimal HIV and drug use prevention and treatment outcomes.

Description: Utilizing CHW as a vehicle and social media as a support platform, we develop and test the Vietnam Providers Network (VPN) Intervention to improve CHW's collaborations with methadone maintenance therapy (MMT) and antiretroviral therapy (ART) treatment providers, enhance outreach and communication skills with PLHUD, and ultimately increase service referrals for PLHUD. Eighty CHW and 240 PLHUD are recruited from 40 communes in four Northern provinces of Vietnam. The VPN Intervention includes two group training sessions, and Facebook groups are formed immediately after the second session. CHW joins the Facebook groups established from the previous study phase to promote virtual communications/collaborations with treatment providers across MMT and ART treatment agencies. Reunion sessions take place every two months to review progress and share challenges and solutions during the entire 12-month follow-up period.

Lessons learned: Our previous intervention projects have demonstrated the efficacy of using communication tools such as "motivational ruler" and "decisional balance sheet" to improve communication skills of CHW. The current study will take full advantages of these tools and combine them with Facebook groups. The Facebook network approach has shown to be an effective tool to enhance communications between treatment providers in this study. To involve CHW in the treatment providers' network will present opportunities for CHW to communicate directly with MMT and ART treatment providers and to strengthen their roles in treatment initiation and adherence for PLHUD. Several proven effective monitoring strategies are used to address implementation challenges in intervention delivery and evaluation.

Conclusions/Next steps: Our program combines proven effective communication tools with new social media platform for CHW's capacity building. We still need to explore ways on how to translate enhanced communications within the providers' network to maximize referrals in practice for the HIV care continuum.

WEPED462

Building workforce capacity to address HIV and substance misuse in rural areas

L.R. Frank
University of Pittsburgh, Graduate School of Public Health, Infectious Diseases and Microbiology, Pittsburgh, United States

Background: The US HIV epidemic has been negatively impacted by the increase in substance use and misuse particularly in rural areas. Rural areas are a distinct disadvantage due to fewer health professionals, lack of transportation, funding for services, stigma, and service coordination. These gaps were assessed through a needs assessment conducted by federally funded training centers to identify priorities for training, technical assistance for capacity development.

Description: The survey instrument (PRO14030407) was sent via email to 15,000 health professionals who attended HIV, substance use, and STI training in 2014. The instrument has been previously piloted in 2012 and revisions made to improve the domains of survey questions that included: HIV clinical management, behavior change,psychosoical issues, STIs, hepatitis, substance treatment. Respondents across all disciplines and domains rated the need for training on substance use and misuse (41%)and psychiatric illness(40%)in HIV patients as priorities. Across all disciplines, triple diagnosis of HIV, substance use and mental illness was ranked first in education and technical assistance need. Rural health professionals of which nurses were the largest number (28%) indicated significant need in increasing knowledge and skills for treating triply diagnosed patients.

Lessons learned: Health professionals continue to remain in acute need of education and training related to substance use, misuse, and mental illness treatment and intervention. This study demonstrates the need is equal to education related to treatment of HIV, hepatitis, and STIs. The study demonstrates that this need is particularly acute for nurses, nurse practitioners and social service providers who comprise important members of the HIV treatment team which is essential to improving the HIV care continuum. Prioritization of training and technical assistance curriculum is needed for practicing health professionals as well as education in medical, nursing, and allied health professions schools.

Conclusions/Next steps: The need for capacity building within health professionals is critical to address the co-morbidities of substance use/misuse and mental illness is critical. In the US and around the world, substance use and mental illness is contributing to increases in HIV, hepatitis, and STIs because both of these disorders put individuals at risk; interfere with treatment adherence, and impede engagement and maintenance in care and treatment.

WEPED463

Risky injection practices and knowledge regarding HCV: A respondent-driven sampling study among people who inject drugs in the Chiang Mai Province, Thailand

M. Prouté[1], S. Le Coeur[1], M. Tiv[1], T. Dub[1], C. Angkurawaranom[2], A. Aramrattana[2], M. Lallemant[3]
[1]French Institute for Demographic Studies (INED), Mortality, Health and Epidemiology Unit, Paris, France, [2]Faculty of Medicine, Chiang Mai University, Department of Family Medicine, Chiang Mai, Thailand, [3]French National Research Institute for Sustainable Development (IRD), IRD174/ PHPT, Marseille, France

Background: In Thailand as in most countries, people who inject drugs (PWID) are the most exposed group to HCV and HIV/HCV coinfection. Drug use remains highly criminalized and PWID have limited access to care due to their marginalization. Harm reduction services are still scarce and are mainly provided by civil society organizations supporting drug users. The objective of our study was to inform a future national HCV policy aiming to control the epidemic in Thailand.
Methods: We used a respondent-driven sampling (RDS) methodology, adapted to hard-to-reach populations. Social and behavioral data were collected with a face-to-face questionnaire. Results were weighted in the analysis using the „Successive Sampling" estimator to limit biases related to the non-random sampling method.
Results: 171 PWID were recruited between April 2016 and January 2017. The average age was 34 years old (range 18-62 years old); 11% were women; 49% belonged to a minority ethnic group. The most frequently injected drugs were heroin
(77% of participants), methadone (21%) and methamphetamine (21%). 22% [95CI 16-29] had shared their needles in the last 6 months and 32% [95CI 24-40] their injection material. Only 27% [95CI 18-35] of PWID had heard of HCV; factors independently associated were membership in a support group for drug users (aOR = 5.1 [95% CI 1.8-14.3]), ethnic group (Lahu aOR = 0.3 [95CI 0.1-0.9]) and voluntary participation in a drug rehabilitation program (aOR = 4.9 [95CI 1.5-16.7]).
5% [95CI 3-8] of participants were screened for HCV; the only factor independently associated was membership in a support group for drug users (aOR = 5.7 [95CI 1.6-19.9]).
Conclusions: The PWID population is poorly informed and screened for HCV despite widespread risky injection practices.
A public health approach aimed at reducing the incidence of HCV will need to target this population by combining rapid diagnosis, direct-acting antivirals and harm reduction measures, and a massive campaign of information and destigmatization, such as the one successfully implemented for the fight against HIV/AIDS in Thailand. Such approach should be launched in collaboration with the civil society organizations already working with PWID, whose actions have shown positive results on level of knowledge and screening of HCV.

WEPED464

Community mobilisation approach: A method for linking drug users to HIV, STI and harm reduction services

W.T. Lotic[1,2,3], E. Muhwezi[4], C. Baguma[4]
[1]Uganda Harm Reduction Network, Health and Human Rights, Kampala, Uganda, [2]International Drug Policy Consortium, Network Member, London, United Kingdom, [3]Eastern Africa Harm Reduction Network, Network Member, Kampala, Uganda, [4]Uganda Harm Reduction Network, Programs, Kampala, Uganda

Background: Injecting-drug users (IDUs) are a hidden community who are unable to access HIV and harm reduction services. These populations rarely access social and health services where they can be identified and documented due to fear of stigma and/or arrest by law enforcers. As a result, there is a high prevalence of HIV and STIs among this network. The 2013 mapping and size estimation of IDUs in Kampala (AMICAALL et al, 2013) indicated that there were 46 IDUs found in three divisions of Kampala. Another similar study in 2012/13 by Crane survey of high-risk populations found 1,170 habitual consumers of drugs in greater Kampala, suggesting the possible existence of a large number of IDUs in Uganda (MoH et al., 2013).
Description: UHRN uses community mobilization approach to reach this hidden population. This bottom-up approach has proved effective in addressing local needs of IDUs and linking them to HIV services. This has been made possible through interaction, integration and coordination with peers, other stakeholders and implementing partners. Peers have been trained on HIV and harm reduction services and are able to identify drug users and link them to various service providers. This approach has enabled UHRN to reach a wide number of IDUs and as a result the approach has contributed to adherence of IDUs to health services. However, this approach has worked in a few communities yet there are a number of drug users with health risks across the nation.
Lessons learned: Since January 2017, the approach has helped over 200 PWUDs to access HIV services from UHRN and partner organizations.
In order for the approach to be sustainable, peers need to be motivated financially to reach the hidden communities, improve visibility and build their capacity on human rights.
There is still a big gap to be filled by research in order to establish the magnitude of the drug users country wide.
Conclusions/Next steps: The approach has worked in the mobilization and engagement of PWUDs in outreach programs and thus helped to realize increased uptake of HIV and harm reduction services by IDUs. UHRN recommends scale up of this approach to other areas.

WEPED465

Satellite centers for women using drugs (WUD): Innovation to address neglect in drug-related treatment management programs in Northeast India

A. Singh[1], B. George[2], P. Goswami[2], S. Mathew[2], N. Bakshi[2], S. Kumar[3], T.H. Holtz[3]
[1]FHI 360, Project Sunrise, Delhi, India, [2]FHI 360, Delhi, India, [3]Division of Global HIV and TB, Centers for Disease Control and Prevention, Delhi, India

Background: Opioid Substitution Therapy (OST) with buprenorphine is part of India's harm reduction strategy for people who inject drugs (PWID). Buprenorphine is dispensed at government-accredited non-government organization (NGO) and government facility-based OST centers. The majority of PWID clients accessing OST are men, and women who use drugs (WUD) are uncomfortable attending OST centers. Often, services are not women-friendly, and apprehension persist on disclosure of status as drug users. Although there are no exclusive OST centers for WUD, NGOs do provide harm reduction services for them in drop-in centers (DIC).
Description: In 2017, Project Sunrise, implemented by FHI 360 and funded by Centers for Disease Control and Prevention (CDC), in the Northeast state of Manipur, consulted WUD to ascertain reasons for low OST enrolment. Perceptions that services are men-centric, and fear of disclosure,

were cited as reasons for poor enrollment in OST. Thus, Satellite OST Centers were established in two DICs for WUD. OST medication was transported every two weeks from the nearest government-accredited OST center, and doctors/nurses visited these DICs every week for induction of WUD and dose management. The pre-established/accredited center is referred to as a "base" center, and the DIC for WUD is termed a "satellite" of the government center that is linked to the base for medication and personnel.
Lessons learned: Enrolment of WUD to OST increased after establishment of satellite OST centres. Within three months, nearly 100 WUD not accessing OST previously registered for OST. Presently >50% of these WUD (55) are taking OST daily for at least 15 days in a month.
Conclusions/Next steps: A A collaboration of NGOs and government can ensure OST access to sub-populations who do not visit "mainstream" facilities. The OST satellite model could be applied to other sub-populations at risk such as young/adolescent PWID, and hard to reach PWID in remote locations. For WUD, the linkage to OST should be treated as an entry point for other services such as HIV testing, ART, sexual and reproductive health services, hepatitis C management, and re-integration into society.

WEPED466

Effect measure modification of association between HIV status and recent overdose among OAT patient in Ukraine

A. Mazhnaya[1,2], F.L. Altice[3,4]
[1]ICF Alliacne for Public Health, Treatment, Kyiv, Ukraine, [2]Johns Hopkins School of Public Health, Department of Health, Behavior, and Society, Baltimore, United States, [3]Yale University School of Medicine, Section of Infectious Diseases, AIDS Program, New Haven, United States, [4]Yale University School of Public Health, Division of Epidemiology of Microbial Diseases, New Haven, United States

Background: Research results suggest that HIV positive people who inject drugs may be at heightened risk for opioid overdose. Demonstrated estimates of associations between HIV and overdose, however, have high heterogeneity suggesting potential interactions with individual and context-specific factors. Opioid agonist therapy (OAT) has been shown to reduce overdose and increase HIV outcomes among PWID, however, its role in the association of HIV infection and overdose remain a research gap. This study aims to investigate whether OAT modifies association between HIV status and risk of recent non-fatal overdose.
Methods: The data for this investigation come from cross-sectional stratified survey of opioid dependent PWID followed by HIV testing in five Ukrainian cities. Opioid dependent PWID (N=1,357) were sampled from January 2014 to March 2015. Using weighted log-binomial regression model we estimated independent and interactive association between HIV status, receipt of OAT and recent (6 month) overdose controlling for age, sex, hazardous drinking, addiction severity, presence of depressive symptoms and unstable housing.
Results: Majority of the sample were male (78%) in their thirties, and less than 5% reported unstable housing. Four out of every ten participant were tested HIV positive and 8% reported experiencing non-fatal overdose within last 6 months. By survey design 31% of the sample were on OAT. Forty four percent of the sample reported hazardous drinking while 60% reported being depressed. In the adjusted multivariable model HIV positive compared to HIV negative status has been independently associated with 20% increase in prevalence of recent overdose (prevalence ratio(PR):1.20, 95% CI 0.78-1.85) among those not on OAT. Being on OAT independently was associated with 60% decrease in prevalence of recent overdose (PR: 0.34, 95%CI: 0.18 - 0.66) compared to those who were not on OAT among HIV negative. Testing HIV positive and receiving OAT, however, were associated with a 2.4- fold increase in reported prevalence of recent overdose (PR: 2.39, 95% CI 1.18 - 4.84), suggesting that OAT modifies the association between HIV status and recent overdose.
Conclusions: These results suggest that factors contributing to heightened prevalence of non-fatal overdose among HIV positive OAT patients should be further investigated and addressed.

WEPED467

Under multiple oppressions: Identifying the main trends in violence against women who use drugs in Georgia

E. Gardapkhadze, M. Khmelide
Aceso, International Organisation for Women, Tbilisi, Georgia

Background: Violence against Women (VAW) is a global issue. Women using drugs become victims of structural violence produced by punitive and repressive drug policy that maximizes the harms caused by drug addiction. Evidence is lacking that would enable the state to implement targeted interventions and monitoring of situation. To fill this gap, Aceso, carried out a qualitative research, which focused on identifying the main trends of rights violation in relation to systemic, domestic, sexual and other types of violence.
Methods: A qualitative research using focus group discussions were carried out by a research team, which made in-depth analysis of complex issue of violence. Each of 6 focus groups had 6-8 (46 in total) women, aged 27-54. Participants were selected among recipients of Opiate Substitution Treatment, Needle Exchange Program, convicted for drug use and possession. All participants were residents of the capital city Tbilisi.
Results: The respondents believe that violence against them is expressed not only in physical and verbal abuse, but also in total control and harassment they have experienced from their families. Most of the cases of domestic violence were associated with spouses or former spouses. All of the respondents with this experience mentioned that they have never approached to law enforcement agencies for the help as it was the same structures who were violating their rights systematically. In this sense, drug user and commercial sex worker women are the most vulnerable. The respondents of the study had been jailed mainly for drug use, possession and other non-violent crimes. Most of the respondents who had previous imprisonment experience mentioned that their rights were violated during the incarceration episode. Non-informing about their rights, physical violence, threatening, verbal abuse were some of the examples recalled by respondents.
Conclusions: Violence against women who use drugs is expressed in physical or verbal abuse, as well as in excretion of a total control and threats from different members of their families. Most frequently abusers are current or former husbands or parents. Furthermore seeking protection, such as from police or relatives, seeking shelter, disclosing facts of violence via media/social media proves to be impossible.

Sex workers

WEPED468

Political impunity and HIV vulnerability among Haitian female sex eorkers in the Dominican Republic

E. Felker Kantor[1], Y. Donatstorg[2], B. Gomez[3], K. Andrinopoulos[1]
[1]Tulane School of Public Health and Tropical Medicine, Global Community Health and Behavioral Sciences, New Orleans, United States, [2]Instituto Dermatologico Dominicana y Cirugia de Piel, Santo Domingo, Dominican Republic, [3]Centro de Promocion y Solidaridad Humana, Puerto Plata, Dominican Republic

Background: In the Dominican Republic (DR), Haitian female sex workers (FSWs) are at increased risk for HIV (5.4% HIV prevalence vs. 0.7% national HIV prevalence). Haitian FSWs in the DR exist in a context of political impunity resulting from lack of citizenship and the liminal criminality of sex work. Exploratory research was conducted to understand the vulnerability of Haitian FSWs to HIV in the DR.
Methods: In-depth interviews were conducted with 40 FSWs of Haitian descent (two interviews each) in Puerto Plata (n=20) and Santo Domingo (n=20). Semi-structured guides asked about sex work, family and social networks, HIV risk behavior, gender and ethnic identity following an intersectional framework. Interviews were recorded and transcribed for thematic analysis.

Results: Participants reported high risk for HIV including low HIV knowledge, alcohol use prior to sex, and challenges in negotiating condom use with clients. Relative to Dominicans, participants reported that they were more likely to be street-based (versus venue), charged less per client, and were more often threatened by the client for deportation. While described as not ideal, sex work was noted as one of the few economic opportunities available to Haitian women. Participants described both spiritual and biomedical illness narratives related to HIV. Discrimination in the healthcare setting was reported, but access to HIV testing and care was seen as feasible. Participants reported experience with and fear of violence from male clients.
Conclusions: Haitian FSWs, similar to other stateless populations globally, are doubly at risk for HIV and in need of increased access to HIV education, substance use services, and condom negotiation skills. Street-based sex work combined with the threat of deportation increases their risk of violence and lowers their ability for condom negotiation. Health services targeted to this population should accommodate their belief in both spiritual and biomedical causes of HIV.

WEPED469

Overcoming challenges in developing a sustainable cervical cancer screening program in Limpopo Province, South Africa: Training of health workers and sex worker advocates

C. Du Preez
Hoedspruit Training Trust, Health, Hoedspruit, South Africa

Background: A major challenge to successful cervical cancer screening is lack of knowledge about the disease. To prepare for integrating screening into current HIV care, a teaching program was designed. The objective was to close the gaps in knowledge for HIV advocates and deliver training in "see and treat" skills to local providers.
Description: Institutional review board approval was obtained from within the United States and South Africa. Workshops were hosted at an HIV clinic in rural South Africa. Thirteen sex worker advocates who function as lay health workers for HIV awareness participated in a one-day cervical cancer awareness program. Five nurses underwent a 4-day workshop in cervical cancer screening using pre /post- knowledge study design. Four didactic modules were presented with additional visual aids and model demonstrations where appropriate. Nurses were then evaluated one year after initial training to assess for quality and performance in cervical screening technique.
Lessons learned: Advocates completed a questionnaire on demographics and knowledge of risk factors for cervical cancer. None of the 13 sex worker advocates had previous knowledge of cervical cancer and all reported acquiring new knowledge that would benefit their community. Sex worker advocates reached out to co-workers and encouraged 84 additional advocates to participate in the screening program. Five nurses were successfully trained in "see and treat" to a level of competence in which they could practice independently. Providers were supervised in the care of 80 patients each on average, with adequate skills obtained after 50 exams. Knowledge markedly increased at the end of training as demonstrated by the post-test. Evaluation by trainers after one year showed screening was being performed correctly by the trained providers. However, additional qualitative interviews showed an expressed need for further education on cervical cancer and screening guidelines.
Conclusions/Next steps: We demonstrate successful teaching of sex worker advocates as lay health workers for increasing community cervical cancer awareness. Additionally we report on successful clinical training of five nurses to be primary providers to ensure a sustainable screening program. There is a further need for additional education for nurses and patients in rural areas on cervical cancer screening.

WEPED470

Cervical cancer screening in rural South Africa among HIV-infected Migrant farm workers and sex workers

E.C. Du Preez[1], O.,. Afzal DO[2]
[1]*Hoedspruit Training Trust, Management, Hoedspruit, South Africa,* [2]*Hoedspruit Training Trust, Health, Hoedspruit, South Africa*

Background: National Policy for cervical cancer screening in South Africa is 3 lifetime pap smears; however some services screen more frequently for high risk women with annual pap smears. At an HIV clinic in the Limpopo province, chart reviews revealed long delays in addressing abnormal Pap smears, difficulty in referrals, poor quality and lost results. To address these barriers, a "see and treat" approach to screening was proposed. The objective was to integrate this method into current HIV care offered by local providers and to obtain demographic and risk factor data for use in future educational and intervention programs in the region.
Description: Institutional review board approval was obtained from within the United States and South Africa for a cross sectional study of HIV farm workers and at-risk sex workers attending an HIV clinic. Five local nurses who had undergone training in see-and-treat screening were the primary providers, administering interview questionnaires and performing visual inspection with acetic acid (VIA) on all consenting participants. Those with positive screens were offered cryotherapy. Clinic charts were reviewed retrospectively for Pap smear results for the previous year. SPSS was used for analysis of all data.
Lessons learned: A total of 403 participants consented and underwent screening with VIA (306 Farm workers and 97 sex workers participated). 83.9% of participants (32.9% sex workers and 100% farm workers) were HIV+. VIA was positive in 30.5% of participants. Cryotherapy was performed on 114 participants; 5 women failed to return for treatment and 4 women were referred for suspicion of cancer. There was no significant difference in VIA positivity between HIV+ farm workers and sex workers (Table 1). Pap smear results were available on 54.8% of participants, of which 26.7% were abnormal. There was a positive correlation between Pap smears and VIAs results (Table 2).
Conclusions/Next steps: We demonstrate successful integration of cervical cancer screening using VIA for HIV+ farm workers and sex workers into an existing HIV treatment and prevention clinic in rural South Africa. Using the see-and-treat approach and following guidelines for triaging of positive screens, abnormal results can be readily addressed and treated promptly

WEPED471

Need for intensified interventions among brothel-based female sex workers in Mumbai, India

S. Acharya[1], S. Katkar[2], S. Joshi[3], S. Venkatesh[4], M.S. Setia[5], P. Keskar[2]
[1]*Mumbai Districts AIDS Control Society, City AIDS Control, Mumbai, India,* [2]*Mumbai Districts AIDS Control Society, Mumbai, India,* [3]*Mumbai Districts AIDS Control Society, TSU, Mumbai, India,* [4]*National AIDS Control Organization, New Delhi, India,* [5]*Consultant, Mumbai, India*

Background: Female sex workers (FSWs) have been the focus of targeted interventions (TIs) for a long time in India. However, there has been a reduction in brothel based sex work, and a higher proportion of female sex workers are now home based, street based, or bar based. We compared sexual behaviour and infections (HIV positivity and VDRL reactivity) among different types of FSWs.
Description: We used programmatic data from 19,547 FSWs collected as a part of the Individual Tracking System. We used data on age, type of sex work, risk assessment, condom use, and STI positivity (including syphilis and HIV). We used poisson regression models to estimate incidence ratios (IR) and 95% confidence intervals (CI).
Lessons learned: Overall, the proportion of syphilis positivity was 0.19% (95% CI: 0.13%, 0.25%), HIV prevalence was 0.31% (95% CI: 0.23%, 0.39%), and HIV incidence was 0.14% (95% CI: 0.10%, 0.21%). Demographic, risk, and health data are presented in Table 1. Street based (IR: 1.44, 95% CI: 1.35, 1.53) and home based (IR: 1.46, 95%: 1.39, 1.53) FSWs were more likely to get tested for syphilis compared with brothel based sex workers. Bar

girls were less likely to be VDRL reactive compared with brothel based FSWs (IR: 0.035, 95% CI: 0.15, 0.84). After adjusting for age and condom use during last sex, the incidence of HIV was significantly lower for home based (IR: 0.06, 95% CI: 0.02, 0.22) and bar girls (IR: 0.08, 95% CI: 0.03, 0.26) compared with brothel based FSWs. However, there were no significant differences in the street based (IR: 0.32, 95% CI: 0.07, 1.36) and brothel based FSWs. FSWs who had used a condom in the last sex act were less likely to become HIV infected (IR: 0.15, 95% CI: 0.06, 0.34).

Conclusions/Next steps: Even though, brothel based FSWs have high risk behavior and high incidence of STIs including HIV; they are less likely to get tested for syphilis and HIV. Thus, they should remain the focus of prevention programmes and targeted intervention programmes should be intensified in this vulnerable group.

		Brothel based n=4761	Street based n=1767	Home based n=5733	Bar girls n=7286	p value
Age	Mean (SD)	30.4 (5.4)	30.7 (6.9)	29.5 (6.8)	26.3 (4.9)	<0.0001
Risk assessment	High volume sex (> 15/week)	4271 (90)	1207 (68)	421 (7)	295 (4)	<0.001
	Condom use during last sex act	3715 (78)	1452 (82)	2087 (36)	3416 (47)	<0.001
Health care access	Tested for syphilis	2404 (50)	1263 (71)	3880 (68)	4028 (55)	<0.001
	Tested for HIV	3184 (67)	1587 (90)	5387 (94)	6189 (85)	<0.001
Health outcomes	Had an STI	585 (12)	246 (14)	609 (11)	880 (12)	0.001
	VDRL reactive	15 (0.32)	2 (0.11)	11 (0.19)	9 (0.12)	0.10
	HIV Prevalence	36 (0.76)	6 (0.34)	10 (0.17)	8 (0.11)	<0.001
	HIV Incidence	19 (0.40)	2 (0.11)	3 (0.05)	4 (0.05)	<0.001

[Comparison of demographics, sexual behavior and HIV/STI infections in different types of female sex workers, Mumbai, India]

WEPED472

Characterizing the influence of structural determinants of risk on consistent condom use among female sex workers in Senegal

J.O. Twahirwa Rwema[1], C. Lyons[2], S. Ketende[2], D. Diouf[3], G. Turpin[2], B. Liestman[2], S. Mboup[4], D. Castor[5], S. Baral[2]
[1]Johns Hopkins Bloomberg School of Public Health, Public Health, Kigali, Rwanda, [2]Johns Hopkins University, Epidemiology, Baltimore, United States, [3]Enda Sante, Dakar, Senegal, [4]Institut de Recherche en Santé, de Surveillance Epidemiologique et de Formations, Dakar, Senegal, [5]USAID, Bureau for Global Health, Arlington, United States

Background: Female Sex Workers(FSW) are disproportionately affected by HIV, even in the most generalized HIV epidemics. While structural HIV risks have been understood to mediate condom negotiation among FSW globally, there remains limited data on the relationship between structural determinants of HIV risk including violence and socioeconomic-status and condom use among sex workers across Sub-Saharan Africa. Here, we describe the prevalence of structural determinants and their associations with condom use among FSW in Senegal.

Methods: In 2016, 758 FSW ≥18 years of age were recruited by Respondent Driven Sampling (RDS) in Senegal. Information on individual, community, and network-level risks were collected through an interviewer-administered questionnaire. Poisson regression with robust variance estimation was used to model the associations of consistent condom use (CCU) and selected structural determinants.

Results: The RDS-adjusted prevalence of CCU in the last 10 sexual acts was 76.8%(95%:CI: 70.8-82.8). In the bivariate analysis, CCU was associated with being legally registered as FSW prevalence ratio PR:1.13 (95% CI:1.05-1.21), stigma PR: 0.98 (95% CI:0.97-0.99), participation in HIV prevention organization PR: 1.08 (95% CI:1 -1.16), being offered more money for condomless sex PR: 0.82 (95%CI: 0.73-0.93), recent drug use PR: 0.87 (95% CI: 0.75-1.0) and STI symptoms in the 12 months preceding the study PR:0.89 (95%CI: 0.83-0.88).

In the multivariable RDS adjusted analysis, structural determinants that remained significantly associated with lower CCU were: sexual violence adjusted prevalence ratio aPR: 0.67 (95% CI: 0.44-1.0), physical violence aPR: 0.73 (95% CI: 0.53-0.99) and difficulty to access condom aPR: 0.45 (95% CI: 0.23-0.87). High income from sex work was associated with higher CCU aPR:1.22 (95% CI:1.03-1.45) after adjusting for demographic characteristics and other determinants.

Conclusions: Taken together, these data highlight the role of structural risk determinants on condom use among FSW in Senegal. Moreover, these results highlight the importance of structural interventions including safe working spaces and violence mitigation programs to support condom negotiation in addition to condom distribution programs to ultimately increase condom use among FSW with their clients and other sexual partners in Senegal.

WEPED473

"I would like not to answer this question": Violence, police and sex work in Ukraine

N. Dorofieieva[1], N. Isaieva[1], A. Tokar[2]
[1]Ukrainian Charitable Organisation 'Legalife-Ukraine', Kropivnickyi, Ukraine, [2]ISGlobal, Barcelona Institute for Global Health, University of Barcelona, Hospital Clinic - Universitat de Barcelona, Barcelona, Spain

Background: Currently in Ukraine, sex work is prosecuted by administrative and criminal laws fuel stigmatization of sex workers (SWs) and lead to a violation of their human rights. Prohibition of sex work results in stigma and discrimination, social exclusion, unsafe working conditions, poor occupational health, low self-esteem, restriction on housing, travel and parenting. Thus, we aimed to examine experience of violence among SWs in Ukraine.

Methods: During July-August 2017, 175 structured interviews, 3 focus group discussions (N=24) with SWs and 14 in-depth interviews with stakeholders (representatives of none-governmental organizations, health care providers, SWs' managers, etc) were conducted in 8 regions of Ukraine: Donetsk, Kyiv, Kropivnytskyi, Kryvyi Rig, Nikolaev, Odessa, Zhytomir, Vinytsya. Convenient sampling strategy was applied. Structured interviews were analyzed using SPSS software; all qualitative data was transcribed and then hand coded using inductive technique.

Ethical approval was obtained from the Research Ethics Boards of the Committee on Medical Ethics of the Gromachevsky Institute of Epidemiology and Infectious diseases.

Results: In total we recruited 165 females, 7 males and 3 transgenders, aged 17-50 years old. The majority started working between 15-22 years old and was engaged in SW for 5-10 years, had full secondary education. The majority of SWs experienced violence (80%) during last year, with psychological violence (75%) being the dominant form. Half of respondents experienced sexual violence. Chances to experience violence increased with years of engagement in sex work (Table 1). Clients and police were two most commonly named sources of violence. Only 15% of victims applied for help, and only few applied to the governmental structures. During in-depth interviews most SW managers were not willing to respond on questions regarding police; still, bribes was the most common ways to deal with police raids. SWs and stakeholders were arguing for decriminalization or legalization of SW as an effective strategy to decrease abuse by the police and to promote utilization of health care services.

Conclusions: Most SWs in Ukraine face violence regularly with clients and police have been most common sources of it. Changes of current SW-related policies might decrease level of violence and support basic human rights of SWs.

Years of engagement in SW	Forms of violence, %			
	Psychological	Physical	Sexual	Economical
≤1 year	50	43	50	14
1-3 years	63	51	46	29
3-5 years	77	70	63	40
5-10 years	84	66	71	55
>10 years	83	73	71	56
Total	75	63	63	44

[Experience of violence among sex workers across 8 regions Ukraine, 2017.]

WEPED474

A randomized controlled trial to test a cognitive behavioral and structural HIV prevention intervention for Ugandan sex workers 15- to 24-years old

R. King[1], M. Nakitto[2], D. Bagiire[2], O. Kamacooko[2], L. Butler[3], J. Seeley[4]
[1]University of California, Kampala, Uganda, [2]Medical Research Council, Kampala, Uganda, [3]University of Connecticut, Storrs, United States, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom

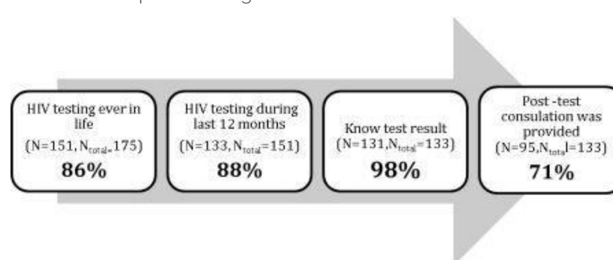
Background: Women 15-24-years old engaging in high-risk sexual behavior, young sex workers (YSW) are a key population in sub-Saharan Africa; HIV prevalence is estimated at 26% compared to 4.9% national prevalence among this group. YSW are especially vulnerable to HIV due to male partner dominance, difficulties negotiating safe sex with clients. HIV-negative YSW are particularly at risk for sexually transmitted infections, including HIV, and unplanned pregnancies. Services are limited for YSW due to stigma and discrimination.
We are currently conducting a randomized controlled trial to test the effectiveness of a combination cognitive-behavioral and structural HIV prevention intervention in Uganda. Our conceptual framework was built on individual, dyadic and structural constructs that formed risk profiles of our population. We developed an intervention to address multi-level risks and vulnerabilities and present on baseline findings.
Methods: Audio Computer Assisted Self Interview was used to administer questions about sexual activity and unprotected sexual exposures. To validate self-reported sexual behavior, a vaginal swab is collected to assess Y-chromosome sequences, a biomarker for unprotected vaginal intercourse. We describe two levels of descriptive and bivariate analysis to assess an association between empowerment variables as a mediator and baseline socio-demographic variables. We present percentages of key variables. At bivariate analysis, Chi-square distributions and Fisher's exact were used to assess associations.
Results: By 1 February, 277 of planned 450 participants have been enrolled. Forty-two percent of participants are between 15-19 years old and 58% are between 20-24 years old. Six percent have completed secondary school, 50% stated that they had a history of intimate partner violence, and 44% reported having used drugs or alcohol. There was a statistically significant association between education and key empowerment variables ($p< 0.05$), history of violence and empowerment ($p< 0.05$); those more educated being more likely to be empowered. The older age group was consistently more empowered, and more likely to use condoms; associations did not always reach significance.
Conclusions: A high level of vulnerability among young sex workers is related to a complex web of personal, relational, structural/environmental factors including education, alcohol use, violence, empowerment and ability to negotiate safer sex and a safer work environment.

WEPED475

Examining accessibility of health care services among sex workers across 8 regions of Ukraine: A mixed methods study

N. Isaieva, N. Dorofieieva, A. Tokar
UCO Legalife-Ukraine, Kropivnickyi, Ukraine

Background: Ukraine has been experiencing one of the fastest growing and largest HIV epidemics in Europe, with HIV prevalence to be around 7% among sex workers (SWs). Despite a widespread testing and free of charge treatment program, early diagnosis of HIV followed by the immediate start of antiretroviral therapy (ART) remains low. We aimed to identify potential barriers to access health care services, including HIV testing and treatment among SWs in 8 regions of Ukraine.
Methods: During July-August 2017, 175 structured interviews, 3 focus group discussions (N=24) with SWs and 14 in-depth interviews with stakeholders (representatives of none-governmental organizations, health care providers, SWs' managers, etc) were conducted in 8 regions of Ukraine: Donetsk, Kyiv, Kropivnytskyi, Kryvyi Rig, Nikolaev, Odessa, Zhytomir, Vinytsya. Convenient sampling strategy was applied. Structured interviews were analyzed using SPSS software; all qualitative data was transcribed and hand coded using inductive technique.
Ethical approval was obtained from the Research Ethics Boards of the Committee on Medical Ethics of the Gromachevsky Institute of Epidemiology and Infectious diseases.
Results: In total we recruited 165 females, 7 males and 3 transgenders, aged 17-50 years old. The majority started working between 15-22 years old and was engaged in SW for 5-10 years, had full secondary education, was unmarried.
66% of respondents have applied for medical health care service during the last 12 months, 26% had no need, and 8% (n=14) did not apply to any health service. The key reasons were: no money (17%), no time (14%), attitudes of health care workers (12%), and absence of trust (10%). Most SWs reported to be tested ever in life (86%), out of whom 88% were tested within the last year *(Figure 1)*; but out of 35 SWs living with HIV, only 16 were prescribed ART, and only 5 received it. The key barriers to start ART were: low trust in health care workers, low self-perceived risk, rejection to accept own HIV positive status.
Conclusions: Even though uptake of HIV testing is close to reach 90-90-90 goals, treatment level remains low. Current HIV treatment programs should urgently incorporate strategies to address persistent barriers and increase ART uptake among SWs.



[HIV testing among SWs across 8regions of Ukraine, 2017.]

A landmark ruling: A Zimbabwean sex worker-led success for human rights and health

M. Mokoele Ndlovu[1], N. Madonko[1], L.R.S. Werlich[2], S. Hendriks[2], S. Gcinekile Ndlovu[3], N. Jagessar[2]
[1]SRC, Buluwayo, Zimbabwe, [2]Aidsfonds, Sex Work Programme, Amsterdam, Netherlands, [3]Independent Consultant, Buluwayo, Zimbabwe

Background: Sex workers face unacceptable levels of violence, stigma and discrimination. It puts them in situations that make them considerably more vulnerable to HIV. Through advocacy work of SRC and ZLHR, the law on soliciting for the purposes of prostitution or loitering was correctly interpreted by the High Court of Zimbabwe, which saw an end to the arbitrary arrest and detention of sex workers in 2016. This abstract shows litigation has a positive effect to reduce violence and HIV risk.
Description: In Zimbabwe, selling sex is officially not a crime, however it is illegal to solicit clients, live on the earnings of sex work or to facilitate and procure sex work. Risks of violence, police abuse and lack of access to healthcare are higher when sex work is criminalized. In 2016, SRC and Aidsfonds conducted a mixed-method study among sex workers (N= 453 sex workers) that showed that 63% of sex workers in Zimbabwe experienced violence in the past year. In total, 32% of the cases were perpetrated by police. When arrested, sex workers were often denied access to ART and condoms were confiscated as evidence.
Lessons learned: Through an evaluation (N=50 sex workers), strategic litigation has proven to be effective, because the number of sex workers arrested dropped immensely. Consequently, sex workers are experiencing less violence by police. In addition, it resulted in increased respect of sex workers' rights among law enforcement staff. However, there were also unexpected outcomes, for example there was confusion about sex work being legalized. A negative outcome of the ruling is that sex workers are experiencing more violence perpetrated by clients, because law enforcement staff is no longer frequently patrolling the areas where sex workers work.
Conclusions/Next steps: Firstly, strategic litigation is an effective approach to reduce number of sex workers being arrested. Secondly, to reduce violence a holistic approach is needed that includes:

1) increasing awareness on the legal rights of sex workers,
2) strengthening sex worker movements, and
3) fostering partnerships with law enforcement and healthcare.
Finally, in order to reduce risks of violence and HIV, full decriminalization of sex work is needed.

WEPED477

Empowering female sex workers to advocate for integrated/comprehensive SRHR/HIV so as to reduce the negative effects of the HIV epidemic among female sex workers in Uganda

B.F. Azizuyo[1,2,3]
[1]*International Community of Women Living with HIV Eastern Africa, Project Officer, Wakiso, Uganda,* [2]*Makerere University, Kampala, Uganda,* [3]*Law Development Centre, Kampala, Uganda*

Background: Uganda has several Most at Risk Populations (MARPs) that are the leading sources of new HIV infections (*UAC MARPs Review 2014, page 6 and 9*) and have challenges accessing HIV and TB services A systematic review conducted in over 25 countries with medium and high HIV prevalence indicated that 36.9% of sex workers in sub-Saharan Africa (Uganda inclusive) were HIV positive with some countries having HIV prevalence as high as 70.7%. Female sex workers (FSWs) are at high risk of HIV infection and transmission by 24% among the youth.
Description: The International community of women living with HIV Eastern Africa with financial support from TASO (U) implemented a three month project in Mukono, Wakiso and Kampala districts. The purpose was to build capacity of selected health care providers from different health facilities in Kampala, Mukono and Wakiso Districts to deliver friendly services to female sex workers. ICWEA trained 73 peer leaders of female sex workers on SRHR/HIV and 70 health workers from 12 healthcare facilities across the three districts.
Lessons learned:
- There was a knowledge gap on PrEP. Amongst the sex workers but the training enlightened them and created demand for PrEP. across the three districts.
- 1063 sex workers were referred by the peer mobilisers to health centres in the three districts over the three months. 61 of these were below the age of 19, 213 in the age of 24 and 789 were 25years and above. Services accessed include HIV testing and counselling, ARVs, family planning and STI services
- Attitude of the trained health workers towards provision of services to sex workers improved. The project has been able to strengthen outreaches by health facilities to the hotspots in the three districts.
- While there was demand created for the SRHR/HIV services amongst sex workers, the biggest challenge was the stock out of essential drugs such as those used to treat STIs in the various health facilities.

Conclusions/Next steps:
- Follow up peer mobilisers to support sensitisation and referral of peers the health facilities.
- Replicate the work in other districts.
- Work closely with health workers to extend services to more hot spots.

WEPED478

Experiences of loss of a parent before age 18 among female sex workers across seven Western and Southern African countries

[1]*Public Health Solutions, Research and Evaluation, Brooklyn, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States,* [3]*Conseil National de Lutte contre le SIDA, Lome, Togo,* [4]*Universite de Lome, Lome, Togo,* [5]*Johns Hopkins University, Center for Communication Programs, Mbabane, Swaziland,* [6]*Institute de Recherche en Sciences de la Sante, Ouagadougou, Burkina Faso,* [7]*Programme d'Appui au Monde Associatif et Communautaire, Ouagadougou, Burkina Faso,* [8]*Côte d'Ivoire Ministry of Health and Public Hygiene/Ministère de la Santé et de l'Hygiene Publique, Abidjan, Cote D'Ivoire,* [9]*Care for Basotho, Maseru, Lesotho,* [10]*Care-Lesotho, Maseru, Lesotho,* [11]*Matrix Support Group, Maseru, Lesotho,* [12]*Enda Sante, Dakar, Senegal,* [13]*Gaston Berger University, Saint-Louis, Senegal,* [14]*North-West University, Potchefstroom, South Africa,* [15]*Human Sciences Research Council, Port Elizabeth, South Africa,* [16]*Arc-en-ciel, Lome, Togo,* [17]*Swaziland National AIDS Program, Mbabane, Swaziland*

Background: In 2015, UNICEF estimated that there were 49.4 million children in sub-Saharan Africa who had lost one or both parents to any cause of death, including 10.9 million due to HIV/AIDS. Concurrently, parents' death has been reported as a reason for entry into selling sex, but there are limited data characterizing the prevalence of orphanhood during childhood among female sex workers (FSW). This study assessed associations between loss of one's parents before the age of 18, self-reporting that a parent had HIV and selling sex under age 18 in seven sub-Saharan African countries.
Methods: FSW ≥18 years old were recruited from 2013-2016 through respondent-driven sampling in Burkina Faso, Cote d'Ivoire, Lesotho, Senegal, South Africa, and Togo and venue-based sampling in Swaziland to complete interviewer-administered surveys including a question about how many of their parents were still living and, if applicable, the participant's age when the first parent died. Bivariate logistic regression analyses were conducted using StataSE 14 to assess the relationship between reporting at least one parent died before the participant was 18 years old and selling sex < age 18.
Results: As shown below, 37.5% (1701/1435) of FSW reported at least one parent died before the participant was 18. Of those, 8.5% (125/1476) reported that their mother had been diagnosed with HIV, and 3.5% (46/1326) reported that their father had been diagnosed with HIV. 29.2% (486/1662) of FSW who lost at least one parent before age 18 started selling sex as minors, compared to 17.9% (467/2611) of those who did not (OR 1.90, p< 0.001). Swaziland was the only location where participants were asked about when their second parent died. 7.5% reported both parents died before the participant was 18. 36.8% of those who lost both parents before age 18 sold sex before age 18, compared to 14.7% of those who lost one or no parents before age 18 (OR 3.38, p< 0.0001).

Country	Sample size	1st parent died before participant was 18		2nd parent died before participant was 18		Orphaned <18, mother had HIV			Orphaned <18, father had HIV			Orphaned <18, sold sex <18			Not orphaned <18, sold sex <18

[Prevalence and correlates of orphanhood among female sex worker study participants, 2013-2016]

Conclusions: Orphans may be particularly at risk for exploitation and economic pressures leading to selling sex as a minor reinforcing the importance of providing child protective and social support structures.

WEPED479

Economic empowerment as a tool for HIV treatment and prevention among a sex worker collective in Nairobi, Kenya

J.M. Gathatwa[1], J. Mathenge[2], M. Njoroge[3], M.B. Clark[4]
[1]Health Options for Young Men on HIV/AIDS, STIs (HOYMAS), Research and Advocacy, Nairobi, Kenya, [2]Health Options for Young Men on HIV/AIDS, STIs, Nairobi, Kenya, [3]Health Options for Young Men on HIV/AIDS, STIs (HOYMAS), Nairobi, Kenya, [4]City University of New York, New York, United States

Background: Male sex workers (MSWs) remain at highest risk for HIV in Kenya. Despite robust HIV prevention and treatment programs, MSWs in Nairobi face structural and social barriers preventing equitable access to health care. Stigma, combined with criminalization of sex work (a primary source of economic support), pushes this population to live in extreme poverty, resulting in diminished health outcomes. Created by MSWs in 2009, Health Options for Young Men on HIV/AIDS and STI (HOYMAS) works to address this gap. One issue that sets HOYMAS apart is its novel approach to economic empowerment.
Description: Big Dreams is an Economic Empowerment Program (EEP) began by HOYMAS in 2015 to address the unique needs of the most vulnerable of MSWs. Many were HIV-positive, living on the street, struggling for food, and leaving antiretroviral treatment (ARV) adherence at a low priority. Substance and alcohol dependence was common and most sex work performed was survival-based, with little opportunity to improve economic situations. By humanizing their situation, peer educators (PE) and participants of Big Dreams were able to agree on key concepts for EEP: Ownership, Inclusivity, and Empowerment. From this place of mutual trust, the participants identified achievable economic, harm reduction, and wellness goals, arriving at a consensus for Empowerment Milestones. As a result, they were able to negotiate with clients for better pay leaving them better equipped to maintain supportive housing, adhere to medication, and improve nutrition.
Lessons learned: Through past initiatives with highly stigmatized populations, PE at HOYMAS knew it was critical to reach people at their level by working in hot spots and pubs frequented by MSWs. Today, Big Dreams has changed the economic future of more than 100 MSWs who had lost hope and given them a reason to dream again. Rates of ARV adherence has improved over 2016 and PrEP uptake for HIV negative MSWs has drastically improved. Most importantly, all have homes and are finally able to negotiate for better pay from clients.
Conclusions/Next steps: This approach of economic empowerment has managed to reach an otherwise inaccessible group of sex workers who avoided accessing services in mainstream clinics due to stigma and low self-esteem.

WEPED481

Achieving higher enrollment to care among female sex workers (FSW) recently diagnosed with HIV to ART care in Myanmar

Y.T.N. Oo[1], M.K. Lwin[2], L.L. Win[3], C.L. Oo[4], A.P. Phyo[4], H.N. Oo[5], P. Sone[6]
[1]Health System Research Division, Department of Medical Research, Yangon, Myanmar, [2]Save the Children, HIV/AIDS Global Fund, Yangon, Myanmar, [3]Health Systems Research Divison, DMR, Yangon, Myanmar, [4]Save the Children, Yangon, Myanmar, [5]National AiDS Program, Department of Public Health, Naypyidaw, Myanmar, [6]National AIDS Program, Ministry of Health, Department of Public Health, Yangon, Myanmar

Background: HIV prevalence among FSW in Myanmar is 14.6 in 2016. Myanmar aims to achieve 90-90-90 treatment targets, based on UNAIDS's fast track strategy, by 2020 in recent National Strategic Plan (2016-2020). There are concerns on percentage of newly diagnosed HIV positive cases actually receiving care. HIV prevalence among FSW is high in Myanmar and referral among this population needs to be understood.
Methods: A mixed method approach was used.Retrospective cohort secondary data analysis was carried out in five high priorty townships. Study population included newly diagnosed FSW diagnosed at NGO clinics in past four months. Secondary data from the testing sites and ART sites during the defined period were extracted using a pretested check list. For qualitative perspective, interviews with FSW and providers were done.
Results: A total of 113 sex workers were identified from NGO clinics records during data collection period. Mean age was 31.6yr (SD 8.9) . 90% of positives FSW were successfully linked to care with geographical variation in study areas. 82% were linked to ART centre within one month. For those 102 FSW linked to care at the time of study, 76.5% were on ART and 23.5% were in pre-ART status. Time from diagnosis to ART is median 33 days and time since enrollment at ART centre to ART initiation is median 15 days(IQR). One third of the FSW were diagnosed and enrolled for care mostly at WHO staging I and II. Only 14.7% of those successful came with a referral form and 91.2% were accompanied by NGO volunteers .Qualitative findings revealed the factors contributing to referral are social and system factors: stigma, migration, multiple testing, weak recording of referral , lack of provision of feedback forms from ART centres, etc.
Conclusions: A great proportion of positive sex workers were linked to care and treatment. This study looks at the first enrollment at ART centre as the outcome and could not provide information on the proportions that are loss once enrolled or not retained in care. Further studies are needed to explore retainment in care.Interventions to improve or facilitate linkage to ART care should be tested

WEPED482

#SWPrEP: HIV pre-exposure prophylaxis and sex work in Canada 2016

P.A. Sorfleet
Triple-X Workers' Solidarity Ass. of B.C., Vancouver, Canada

Background: In October 2016, funded by Elton John AIDS Foundation, Triple-X in partnership with the Dalla Lana School of Public Health, University of Toronto, organized and hosted a national consultation and invited 23 organizations from 10 provinces and territories who provide advocacy or services for sex workers.
Description: The purpose of this national consultation was to give participants the opportunity to educate themselves, explore and grapple as a group with the implications of PrEP on the sex industry.
Triple-X and DLSPH released „#SWPrEP: HIV Pre-Exposure Prophylaxis and Sex Work in Canada 2016" [http://triple- x.org/pdf/SWPrEPbook.pdf] at an ancillary event at the 2017 CAHR Conference in Montreal on April 5, 2017. The report contains transcripts of all the presentations, as well as the discussions that ensued between sex workers and those who provide services for sex workers. In addition, „#SWPrEP," a seven-minute video that teases out the issues discussed at the consultation was released. [https://vimeo.com/209825247]
Lessons learned: The Facilitator's Summary (p. 135) highlights the top 10 concerns coming out of the consultation. For example, participants did not want PrEP side-effects played down. They wanted PrEP to be presented within the spectrum of HIV prevention and for more and equal promotion of condom use. They wanted educational presentations from healthcare professionals as well as from PrEP critics. Furthermore, sex workers and sex work advocates were concerned that this new HIV prevention drug could result in elevated risks for sex workers, including new pressures from market competition to provide services without condoms if there is an expectation that sex workers are on PrEP.
Conclusions/Next steps: By December 2017, triple-x.org website recorded 51,000 downloads of the #SWPrEP book since the time of its release. New Canadian guidelines on PrEP were released November 27. „National data on HIV incidence among sex workers and their clients are scarce, perhaps in part because sex work is criminalized in Canada; as such, this guideline should be applied to these individuals based on the presence of other risk factors."
Free access to PrEP should be made available to sex workers based on individual risks discussed with their healthcare provider.

WEPED483

Better services for less money: Assessing prevention service needs among sex workers in Kyrgyzstan. Results of cross-sectional community-based participatory research

U. Tursunbaev
Ulukman Daryger, Karakol, Kyrgyzstan

Background: HIV/AIDS prevention programs for sex workers (SWs) funded by international donors have been delivered in Kyrgyzstan for over 22 years. Some services will be cut in 2018 due to funding shortages and many will transition to local funding. This qualitative research, conducted among SWs May-September 2017 in four oblasts in Kyrgyzstan, aimed to identify the services in highest demand from SWs.

Methods: The views of SW representatives were collected to analyze how their experience and attitudes influence provision of and access to services. Methods involved a situational analysis in four Kyrgyz cities, through focus groups and a survey of 110 SWs. Brainstorming and rapid needs assessment techniques were used for the focus groups. All research was conducted where SWs live and work, i.e. saunas, hotels, drop-in centers and NGO premises.

Results: Outreach work is the most popular and effective model for providing services to SWs. The majority of respondents (98 / 110) said outreach workers (OWs) form a "bridge" between service providers and SWs. They rated positively the fact that almost all OWs are from their community and this plays a very important role in removing inhibitions and barriers to communication. OWs are the main source of information in addition to advice on HIV prevention. They also develop leadership skills and qualities among SWs and identify needs to ensure provision of targeted assistance. Respondents stated the highest-priority service was condom distribution, citing the low rate of free condom availability - one per day. A new service needed by SWs aged over 30 is retraining and employment programs: younger SWs are in greater demand and those over 30 are often left with no secure income, at a time in their lives when for many their needs are increasing. This pushes them into more risky behaviors, impacting negatively on the spread of HIV among SWs.

Conclusions: With the transition to local funding, outreach work and condom distribution must be maintained at the same level in the same regions of Kyrgyzstan, as these are the services in greatest demand from SWs. Retraining and employment programs for SWs over 30 are also needed.

WEPED484

Sex work regulation and HIV risk: A qualitative analysis of the impact of different regulation regimes on HIV prevention among female sex workers in two U.S.-Mexico border cities

E. Andrade[1], M.-P. Kwan[2], C. Magis[3], H. Stainez-Orozco[4], K. Brouwer[5]
[1]University of Pittsburgh, Behavioral and Community Health Sciences, Pittsburgh, United States, [2]University of Illinois Urbana-Champaign, Geography and Geographic Information Science, Urbana, United States, [3]Centro Nacional para la Prevención y Control del Sida, Secretaria de Salud, Mexico City, Mexico, [4]Universidad Autónoma de Ciudad Juárez, Departamento de Ciencias Médicas, Ciudad Juarez, Mexico, [5]University of California San Diego, Department of Family Medicine and Public Health, La Jolla, United States

Background: Sex work regulation policies have been linked to HIV risk. In Mexico, sex work enjoys a quasi-legal status, where each state is responsible for implementing its own form of regulation. Thus, different regulatory regimes exist in the country, with differential effects on female sex workers (FSW) risk for HIV. This study analyzed the experiences of FSW in the U.S.-Mexico border, Tijuana and Ciudad Juarez, which operate different regulation regimes; compulsive registration and HIV/STI testing, and unsanctioned policing, respectively.

Methods: This analysis is part of a larger project that explored the HIV risk environment of FSW in both cities. We conducted 34 in-depth interviews with FSW in both cities, exploring different aspects of their work environment (i.e. type of venue, location, control over working conditions, etc.) and how the regulatory regimes in place in each city affect their ability to practice HIV prevention, harm reduction and influence their decisions regarding how and where they engage in sex work.

Results: Participants under compulsive registration and testing report registration fees are en economic burden; FSW who use drugs are not allowed to register; testing positive for an STI suspend work card until FSW can prove having received treatment, registration does not improve working conditions. FWS in Cd. Juarez, reported being subjected to policing practices including payment of quotas to police officers, requests for proof of HIV negative status, and displacement due to demolishment of sex work tolerance area. In both cities, sex workers who also inject drugs reported being constantly subjected to police harassment and excluded from the registration program in Tijuana, due to their drug use, thus pushing them to work in areas of the city that are less safe.

Conclusions: The current forms of regulation in both cities limit the capacity of sex workers to practice HIV prevention and engage in sex work in an environment where they can exert greater control. Considering the burden of HIV on this population in this region, sex work regulation policies need to move beyond policing and surveillance of HIV-STIs and be reoriented towards the promotion of sex workers' rights, HIV prevention and harm reduction strategies.

WEPED485

A qualitative study on male sex workers in Zimbabwe: Sex work, structural stigma and vulnerabilities for HIV acquisition and transmission

S. Qiao[1], E.Y.H. Tsang[2], F. Lipeleke[2], J. Wilkinson[3], J. Lowe[2], X. Li[4]
[1]University of South Carolina, Columbia, United States, [2]City University of Hong Kong, Hong Kong, Hong Kong, [3]Sino-US College, Beijing Institute of Technology, Zhuhai, China, [4]Univeristy of South Carolina, Columbia, United States

Background: Male sex work has been underexplored globally including in African countries. In Zimbabwe, a proliferation of MSWs in major cities was reported. However, a dearth of studies has explored their lives. The current qualitative study aims to describe the practices of sex work, life contexts, and HIV/STI risks and vulnerabilities.

Methods: Data comes from in-depth interviews among 15 MSWs recruited in Bulawayo through snowball sampling. The interviews took 30-40 minutes on average. All the interviews were conducted in privacy settings and in native language. The audio records were transformed verbatim and analyzed in Nvivo 11.

Results: MSWs got to know their clients though friends, at night clubs/bars, or through internet. Low-paid MSWs always waited for being picked up by gatekeepers ("big boss"). MSWs, particularly the low-paid ones didn't develop any romantic or stable relationship with their clients; but took the risks of abuse and physical violence during or after the sex. The structural stigma against MSM, especially the homosexuality, comes from diverse sectors including politics ("homosexuality is un-African, introduced by the White"), religion ("same sex is a sin before the God"), culture ("men should marry a woman and bear children"), law and police ("homosexuality is illegal in Zimbabwe. Engaging it can send one to prison"), media ("the media is hostile to sex workers particularly men as we are regarded as abnormal and unclean"), and their family ("should they get to know about it, they will disown me"). MSWs had limited knowledge and many misconceptions about HIV. Many MSWs were not able to consistently use condoms during sex work because of lack of knowledge, influence of alcohol or drug, and limited negotiation space as in a powerless positon. Stigma from healthcare providers also impeded them from health seeking or HIV testing. Non-disclosure to their female stable partners and sexual behaviors with female sex workers further increase their vulnerabilities for HIV infection and transmission.

Conclusions: MSWs in Zimbabwe, particularly the low-paid ones report high HIV/STI risks. The vulnerabilities for HIV infection are exacerbated by structural stigma. MSWs need support and tailored HIV prevention and treatment services to improve their HIV/STI prevention practices, health, and well-being.

WEPED486

Reaching culturally and liguistically diverse sex workers of mirgant status background in response to HIV and related infections

N.M. Cheung[1], C. Cox[2]
[1]Sex Workers Outreach Project Inc., Mulitcutural Project, Surry Hills, Australia, [2]Sex Workers Outreach Project Inc., Surry Hills, Australia

Background: Migrant sex workers from Culturally and Linguistically Diverse (CALD) backgrounds face a multitude of barriers in accessing support: These include discrimination based on race, gender, politics as well as myths and stigma attached to sex work, the criminalisation of sex work and also barriers created by language and marginalisation.

Methods: The SWOP Multicultural Project produces award winning original resources, online correspondence support and peer outreach and education programs via thorough consultation with each community/language/cultural group. Utilising Focus Testing within the language/cultural group and drawing on the expertise of a Steering Committee from the language/cultural group targeted these original resources and programs are not produced in English by non-CALD people and then translated. Rather, each original program and resource is produced from scratch by sex working members of that community/language/cultural group and each produced in a different language. The resulting Safe at Work resources won the 2017 New South Wales Government Multicultural Health Communication Awards.

Results: When accessing support, marginalisation, discrimination and the myths and stigma associated with CALD migrant sex workers are recognised as stronger barriers than language, and the input of the CALD migrant sex worker community has proved to be effective in overcoming these barriers. Since the inception of the Multicultural Project, there has been a marked reduction in the number of sexually transmitted infections among CALD sex workers, and the virtual elimination of HIV from the sex industry continues.

Conclusions: To overcome key barriers experienced by CALD migrant sex workers have been developed throughout the life of the Multicultural Project. These include extensive peer involvement such as peer interpreting support, peer translated resources, peer produced resources, peer held interagency training, workplace outreach, peer supported access to culturally responsive services and industry specific health and safety training provided in sex workers' first languages..

WEPED487

Female sex workers who use drugs and HIV/STI risk in Kazakhstan: Implications for HIV prevention

T. McCrimmon[1], G. Mergenova[2], S. Witte[1], M. Meinhart[3], A. Terlikbayeva[2], S. Primbetova[2], N. El-Bassel[1]
[1]Columbia University, Global Health Research Center of Central Asia, New York, United States, [2]Global Health Research Center of Central Asia, Almaty, Kazakhstan, [3]Columbia University, New York, United States

Background: Female sex workers (FSW) are at high risk of contracting and transmitting HIV. The prevalence of HIV among FSW in Kazakhstan is rising, and has been shown to be higher among FSW who use drugs. However, little is known about the sex work environment in Kazakhstan or in Central Asia. We utilize baseline data from an HIV prevention study among 399 FSW who use drugs in two cities in Kazakhstan to address this gap.

Methods: Women were recruited through sex work venues and peer networks. Participants completed a computerized baseline survey including sociodemographic characteristics and risk behavior assessments. This paper provides an overview of participant's sex work environment: history, employment structure, frequency and venue, and goods exchanged. It also examines sexual risk behaviors in commercial interactions, including number of partners and encounters and condom use. We use descriptive statistics and ordinary least squares (OLS) regression to examine the association between sex work environment and sexual risk behaviors.

Results: Participants averaged 34.6 years old (8.4 SD). The average age of initiation of sex work was 20.9 years (5.51 SD). Few participants (n=41, 10.3%) worked for a boss or pimp, and they worked an average of 8.9 months (4.18 SD) per year. Women exchanged sex for money (n=351, 87.9%), drugs (n=126, 31.6%), and basic needs such as food (n=97, 24.3%) and clothing (n=73, 18.3%). Participants averaged 6.78 (18.6 SD) commercial partners, and 28.9 (52.9 SD) vaginal sexual encounters with these partners in the prior 90 days. Only 13% (n=51) reported consistent condom use with these recent partners. Having a boss/pimp, working more months per year, and exchanging sex for basic needs were associated both with a higher number of paying clients and a greater number of sexual encounters. Few factors were significantly associated with condom use.

Conclusions: Our findings highlight the risks for FSW who use drugs in Kazakhstan and the need for HIV prevention efforts to increase safe sex practices. Moreover, prevention must address the structural characteristics faced by this population, such as their socioeconomic status and employment.

	Number of commercial partners in the prior 90 days	Number of vaginal sexual encounters with commercial partners in the prior 90 days

Uptake of HIV oral self-testing among female sex workers in Starehe Nairobi: Lessons from the key population implementation science study

E.O. Athowe[1], A.K. Kinyua[2], E. Mukiri[2]
[1]Partners for Healyh and Development in Africa, Monitoring and Evaluation, Nairobi, Kenya, [2]Partners for Health and Development in Africa, HIV/STDs Prevention, Nairobi, Kenya

Background: The HIV epidemic in Kenya is largely generalized, but concentrated among key populations. The HIV prevalence among Female Sex Workers (FSW) is estimated at 29.3% compared to 6.9% national average for women. Using an implementation science approach, we sought to ascertain if HIV oral self- testing (HOST) would increase uptake of HIV Testing Services (HTS) among first-timers or infrequent FSW testers into FSW programs.

Description: A quasi-experimental crossover design was used. Two ongoing Sex Workers Outreach Program (SWOP) clinics, Langata and City, based in Nairobi were matched based on the number of enrolled FSW. Using Peer Educators (PE), eligible FSW were identified, counseled, and trained on HOST procedures and interpretation of results. Within the hotspots, PE distributed HOST to eligible FSW and instructed them to use and confirm their test result at SWOP City clinic within a three-month period. SWOP Langata clinic's routine program data was used for comparison to measure proportion of HTS uptake and enrollment rate.

Lessons learned: Out of the 113 FSWs who received HOST kit, 2 did not meet the eligibility criteria, and 1 participant withdrew from the study. The remaining 110 (97%) used the kit, 72 confirmed their results in the DICE, 24 confirming results at other health facilities, while 2 did not confirm their results. All the 72 enrolled into the program and of whom 6 (8%) tested HIV positive.

Follow up of individuals given the OST kits revealed various reasons that impeded or delayed confirmation of results. Of the 196 follow-ups conducted, 96 (49%) mentioned lack of time or inconvenient clinic operating hours, 45 (23%) had travelled, 24 (12%) were scared of testing positive, 17 (9%) had unfavorable home environment due to family, and 14 (7%) forgot to confirm.

Conclusions/Next steps: HIV Oral-Self Testing encouraged extra testing and enrollment at the FSW clinic for the targeted hard-to-reach FSW. Those who did not confirm their result at the clinic cited constraints that can be addressed programmatically. Overall, majority of the hard-to-reach FSW got to know their HIV status and therefore HOST scaled up should be considered in FSW programs.

WEPED489

Sex worker driven approaches to enable the optimal introduction of HIV self-tests: Addressing social and structural barriers

K. Kanivale, J. Kim, T. Powell
Scarlet Alliance, Newtown, Australia

Background: There is a dearth of reliable research examining the potential implications of introducing HIV self-tests into legal and policy environments that discriminate against sex workers, particularly sex workers living with HIV and other STIs. In Australia, self-testing is anticipated to be introduced in the near future. Not surprisingly, sex workers are anticipating new challenges as well as new opportunities with the introduction of the tests.

Description: Scarlet Alliance, the national sex worker organisation in Australia, conducted a multi-stage consultation, consisting of focus groups, individual interviews and an online survey, on self-testing with peer educators and individual sex workers of different genders, backgrounds, sero-status and experiences in each state and territory in Australia. The participants were asked about the potential risks, barriers to, and benefits of self-tests in different social, legal and policy environments in Australia.

Lessons learned: Although the participants noted that self-tests present sex workers with an opportunity to test outside of a clinical setting, the discriminatory legal restrictions placed on sex workers living HIV may deter sex workers from getting confirmatory testing upon receiving a reactive self-test result. This may be additionally exacerbated by the limited availability of free, voluntary, anonymous and sex worker friendly sexual health services in general. The participants noted that self-testing may affect safer sex negotiations with clients, such as the implementation of universal protections, despite the self-test results not being definitive. Also, the participants from jurisdictions with mandatory testing noted that introducing self-tests in an already coercive testing environment may result in the tests being added onto existing mandatory testing regimes.

Conclusions/Next steps: To ensure self-tests do not inadvertently further deter sex workers from accessing comprehensive sexual health care or exacerbate human rights violations, laws and policies that generally create barriers to testing for sex workers need to be reformed. Alongside, the participants advocated for formal legal protections from coercive testing in the form of occupational health and safety and industrial protections. Additionally, there is a need to address structural barriers to testing such as by increasing investment in voluntary, free, anonymous and peer sexual health services.

WEPED490

Acceptability of Pre-Exposure Prophylaxis (PrEP) amongst sex workers in South Africa

S. Nene[1], K. Govender[1], G. George[1], T. Khoza[2], C. Braga[3]
[1]University of KwaZulu-Natal, Health Economics and HIV/AIDS Research Division, Durban, South Africa, [2]North Star Alliance Southern Africa, Durban, South Africa, [3]University Eduardo Mondlane, Maputo, Mozambique

Background: Sex workers in Southern Africa are at high risk for HIV acquisition, yet access to and uptake of HIV prevention services are low. This study sought to determine the individual and socio-economic factors that enable or hinder the use of HIV prevention methods, access to health services, and knowledge of new prevention measures such as PrEP and acceptability of such services by sex workers.

Methods: This paper presents the qualitative part of a mixed-methods study conducted with sex workers in Bloemfontein, South Africa from August to September 2017. Specifically, it presents their perceptions on factors underlying ability to practice safe sex, knowledge of PrEP and willingness to adopt it as a preventative tool, and treatment conditions and providers for its distribution to sex workers. Semi -structured in-depth individual interviews were conducted. Snowball sampling was employed to recruit participants. Data was analysed using NVIVO version 11 and conventional content analysis.

Results: Thirty five interviews were conducted with thirteen self-identified gay male and twenty two female sex workers. Participants reported an awareness of increased risk to HIV infection but majority reported inconsistent condom use citing money and violence as barriers to condom negotiation. Knowledge and awareness of PrEP and its providers were low. Once informed, all participants expressed willingness to use it if it were made available to them. Participants reported that a collaboration between government and NGOs would ensure distribution to the group as public health facilities are easily accessible and NGOs work closely with vulnerable populations such as sex workers and were perceived to be in a good position to motivate for their prioritization with PrEP roll- out.

Conclusions: This study aimed to gather knowledge on HIV prevention among sex workers in light of South Africa's 2016 launch of PrEP at selected demonstration sites as per National Sex Work HIV Plan guidelines which encompass combination HIV prevention interventions for sex workers. The study showed that difficulty in negotiating safe sex together with financial incentives not to use condoms are primary drivers for sex workers wanting alternate HIV prevention options.

Condom Use Patterns among FSWs: Women in Transactional Sex and Casual Sex in High HIV Risk Venues in Abuja FCT, Nigeria

G. Ashefor, F. Agbo
National Agency for the Control of AIDS, Survey Research and Monitoring and Evaluation, Abuja, Nigeria

Background: The World Bank has been providing technical assistance to Nigeria to improve the efficiency and effectiveness of HIV prevention services. This technical support enabled Nigeria to conduct local epidemic appraisals and in 2015 the World Bank supported the design and implementation of a study on the sexual ethnography of high risk venues and locales in urban areas of Nigeria to provide in-depth knowledge about the context of risk and thereby contribute to the design of effective and efficient HIV prevention strategies. A pilot study that focused on how and what type of sexual networking is developed within high-risk settings was conducted in the Abuja, Federal Capital Territory (FCT). In addition, socio-demographic profile and sexual behaviors of women with risk behaviors attending these venues were also explored.
Methods: : The study population consisted of 450 female sex workers (FSWs), 200 women in transactional sex and 200 women in casual sex respectively in 105 active hotspots in Abuja. In addition to other parameters the study investigated condom use behavior among women in each group by their different types of partners.
Results: 88% of the occasional clients used condom at last sex with the FSWs. The occasional partner also used a condom with their transactional partner (86%). Men who visit the women repeatedly are more likely to use condom and about 95% reported that they used condom at last sex with their clients who either pay cash or gifts. On the other hand, non-paying partners were less likely to use condom with their partners (66% among FSW and 75% among women in transactional sex. Condom use with the most recent sexual partner is lowest (32%) among women in casual sex, though it was about 43% with the second last and 48% with the third last sexual partners.
Conclusions: The study underscores the need for sexual ethnography of high risk venues and locales in Nigeria to provide in-depth knowledge about the context of HIV risk and thereby contribute to the design of effective and efficient HIV prevention strategies. The next step is to conduct this study in additional cities in Nigeria

Crystal methamphetamine use and its associated factors in female sex worker in Iran, 2015

M. Shokoohi[1,2], M. Karamouzian[1,3], H. Sharifi[1], A. Rahimi-Movaghar[4], A. Carrico[5], S. Hosseini-Hooshyar[1], A. Mirzazadeh[1,6]
[1]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman University of Medical Sciences, Kerman, Iran, Islamic Republic of, [2]Epidemiology & Biostatistics, Schulich School of Medicine & Dentistry, University of Western Ontario, London, Canada, [3]School of Population and Public Health, Faculty of Medicine, University of British Columbia, Vancouver, Canada, [4]Iranian National Center for Addiction Studies (INCAS), Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [5]University of Miami, Department of Public Health Sciences, Miami, United States, [6]University of California, Epidemiology and Biostatistics, Oakland, United States

Background: Crystal methamphetamine (CM) use has been associated with increased sexual risks and elevated risk of HIV as well as other sexually transmitted infections (STIs) among female sex workers (FSW). Given the dearth of evidence on CM use among FSW in the conservative context of the Middle East, this study aimed to examine the prevalence and correlates of CM use among FSW in Iran.
Methods: We analyzed data of the second bio-behavioral surveillance survey among 1,347 FSW across 13 major cities in Iran in 2015. We recruited a facility-based and outreach sample of women aged ≥ 18 years who reported penetrative sex with more than one client in the previous year. Data were collected by one-to-one interviews using a standardized risk-assessment questionnaire. The study outcome was a binary measure of any past-month self-reported CM use or injection. To examine the correlates of CM use, adjusted prevalence ratio (APR) and 95% confidence intervals (CI) obtained from Poisson regression models were reported (final analytic sample=1,295).
Results: Non-injecting CM use was reported by 15.0% (95% CI: 8.7, 24.7), while injecting CM use was only reported by 0.9% (95% CI: 0.4, 2.1). Overall, self-reported CM use was reported by 15.7% (95% CI: 9.3, 25.1) of the participants. CM use was more likely to be reported by FSW who reported opium use (APR: 2.08; 95% CI: 1.13, 3.81), heroin use (APR: 3.84; 95% CI: 2.62, 5.62), non-prescription methadone use (APR: 3.10; 95% CI: 1.50, 6.35), had forced sex (APR: 1.47; 0.99, 2.18), had more than one non-paying sexual partner (APR: 2.05; 95% CI: 1.14, 3.69), and unstable housing status (APR: 3.54; 1.82, 6.89). In contrast, CM use was less likely to be reported by FSW who had higher levels of education (APR: 0.35; 0.11, 1.07).
Conclusions: A considerable number of FSW reported CM use, which was associated with concomitant opioid use, higher number of sexual partners, violence and unstable housing. Gender-specific and couple-focused harm reduction and prevention strategies are essential to address substance use in this key population and their intimate drug-using partners to help improve their health and well-being.

WEPED493

"The society around us is the one that segregates us": A comparative exploration of sex work stigma among female sex workers living with HIV in Tanzania and the Dominican Republic

T. Karver[1], C. Barrington[2], Y. Donastorg[3], M. Perez[3], H. Gomez[3], J. Mbwambo[4], S. Likindikoki[4], C. Shembilu[4], S. Beckham[1], D. Kerrigan[5]
[1]Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States, [2]University of North Carolina-Chapel Hill, Department of Health Behavior, Chapel Hill, United States, [3]Unidad de Vacunas IDCP-COIN-DIGECITSS, Santo Domingo, Dominican Republic, [4]Muhimbili University of Health and Allied Sciences, Department of Psychiatry and Mental Health, Dar es Salaam, Tanzania, United Republic of, [5]American University, Washington, United States

Background: Female sex workers (FSWs) are among the most marginalized populations globally, experiencing high levels of occupational stigma and discrimination. Prior research suggests that internalized sex work stigma is significantly associated with decreased retention in HIV care and ART interruption among FSWs living with HIV. We conducted a comparative qualitative study to explore the dynamics and contexts of sex work stigma among FSWs in Tanzania and the Dominican Republic (DR).
Methods: We conducted 40 in-depth interviews (20 per country) with FSWs living with HIV, recruited from established cohorts in Iringa, Tanzania and Santo Domingo, DR. Interviews were audio-recorded, transcribed, and systematically analyzed using narrative and thematic coding techniques to explore a priori and emergent domains and themes.
Results: Participants in both countries exhibited patterns of silence and secrecy related to disclosing their involvement in sex work, including with their close personal networks and healthcare providers. Internalized sex work stigma manifested through feelings of shame, perceptions of being a bad example, and beliefs that they were abnormal for engaging in sex work. FSWs in DR often reported receiving support from family regarding their HIV status, but feared losing this support if their engagement in sex work was revealed. Across countries, women reported facing enacted sex work stigma or discrimination from their communities, where disapproval about their involvement in sex work induced experiences of humiliation, judgment, and isolation. Women in both countries expressed the perception that society views FSWs as a threat to marriage and families. The link between FSWs as vectors of disease responsible for "contaminating others with venereal diseases" and HIV was more pronounced among women in Tanzania.
Conclusions: The multiple manifestations of sex work stigma are powerful and salient factors among FSWs living with HIV, challenging norms associated with womanhood across settings and creating social exclusion. Findings highlight key themes within the domains of internalized, enacted and perceived stigma to include in an aggregate measure of sex work stigma, including secrecy, silence, and experiences of deviance. Such a measure could be used for a more nuanced assessment of the relationship between sex work stigma and HIV outcomes among FSWs.

WEPED494

Factors influencing transgender and male sex workers' access to sexual health care, HIV testing and support

J. Jones[1], J. Dean[2], L. Fitzgerald[2], R. Brennan[2]
[1]*Respect Inc, Spring Hill, Australia,* [2]*The University of Queensland, Herston, Australia*

Background: Globally, male and trans sex workers are reported to be at elevated risk of HIV transmission. However, current literature on their sexual health behaviours and needs is limited. Data suggests 20 per cent of workers are male or trans. Our research investigated the sexual health and HIV prevention behaviours of male and/or trans sex workers in Queensland, Australia, focusing on newer health technologies including PrEP and rapid HIV testing, to determine their needs. This is the first qualitative research on male and trans sex workers in Australia.
Methods: 35 male and/or trans sex workers in Queensland participated in interviews conducted by peer researchers. The workers were both urban and regional based, and of various ages, nationalities, and socioeconomic backgrounds. The interviews discussed work practices, stigma, sexual health, access to testing, and knowledge and attitudes about HIV testing and prevention.
Results: Participants reported diligent sexual health practices, including condom use and regular testing, even those working outside of regulated settings. A significant number experienced stigma in healthcare and other settings. Most were familiar with rapid testing and some, particularly migrant workers, relied solely on rapid testing for their sexual health checks. Migrant workers in particular reported not knowing how to access other sexual healthcare. Many were familiar with PrEP and some had used it. Attitudes were divided, with some seeing PrEP as a valuable sexual health tool and others holding concerns, either seeing it as a risk for condomless sex leading to other STIs or fearing it was still an ´experimental´ drug. Asked about their needs as sex workers, most discussed the need to reduce stigma and for law reform around sex work.
Conclusions: Trans and male sex workers in Queensland are generally well informed about sexual health, and many are accessing newer HIV prevention and testing technologies. Healthcare workers must be trained to work with sex workers and people of diverse genders and sexualities, to reduce stigma and improve access to care. Sex workers need to made aware of friendly, accessible sexual health facilities. Decriminalisation of sex work is increasingly demanded by workers to ensure safe working conditions.

WEPED495

General self-efficacy as a predictor for HIV testing among female sex worker in Mombasa, Kenya

M. Pham[1,2], G. Manguro[3], F. Ampt[1,4], C. Gichuki[5], M. Chersich[6], M. Stoove[1,4], M. Hellard[1,7], K. L'Engle[8], W. Jaoko[9], M. Lim[1,4], M. Temmerman[5,10,11], P. Agius[1,4,12], P. Gichangi[5,9,10], S. Luchters[1,4,10]
[1]*Burnet Institute, Melbourne, Australia,* [2]*Hanoi Medical University, Institute for Preventive Medicine and Public Health, Hanoi, Vietnam,* [3]*International Centre for Reproductive Health (ICRH), Mombasa, Kenya,* [4]*Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia,* [5]*International Centre for Reproductive Health (ICRH, Mombasa, Kenya,* [6]*University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa,* [7]*The Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia,* [8]*University of San Francisco, San Francisco, United States,* [9]*University of Nairobi, Nairobi, Kenya,* [10]*Ghent University, International Centre for Reproductive Health, Department of Obstetrics and Gynaecology, Ghent, Belgium,* [11]*Aga Khan University, Narobi, Kenya,* [12]*La Trobe University, Judith Lumley Centre, Australia*

Background: Female sex workers (FSWs) in Kenya continue to bear a high burden of HIV infection and will benefit from repeated HIV testing and counselling (HTC). General self-efficacy (GSE) is a psychological construct that refers to one's belief in their own ability to respond to challenges to achieve positive outcomes across multiple domains. GSE is, therefore, likely to be predictive of individuals' health-seeking behaviour. This secondary analysis assessed whether GSE is associated with self-reported uptake of HTC services in the past six months among FSWs in Mombasa, Kenya.
Methods: We analysed baseline data from 883 randomly selected HIV-negative FSWs enrolled in a larger two-arm cluster-randomised mHealth trial (WHISPER or SHOUT study), which aims to improve their sexual and reproductive health or nutrition. A structured questionnaire collected information on socio-demographics, sex work, sexual and other risk behaviours, psychosocial variables and HIV testing uptake. Self-efficacy was measured using the validated GSE scale (10-items, Cronbach's alpha=0.80) and dichotomized at the median score. The association of GSE with self-reported uptake of HTC in the past six months was determined in stepwise hierarchical regression analysis, controlling for potential confounders including age, education, sex work characteristics, substance use, condom use and perceived stigma.
Results: Median age of study participants was 25 years (interquartile range (IQR)=22-29) with a median duration in sex work of four years (IQR=2-6). GES score range was 18-40, median score was 36 (IQR=32-39). One quarter 226/883 (25.6%) had sought HTC services in the past six months. Regression models showed that higher self-efficacy (i.e. stronger belief in ability to respond to challenges), was associated with higher self-reported attendance of HTC services, and did not alter with sequential introduction of potential confounding factors (adjusted odds ratio (AOR)=1.69; 95% confidence interval=1.29-2.22; p< 0.001).
Conclusions: Better strategies are needed to increase regular HIV testing uptake among FSWs given current inadequate levels. Sex workers' GSE was an important and independent predictor for uptake of HTC services, and screening for low GSE might identify women requiring additional motivation and support. Further efforts are needed to develop interventions to improve women's personal agency and determine the impact on HIV and other health outcomes.

WEPED496

I did not believe I could trust anyone with what I was living through: The HIV continuum of care as a site of support for us based sex workers

J. Brown[1,2], B. Robinson[1]
[1]*Call Off Your Old Tired Ethics Rhode Island (COYOTE RI), Providence, United States,* [2]*Brown University, Alpert Medical School, Providence, United States*

Background: In the United States, sex workers (SWs) are a key population that experience disproportionately high rates of HIV but are often hesitant to seek care due to the criminal status of sex work. SWs are often not reached by HIV education, prevention, and treatment programs and stigma surrounding sex work isolates SWs from crucial support systems. A community-based research project conducted by COYOTE RI carried out to understand how SWs experience the HIV continuum of care found that SWs are able to find and initiate support within healthcare settings if cared for in an understanding way. This study looks to explore how HIV care settings can best serve to counter the isolation many US SWs experience.
Methods: This community-based research project was carried out by sex workers rights organizations that have been working in the US to uphold the rights of sex workers for many decades. This study surveyed people working in various areas of the sex industry in all regions of the US [n = 1,496]. Analysis of the data utilized qualitative and quantitative methodologies and key findings were developed through the use of grounded theory.
Results: Respondents provided complex narratives surrounding the difficulties of disclosure of SW status within healthcare settings. Responses stated that being able to explain SW status and confide in HIV care providers played, or would play, an invaluable role in the respondent feeling socially connected, valued, and would build hope. As stated by a respondent „please understand that you are probably the only person they can go to and the only person aware of these situations."
Conclusions: The ability of a provider to care for SWs in a non-judgmental way would greatly reduce isolation and serve as an entry point to other forms of care and support. Widespread discrimination against SWs in and out of healthcare continues to exist in the US and education for providers on caring for SWs in a compassionate way could greatly improve HIV outcomes.

WEPED497

Just give me the information I need to survive: Understanding the needs of US based sex workers within the HIV continuum of care

J. Brown[1,2], B. Robinson[1]
[1]*Call Off Your Old Tired Ethics Rhode Island (COYOTE RI), Providence, United States,* [2]*Brown University, Alpert Medical School, Providence, United States*

Background: In the United States, sex work remains criminalized and sex workers (SWs) are often isolated from basic healthcare and social support systems. SWs are a key population and experience a disproportionately high rate of HIV but it is challenging to connect with SWs due to their fear of being prosecuted for being open about being SWs. It can be difficult for SWs to engage with the HIV continuum of care and COYOTE RI developed this research project to understand the experiences of US-based SWs within the HIV continuum of care. This project seeks to use a human rights-based approach to understand the complexities of how existing HIV programs serve or fail US-based SWs.
Methods: This community-based research project was carried out by sex workers rights organizations that have been working in the US to uphold the rights of sex workers for many decades. This study surveyed people working in various areas of the sex industry in all regions of the US [n = 1496]. Analysis of the data utilized qualitative and quantitative methodologies and key findings were developed through the use of grounded theory.
Results: Through this study it was shown that US-based sex workers experience the HIV continuum of care in a range of ways that are fundamentally different from other populations. SWs frequently do not disclose their SW status, experience high rates of many forms of discrimination, and frequently avoid HIV services for fear of being surveilled or outed in other areas of their life.
Conclusions: Throughout the sample, respondents articulated the desire to be treated the same as other patients, with respect and attention, and provided additional insights into what SW-inclusive care could look like in the US. This study provided a nuanced exploration of the challenges SWs face in receiving education, preventative services, and treatment surrounding HIV. As a key population that faces legal persecution within the US, the perspectives and suggestions of SWs in this study provide valuable insight into how to improve how the HIV continuum of care in the US works to uphold the rights of US SWs.

WEPED498

Awareness, practice and preferences of PrEP among female sex workers in Lagos, Nigeria

V.A. Adepoju[1], C.-E. Udofia[2], T. Eyohwo[2], O. Lawal[3], V. Okafor[4], O. Adejumo[5]
[1]*KNCV Tuberculosis Foundation, TB/HIV Prevention, Care and Treatment, Lagos, Nigeria,* [2]*Center for the Rights to Health, Key Populations, Lagos, Nigeria,* [3]*KNCV Tuberculosis Foundation, Laboratory Health Systems Strenghtening, Lagos, Nigeria,* [4]*Project Support Officer, Improved TB/HIV Prevention and Care, Lagos, Nigeria,* [5]*Mainland Hospital, Lagos, Community Medicine and Public Health, Lagos, Nigeria*

Background: Little is known in Nigeria about the knowledge, practice and preferences of FSWs on PrEP despite its proven efficacy in the prevention of HIV among Female Sex Workers. The objective of the study is to describe knowledge, practices and preferences towards PrEP among FSWs in high HIV prevalent setting, Lagos, Nigeria.
Methods: Interviewer administered questionnaires was administered to 130 FSWs selected across various hotspots in Lagos, Nigeria. The questionnaire was adapted from University of California; San Francisco Center for HIV research. The questionnaire was adapted and modified for the Nigerian context and used to collect participants' behavioral and social network data. The data was part of regional surveys conducted among biological female sex workers aged 18 years and above in Lagos, Nigeria between December 2017 and January 2018.Data was entered into SPSS. Bivariate analysis was conducted to determine associations with PrEP awareness, practice and preferences.
Results: A total of 130 FSWs participated in the study. 1(0.8%) were 1-19 years, 125(94%) were 20-39 years and 7 (5.3%) were 40-45 years. Majority 68.8% (86/125) of the FSWs were Christians and attended secondary school, 66.2% (84/127).60% is either Yoruba or Igbo ethnicity. 79.2% were neither in school nor learning trade while 20.8% were students. The median age of the FSWs was 29 yrs (19-45, IQR-7.81.3% were negative and 18.3% were positive. 79.4% (85/107) of respondents have experienced sexual assault or rape over the last 12 months. 46.2% (60/130) have heard and aware of PrEP, 24.6% (32/130) are using PrEP; 34% (11/32) use PrEP alone while 65% (21/32) use PrEP in combination with condom. 11/30(37%) preferred daily prep while 63% (19/30) preferred on-demand PrEP. FSWs who have experienced sexual assault or rape over the last 12 months are more significantly aware of PrEP (86.4%vs13.6%, p<0.001).
Conclusions: The study revealed low level of awareness of PrEP among Female Sex Workers and those sexually assaulted more likely to be aware of PrEP. There is a need to protect the right of FSWs in Nigeria including sexual rights. Interventions aiming at translating knowledge of PrEP to usage need to be strengthened among FSWs who are at higher risk of HIV.

WEPED499

Trends in HIV testing uptake among female sex workers in Ukraine: Findings from four integrated bio-behavioral surveys

A. Tokar[1], I. Sazonova[2], M. Becker[3], S. Mishra[4,5], J.V. Lazarus[1], J.E.W. Broerse[6], J. Blanchard[3]
[1]*Barcelona Institute for Global Health (ISGlobal), University of Barcelona, Hospital Clínic - University of Barcelona, Barcelona, Spain,* [2]*International Charitable Foundation "Alliance for Public Health", Kyiv, Ukraine,* [3]*Centre for Global Public Health, Department of Community Health Sciences, University of Manitoba, Manitoba, Canada,* [4]*Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, Canada,* [5]*Department of Medicine, University of Toronto, Toronto, Canada,* [6]*Athena Institute, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*

Background: Ukraine has one of the fastest growing HIV epidemics in Europe with high rates of HIV among female sex workers (FSW). Despite a widespread testing program HIV testing uptake remains low.We examined temporal trends in outcomes of HIV testing among female sex workers using self-reported data from four rounds of integrated bio-behavioral surveys (IBBS) in Ukraine in 2009, 2011, 2013, and 2015.
Methods: The outcomes of interest included accessibility of HIV testing, ever in life testing for HIV, testing for HIV in the last 12 months and knowledge of HIV status. We examined correlates of accessing HIV testing. We collected IBBS samples from FSW in major regional cities of Ukraine (3,286-2009, 5,023-2011, 4,906 -2013; 4,300-2015). Each year a combination of different recruitment methodologies was applied in different cities, such as respondent-driven sampling (RDS), time-location sampling (TLS), and convenience sampling. Therefore, we used unweighted pooled analyses of samples and made no inferences to the overall population of FSW. We first calculated prevalence of each HIV testing behavior for each year and then performed Cochrane-Armitage test for trend to examine differences across the rounds. Next, using unweighted multivariable logistic regression we examined annual correlates of accessing testing.
Results: The reported testing accessibility progressively increased from 87% in 2009, to 90% in 2011, 94% in 2013, and 97% in 2015 (p< .0001). The prevalence of ever testing for HIV and knowledge of one's HIV status also increased from 69% and 67% in 2009 to 80% and 84% for both indicators in 2013 and in 2015 (p< .0001). Testing for HIV in the last 12 months showed no significant change over time and ranged between 60-63% (p< .0001). In all samples, younger FSW (less than 25 years old) were significantly less likely to access testing. Injecting drug use during last 30 days was the strongest predictor of testing accessibility.
Conclusions: HIV prevention and testing programs in Ukraine should focus on younger FSW as they report less ability to access it. FSW who inject drugs have better access to testing services, probably because of strong national harm reduction and testing programs for people who inject drugs.

WEPED500

Characterizing the prevalence and determinants of incentivized condomless sex among female sex workers in Lesotho

O.M. Olawore[1], S. Ketende[1], N. Taruberekera[2], T. Mothopeng[3], J. Nkonyana[4], S. Sweitzer[1], A. Grosso[5], S. Baral[1]
[1]Johns Hopkins University School of Public Health, Epidemiology, Baltimore, United States, [2]Population Services International, Johannesburg, South Africa, [3]Matrix Support Group, Maseru, Lesotho, [4]Ministry of Health, Maseru, Lesotho, [5]Public Health Solutions, New York, United States

Background: Even in the context of a generalized HIV epidemic in Lesotho, female sex workers (FSW) carry a disproportionate burden of HIV with 72% estimated to be living with HIV. In the context of emerging HIV prevention strategies including PrEP, consistent condom use (CCU) remains a crucial HIV prevention strategy. We present prevalence and determinants of incentivized condomless sex among FSW in Lesotho.
Methods: Adult FSW were recruited using respondent-driven-sampling between February-September, 2014 with analyses reported here limited to those who were offered money for condomless sex. Bivariate and multivariate logistic regression models were used to evaluate factors associated with accepting money for condomless sex.
Results: 744 women were recruited into the study, 585(79%) reported to have been offered money for condomless sex, and 351/585(60.4%) accepted the offer. The median amount offered for sex with condom was R50 (IQR:R20-R500) and R100 (IQR:R30-R1000) for condomless sex. FSW who self-reported to be living with HIV were more likely to accept money for condomless sex compared to those who self-reported to be HIV negative (OR:1.41 [95%CI:0.99-2.01], p=0.056), (aOR:1.40 [95%CI: 0.93-2.08], p=.0.103). Lack of HIV-related knowledge was also associated with accepting money for condomless sex.
Conclusions: Despite a high burden of HIV among FSW Lesotho necessitating sustained HIV preventions, our findings show an increased prevalence of incentives for, and willingness to accept more money for condomless sex. This dynamic highlight the challenges of HIV prevention using CCU. New approaches are needed including structural approaches to safely increase condom use as well as better condoms to prevent transmission and acquisition of HIV.

WEPED502

Violence victimization among male sex workers in the U.S. Northeast

E. Brown[1], M. Mimiaga[1,2,3], S. Safren[4], K. Mayer[1,5,6], K. Biello[1,2,3]
[1]Fenway Health, The Fenway Institute, Boston, United States, [2]Brown University School of Public Health, Behavioral & Social Sciences and Epidemiology, Providence, United States, [3]Brown University School of Public Health, Center for Health Equity Research, Providence, United States, [4]University of Miami, Department of Psychology, Coral Gables, United States, [5]Harvard Medical School/Beth Israel Deaconess Medical Center, Division of Infectious Disease, Boston, United States, [6]Harvard T. H. Chan School of Public Health, Global Health and Population, Boston, United States

Background: Intimate partner violence is associated with HIV transmission risk among men who have sex with men; however, research is lacking on intimate partner and client-perpetrated violence against male sex workers specifically—a group at high HIV transmission risk. Male sex workers may be at increased risk of violence due to heightened stigma and power imbalances in transactional relationships.
Methods: One hundred male sex workers living in Boston, MA and Providence, RI were enrolled in a cohort study to assess social, sexual and substance use networks. We estimated baseline prevalence of physical, sexual, and emotional violence victimization perpetrated by intimate partners and/or clients. Multivariable logistic regression models were used to examine sociodemographics (i.e., age, race, employment, sexual orientation, housing status, street- vs. internet-based sex work, source of income outside of sex work) and potential psychosocial (i.e., depression, stigma associated with sex work) and behavioral (i.e., alcohol use, drug use, condomless anal sex [CAS]) risk factors for violence victimization.
Results: Participants' mean age was 33.6 (SD=11.4), and 40% identified as White, 32% Black and 19% Latino. Nearly 50% identified as bisexual, 36% gay and 12% straight. Most (63%) were unemployed and 43% reported recent unstable housing. Half had no income outside of sex work, and two-thirds participated in street-based sex work. While engaging in sex work, participants reported previously experiencing: verbal abuse (22%), physical abuse (10%), rape (8%), forced CAS (9%), forced drug use (11%), and forced drinking (6%). In the past 6 months, 30% reported experiencing emotional (24%), physical (10%) and/or sexual violence (9%) by a client or intimate partner. In multivariable models, higher CESD depression scores (OR=1.09, 95%CI 1.01-1.17, p=0.022) and stigma scores (OR=1.60, 95%CI 1.23-2.08, p< 0.0001) were associated with recently experiencing violence perpetrated by a client or intimate partner.
Conclusions: Violence victimization was common among male sex workers in the US Northeast particularly when engaging in sex work, underscoring the need for violence education and prevention. Psychosocial risk factors were associated with violence victimization among male sex workers, suggesting the need for access to comprehensive health and social services for this deeply marginalized population.

Transgender people

WEPED503

Advocacy in health care coverage for the transgender population in Argentina

N.F. Cardozo, M. Romero
Asociación de Travestis, Transexuales y Transgéneros de Argentina (ATTTA), Buenos Aires, Argentina

Background: The Association of Transvestites, Transsexuals and Transgenders of Argentina
(ATTTA) is an organization founded in 1993 that aims to fight against violations of Human Rights. One of the most important achievements has been the approval of the Gender Identity Law No. 26743, enacted on May 9, 2012.
Description: Despite the fact that 5 years and eight months have passed since the approval of the law, most of the Argentine territory does not comply with article 11 that guarantees integral health care of trans people. This means that trans people still continue to find barriers in access to health care system.
Lessons learned: Therefore, ATTTA has established a strategy of community, territorial and political advocacy to guarantee trans people access to health care services without stigma or discrimination. In the first place, ATTTA has established cooperation agreements for the creation of inclusive health care centers. Currently these centers operate in the city of Buenos Aires, Lomas de Zamora, San Martin, Avellaneda, Mar del Plata, Chivilcoy, San Juan, Córdoba,. In addition, ATTTA coordinates a program in the main referral center for HIV-AIDS treatment, Francisco Muñiz Infections Hospital, where it works
„Trans Vivir", which provides support and accompaniment to trans women living with HIV-AIDS.
Additionally, ATTTA has signed an agreement with the Global Fund to fight AIDS, Tuberculosis and Malaria and has sensitized 43 health care personnel since 2016/17. The inauguration of the first Trans House is a model to replicate throughout the region. So far this year, 1,800 transgender women and men have passed for counseling, material delivery, vaccination, HIV testing.
Conclusions/Next steps: The best strategy to reverse the prevalence rates of HIV-AIDS, which in Argentina is around 35% and the life expectancy that is 35 years for the trans population is the community work of organized civil society with the support of the State. This result had been caused by the continuous violation of human rights and institutional violence. It is necessary to increase efforts to continue holding awareness-raising workshops in different public and private health care spaces, and continue with political advocacy to continue with the opening of more inclusive centers for the trans population.

WEPED504

Understanding the impact of incarceration and re-entry on HIV risk and treatment for transgender women in the United States

S.L. Creasy[1,2], M.E. Hawk[1,2], M.R. Friedman[1,2], C. Mair[1], J. McNaboe[3], J.E. Egan[1,2]
[1]University of Pittsburgh Graduate School of Public Health, Pittsburgh, United States, [2]Center for LGBT Health Research, Pittsburgh, United States, [3]Beth Israel Deaconess Medical Center, Boston, United States

Background: Transgender women (TW) experience higher rates of both HIV and incarceration than their cisgender counterparts, and this cycle of incarceration and poor health is understudied. Previously incarcerated TW who are living with HIV, particularly TW of color, are less likely to receive the HIV treatment they need due to economic and discrimination-related barriers. Furthermore, TW have unique challenges that may not be addressed in standard re-entry programs. The purpose of this mixed-methods study is to understand the experiences, needs, and resiliencies of TW during incarceration and re-entry in order to understand the cycle of poor health and recidivism in this population.
Methods: In this ongoing study we use qualitative interviews and spatial analysis to describe lack of access to resources, as well as challenges regarding HIV treatment and other healthcare services. We interview previously incarcerated adult TW residing in a mid-size city in the United States regarding experiences during incarceration, re-entry, and post-release. Additionally, we map city neighborhoods, bus lines, mental health providers, and trans-inclusive resources using geographic information system (GIS) software to explore barriers to transportation and access.
Results: Currently 50% of participants are HIV+ and 67% identify as Black/multiracial. Of the participants who received re-entry services, all were placed with cisgender men and no programs were trans-inclusive. Preliminary results indicate that immediate access to HIV treatment and other healthcare, housing, transportation, and trans-inclusive community support are the most significant barriers to successful re-entry. The spatial relationship between low-income neighborhoods and proximity to community resources suggests that TW residing outside urban areas have increased difficulty regarding access to HIV treatment and other needs.
Conclusions: TW face significant and unique challenges during re-entry and post-release from incarceration, particularly related to consistent HIV care. Future multilevel interventions should incorporate HIV treatment and other healthcare services, trans-inclusive community support, access to stable housing, and the alleviation of transportation barriers. Co-location of re-entry services will increase access, support, and treatment for TW re-entering the community. Developing trans-inclusive interventions during this vulnerable time of heightened HIV risk is vital for improving the health and well-being of TW and our communities.

WEPED505

My health, my rights/two case studies on the conditions of transgender women and effeminate gay men in prison

C. Cruz-Camacho[1], J.J. Hernandez[1], J. Elizalde[2], R. Suarez[3], R. Boivin[1]
[1]Colectivo Sol A.C., Salud y Derechos, Mexico D.F., Mexico, [2]Colectivo SerGay de Aguascalientes, Aguascalientes, Mexico, [3]Centro de Apoyo a las Identidades Trans, Salud y Derechos, Mexico D.F., Mexico

Background: My health, my rights (MHMR) has the purpose of strengthening the sense of citizenship of key populations in Mexico -mainly transgender women and gay men- to ensure access to stigma and discrimination-free HIV/STI prevention and care services, through community systems strengthening, evidence-based advocacy actions and external relations.
Description: Case studies describe and document in detail abuses and violations to the human rights of imprisoned and sentenced transgender women in two states in Mexico. The study describes how these violations affect their health and wellbeing; it denounces how in-prison transphobic violence is a threat to their lives and impinge on their human rights and dignity. Case studies include a groundbreaking and exhaustive analysis of how abuses entail law breaking by police, general attorneys and judges and expose the denial of health services to address HIV and consequences of bodily transformation of trans women.
Lessons learned: MHMR designed and developed a set of practical tools to implement participatory community assessments (PCA) to specifically collect data on HR abuses against TTT. The PCA methodology allows full and meaningful involvement of target populations in data search, identification, documentation, organization and analysis. As a result, the program documented and systematized for the first time in Mexico violations of human rights of trans people in prison, as described and analyzed in the two case studies of HR abuses. Both case studies reveal the ordeal Liz and Karina went through -starting with their apprehension- and demonstrate how ingrained homophobic and transphobic prejudice of public servants have a detrimental effect on due process, access to justice and to specific HIV/STI-related health services. The publication of the Case Studies as a key program output, sets the stage for further rapid research in other prisons at state and federal level and serves as a tool to generate and enrich new data, showing the impact that discriminatory and abusive practices by civil servants in the justice system are a threat to the health, safety and lives of these populations.
Conclusions/Next steps: New case studies on the conditions of transgender women and effeminate gay men in prison.

WEPED506

Understanding barriers, working alongside the community: A formative study for the implementation of a peer-navigation intervention among transwomen living with HIV in São Paulo, Brazil

G. Saggese[1], D. Barros[1], R. Batisteli[1], H. Gilmore[2], J. Sevelius[2], S. Lippman[2], M.A. Veras[1]
[1]Santa Casa de Sao Paulo School of Medical Sciences, Sao Paulo, Brazil, [2]University of California, San Francisco, UCSF School of Medicine, San Francisco, United States

Background: Transwomen are disproportionately affected by HIV worldwide. Their lived experiences often include stigma and gender-related discrimination, which may hinder access to healthcare services and create cycles of violence that exacerbate existing health disparities. If diagnosed with HIV, transwomen also often face difficulties engaging in HIV care and adhering to ART. This study aimed to explore these challenges to inform a peer-navigation intervention for improving engagement in HIV care among HIV-positive transwomen in São Paulo, Brazil.
Methods: Between October 2017 and January 2018, we conducted 10 in-depth interviews with key informants (transwomen and health professionals working with transwomen), as well as 3 focus groups with transwomen only. A total of 33 people participated. Semi-structured guides sought to elicit experiences around access to social and healthcare services, with an emphasis on HIV care, as well as to understand the potential benefits and challenges of peer-navigation for transwomen living with HIV.
Results: Main barriers included access to social and healthcare services due to limited service hours and the lack of sensitivity and preparedness of professionals in addressing transwomen's specific needs, such as the correct use of the preferred name, medical knowledge regarding hormone provision and complications related to industrial silicone. Low adherence to ART appears to be related not only to the obstacles transwomen face accessing care in general, but also to reduced prospects for successful careers, financial stability, and general safety and well-being. All participants, however, were very enthusiastic that peer-navigation could provide needed support.
Conclusions: This formative study confirmed that a peer navigation intervention among transwomen living with HIV in São Paulo has potential to enhance ART adherence and well-being by addressing some of the barriers pointed out with the help of empowered and adherent peers, at both medical and social levels. Consulting affected communities prior to program development and implementation will certainly improve its success.

WEPED507

Inclusion of transgender youth in educational institutes to mainstream the community and reduces the vulnerabilities to HIV & mental health

Y. Singh[1], V.R. Anand[2], S. Gupta[2], M. Benjwal[1], G. Yadav[1], S. Parashar[2], M. Sivasubramanium[2], S. Rawat[2]
[1]Humsafar Trust, New Delhi, India, [2]Humsafar Trust, Mumbai, India

Background: The Indian Supreme Court's NALSA judgement of 2014 recognized the third gender, and recommended for reservations in jobs and education. Despite this, the enrolment of TG youth in educational institutes and jobs remains suboptimal. The literacy rates continue to remain low among TGs, and the community sustains on begging and sex work, which increases their vulnerability towards HIV and other health issues. The Humsafar Trust, conducted sensitization meetings with educational institutes in Delhi NCR to facilitate enrolment of TG communities for higher education.
Description: Under the CONNECT project, we conducted 10 meetings of 120 community members with national open educational institutes like Indira Gandhi National Open University. The meetings were attended by more than 30 staff members from these institutes who were sensitized on issues faced by the community in providing required documentation for enrolment. The sensitization workshops further helped clarify myths and foster understanding on complex issues of sexuality, gender and PLHIVs. This resulted in first ever declaration from Indira Gandhi National Open University that will support transgender communities in pursuing higher education. They also assured scholarships and free education support to the TG communities.
Lessons learned: The major challenges were in gathering the documents from transgender youth, as majority of them either didn't have documents with them or were having it with the gender & name assigned to them at birth. As an immediate step, we were successful in securing appointment of a TG person as a Help Desk Facilitator, at the educational institute who facilitated admission process for 32 TG women/men who were enrolled into the university. This was done in collaboration with other grassroots level organizations further strengthened this process not only in terms of institute sensitization but also the admission process.
Conclusions/Next steps: Along with sensitization workshops with faculty, there is need to institutionalize the processes of education opportunities for TG communities. The setting up of the systems (helpdesk) at educational institutes, will help ensure the stigma and discrimination free education to TG youth; will empower them and thus will help in overall reducing the vulnerabilities of the TG youth.

WEPED508

Inclusion of married transgender population in HIV-related services

S.K. Giri
Kolkata Rista, Kolkata, India

Background: Both in India and globally, there is no specific targeted intervention or program for the MTG (married transgender) community, transgender people assigned male at birth who are married to women out of familial compulsion or choice, and who are often socially compelled to live as heterosexual men. In that context, Kolkata Rista, a community-based organization of transgender, hijra and MSM people, conducted a year-long study of the barriers to HIV-related services faced by MTG people in three states of India: West Bengal, Bihar and Uttar Pradesh.
Description: The project was a qualitative multi-sited study of the barriers to HIV-related services faced by MTG (married transgender) population. It was conducted between January 2017 and December 2017 at 6 sites (both urban and rural) in three states of India: West Bengal, Bihar and Uttar Pradesh. The study included 12 FGDs (Focus group discussions), two at each site, and a total of 60 interviews, ten at each site. The FGDs were conducted with MTG people, while the interviews were conducted with both MTG people and their partners.
Lessons learned: As per the FGDs and interviews, over 90% of MTG individuals reported that compared to the rest of the transgender population, they experience double barriers to accessing services such as HIV/STI testing and antiretroviral treatment (ART). Firstly, MTG experience huge stigma and discrimination from the broader transgender community, which prevents them from accessing community-based intervention programs.
Secondly, they also face barriers accessing services from non-community-run service centers because of the general isolation of transgender people in mainstream health services. They thus face compounded intersectional forms of vulnerability to HIV.
Conclusions/Next steps: While we are talking of Universal Health Coverage for all by 2030 and LNOB (leave no one behind), we are leaving behind the doubly marginalized MTG community. Since the present scenario of health services for MTG is unfriendly and discriminatory, it is essential to implement specifically targeted projects for MTG population if we really want to end HIV by 2030. Such targeted projects would help to bring HIV services to all marginalised communities, such that no one is truly left behind and we can achieve UHC 2030.

WEPED509

Health care guide for the respect of trans people in Latin America and the Caribbean

M. Romero
Red Latinoamericana y del Caribe de Personas Trans, Buenos Aires, Argentina

Background: In the framework of the proposal „Women Trans without Borders against Transphobia and HIV / AIDS" of the Global Fund to Fight AIDS, Tuberculosis and Malaria, REDLACTRANS has developed the only Health Guide developed by trans woman of Latin America and the Caribbean with the purpose of raising awareness among health care professionals about comprehensive care for this population.
Description: Over the past 2 years, REDLACTRANS conducted 57 awareness-raising workshops in 13 different countries in Latin America and the Caribbean, reaching a total of 2065 health care providers who were sensitized about comprehensive health care and HIV-AIDS towards the trans population. The „Recommendations Guide on Comprehensive Health Care for Trans Women in Latin America and the Caribbean" has increased the reach of this audience and its socialization has led to the reduction of discriminatory practices in health care centers, which impede access by trans people to health care services.
Lessons learned: On the one hand, the awareness workshops were led by trans women who could sensitize health care providers from their own experiences. This dynamic reaffirmed the importance of trans people sensitizing health care professionals about their own needs. On the other hand, these instances have been the first steps for the development of inter-institutional agreements between Civil Society Organizations and Hospitals in order to guarantee unrestricted access to health care services. Among these advances, it is necessary to highlight the opening of Health care Centers and the respect for the identity of those trans people living with HIV / AIDS.
Conclusions/Next steps: These achievements highlight the importance of carrying out political strategies that articulate actors from both civil society and the government agencies with the purpose that trans people can freely access an elementary Human Right: health care.

WEPED510

The *Transcendendo* cohort study - unveiling the social vulnerabilities of transgender women and *travestis* in Rio de Janeiro, Brazil

A.C.G. Ferreira, L.E. Coelho, E.M. Jalil, R.K. Friedman, S.W. Cardoso, R.C. Moreira, L.F. Eksterman, C.V. Castro, M. Derrico, R.I. Moreira, M.R. Guimarães, B. Fernandes, P.M. Luz, V.G. Veloso, B. Grinsztejn
Evandro Chagas National Institute of Infectious Diseases, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil

Background: Transgender women and *travestis* (transwomen) are the most affected population in the Brazilian HIV epidemic. Recent data showed high HIV prevalence among transwomen in Rio de Janeiro. However, transwomen are underrepresented in HIV epidemiologic, be-

havioral and clinical studies and have poor access to prevention and health care services. The Fiocruz Transgender Health Clinical Cohort (*Transcendendo*) was created in 2015 to improve our knowledge of this population.
Methods: The Fiocruz Transgender Health Clinical Cohort is a clinic-based open cohort of HIV-infected and at risk HIV-uninfected trans-women ≥18 years living in Rio de Janeiro, Brazil. Data are prospectively collected at annual visits that include face-to-face interviews, clinical, behavioral and laboratory assessments. Additional information is retrieved from medical records and linked national databases. Baseline data are presented.
Results: From August 2015 to July 2017, 323 transwomen were enrolled. Median age was 31.5 (IQR 25.7 - 39.5), age of transformation was 16 (IQR 14-18) and age of sexual debut was 6 (IQR 4-11). Markers of vulnerability, such as poor schooling (36.9% with less than 8 years of education), high rates of physical (54.0%) and sexual (46.0%) violence were prevalent. Access to reassignment surgery (5.9%) and feminization procedures (41.0%) was poor and frequent use of unsupervised hormone therapy (75.0%) and industrial liquid silicone injection (49.0%) was observed.
The HIV-infected group (N=175, 54.0%) had higher rates of less than 8 years of education (42.9% vs. 29.4, p=0.015), were younger at the time of gender transformation (15 [14-18] vs. 16 [15-18.2], p=0.048) and sexual debut (6 [4-10] vs. 7 [5-13], p=0.034), were more frequently engaged in sex work (52.9% vs. 39.2%, p=0.022) and had higher rates of sexually transmitted infections, tobacco and cocaine dependence. At cohort enrollment, the median time since diagnosis was 1.8 years (IQR 0-7.3), 67.0% were on antiretroviral therapy, with a median CD4+ cell count of 617 (IQR 373-804) and 69.7% had undetectable viral load.
Conclusions: Data from *Transcendendo* cohort highlighted alarming socioeconomic vulnerability, high rates of violence, substance dependence and poor access to gender affirming care among the transgender population.

	HIV negative N=148	HIV positive N= 175	Total N=323	p-value
Alcohol ASSIST index ≥ 4	65 (59.1)	76 (51.7)	141 (54.9)	0.420
Tobacco ASSIST index ≥ 4	47 (44.7)	86 (58.6)	134 (52.1)	0.055

Knowledge and attitude towards transgender-related healthcare among Malaysian medical doctors: Implications for HIV treatment and prevention

M.H. Cha[1], A. Vijay[2], Y.C. Tee[1], S.H. Lim[1,3], F.L. Altice[1,2,4], J.A. Wickersham[1,2]
[1]University of Malaya Faculty of Medicine, Centre of Excellence for Research in AIDS, Kuala Lumpur, Malaysia, [2]Yale University School of Medicine, Internal Medicine, New Haven, United States, [3]University of Malaya Faculty of Medicine, Social and Preventive Medicine, Kuala Lumpur, Malaysia, [4]Yale University School of Public Health, Epidemiology of Microbial Disease, New Haven, United States

Background: Effective HIV treatment and prevention for transgender people requires physicians who can address their unique needs. For transgender patients, gender-affirming healthcare that is coupled with HIV treatment and prevention may have a synergistic effect on outcomes. This study reports on Malaysian physicians' knowledge and experience of transgender healthcare.
Methods: A total of 436 physicians in Kuala Lumpur, Malaysia, completed an online survey about transgender healthcare. Measures included socio-demographics, clinic- and provider-level attributes, and transgender stigma-related constructs, including prejudice, internalized shame, fear, stereotypes, and belief that transgender people deserve good care. Descriptive statistics are reported and chi-square and t-tests were used to examine correlates of contact with transgender persons.
Results: Physicians were mostly female (52.8%) and specialized in internal medicine (25.2%) or primary care (11.9%). Average age was 34.7 years and medical officer (37.4%) and specialist (28.4%) were the most common clinical statuses. Transgender-specific care was not offered in most clinics (76.6%) and physicians ranked themselves as novice or beginner (84.4%) on transgender health; most (95.4%) had no formal training in transgender care. Nearly all (95.2%) said their clinic had no intake/triage procedure to identify transgender patients and most (58.9%) viewed such screening as unnecessary. Regarding sex reassignment surgery, 46.1% said it should not be available to transgender patients; and most (59.6%) said transgender people should be prohibited from changing their sex on government-issued identification. Physicians who recently provided care to transgender patients (26.6%) had lower prejudice (p< 0.05) and fear (p< 0.05) and were more willing to provide care to transgender patients (p< 0.05) compared to physicians who had not provided care. No differences in stereotype, internalized shame, and belief in good care were observed. Personally knowing a transgender person was associated with lower fear of transgender people (p< 0.05) and greater interest in receiving training in transgender healthcare (p< 0.05).
Conclusions: Effectively engaging transgender patients in HIV treatment and prevention requires trans-competent physicians. Concerning from these results are the low knowledge of transgender care and low support for gender-affirming procedures. Contact with transgender persons, however, appears to mitigate prejudice and fear. Curriculums, including continuing medical education, should scale-up training in transgender care.

WEPED512

Combating violence and promoting sexual health among transgender persons using trauma-informed psychosocial support in the Federal Capital Territory, Nigeria

P. Umoh[1], T. Jaiyebo[1], G. Emmanuel[1], B. Ochonye[2], A. Yusuf[1], C. Trout[3]
[1]Heartland Alliance International, Programs, Abuja, Nigeria, [2]Heartland Alliance International, Abuja, Nigeria, [3]Heartland Alliance International, Los Angeles, United States

Background: Intimate partner violence (IPV) often results in acute and chronic physical and mental health problems. Though there is no data on IPV against transgender (TG) individuals in Nigeria, studies from other countries have shown that the lifetime prevalence of IPV against TGs is higher than among the general population. IPV is associated with low self-esteem, drug and alcohol abuse and high-risk sexual activities which are also risk factors for sexually transmitted infections, including HIV.
Methods: In 2014, Heartland Alliance International (HAI implemented a 10-month trauma-informed psychosocial intervention to reduce IPV and mitigate its effects among TG during support groups. A questionnaire was used to collect categorical quantitative data on sexual behavior, history and attitudes relating to IPV and emotional intelligence before and after the intervention. We used the calculator at http://vassarstats.net/propcorr.html to construct odds ratios for each outcome and perform two-tailed McNemar's tests to check if the changes in outcomes between start and finish were statistically significant at the P=0.05 level.
Results: In total, 34 TG participants were recruited into the project in the Federal Capital Territory. Assertiveness skills increased by the end of the project. At baseline, 68%% (23) were sure about negotiating condom use but 88% (30) were at the end. At baseline, 23 participants (68%) would not stay with a partner that beat them which increased to 82% (28). Those who did not seek self-validation from a high number of sexual partners increased from 56% (19) to 92% (31) and 88% (32) said they felt good about themselves despite not dating anyone at the end, up from 71% (24). Also, 79% (27) now had people in their life to rely upon, up from 58% (20). Awareness of serostatus increased from 82% (28) to 97% (33). The changes in all five outcomes before and after the intervention were statistically significant at the P=0.05 level. (Table 1)

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July

Publication Only Abstracts
Author Index

Conclusions: While the sample was small, TG who participated exhibited healthier attitudes regarding relationships, IPV and were more likely to know their status. HAI intends to scale up this intervention to prevent and mitigate IPV and promote healthy attitudes among TG.

	Total #	Baseline #	Baseline %	Endline #	Endline %	OR	OR Confidence Interval	P (McNemar's two-tailed test)
Sure about negotiating condom use	34	23	68%	30	88%	5.75	1.99-16.63	0.0003
Not Stay with a violent partner	34	23	68%	28	82%	2.88	1.29-6.43	0.01
Doesn't need Self-validation from increased sexual partners	34	19	56%	31	92%	6.33	1.87-21.40	0.0009
Feels good despite not dating anyone	34	24	71%	32	94%	12	2.84-50.8	<0.0001
Have people to rely on	34	20	58%	27	79%	2.86	1.21-6.76	0.0192
Aware of HIV status	34	28	82%	33	97%	28	3.81-205.80	<0.0001

WEPED513

A literature review of the factors that affect use and uptake of Pre-Exposure Prophylaxis (PrEP) among young transgender women (TGW) aged 15-24 years in sub-Saharan Africa

J. Kottutt[1], C. Kottutt[2]
[1]Emory University, Rollins School of Public Health, Global Health, Atlanta, United States, [2]Ferris State University, School of Pharmacy, Big Rapids, United States

Background: Current literature on PrEP adherence has mostly focused on men who have sex with men (MSM) with limited studies on transgender populations (TGP). However, TGP particularly TGW, are disproportionately affected by HIV and the evidence is extremely lacking, particularly in sub-Saharan Africa. The purpose of this study was to conduct a literature review of peer-reviewed literature to establish the factors that affect the uptake of PrEP among TGW so that culturally appropriate biomedical and behavioral interventions can be created.

Methods: Two independent reviewers electronically searched published studies and articles from 2000 to 2018 on PubMed, EMBASE, Web of Science, and Google Scholar. The reviewed resources focused on PrEP adherence, uptake, and use among TGW living in sub-Saharan Africa. A transgender individual was defined as someone who identified as being different from the assigned sex at birth. The search terms included "PrEP adherence", "PrEP uptake", "PrEP use" among "transgender-women" AND "HIV" AND "15-24 years". Due to the limited number of resources, we included studies with PrEP adherence, some not specific to TGW in sub-Saharan Africa.

Results: 77 studies were reviewed to establish the factors that affected PrEP adherence among young TGW. Individual factors include sexual position during anal intercourse, having multiple high-risk sexual partners and, internalized transphobic stigma. A major epidemiological factor is the failure of most studies to differentiate between MSM and TGW in the pathophysiology and etiology of HIV. Structural factors include marginalization of trans populations, which make them prone to poverty and sex work; parental permission laws; lack of youth/adolescent friendly HIV services; stigmatization and discrimination of youth/adolescent HIV/AIDS services; criminalization, and in some cases punishment.

Conclusions: Insufficient scientific studies on PrEP adherence among TGP and this has resulted in a limited understanding of the epidemiological, structural and individual barriers that affect TGW. Moreover, it has impeded the development of culturally appropriate interventions as well as policies that address the unique challenges of PrEP provision among young TGW in sub-Saharan Africa. Future research should focus on qualitative methods in order to establish the specifics needs of TGW so that culturally appropriate biomedical and behavioral interventions for PrEP adherence can be created.

WEPED514

Princess project: Increasing health and well-being for African American transwomen living with HIV in Oakland, CA, USA

T. Nemoto, M. Iwamoto, S. Suico
Public Health Institute, Oakland, United States

Background: HIV prevalence is high among transwomen in the U.S., particularly among African American transwomen; however, they tend not to enroll in HIV primary care and also drop out from care.

Description: The Princess Project provided a Motivational Enhancement Intervention (MEI) to facilitate the enrollment and retention in HIV primary care for African American transwomen living with HIV in Oakland/Alameda County, California. Participants were asked to take the initial 3 MEI sessions, and then monthly 6 MEI sessions. Working with trans Health Educators, participants developed a realistic and workable behavioral change plan and strived to attain the objectives through client-centered MEI sessions. Participants were also encouraged to participate in a weekly support group.

Lessons learned: Among 63 participants enrolled, 54% had completed the required 3 MEI sessions, and 21% completed additional 6 MEI sessions. At intake, half of the participants (33 out of 66) had not enrolled in HIV primary care even though they knew their HIV positive status. Through MEI intervention, 11 out of 33 participants enrolled in HIV primary care and continued to be in care. Health Educators made a number of referrals in addition to HIV care, such as to drop-in centers, housing assistance, substance abuse treatment, legal assistance, mental health treatment, and food assistance programs. Participants had a number of barriers to enroll in and maintain HIV primary care (e.g., priorities for securing income and housing). A weekly support group was successful to assist participants to increase access to information about HIV care and other health issues (e.g., hormone therapy).

Conclusions/Next steps: A large proportion of African American transwomen living with HIV had not enrolled in or dropped out from HIV primary care and lacked access to comprehensive care and support in Oakland/the San Francisco Bay area where a number of HIV care and health services for transwomen are available. In order to reduce the number of HIV positive African American transwomen without HIV primary care, trans sensitive and comprehensive programs are needed to address their urgent needs (e.g., financial security, food, housing, and gender affirmation health care), as well as to build supportive communities for transwomen of color.

WEPED515

Factors associated recent HIV testing among transgender women in Cambodia: Findings from the National Integrated Biological and Behavioral Survey (TG-IBBS 2016)

S. Yi[1], S. Tuot[1], S. Chhim[2], P. Chhoun[1], P. Mun[3], K. Chhim[4]
[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]FHI 360 Cambodia, Phnom Penh, Cambodia, [3]National Center for HIV/AIDS, Dermatology and STD, Phnom Penh, Cambodia, [4]KHANA, HIV/AIDS Flagship Project, Phnom Penh, Cambodia

Background: Globally, the HIV prevalence among transgender women remains high, and a large proportion of transgender women are unaware of their HIV status. This study aimed to identify factors associated with recent HIV testing among transgender women in Cambodia.

Methods: The National Integrated Biological and Behavioral Survey was conducted in 2016 among a nationally representative sample of transgender women recruited from the capital city and 12 provinces with a

high HIV burden using Respondent Driven Sampling method. Face-to-face interviews were conducted using a structured questionnaire. A multivariate logistic regression analysis was performed to explore factors associated inconsistent condom. This study was approved by the Cambodian National Ethics Committee for Health Research.

Results: In this analysis, we included 1375 transgender women with a mean age of 25.8 years (SD= 7.1). Of total, 49.2% had been tested in the past six months. After controlling for several potential confounding factors, participants who had been testing for HIV in the past six months remained significantly less likely to be a student (AOR= 0.36, 95% CI= 0.20-0.65), to perceive that they were unlikely to be HIV infected (AOR= 0.50, 95% CI= 0.32-0.78), and to report always using condoms with male non-commercial partners in the past three months (AOR= 0.65, 95% CI= 0.49-0.85) compared to those who had not been tested. Regarding access to community-based HIV services, participants who had been testing for HIV in the past six months remained significantly more likely to report having been reached by community-based HIV services in the past 6 months (AOR= 5.01, 95% CI= 3.29-7.65) and receiving some forms of HIV education and materials in the past six months (AOR= 1.65, 95% CI= 1.06-2.58) compared to those who had not been tested.

Conclusions: More than half of transgender women in this study had not been tested for HIV in the past six months despite the availability of extensive community-based HIV testing services across the country. HIV testing promotion programs with both HIV education and HIV testing services should be tailored to reach sub-groups of this high-risk population who have not been reached by the existing strategies.

WEPED516

Exposure to gender-based violence and depressive symptoms among transgender women in Cambodia: Findings from the National Integrated Biological and Behavioral Survey (TG-IBBS 2016)

S. Yi[1], S. Tuot[1], P. Chhoun[1], S. Chhim[2], P. Mun[3], G. Mburu[4]
[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]FHI 360 Cambodia, Phnom Penh, Cambodia, [3]National Center for HIV/AIDS, Dermatology and STD, Phnom Penh, Cambodia, [4]Lancaster University, Division of Health Research, Lancaster, United Kingdom

Background: Transgender women are at significant risk of HIV and they face intersecting barriers to health, social, and legal services. However, data regarding the unique needs and experiences of transgender people is scant globally. This study examined the relationship between gender-based violence and depressive symptoms among transgender women in Cambodia.

Methods: This cross-sectional study included 1,375 sexually active transgender women recruited by using respondent-driven sampling in the capital city of Phnom Penh and 12 provinces of Cambodia. Data were collected between December 2015 and February 2016. Depressive symptoms were assessed using the Center for Epidemiologic Studies Depression scale (CES-D). Multivariate regression analysis was conducted to explore factors associated with depressive symptoms.

Results: Of total, 45.0% of the participants had depressive symptoms, and 21.8% had severe depressive symptoms. After controlling for potential confounders, transgender women with depressive symptoms remained significantly more likely to report several negative experiences of gender-based violence such as a feeling that co-workers or classmates were not supportive regarding their transgender identity (AOR= 2.00, 95% CI= 1.22-3.28), having difficulties in getting a job (AOR= 1.67, 95% CI= 1.29-2.16), having been denied or thrown out of a housing (AOR= 1.53, 95% CI= 1.02-2.26), having difficulties in getting health services (AOR= 2.40, 95% CI= 1.50-3.82), having been physically abused (AOR= 1.54, 95% CI= 1.15-2.08), and having been fearful of being arrested by police or authorities (AOR= 2.18, 95% CI= 1.64-2.91) because of their transgender identity. Regarding their childhood experiences, transgender women with depressive symptoms remained significantly more likely to report that someone had tried to touch them or make them touch in a sexual way when they were growing up (AOR= 2.08, 95% CI= 1.61-2.68).

Conclusions: Transgender people in Cambodia experience high levels of depressive symptoms. To address this concern, a combination of service and policy interventions are required. These may include training and sensitization of trained and lay health providers in screening for depressive symptoms and integration of mental health services into facility- and community-based HIV services with enforcement of policies and laws that protect the rights of transgender women against gender-based violence.

WEPED517

Potential barriers in access to community-based HIV services among transgender women in Cambodia: Findings from the National Integrated Biological and Behavioral Survey (TG-IBBS 2016)

K. Chhim[1], S. Tuot[1], P. Mun[2], S. Chhim[3], P. Chhoun[1], S. Yi[1]
[1]KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]National Center for HIV/AIDS, Dermatology and STD, Phnom Penh, Cambodia, [3]FHI 360 Cambodia, Phnom Penh, Cambodia

Background: Transgender women are at significant risk of HIV, and they face intersecting barriers to health, social, and legal services. However, data regarding the unique needs and experiences of transgender people is scant globally. This study was conducted to explore barriers in access to community-based HIV services among transgender women in Cambodia.

Methods: These cross-sectional data were collected in 2016 as part of the National Integrated Biological and Behavioral Survey. Sexually active transgender women were recruited from the capital city of Phnom Penh and 12 provinces using respondent-driven sampling method. A structured questionnaire was used for face-to-face interviews. Multivariate regression analysis was conducted to explore factors associated with depressive symptoms. This study was approved by the National Ethics Committee for Health Research.

Results: The study sample included 1375 transgender women with a mean age of 25.8 (SD= 7.1); of whom, 45.0% reported having received at least one community-based HIV service in the past three months. Transgender women with access to community-based HIV services remained significantly more likely to reside in a rural setting, report having used gender-affirming hormones, have been tested for HIV in the past six months, and have been arrested by police or authorities because of their transgender identity or expression compared to transgender women without access to community-based HIV programs. However, transgender women with access to community-based HIV services were significantly less likely to report being in receptive role, using condom consistently with men not in exchange for money or gifts, and not using condoms because it was not available. Regarding gender-based discrimination and violence, transgender women with access to community-based HIV programs were significantly less likely to perceive that their co-workers or classmates were very supportive regarding their transgender identity compared to that of transgender women without access.

Conclusions: We found that the respondent-driven sampling method enabled us to reach a large proportion of transgender women who had not been reached by community-based HIV programs. This method may be adapted to increase the coverage of the programs reaching out sub-groups of this high-risk population who could not be reached by the existing interventions.

WEPED518

The HIV care cascade among trans women in Canada: Barriers and facilitators

A. Lacombe-Duncan[1], G. Bauer[2], P.A. Newman[1], C.H. Logie[1], Y. Persad[3], M. Shokoohi[2], A. Kaida[4], A. de Pokomandy[5,6], N. O'Brien[7,8], M. Loutfy[9,10]
[1]Factor-Inwentash Faculty of Social Work, University of Toronto, Toronto, Canada, [2]Western University, Department of Epidemiology & Biostatistics, London, Canada, [3]The 519 Community Centre, Toronto, Canada, [4]Simon Fraser University, Faculty of Health Sciences, Vancouver, Canada, [5]McGill University Health Centre, Chronic Viral Illness Service, Montreal, Canada, [6]McGill University, Department of Family Medicine, Montreal, Canada, [7]McGill University, Family Medicine, Montreal, Canada, [8]Chronic Viral Illness Service, Montreal, Canada, [9]University of Toronto, Department of Medicine, Toronto, Canada, [10]Women's College Hospital, Women's College Research Institute, Toronto, Canada

Background: Transgender (trans) women experience a disproportionate HIV prevalence, yet little is known about the engagement of trans women living with HIV (WLWH) in the HIV care cascade and associated socioecological factors. This study sought to describe
a) the proportion who attained each HIV care cascade outcome, and
b) socioecological factors associated with each HIV care cascade outcome among trans WLWH in Canada.

Methods: The Canadian HIV Women's Sexual and Reproductive Health Cohort Study (CHIWOS) collected national baseline survey data from 2013-2015. Of 1422 WLWH, 50 self-identified trans women were included in this analysis. Proportions of trans WLWH linked to HIV care (ever accessed), engaged in care (received any, past year), initiated and currently using antiretroviral therapy (ART), adhered to ART (≥ 95% ART taken, past month), and reported an undetectable HIV viral load (< 50 copies/mL) were summarized. Bivariate analyses identified correlates of each outcome.

Results: Results showed that 92% (n=46/50) (95% Confidence Interval (CI): 84%-100%) were linked to care. Of those linked to care, 91% (n=42/46) (83%-98%) were engaged in care. Additionally, 78% (67%-89%) (n=36/46) of those linked to care had initiated and were currently using ART, among whom optimal adherence to ART was reported by 67% (n=24/36) (52%-83%). Among those with optimal adherence, 96% (n=23/24) (85%-100%) reported an undetectable viral load. Statistically significant associations were identified with linkage (positively correlated: years living with HIV, violence; negatively correlated: physical health-related quality of life [HRQoL], barriers to care access); engagement (negatively correlated: affectionate social support, social interaction, trans stigma); ART initiation/use (positively correlated: years living with HIV, hazardous alcohol use, recreational drug use, violence; negatively correlated: increased age, physical HRQoL, personalized HIV-related stigma, unstable housing, racism, barriers to care access, access to a family physician, trans stigma); and ART adherence (negatively correlated: depression, PTSD).

Conclusions: Findings suggest gaps in care access across the cascade for trans WLWH, particularly for ART use and adherence. Targeted research is needed to further understand the mechanisms by which socioecological factors impede care access for trans WLWH, in particular trans-specific factors (e.g., trans stigma), in order to inform contextually-relevant interventions to increase HIV care engagement for this population.

WEPED519

Factors predicting viral suppression and retention in HIV care among transgender women of color living with HIV in four urban centers in USA

G. Rebchook[1], S. Shade[2], D. Chakravarty[1], J. Keatley[3], J. Xavier[4], C. Reback[5], R. Contreras[6], J. Perloff[7], T. Woods[8], J. Birnbaum[9], K. Ducheny[10], T. Nemoto[11], Special Projects of National Significance Transgender Women of Color Study Group
[1]UCSF Center for AIDS Prevention Studies, Medicine, San Francisco, United States, [2]UCSF, Epidemiology & Biostatistics, San Francisco, United States, [3]UCSF Center of Excellence for Transgender Health, Family and Community Medicine, San Francisco, United States, [4]Independent Consultant, Silver Spring, United States, [5]Friends Research Institute, Los Angeles, United States, [6]Bienestar Human Services, Los Angeles, United States, [7]Chicago House and Social Service Agency, Chicago, United States, [8]Tri-City Health Center, Fremont, United States, [9]SUNY Downstate Medical Center, Department of Pediatrics, Brooklyn, United States, [10]Howard Brown Health, Chicago, United States, [11]Public Health Institute, Oakland, United States

Background: Transgender women of color (TWOC) experience high HIV infection rates while facing unique barriers to healthcare engagement. HRSA's Special Projects of National Significance TWOC initiative is an evaluation of care engagement interventions implemented by 9 demonstration projects in 4 US urban centers.

Methods: The demonstration sites conducted computerized surveys (baseline and 4 follow-up surveys every 6 months) with 858 TWOC living with HIV between December 2013 and August 2016 (mean age=37; 49% Latina, 42% Black) to assess key barriers and facilitators to healthcare engagement. Medical chart data were also collected throughout the initiative. We defined retention in care as at least one visit in each of two prior six month periods, separated by ≥ 60 days. We conducted exploratory analyses to uncover changes in viral suppression (VS) (viral load< 200) and retention in care (both evaluated from medical chart data) over time, by the facilitators and barriers to care (from the baseline survey data). We used GEE modeling used to assess how changes over time in retention and VS were associated with multiple self-reported barriers and facilitators to care at baseline.

Results: A significant improvement in VS at the 24-month follow-up period was detected among participants who at baseline, reported (for previous 6 months): drug use, homelessness, transience, food insecurity, transportation challenges, and disclosing their gender identity compared to those who did not report those barriers or facilitators at baseline (Table 1). A significant improvement in retention in care at the 24-month period was associated with baseline reporting of: childhood sexual abuse, transience, transportation challenges, disclosing gender identity, and higher levels of healthcare empowerment.

EXPLANATORY VARIABLES±	ODDS RATIO		
	Baseline	12-month	24-month
Outcome: Viral Suppression			
Drug use	0.34**	1.48	1.58*
Homelessness	0.51***	1.24	1.34*
Moved 2 or more times in 6 mos.	0.40**	1.52**	1.84**
Food insecurity	0.54***	1.11	1.38*
Transportation challenges	0.51	1.46***	1.67***
Disclosed gender identity	1.07	1.64**	1.47*
Outcome: Retention in HIV Care			
Childhood sexual abuse	0.59**	1.28**	1.67**
Moved 2 or more times in 6 mos.	0.57**	1.22**	1.49**
Transportation challenges	0.43***	1.80**	2.01*
Disclosed gender identity	0.62	2.40***	2.38*
Healthcare empowerment	1.22	1.43*	1.57*

*p<.05; **p<.01; ***p<.001 (Non-significant barriers/facilitators are not presented in table)
±Recall period for all variables: previous 6 months

[Table 1: Baseline barriers and facilitators associated with changes in VS and retention in care over time in bivariate GEE models]

Conclusions: People reporting barriers at baseline generally had lower levels of engagement in care than those who did not report barriers. But, those who reported certain barriers (e.g., drug use, childhood sexual abuse, food insecurity, homelessness, transience, transportation barriers) demonstrated more improvement than others over 24 months. Disclosure and healthcare empowerment are important facilitators to consider in interventions to improve engagement in care.

These findings indicate that the interventions were successful at improving engagement in care for the most vulnerable groups of transwomen of color living with HIV.

WEPED520

Sex work is associated with sexual violence and HIV among transwomen in São Paulo, Brazil

G. B. de Souza[1], E. C. Wilson[2], C. Turner[2], A. B. M. da Rocha[1], M.A. M. Veras[1], Divas Project
[1]Faculdade de Ciências Medicas da Santa Casa de São Paulo, Public Health, São Paulo, Brazil, [2]San Francisco Department of Public Health, San Francisco, United States

Background: Studies have shown that transwomen (TW) engage in sex work to survive, but little is known about the health and wellness of TW who do sex work in Brazil. Data from other regions suggest TW who do sex work suffer high rates of discrimination, physical, and sexual violence, which may precipitate poor health outcomes. The present study was conducted to determine the prevalence and correlates of sexual violence and HIV infection among TW sex workers living in São Paulo.
Methods: DIVAS was a cross-sectional study of 386 adult TW conducted from November 2016 to May 2017 in São Paulo, Brazil. Descriptive analyses and multivariable logistic regression models were used to calculate the HIV prevalence among TW with a history of sex work and to examine the associations between sex work (lifetime and current) and sexual violence, forced sex without a condom, and HIV infection. Odds Ratios were adjusted based on significant demographics and risk factors (use of condom, housing, gender, race, and education) associated with sex violence in bivariable analyses.
Results: Among all TW in DIVAS, 90.41% (N=349) ever experienced sexual violence and 80.00% (N=308) were ever forced to have sex without condoms. Most participants had a history of sex work (N=326, 84.46%), and of those, 92.02% (N=300) reported experiencing sexual violence and 43.97% (n=135) tested positive for HIV. TW who were currently engaged in sex work had greater odds of experiencing sex violence (adjusted odds ratio, AOR=2.41;[95%CI]=1.07-5.41) and being forced to have sex without a condom (AOR 2.21;[95%CI]=1.92-7.79) than those not currently engaged in sex work. TW with a history of sex work had 2.59 ([95%CI]=1.20-4.07) times the odds of having HIV compared to those with no history of sex work.
Conclusions: HIV and sexual violence is prevalent among TW in São Paulo; even more so among TW who do sex work. TW sex workers are at greater risk for being forced to have condomless sex, which has important implications for their wellbeing and the transmission of infectious diseases. Interventions that address violence, particularly among transwomen engaged in sex work, are needed to promote well-being and reduce risk for sexually transmitted infections.

Sex Work Involvement	Sex Violence	Forced to have sex without condom	HIV infection

WEPED521

Sexual behavior and health of transgender people who are sexually active with MSM in Japan: An online survey through gay geosocial networking mobile application, *LASH study*

T. Ohtsuki[1], Y. Ikushima[1], T. Miwa[1], M. Yamaguchi[2], C. Ikegami[1], M. Tarui[1], LASH Study Group
[1]PLACE TOKYO, Tokyo, Japan, [2]Bunan Hospital, Saitama, Japan

Background: MSM account for 60-70% of people living with HIV in Japan. However, little is known about those transgender individuals who are sexually active with MSM. The objectives of this study were to better understand their sexual behavior and health issues so that their needs for prevention, care, and support could be filled.
Methods: Data come from the LASH study conducted from September to October 2016. MSM including transgender people who have sexual relationship with MSM were subjected for the study, and the respondents were recruited through Japan's most popular gay geosocial networking mobile application. Then an anonymous, self-completed online survey, composed of 97 questions about love, sex, and health, was conducted to measure their view of relationships and sexual health such as HIV-related risk behaviors and knowledge.
Results: Of total 6,921 respondents who completed the survey, 83 respondents were transgender (41 trans women, 23 trans men, and 19 others, e.g. X-gender persons) with a mean age of 31.0 years (95%CI 29.1-32.9). Among trans women, 41.5% had sexual contact with 2 to 5 men and 29.3% with 6 or more men over previous six months; meanwhile, 56.5% had sexual contact with 2 to 5 men and 8.6% with 6 or more men among trans men. Compared to 62.3% in all respondents, 56.6% in trans men, 39.0% in trans women, and 57.9% in other transgender persons had tested for HIV at least once in their lifetime.
When asked about knowledge of HIV, transgender respondents less understood (more than 10% of gap between transgender and all respondents) the effect of ART, social welfare services for HIV/AIDS, and links between HIV and STIs.
Conclusions: The results suggest that most of transgender people are sexually active, but they neither grasp HIV risk nor test for HIV as often as non-transgender populations. Since it is limited to gay mobile application users, future in-depth research is expected to prepare appropriate strategies of prevention, care, and support for this population.
*This study was conducted for Research on Support for PLHIV and Drug Users in Regional Communities by Research on HIV/AIDS from Health, Labour and Welfare Sciences Research Grants (fiscal 2015-17).

WEPED522

Transgender stigma - barrier to accessing HIV testing and treatment services in Federal Capital Territory (FCT), Nigeria

T.A. Alamu[1], C. Trout[2], J. Stapleton[2], B. Ochonye[3], A. Kalaiwo[4], G. Emmanuel[3], O. Ugege[3], A. Ojemeire[3], O. Irinoye[3]
[1]Heartland Alliance International, Strategic Information and Knowledge Management, FCT, Nigeria, [2]Heartland Alliance International, Chicago, United States, [3]Heartland Alliance International, FCT, Nigeria, [4]USAID, FCT, Nigeria

Background: Globally, many transgender people face stigma, discrimination, social rejection and exclusion that prevent them from fully participating in society, including accessing health care, education, employment and housing[1]. Transgender people are 49 times more likely to be living with HIV infection than the general population[2]. Recently, Heartland Alliance International (HAI) began implementation of HIV comprehensive care and treatment among the transgender population in Nigeria.
Description: From February through December, 2017, HAI recruited 746 (169 male, 577 female) transgender individuals through mobile outreach and in "One Stop Shops" (fixed locations that provide specialized comprehensive HIV prevention, care and treatment for key populations). The service package included HIV prevention services, HIV testing services (HTS), sexually transmitted infection (STI) syndromic management and

tuberculosis (TB) screening and referrals, comprehensive care and treatment to HIV-positive clients, and mobile refills of medication prescriptions to clients in FCT.

Lessons learned: HAI ensured 100% of clients 746 (169 male, 577 female) knew their HIV status out of which 62 (8.3%) were identified to be HIV positive (22 male, 40 female); 725 (169 male, 556 female) or 97.2% of 746 were screened for other sexually transmitted Infections (STIs). Four females had STIs and were treated. From the 62 who were HIV positive, 31 (50%) (11 male, 20female) were successfully initiated on ART by the mobile OSS and 100% retained, while 31 or 50% (13 male, 18 female) were not prepared to commence ARV treatment.

Conclusions/Next steps: HAI has successfully implemented an intensive, mobile-based approach to mitigating the HIV epidemic among the transgender population. While HAI will continue to provide access to quality HIV services for transgender people, there is a dire need for additional mapping in order to recruit more trans individuals into HIV prevention services. Additionally, outreach must be done to raise awareness in the transgender community about the availability of stigma-free services in order to increase demand for HTS.

Other populations vulnerable in specific contexts

WEPED523

Improving targeted HIV testing services (HTS) in Zimbabwe: A study to identify orphan and vulnerable children (OVC) sub populations most at risk for HIV

C. Sisimayi[1], R. Malaba[2], P. Ndlovu[2]
[1]PSRT Centre, Harare, Zimbabwe, [2]World Education, Inc., Harare, Zimbabwe

Background: OVC programs have increasingly been called upon to increased uptake of HTS in pursuit of UNAIDS 90-90-90 goals. Experience in Zimbabwe demonstrates that mass testing efforts among broad OVC populations however, have not yielded high positivity rates. More targeted testing is needed to ensure limited resources are applied to finding, testing, and initiating those OVC most in need onto treatment and care. This study set out to inform community-based screening processes that feed into targeted testing by establishing which social and clinical characteristics among the OVC population best represent individuals with the greatest HIV risk.

Methods: A retrospective case control study was conducted in Bubi District in November 2017 to identify index markers related to HIV infection. Secondary data on HIV status of OVC and primary data generated through administration of a 14-item, standardized questionnaire to 159 OVC caregivers via interviews by a Community Health Worker were gathered. Study participants included OVC caregivers of both HIV-positive and HIV-negative children enrolled in Bantwana Initiative's OVC program activities. Data were analyzed utilizing advanced predictive techniques (Logistic Regression, Chi-square Automatic Interaction Detector-CHAID and Random Forest Modeling) to elicit the relationship between risk markers and HIV status.

Results: The study identified 56 cases and 103 controls (54.1% male, 45.9% female). 92.9% of the study population was over 5 years of age and 42% cared for by a grandparent. 58.5% of caregivers had at least secondary level education. Regression analysis identified 'poor school attendance', 'orphanhood' and 'living with an HIV+ contact' as the social markers strongly associated with HIV infection (p <0.05). CHAID and Random Forest analysis recognized 'living with an HIV+ contact' as a strong predictor of HIV infection.

Conclusions: Children who demonstrate irregular/no school attendance, orphans and those residing with a person living with HIV are at heightened risk of HIV infection and should be targeted for HTS. Given the similar performance of social and clinical index markers in predicting HIV positivity, community-focused OVC programs are well positioned to carry out comprehensive social profiling to identify and track socio-demographic determinants related to HIV risk that can inform more targeted testing.

WEPED524

Increasing uptake for HIV testing services (HTS) among key populations using linkage facilitators

M. Irene, N. Hellen, K. Carol, K. Francis
IntraHealth International, Programs, Kampala, Uganda

Background: Addressing the second 90, in the 90:90:90 global agenda is becoming a key challenge due to poor adherence and loss to follow up, using health facility linkage facilitators who are Key populations peers already in care to bring the gap of HTS among key population community as helped increase adherence and treatment compliance in Eastern Uganda. This approach was adopted after the move by the ministry to roll out test and treat strategy where by any patient who tests positive is immediately enrolled in care Improving performance in linking HIV Positives to Care as part of the second 90**.** Overall, 55% of the HIV positive clients identified in FY 2017 were linked to care.

Description: RHITES-E worked to improve performance on this indicator by enlisting a key population peer leader per health facility as a linkages person for fellow key populations who test positive this resulted in 88.8% initiation to care under the new test and treat strategy. RHITES-E provided educational materials, condoms, moon light testing to KPs at identified bars as a way to address the first 90 in, brothels and known hot spots targeting female sex workers (FSW), Men who Sex with Men (MSM) and People who inject drugs (PWID) in Mbale and Tororo districts.

Lessons learned: The performance of RHITES-E in getting HIV+ individuals into ART is significantly stronger in its work with Key Populations, with 81.3% of all HIV positive KP initiated on ARVs.

RHITES improved linkage to care to 60% in this reporting period. This high linkage percentage can be attributed to the role played by peers as linkage facilitators from community to facilities.

Conclusions/Next steps: This practice, coupled with a team of four health workers per facility as contact persons for key populations was found to boost key population facility attendance and continuity of services, a practice that will be scaled up in other hot spots.

WEPED525

Breaking the silence for learners with disabilities

J. Hanass-Hancock
South African Medical Research Council, HIV-Prevention Research Unit, Durban, South Africa

Background: Adolescents and youth with disabilities in South Africa lack access to comprehensive sexuality education, which increases their vulnerability to HIV and other sexual reproductive health issues. This is exacerbated for learners with intellectual disabilities whose educators often lack skills and tools to accommodate these learners in sexuality education lessons and who may hold negative believes about these learners sexuality. In response, the Breaking the Silence approach, a curriculum implementation and disability-accommodating approach, was developed, piloted and formatively evaluated in KwaZulu-Natal, South Africa.

Methods: We conducted a formative evaluation of the approach with educators of learners with intellectual and learning disabilities from eight special schools. Using in-depth interviews we describe the educators' understanding and experiences of using this approach and what contextual factor provided barriers or enablers for implementation. The analysis used conventional content analysis and NVIVO software.

Results: Educators still conceptualized sexuality education within a risk-protection discourse but began to break through towards a rights-based approach. They revealed that the training and tools enabled them to provide sexuality education in accessible formats, tackle difficult topics such as sexual orientation and masturbation, and improved awareness and assertiveness within their learners. Educators began to address cultural taboos related to talking about sexuality and disability. The findings revealed that contextual factors impacted the degree of implementation. These factors were related to perceptions of socio-cultural norms, interpersonal engagement with peers and management, the structural environment of school settings, and the wider community setting. In particular negative attitudes of untrained staff and cultural taboos were

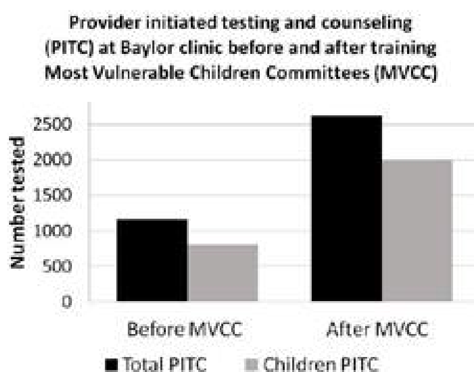
experienced as major barrier. The heightened risk of sexual violence against these learners was an additional challenge in their work.
Conclusions: Through its application within the South African mainstream Life Orientation curriculum, this approach lends itself for further development and testing through implementing the approach within a whole school setting and ongoing support that will not only drive change in educators' skills and knowledge but also drive the needed shift in cultural norms and values. The further development also needs to respond to the socio-cultural context in which educators have to implement comprehensive sexuality education.

WEPED526

Vulnerable children committees pave the way towards achieving first UNAIDS 90-90-90 for pediatrics in Tanzania

R. Mushi[1], T. Roche[1], M. Mgawe[1], A. Salum[1], F. Swai[1,2], S. Makungu[1], J. Cataldi[1,3], J. Gwimile[1], M. Minde[1,3], L. Mwita[1,3]
[1]Baylor College of Medicine Children's Foundation-Tanzania, Mwanza, Tanzania, United Republic of, [2]Bugando Medical Centre, Mwanza, Tanzania, United Republic of, [3]Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States

Background: Despite the outstanding progress towards an AIDS-free generation, Tanzania faces challenges in meeting the UNAIDS 90-90-90 targets for pediatrics. These challenges include identifying HIV positive children and linkage to care and treatment. Only 67% of the estimated 91,000 children living with HIV in Tanzania have been identified. Baylor Tanzania conducted a community-based educational program with the Most Vulnerable Children Committees (MVCCs) in our catchment area.
Description: Beginning November 2016, we identified, trained, and supported members from the MVCC along with district, ward, and village community leaders. MVCC members were trained to educate and sensitize families and caregivers of orphans and vulnerable children (OVC) for HIV testing, care and treatment services. MVCC received monthly ongoing support and feedback. A retrospective review of provider-initiated testing and counseling (PITC) monthly clinic reports was performed.
Lessons learned: During the six months preceding MVCC training, the 1163 clients received PITC services at Baylor: 70% (810/1163) clients were children and 1% (9) were referred by MVCC members. Of the total clients tested, 10% (119) were HIV positive, including 6% (47/810) of children. During the six months after the MVCC initiative began, 2618 clients received PITC services: 77% (2004) were children and 69% (1805) were referred by MVCC members. Of clients tested during the post-training period, 5% (136) were positive including 3% (62/1805) of children tested. 46% (62/136) of all newly identified HIV positive clients were children and all were linked to care and treatment services.
Conclusions/Next steps: MVCC sensitization efforts substantially increased the number of children and family members knowing their HIV status and were successful at identifying HIV positive children and linking them to care. Targeting priority groups using community members may contribute in closing the gap needed to achieve "the first 90" for pediatrics.



[Number of clients tested for HIV at Baylor clinic before and after MVCC training]

WEPED527

The economic empowerment of women vulnerable to HIV: Experience from Kyrgyzstan

E. Zhirnova
AFEW Kyrgyzstan, Project Management, Bishkek, Kyrgyzstan

Background: Traditional interventions for marginalized women, including women living with HIV in Kyrgyzstan, usually focus on providing crisis interventions. However, this ignores other aspects of women's lives, especially high levels of poverty and stigmatisation. The project "*Our choice: economic empowerment of vulnerable women in Kyrgyzstan*" set the goal to enhance the social and economic capabilities of vulnerable women in Kyrgyzstan (single mothers, sex workers, women living with HIV, partners of drug users, former prisoners, mothers of children living with HIV).
To achieve the goal the following comprehensive approach is being offered to vulnerable women during the project framework (August 2017-January 2020).
Description: The initial intervention is client management to help women in solving a wide range of social, medical and legal problems. The client managers also encourage women to participate in first stage training on personal development in order to increase women's self-esteem and internal strength. The next intervention is second stage training about economic independence which aims to mobilize the resources of each participant and design a business plan. The most interesting and feasible business plans are awarded with micro-grants.
By December 2017, 172 women were reached by the client management program through outreach and referrals from partner organizations. 79 started changing their lives through participation in the trainings on personal development. 46 women attended the economic independence sessions. 19 women demonstrated legible financial goals and started implementing their business plans with the support of the Project.
Lessons learned: Making positive changes in people's lives is impossible without integrated support which includes economic empowerment and personal development. Questionnaires confirmed that 89% of the project participants had an increased sense of internal strength and motivation to resist stigma. 100% of second stage training participants announced that they became stronger in financial computations. All grantees increased their income by at least 15 %.
Conclusions/Next steps: The project's approach is broader than resolving client's critical situation. Using consecutive steps of complex program we intend to change women's life perception, focusing on economic empowerment, and improve their quality of life.

WEPED528

Turning the tide, breaking the barriers to access, adherence and retention to antiretroviral therapy and prevention of mother to child transmission of HIV among adolescents in Kenya

M. Murenga
Lean on Me Foundation, Nairobi, Kenya

Background: The shift to combination therapies for treating people living with HIV has increased adherence and improved health outcomes. However, HIV morbidity and mortality among adolescents is still on the rise. We set to identify barriers associated with adherence to antiretroviral therapy (ART) among adolescents and find sustainable solutions to improving health outcomes for them.
Description: The program engaged 250 adolescents (ages 15 - 24 years) living with HIV who had been on antiretroviral therapy for over 1 year with high viral loads. We had 100 males and 150 females of which 72 needed Prevention of Mother to Child Transmission (PMTCT) services, 11 had HIV/TB co-infection. We employed both qualitative data collection methods in form of individual and focus group discussions to identify barriers to adherence. The quantitative involved using hospital records to assess the impact of adherence on viral load and clinical outcomes.
Lessons learned: Factors that influence adherence were identified as:
(1) Individual factors such as stigma, discrimination, disclosure, fatigue, pill burden, poverty and treatment literacy.

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

(2) Medication regimen such as dosing, side effects and food requirements.
(3) Relationship with health care providers.
(4) The system of care such as short waiting time.
We conducted treatment literacy and adherence counselling; held group therapies for peer learning and sharing; had dialogue sessions with health care providers to improve relationships; supported in reduction of self-stigma; supported disclosure; aided provision of differentiated care and provided nutritional support to those who had TB/HIV co-infection. After 24 months, out of 250 adolescents who were active on antiretroviral therapy, 94% (*N* = 235) achieved viral suppression, 100% (*N* = 72) who were on PMTCT had HIV free babies and 82% (*N* = 9) who had TB co-infection completed their treatment got cured of TB. We had 0.8% (N=2) Mortality.
Conclusions/Next steps: Turning the tide against AIDS is possible but will require more concentrated focus on adolescents and young people. It is critical to understand the epidemic among the adolescents. We need to put deliberate efforts to improve treatment literacy and address stigma, gender-based violence and other human rights related barriers to access to HIV services.

WEPED529

Accessing healthcare services and supports in remote communities: The stories of 29 First Nations people living with HIV in Ontario, Canada

S. Hillier[1], L. Lavallée[2]
[1]*Ryerson University, Policy Studies, Toronto, Canada,* [2]*University of Manitoba, Office of Indigenous Engagement, Winnipeg, Canada*

Background: In 2014-2015 Indigenous peoples represented 17.5% of all HIV infections in Canada, yet account for only 3.2% of the population. In 2008 in Ontario (ON), Indigenous people accounted for an estimated 3.2% of people living with HIV, while comprising 2.4% of the population. From 2009 to 2011, 2.7% of new HIV diagnoses in ON were Indigenous people, of whom 7.2% were women. One in three Indigenous people is infected through the use of drugs. This research study sought to assess the efficacy of funding and services for HIV/AIDS services within ON First Nations (FN) communities. This research will improve understanding of services available to people and communities affected by the HIV/AIDS epidemic.
Methods: ON FN people who were at least 16 years of age and living with HIV/AIDS (n=29) participated (demographics are outlined in Table 1). Using the Indigenous based method of storytelling, participants were asked five open-ended questions related to their use of and access to healthcare services. Stories were transcribed and analyzed using Nvivo. Grounded theory formed the basis of analysis which brought forward common themes from each story. Transcriptions form the bases of re-written first-person stories, detailing the life and experiences of the participants and their experiences of living with HIV/AIDS and accessing care.

Table 1	Gender Identity		
	Female	Male	2-Spirited
Demographics			
Age (High)	65	63	60
Age (Average)	50	45	51
Age (Low)	41	31	43
Avg. Monthly Net Income (CAD)	$1,329	$1,214	$1,942
Sexual Orientation			
Straight	11	11	-
2-Spirited	1	2	2
Gay	-	-	1
Not Straight	-	-	1
Total	12	13	4

[Table 1]

Results: In northern communities, all participants experienced issues with access to care and supports. Participants were forced to leave their northern communities, either permanently or temporally, due to limited access to care. HIV related stigma played a role in access to prevention, testing, and care. All participants indicated difficulties with HIV education either in understanding their own HIV status or in the lack of education within the broader community. Historical traumas (residential schooling & the 60s scoop) and discrimination were a central theme to many stories, impacting the lives of participants and their overall health outcomes.
Conclusions: Greater access to community based, holistic care in northern FN communities is urgently required. There is pressing need for culturally competent and relevant HIV prevention measures and education within communities to reduce stigmatization and improve access to prevention and care services.

WEPED530

Moving ART services behind bars: A differentiated service delivery model for ART services results in high viral load suppression among inmates in correctional facilities in Zambia

K. Mwanda[1], M. Chikuba Mcleod[2], D. Phiri[3], E. Mwila[4], K. Chibesakunda[5], D. Chikondi[6], M. Banda[3], L. Kawanga[7], J. Jose[7]
[1]*JSI/USAID DISCOVER-Health Project, HIV/AIDS Clinical Services, Lusaka, Zambia,* [2]*JSI/USAID DISCOVER-Health Project, Lusaka, Zambia,* [3]*JSI/USAID DISCOVER-Health, Kabwe, Zambia,* [4]*JSI/USAID DISCOVER-Health, Lusaka, Zambia,* [5]*JSI/USAID DISCOVER-Health, Kitwe, Zambia,* [6]*JSI/USAID DISCOVER-Health, Solwezi, Zambia,* [7]*JSI/USAID DISCOVER-Health, Ndola, Zambia*

Background: HIV prevalence among prison inmates in Zambia is twice as high as that in the non-incarcerated population, 27% compared to 13.3%. Correctional facilities are overcrowded and the warden to prisoner ratio is often low, resulting in challenges in escorting HIV positive inmates to health facilities for ART and related care. USAID DISCOVER-Health project applied a differentiated service delivery (DSD) model for the provision of ART, care and adherence support to prisoners. The objective was to eliminate key barriers to comprehensive HIV treatment/care in correctional facilities and improve treatment outcomes.
Description: Working together with the Zambia Correctional Services between October, 2016 and December, 2017, the Project established service provision within prison grounds and prison walls at eight correctional facilities. Standard of care in these prisons was typified by inmates only get to a health facility upon being escorted by a wader or a prisoner enlisted for parole. In contrast, the DSD model addressed the risk of missed clinic appointments and provided comprehensive HIV treatment and care including adherence within easier reach.
Lessons learned: Viral load investigations were conducted in line with national guidelines. 241 (55%) viral load results were received of the 438 submitted. Of these 234 (97.1%) were males and seven (2.9%) were females. 221 (98.2%) were virally suppressed. Of this figure, all the seven females were virally suppressed (100%), while among the males, 214 (98.1%) were suppressed. For the suppressed males, the majority, 178 (83.2%), were initiated in prison while 25 (16.8%) were already on treatment at the time of imprisonment. All the females were initiated on ART in prison. Inmates benefiting from this differentiated model had higher viral load suppression rates (98.2%) compared to the non-incarcerated population (89.2%) (ZAMPHIA, 2016).
Conclusions/Next steps: Eliminating barriers to treatment, care, and adherence support in prison settings can yield better viral suppression rates. The Project's next steps include undertaking an empirical study to scientifically ascertain this correlation. The Project will engage government and other stakeholders to both scale-up this model to other correctional facilities and to implement structural changes that will sustainably support similar innovations in Zambia.

WEPED532

Towards 90-90-90: Examining the knowledge and attitude of prisoners in Nigeria towards HIV/AIDS

A. Ekpenyong[1,2], Y. Adebisi[3], S. Adeyemi[4], B. Ntacyabukura[5]
[1]University of Uyo, Faculty of Pharmacy, Uyo, Nigeria, [2]National Assembly Clinic, Abuja, Nigeria, [3]University of Ibadan, Ibadan, Nigeria, [4]Federal Medical Center, Ondo, Nigeria, [5]University of Rwanda, College of Medicine and Health Sciences, Kigali, Rwanda

Background: Prisoners risk for infections including HIV/AIDS is very high due to their lifestyle. This made it pertinent to understand their knowledge and attitude towards HIV/AIDS which will further contribute to the achievement of the 90-90-90 treatment target in 2020. The aim of our study was to systematically review available evidences on the knowledge and attitude of prisoners towards HIV/AIDS in Nigeria.
Methods: A systematic review of literature on PubMed, Scopus, Web of Science, Embase and Cochrane Library was performed from 2010 to 2017. This search was complemented with conference abstracts and unpublished research reports. The studies were screened for eligibility. 13 studies were carefully chosen: 7 qualitative, 2 quantitative and 4 mixed methods studies. Qualitative content analysis was carried with the resultant data extracted and summarized to highlight prisoner's knowledge and attitude towards HIV/AIDS.
Results: From the systematic review, the knowledge and awareness about HIV/AIDS was identified to be high with the mass media as the main source of information. The knowledge of the 90-90-90 target and antidiscrimination laws protecting people living with HIV/AIDS however was found to be minimal. There were certain misconceptions about HIV/AIDS along with incidences of high risk behaviors among inmates despite the perceived increase in knowledge and awareness about HIV/AIDS. Injection of drugs was also found to be common among the prisoners using unsterilized materials. The common sexual practices identified among the articles reviewed were masturbation and homosexuality, with the latter representing a significant source of HIV in Nigerian prisons. Sociocultural factors and religion were not prominent factors influencing the knowledge of inmates. However, it had a significant effect on their attitude towards HIV/AIDS.
Conclusions: More awareness needs to be carried out to address misconceptions about HIV/AIDS as well as reduce the prevalence of risky behaviors among inmates in Nigerian prisons, a necessary step in achieving target 90-90-90. Furthermore, mass sensitization of the inmates on antidiscrimination laws is essential to prevent incidences of stigmatization and ensure improved treatment outcomes.

WEPED533

Mobilization efforts to ensure an uninterrupted access to treatment, care and support for PLWH in the armed conflict zone at the non-government controlled areas in Ukraine

Y. Strelnikov
CO, Kyiv, Ukraine

Background: Abstract focuses on mobilization efforts to ensure an uninterrupted access to treatment, care and support for PLWH in the armed conflict zone.
Description: Since the beginning of the armed conflict in Ukraine Charitable Organization "Variant" has been providing an interrupted access for treatment, care and support for people with HIV infection. In 2014, there was a threat of interruption of treatment of 6,500 HIV positive people due to inability to supply the antiretroviral medications from the Ukraine government to non-government controlled areas in Ukraine. Using the status of a non-governmental organization, CO 'Variant" managed to mobilize efforts of local medical facilities and HIV-service organizations to ensure human rights and access to treatment for people with HIV infection, including convicts.
Lessons learned:
· Since the beginning of the armed conflict, the organization has been working in 13 prisons (providing services for secondary HIV prevention for more than 5,000 convicts);
· 600 HIV positive convicts and 1,500 people living with HIV in Donetsk and neighboring towns are under social support program;
· In 2016 the primary HIV prevention program has been renewed (now 8,000 adolescents are under this program);
· CO "Variant" serves as a subject matter expert and an accredited partner for Humanitarian Missions at the non-government controlled areas in Ukraine.
Conclusions/Next steps: Practical experience of CO "Variant" can be considered as the best practices in HIV/AIDS advocacy, community mobilization, harm reduction and protection of PLWH's rights at the armed conflict zones. And we will be proud to share our experience with others to work to end the HIV epidemic all over the world.

WEPED534

Mental health resilience for young children whose parents have died

L. Sherr[1], A. Macedo[1], M. Tomlinson[2], S. Skeen[2], K. Roberts[3]
[1]UCL, Global Health, London, United Kingdom, [2]Stellenbosch University, Stellenbosch, South Africa, [3]UCL, London, United Kingdom

Background: Parental loss is a major stressful event that has been found to increase risk of mental health problems in childhood. Option B+ and ARV treatment will dramatically affect parental survival, but the legacy of AIDS parental deaths still remain. Yet, some children show resilient adaptation in the face of adversity across time. Studies focus on the negative implications, but we explore predictors of mental health resilience among parentally bereaved children, and their cumulative effect.
Methods: Consecutive child attenders (aged 4-13) of HIV community services randomly selected in South Africa and Malawi were interviewed at baseline and 15-18 month follow up (N=833 - 0.7% refusal rate;; 84% follow up). Interviews comprised study specific and standardised inventories on demographic information, child and family data, child mental health, bereavement experience and community characteristics. Resilience was the absence of symptoms of depression, suicidality, trauma, and emotional and/or behavioural problems at baseline and followup.
Results: 490 (58.8%) had lost one or both parents (182 paternal orphans, 84 maternal orphans, 224 double orphans). One quarter of orphaned children, 70 girls, 54 boys, showed no mental health problems at either wave and were classified as resilient. Resilience status did not differ by age (OR=1.03, 95% CI= 0.95, 1.11) or gender (female: OR=1.20, 95% CI=0.80,1.91).8 significant predictors were identified. Being a quick learner, having a role in helping ill family members, positive caregiving, living in a home where someone was employed, higher community support, and lower exposure to domestic violence, harsh physical punishment, or stigma at baseline predicted sustained resilience. There were cumulative influences of predictors of resilience. For those experiencing one of the predictors, resilience rates were 11.1% climbing to 42.3% with 7 predictors. OR=1.42, 95% CI=1.21, 1.66, p< .001). Only 4 children experienced all 8 protective factors.
Conclusions: This study enhances understanding of resilience in younger children in the wake of parental death. Attention should be given to both positive and negative mental health. The longitudinal study identifies a number of potential environmental and psychosocial factors for bolstering resilience in orphaned children. These should be incorporated into the AIDS response.

Increasing TB case detection and treatment among street children in the slums of Kampala District; the case of Kamwokya Christian Caring Community (KCCC)

N. Seruma[1], A. Namugwere[2], KCCC Study Group
[1]Kamwokya Christian Caring Community, Monitoring and Evaluation, Kampala, Uganda, [2]Kamwokya Christian Caring Community, TB Section, Kampala, Uganda

Background: Despite concerted efforts to curb TB in the slums of Kampala district, KCCC realized that there was no intervention to increase TB case detection and treatment among Street Children in Kampala district and TB still remained a public health burden among street children. The Stigma and social economic status of street children makes it difficult for them to access treatment from public clinics and information on TB. In 2015 KCCC launched a 3 year project aimed at strengthening TB/HIV Prevention and care among street and other vulnerable children in Kampala district.
Description: 144 Community Health Works were trained to map dwelling places for street children, Weekly community outreach clinics were launched to screen children on the streets, Sputum samples for children aged 0-17 years were examined using Microscopy or Genexpert, Clinical Diagnosis, X-Ray tests were done for children whose sputum results tested negative but had signs of TB. Nurses and Community Health Workers visited children on treatment on a daily basis to collect adherence data. Nutritional support was given to Street Children on TB treatment so as to adhere to medication. Those Co-Infected with HIV were initiated on ARVS.
Lessons learned: Between 2015 and 2016, 1532 street/vulnerable children were tested for TB using microscopy, Genexpert, X-ray and clinical diagnosis. 26 had TB (5 females and 21 males) This year 160 children tested for TB and 9 tested positive; An overall 35 children since 2015 have been diagnosed with TB and of those, 5 were co-infected with HIV/AIDS and initiated on ART. 2 children were pregnant and also co-infected with HIV/AIDS. All street children diagnosed with TB have registered 100% adherence to TB medication.
Conclusions/Next steps: TB detection in children requires a combination of diagnosis methods such as Genexpert, Clinical diagnosis, microscopy and x-Ray, because using one method is difficult to detect TB in children.

WEPED536

Closing the gaps: Addressing sexual and reproductive health needs of young persons with disabilities (PWDs) using school based minimum prevention package intervention (MPPI) strategy

R. Ajayi[1,2], B. Osuolale[3], A. Ajumobi[4]
[1]PEDOFAT, Community Mobilization and Program Planning, Ado - Ekiti, Nigeria, [2]Ekiti State AIDS Control Agency, Community Mobilization and Program Planning, Ado - Ekiti, Nigeria, [3]Irewolu Women Society, Community Mobilization and Program Planning, Ado - Ekiti, Nigeria, [4]Ekiti State AIDS Control Agency, Monitoring and Evaluation, Ado - Ekiti, Nigeria

Background: Young person with disabilities are found to be more vulnerable to HIV compared to those without disabilities and yet they face several challenges in accessing HIV services due to many factors such as stigma from their host community and health care providers, transport challenges,long queue, requirement for escort, facility infrastructure not being physically accessible and lack of skills and sensitivity on the part of Care providers.
The HAF project (funded by the World Bank) in Ekiti State Nigeria designed a two years disability-inclusive HIV/RH programme to address sexuality and health needs of PWDs.
Description: Three special government schools for PWDs, one urban and two rural were selected as project sites. A cohort of health Care providers comprising of Government health facility, civil society, private sector organizations and the host schools were constituted under the supervision of three (3) local programme officers on HIV/RH services. PWDs in the four categories (blind, deaf, physically challenged and intellectually impaired) were profiled to explore their sexual vulnerability using psychosocial, health, legal and education indices. HIV/SRH facilities were mapped and designated. Specially PWDs tailored tools and materials such as braille, pictorial, audio- aids, sign language manual, PEP model were developed to deliver a comprehensive MPPI program among PWDs. The result of the intervention was collated, analyzed and documented using District Health Information Service (DHIS) and implementation completion report(ICR).
Lessons learned: The result showed a varied sexual and reproductive health requirement of young persons with disabilities as the project outcome revealed that 45% of PWD access condom services, 25% HIV Testing and Counselling, 3% STI services, 0.5% family planning services,1% TB services,86% health education, 25% educational support, 15% nutritional support services, 76% psychosocial support services and 5% legal protection.
1157 individuals representing 89% of the host community were enrolled and assessed HIV/RH services within the two years project,increase in health seeking behaviour among PWD rose from 12% to 68%.
Conclusions/Next steps: Provision of disability inclusive HIV/RH services for PWDs is key in meeting their sexuality and reproductive needs where it also addresses PWDs vulnerability challenges to accessing services like other person without disabilities. More still need to be done in overcoming communication barriers to reach a large segment of PWDs.

WEPED537

Utilization of PHC services of rural Migrant communities in South Africa

J.A. Kruger[1,2], B. van Wyk[2], C. Zarowsky[2]
[1]Western Cape Government, Health, Cape Town, South Africa, [2]University of the Western Cape, School of Public Health, Cape Town, South Africa

Background: Large scale labour migration is central to the regional economy of southern Africa. With millions of people already on HAART and with a growing burden of chronic disease, health systems based on models of stable catchment area populations are increasingly unable to respond to the real health needs and social realities of the people they serve both migrant and sedentary. 11,000 migrant workers from Zimbabwe, Lesotho, Malawi and other provinces in South Africa come to the fruit growing areas of Cape Winelands District between September and March each year, increasingly including families with young children. Farmworkers often travel between many locations as different crops mature hence risk suboptimal continuity of care and poor health outcomes for both migrants and the community where they reside. The children are also at high risk of neglect, malnutrition and diarrhoea.
Methods: A cross-sectional, quantitative survey of 807 households in De Doorns were administered to 807 migrant workers (334 = male; 473 = female; mean age = 35 years) by trained research assistants. Descriptive analysis was conducted to describe utilization of health care services.
Results: Both women (89%) and men (74%) reported high utilization of public primary health care services. TB (21 %) and HIV (18%) health services were mostly accessed by male migrants; while females mostly accessed health services for Maternal and Child Health (MCH) 37% ((pregnancy (17%), child care (20%)), and HIV (16%). Services for non-communicable diseases (NCDs) were less utilized at 8% and 7% for diabetes and 12% and 26% for Hypertension amongst men and women, respectively, which indicate undetected and/or uncontrolled chronic conditions.
Conclusions: High utilisation of public health services for HIV/TB and maternal and child health indicates high trust in public health care services, and holds promise for realizing universal health coverage. HIV/TB and MCH services should be used as access points to reach migrant populations with chronic care services such as undiagnosed diabetes and hypertension and other NCDs.

WEPED538

Suicidal feelings and attempts among HIV/AIDS-positive sub-Saharan African Migrant women in Belgium: A qualitative study

A. Arrey[1], J. Bilsen[1], P. Lacor[2], R. Deschepper[1]
[1]Vrije Universiteit Brussel, Mental Health and Wellbeing Research Group, Public Health, Brussels, Belgium, [2]Universitair Ziekenhuis Brussel, Internal Medicine and Infectious Diseases, AIDS Reference Center, Brussels, Belgium

Background: Globally, suicide remains a major public health problem and should be given high priority especially in chronic illness management. In Belgium about seven cases of successful suicides are reported daily. Suicidal feelings are not uncommon among people with diverse psychosocial issues or diagnosed with chronic and incurable diseases like cancer, mental health issues and HIV. There is dearth of research on suicidal ideation and attempts among Africans with HIV/AIDS. This paper examines suicidal feelings and attempts among HIV-infected sub-Saharan African (SSA) migrant women in Belgium.
Methods: We conducted a qualitative research between April 2013 and December 2014 in Belgium consisting of semi-structured interviews and observations. Participants were recruited through purposive and snowball sampling techniques if from SSA, females, >18 years, diagnosed HIV-positive for more than 3 months, receiving treatment and care in Belgium. Thematic analysis was used to analyze study data. To enhance the validity of this qualitative research, different data collection methods were used: interviews, observations and document analysis to increased credibility. Ethical approval was obtained from the Ethics Committee of the Universitair Ziekenhuis Brussel and the Internal Review Board of the Institute of Tropical Medicine, Antwerp, Belgium.
Results: 44 women were interviewed. 25 of the 44 reported having seriously contemplated or attempted suicide because of shame, guilt, blame, depression, stigma, discrimination, fear and uncertainty since diagnosed HIV positive. Many of those who reported suicidal feelings/attempts did not indicate seeking any type of mental health services. Participants also indicated intermittent periods of depression and anxiety. A relationship between suicidal ideation and awareness of successful suicide of others was found among participants. No timeline for suicidal thoughts was mentioned by participants.
Conclusions: Our findings highlight the ubiquity of suicidal ideation/attempts among HIV-infected SSA migrant women in Belgium. Understanding the relationship between the outcomes of stigma/discrimination and suicidal ideation may contribute to a holistic care of HIV-infected women. Assertive interventions to reduce suicidal feelings/attempts among SSA migrant women and other people living with chronic illnesses early in their disease trajectory should be redesigned. Future research is needed to investigate the increasingly aging HIV population at risk of neuropsychiatric diseases and other co-morbidities.

WEPED539

Innovative model HIV, recidivism and risk behavior prevention among adolescents in conflict with the law in the context of juvenile justice reform in Ukraine

H. Skipalska[1], T. Castillo[2], M. Snitko[3], N. Pustilnik[1]
[1]Ukrainian Foundation for Public Health, Kyiv, Ukraine, [2]HealthRight International, New York, United States, [3]HealthRight International, Kyiv, Ukraine

Background: In 2017, there were 1164 adolescents on probation and 260 adolescents in closed settings in Ukraine. Juveniles in conflict with the law commonly face higher risks of HIV because of low access to information, social circles with high prevalence of HIV and drug use, risks of re-offence and incarceration in adult prisons. The juvenile justice reform shifted focus from incarceration to suspended sentences for minor offenders creating an opportunity for NGOs and probation services work together with adolescents in the community.
Description: Our HIV and recidivism prevention model is focused on adolescents on probation or in juvenile prisons. NGOs collaborate with probation services providing high-quality case management support, HIV/HCV testing and counseling, and innovative behavior change programs. The model is built into the existing penitentiary system delivering training on non-discriminatory approaches for juvenile justice professionals. The collaboration between NGOs and prison officers is an effective referral system in supporting resocialization and reducing risk behavior. Probation officers provide official supervision of the case and refer clients to NGOs who are responsible for comprehensive case management support.
Lessons learned: Combining HIV and recidivism prevention activities for adolescents in conflict with the law has been an effective mechanism for prevention of HIV transmission. Behavior change programs are specifically designed to meet adolescents' needs, address main causes of re-offence (i.e. substance use, aggressive behavior) and incorporate HIV education. HIV counselling and testing should be combined with other approaches, such as case management, behavior change programs and working with families. The analysis of 116 queues filled by participants of an HIV prevention program showed the increase in HIV- and health-related knowledge by 32.2%. Implementation of complementary program for parents reduces risks by influencing the social environment of a person. Finally, case management approach improves the quality of services and reduces recidivism risks.
Conclusions/Next steps: The introduction of HIV and recidivism prevention activities in probation services showed positive results in reducing risky behaviors among adolescents serving their sentences in the community. It is an effective strategy for HIV prevention using a comprehensive approach to address health risks and recidivism. We are adapting this model to reach soon-to-be released female prisoners.

WEPED540

Call to action: Why a disability sensitive SRH policy is needed in Lagos State

O. Akanni[1], A. Adebayo[2], E. Okotie[2], F. Fijabi[1], D. Ayinla[1], Journalists Against ADS(JAAIDS) Nigeria and Nigeria Association of the Blind (NAB)
[1]Journalists Against AIDS (JAAIDS), Lagos, Nigeria, [2]Nigeria Association of the Blind (NAB), Lagos, Nigeria

Background: Lagos State is arguably the most populated state in Nigeria with an estimated population of nearly twenty million. About three million of the populations in Lagos State are persons with disabilities (PWDS), who are mostly neglected, excluded and unable to access basic services including health. Research has shown that the marginalization and exclusion of PWDS from basic health services results from three broad factors namely low awareness, poor capacity and the inadequacy or absence of appropriate legal and policy frameworks.
Description: Journalists Against AIDS [JAAIDS) Nigeria in collaboration with the Nigeria Association of the Blind (NAB) with support from the AMPLIFY CHANGE is working on a project titled *Voices for Change: Promoting increased uptake of SRH services among People with Disabilities (PWDs) in Lagos State.* The project, involves a research to assess current legal provisions and practices in order to build an evidence base and includes media monitoring, focused group discussions with PWDs, key informant interviews (KII) with health care workers and a desk review of HIV/SRH policies.
Lessons learned: Outcomes of the research revealed t that Lagos state currently has no specific policy on sexual and reproductive health; although, the state implements a number of SRH programmes none of which are disability-inclusive. While existing health sector legal and policy frameworks in the state make barely minimal provisions which promote access of PWDs to health services, there are significant limitations in these health laws and policies which largely inhibit the uptake of HIV/SRH and other health services by PWDs. There is also limited knowledge on the part of the PWDs about HIV/SRH issues and a dearth of information, education and communication (IEC) materials in accessible formats. Limiting societal and behavioural attitudes also impact on the SRH rights of PWDs..
Conclusions/Next steps: Beyond facilitating PWDs participation in the state health budget consultations, efforts are ongoing under the project to strengthen collaboration between the State Ministry of Health, PWDs Organisations and Civil Society Organisations in order to intensify awareness raising, capacity building of PWDS and promotion of disability sensitive policies that will promote and protect the SRH rights of PWDs.

Multidisciplinary approach to TB Control in Uzbekistan

N. Parpieva[1], S. Tashkhodjaeva[2], E. Mun[2], E. Suleymanova[2], M. Volik[3]
[1]Republican Specialized Scientific - Practical Medical Center of Tuberculosis and Pulmonology, Tashkent, Uzbekistan, [2]USAID TB Control Program in Uzbekistan, Tashkent, Uzbekistan, [3]USAID TB Control Program in Central Asia, Tashkent, Uzbekistan

Background: Uzbekistan is among 18 TB high-priority countries in the Eurasian Region and one of the 30 high MDR-TB burden countries in the world. Labor migrants, people living with HIV, and ex-prisoners are the most affected populations with TB. The USAID TB Control Program together with the National TB Program (NTP) has been pioneering a multidisciplinary approach to ensure their equitable access to TB services. To reach these key populations, the Program helped the NTP to establish four multidisciplinary teams (MDT) in pilot areas. The MDT includes coordinator, TB doctor, Infection Disease specialist, psychologist, nurse, and five outreach workers. The MDTs link TB health providers and local communities to provide the program clients with TB diagnosis, treatment, and psychosocial support.
Description: Clients who are supposed to undergo TB screening are referred for further examination and diagnosis. The clients diagnosed with TB are enrolled in TB case management and receive peer-to-peer and psychosocial support until they complete TB treatment.The Program introduced the MDT and outreach in TB care in 2015. Each adult, belonging to the key populations who have not received proper TB services, can become a MDT client. To monitor client responses to referrals, prevent double counting, and prevent disclosure of personal information, the Program uses unique identifier codes. On average, outreach worker communicates monthly with 35-40 clients including TB/HIV educational sessions, personal risk assessments, and referrals to TB testing.
Lessons learned: Within the period of June 2015 to March 2017, the MDTs have reached out to 21,400 individuals with more than 45,000 peer educational mini-sessions related to TB and HIV. About 14,500 individuals were referred to TB services, and 87% (12,500) of the referred clients were tested for TB. 110 TB cases were detected. 105 started TB treatment.
Conclusions/Next steps: The MDT approach along with peer-to-peer outreach is an effective way to deliver TB health care services among vulnerable populations that helps to increase TB detection and improve TB treatment adherence in Uzbekistan.
Using MDT improves awareness of TB and HIV, coverage of the target population, referral to TB services; and supports TB patient treatment adherence through the TB case management program.

WEPED542

Understanding perceived internalized stigma among pregnant HIV positive women in rural Mpumalanga province, South Africa

S. Ramlagan[1,2], S. Sifunda[1,2], K. Peltzer[1,3], J. Jean[4], R.A.C. Ruiter[2]
[1]Human Sciences Research Council, HIV/AIDS, STI and TB (HAST), Pretoria, South Africa, [2]Maastricht University, Department of Work & Social Psychology, Maastricht, Netherlands, [3]University of Limpopo, Department of Research and Innovation, Sovenga, South Africa, [4]University of Miami, Miller School of Medicine, Miami, United States

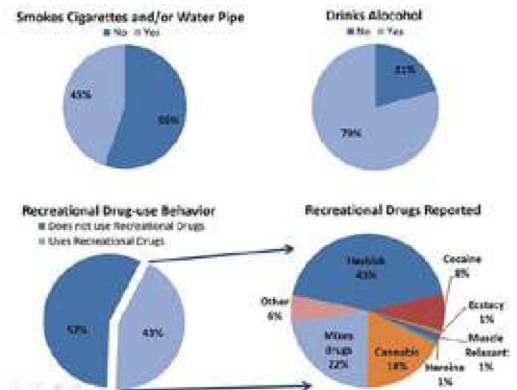
Background: Given the varied and profound ways in which HIV-related stigma, particularly internalized stigma, affects the lives of PLHIV and their ability to access and maintain HIV-related, care it becomes imperative to understand how that affects pregnant HIV positive women as they navigate through the added layers of negotiating their socially constructed roles of womanhood and motherhood. The goal of this study was to assess the correlates of HIV-related internalized stigma among HIV positive pregnant women in rural Mpumalanga province, South Africa.
Methods: A total of 673 HIV positive women, less than 6-months pregnant were recruited from 12 community health centres in rural Mpumalanga province. The Berger et al. (2001) 40 item internalised stigma scale (= 0.96) was utilized along with demographic, and HIV related variables. Factor analysis was performed using SPSS 24.0 to produce four factors, namely personalised stigma (17 items), concerns with public attitudes about people with HIV (7 items), disclosure concerns (6 items), and negative self-image (10 items). Cronbach's Alpha for each of the four subscales was between = 0.79 to = 0.94. Bivariate and multivariate analysis was carried out to predict associations that would lead to the likelihood of participants experiencing internalised stigma.
Results: The mean age of the 673 HIV positive pregnant participants were 28 years old (SD=5.73). The multivariate model on personalized stigma found associations with not completing schooling i.e. Grade 11 or less, income of less than R310, those who experience IPV, and those that have no male involvement in their current pregnancy. With the components of public attitude and disclosure concerns stigma, significance was found with those who receive a monthly household income of less than R310 and those that have no male involvement. Those who have no male involvement were more likely to experience negative self-image.
Conclusions: This study revealed the ways in which higher levels of education, income and partner involvement (outside of the context of IPV) serve as protective factors against internalized stigma, at multiple layers.

WEPED543

Sexual health, condom-use agency and substance-use behavior among 1222 sexually active unmarried women in Lebanon

S. Abu Zaki[1], J. Naous[1], A. Ghanem[1,2], D. Abou Abbas[1], N. Kinge[1], R. Aaraj[1], R. Majed[1], S. Mandour[1], R. Tomb[2], A. Assi[1,2]
[1]Marsa Sexual Health Center, Beirut, Lebanon, [2]Faculty of Medicine, University of Saint-Joseph, Beirut, Lebanon

Background: Women residing in Lebanon, who are unmarried, are reluctant to seek sexual health services for fear of being stigmatized (Jimenez 2013). It was shown that stigma increases women's vulnerability to sexually transmitted infections (STIs), risky sexual practices and substance-use (Poteat 2015). There are no studies on rates of STIs and common sexual practices among unmarried women in Lebanon and MENA region. The aim was to assess rates of STIs and risky behaviors including substance-use among women in Lebanon.
Methods: An anonymous questionnaire was administered by trained sexual health educators to 1222 sexually active unmarried women who presented consecutively to a sexual health clinic in Lebanon between 2015 and 2017. Collected sexual health indicators were: demographics, substance-use, sexual practices and risky exposures. STI status was collected through rapid testing and/or medical consultation. Determinants of condom-use and substance-use behaviors were assessed using regression models.
Results: Majority of the sample (95%) were women having sex with men. There were no cases of HIV, Syphilis, HBV or HCV. Symptoms indicative of HPV were in 15.6% and of Gonorrhea/Chlamydia in 10%. The majority (79%) reported inconsistent condom-use for various reasons among them: 26% were attributed to lack of agency (she was coerced, nervous or uninformed), and 11% were due to being under the influence of a substance. Only 24% reported receiving sexual health information from reliable sources and 43% reported using recreational drugs (fig.1).



[Figure 1. Substance use behavior of 1222 woman in Lebanon: cigarette/ water pipe smoking, alcohol consumption, recreational drug use and the reported drugs used]

Recreational drug use behavior was associated with smoking and alcohol consumption (p< 0.001, OR=4 each). Risky condom-use behavior was associated with having more than 5 sexual partners in last 3 months (p=0.04, OR=1.4) and substance-use behavior (p= 0.028, OR=4).

Conclusions: This is the first study in Lebanon and MENA region to assess prevalence of STIs, sexual behaviors and substance-use among unmarried women. HPV was prevalent, showing that a nationwide campaign on methods of prevention and treatment is necessary. Moreover, the results showed that women were not involved in condom-use decisions which makes them more vulnerable to STIs. This study indicates an urgent need of empowering women in Lebanon to become more informed and proactive in decisions concerning their sexual health and wellbeing.

WEPED544

Condom use at first sex protects young women in South Africa from HIV and teenage pregnancy

M. Rampedi[1], S. Magni[1], S. Johnson[1], S. Goldstein[2], V. Nkumanda[1], A. Ismail[3]
[1]Genesis Analytics, Health, Johannesburg, South Africa, [2]Soul City Institute for Justice, Johannesburg, South Africa, [3]Genesis Analytics, Johannesburg, South Africa

Background: Young women in South Africa have persistently high rates of HIV and teenage pregnancy. Understanding what influences this is essential in designing programmes to address this problem. We used data from an existing impact evaluation to explore this.

Methods: 403 women aged 18-26 from Gauteng and KwaZulu-Natal were sampled as a part of a retrospective cohort study which included HIV testing. We measured pregnancy based on women's self-reported pregnancy status. This included women who have been pregnant in their lifetime and those have experienced teenage pregnancy.

Results: 79% (n= 320) of young women had ever had sex. Of these, 16% (n =38) were HIV positive and 42% (n=134) reported having been pregnant. Young women who used a condom at first sex were significantly more likely be HIV negative (AOR 2.50, 90% CI 1.15 - 5.42, p = 0.02). Young women who used a condom the first time they had sex were also less likely to have ever been pregnant (AOR 0.47, 95% CI 0.27 - 0.80, p =0.006) and less likely to have had a teenage pregnancy AOR 0 .34, 95% CI 0.14 - 0.82, p = 0.016).

Conclusions: In this study condom use at first sex seems to protect young women against both HIV infection and early pregnancy. Health programmes need to improve self-efficacy for condom use and assist young women to have the confidence and ability to use condoms. Programmes need to reinforce messaging around condom use at first sex and emphasise the need for consistent condom use in order to reduce HIV and teenage pregnancy in South Africa.

WEPED545

Factors associated with perceived access and utilization of HIV testing services among international students studying in Japanese language schools in Tokyo

P. Shakya[1,2], T. Sawada[2,3], H. Zhang[1], T. Kitajima[1,2]
[1]Kyorin University, Tokyo, Japan, [2]University of Tokyo, Department of Community and Global Health, Tokyo, Japan, [3]Minatomachi Medical Center, Yokohama, Japan

Background: Migrants receive the least healthcare services in society. Japan hosts around 260,000 international students, mostly from Asian developing countries. Among them, language school students have tripled from 2011 to 2017, against the backdrop of labor force shortage in Japan. Most of these students are also engaged as cheap labors and are high risk population with poor access to health services. Several socio-economic and behavioral factors may increase their vulnerability to HIV and also prevent them to access HIV testing services in Japan. However, evidence is scarce in Japan on these issues. We examined the factors associated with perceived access and utilization of HIV testing services among international students in language schools in Tokyo.

Methods: From September to December 2018, we conducted a cross-sectional survey among international students studying in Japanese language schools in Tokyo. We collected data from 769 Chinese, Vietnamese and Nepalese students using self-administered questionnaire. We used multivariable logistic regression models to analyze the data.

Results: Nepalese students were less likely to have better perceived access to HIV testing services in Japan than Chinese students (AOR=0.12, 95% CI 0.01-0.96). Students who had poor perceived access to health worker (AOR=0.47, 95% CI 0.28-0.81) and who did not have knowledge on free and anonymous HIV testing services (AOR=0.18, 95% CI 0.08-0.42) were less likely to have better perceived access to HIV testing services. Student who did not need Japanese language interpreter during visit to health facility were more likely to have better perceived access to HIV testing services (AOR=1.93, 95% CI 1.14-3.25). Students who had not utilized HIV testing services in their home country (AOR=0.09, 95% CI 0.03-0.28) and who did not have knowledge on free and anonymous HIV testing services (AOR=0.06, 95% CI 0.02-0.20) were less likely to utilize HIV testing services in Japan.

Conclusions: Factors associated with perceived access and utilization of HIV testing services among language school students in Tokyo are nationality, need of Japanese language interpreter, perceived access to health worker, and knowledge on free and anonymous HIV testing services. These findings may help to design interventions for improving access to HIV testing services among international students in Japan.

WEPED546

An integrated approach of addressing GBV and HIV for AGYWs. The case of DREAMS project in Malawi

T. Mwandira[1], A. Mwenifumbo[2], P. Mkandawire[3]
[1]PSI Malawi, HIV, Blantyre, Malawi, [2]PSI Malawi, Blantyre, Malawi, [3]PSI Malawi, Lilongwe, Malawi

Background: Half of the 100,000 new HIV infections in Malawi occur among young people (15-24 years).
[1] Early sexual debut coupled with socio-cultural practices involving unprotected sex increase young girls vulnerability to sexually transmitted infections. In Malawi, 65% of girls experience some form of child abuse during their lifetime.
[2] Despite strong evidence highlighting the risks gender based violence (GBV) poses for HIV, specifically for girls, most programs continue to address the two epidemics separately.
[1] Malawi - 2013 UNAIDS modes of HIV Transmission model
[2] Malawi - 2013 Violence against Children and Young Women Ministry of Gender and Children Welfare.

Description: Through the DREAMS initiative, PSI Malawi offer integrated health services including GBV to Adolescent Girls and Young Women (AGYW) in Machinga district. Health services on offer to AGYW's through mobile outreach clinics are STI screening, HIV testing and first-line support to survivors of GBV. Program data was used to understand the effectiveness of integrating GBV and HIV service for AGYW.

Lessons learned: Program data show steady increase in number of GBV cases reported and biomedical services given to survivors of GBV. 90% of the 81 GBV survivors mentioned their sexual partners as perpetrators of the violence. Although most AGYWs experienced different forms of violence, most (82%) only disclosed physical violence. Out of the 81 AGYW survivors of GBV, 4 HIV +cases were identified with most (3 HIV+ cases) among survivors of physical violence compared to survivors of sexual violence (1 HIV+ case). This highlights the need for an integrated effort in addressing all forms of GBV and HIV.

Conclusions/Next steps: An integrated approach of addressing GBV and HIV for AGYWs is a potentially powerful strategy to address the two epidemics considering the risks GBV poses for HIV.

WEPED547

Community-based strategies to ward off new HIV infections among sex workers, substance users, women, and transgender people who live in homeless encampments in the Oakland, San Francisco Bay Area

G. Lockett[1], C. Carey-Grant[2], B. Green-Ajufo[1,3]
[1]California Prostitutes Education Project (CAL-PEP), Oakland, United States, [2]Women Organized to Respond to Life-Threatening Diseases (WORLD), Oakland, United States, [3]University of California San Francisco, Center for AIDS Prevention Studies, Department of Medicine, San Francisco, United States

Background: The growing number of homeless encampments in the Oakland, San Francisco Bay Area, with people living in tents under freeways and bridges, has required California Prostitute Education Project (CAL-PEP) and Women Organized to Respond to Life-Threatening Diseases (WORLD) to develop new, creative outreach and linkage strategies within their existing programs. From 2015 to 2017, the homeless population in Oakland increased by 26%. Members of key HIV populations experience homelessness at higher rates than the general population.
This growing public health crisis is a concern for local AIDS service organizations (ASOs) and their partners committed to helping vulnerable populations most impacted by the epidemic.
Description: CAL-PEP and WORLD are partnering to address the explosion of homelessness among women - inclusive of transwomen - sex workers and drug users at increased risk of HIV infection. Outreach is adapted to take into account the lack of privacy, safety, hygiene products and facilities, as well as water and nutrition affecting homeless populations. Outreach staff consists of peer individuals "buddies" from the same community as the target groups and with similar firsthand experience. Staff distributes prepared meals and hygiene kits along with condoms and harm reduction materials from mobile testing units provided by corporate sponsors. Collaboration with safety net providers, local government, healthcare providers and research institutions supports this expanded work.
Lessons learned: Non-traditional, cross sector collaborations are necessary to address the complex, intersecting needs of homeless communities and communities highly impacted by HIV/AIDS.
Passive recruitment of people into services is no longer adequate. The complex social circumstances associated with being homeless and being at risk for HIV infection require outreach wherever people are at anytime.
Hiring and training people with similar life experience (e.g., peers/buddies) to work alongside service providers is particularly relevant when serving homeless populations.
Conclusions/Next steps: The homeless community is a potential emerging key population for the HIV epidemic. The current, ongoing work of CAL-PEP and WORLD recognizes the importance of addressing this situation head on to ensure that HIV does not become more prevalent in our fluid homeless encampments.

WEPED548

Sexual network-structure and vulnerability of HIV: Observation from Indian village

S. Roy
NIT, Durgapur, Humanities and Social Science, Durgapur, India

Background: This study is trying to explore dynamics,social context and pattern of sexual network between migrant, wives of migrant and adolescent boys (15-19)from the same villages and their use of contraceptives and knowledge of HIV and S/RTI.
Methods: 896 women with migrant husbands, 881 adolescent boys (15 to 19 years old) were surveyed followed by in depth interview of 40 migrant husbands from 12 high migration blocks of 4 districts of two states of India. Multi-stage stratified random sampling was used. Migrant men were purposively selected for this study from the same villages and invited to participate In In-depth Interview. For further and in-depth understanding of the field, particularly to understand local custom, culture, jargons and terminology we had repeated discussion with community workers from same field. Cross sectional mixed methodology was adopted to triangulate information.
Results: More than 70% women of total sample reported that they suspected their husbands extramarital relationship. Even after underreporting, around 10% women reported physical relationship outside marriage, often with the younger guys in the neighbourhood. Out of 896,130 used condoms, only 88 reported that they ever had used condoms with their husbands.66% women of all respondents reported symptoms of RTI or STI, 1.4% knew about two ways of preventing HIV transmission. Significant number of women reported that their husbands have symptoms of S/RTI. Less than 1%knew about HIV. Almost all migrant men reported symptoms of S/RTI.12 out of 40 reported extramarital relation with low to no condom use.50% of adolescent reported physical relation with their partners and significant number reported relation with married women, both of adolescent and migrant men´s group reported low condom use and low level of HIV related knowledge.
Conclusions: The study findings indicate that three groups are connected to each other through sexual network. Study findings reveal low level of condom use in concurrent and serial monogamous relation; coupled with low level of knowledge regarding HIV, R/STI are increasing vulnerability to the whole sexual network and which is reflecting in increasing number in ANC clinic.

WEPED549

Nepalese returnee migrants from India: Are they at risk of HIV?

R. Adhiakri[1], B. Rawal[2], K. Ranju[3]
[1]Mahendra Ratna Campus, Tahachal, Kathmandu, Nepal, [2]National Centre for AIDS and STD Control, Kathmandu, Nepal, [3]School of Planning Monitoring Evaluation and Research, Kathmandu, Nepal

Background: Nepal is one of the major source countries of migrant laborers in Asia and abroad. Migrants may serve as a „bridge" population transmitting HIV/STDs from high-risk groups to the general population. The objective of this paper is to assess the sexual risk behaviors related to HIV among the returnee migrants from India.
Methods: The data from this study was drawn from cross sectional study entitled 'Integrated Biological and Behavioral Surveillance (IBBS) Survey among Male Labor Migrants in Western and Mid to Far Western Region of Nepal. A total of 720 MLMs were selected for the interview and testing of blood samples. Bivariate and Multivariate analysis were performed.
Results: Almost a third of the sampled returnee migrants (32%) were involved in sexual risk behavior. Multivariate analysis showed that age group, level of education, caste, marital status, place of residence (region), alcohol consumption and participation in HIV and AIDS awareness program in community were significant predicators for sexual risk behaviour. Illiterate migrant were more than two times (aOR=2.35) more likely to involve in risk sexual behaviour than who had grade 10 or more. Similarly, migrants who consumed alcohol every day, at least once a week and less than once a week were 5 times, 2.9 times and 2.7 times more likely to involve in high sexual risk than those who never consumed alcohol. Migrant who every involved in HIV/AIDS awareness program in community were less likely to involve in high sexual risk behaviour (aOR=.68) than those who never participated in HIV/AIDS awareness program in community
Conclusions: The findings show that returnee migrations are exposed to health hazards through their sexual behavior. This problem should be addressed early by targeting these groups of high-risk students.

WEPED550

"Prepara, Nem": An innovative strategy to empower, promote education and human rights among LGBTQI communities living in Rio de Janeiro, Brazil

L. Montenegro[1], M. Malta[1], V. Giraldo[2], C. Costa Neto[3], M. Seixas[4], G. Cunha[4]
[1]Oswaldo Cruz Foundation, National School of Public Health, Rio de Janeiro, Brazil, [2]Federal University of Rio de Janeiro, Mathematics, Rio de Janeiro, Brazil, [3]Federal University of Rio de Janeiro, Aplication School, Rio de Janeiro, Brazil, [4]NGO Conexão G, Rio de Janeiro, Brazil

Background: Brazil has the unfortunate reputation of being one of the deadliest places in the world in terms of recorded anti-LGBTQI violence. About one LGBTQI Brazilian is killed in a hate-motivated crime each day, but the police are often reluctant to register anti-LGBTQI crimes as hate attacks. The extreme social exclusion faced by Brazilian LGBTQI translates into increased vulnerability to HIV, other diseases, including mental health conditions, limited access to education and employment, and loss of opportunities for economic/social advancement.
Description: Our group implemented a project called "Prepara, Nem", in English something like "Get ready, baby" - a free college prep course that happened twice a week at a leading Public Health School in Brazil (ENSP/FIOCRUZ) in close partnership with Rio de Janeiro Federal University (UFRJ). Students received personalized study plans, top-quality supplementary materials, transportation, and food support. The intervention was implemented during 1 year and improved LGBTQI access to formal education and to HIV-related interventions available at ENSP/FIOCRUZ: free HIV testing, Prep, PEP and HIV-treatment. (https://www.youtube.com/watch?v=MPClXuos9UM)
Lessons learned: The engagement of activists, researchers, educators and the LGBTQI community at large improved the intervention outcomes and impact. The non-judgmental, cultural sensitive and engaging environment promoted students engagement. Nowadays "Prepara, Nem" is being offered inside a large slum complex from Rio de Janeiro (Complexo da Maré), within a close partnership between educators, UFRJ and a local NGO (Conexão G). The strong college-prep curriculum allowed many students to meet the requirements for entry into colleges and universities, become tutors and peer educators.
Conclusions/Next steps: This work directly relates to advancing the rights of disenfranchised LGBTQI people living in Rio de Janeiro slums. Thought a close partnership between the LGBTQI community, researchers and educators we were able to improve access to education, HIV-prevention and treatment services.
Our intervention will be replicated in other slums from Rio de Janeiro, aiming at promoting human rights, gender equality, strengthen social/economic development, put a stop to untrammelled violence and properly respond to high HIV vulnerability among LGBTQI living in Rio de Janeiro slums.

WEPED551

Between the Rock and a hardplace: Comprehensive sexuality education vs cultural religious norms in rural Zimbabwe a case study of young women in Masvingo youth friendly corners

L. Hwenga
Zimbabwe National Family Planning Council, Marketing and Communications, Masvingo, Zimbabwe

Background: The study explores the impact of the reception of HIV and and AIDS communication on self efficacy among young women in Masvingo Province youth friendly corners. The study arises from the realisation that female reproductive health remains low, particularly in marginalised communities as mass media seem not to prioritise reproductive health communication.
Various organisations including NGOs have created alternative communication on HIV and AiDS which do not take into cognisance the cultural and religious norms of the recipients. However engaging traditional leaders improved support for HIV communication that was perceived to be at odds with socio cultural norms.
Description: In this qualitative research. Data was collected through archival research complimented by semi structured interviews of key informants focus group discussions Wit young women to establish their reception patterns., the impact of HIV communication on their self efficacy as well as the role of traditional leader in the intervention.
Lessons learned: The study revealed that comprehensive sexuallity education exposed the young females to HIV and AIDS messages which contradicted with their cultural and religious norms on appropriate social and and sexual behaviours. Social factors associated with stigma and culture disempower young females from undertaking SRH promotion activities tailored for unmarried adolescents. Therefore unsafe sexual practices among young females in Masvingo rural Youth friendly corners are sustained not only byvlack of access to SRH services but also the social structures or norms that support such practices.
Conclusions/Next steps: SRH communication alone thus had no capacity to improve self efficacy among young females in societies where ambiguous social norms were central to adolescent sexual behaviors.

Sexualities and sexual cultures: meanings, identities, norms, and communities

WEPED552

Gangsterism on the Cape Flats: Gangster masculinity and HIV risk for young men in a Coloured township in Cape Town, South Africa

C. Chantre[1], C.J. Colvin[2]
[1]University of Cape Town, Cale Town, South Africa, [2]University of Cape Town, Cape Town, South Africa

Background: The communitied of the Cape Flats of Cape Town are recognized for their high incidences of gang violence, drug abuse, and exceptionally high rates of HIV and TB. Most studies concerning community dynamics and their relation to HIV prevention and/or ARV adherence however, tend to concentrate on interpersonal relationships, economic factors, and populations such a women and girls. This study focused on a critical population: men, and their relationship with gangsterism, a dynamic force operating throughout most of the townships in the Cape Flats. This study examined masculinities existing in relation to gangsterism and their relationship with HIV risk and ARV adherence in a Coloured township of the Cape Flats.
Methods: This qualitative study consisted of a nine month long participant observation along with semi-structured interviews among residents of a Coloured township inn Cape Town, South Africa. Interview included four focus group discussions and foury four in-depth interviewsaong a target group of 18-30 year olds and staff at the local community health clinic and hospital, respectively.
Results: Part of upholding a gangster masculinity included in partaking in gang activity, consuming illicit drugs, engaging in risky sex, and experiencing constrained social and physical environments due to entrenched gang territories. Visibly marked gang territories prohibited both gangsters and non gangster residents of the township from accessing their local clinic and hospital which translates into reduced visits for HIV testing and pickup of ARV medication.
Conclusions: Gangsterism organizes a sizable area of The Cape Flats and influences mens´ behaviors in two chief ways: encouraging risky behavior that renders them vulnerable to HIV infection as well as hindering their access to HIV testing and treatment. The results demonstrate a greater need for interventions hat respond to the realty of the gang dominated areas of the Cape Flats principally those that provide men improved access to testing and ARV medication.

WEPED553

Socio-legal and the religious environment vrs. the human rights approach and it´s implications of LGBTI activities in Ghana

M.-J. Blantari[1], E. Awotwi[2], T.S. Ndeogo[1]
[1]Ghana Police Hospital, Public Health Department, Accra, Ghana, [2]UNFPA, Accra, Ghana

Background: The Human Rights Approach to Law Enforcement and its pursuits promotes Freedom, dignity and worth of every individual especially marginalized groups. Evidence abounds to show that Rights based Approaches, protective and enabling legal environments reduce the vulnerability of LGBTI individuals to HIV infections. This is because these groups are often marginalized and stigmatized coupled with harmful legal environments and practices not founded on Human Rights exclude or punish those that are marginalized. They also perpetuate stigma and discrimination by dehumanizing and criminalizing those who are vulnerable and they place a disproportionate burden on those affected by HIV.

Description: To promote rights-based policing approaches towards KPs The Ghana Police AIDS Control Program with support from the Ghana AIDS Commission/CEPERGH implemented orientation sessions in 6 out of 10 Regions in Ghana for members of the LGBTI Community. The program targeted 180 community members who were decision makers in their respective NGOs. Qualitative methods were employed through the holding of FGDs for 6 gay groups, 6 Lesbian Groups and 6 bisexual groups.to:

a) Solicit information on challenges faced by community members from
- their peers
- general society
-law enforcement officials

b) How these challenges could be addressed or minimized.

Lessons learned: There were similar levels of threats and challenges across the sites

From Community members
- Neglect and torture
- Blackmail and extortion
- Negative name-calling
- stigmatization especially if one partner contracts STI

From Society
- we are considered as demon-possessed
- parental neglect and denial of job opportunities including family support
- misconceptions from religious groups

From Law Enforcement
- Police often side with and defend perpetrators of crime because of our presumed sexuality
- Police more often than not focus on our sexual orientation instead of the law and this leads to unlawful detentions
- Unsupportive and unwillingness to prosecute those who violate the rights of LGBTI.

Conclusions/Next steps: Acceptance of misconduct is a major breakthrough to reform. This program has the support of the Police hierarchy and seeks to punish subsequent perpetrators of abuse of KPs. Consensus building among the police and efficient use of available resources will help sustain the program.

WEPED554

Health risks of lesbian, bisexual, queer and transgender women in Kazakhstan

Z. Sekerbayeva
Kazakhstan Feminist Initiative, Almaty, Kazakhstan

Background: The needs assessment research on the situation of lesbian, bisexual, queer and transgender women in Kazakhstan was initiated by Kazakhstan Feminist Initiative „Feminita". It is the first research of its kind that reaches out to cities and towns other than Astana and Almaty, which majority of researches focus on. It is also so far the first and only research in Central Asia focusing on LBQT women.

Methods: A mix of qualitative and quantitative methods was used for the purposes of the research. All respondents filled out a 92-question multiple choice survey, participation in the deep semi-structured interviews was offered to all participants on voluntary basis (43 agreed). The survey topics covered demographics, economic and social status, general health, sexual health, mental health, access to healthcare, sexuality, civic and political attitudes, human rights and discrimination. The interview topics focused on significant moments of their lives, self-awareness, self-identification relationships, violations of human rights.

Data from 228 respondents from 16 cities - Aktau, Atyrau, Taraz, Temirtau, Kostanay, Kokshetau, Kyzylorda, Petropavlovsk, Almaty, Aktobe, Astana, Karaganda, Semey, Shymkent, Uralsk, Ust-Kamenogorsk - was analysed. These cities cover a wide geographical range of the country with its north, south, west and east.

Results: Only 5% from 228 respondents of the research know about HIV/AIDS as a potential health risk for LBTQ women. 71% - did not answer the question: „What do you know about potential health risks for LBTQ women?" Both of these percentages indicate an alarming rate of illiteracy regarding sexual health risks for lesbian, bisexual, trans and queer women. Considering at least 24% of them are or have been in heterosexual marriages or have had or were forced to have heterosexual contacts, the rate of illiteracy is dangerously high.

Conclusions: Research suggests that the needs of LBQT women are not catered for in traditional health education messages; for example, perception of risk of cervical cancer may be different in heterosexual women. They are excluded from health education materials in sexual health where the emphasis is on heterosexual sexual relationships. Health risks of lesbian, bisexual, queer women in Kazakhstan are a huge lacuna in general public health.

WEPED555

Resilience, heritage and vulnerability: Qualitative assessment on violence and HIV among indigenous women and girls in the Amazon region

G. Braga-Orillard[1], C. Euzebio[1], E. Carrasco[2]
[1]UNAIDS, Brasilia, Brazil, [2]UNAIDS, Panama, Panama

Background: The study aimed to provide an overview of the situation of violence and HIV among indigenous women in the Amazonian region of Alto Solimões - border with Brazil, Peru and Colombia, in order to influence policies and implementation of programmes. The study identified:
(i) the needs of indigenous women and girls for HIV and violence-related interventions;
(ii) the gap of services with a holistic approach to HIV and violence;
(iii) community-based organizations in the area.

Methods: The study focused on the indigenous areas of Umariaçu I (population: 2374 in 2016), Umariaçu II (population: 5389 in 2016) and Belém do Solimões (population: 10918 in 2016).
(i) A desk review of the demographic, epidemiological, historical and ethnographic data was performed;
(ii) field interviews of public officials and non-governmental organizations;
(iii) interviews with indigenous women and men, previously identified by community leaders. UNAIDS counted with the support of Portuguese-Tikuna translators for the exercise.
(iv) systematization and analysis of qualitative data.

Results: The cross-border setting brings several concerns:
(i) difficult access to public services;
(ii) trafficking of illicit drugs;
(iii) exchange of sex for alcohol and/or drugs
(iv) various forms of violence.
(v) violence impacting disproportionately the young indigenous populations.

Gender-based violence identified:
(i) physical;
(ii) psychological;
(iii) sexual,
(iv) patrimonial and
(v) domestic. Violence was identified, especially by the elderly, as a consequence of non-respect of traditions, as well as abuse of drugs and alcohol.

Due to fear, the interviewees declared to witness daily violence against women, but did not declare themselves as victims. Episodes of intra-community violence appear as an embarrassment factor for families.
Conclusions: Violence is closely associated with the abuse of drugs/alcohol. Indigenous women who are victims of violence feel shame and fear, what limits their possibilities to cope with these situations. The study made a set of recommendations to tackle this.
Although the indigenous living with HIV represent only 0.5% of all people living with HIV in the country, the impact for the individual is important. Sanctions from the community to people who acquire HIV can vary from domestic reprimand to public beating, resulting in ostracism or even suicide.

Young hearts - I just want to love: The success story behind the Emmy-nominated web series and the use of edutainment to talk about HIV to very young audiences in Brazil

D. De Castro[1], G. Braga-Orillard[2], G. Estrela[3], E. Jacobina[4]
[1]*UNAIDS, Communications, Brasilia, Brazil,* [2]*UNAIDS, Brasilia, Brazil,* [3]*Projeto Boa Sorte, São Paulo, Brazil,* [4]*Globo Network, Entertainment, Rio de Janeiro, Brazil*

Background: Since 2015, UNAIDS has been Globo TV's main partner on HIV- and discrimination-related issues. The office has supported fine-tune language and contributed with ideas for storylines, scenes, and characters. The strategy:
(i) To partner with the team of writers of Globo's longest running tele-novela 'Malhação', with a 20-million viewers daily audience;
(ii) To introduce in the plot an HIV-positive character for five months to help break down stigma and misinformation;
(iii) To build on this experience and create the internet complement 'Young Hearts' go more in-depth about issues related to serodiscordant couples, based on the love story of Henrique and Camila, mixed with real-life stories.
Description: Mixing fiction and documentary, the five-episode series tells the stories of young serodiscordant couples, encouraging debate about sexuality and relationships involving people living with HIV. In the spin-off production, Henrique and Camila are invited to be part of a web documentary, alongside four real serodiscordant couples, talking about the impact of HIV in their daily lives.
Lessons learned: The partnership led us to realize the need to speak about sex, sexuality, and HIV to this young audience. Considering the limitations imposed in Brazil to broadcast TV in afternoon slots, a digital series for Globo's streaming platforms was chosen as the best fit for purpose. The production soon became a hit: from April-June 2016, it was the third most-watched original series on the platform: almost 1 million views. On 16 October 2017, it was nominated for the Emmy Kids 2017 in the digital category, alongside productions from Norway and Japan.
Conclusions/Next steps: (i) UNAIDS supported Globo to get HIV back on the agenda for young people in Brazil, where AIDS detection rates have more than tripled in the past decade among young men aged 15-19 years, and almost doubled among those aged 20-24 years;
(ii) Initiatives in partnership with mass media can positively contribute to breaking HIV-related barriers and change behavior of millions of people at very low cost
(iii) edutainment designs characters and storylines to provide viewers with positive role models to relate to, often at a personal and emotional level.

[Young Hearts - Digital series on serodiscordant couples - Globo and UNAIDS in Brazil]

WEPED557

Who are the male partners of adolescent girls and young women in DREAMS sites in Malawi, and how can they be more engaged in HIV services?

N. Pilgrim[1], W. Chimwaza[2], E. Chipeta[2], V. Mwapasa[2], L. Tenthani[3], N. Jani[1], S. Mathur[1]
[1]Population Council, HIV & AIDS Program, Washington, United States, [2]University of Malawi, College of Medicine, Blantyre, Malawi, [3]Population Council, HIV & AIDS Program, Blantyre, Malawi

Background: A successful HIV/AIDS response in sub-Saharan Africa requires identifying and engaging the male partners of adolescent girls and young women (AGYW) in HIV testing, care and treatment services. AGYW vulnerability to HIV is in large part related to male partners. Yet, men generally are reluctant to access HIV services. We sought to 1) identify and locate the male partners of AGYW in Malawi; 2) understand the challenges to and facilitators of them accessing HIV services; and 3) identify strategies to engage them in HIV services.
Methods: We conducted four community mapping exercises with AGYW and community opinion leaders to identify locations within Zomba and Machinga districts—two DREAMS intervention sites—where AGYW meet male sexual partners. The participants identified the types of men who had sexual relationships with AGYW and where they could be found. Afterward, the study team visited the identified venues (e.g., football grounds, markets) and invited men, aged 18 and older, to participate in focus group discussions (FGDs). Men were eligible if they were in a relationship with a woman aged 15-24. Thematic content analysis was conducted.
Results: The profile of men recruited in the FGDs matched those identified during the mapping experience, representing a range of ages and occupations. A total of 157 men, with mean age of 27.5 (range 18-55), participated in 16 FGDs. The male partners of AGYW were teachers (15%), transporters (e.g., bus driver) (13%), businessmen (12%), and football players (11%). Representing less than 10% each were students, vendors, farmers, health workers, fishermen, and estate workers.
Barriers to HIV service use included fear of testing positive, stigma, long waiting times that disrupted income generation, and lack of privacy and confidentiality. Peer and partner influence facilitated HIV service use.
Strategies to engage men proposed by FGD participants included offering male-only services, incorporating features from traditional circumcision initiation camps into circumcision services, providing community-based services, and leveraging media and technology for HIV prevention services.
Conclusions: The male partners of AGYW in Malawi are diverse. Given their gender-specific needs and preferences, they should be engaged in the development of HIV services and reached through venues where they meet AGYW.

WEPED558

Feasibility of accessing sexual partners of young women at high risk of acquiring HIV in rural KZN

H. Humphries[1], S. Phakathi[1], M. Mdladla[1], Q. Abdool Karim[1,2]
[1]CAPRISA, Durban, South Africa, [2]Columbia University, Department of Epidemiology, Mailman School of Public Health, New York, United States

Background: Accessing sexual partners of young women at high risk of acquiring HIV remains a challenge. Respondent-driven sampling to access sexual networks provides an opportunity to locate male sexual partners, understand overlaps between sexual networks and obtain a more nuanced understanding of partner characteristics and behaviours.
Methods: This study took place in 2 phases between October 2016 and January 2018 in Vulindlela, a rural sub-district located 150km west of Durban, South Africa. Phase 1 identified and interviewed 11 female index cases aged 18-24 years old, 6 sexually active with no negative sexual health outcomes (SARS) and 5 who had experienced at least one negative SRH outcome (SARU). Index cases were asked to identify their male sexual partner(s) and a sexually active girl friend who were followed up for an interview. In Phase 2, we identified 5 SARU and 3 SARS index cases and only interviewed partners. We also assessed the feasibility of accessing partners of identified partners. Basic descriptive statistics were used to summarise key quantitative data, and thematic analysis was used to analyse interview transcripts.
Results: We were able to conduct interviews with 84.2% of the partners identified by the 19 index cases (Phase 1 and 2) and 72% of the friends in Phase 1. Age range of SARS cases was 18-24 years, and their partners 18-46 years. Age range of SARU cases was 19-24 years, and their partners 18-28 years. 44.4% of SARS and 27.3% of SARU cases reported more than one current partner, 40% of partners in both groups reported having other current partners. There were many discrepancies between what women and men believed about their partners sexual behaviours, and what partners reported including being the only current partner, being the main partner, HIV status belief discrepancies and age of partner.
Conclusions: Our findings highlight many discrepancies between believed and actual sexual behaviours within these sexual networks. Sexual networks of young women were high-risk and underscore the importance of expanding the study to advance our understanding of young women's sexual networks.

WEPED559

Addressing challenges among adolescents living with HIV(ALHIV) using structural approaches - a practical example from rural Kenya

F. Mutiria
Nazareth Hospital, HIV/TB Clinic, Nairobi, Kenya

Background: Adolescents face multiple challenges that obstruct their access to quality, accessible and affordable HIV prevention, treatment and support services. Obstacles facing adolescents include: disclosure, non adherence to ART, stigma and discrimination, unmet sexual and reproductive health, drug and substance abuse, lack of education, unemployment, violence and lack of social support.
Description: Structural approaches work by altering the context within which health is produced or reproduced. This is by addressing the factors that affect individual behavior in contrast to behavioral approaches that attempt to change of behavior. These are the contexts that shape or constrain individual communities and societal health outcomes. In addition they also address societal factors that increase vulnerability to HIV, promote human rights to remove punitive laws that block the AIDS response.
The approaches help in combating gender inequality and HIV related stigma and discrimination, encourages joint planning and captures potential synergies and replaces the fragmented approach of HIV prevention programs as well as discouraging the silo approach that focuses on single intervention. The structured approach in our community involved engaging the adolescents in activities that are of their interests. Such activities include;
1. Support group activities such as; i) Green house farming ii) Bead making iii)Soap Making
2. Health club where they use the 'wheel of knowledge' to learn and Understand adolescent package of care through role play, discussions, games and competition.
3. Adolescents led initiative for example home visits for adolescent facing challenges by the youth champions.
Lessons learned:
1. Adolescent led meetings planning and organization has built their esteem and empowered them in leadership.
2. Viral suppression from 79% to 91% among ALHIV in the last three year.
3. Self assertiveness where youth champions were invited to facilitate on positive living to the university students and engaged on sexual-gender based violence conference.
4. Social economic empowerment through #beadsforhealth, #farmingiscool.
Conclusions/Next steps: Adolescents living with HIV need a space within which they can express themselves freely devoid of social stigma and pressure. These spaces need to be structured just like the society is structured.

[Adolescents during bead making as they share on health issues]

WEPED560

Capitalizing on aspirations of adolescent girls to reduce their sexual health risks: Implications for girls' HIV prevention in Tanzania

J. Wamoyi[1], D. Nyato[2], N. Kyogombe[3], A.M. Buller[3], L.H. Heise[3]
[1]Natioal Institute for Medical Research, Sexual and Reproductive Health, Mwanza, Tanzania, United Republic of, [2]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Young people have aspirations and will use whatever means to achieve them. Little has been done to understand how young people's aspirations are key in determining the sexual decision-making. This paper set out to explore aspirations of young people and the strategies they used to meet them and how that enhanced or reduced their risk for HIV.

Methods: This study employed ethnographic research design involving 18 participatory focus group discussions and 43 in-depth interviews with girls and boys in-and-out-of-school, adult men and women within the study sites. Fieldwork was undertaken in rural and urban Tanzania in 2016. Participants were sampled purposively and by snowball sampling techniques. Thematic analysis was conducted with the aid of NVIVO 10 software.

Results: Girls mentioned their aspirations as: getting education; having a job; having nice clothes; an attractive body; a good life; good behaviour that is praised by everyone; having someone to take care of their needs; getting married and having children. Men were aware of the aspirations and desires of adolescent girls and mentioned these as: status among peers; trendy things such as smartphones, clothes; and marriage. Young men mentioned that a popular girl was one who had several pairs of clothes and was always in nice clothes; and a smart one at school. Young men talked about their aspirations as: performing well at school and having many friends and has behaviour that is acceptable among peers. Sex was one of the ways girls met their material and non-material aspirations. For example, sexual relationships with adults in power fulfilled some of their non-material aspirations (e.g. education) as well as material ones (trendy clothes mobile phones). Girls aspired for young men with certain characteristics (attractive, hardworking, smart at school) to help them meet some of their long-term aspirations such as marriage and passing examination at school.

Conclusions: The aspirations of young women were important in determining their sexual decision making and ultimately risk for HIV. There is need for interventions to capitalize on these aspirations by addressing them in interventions as they are critical for their sexual decision making, sustainable development and achievement of future goals.

WEPED561

Understanding the influence of a conditional cash transfer on sexual behavior among adolescent girls and young women in Northwestern Tanzania

K. Atkins[1], J. Wamoyi[2], P. Balvanz[1], S. Maman[1], A. Pettifor[3,4]
[1]University of North Carolina Gillings School of Global Public Health, Health Behavior, Chapel Hill, United States, [2]National Institute for Medical Research, Tanzania, Mwanza Research Centre, Mwanza, Tanzania, United Republic of, [3]University of North Carolina Gillings School of Global Public Health, Epidemiology, Chapel Hill, United States, [4]University of North Carolina, Carolina Population Center, Chapel Hill, United States

Background: Adolescent girls and young women (AGYW) aged 15-24 in Tanzania face increased vulnerability to HIV infection compared with their male peers. This is exacerbated by structural factors, including poverty and gender inequality, that shape HIV risk behaviors. Conditional cash transfers (CCT) may address AGYW's economic vulnerability, in turn reducing HIV risk behaviors such as transactional sex. This study sought to understand how CCT to AGYW in Northwestern Tanzania may influence their sexual behavior, including partner choice and engagement with transactional sex.

Methods: We conducted in-depth interviews (n=20) with AGYW enrolled in a CCT project in Northwestern Tanzania. Interviews sought to understand their sexual partnerships, sexual decision-making, and the influence of the CCT, which was conditional on participation in an HIV prevention and economic strengthening program, on sexual behavior. In addition, we used Photovoice (n=15), a qualitative community-based participatory research methodology, to record AGYW's strengths and concerns and promote critical dialogue through photography and focus group discussions with AGYW. We analyzed interview and Photovoice data to understand initial impacts of the CCT on sexual partnerships and behavior.

Results: Preliminary evidence shows that CCT influenced AGYW's sexual behaviors and partner choice, particularly among unmarried women. AGYW reported reduced engagement in compensated sex and condomless sex, reduced numbers of sexual partners, and increased interest in men who provide emotional, rather than financial, support. Unmarried AGYW reported decreased engagement with partners overall. In addition, while married women relied on their husbands for advice regarding CCT use, unmarried women relied more on female family members for financial advice than their partners. AGYW saw CCT as a way to promote gender equality and reduce their reliance on men for support; partner and family expectations and support for AGYW may have influenced the extent to which these changes occurred.

Conclusions: This study showed that CCT for HIV prevention may play a role in AGYW's sexual behavior by influencing their partner choice and motivations for engagement with sexual partners. The impact of CCT may vary based on AGYW's age, relationship history, or family context; future implementation should take these factors into account when enrolling AGYW in CCT programs.

WEPED562

Effect of time change on adolescent and young people accessibility to youth friendly health services in Akure, Ondo State Nigeria

O. Aiwanfo, Monitoring and Evaluation Team
Kids & Teens Resource Center, Monitoring & Evaluation Department, Benin City, Nigeria

Background: The Government of Ondo state have made significant effort in establishing youth friendly health care centres to increase young people´s access to health and social services. But it became very frustrating to see very few young people patronizing such centres due 8am-4pm working hours.Change in time to 4pm-8pm showed a significant difference in young people access to Adolescent and youth friendly health centre services.

Description: Young people 10-35years in Akure either attend school from 8am-4pm or go to centres where they learn skills from 8am-6pm. With this kind of schedule, it is very difficult for young people to leave

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

school or their skill centres to access the services provided by this adolescent and youth friendly health centres. In 2017, there was an extension in service time to 8pm, there was an increase from 2persons per day to 12persons per day of adolescent and young people accessing social and health services at this centre's from 4pm-8pm.

Lessons learned: It was observed that the additional 10 persons came between 4pm to 8pm. Most of the young people preferred the evening hours because it was very convenient and it allowed them do their daily activities. Also it reduced stigmatization because absence at school or work leads to questions been raised

Conclusions/Next steps: Provision of Adolescent and youth friendly health centre isn't enough, passionate Friendly health workers should be employed and Service time should be convenient for young people to come as well as the location should be strategic.

WEPED563

Adolescents, sexuality, and relationships among girls aged 10-14 in Homa Bay and Siaya counties, Western Kenya

A.M. Muthigani[1], I. Jurkevich[2], S. Goldfrank[2]

[1]Kenya Conference of Catholic Bishops, Nairobi, Kenya, [2]American International Health Alliance, Washington, United States

Background: The Kenya Conference of Catholic Bishops (KCCB) is implementing a DREAMS project geared to reduce the rate of HIV infection among adolescent girls in Homa Bay and Siaya counties in Kenya. DREAMS is an evidence-based approach addressing structural drivers that increase HIV risk for girls, including gender inequality, lack of education, poverty, and sexual violence. KCCB collaborates with American International Health Alliance (AIHA) to implement this DREAMS intervention targeting girls between the ages of 10 and 14. The program has assisted 24,842 adolescent girls to develop life skills and enhance supportive relationships that will keep them safe from risky behaviors that hinder achievement of life goals.

Description: From April 2016 to September 2017, KCCB/AIHA delivered a school-based HIV prevention program called Making Life's Responsible Choices (MLRC) in 185 primary schools in target counties, reaching 19,227 girls in Siaya and 5,615 in Homa Bay. The intervention package, delivered by 344 volunteer teachers, covered self-awareness, human sexuality, relationships, peer pressure, sexually transmitted infections (STIs), HIV and AIDS, and life skills. In project Safe Spaces, 205 DREAMS mentors provided continuous psychosocial support to all enrolled girls, while 9,342 parents in Siaya County and 3,891 in Homa Bay participated in a complementary Families Matter! Program (FMP) designed to enhance parent-child communication about sexuality and sexual risk reduction. This multi-pronged approach ensures adolescent girls are supported by parents, teachers, and mentors to strengthen positive relationships that encourage achievement of their life goals.

Lessons learned: Faith-based approaches offer great opportunities through educational institutions to address HIV interventions at the community-level. Volunteer MLRC teachers ensure sustainable change due to their interaction, availability, and acceptability to the girls targeted through DREAMS. School-based prevention programs intended to help girls and young women develop life skills, link them to more school and community activities, and increase their hope for the future may delay their involvement in sexual activity.

Conclusions/Next steps: Many adolescent girls and young women have limited opportunities and are often devalued or seen as unworthy of investment or protection. A multi-faceted intervention involving volunteer teachers, mentors, and parents enhances relationships can effectively reduce vulnerability of targeted adolescent girls.

WEPED564

What do adolescent girls and young women tell us about their male partners and their relationship characteristics?

J. Okal[1], J. Matheka[1], S. Mathur[2]

[1]Population Council, HIV/AIDS, Nairobi, Kenya, [2]Population Council, HIV/AIDS, Washington DC, United States

Background: Adolescent girls and young women (AGYW) in Kenya are at high risk of HIV infection, in part because of their partner's behaviors and characteristics. Yet, less is known about male partners of AGYW. This study examined characteristics of male partners of AGYW to inform targeted HIV prevention interventions.

Methods: Survey was conducted with AGYW, 15-24 years (N=1,778) in urban and peri-urban locations in Kisumu, Kenya from October 2016-February 2017. Questionnaires assessed characteristics of recent male partners, their relationship characteristics and their partner's HIV risk characteristics. Descriptive analysis was conducted to assess attributes of current male partners among adolescent girls (AG, 15-19-year olds) and young women (YW, 20-24-year olds).

Results: Respondents' average age was 19 years and 58% were currently in school. Nearly half, 49% of all AGYW (24.16%, AG and 69.76%, YW) had a current sexual partner, and 67.0%, YW vs. 33.0%, AG were married. Mean age of AG's partners was 22.0 ±4 years and 27.0 ±4.3 years for YW. 65.7% of YWs partner lived within the community, versus 38.5% of AGs partners, p< 0.00. Over 22% of the male partners had high-risk jobs, e.g. trucker (22%, AG vs. 31%, YW). Over 70% of all AGYW were in relationships of 1-4 years in length. Reported condom use at last sex was 74.3% among AG vs. 48.7% among YW, p< 0.00. AGYW knew their partner's HIV status (88.8%, AG vs. 88.5%, YW); 16.6% of AG vs. 14.7% of YW knew that their partner had other partners in the last year, and less than 1 in 5 AGYW perceived their partner at elevated risk for HIV. Recent experiences of physical (17%, AG vs. 30%, YW: p< 0.00) and sexual violence (17%, AG and YW) from intimate partners were high.

Conclusions: Key differences emerged between AG and YW's partner age, residence, condom use, and physical violence. Similarities emerged in partner occupation, duration of relationship, knowledge of partner's HIV status and sexual concurrency, HIV risk and sexual violence. Programmers need to understand the differential patterns and experiences of AGYW within partnerships to design effective couple-level HIV prevention and risk mitigation among AGYW.

WEPED565

From peer education to full engagement: Promoting adolescents and youth friendly HIV services in Jiangsu Province

J. Li, X. Huan, G. Fu, X. Liu, L. Shi

Jiangsu Provincial Center for Disease Control and Prevention, Department of STD/AIDS Prevention and Control, Nanjing, China

Background: As of the end of 2017, there are cumulatively 4660 reported HIV cases aged 15-24 in Jiangsu, China. To encourage multi-sectoral participation in adolescent and youth HIV prevention, especially youth themselves, we started the Youth Engagement Prevention programme "YouAI" in 2015.

Description:

1. Management: Jiangsu CDC was the lead agency for this programme. UNICEF China was engaged to provide financial and technical support to "YouAI" and this abstract.
2. Design: A 2-level approach was used with youth engagement every step of the way: firstly, a provincial Youth Peer Educator contest mobilized a large number of youths to creative publicity and a supportive social environment for students to use services. Secondly, a youth-designed "Test and Assess" campaign was launched to empower young clients walk into healthy facilities as "secret clients", ask for a test, and evaluate youth-friendliness.
3. Operation: More than 2000 youths participated in "YouAI", 64% of them getting tested for HIV, 85% shared their experience with friends. Their experience and findings were shared with provincial CDC, leading

to measurable improvements in service quality and understanding of adolescent needs among providers. As a result, percentage of providers willing to provide test to adolescents increased from 60% to 89%, referral rate increased from 6% to 60% in 2017, compared with 2016.

Lessons learned:

1. Traditional peer education model of information and knowledge sharing can contribute to improved youth access to quality HIV-SRH services, if combined with youth-driven, creative models of service promotion and quality improvement; it also helps create awareness and support from multiple stakeholders including youth.
2. The "Test and Assess" campaign not only provided evidence for service quality improvement, but also adolescent and youth health seeking literacy and self-efficacy. Technology has great potential to quickly mobilize youth, collect, analyze and share data, and advocate with stakeholders for positive change, going beyond the traditional KAP model.

Conclusions/Next steps: Adolescents and youth are at increased risk for HIV due to a number of factors in Jiangsu, China. Their participation in all stages of HIV prevention must be integrated into the overall HIV prevention plan to improve service access, uptake and quality for this age group.

WEPED566

The status of sex education in times of political turmoil in Peru: HIV-related findings indicate progress but also important needs

J.C. Enciso Durand[1], A. Motta[1], C. Sandoval[1], K. Konda[1,2], A. Nunez-Curto[1], C. Caceres[1]
[1]Cayetano Heredia University, Center for Interdisciplinary Studies in Sexuality, AIDS and Society, Lima, Peru, [2]University of California Los Angeles, Division of Infectious Diseases, Department of Medicine, Los Angeles, United States

Background: Sex education can be a useful supporting strategy for HIV/STI prevention. Sex education in public schools of Peru has been facing strong criticism from religious groups since November 2016. Initially a political weapon against the administration, the ['Don't mess with my children'] movement gained momentum and put the national policy into question. We conducted a large evaluation of sex education across three geographical regions in Peru, as part of an international study, aimed at performing an in-depth exploration of sex education across three regions of Peru covering knowledge, practices and opinions from teachers and principals, as well as knowledge, practices, beliefs and experiences among students.

Methods: Data were collected between 2015 and 2016 in three Peruvian provinces (Lima, Ayacucho and Ucayali representing the coast, the highlands, and Amazonia, respectively). The study used multi-stage probabilistic sampling of schools and students; 2528 adolescents participated. Analysis used descriptive statistics such us frequency and contingency tables.

Results: Most students 75% (n=1896) reported that they had received at least one sex education class at school, and 85% of them had been taught about HIV and STIs. Only 52% knew where to obtain HIV/AIDS prevention and treatment services. Over 35% of students wanted to know more about HIV/AIDS and where to get prevention and treatment services. Additionally, 40% hoped to learn how to talk with their partner about being tested for HIV. Nearly three-quarters of students would be willing to befriend a person living with HIV. 70% of adolescents think that the sex education they receive is useful for their HIV-preventive practices. Some differences across regions exist, with indicators often showing better estimates of positive attitudes and adequate knowledge in Amazonia.

Conclusions: The sex education that students receive is valued, but its gaps are well-identified by them, including lack of information on HIV services. Our study helped reframe the discussion based on evidence that It is important to address differences across regions mainly in the areas with lack of knowledge (Highlands and Amazonia). As the majority were willing to befriend people living with HIV, this suggests that forces sustaining stigma and discrimination may be receding.

WEPED567

Successfully reaching young key populations with essential HIV prevention, care, and treatment services in Mali

T. Madani Moctar Saidou[1], A. Ag Altini[2], A. Lambert[3], D. Mohamed Amadou[4], F. Sidibe[2], D. Bore[1], M. Hamdallah[3], A. Dit Agali Wele[4], S. Garangue Souko[2], H. Rodriguez Sherman[3], S. Cisse[5], J. Bashi Bagendabanga[1]
[1]FHI360, LINKAGES, Bamako, Mali, [2]SOUTOURA, Bamako, Mali, [3]FHI360, LINKAGES, Washingtown, United States, [4]CSLS, Bamako, Mali, [5]USAID, Bamako, Mali

Background: There is scarce epidemiological and service uptake data on young key populations (YKP) in Mali. The USAID- and PEPFAR-supported LINKAGES project in Mali implemented a comprehensive package of HIV services for key populations, including YKP. This program analysis describes HIV outreach, care and treatment services for young female sex workers (FSW) and young men who have sex with men (MSM) in Mali.

Description: Program activities were conducted from July to December 2017 by local NGO, Soutoura, in four regions: Bamako, Kayes, Segou, and Sikasso. YKP age groups were defined as 18-19 and 20-24 years old. Aggregate data from monthly reports captured and disaggregated by KP group included: number of YKP reached, tested, enrolled into care, and enrolled in ART; number experiencing gender based-violence (GBV); and number screened for STIs. We conducted a chi-square test to compare results among groups.

Lessons learned: A total of 2,672 (49%) of all KP reached (5,417) were YKP, of which 79% were FSW and 21% were MSM. Table 1 presents data disaggregated by FSW and MSM. Of the YKP, 24% were under 20 and 76% were 20-24 years old; 48% were located in Bamako and 52% in other regions. HIV testing was provided to 70% of those reached. HIV case finding was 3.7%, with higher rates observed among MSM 20-24 years old (8.8%) and among YKP in Bamako (7.8%). Enrollment into care and initiation on ART for HIV+ YKP was 65% and 56%, respectively. Prevalence of GBV among YKP was 7.6% and higher in Bamako (6.8%) and the MSM group (18.6% and 15.7% respectively for 20-24 and under 20 years old). Primary care was provided for 88% of incidents of GBV. STI screening services were provided to 74% of YKP reached. Among those screened, 34% were diagnosed and treated for STIs.

Conclusions/Next steps: In Mali, half of the KP reached are under 25. The LINKAGES program, jointly with the Ministry of Health, will use these findings to develop urgently a youth-friendly approach to reach, improve access to care and treatment, and retain YKP in the program.

	FSW		MSM		Total
	18-19	20-24	18-19	20-24	
Number of YKP	483	1,627	147	415	2,672
Number of YKP screened for HIV	349 (72%)	1,133 (67%)	114 (78%)	274 (66%)	1,870 (70%)
HIV+	14 (4%)	29 (2.6%)	2 (1.8)	24 (8.8%)	69 (3.7%)
Enrolled into care	8 (57%)	24 (83%)	2 (100%)	11 (46%)	45 (65%)
Initiated ART	5 (63%)	16 (67%)	1 (50%)	3 (27%)	25 (56%)

[Young key populations (YKP) reached and tested in four regions in Mali, July-December 2017]

The relationship as a safety bubble: Reasons for not testing for HIV regularly among gay male couples in the US

L. Darbes[1], D. Chakravarty[2], T. Neilands[3], C. Hoff[2]
[1]University of Michigan, Department of Health Behavior and Biological Sciences, Ann Arbor, United States, [2]San Francisco State University, Center for Research on Gender & Sexuality, San Francisco, United States, [3]University of California, San Francisco, Center for AIDS Prevention Studies, San Francisco, United States

Background: Gay men in relationships are at high risk for HIV infection, yet many men may perceive being in a relationship as being protective. Although biomedical strategies (e.g., PrEP, TasP) offer effective prevention tools, HIV testing is the first step in the HIV treatment continuum. CDC guidelines recommend sexually active gay men test for HIV every 3-6 months. However research indicates that men in relationships may not adhere to these guidelines.

Methods: The Gay Couples Study is a longitudinal survey of 441 gay male couples (336 concordant HIV-negative, 105 serodiscordant) in San Francisco, California. To be eligible, couples had to have been together for at least 3 months, and at least one partner had to report anal intercourse in previous 90 days. Couples concurrently but independently completed computerized surveys regarding HIV testing, reasons for not testing, and sex behavior. We explored time since last test and reasons for not testing among the HIV-negative men (N=777) in the baseline sample.

Results: Average age was 41.7 years; median relationship was 5 years. Over one third of the sample (36%) had not tested in over one year. For men in concordant HIV-negative relationships who reported condomless anal intercourse (CAI) with an outside partner of unknown or discordant HIV status (DISC), more than one quarter (26%) had not tested in at least six months; 10% had not tested in over two years. For men in serodiscordant relationships, among those who reported CAI with a DISC primary or outside partner, more than one third (35%) had not tested in over six months. "I am in a relationship" was among the reasons for not testing endorsed by 54% of the twenty-four men who had never tested and 47% of those who had not tested in over one year. Only 36 (4.6%) HIV-negative participants reported being on PrEP.

Conclusions: Gay men in relationships may underestimate their need for HIV testing due to perceiving relationships to be protective, even when behavior may confer increased risk for HIV. We identified high rates of non-adherence to CDC HIV testing guidelines. Gay couples may need tailored messages and interventions to increase their HIV testing frequency.

Gender issues and gendered relationships

WEPED569

Association between intimate partner violence and HIV status among Haitian women

A. Saxena[1,2], M.-M. Deschamps[3], N. Dorvil[3], I. Christophe[3], R. Rosenberg[1], M. Jean-Gilles[1], J. Pape[3,4], J. Dévieux[1]
[1]Florida International University, AIDS Prevention Program, Miami, United States, [2]Baptist Health South Florida, Center for Healthcare Advancement and Outcomes, Miami, United States, [3]GHESKIO, Port-au-Prince, Haiti, [4]Cornell University, Center for Global Health, Department of Medicine, New York, United States

Background: The prevalence of intimate partner violence (IPV) among women in Haiti has increased from 25% to 29%. A number of studies have associated higher levels of STD/HIV transmission with IPV among women, in part due to forced sexual activity and microscopic vaginal and anal tears that increase viral contact through raw wounds. This study examined the associations between IPV and HIV status and the factors contributing to this relationship.

Methods: Participants included HIV+ women (n = 55) drawn from a larger sample of women (N=513) who had experienced IPV and were attending the GHESKIO clinics. From the larger sample, a 1:2 optimized matching was performed to get a control group of HIV- women (N=110) with a history of IPV, matched on demographic and mental health variables. Attitudes towards gender roles, mental and physical well-being, and partner violence were assessed using a culturally adapted version of the questionnaire from the from the World Health Organization multi-country study. Logistic regressions were utilized to calculate multivariable adjusted odds ratios.

Results: HIV+ participants reported poorer general and mental health. Both groups reported very high partner control, however HIV+ women were more likely to report more severe forms of psychological violence such as being belittled or humiliated in front of other people ($p < 0.05$) and made to feel scared on purpose ($p < 0.01$) as well as severe physical violence such as being choked or burnt on purpose and being threatened to use or actually having their partner use a gun, knife or other weapon against them ($p < 0.0001$). Women who experienced severe forms of IPV were 3.5 times more likely to have an HIV positive status compared to those who did not experience severe IPV (= 1.248, $p < 0.0001$).

Conclusions: This study points to the significant associations between severe forms of physical and psychological IPV and HIV status, indicating important areas for future studies and interventions among Haitian women.

WEPED570

Sexual violence, stigma and HIV vulnerability experienced by lesbian women from Rio de Janeiro, Brazil: The women group 'Felipa de Souza'

M. Seixas, R. Fernandes de Castro, M.C. Nobua Cruz
Grupo de Mulheres Felipa de Souza, Rio de Janeiro, Brazil

Background: Brazil is experiencing a wave of ´corrective rapes´, with many men raping lesbian women to ´cure them´ or their homosexuality. Overall less than 30% of rapes are reported, and yet governmental statistics indicate that one woman is raped every 11 minutes - the vast majority adolescents and young adults.There are five women beaten every two minutes in Brazil, and an average of 13 murdered every day, according to the nonprofit 'Mapa da Violencia' (Violence Map). Latin America is the region with the most female murders on earth. An estimated one in three women and girls worldwide report suffering physical or sexual abuse, making gender-based violence one of the most widespread human rights violations.

Description: The Women Group 'Felipa de Souza' develops several interventions targeting black lesbian from disenfranchised communities in Brazil. Thought group interventions the NGO address sexual violence and proper reporting of it, homophobia, family issues, sexism, racism, and assertiveness skills development. The vast majority of participants live in Rio de Janeiro slums or other hard to reach and disenfranchised communities with high rates of violence.

Lessons learned: Participant narratives reveal a trajectory of marginalization. Structural factors such as social exclusion and violence elevate their risk for HIV infection; this risk was exacerbated by inadequate HIV prevention information targeting lesbian. Participants face multiple barriers to HIV testing and proper care, including pervasive stigma, heteronormative assumptions in HIV-testing and treatment facilities, discriminatory and incompetent treatment by health professionals. Underrepresentation of lesbian women in HIV research further contribute to marginalization and exclusion.

Conclusions/Next steps: Structural factors elevate HIV risk among lesbian black women, limit access to HIV prevention and present barriers to HIV care and support. This intervention conceptualization of a trajectory of marginalization enriches the discussion of structural factors implicated in the wellbeing of lesbian black women and highlights the necessity of addressing lesbian black women needs in HIV prevention, care and research. Interventions that address intersecting forms of mar-

ginalization (e.g. sexual stigma, transphobia, HIV-related stigma) in community and social norms, HIV programming and research are required to promote health equity among lesbian black women.

WEPED571

Comparative analysis of intimate partner violence among HIV positive pregnant and non-pregnant women in a health facility in Mozambique

H. Muquingue[1], E. Matsinhe[1], R. Frescas[1], D. Correia[2], N. Carter[3], J. Gleckel[4], R. Cuco[5], R. Cossa[6], C. Lee[7], E. Necochea[7], A. Baptista[8], A. Jaramillo[1]
[1]Jhpiego Mozambique, Maputo, Mozambique, [2]CDC Mozambique, Maputo, Mozambique, [3]University of California, Center on Gender Equity and Health, San Diego, United States, [4]Public Health Institute of Western Massachusetts, Springfield, United States, [5]Ministry of Health, National Directorate of Public Health, Maputo, Mozambique, [6]Ministry of Health, Maputo, Mozambique, [7]Jhpiego, Baltimore, United States, [8]Jhpiego Mozambique, Gender Based Violence, Maputo, Mozambique

Background: Intimate partner violence (IPV) is a highly prevalent form of gender-based violence (GBV), widely recognized as one of the leading causes of poor health, disability, and death among reproductive-age women. In Mozambique, HIV prevalence among women aged ≥15 years is 15.1%, and 32% of women have experienced GBV in their lifetime. To improve HIV-related outcomes, the Ministry of Health piloted an intervention addressing women's experiences of GBV as driver for poor HIV outcomes. Through routine GBV screening in health facilities with the highest HIV prevalence, MOH sought to increase IPV identification, and link survivors to GBV care.
We compared IPV rates among HIV positive (pregnant and non-pregnant) women, and assessed whether HIV seropositivity is associated with more IPV in pregnant women.
Methods: We conducted a cross-sectional study of 4,664 women aged 15 to 49 years attending antenatal consultations (ANC) or voluntary HIV testing (VCT) at a peri-urban health facility. All were screened for exposure to IPV in the previous 12 months. We compared HIV test results and GBV screening results over nine months. Analysis used Pearson Chi-square test, stratifying by pregnant and non-pregnant women.
Results: At both ANC and VCT sites, 4,664 women were screened for IPV; 2,385 (51%) were in ANC and 2,279 (49%) were in VCT. Overall IPV prevalence was 4.8%. At ANC, 27 women who were HIV positive were IPV survivors (7% of the 370 HIV positive women). At VCT, 30 women who were HIV positive were IPV survivors (12% of the 246 HIV positive women). HIV positive pregnant women were more likely to have experienced IPV than HIV-negative pregnant women (p=0.0032); the same was observed among non-pregnant women (p=0.00001). Reported IPV among HIV positive pregnant women was as frequent (1.1%) as in HIV positive non-pregnant women (1.3%).
Conclusions: HIV positive women were more likely to have experienced IPV than HIV-negative women, and this was true for both pregnant and non-pregnant HIV positive women. There is need to expand GBV screening in both ANC, to improve support services for pregnant seropositive women, and in VCT settings to ensure post-GBV services are offered and provided to women who need them.

WEPED572

HIV status disclosure patterns and male partner reactions among HIV+ pregnant women on lifelong ART in southwestern Kenya

L. Abuogi[1], K. Hampanda[2], M. Njuguna[3], A. Helova[4], T. Odeny[3], M. Onono[3], E.A. Bukusi[3], J. Turan[4]
[1]University of Colorado, Denver, Pediatrics, Denver, United States, [2]University of Colorado, Denver, School of Public Health, Denver, United States, [3]Kenya Medical Research Institute, Centre for Microbial Research, Nairobi, Kenya, [4]University of Alabama, Birmingham, Department of Health Care Policy and Organization, Birmingham, United States

Background: Disclosure of HIV status to sexual partners in the context of prevention of mother-to-child transmission (PMTCT) may contribute to adherence to antiretroviral medication and improved PMTCT outcomes. We report on patterns of disclosure and male partner reactions to status disclosure.
Methods: We conducted semi-structured surveys of 200 HIV positive postpartum women within the Mother-Infant Visit Adherence and Treatment Engagement (MOTIVATE!) study (R01HD0808477; Abuogi, Turan) in southwestern Kenya. We sampled HIV-positive women on ART at 12 months postpartum between April-August 2017. Women completed an in-person semi-structured survey administered by female interviewers in their preferred language. Descriptive analysis of patterns of disclosure and male partner reactions are described.

	Total	Positive (Male partner reaction)	Negative/Mixed (Male partner reaction)	Odds Ratio [95% Confidence Interval]	p-value
	N=168 (%)	N=147	N=21		
Age of woman (mean sd)	28.2 (5.0)	28.3 (5.1)	27.6 (5.0)	1.0 (0.94 - 1.13)	0.55

Rarely†	88.4% (145)	89.5% (128)	81.0% (17)	ref	

[Table 1. Association between male partner reaction to HIV disclosure of post-partum HIV positive women]

Results: A total of 180 (90%) women reported having a main male partner of whom 95.5% respondents reported disclosing their HIV status to that partner. The majority of women (82.8%) reported disclosure to their male partner occurred within one year of their diagnosis, with 62.7% of disclosure occurring within one week. Most common forms of disclosure were: self-disclosure (55.4%), couple's HIV testing (31.5%), and at antenatal care visit (7.7%). Women reported 87.5% of male partner reactions to disclosure were positive. There were no reports of gender-based violence, threats or break up as a result of disclosure. Women reported 162 (90%) of their male partners had an HIV test, 8 (4.4%) untested, and 10 (5.6%) unknown. Of those who also knew their partner's HIV status, 62% were HIV-positive and 29% HIV-negative. Disclosure to male partners via couples counseling and testing was positively associated with a positive reaction to disclosure compared to self-disclosure (Odds Ratio (OR) 9.3; p=0.03). (Table 1) Women experiencing verbal intimate partner violence were nearly 80% less likely to experience a positive response to disclosure (OR 0.23; p=0.01).

Conclusions: The majority of HIV+ pregnant and postpartum women in this cohort disclosed to their male partners early after diagnosis and experienced a positive reaction. According to women, knowledge of HIV status is high among male partners but most often does not occur at the same time as women's HIV diagnosis.

WEPED573

Harnessing peer support amongst women living with HIV in positively women: A case for gender sensitive interventions

D. Onyango[1], S. Petretti[1], H. Rogers[1], S. Paparini[2]
[1]Positively UK, London, United Kingdom, [2]Graduate Institute of International and Development Studies, Geneve, Switzerland

Background: Around 29,000 women are living with HIV (WLWH) in the UK and Black African women are disproportionately affected. Sex and gender interact with HIV status, ethnicity, socio-economic background, immigration status, and personal factors. The Positively Women's project was initiated in recognition of women's specific needs following a wide consultation with WLWH at the 2014 Women Know Best conference in London.
Description: The Project aims to increase women's agency in managing health through peer support. Collective activities support women in all aspects of life and women can train to become peer mentors. Interventions include: individual peer support from specialised case workers and volunteer peer mentors in HIV clinics and at our premises; regular group support and workshops on topics chosen by women (e.g. sex and relationships, legal rights, financial management); partnership and sustained advocacy with other services.
Lessons learned: Gender-based power imbalances at home and work and structural barriers in UK welfare and immigration policies affect a large proportion of the women in the project, constrain our capacity to meet their intersecting needs, and limit their ability to become peer mentors. Other public and voluntary service providers do not always display awareness of the specific material and psychosocial needs of WLWH. It is challenging to deliver an inclusive service to women who differ in terms of: employment, age, motherhood, ethnicity, literacy, gender identity, sexuality, citizenship and legal rights. Yet issues with isolation, stigma, and disclosure are common irrespective of this diversity. Ongoing feedback from project beneficiaries, volunteers, staff and the evaluation team enable tailoring of the project. The project success is growing: 140 group and 244 individual sessions have been held this year and increasing numbers of women access the service; collaboration with other services is strengthening; project staff are invited to present on project activities at other organisations and events in local communities.
Conclusions/Next steps: The task of meeting the needs of a heterogeneous population of WLWH in the UK remains a challenge. However, the project is needed and well-attended as it empowers women to live positively with HIV, help their peers through training as volunteer peer mentors, and be active stakeholders in service delivery.

WEPED574

Engaging men and boys is key to preventing violence against women and for promoting better health outcomes for women and children

M. Umoh, A. Adetunji, P. Inyang, E. Babatunde
Health Initiative for Safety and Stability in Africa (HIFASS), Calabar, Nigeria

Background: Health initiative for safety and stability in Africa (HIFASS) through USAID funding is currently supporting Cross River State, South-South Nigeria to provide quality care, protection and support services to orphans and vulnerable children (OVC) and their households especially in rural and hard to reach communities. Violence such as rape and physical assault against girls and women have been a major occurrence in these communities.
This paper examines the outcome of interventions to reduce violence against women and girls in rural communities.
Description: Violence against women have been a major challenge in the rural communities where we work. These violence against women are mostly are perpetrated by men. Violence is being condoned by these communities because it is regarded by culture as a show of masculinity and power control by the men folk. Hence the need to reach out to men within these communities and sensitize them on the effect of violence against women and the overall impact on the health of women and children.
Several advocacy and sensitization visits were made to the community leaders who were mostly men. In-depth interviews were held to obtain information on their knowledge, attitude and practices on HIV/AIDS related issues. In addition, community sensitization and outreach activities targeting men and boys were conducted in eighteen communities to create awareness on the effect of negative social norms in the community and how they predispose women and girls to HIV infection and other sexually transmitted infections.
Lessons learned: Results from in-depth interviews conducted reveal that most boys and men were ignorant of the consequences of sexual violence on women/girls and the impact on children. After 12 months of consistent community engagement meetings and sensitization outreaches, uptake of HIV testing services in the community increased from 35% to 70% while number of reported cases of sexual assault including rape decreased from 10 -15 reported cases per month to 4 - 6 cases.
Conclusions/Next steps: Active engagement of men within the community play a significant role in the reduction of violence against women since critical decisions affecting the wellbeing of women & girls in most communities are made by men.

WEPED575

An Exploration of the interplay between perceived relationship power imbalance, couple-race, and sexual risk behavior for HIV among gay male couples

C. Hoff[1], D. Chakravarty[1], S. Dworkin[2], T. Neilands[3]
[1]San Francisco State University, Center for Research and Education on Gender and Sexuality, San Francisco, United States, [2]University of Washington, Bothell School of Nursing and Health Studies., Seattle, United States, [3]University of California, Center for AIDS Prevention Studies, San Francisco, United States

Background: Between 40% and 68% of new HIV infections among MSM in the USA is attributed to sexual risk behaviors within male couples. While relationship power is known to shape HIV risk in male-female couples, few studies measure relationship power among male couples or examine its association with HIV risk. Using a newly developed relationship power scale for same-sex male couples, we examined the association between relationship power and sexual risk for HIV as it intersects with couple-race.
Methods: Between June 2012 and October 2014, Black, White and biracial Black-White male couples (N=377 couples) were recruited in New York City and the San Francisco Bay Area and completed a self-administered ACASI survey exploring relationship power, sexual risk behavior and relationship dynamics. Each partner was categorized based on his perceived power imbalance (PPI) within the relationship
(0: less imbalance; 1= more imbalance). Using logistic generalized estimating equations (GEE) accounting for data clustering within couples, we tested the association of PPI and couple-race with sexual risk, defined as condomless anal sex with an outside partner of discordant or unknown HIV status (CASDU) in the previous 3 months.
Results: The sample contained 53.6% White, 23.7% Black and 22.7% Black-White couples where 72.7% were concordant HIV-negative and 27.3% were serodiscordant. CASDU was reported by 10.4% of the participants. The model demonstrated a statistically significant interaction between PPI and couple-race. Specifically, among Black-White couples, controlling for relationship length and couple serostatus, the partner with higher PPI had significantly greater odds of reporting CASDU compared to his partner (aOR=3.88; p=0.005). This was not true for Black and White same-race couples. Further, in Black-White couples, the White partner had the higher PPI in significantly more instances.
Conclusions: Greater perceived power imbalances among partners in Black-White couples is associated with greater odds of sexual risk for HIV. Further exploration of various factors that possibly interplay with

couple-race including couples' socio-economic status, individual HIV-statuses, agreement type, and relationship dynamics such as communication (levels and -types) is needed to uncover the mechanisms behind this association. Meanwhile, HIV prevention programs for male couples should incorporate the handling of relationship power imbalances to minimize this risk.

WEPED576

Are relationships protective for trans women and trans men partnered with cis gendered men?

C. Hoff[1], S. Castellanos[1], C. Michels[1], V. Tykulsker[1], S. Sicro[1], C. Tate[2]
[1]San Francisco State University, Center for Research and Education on Gender and Sexuality, San Francisco, United States, [2]San Francisco State University, Psychology, San Francisco, United States

Background: HIV disparities in the U.S. continue to affect the most marginalized groups. Transgender women represent alarmingly high rates of HIV, and trans men report high risk sexual behaviors, particularly with cis men, and increasing rates of HIV. Past research has identified important relationship factors associated with risk among gay couples. However, little is known about relationships that feature a trans partner. We conducted a study that explored relationship factors associated with HIV risk among trans women and trans men in committed relationships with cis men.
Methods: Between May 2016 and May 2017 we recruited *N* = 39 couples in the San Francisco Bay Area. Targeted recruitment strategies were used at transgender community events, community-based organizations, as well as social media (e.g., Facebook). Couples were interviewed simultaneously but separately at our offices in downtown San Francisco. Semi-structured interviews explored gender identity, discrimination, sexual behavior, agreements, HIV prevention and relationship satisfaction. Interviews were transcribed, coded and analyzed by the study team.
Results: Of the 39 couples, 22 were trans women with cis male partners and 17 were trans men with cis male partners. Approximately 48% of the sample identified as White, and 19% were HIV-positive. Of those who were HIV-positive, approximately half were trans women and half were cis men. None of the trans men in the sample reported being HIV-positive. Overall, sexual risk behavior for HIV was low. Factors contributing to this included: a clear understanding of agreements about whether or not sex with outside partners was allowed; condom use with outside partners; and few reports of broken agreements. Most couples did not perceive themselves to be at risk, none were taking PrEP, and most were satisfied with their sexual relationship with their partner. Few discrepancies between partners were reported in any of the interview topics.
Conclusions: Trans women and trans men in committed relationships with cis men reported low sexual risk for HIV. Relationship factors like having clear agreements and not breaking agreements support these couples to have satisfying sexual relationships without the burden of significant risk. Relationships may serve as a protective mechanism against risk for HIV among these couples.

WEPED577

Sexual agency and disproportionate risk: Young women's experience with HIV risk in Cape Town, South Africa

S. Manley
York University, Department of Politics, Toronto, Canada

Background: Young women in South Africa are experiencing a greater disproportionate risk of HIV than their male counterparts. Relationship dynamics and gender roles shape the environment within which men and women can engage successfully with HIV risk prevention. This study investigates gender imbalances in sexual relationships that exacerbate women's risk and looks to how gendered HIV risk perception is understood and performed in sexual partnerships.
Methods: The primary data findings are based on a sample study from field research conducted in Cape Town, South Africa from February 2016 - June 2016. This study conducted focus group discussion and used qualitative thematic content analysis to analyze responses from 280 men and women (18-30) who engaged in heterosexual partnerships in the past 6 months in Kilpfontein sub-district and Khayelitsha sub-district.
Results: The themes derived from recurrent and similar patterns of discussion revealed:
(a) Maintaining the relationship with the main partner as more important then communicating HIV prevention;
(b) The sexual decision making power was constrained for women in sexual partnerships. Women chose their male partners but would submit to the demands of the male partner when gift giving was present;
(c) Men and women spoke of the lack of trust between genders, minimal communication about prevention and openly acknowledged engaging in multiple partnerships.
This lack of trust by both the men and women has culminated into an increase in risk actions taken by young women. The study revealed that women age 25-30, were more likely to be waiting at home for their partner to bring HIV to them, while the younger women age 18-24, suggested that they are purposefully seeking multiple partnerships. There is strong link between women's means of subsistence (money), sexual partnering and the risk actions taken. These gendered dynamics contribute to agency constraints for young women.
Conclusions: This study reveals an important connection between HIV risk perception, agency and sexual partnering dynamics. Prevention efforts need to be tailored to recognize the constraints of sexual agency for young women and reduce barriers to effective and more sustainable gendered combination prevention strategies that focus on the underlying sociocultural and economic factors related to gender inequality.

WEPED578

Religious leader a mechanism for change in HIV prevention and gender based violence: A community approach

A. Erinmwinhe
Nigeria Network of Religious Leaders Living with or Personally Affected by HIV/AIDS, Programs, Federal Capital Teritory, Nigeria

Background: Studies show that violence perpetuated against women and Men can directly or indirectly enable HIV transmission. Justifications for violence frequently are on based gender norms that is, social norms about the proper roles and responsibilities of men and women. These cultural and social norms socialize males to be aggressive, powerful, unemotional, and controlling, and contribute to a social acceptance of men as dominant. Similarly, expectations of females as passive, nurturing, submissive, and emotional also reinforce women´s roles as weak, powerless, and dependent upon men. The socialization of both men and women has resulted in an unequal power relationship between men and women. Some faith teachings have been implicated as drivers of HIV stigma and erroneous gender narratives that trigger violence against women.
Description: Nigerian Network of Religious Leaders living with or Personally Affected by HIV/AIDS (NINERELA+) in collaboration with INERELA+ South Africa conducted community/media dialogues and education for female religious leaders on HIV prevention stigma & SGBV. The dialogue was aimed at building the capacity of female religious leaders to serve as champions in fight against HIV/AIDS, SGBV,SD by educating community who are likely perpetuators, identifying cases and linkage into care/justice. Participants identified innovative strategies to address SGBV and HIV Issues in churches/mosque to curb issues.
Through CD meetings religious leaders who were living in denial of SGBV/HIV publicly disclosed their experiences and shared personal testimonies as HIV persons who has overcome stigma and are reporting cases of injustice. These has led community ownership of the project by clerics.
Lessons learned: Using religious leaders has help victims disclose their status.
Different strategies were adopted by Female leaders to address common problems.
Female leaders created save space for women to confront issues that were not initially discussed comfortably.
Media enlightenment helps to promote cases of injustice and stigma cases.

Conclusions/Next steps:

1. Religious leaders are to expand the network of women working on gender and stigma reduction in their communities.
2. The community should be allowed to take ownership of the project and the lead the process.

WEPED579

Determinants of post-disclosure violence against HIV positive women in serodiscordant unions: A cross-sectional study in Kumasi, Ghana

Y.O.I. Hardy[1], E.K. Agbeno[2], A. Enimil[3], P.K. Antwi[4], F. Agyemang-Yeboah[5], N.K. Mensah[6]
[1]School of Medical Sciences, Kwame Nkrumah University of Science and Technology/Komfo Anokye Teaching Hospital, Internal Medicine, Kumasi, Ghana, [2]School of Medical Sciences, University of Science and Technology, Obstetrics and Gynaecology, Cape Coast, Ghana, [3]School of Medical Sciences, Kwame Nkrumah University of Science and Technology / Komfo Anokye Teaching Hospital, Paediatrics, Kumasi, Ghana, [4]Arocha Ghana, Environmental Science, Kumasi, Ghana, [5]School of Medical Sciences/University of Science and Technology, Molecular Medicine, Kumasi, Ghana, [6]Komfo Anokye Teaching Hospital, Public Health Unit, Kumasi, Ghana

Background: Violence against women is a global epidemic that infringes on their rights and has negative health outcomes. In sub-Saharan Africa lifetime prevalence of partner violence is over 30%. HIV positive women in serodiscordant unions are at risk of violence after disclosure of their status. This can hinder their adherence to antiretroviral therapy, with serious public health consequences. Knowledge of the determinants of violence can help design appropriate interventions. This study assesses the risk factors for post-disclosure violence against HIV positive women in serodiscordant unions in Kumasi, Ghana.
Methods: A cross-sectional study was conducted among 129 consented HIV positive women in serodiscordant unions attending the HIV clinic at a tertiary health facility in Kumasi, Ghana from May to October 2017. Self reported biodata, social history and experience of post-disclosure violence from their partners were confidentially obtained from each participant using standard interviewer administered questionnaires and analysis done using SPSS version 20 statistical software. Characteristics of the respondents who reported violence and those who did not were compared using Chi square analysis at 5% level of significance.
Results: The mean (sd) age in years of respondents and their partners was 40(±8) and 46.9(±9.3) respectively. Post-disclosure violence was reported by 24 (18.6%) respondents; psychological violence was the most common (n=18, 75%), followed by physical (n=3, 12.5%) and sexual violence (n=3, 12.5%). Women who experienced violence were more likely to be financially independent of their partners than those who did not (40.7% vs 13.3%, p=0.005), more likely to be in a polygamous relationship (61.1% vs 10.8%, p< 0.001) and more likely to have partners who took alcohol (83.3% vs 16.7%, p=0.006).
Conclusions: Screening for partner violence and provision of the needed support should be integrated into routine ART services especially for vulnerable HIV positive women who are prone to violence. Behaviour change communication strategies against alcohol intake and polygamy should also be developed. Furthermore caregivers should be trained to empower women, with identified risk factors for violence, with skills on status disclosure so as to minimize violence.
There is a need for further research into factors that determine violence among financially independent women.

WEPED580

Sex and age differences of clients accessing post gender based violence care services in selected states in Nigeria

O. Idoko[1], P. Ikani[1], T. Akibu[1], T. Philip-Ononye[2], A.A. Aliu[3], C. Agbakwuru[1], E. Iwara[1], E. Oladele[1], O. Adedokun[1], S. Raj Pandey[1], H. Khamofu[1]
[1]FHI 360, Abuja, Nigeria, [2]USAID, Abuja, Nigeria, [3]Federal Ministry of Women Affairs and Social Development, Abuja, Nigeria

Background: Gender-Based Violence (GBV) is a global pandemic that afflicts men, women and children. However, women and girls are the most affected by gender-based violence. An estimated one in three women worldwide has been beaten, coerced into sex, or abused in her lifetime. Nigeria in recent years witnessed instability in various political, ethnic and religious conflicts, which has been further heightened by the terrorist group Boko Haram in northeastern Nigeria. With these conflicts, came media reports of increased GBV and sexual assault of women and children. The USAID funded SIDHAS project has a design that includes strategies to increase awareness of GBV, post-exposure prophylaxis uptake, and post-GBV care at all supported health facilities and communities. This review describes sex and age difference among clients receiving Post-GBV care in the SIDHAS supported treatment program in Nigeria.
Methods: We reviewed data from 143 supported public health facilities located across 13 states in Nigeria. Post-GBV care was available for both sexual violence and physical violence at the facilities. Post-GBV care data dis-aggregated by type of violence was documented in the National register and reported monthly in the DHIS. We reviewed Post-GBV data reported from January 2016 to October 2017.
Results: A total of 5,986 individuals received post-GBV care services of which 2,941 and 3,045 were cases of sexual and physical violence respectively. Females accounted for 83% (2,438) of individuals that received post-GBV care for sexual violence and 65% (1,981) for physical violence. Individuals below 25 years accounted for 68% (1,992) and 45% (1,368) of people that received post-GBV care for sexual violence and physical respectively. Children 0-9 years contributed 14% and 3% to post-GBV care for sexual and physical violence respectively. Majority (53%) of all the sexual violence cases reported was from the South-south states with the North-East accounting for 13% (383). Sixty nine percent (2,032) of clients receiving post-GBV care for sexual violence received post-exposure prophylaxis (PEP), of which 84% (1,711) were females (p< 0.001).
Conclusions: This highlights the need for a comprehensive GBV intervention in Nigeria, addressing first and foremost violence against women and girls and secondarily men and boys.

Sexual concurrency and sexual networks

WEPED581

Using virtual reality to make young people more aware of their sexual network in order to reduce unfounded trust in their partner´s STI status

H. Roosjen, F. Zimbile, E. Fisser, K. Vermey
Soa Aids Nederland, Amsterdam, Netherlands

Background: International research into the determinants of condom use shows repeatedly that trusting your partner, however long you've known him or her, is the main reason for not using condoms - "they wouldn't have an STI!". Confronting young people with the unknown factor of their sexual network, by asking them how many exes they have, is a good way to make them think again.
Description: That's why Soa Aids Nederland has developed the Ex-O-Meter: an online application that calculates and visualises the size of a sexual network based on details given by the person themselves. Being confronted with the size of their network seems to heighten a young

person's perceived necessity for using condoms. When the network is visualised, it makes them aware that they actually have to trust their ex's ex too if they want to have safe sex without a condom.

Lessons learned: The Virtual Reality version currently in production will further increase the impact of the Ex-O-Meter. Rather than being just a spectator, you really enter the network of exes, making the experience much more intense. Interacting with them provides you with information that convinces you of the risks of unsafe sex.

Pretesting the prototype showed us that it does increase awareness of the network: "I see the reality that I don't dare think about. We all know the risks of unsafe sex, but tell ourselves that nothing will actually happen." Making the experience too scary proofed to be counterproductive.

Conclusions/Next steps: VR is an innovative method for bringing about behavioural change. The preliminary results of the Ex-O-Meter suggest that it enhances the experiences of the users and therefore might have a bigger impact on the determinants of condom use, namely awareness, risk perception and intention. An important condition is that it does not arouse fear.

Soa Aids Nederland believes the Ex-O-Meter can be effective as an interactive installation at schools and events. The organisation has an extensive national network that enables us to reach many young people. We will also be exploring possibilities for exporting our VR experience internationally, to middle-income and even low-income countries.

[Ex-O-Meter in virtual reality]

WEPED582

A longitudinal analysis of the impact of PrEP on sexual behaviour and drug use among Australian gay and bisexual men

G. Prestage[1], L. Maher[1], F. Jin[1], L. Degenhardt[2], S. Vaccher[1], A. Bourne[3], M. Hammoud[1]

[1]University of New South Wales, Kirby Institute, Kensington, Australia, [2]University of New South Wales, National Drug and Alcohol Research Centre, Kensington, Australia, [3]La Trobe University, Australian Research Centre in Sex Health and Society, Bundoora, Australia

Background: It has been claimed that PrEP may change sexual and drug using behaviors among gay and bisexual men (GBM) but few studies have assessed this longitudinally.

Methods: Between 2014-2017, we enrolled into the FLUX online cohort study 1246 GBM who were not HIV-positive and who provided five rounds of six-monthly follow-up data collection. We describe changes in sexual behavior and methamphetamine use following PrEP uptake.

Results: .At baseline, mean age was 33 years and 13 men (1.1%) were using PrEP.

Among 228 men (15.1%) who commenced PrEP during 24 months follow-up, number of partners in the previous six months increased from baseline (Mean=24) to 24 months (Mean=44) ($p< 0.001$); the proportion reporting group sex also increased from 25% to 49% (p-trend< 0.001). Nearly 60% of men who commenced PrEP reported condomless anal intercourse (CLAIC) in the round prior to commencing PrEP, and almost 25% reported methamphetamine use. In particular, receptive CLAIC increased among these men who commenced PrEP, from 45% at baseline to almost 80% by 24 months follow-up, but methamphetamine use remained steady. Also, whereas 5% reported 'often' engaging in receptive CLAIC at baseline, this increased to 16% at 24 months.

Of 930 men who had never used PrEP throughout the study period, 23% reported recent CLAIC and 9% reported methamphetamine use at baseline; they reported a mean of 10 recent partners. Prevalence and frequency of these behaviours remained steady over time.

Among men who reported any receptive CLAIC during 24 months follow-up, 29% of men who had commenced using PrEP and 15% of men who never used PrEP reported receptive CLAIC only with partners who were using PrEP.

Conclusions: Men who initiated PrEP became significantly more sexually active in general and were more likely to engage in CLAIC, and to do so more often. Methamphetamine use remained steady after commencement of PrEP. GBM who commence using PrEP change their sexual behavior, though not necessarily their drug use behavior. These behavior changes appear not to have affected men who do not use PrEP.

WEPED583

Hearing from the men: Multiple partnerships, HIV risk, and drivers of their relationships with AGYW in Swaziland and Uganda

J. Pulerwitz[1], A. Gottert[1], G. Siu[2], P. Shabangu[3], P. Keilig[1], S. Mathur[1]

[1]Population Council, HIV and AIDS Program, Washington, DC, United States, [2]Makerere University, Child Health and Development Centre, Kampala, Uganda, [3]Institute for Health Measurement, Mbabane, Swaziland

Background: Given very high incidence rates among adolescent girls and young women (AGYW) in eastern and southern Africa, HIV risk experienced by AGYW and their male partners is a major concern in the HIV field. However, little is still known about these relationships from men's perspectives. We conducted in-depth qualitative research with 135 men as part of implementation science research to reach and characterize male sexual partners of AGYW, and understand drivers of their relationships.

Methods: From March-August 2017, we conducted in-depth interviews (IDIs) with 40 men in Swaziland and 95 in Uganda, ages 18+. Respondents were recruited primarily at community 'hot spot' venues. Data analysis involved coding in atlas.ti and synthesizing findings.

Results: Respondents were 28 years old on average in both countries (range of 20-47 in Swaziland; 19-45 in Uganda). Most men reported sexual relationships with AGYW over the past year, who were usually 3-7 years younger than them. Eighty percent of men in Uganda and 33% in Swaziland were married/cohabiting. Men's relationships in Uganda generally consisted of multiple, overlapping long-term partners, whereas in Swaziland they reported multiple shorter-term casual relationships. Most men in both countries described norms supporting multiple partnerships and common patterns of conflict within their relationships. In Uganda this manifested primarily as unresolved discord in their marriage, which men said drove them to seek younger side partners who would be more likely to value and respect them. In Swaziland, men described ubiquitous distrust within relationships, which they said has led to a shift among youth to delay formalizing relationships in marriage until older (e.g., age 30+). In both countries, couples report infrequent and/or blaming communication about HIV prevention and family planning.

Conclusions: Inability to resolve conflict in relationships, and to communicate about HIV and reproductive health, emerged as a root cause of both relationship dissatisfaction and men's multiple concurrent relationships in Swaziland and Uganda. Carefully designed interventions focused on healthy couple communication and conflict resolution skill-building, and critically examining norms around the need for multiple partnerships, are urgently needed for both men and their partners.

Sexuality, gender, and prevention technologies (including condoms, treatment as prevention, male circumcision, pre-exposure prophylaxis)

WEPED584

"I feel like shackles have been loosened a little": The impact of PrEP on gay men's sexual cultures in Australia

B. Haire[1], S. Vaccher[1], L. Maher[1], D. Murphy[2], I. Zablotska-Manos[3]
[1]UNSW Sydney, Kirby Institute, Sydney, Australia, [2]University of Sydney, Sydney, Australia, [3]University of Sydney, Sydny, Australia

Background: Background: By the end of 2017, more than 14,000 gay and bisexual cisgender and transgender men (GBM) were accessing HIV pre-exposure prophylaxis (PrEP) in Australia. This study explores the culture of PrEP adoption and the evolving concepts of 'safe sex'.
Methods: Between September 2015 and February 2018, 38 in-depth interviews were conducted with 24 GBM using PrEP, and seven sexually active GBM not using PrEP. Twelve participants completed a follow-up interview 9-18 months later. Interviews were electronically recorded and transcribed. Data were analysed thematically.
Results: Of the 24 PrEP users, three had ceased use by the follow-up interview. Cessation due to side effects provoked anxiety due to renewed HIV acquisition risk. Some PrEP users reported sporadic or non-existent condom use prior to PrEP access, and most reported reducing condom use following PrEP uptake. Many participants associated condoms with HIV-related anxiety and loss of pleasure and intimacy, however some positively associated condoms with practices of negotiation and expressions of mutual care. HIV-negative men not on PrEP reported an increasing difficulty in having sex with condoms, and feeling stigmatised as non-PrEP users. Some participants described PrEP as a means of reducing barriers based on serostatus, but most PrEP users still wanted HIV-positive partners to have undetectable viral loads. Positive impacts of PrEP included reduced HIV-related anxiety, improved sexual negotiation, and the resurgence of peer-based sexual health support. Negative impacts included concerns about sexually transmissible infections and perceived loss of sexual capital by those who wanted to continue condom use.
Conclusions: Many study participants reported irregular or infrequent condom use prior to PrEP initiation, which declined further after adoption. However, this is not a concern for HIV transmission in a high adherence context. Reduction in HIV-related anxiety suggests a mental health benefit for PrEP users. Of concern are reports of normative pressure on non-PrEP users to adopt PrEP. While PrEP has made HIV prevention easier for many, findings suggest that the sex culture has not yet shifted to an inclusive 'combination prevention' approach. Paradoxically, maximising the benefits of PrEP may require further support for those opt to continue condom use.

WEPED585

Community research engaging women (CREW): Utilizing participatory action research to understand women's knowledge, attitudes, and beliefs about PrEP

C. Carey-Grant
WORLD (Women Organized to Respond to Life-threatening Disease), Oakland, United States

Background: African American and Latina women in Oakland are at significant risk of HIV infection. According to the Oakland TGA Comprehensive HIV Service Plan, women comprise 19% of people living with HIV/AIDS- higher than in any major metropolitan area in the western US; with 64.9% being African American and 13.1% Latina. PrEP can reduce the risk of HIV by almost 90% among HIV discordant heterosexual couples.
While studies show using PrEP properly can reduce the risk of HIV transmission, uptake has been slow. •At the 2014 HIV and Drug Therapy Congress in Glasgow, community level data collection was recommended as a means to integrate PrEP into HIV prevention messaging and service.
Description: CREW engages and empowers women in Oakland to better identify the opinions, motivators, and barriers to PrEP adoption by our community. Using Participatory Action Research (PAR), our research was based on what our constituency knows about their unique circumstances-rather than from external research. WORLD trained 25 women to become Peer Researchers during a 1.5 day training which included information on PAR, the power of research in policy & advocacy, and how to ethically conduct research in the community setting.
Of the 25 women who graduated from the training, 17 went on to interview women. Data from 503 women were collected using a 12 page interview tool with self-identified women, age 18 or over.
Lessons learned: 21% of sample have heard of PrEP (n=105) Of those, 31% have never heard of PrEP for women
• Many know it's a pill taken orally & daily to prevent HIV but there are many misconceptions
• Confused PrEP with PEP
• For gay men only. 16% know where to access PrEP
• 12% have accessed PrEP •2% have a partner who uses PrEP
Conclusions/Next steps: Through the data we gathered, we were able to develop a tailored PrEP 101 fact sheet geared towards women. Our fact sheet address the concerns women have about PrEP and provides a guide for their own personal decision making regarding PrEP. The data was shared at a one day convening with over 70 attendees comprising of community members, researchers, physicians, policy makers, consumers, and social service providers.

WEPED586

Will male partners of adolescent girls and young women (AGYW) support their PrEP use? A comparative analysis of AGYW and male partners of AGYW views in Tanzania

N. Jani[1], N. Pilgrim[1], V. Saria[1], C. Kahabuka[2], N. Makyao[3], L. Apicella[1], J. Pulerwitz[1], S. Mathur[1]
[1]Population Council, HIV & AIDS Program, Washington, United States, [2]CSK Research Solutions, Dar es Salaam, Tanzania, United Republic of, [3]National AIDS Control Programme, Dar es Salaam, Tanzania, United Republic of

Background: Power differentials in AGYW's sexual relationships are a contributing factor to AGYW vulnerability to HIV. Although PrEP is a female-initiated HIV prevention method, AGYW's relationship contexts could potentially influence uptake and adherence to PrEP. We assessed male partners of AGYW's support of AGYW PrEP use in Tanzania via a qualitative comparative analysis of AGYW's and male partners of AGYW's views.
Methods: Twenty-four in-depth interviews (IDIs) and four focus group discussions (FGDs) were conducted with AGYW aged 15-24 residing in Dar Es Salaam and Mbeya. Sixteen IDIs were conducted with men aged 18 or older who were married to or in a relationship an AGYW. To acquaint participants with PrEP, a visual, standardized script of PrEP information was shared with them prior to IDIs and FGDs. AGYW and male partners were asked the same questions during their interviews, including perceptions of their partners' use of PrEP and reactions of their partners' to their PrEP use. Thematic content and constant comparative method analyses were used.
Results: Both AGYW and male partners agreed that most male partners would be willing to support PrEP use by AGYW partners. However, both expressed that male partner support would be dependent on his early inclusion in the decision-making process. This early inclusion, respondents noted would remove suspicion of infidelity and alleviate negative consequences associated with late or inadvertent-disclosure of PrEP use.
AGYW noted potential consequences associated with covert use of PrEP. Potential consequences included relationship dissolution, loss of financial support, and verbal and physical violence. Male partners however denied such potential extreme consequences associated with their partner's covert use of PrEP.

Male partners recommended engagement in PrEP initiatives targeted toward AGYW - including providing education to men on PrEP, equipping AGYW with skills educate their partners, couples counseling by providers, provision of PrEP for men, and community education and sensitization as strategies for gaining men's support of PrEP.
Conclusions: Engaging male partners may need to be an essential component to ensure AGYW's access and use of PrEP. Educating male partners about PrEP and engaging them in implementation activities should be part of PrEP roll-out strategies for AGYW.

WEPED587

Gender in biomedical HIV prevention trials in sub-Saharan Africa: A review of the issues and recommendations for gender transformative research

L. Lorenzetti, K. MacQueen, J. Tharaldson, N. Eley
FHI 360, Durham, United States

Background: Since the early 2000s, biomedical HIV prevention trials have embraced approaches emphasizing community engagement and social protection. Despite the importance of gender dynamics in influencing decisions to participate, use products, and be retained in a trial, gender considerations are not explicitly addressed in such research. Furthermore, given past controversies regarding biomedical trials with vulnerable populations, including female sex workers (FSW), there are arguments to adopt procedures that promote gender transformative practices. We conducted a systematic review of articles from 2001-2017 to analyze gender-related issues in biomedical HIV prevention trials and generate recommendations to make such trials gender transformative.
Methods: A search of eight databases and sourced bibliographies identified 4832 unique articles. Title, abstract, and full texts were reviewed, yielding 99 peer-reviewed publications of biomedical HIV prevention trials and associated social and behavioral research that included discussions relevant to gender-related themes. We examined gender-related themes for general trial populations and key groups: adolescent girls, FSW, pregnant women, men who have sex with men (MSM), and transgender women (TGW).
Results: We examined themes related to pregnancy, contraceptives, partner engagement and communication, decision-making, violence, stigma, and others. Pregnancy and birth control requirements were major themes; trials typically required participants to avoid pregnancy to remain on product. This was often at odds with gender norms and participants' family planning desires. Some women and gender minority participants experienced distrust, discrimination, or violence when partners or the community misunderstood the study or product's intent. Certain products were designed as women-controlled options, allowing for covert use if necessary; however, most women discussed product use and trial participation with partners to promote engagement, potentially transforming sexual decision-making norms. Some partners were not engaged due to inequitable gender attitudes or fear of abuse or abandonment. Gender themes for MSM and especially TGW were rarely addressed.
Conclusions: To make biomedical HIV prevention trials gender transformative, researchers should become competent in and responsive to gender norms affecting study populations; educate communities while promoting gender equitable attitudes; empower women to decide how to involve their support networks, if at all; and consider the needs of under-represented groups, such as TGW.

WEPED588

Internalized homonegativity decreases access to condoms among MSM in 10 countries of Eastern Europe and Central Asia

O. Shestakovskyi[1], M. Kasianchuk[2], A. Garner[3], S. Howell[3], V. Djuma[2], P. Sabelashvili[2]
[1]Independent Scholar, Kyiv, Ukraine, [2]Eurasian Coalition on Male Health, Tallinn, Estonia, [3]Hornet Gay Social Network, San Francisco, United States

Background: Condom distribution coverage should be increased among men having sex with men (MSM) in Eastern Europe and Central Asia (EECA) region. There is evidence that internalized homonegativity (negative attitudes on own same-sex attractions, IH) can be a significant predictor of a lower coverage. We test a link between IH and receiving free condoms in EECA countries that is for the first time in the region.
Methods: A cross-sectional online survey of MSM was conducted by Eurasian Coalition on Male Health (ECOM) from August 13 until October 2, 2017. Total sample includes 5775 respondents from 10 countries (Armenia, Azerbaijan, Belarus, Estonia, Georgia, Lithuania, Kazakhstan, Kyrgyzstan, Russia, and Ukraine). We used binary logistic regression to examine relationship between IH and condoms distribution coverage. Receiving free condoms in the last 6 months (22%) served a dependent variable.
A reversed 8-item Short Internalized Homonegativity Scale (SIHS) measured IH. As confounders, we employed country, residence (capital, other big city, small town/village), availability of a MSM-service NGO, sexual identity, "outness" of one's sexuality to the others, age, education, and cohabitation status.
Results: Reversed SIHS increase significantly associated with lower chances of receiving free condoms holding all confounding variables constant (OR:0.90 [CI:0.84-0.97] per one-unit change). Other significant effects include having an NGO available (7.83 [6.70-9.16]); living in Belarus (1.84 [1.39-2.44]), Kyrgyzstan (2.94 [1.89-4.57]) or Ukraine (2.55 [2.12-3.07]) vs. living in Russia; cohabitation with a female partner (0.46 [0.30-0.70]); being less "out" as an MSM (0.87 [0.81-0.93]); older age (0.987 [0.978-0.997] per year); living in a non-capital big (0.74 [0.63-0.88]) or small domicile (0.76 [0.59-0.98]) vs. living in a capital city; having below tertiary (1.30 [1.06-1.59]) or basic tertiary (1.31 [1.09-1.57]) vs. full tertiary education. In a similar logistic model on those who has an NGO available (N=1594, 55% received condoms) SIHS remained significant (OR:0.83 [CI:0.75-0.92]).
Conclusions: IH among MSM significantly diminishes their chances to be covered by condom distribution in EECA countries, even if a service NGO is available. Interventions against MSM self-stigmatization are needed to increase this prevention effect.

Approaches to scale and the optimisation of service delivery

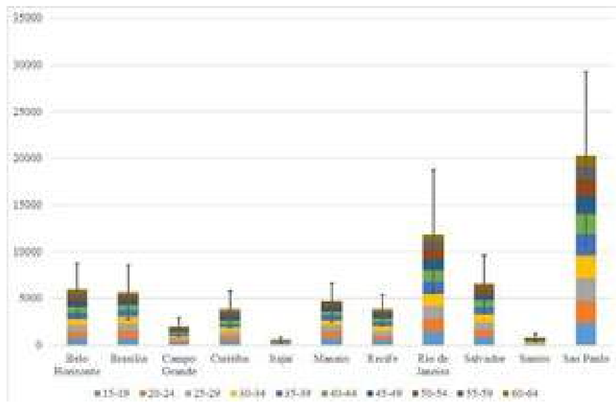
WEPEE589

PrEP adopted by the Brazilian National Health System: What is the size of the demand?

P. Luz[1], A. Benzaken[2], T. Alencar[2], C. Pimenta[2], V. Veloso[1], B. Grinsztejn[1]
[1]Oswaldo Cruz Foundation, National Instittute of Infectious DIseases, Rio de Janeiro, Brazil, [2]Ministry of Health, Department of Surveillance, Prevention and Control of STI, HIV/AIDS and Viral Hepatitis, Brasilia, Brazil

Background: Brazil's response to the HIV epidemic now includes free access to pre-exposure prophylaxis (PrEP) to populations at substantial risk for HIV infection including men who have sex with men (MSM). We used nationally representative demographic, epidemiologic and surveillance data to offer estimates for the number of MSM at substantial risk for HIV infection who might be eligible and willing to use PrEP in Brazil.
Methods: Starting from the age/sex-stratified population, we calculated the number of men aged 15-64 years, in 5-years age groups, and the proportion of those who report sex with other men during their lifetime.

We focused on 11 cities (representing all regions) that are responsible for a significant fraction of the HIV burden of the country and used city-specific HIV-prevalence estimates to infer the fraction of MSM that is HIV negative. We then derived the proportion of HIV-negative MSM under substantial risk for HIV infection defined as having unprotected receptive anal intercourse in the six months prior to study participation. Finally, PrEP uptake among the eligible was inferred from the PrEP Brasil study.
Results: Our results show that PrEP demand in these 11 cities is of 66,120 men aged 15-64 years. When we consider the lower and upper bounds for the available parameters, we find that PrEP demand in these 11 cities might vary from 33,378 to 97,962 men. If PrEP is restricted to those aged 15-49 years, demand drops by 20%. PrEP demand varies considerably by city, mostly due to the differences in population size and city-specific HIV prevalence (Figure).
Conclusions: We have shed light on the probable size of PrEP demand in Brazil certain that the incorporation of PrEP as part of Brazil's combination prevention for populations at substantial risk for HIV infection is a necessary challenge. PrEP will not only prevent HIV infections, it will also expand testing among the most vulnerable with the added benefit of offering combination prevention for the uninfected and immediate treatment for those already infected. As such, expected added benefits of PrEP will be earlier linkage to care, prompt treatment initiation leading to health benefits and decreased transmission.



[Figure. Estimated pre-exposure prophylaxis demand by city and age group.]

WEPEE590

Experience of reaching hard-to-reach people who inject drugs through field mentors with HIV prevention and treatment services in northeastern states of India

S. Mathew, B. George, P. Goswami, A. Singh, N. Bakshi, K. Ditya, T. Jamir, N. Roshan, R. Khiangte
FHI 360, New Delhi, India

Background: Reaching people who inject drugs (PWID) with comprehensive HIV prevention services is challenging. Only 65% of PWID in India report ever having been tested for HIV. Field mentors selected from the PWID community implemented innovative strategies for PWID who are unreached and hard-to-reach through government-supported targeted interventions (TI).
Description: Field mentors were placed in 12 priority districts under Project Sunrise, funded by President's Emergency Plan for AIDS Relief (PEPFAR) in the northeast states of India. Strategies implemented through mentors included:
(a) Secondary distribution of needle and syringe (SDNS) for unreached PWID;
(b) Community-based Index case testing for HIV;
(c) Tracking of clients lost to follow-up from opioid substitution therapy (OST) and ART services;
(d) Accompanied referral for HIV positive PWID to ART services;
(e) Registering new, more vulnerable and young PWID through non-incentivized snow balling approach;
(f) Organising testing camps beyond the coverage areas of targeted interventions;
(g) Facilitating new OST enrolments through client motivation and support group meetings; and
(h) Collecting and consolidating feedback from the PWID and refining program approaches.
Lessons learned: A total of 28 mentors were trained. Of the estimated 2,039 unreached and hard-to-reach PWID in the districts, mentors distributed clean needles and syringes to 373 hard-to-reach PWID through SDNS. Through community based index testing 383 unreached PWID were identified, 238 PWID were contacted and 211 PWID were tested for HIV and 23 (10.9%) were confirmed HIV positive and initiated ART. Of the 931 PWID who were tested through camp approach, 444 PWID who were not registered with TI were having higher positivity (5%) compared to those registered with TI (2%). Around 303 PWID were navigated to the ART centres and initiated on ART. Mentors enrolled 1,229 new OST clients, increasing OST coverage from 2,611 to 3,840 clients from April to September 2017.
Conclusions/Next steps: The mentoring model has improved access to HIV prevention and treatment services altogether for 1,200 unreached and hard-to-reach PWID. The National AIDS Control Program is replicating and scaling up the mentor model in its targeted intervention programs for key populations.

WEPEE591

Integration of community and facility care across the continuum to improve pediatric ART enrolment and retention: Lessons learned from Munhava Health Centre, Beira-Mozambique

B. Rato[1], V. Macome[2], J. Fernando[2], N. Juma[2], G. Garfo[1]
[1]Family Health International FHI 360, CHASS, Beira, Mozambique, [2]Family Health International FHI 360, CHASS, Maputo, Mozambique

Background: ART initiation for children exposed to HIV is a challenge. In Beira City in Mozambique, in 2015 just 50% of HIV infected children were enrolled in care and only 70% of those were retained in treatment after 12 months. The reasons include long turnaround time for PCR early infant diagnosis (EID) results and poor linkage of high risk children into ART services due to limited psychosocial support and adherence counselling and the absence of paired consultation for mother and baby. Innovative interventions involving community support and reorganization were piloted by the Clinical and Community HIV and AIDS Services Strengthening (CHASS) project to improve enrollment and retention.
Description: Between November 2015 and April 2016, CHASS worked with facility staff at Munhava health center to improve these linkages by introducing a point of care (POC) machine for EID in the consultation room for children at high risk, reallocated staff to provide pediatric ART, and assigning a community case manager to follow defaulters and strengthen psychological support. Regular supervision and mentoring supported these innovations. Routine clinic data were collected from patient registers and clinical files from of exposed and infected children. Retention rates were tracked for six months. Results following the introduction of the intervention were compared to those in the 6 months prior to the intervention.
Lessons learned: In the 6 months prior to the intervention 282 exposed children were enrolled versus 352 in the 6 months post intervention. The percent of children tested for PCR EID increased from 73% to 100% and positivity increased from 4 percent to 7.9 percent. Enrollment in care increased from 84% to 100% and 6-month retention from 79% to 95%.
Conclusions/Next steps: Simple reorganization in the high risk consultation room for children in combination with integrating testing services and providing a community case manager for immediate identification for follow up and psychosocial support can improve enrollment and retention without substantial additional effort or resources. Given the simplicity of the interventions and positive feedback from clinical and managerial staff, this approach can be easily scaled up in similar health facilities in the country.

WEPEE592

Acceptability and feasibility of promoting HIV testing to sexual partners using self-testing among HIV-positive men who have sex with men in Guangzhou, China

H. Xu[1], W. Cheng[1], W. Jin[2], Y. Gu[1], F. Zhong[1]
[1]Guangzhou Center for Disease Control and Prevention, Guangzhou, China, [2]China Southern Airlines Henan Airlines Co. Ltd., Zhengzhou, China

Background: HIV testing of sexual partners (SPs) of HIV-positive men who have sex with men (MSM) has always been a significant challenge. Owing to the convenience and privacy, HIV self-testing (HIVST) has become increasingly acceptable. But it is unclear whether HIVST could enhance the uptake of testing among SPs of HIV-positive MSM. Therefore, the current study aimed to evaluate the attitude and the influencing factors about promoting HIVST to SPs among HIV-positive MSM in Guangzhou, China.

Methods: Participants were recruited at the HIV voluntary counseling and testing (VCT) clinic of Guangzhou Center for Disease Control and Prevention between April and December 2016. Attitude and the associated information were collected by electronic-questionnaire and analyzed using logistic regression.

Results: 340 HIV-positive MSM were included in the study, with the median age of 28 (18~52). 76.8% (261/340) participants would recommend HIVST to SPs for HIV testing. The proportion of participants who had anal intercourse with regular SPs and casual SPs within the past 6 months were 81.5% (145/178) and 70.3% (104/148), respectively. The willingness to promote testing to regular SPs by HIVST was higher for participants who got diagnosis less than 6 months (aOR: 3.50, 95%CI: 1.09~11.28), once notified the regular SPs for the past 6 months (aOR: 2.37, 95%CI: 1.06~5.29), with self-experience (aOR: 2.84, 95%CI: 1.02~7.92) or experience from friends (aOR: 2.72, 95%CI: 1.16~6.38) about HIVST. Regarded HIVST as non-inferior to VCT (aOR: 6.56, 95%CI: 1.36~31.61), got diagnosis less than 6 months (aOR: 3.80, 95%CI: 1.31~11.01) and once notified the casual SPs for the past 6 months (aOR: 2.93, 95%CI: 1.32~6.46) may be the associated factors for recommending HIVST to casual SPs. Among participants that finished the questionnaire at VCT and preferred to bring HIVST to SPs by themselves, 46.7% (7/15) really took the HIVST kits.

Conclusions: Positive attitude about promoting HIVST to SPs for HIV testing was found among HIV-positive MSM in Guangzhou, China. Enhancing the perception of HIVST, strengthening the consciousness of partner notification and to mobilize SP testing as early as possible after diagnosis of HIV infection, would be the crucial factors for the actual implementation. Anyway, a feasible operation mode is needed.

WEPEE593

Scale-up of a passive referral model of HIV Index case testing to accelerate case identification in Mangochi, Malawi

T. Tembo[1], K. Simon[1,2], S. Ahmed[1,2], T. Beyene[1,2], E. Wetzel[1], A. Kabwinja[1], W. Kammera[1], H. Chibowa[3], B. Chavula[1], Z. Nkhono[1], E. Kavuta[1], P. Kazembe[1,2], M. Kim[1,2]
[1]Baylor College of Medicine Children's Foundation Malawi, Lilongwe, Malawi, [2]Baylor College of Medicine International Pediatric AIDS Initiative, Houston, United States, [3]Malawi Ministry of Health, Lilongwe, Malawi

Background: Timely identification of people living with HIV (PLHIV) is a critical first step towards the elimination of HIV/AIDs. Index case testing (ICT) can be a high yield strategy to identify PLHIV. Malawi's national HIV Testing Services (HTS) guidelines recommend ICT through passive referral using family referral slips (FRS). However, only 40% of newly diagnosed PLHIV received FRS in the last quarter of 2016. We describe the scale up of ICT via passive referral and its impact on HIV case identification in Mangochi, Malawi (estimated HIV prevalence 10.1%).

Methods: A total of 753 HTS and antiretroviral therapy (ART) providers from 33 health facilities supported by the Tingathe Program in Mangochi district, received a 2-hour on-site training on ICT and how to issue FRS to clients from May-June 2017. "Index cases" defined as clients either newly diagnosed with HIV or known to be HIV-infected and on ART were educated on the importance of ICT. Those who consented to index testing were given a FRS for each household contact with unknown HIV status. FRS contained information inviting the individual to the facility for family health education. We conducted a descriptive analysis of routinely collected program data from these facilities to examine the number of index cases screened as well as the proportion of and yield amongst contacts tested over a 6-month period post-training.

Results: Between June-November 2017, 4177 index clients were screened. There were 7956 FRS issued; a 50% increase from the 4028 issued from December 2016 to May 2017. Of the FRS issued, 1315 (17%) were for sexual partners and 6641 (83%) for children. There were 1035 (13%) contacts who reported for HTS; 159 tested HIV-positive (15.4% yield). Among those returning for HTS, 228 (22%) were sexual partners, 745 (72%) children and 62 (6%) guardians. Of sexual partners tested, 135 (59%) were male.

Conclusions: Facility-based ICT through passive referral using FRS is scalable with a brief targeted training. Further, it is a high-yield strategy for identifying PLHIV. To optimize the impact of this intervention on case identification, additional efforts are needed to increase the proportion of contacts reporting for HTS.

WEPEE594

Piloting community-based saliva testing increases coverage of key populations in Armenia

S. Orbelyan, Y. Amirkhanyan, N. Kostanyan
Mission East Armenia, Mission East GFATM NGO PR Unit, Yerevan, Armenia

Background: The National Programme on the Response to the HIV Epidemic in Armenia for 2017-2021 adopted United Nations' 90-90-90 targets. Among the challenges for reaching these targets is new case detection among key populations (KP). Within Global Fund to fight AIDS, TB and Malaria (GFATM) HIV grants for the last 5 years testing among KPs is done with HIV rapid blood tests. The current legislation permits HIV blood testing only within licensed laboratories, which limits testing coverage particularly among hard-to-reach KPs. To mitigate this challenge community testing with saliva tests for KPs was introduced in August, 2017.

Description: Six-months pilot project in capital city Yerevan envisaged testing of KPs (MSM, PWIDs, CSWs) with "OraQuick HIV-½" tests procured with GFATM support in August 2017-January 2018. The project was aimed to increase the uptake of testing services among KPs. Outreach workers working with KPs underwent a 3-day training on tests application and counseling at the National Center for AIDS Prevention (NCAP). Beneficiaries were tested either at the implementing NGO premises or in the field. Testing and pre- and posttest counseling were provided on 24/7 basis. Positive feedback was received from implementers and beneficiaries during monitoring visits.

Lessons learned: During the pilot 1388 beneficiaries were tested in all KP groups. Overall, 17 HIV-positive cases were detected with further linkage to NCAP for care (8 cases detected within health care settings during the previous semester). Virtually all cases (16) were new beneficiaries. The results of the project suggest that a) application of saliva tests at the community level allowed reaching primarily beneficiaries, who avoid testing within health care settings due to stigma and discrimination; b) provision of testing unbounded to regular day-time working hours was another advantage for testing expansion.

Conclusions/Next steps: The pilot project proved that community-based saliva testing attracts new hard-to-reach beneficiaries into prevention projects. The project results and positive feedback from the KP communities shaped country consensus on future testing approach in Armenia. Scale-up of community-based testing with saliva tests was considered by country stakeholders as a measure to alleviate low case detection among KPs in Armenia in the GFATM proposal development process.

WEPEE595

Distance learning course about rapid test for healthcare professionals as an strategy to increase the access to HIV diagnosis in Brazil

P.C. Gaspar[1], R.A. Comparini[1], A.F. Pires[1,2], J.B. Alonso Neto[1], M.V. Martins[1], D.C. Soares[1], L.M.B.B. Parucker[3], A.S. Benzaken[1]
[1]Ministry of Health of Brazil, Department of Surveillance, Prevention and Control of Sexually Transmitted Infections, HIV/AIDS and Viral Hepatitis, Brasília, Brazil, [2]University of Brasilia, Postgraduate Program in Collective Health, Brasília, Brazil, [3]Federal University of Santa Catarina, Department of Clinical Analysis, Florianópolis, Brazil

Background: Increasing the population´s access to HIV diagnosis, especially with the use of rapid tests (RT), is a key strategy of the Brazilian Ministry of Health (MoH) to reach the 90-90-90 target by 2020. Only in 2017, MoH distributed more than 12 million RT, 23 times more than in 2005 (509,180 tests), when they were adopted as public health policy. In addition, it is also necessary to increase the number of healthcare professionals capable to perform the RT. Considering the continental dimension of the country, with 5570 cities, and the need for an alternative to on-site trainings, MoH offers a free distance learning course called TELELAB. We present the extent of the coverage of this education strategy.

Methods: TELELAB provides online courses about diagnostic of sexually transmitted infection with video lessons and instruction manuals. For places with difficult internet access, it is also possible to request and receive all TELELAB contents on a DVD by post office. After the course is completed, professionals are awarded a certificate once they pass an exam with 70% or higher. We conducted a descriptive analysis using Excel regarding the healthcare professionals who obtained certification in "HIV diagnosis course" during 2017.

Results: In 2017, 14,278 healthcare professionals were certified (61% more than 2016; and 322% more and 2015) (Figure 1). Nurses are the highest number of certification (i.e. 61% of the total). 1,943 different municipalities were observed. Out of this, 10,264 healthcare professionals (i.e. 72% of the total) reside out of capital, and many of them in remote and rural areas with no access to laboratory services.

Conclusions: TELELAB turned out to be an important strategy to ensure greater access to HIV diagnosis, since it better qualifies healthcare professionals, especially nurses, which are present in major primary healthcare services in Brazil. In addition, because more professionals are qualified, it became possible to increase the number of RT distributed annually by MoH. Considering we still need to expand TELELAB use countrywide, in 2018 TELELAB will be available as cell phones application, consisting a new alternative to encourage even more the professional continuing education.

[Figure 1. Number of healthcare professionals certified at HIV diagnosis course per year (2013-2017).]

WEPEE596

Estimating health workforce requirements for achieving the UNAIDS 90-90-90 targets in three regions of Ukraine and developing strategies to address projected gaps

A. Latypov[1], Y. Sereda[2], S. Belyakov[1], O. Danylenko[3], N. Ryzhenko[4], O. Chernenko[5]
[1]Deloitte Consulting LLP, The USAID HIV Reform in Action Project, Kyiv, Ukraine, [2]Independent Consultant, Kyiv, Ukraine, [3]Poltava Regional AIDS Center, Poltava, Ukraine, [4]Kherson Regional AIDS Center, Kherson, Ukraine, [5]Mykolayiv Regional Center of Palliative Care and Integrated Services, Mykolayiv, Ukraine

Background: Health workforce is a key resource required for a major scale-up of HIV testing, treatment and care services in Ukraine. We aimed to estimate the needs in human resources for health (HRH) for achieving the UNAIDS 90-90-90 targets in three regions of Ukraine representing medium (Poltava and Kherson) and high (Mykolayiv) HIV burden oblasts.

Methods: Study design included five steps for estimating HRH for HIV requirements for the period up to 2020:

(1) defining HIV service package components and annual frequencies of service provision per person;

(2) chronometric study of time spent on each service component and proportion of services provided by different groups of health cadres (observation of 154 health workers at 59 facilities during 5 days; 44,735 cases of service provision measured);

(3) predicting targets using Box-Jenkins models for service coverage for two scenarios: continuation of on-going trends and achieving the UNAIDS 90-90-90 targets;

(4) measuring HRH for HIV requirements in full-time equivalents (FTE) based on chronometric data and coverage targets;

(5) estimating gaps.

Results: In Poltava region, the availability of HRH for delivery of HIV services was estimated as 122.0 FTE, while HRH for HIV availability was lower in Kherson (78.6 FTE) and Mykolayiv (84.0 FTE) regions. To achieve 90-90-90 targets by 2020 and ensure major scale-up of opioid substitution therapy (40% coverage of people who inject opioids), the required HRH would be 100.8 FTE (95% CI: 87.6-113.9) in Poltava, 144.9 FTE (95% CI: 125.4-164.4) in Kherson, and 256.7 FTE (95% CI: 224.4-288.9) in Mykolayiv regions. In all regions, projected needs for physicians and psychologists/social workers were much greater than for nurses.

Conclusions: To address projected gaps in HRH for HIV for achieving the UNAIDS targets (Kherson and Mykolayiv regions), regional authorities need to implement rapid decentralization strategies. Health service delivery standards need to be reviewed/adopted and enforced to address potential inefficiencies. As supply of new cadres might be limited, task-shifting options from specialized providers to primary healthcare practitioners and nurses with shorter training and fewer qualifications must be fully embraced, including through legislative amendments and provision of required training for those who assume new HIV tasks.

WEPEE597

Reaching more men with HIV testing through PMTCT program in Southern regions of Tanzania

J. Gamaliel[1], C. Mbelwa[1], B. Christian[2], H. Haule[3], A. Ikonje[3], M. Njozi[3], J. Bisimba[4], E. Okechukwu[1], M. Njelekela[3]
[1]Family Health International (FHI 360), USAID Boresha Afya Southern Zone, Dar es Salaam, Tanzania, United Republic of, [2]Management and Development for Health, USAID Boresha Afya, Dar es Salaam, Tanzania, United Republic of, [3]Deloitte Consulting Limited, USAID Boresha Afya Southern Zone, Dar es Salaam, Tanzania, United Republic of, [4]United States Agency for International Development, Health, Dar es Salaam, Tanzania, United Republic of

Background: With the global adoption of the 90-90-90 HIV epidemic control strategy, the first 90 is very crucial and an entry point into the cascade. In Sub Sahara Africa, most of the clients receiving HIV care are women and reaching men has been a challenge. Male partner testing using the Ante Natal Clinic (ANC) platform has been one of the ap-

proaches that could improve access to HIV testing for men. We evaluated the effect of PMTCT program in influencing male partner's testing in facilities supported by USAID funded projects; the former (TUNAJALI II 2012-2017) and follow on (USAID Boresha Afya 2016-2021) in Morogoro, Iringa and Njombe, Tanzania.

Description: The National PMTCT program and PEPFAR through USAID in 2013 and subsequent years supported roll out of PMTCT Option B+ to scale up ART services among pregnant and breastfeeding women. This was preceded by awareness campaigns encouraging women to come with their male partners for ANC services. The healthcare providers were trained and oriented on couple counseling and pregnant women who came with their male partners were prioritized. Monthly supervision and mentorships were conducted by trained mentors and program staff to improve quality of data and services.

Annual PMTCT program data (October 2013-September 2017) from 653 supported health facilities from Morogoro, Iringa and Njombe regions were extracted from DHIS2 into excel and analyzed using STATA. Comparison of proportion of male HIV testing yearly with respect to women attended ANC was conducted.

Lessons learned: A total of 636,440 pregnant women attended ANC services, 545,429 (86%) were tested for HIV and 4% were HIV positive. Over the period 275,349 male partners had attended for HIV testing and positivity was 3%. Increasing proportion of male partner (31%, 40%, 47% and 53%) brought by their female partners over the period was 22% (p< 0.001). The increase was gradual with more men testing in each subsequent year.

Conclusions/Next steps: ANC clinic has the potential as the platform for reaching men with healthcare services especially for HIV testing. This entry point for optimizing HIV testing to reach more men should be emphasized as one of the approaches toward achieving the first 90.

WEPEE598

Mobile health and behavioral PMTCT intervention among community health workers improves exclusive breastfeeding and early infant diagnosis in India: A cluster randomized trial

[1]Lakshya, a Society for Public Health Education and Research, Pune, India, [2]National AIDS Control Organisation, New Delhi, India, [3]Centers for Disease Control and Prevention, Division of Global HIV and TB, New Delhi, India, [4]Johns Hopkins University, Center for Clinical Global Health Education,School of Medicine, Baltimore, United States, [5]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States

Background: During the roll out of Option B+ prevention of HIV mother-to-child transmission (PMTCT) services in India, we assessed a strategic, integrated mobile health and behavioral intervention that aimed to enhance the capacity of community outreach workers (ORW) in the national program, to optimize PMTCT services uptake.

Methods: From April 2015-March 2017, a cluster randomized trial was conducted in four districts of Maharashtra, India. Integrated counselling and testing centers (n=119), their ORWs (n=124) and their assigned HIV+ pregnant/ breastfeeding women (n=1191) were randomized to standard of care (SOC) vs. COMmunity Home Based INDia (COMBIND) PMTCT intervention (Figure 1) that had 4 strategies: 1) Specialized ORW interactive motivational counseling training; 2) Strategic feedback to ORWs; 3) Targeted feedback to HIV+ women; and 4) Use of an mhealth platform (eMOCHA) to facilitate communication with ORWs and women using educational videos and smart form-based counselling scripts. To account for multilevel structure of the data and to assess the effect of COMBIND intervention on study endpoints (Table 1) univariable and multivariable random-effects logistic regression model with random effect for districts and ORWs was used.

Results: Of 884 eligible for outcome assessment, 487 women assigned to 60 ORWs were cluster randomized to COMBIND arm, and 397 women (56 ORWs) were assigned to SOC arm. Median age was 25 (IQR, 22-28) years; median CD4 count was 420 (IQR, 248-587) cells/ml. HIV+ women in COMBIND arm showed increased uptake of exclusive breastfeeding (EBF) at 2 months (aOR, 2.10; 95% CI 1.06-4.15), and early infant diagnosis (EID) at 6 weeks (aOR, 2.19; 95% CI 1.05-3.98). We also found a trend towards higher uptake of EBF at 6 months (aOR, 1.74, 95% CI 0.95-3.16), and EID at 6 months (aOR, 1.54, 95% CI 0.94-2.51) (Table 1).

Conclusions: While uptake of key PMTCT services were high in both COMBIND and SOC arms, uptake of EBF and EID among HIV+ pregnant/ breastfeeding women was 2-fold higher in the COMBIND arm compared to the SOC arm. Our study provides evidence that a scalable mHealth strategy supporting strategic motivation and education of ORWs and HIV+ pregnant women can improve implementation of key components of PMTCT services.

Study Endpoints (Eligible participants)	COMBIND arm endpoints Achieved / Eligible N (%)	SOC arm endpoints Achieved/ Eligible N (%)	Unadjusted Odds Ratio (95% CI), p-value	Adjusted* Odds Ratio (95% CI), p-value

WEPEE599

Difference-in-difference estimate of effect of PEPFAR human resources for health investments on HIV treatment results, fiscal year 2016-2017

T. Lim[1], P. Hosseini[2], D. Frymus[3], V. Vasireddy[2], A. Hurst[3], C. McKinney[1]
[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV & Tuberculosis, Atlanta, United States, [2]U.S. Department of State, Office of the U.S. Global AIDS Coordinator, Washington, United States, [3]United States Agency for International Development, Office of HIV/AIDS, Washington, United States

Background: In order to accelerate the global fight against HIV and achieve the UNAIDS 95-95-95 fast track targets, PEPFAR supports human resources for health (HRH) who provide HIV prevention, care and treatment services directly to patients in most long term strategy countries. The effect of increasing support for HRH on HIV treatment programs has not been estimated globally; PEPFAR is the largest bilateral funder of global HIV programs.

Methods: Our units of analysis were geographic subnational units ("SNU", such as districts) nested in countries where PEPFAR programs directly support both HRH and HIV treatment. PEPFAR implementing partners report annually on the full-time equivalent (FTE) person-time that PEPFAR compensates for HIV services, as well as total patients on antiretroviral therapy (ART). HRH FTE was a zero-inflated non-normal variable that we split into quartiles for modeling. We fit a mixed effects negative binomial model in Stata 14 for total patients currently on ART, as a function of fiscal year, overall quartile of PEFPAR-supported HRH FTE, and SNU treatment prioritization level. To reduce selection bias and unobserved confounding, we further estimated a difference-in-difference (DID) effect as the interaction term between year and HRH FTE quartile. We modeled a random intercept for country.

Results: 1,618 SNUs across 19 countries were included in our model. Higher PEPFAR support of HRH was associated with higher total ART patients. Moreover, the DID coefficients showed that the highest relative net increase in ART patients between FY16 and FY17 were in SNUs with the third and fourth highest quartile of PEPFAR HRH support (1.52 times [95% CI: 1.06 - 2.17] and 1.43 times [95% CI: 1.01 - 2.03] higher than first quartile, respectively, Table 1a). This association is similar when looking only at clinical cadres (Table 1b); but is not statistically significant when looking only at lay cadres.

Conclusions: DID estimation suggests that higher levels of PEPFAR support for HRH facilitated a higher net increase of patients on ART over time, and clinical HRH, rather than lay workers, may be most responsible. Lack of global subnational confounder data, including total HRH not supported by PEPFAR, is a limitation to address in further analysis.

Trend analysis of HIV/TB integrated services utilization and coverage in Uganda Harm Reduction Referral Points in Kampala, Gulu, Mbarara and Mbale

W.T. Lotic[1,2,3], E. Muhwezi[4], C. Baguma[5], S. Ajuna[5]
[1]Uganda Harm Reduction Network, Health and Human Rights, Kampala, Uganda, [2]International Drug Police Consortium, Network Member, London, United Kingdom, [3]Eastern Africa Harm Reduction Network, Network Member, Kampala, Uganda, [4]Uganda Harm Reduction Network, Kampala, Uganda, [5]Uganda Harm Reduction Network, Programs, Kampala, Uganda

Background: TB and HIV co- infection places patients at sharply increased risks of mortality and morbidity. Strengthening access to TB/HIV co- infected patients with needed ART and TB treatment and monitoring is a priority to health service partners. Through implementation of the HIV and Harm Reduction Project in Uganda, a Global Fund-funded project started in 2016. Most at Risk Population Initiative (MARPI)-Mulago through its regional branches has been providing health services or act as Drop in centres for People who use and inject drugs.

Methods: Using routine aggregate HIV/TB program data, an observational, one year trend analysis was conducted in January 2017. Quarterly health facility TB/HIV reports were the data sources. TB/HIV integrated services indicators analysed included: number of TB registered cases, percentage of TB cases tested for HIV, HIV positivity rate among TB patients, percentage of TB cases who were started on cotrimoxazole prophylaxis, and percentage of TB/HIV co-infected started on ART.

Results: From January 2016 to December 2016, the number of TB registered cases varied between 350 and 700 per quarter. The analysis revealed an increasing trend in HIV test coverage in TB registered patients (from 41% in the first quarter of 2016 to 70% in December 2016); a similar pattern was observed in cotrimoxazole prophylaxis initiation (53% to 90% in the same period).

Conclusions: Although this trend analysis has limitations to establish causation, the implementation of HIV and Harm Reduction Project in 4 districts of Uganda and the expansion of ART services with integrated TB services for Drug users has contributed to a scale-up in TB/HIV services utilization in other referral MARPI points in other districts. HIV patients have obtained growing access to TB services over time and TB/HIV co-infected patients are being identified and are more widely accessing ART, which will undoubtedly have a positive impact on health outcomes.

WEPEE601

Optimizing HIV case finding and linkage to care and treatment among adolescents in western Kenya through a comprehensive case finding intervention package

J. Kose-Otieno[1,2], A. Tiam[2,3], B. Ochuka[1], E. Okoth[1], J. Sunguti[1], M. Waweru[1], E. Mwangi[1], T. Wolters[2], N. Rakhmanina[2,4,5]
[1]Elizabeth Glaser Pediatric Aids Foundation, Programs and Research, Nairobi, Kenya, [2]Elizabeth Glaser Pediatric Aids Foundation, Medical and Scientific Affairs, Washington DC, United States, [3]University of Bergen, Bergen, Norway, [4]George Washington University, Washington DC, United States, [5]Children's National Medical Centre, Washington DC, United States

Background: Low HIV testing uptake among adolescents affects identification of HIV-positive adolescents and their effective linkage to care and treatment services. To address this gap, an innovative package was implemented to improve HIV testing uptake and linkage to care among adolescents aged 10-19 years in Western Kenya.

Methods: This quasi-experimental study used program data at pre- and post-intervention periods to describe effects of an innovative adolescent package at 139 health care facilities (HCFs). The study population was adolescents aged 10-19 years divided into early- and late-age cohorts (10-14 years and 15-19 years). Three types of HCFs were included: hospitals, health centers, and dispensaries. The innovative adolescent package included staff capacity building, program performance monitoring tools, an adolescent-focused HIV risk screening tool and adolescent-friendly HCF hours. Implementation began in July 2016. Data collected included numbers of adolescents tested for HIV, tested HIV-positive,

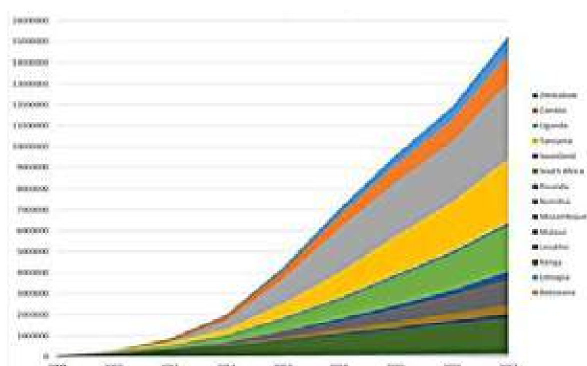
and were linked to care services. Data were analyzed with descriptive statistics. Pre- and post-intervention demographic and testing data were compared using the Poisson mean test, while Chi-square testing was used to compare the linkage to care rates.
Results: Pre-intervention data were collected from January to March 2016, and post-intervention data collected from January to March 2017. During the pre-intervention period, 25,520 adolescents were tested and 198 were HIV-positive (0.8%) compared to 77,644 adolescents tested with 534 being HIV-positive (0.7%) during the post-intervention period (Seroprevalence was unchanged but p< 0.001 - for absolute numbers tested and testing positive). HIV positivity was highest in TB clinics followed by maternal and child health and in-patient clinics. The HIV positivity was also high in nutrition clinics among younger adolescents. The proportion of HIV-positive adolescents linked to care increased from 61.6% to 94.0% (p< 0.001). This increase was seen for both males and females, both early and late adolescent cohorts, and in all HCF types (all p-values < 0.001).
Conclusions: Implementation of the adolescent service package in western Kenya improved new HIV case identification and linkage to treatment services among adolescents aged 10- 19 years. The package addressed factors associated with increased testing such as staff training, program performance monitoring and provision of adolescent-friendly HCF hours.

WEPEE602

Making the impossible possible: Progress in scale-up of voluntary medical male circumcision for HIV prevention supported by the United States President's emergency plan for AIDS relief through 2017

C. Toledo[1], S. Davis[2], J. Hines[2], M. Habel[2], L. Hinkle[2], K. Izenour[2], A. Thomas[3], V. Kiggundu[4], C. Cooney[5], D.H. Watt[5]
[1]US Centers for Disease Control and Prevention (CDC), Atlanta, United States, [2]US CDC, Atlanta, United States, [3]DoD HIV/AIDS Prevention Program, Defense Health Agency, US Department of Defense, San Diego, United States, [4]USAID, Washington, DC, United States, [5]Office of the U.S. Global AIDS Coordinator and Health Diplomacy, US Department of State, Washington, DC, United States

Background: Voluntary medical male circumcision (VMMC), which offers men with lifelong partial protection from HIV and other sexually transmitted infections (STIs), has become a cornerstone of the global HIV prevention portfolio through support by national and global programs, such as PEPFAR. VMMC was introduced in 14 southern and eastern African countries, which scaled-up services progressively between 2007 and 2011. Since then, the PEPFAR program has experienced rapid growth and is contributing to epidemic control in these countries.
Description: All PEPFAR-supported programs report key metrics, including total VMMCs performed and disaggregations of client age range, technique, HIV test results, and post-operative follow-up. These indicators provide an overview of accomplishments and key characteristics of the program.
Lessons learned: From 2007 through 2017, 15.2 million VMMCs were performed with PEPFAR support (Figure 1); representing over 80% of global procedures performed. 2010-2014, annual performance approximately doubled each year. After temporarily slowing of performance during 2015-2016, 2017 represented the highest single year of VMMCs performed since program inception, contributing nearly one-fourth (22%) of all PEPFAR-supported circumcisions performed to date.
In 2017, 48% of VMMC clients were between the ages of 15-29 years, a priority age group for immediate impact on HIV incidence. Over twenty-four thousand clients tested positive for HIV at VMMC sites. Device-based techniques constituted a minority of circumcisions, except in Rwanda where they dominated (53%). Post-operative follow-up rates were over 80% overall, ranging from between 60% in South Africa to 100% in Rwanda.
Conclusions/Next steps: VMMC has undergone an historic scale-up within global health, enabled by dedicated resources, targets setting, leadership, rapid expansion of surgical skills and responsibilities to non-physicians, and public outreach campaigns. Models estimate that the VMMCs conducted through 2016 will avert at least 500,000 infections by the end of 2030. VMMC has also helped prevent HIV and STIs among women. The PEPFAR program's achievements demonstrate the feasibility of rapid expansion of circumcision, but global strategy must continue evolving to maximize impact, achieve revised UNAIDS targets including circumcising 27 million men during 2016-2020, maintain safety, and meet broader UNAIDS and PEPFAR objectives.



[Cumulative Number of PEPFAR-Supported Voluntary Medical Male Circumcisions by Country, 2009-2017]

WEPEE603

Can a short-haul specimen referral system work efficiently to access "point-of-care" early infant diagnosis testing? Lessons from Lesotho and Zimbabwe

T. Samosamo[1,2], H.W. Mafaune[2,3], A. Mataka[1], A. Chadambuka[3], J.-F. Lemaire[4], UNITAID EGPAF POC EID Group
[1]EGPAF Lesotho, Maseru, Lesotho, [2]Authors Contributed Equally, -, United States, [3]EGPAF Zimbabwe, Harare, Zimbabwe, [4]EGPAF, Innovation and Technical Leadership, Geneva, Switzerland

Background: Specimen referral systems can increase access to diagnostic services but are also vulnerable to logistical and system efficiency challenges. An efficient specimen referral over short distances (< 1 hour) was adopted to increase access to point-of-care (POC) early infant diagnosis (EID). We compared key clinical and service delivery outcomes observed within testing facilities (POC model) to those within referring facilities (referral model), in Lesotho and Zimbabwe.
Methods: We used data from POC EID testing forms routinely used across all 109 facilities (27 testing facilities; 82 referring facilities) having access to POC EID from February to October 2017 across Lesotho and Zimbabwe combined. Key POC EID clinical outcomes (percentage of results returned to caregivers at facility and percentage of HIV-infected infants initiated on treatment) and key service delivery outcomes, including intermediate turnaround times (TAT) (between specimen collection, transport, processing, result transmission facility, and return to caregiver) and total TAT (from specimen collection to result return to caregiver at facility) were aggregated per facility. We assess differences between the two delivery models using the Wilcoxon rank-sum test on summary statistics (median, range intervals, proportions) from aggregated facility outcomes.
Results: In both POC and referral models, there were no significant differences in percent results returned (100%), or in the proportions of HIV-infected infants initiated on treatment (100%), despite the latter having a small but significant distribution difference (Table 1). The total TAT median observed in the referral model (2 days [0-28]) was only two days longer than in the POC model (0 days [0-3]), with a significant difference in the TAT groups' distributions (Figure 1 and Table 1). Whereas both models experienced same-day specimen transportation, caregivers took significantly longer (1 day vs 0 days) to collect the result from facility in the referral model (Table 1).
Conclusions: A short-haul POC EID specimen referral system showed no significant differences in key clinical outcomes, and a significant increment of only 2 days in the final TAT, (mostly due to time required for caregivers to collect results) as compared to patients seen at POC testing sites, and may be considered to increase access to POC EID.

Indicator		POC Model	Referral Model	p value*
Number of facilities analyzed		27 testing facilities (2,670 specimens)	82 referring facilities (2,076 specimens)	
Percentage of results returned to caregiver (medians)		100% [91-100]	100% [75-100]	p=0.996
Percentage of HIV-infected infants initiated on treatment (medians)		100% [0-100] (n=67)	100% [0-100] (n=53)	**p=0.018**
	Blood collection to reception at testing site (including sample transportation)	0 days [0-0]	0 days [0-2]	**p=0.004**
	Blood reception to processing at testing site	0 days [0-0]	0 days [0-1]	p=0.059
Median TAT from:	Processing to result sent to requesting unit	0 days [0-0]	0 days [0-5]	**p=0.008**
	Result at Requesting unit to result received by caregiver	0 days [0-1]	1 days [0-24]	**p<0.001**
	Blood collection to result communication to caregiver	**0 days [0-3]**	**2 days [0-28]**	**p<0.001**
*The significance threshold was set at 0.05

Patient's preferences for differentiated HIV service delivery in a routine program setting in Uganda: A cross sectional survey

F.C. Semitala[1,2,3], E. Atuhumuza[3], W. Muyindike[4], L. Sabiti[2], G. Karirirwe[5], S. Walusimbi[2], A. Cattamanchi[6], M.R. Kamya[1,3]
[1]Makerere University School of Medicine, Internal Medicine, Kampala, Uganda, [2]Makerere University Joint AIDS Program, HIV/TB Treatment and Implementation Research, Kampala, Uganda, [3]Infectious Diseases Research Collaboration, Research, Kampala, Uganda, [4]Mbarara University of Science and Technology, Medicine, Mbarara, Uganda, [5]Makerere University, Medicine, Kampala, Uganda, [6]University of California, Division of Pulmonary and Critical Care Medicine, San Francisco, United States

Background: The World Health Organization recommends implementation of Differentiated Service Delivery Models to optimize the quality of HIV care and efficiency of service delivery. Current models of care are typically facility-based, with limited choice of other options for people living with HIV (PLHIV). We evaluated PLHIV's preferences for facility- vs. community-based care, and desire to be engaged in making a choice as to how to receive treatment.

Methods: .We conducted a cross sectional survey that included PLHIV who were receiving facility-based care at three clinics in Uganda: an urban clinic (Mulago AIDS Clinic, Kampala), a peri-urban clinic (Mbarara Municipality clinic) and a rural clinic (Bwizibwera Health centre IV, Mbarara District). Consecutive adults presenting for care at the three clinics were included unless they were unable or declined to provide informed consent. Data on age, sex, median CD4 cell count and duration in HIV care were extracted from clinic records. We administered a questionnaire to assess preferences for facility- vs. community-based ART, and for being engaged in the decision related to model of care (vs. having health care providers decide on their behalf). We summarized data using appropriate descriptive statistics, and compared survey responses by clinical characteristics, clinic location, gender and other variables using the chi-squared test.

Results: During November and December 2016, 532 of 604 PLHIV with complete data were included in the analysis. Majority 337 (63%) were women, median age 39.5 years (IQR, 33.6-47.5) and median CD4 count 502 cells/µL (IQR, 359-657). 517 (97.2%) clients had been in HIV care for at least six months. Most PLHIV visited the clinic every 2 months (N=323, 60.7%) or every 3 months (N=190, 35.7%). The majority (N=465, 87.4%) preferred community-based care. Nearly half (N=242, 45.5%) preferred to be engaged in making a choice for the ART delivery model. PLHIV in the urban clinic were more likely to prefer choosing a model for ART delivery (OR 1.33, 95% CI, 1.07 - 1.66) compared to PLHIV in peri-urban and rural clinics.

Conclusions: Most PLHIV preferred community-based care and many desired to be engaged in making decisions for the models of HIV service delivery, particularly in the urban clinic.

WEPEE605

Adaptive social and behavior change communication strategies achieve modification in social norms around uptake of voluntary medical male circumcision services in traditionally non-circumcising communities in three regions of Tanzania

M. Makokha[1], A. Christensen[1], A. Hellar[1], M. Machaku[1], C. Francis[1], S. Tesha[1], P. Massawe[1], K. Curran[2], Z. Mwandi[3], M. Carrasco[4], V. Kiggundu[4], E. Mlanga[5], G. Lija[6], G. Msalale[6], P. Luvanda[6], E. Kessy[6]
[1]Jhpiego, AIDSFree, Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego, Washington, United States, [3]Jhpiego, AIDSFree, Nairobi, Kenya, [4]U.S. Agency for International Development (USAID), Washington, United States, [5]USAID, Dar es Salaam, Tanzania, United Republic of, [6]Ministry of Health, Community Development, Gender, Elderly and Children (MOHCDGEC), Dar es Salaam, Tanzania, United Republic of

Background: In 2009, Jhpiego collaborated with the Tanzania Ministry of Health to start offering voluntary medical male circumcision (VMMC) for HIV prevention to males ages 10 years and older in Iringa, later expanding to Njombe and Tabora regions. At inception, male circumcision (MC) prevalence in Iringa, Njombe, and Tabora (all traditionally non-circumcising regions) was 29%, 29%, and 38%, respectively, compared to 67% nationally.

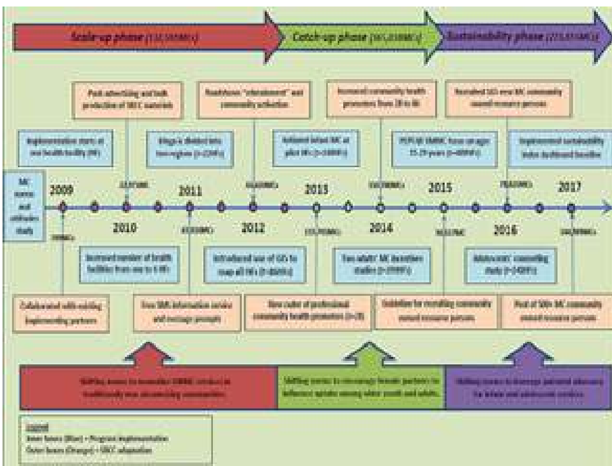
As of September 2017, the program had performed 721,444 VMMCs, contributing to an MC prevalence of 80%, 62%, and 67%, respectively, in the three regions, compared to 80% nationally.

Description: Social and behavior change communication (SBCC) strategies were developed to support three VMMC implementation phases: a scale-up phase focusing on normalizing VMMC in traditionally non-circumcising communities, implemented at the beginning when coverage was low among all age groups; a catch-up phase mobilizing female partners to influence VMMC uptake among older youth and men, implemented as the program expanded VMMC in all communities in the three regions; and a sustainability phase leveraging parental advocacy to cultivate future demand for infant and adolescent VMMC services, implemented as coverage reached 80% among males ages 15-29 years.

The program used experiential learning approaches backed by independent operational research on motivational incentives, message dissemination and timing options, service environment, and the role of community-owned resource persons as drivers of VMMC uptake.

The main SBCC strategies corresponding to each phase were mass media campaigns promoting self-reinforcing messages; community mobilization at village level incorporating social routines and schedules; and setting-based one-to-one interactions to address individual needs and support linkage to services.

Lessons learned: SBCC strategies responsive to context factors and incremental service coverage, augmented by experiential learning and operational research, helped VMMC to evolve from a cultural novelty to a normative practice in these communities. Figure 1 shows how SBCC strategies adapted as VMMC evolved in the program.



[Figure 1: How SBCC adapted as VMMC evolved in the program]

Conclusions/Next steps: The program is working to integrate VMMC into routine facility-based health services. SBCC's new challenge is to promote and maintain peer-to-peer advocacy among VMMC adopters, friends, and networks to make future demand for VMMC self-sustaining.

WEPEE606

Scaling up pediatric HIV treatment coverage in Uganda through a prioritized approach

S. Jaidev[1], B. Kabasomi[2], B. Mirembe[2], N. Hariharan[2], P. Nawaggi[2], H. Busobozi[2], C. Amulen[2], K. Suggu[1], A. Musoke[2], C. Katureebe[3]
[1]Clinton Health Access Initiative, eMTCT and Pediatric HIV, New York, United States, [2]Clinton Health Access Initiative, eMTCT and Pediatric HIV, Kampala, Uganda, [3]Ministry of Health, Pediatric HIV Coordinator, Kampala, Uganda

Background: Among the 193,500 children living with HIV in Uganda in 2014, only 27% were on treatment, compared to 52% of adults. Efforts needed to be accelerated to improve pediatric coverage, balancing resource availability and prioritizing areas with the greatest gaps. However, there was a lack of peds surveillance data, with 2005 AIDS Indicator Survey (AIS) data being the most up to date information available.
Description: Using available ART data, a district prioritization exercise was conducted to determine districts and facilities with the highest pediatric scale-up potential, defined as the number of children needed to be put on ART to reach parity with adult coverage rates. The underlying hypothesis was that HIV-positive children were likely to be where HIV-positive adults lived, and we could maximize early impact by focusing on the districts with high adult coverage and relatively low pediatric coverage rates. A target proportion of pediatric patients relative to adult patients was determined based on the underlying goal of scaling up pediatric coverage to adult levels. For each district and facility, the current proportion was calculated, and if below target, scale-up potential was determined, and districts were ranked from largest to smallest potential.
Lessons learned: The district prioritization exercise revealed that 30 of Uganda's 112 districts held 75% of the total pediatric treatment scale-up potential of 51,000 children, with 19 districts holding 53% and the remaining 11 districts holding 22%. 15 out of Uganda's 1,061 facilities with active pediatric patients held 25% of the total scale-up potential alone, suggesting the opportunity for a targeted and prioritized approach. Based on these findings, Ministry and partners agreed to prioritize facilities in 19 districts accounting for 53% of the scale-up potential, representing 26,694 children.
Conclusions/Next steps: This approach shows that targeting and prioritization can be used to improve resource allocation of funding in resource-limited settings and have high impact. This consortium has been funded by ELMA Philanthropies, and has moved from contributing to 35% of national pediatric identifications in Q3 2015 to contributing 41% of pediatric identifications as of Q3 2017.

WEPEE607

How many are eligible for PrEP? Implementing New Zealand's new publicly funded and targeted PrEP policy

P. Saxton[1], S. McAllister[2]
[1]University of Auckland, Gay Men's Sexual Health Research Group, Dept of Social and Community Health, Auckland, New Zealand, [2]University of Otago, AIDS Epidemiology Group, Dunedin, New Zealand

Background: New Zealand (NZ) will be among the first countries internationally to launch a publicly funded PrEP programme in March 2018. Eligibility focuses on gay and bisexual men (GBM) with a recent history of condomless anal intercourse with casual partners, rectal bacterial sexually transmitted infection and methamphetamine use (criteria 1), and regular sexual partners of people with diagnosed but untreated or unsuppressed HIV (criteria 2).
PrEP could have a substantial population-level impact on HIV transmission and be cost effective if targeted and scaled-up rapidly but a key question is the size of the eligible population.
Methods: We drew on nine sources to estimate the PrEP-eligible population:
(i) Statistics NZ data;
(ii) PHARMAC data on the number of adults receiving funded ART;
(iii) expert advice;
(iv) estimates of the HIV Care Cascade;
(v) active surveillance of diagnosed and undiagnosed HIV in a community sample of GBM;
(vi) passive surveillance of new HIV diagnoses;
(vii) NZ Health Survey data;
(viii) HIV behavioural surveillance among GBM;
(ix) behavioural data among people living with HIV from the HIV Futures NZ study.
From these we derived three estimates relating to
(a) GBM (criteria 1 and 2);
(b) non-GBM (criteria 2);
(c) total eligible.
Results: We estimated that 17.9% of currently sexually active HIV negative GBM would be eligible for PrEP in New Zealand under criteria 1 or 2, equating to 5,816 individuals. We estimated that 31 non-GBM individuals would be eligible under criteria 2. In total 5,847 individuals would be eligible for PrEP, comprising 99% GBM and 1% non-GBM. A number of data sources were imperfect, including poor information on transgender populations potentially eligible.
Conclusions: The estimated PrEP-eligible population in New Zealand is modest. Public health actors can apply estimates of the PrEP-eligible population to make a number of strategic decisions. Policy makers can utilise enumeration to monitor the speed, scale and gaps in coverage once implementation begins. Sexual health and primary care services can apply enumeration to forecast anticipated demand for PrEP and plan accordingly. The process of enumeration also identifies knowledge gaps that can subsequently be addressed to improve accuracy.

WEPEE608

HIV-positive women have higher risk of precancerous lesions and cervical cancer: Results from an integrated HIV and cervical cancer screening program in Zambia

G. Mburu[1], Y. Mulenga[2], P. Koni[2]
[1]PCI Global, HIV/AIDS Programs, Washington DC, United States, [2]PCI, Programs, Lusaka, Zambia

Background: Screening of cervical cancer is recommended for women of reproductive age.
Precise method of screening may include varied combinations of HPV test, pap test, cytology, or visual inspection with acetic (VIA), based on resource availability. In Zambia, where prevalence of HIV among adult women 15-49 is 15% and health resources limited, we integrated VIA within HIV services, using screen and treat approach. This abstract documents the results of this screening.

Description: Retrospective analysis of program data was conducted. Participant characteristics and results of integrated HIV testing and VIA were summarized. Association between HIV status and outcomes of cervical cancer screening were explored using SPSS.
Lessons learned: Overall, 6,527 women were screened for cervical cancer between October 2016 and September 2017. Their mean age was 33 years (Range 14-88 years). Overall, 39.5 % (n=2,577) were aged below 30 years, 49.5 % (3,228) were aged 30-49 years, and 11.0 % (n=715) were aged 50 and above. Of the total screened, 3.6% (n=234) were found to have positive findings (mild, moderate or severe dysplasia) on unaided VIA, while 96.4% did not have any abnormalities. A total of 11 women had precancerous lesions (CIN II, CIN III, carcinoma in situ) or cervical cancer. Additionally, 12 women had benign lesions including cervicitis (n=2), condyloma acuminata (n=5), warts (n=1), herpes (n=1), and Nabothian cysts (n=1) and follicles (n=2). Access to treatment was moderate, with 58.5% of those with positive findings on VIA, benign lesions, precancerous lesions, or cervical cancer accessing treatment within the 12-months period analyzed. Furthermore, 17.9% (n=1166) of the 6,527 screened women were HIV positive. HIV positive status was associated with positive findings on VIA (OR=1.206, 95% CI: 2.552-4.375, p< 0.001), and with precancerous lesions and cervical cancer (OR=1.913, 95% CI: 1.825-25.128, p< 0.001).
Conclusions/Next steps: Cervical cancer screening using VIA reached a large number of women when offered through integrated HIV services. Given the higher risk of dysplasia, precancerous and cervical cancer among HIV positive women, the integration VIA within HIV services model is a promising strategy for cervical cancer prevention, which can be enhanced with cytology, HPV or pap tests in future.

WEPEE609

Combining online and offline strategies: 15 years of lessons learned from the hepatitis B vaccination program for Dutch men who have sex with men and sex workers

K. Vermey[1], A. Urbanus[2], T. Stewart[1], W. Zuilhof[1], A. Meiberg[2]
[1]Aidsfonds - Soa Aids Nederland, Amsterdam, Netherlands, [2]National Institute for Public Health and the Environment, Bilthoven, Netherlands

Background: Men who have sex with men (MSM) and female, male and transgender sex workers (SW) are at increased risk for sexual transmission of hepatitis B in the Netherlands. Subsequent to a successful pilot, national partners have been collaborating with local public health services to provide a targeted hepatitis B vaccination program (HBV) among SW and MSM since 2002.
Description: Public health services offer vaccination free of charge during consultations hours and community outreach activities (at saunas, festivals, brothels etc). To increase vaccination coverage and adherence, targeted campaigns are conducted each year via social media, online dating platforms and commercial sex websites. These campaigns refer to websites with sexual health information, tailored advice and an online module to directly schedule vaccination appointments. Nurses and volunteers conduct online outreach on dating platforms for MSM and commercial sex websites to promote vaccination.
Lessons learned: To improve the program, qualitative research into motivations and barriers, cost effectiveness studies and process evaluations were conducted. In 15 years' time, the HBV program reached over 58,000 MSM and 22,000 SW with a combination of offline and online strategies. Acute hepatitis B infection rates dropped significantly while vaccination coverage increased. Reaching MSM and SW during physical outreach became less effective and more costly. The opportunities for online service provision strongly increased however. In 2017, approximately 10% of the first vaccinations among MSM was facilitated by the online appointment module. The shift from offline towards online promotion activities necessitated new funding allocation procedures and the valorization of online counseling skills in professionals' competency frameworks.
Conclusions/Next steps: In 2011, universal hepatitis B vaccination of Dutch newborns was implemented. Until this first cohort turns sexually active around 2030, a combination of targeted strategies to promote HBV among MSM and SW will remain necessary. This applies especially to groups with the lowest vaccination rates, including young MSM, SW working from home and migrant MSM and SW. To reduce costs and improve effectiveness in the coming years, the HBV program will place more emphasis on service provision in online communities and a more effective interplay between campaigns, outreach and direct vaccination.

WEPEE610

A ten-year trend analysis of inpatient utilization between 2007 and 2016 for New York State among those diagnosed with both HIV and hepatitis C

D. Tsui, C. Gonzalez, I. Feldman, F. Laufer, W. Levey
New York State Department of Health, AIDS Institute, Albany, United States

Background: As part of New York State Governor's Ending the AIDS Epidemic initiative, reducing HCV-related morbidity and mortality among those co-diagnosed with HIV/HCV is a priority. The current analysis was undertaken in an effort to examine the effectiveness of this priority.
Methods: The hospitalized HIV/HCV co-diagnosed population was identified utilizing diagnosis codes from the New York State Statewide Planning and Research Cooperative System (SPARCS) data. Utilization and mortality trends of adult emergency department (ED) and inpatient (≥ age 18) discharges between 2007 and 2016 were reviewed. Multivariate regression was then applied to predict the likelihood of inpatient mortality. Zero-order correlations were applied between two variables to calculate the confidence levels.
Results: Results showed the individuals co-diagnosed with HIV/HCV infections with inpatient hospitalizations significantly decreased from 6,077 to 3,843 (36.8%, *p*< 0.0001) during the decade under review. Inpatient admissions via the ED decreased from 3,380 to 2,957 (12.5% *p*< 0.0001). Co-diagnosed patients expiring during hospitalization also gradually declined from 221 to 138. After controlling for patients who expired during hospitalization, the average length of hospital stays (ALOS) decreased from 10.3 days in 2007 to 7.6 days in 2016. The decrease in ALOS of those ≥60 year of age decreased from 14.4 days to 8.2 days, while the 18- to 29-year-old cohort increased from 7.6 days to 10.1 days. The multivariate result showed HIV/HCV co-diagnosed patients are 1.5 times more likely to be admitted to New York City (NYC) hospitals than hospitals outside NYC (odds ratio 1.520; 95% confidence level 1.618-1.698, *p*< 0.0001).
Conclusions: Ongoing trend analysis is needed to identify if the hospital utilization patterns reflect effective HCV cure rates or changes in demographic trends in HIV/HCV co-diagnosed patients.

WEPEE611

Comparative yield of community active tuberculosis case finding approaches in Zimbabwe

R. Ncube[1], C. Zishiri[1], M. Mapfurira[2], S. Machekera[1], C. Sandy[2]
[1]International Union Against TB and Lung Disease, TB HIV, Harare, Zimbabwe, [2]Ministry of Health Child Care, National TB Program, Harare, Zimbabwe

Background: Zimbabwe is ranked among the top 30 high burden countries for TB, TB-HIV and drug-resistant TB, with estimated treatment coverage at 81% in 2016. As part of efforts to find missed cases within the framework of the post 2015 end TB agenda, the country has adopted innovative active case finding approaches.
Description: In 2017, The Union in collaboration with the Ministry of Health and Child Care supported three models of active case finding namely; 1) Targeted active case finding among high risk communities using a mobile X-ray van 2) Intensified contact investigation using community health workers (CWHs) on motorcycles in two high burden districts and 3) Door to door screening for TB through a network of CHWs in two rural districts. We set out to compare the yield of the different active case finding approaches.
Lessons learned: For the period February-December 2017, 60,807 clients were screened for TB through the X-ray van and 1,080 diagnosed with TB. The number needed to screen (NNS) was 56 at a cost of $781 per case diagnosed. Through contact investigation for the period August

2016-June 2017, 1,443 contacts were screened from 604 index cases. A total, 31 were diagnosed TB and the NNS was 53, at a cost of $647 per case diagnosed. Between January-December 2017, the door to door case finding approach screened 54,332 for TB, among whom 177 were diagnosed with TB. The number needed to screen was 307, at a cost of $1,534 per case diagnosed.

Conclusions/Next steps: The yield or NNS was comparable for the X-ray van and contact investigation approach, though the later was much cheaper per case diagnosed. In comparison, the yield was much lower and more expensive for each case diagnosed using the door to door approach. These findings bring to focus the need for more comprehensive cost-effectiveness analysis to inform future scale-up.

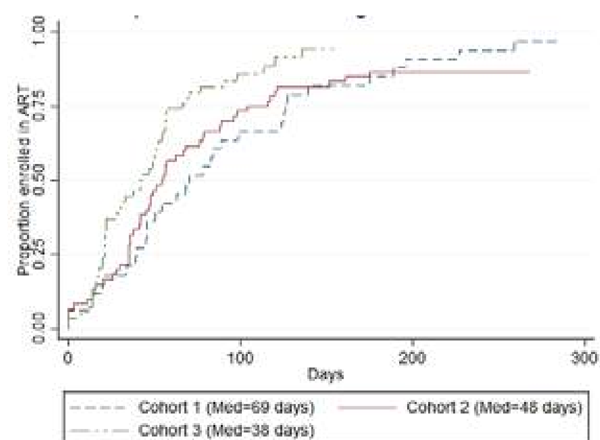
WEPEE612

Rates of ART initiation and time from HIV diagnosis to ART initiation in selected Namibian health facilities one year before the national rollout of Namibia´s Treat All guidelines

J.B. Zieman[1], J. Mdala[2], L. Stoman[3], N. Hamunime[4], P. Kamilugogo[2], A. Zegeye[5], S. Geibel[1], L. Vu[1]
[1]Population Council, Project SOAR, Washington, United States, [2]IntraHealth International, Windhoek, Namibia, [3]Survey Warehouse, Windhoek, Namibia, [4]Ministry of Health and Social Services, Windhoek, Namibia, [5]USAID/Namibia, Windhoek, Namibia

Background: Research shows that reducing the time between a confirmed HIV diagnosis and subsequent ART initiation can expedite viral suppression and reduce loss to follow-up for people living with HIV (PLHIV). This abstract describes current trends in time-to-initiation based on data collected from HIV clinics in Northern Namibia as part of a larger study assessing the effects of the national implementation of Treat All guidelines—under which all PLHIV are immediately eligible to begin ART.

Methods: We conducted a secondary analysis of routine health records from 10 purposefully-selected ART clinics, supported by the USAID HIV Clinical Services Technical Assistance Project (UTAP). The dataset contains patient demographics, dates of HIV diagnosis and ART initiation, and longitudinal data on clinic visits during the 12-months preceding the national introduction of Treat All: 1 April 2016-31 March 2017. We examined a subset of 147 PLHIV whose diagnosis occurred between 1 April 1-31 December 2016. To assess how changes to ART guidelines and practices affected time-to-initiation, we stratified the records into three 90-day cohorts by HIV diagnosis date: 1 April-30 June (n=33), 1 July-30 September (n=54), and 1 October-31 December (n=60). Using Kaplan-Meier and log-rank analyses, we describe and visualize trends across the three cohorts.



[Time elapsed between HIV diagnosis and ART Initiation]

Results: Of the records analyzed, 61% (n=89) were women, median age was 34 years. On average, patients transitioned onto ART within 72 days of HIV diagnosis; half started ART within 51 days, and 7% started within one week. Neither sex nor age were associated with ART initiation or time-to-initiation. Nearly 90% of patients in all three cohorts initiated treatment by 31 March 2017 (p=0.269),and median time-to-initiation decreased sequentially (Chart 1). The log-rank test indicates this trend is significant (chi^2=159.6; p< 0.0001).

Conclusions: High treatment initiation rates and the decreasing trend in time-to-initiation suggest that the facilities surveyed are making progress toward ensuring that 90% of all diagnosed PLHIV are linked to treatment. Factors influencing this trend may include UTAP's continuing technical support, ART service decentralization, expanding CD4-based ART eligibility from 350 to 500 (cells/mm^3), and preparations for Treat All. We will repeat this analysis using data collected after the first 12-months of Treat All implementation.

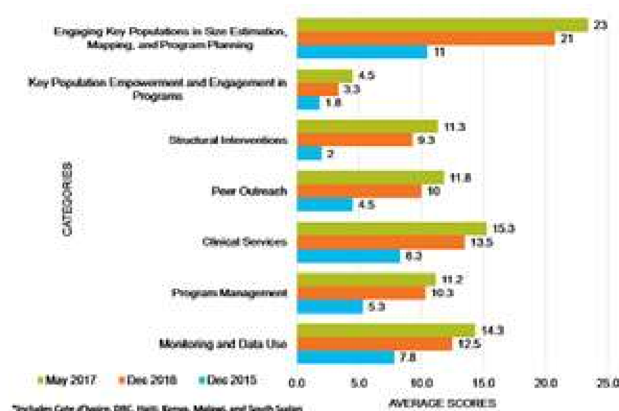
WEPEE613

Accelerating implementation and scale-up of comprehensive programs for HIV prevention, diagnosis, treatment and care for key populations: Critical to HIV epidemic impact

M. DiCarlo[1], P. Bhattacharjee[2]
[1]FHI 360, Washington, United States, [2]University of Manitoba, Nairobi, Kenya

Background: Key populations (KP) face disproportionate barriers to accessing services compared to other populations and have the highest incidence of HIV infection. To achieve epidemic control, national program coverage of KP must be accelerated to ensure HIV transmission is stopped and KP PLHIV are identified, and initiate and remain on treatment. Scaling quality KP programming is thus essential and means must be in place to accelerate the impact of those programs on the HIV epidemic.

Description: In late 2015, the USAID- and PEPFAR-supported LINKAGES project developed a method for accelerating the scaled delivery of quality interventions for KP in 17 countries in Africa and the Caribbean. This included development of a common core KP program and implementation guide that covered size estimation, mapping, KP engagement, structural interventions, peer outreach, clinical services, program management, and monitoring/data use. The step-by-step guide, designed to be adaptable at country level, served as the basis for development of country operational plans, as well as training, technical assistance (TA) and monitoring and evaluation. Frequent, rapid, and targeted TA was provided to countries to support implementation of the common core program. A technical checklist aligned with the guide allowed for frequent evaluation of progress.



[Figure 1. Average scores on quality KP program implementation in the seven core program areas]*

Lessons learned: The common core ensured that a standardized package of essential KP services could be delivered consistently in each country, while allowing for adaptation to various settings. The method promoted constant course adjustments to respond to changing KP locations and denominators, differentiated service delivery models that could be adjusted by location/population type, constant community engagement, and a culture of data use at site level to track individuals

throughout the HIV cascade. Implementation quality was assessed using the checklist linked to the common core. In a sample of 6 countries, quality implementation scores improved in all seven areas of the common core, from an average score of 40.7 in December 2015 to 91.4 in May 2017.
Conclusions/Next steps: The described method and standard package have been successful at improving and scaling KP services across multiple country contexts and can be used and adapted anywhere for similar results. These lessons could also be transferred to other health and development challenges.

WEPEE614

A ten-year trend analysis of inpatient diagnoses of cellulitis, endocarditis, osteomyelitis and pneumonia for intravenous drug users between 2006 and 2015

C. Gonzalez[1], D. Tsui[2], I. Feldman[2], F. Laufer[2], W. Levey[2]
[1]New York State Department of Health, AIDS Institute, New York, United States, [2]New York State Department of Health, AIDS Institute, Albany, United States

Background: The re-use of syringes in the context of persons who inject drugs has an increased risk for the development of soft tissue, endovascular, bone and pulmonary infections. Since 1992, the New York State (NYS) Department of Health's AIDS Institute has implemented the harm reduction strategy of expanded syringe access. We analyzed the global impact of syringe access on emergency department (ED) and hospital inpatient utilization for the aforementioned infections.
Methods: Reviewing the New York State Statewide Planning and Research Cooperative System (SPARCS) data, we examined trends of adult (≥18 years old) ED and hospital inpatient utilization and mortality between 2006 and 2015 for soft tissue, endovascular, bone and pulmonary infections among persons who inject drugs. Multivariate regression was then applied to predict the likelihood of inpatient mortality. Zero-order correlations were applied between two variables to calculate the confidence levels.
Results: From 2006 to 2015, the number of discharges among persons who inject drugs decreased 22.4% (from 123,624 to 95,872, $p< 0.0001$). Among patients who use injection drugs, cellulitis-related to injection drug discharges also significantly decreased from 5,254 to 4,526 (13.9%, $p< 0.0001$) during this period. The mortality rate for persons who inject drugs-related discharges increased from 793 to 822. Expired patients who inject drugs had the highest average length of stay (ALOS), but they also declined from 13.6 to 11.2 days.
When controlling for patients expiring during hospitalization, the ALOS averaged 6.9 days through the decade. As expected, no significant changes were noted in aspiration pneumonia rates. Osteomyelitis maintained the highest ALOS of 16.3 days in 2006 to 12.7 days in 2015. The multivariate result showed patients who inject drugs with endocarditis are 1.4 times more likely to be admitted to inpatient through emergency department (odds ratio 1.434; 95% confidence level 1.399-1.469, $p< 0.0001$).
Conclusions: The expanded syringe access harm reduction strategy has health care impact beyond decreasing HIV and HCV transmission dynamics.

WEPEE615

Implementation of the community adolescents treatment supporters programme with Africaid

T. Chigadza[1], P. Matyanga[1], A. Ricotta[2]
[1]Africaid, Programmes, Harare, Zimbabwe, [2]Africaid, Technical Support Team, Harare, Zimbabwe

Background: World Health Organization (WHO) in 2015 recommended that HIV treatment to children, adolescents and young people (CAYPLHIV) should be started regardless of CD4 cell count or disease stage 'Treat All' approach has been adopted by the Zimbabwe Ministry of Health and Child Care and has been cascaded to Goromonzi district in Mashonaland East Province.
Methods: 'Treat all' is anticipated to increase the number of CAYP enrolled in HIV treatment and care. HIV programs in high prevalence areas are overstretched and seek efficient ways to deliver care and treatment that meet clients' diverse needs and lower barriers to care while optimizing efficiency. The 2015 Africaid operations research in rural Zimbabwe measured the effectiveness of the peer-led model and community approach to strengthening adherence and retention. Compared adherence and retention among those receiving standard of care and the Africaid supported clients receiving standard of care plus Community Adolescents Treatment Supporters (CATS) services showed improved adherence in the latter. From these results, the model was cascaded to Goromonzi District and has been implemented from October 2016 to date.
Results: 32 CATS were trained, mentored and have provided differentiated services to 2,378 CAYPLHIV below 24 years. The CATS model has resulted in 856 newly diagnosed CAYPLHIV and 70% were linked into care under 'treat all' initiative. Improved adherence as evidenced by viral load (VL) was witnessed among those receiving CATS services. 81.7% of 2,378 have had a viral load, 1,927 which amount to 81% have a VL below 1000 copies/mm and 15 have a VL above 1000 copies/mm which is 0.77%. Then 64.8% of 2,378 having been referred for services thus improving retention. CATS are well integrated with strong systems so that they can refer their peers who are in need of further support including mental health.
Conclusions: Working with CATS programs, MoHCC recommended to work with more expert clients to ensure timely linkages of CAYPLHIV for this has shown a greater improvement especially on adherence. This also works best for differentiated care implementation. Linkage to care was significantly associated with the period of engaging expert clients in the project.

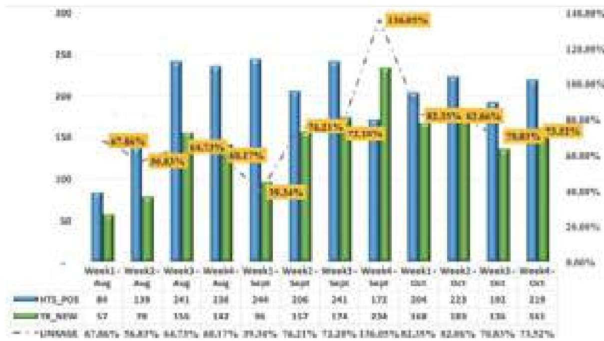
WEPEE616

The benefits and utility of surge strategies with HIV-positive patient tracing exercises: The Zomba, Malawi experience

M. Marco[1], P. Mwala[1], S. Zungu[1], D. Malema[2], B. Mpila[1], J. Theu[3], M. Jagriti[3], J. Moorman[2], T. Xulu[1], I. Sanne[1],
Right to Care - EQUIP, Centutrion South Africa
[1]Right to Care - EQUIP, Centurion, South Africa, [2]Right to Care - EQUIP, Lilongwe, Malawi, [3]Dignitas Interternational, Zomba, Malawi

Background: Meeting the UNAIDS/PEPFAR 90-90-90 targets are necessary but often difficult to achieve for HIV treatment and care sites in resource-limited countries like Malawi. The USAID-sponsored EQUIP consortium, with its implementing partners (IP), currently provide comprehensive rapid scale-up of antiretroviral therapy (ART) services across 245 health facilities in Malawi. EQUIP's IP, Dignitas International (DI), provides direct service delivery in Zomba and Machinga districts of south-east Malawi.
Description: In July 2017, EQUIP placed 17 of DI's 28 Zomba health facilities under remediation based on gaps in specific indicators of the cascade, namely < 75% of those testing HIV-positive were not initiated on ART. Between 13-30 September 2017, EQIUP Central's technical team joined members of EQUIP Malawi and DI representatives in Zomba to implement a surge strategy to delineate how many HIV-positive patients from site registers had not been ART initiated. This information was used to commence with a tracing exercise from 23-29 September to bring those not initiated and lost to follow-up (LTFU) back into treatment.
Lessons learned: Of the 1,057 patients from 17 facilities needing tracing, HIV diagnostic assistants (HDAs) were able to actively trace 1,028 (96.3%) patients in 7 days. From the 1,028 traced patients, 400 (38.9%) were already on ART at their initial site or another one nearby. From the remaining 520 traced patients who were physically locatable, 130 (25%) returned to the clinic and initiated ART. These 130 (92.9%) patients were from the group of the 140 patients who told their HDA that they definitively would come back to the clinic for treatment, and thus did so. From onset of the surge through the tracing exercise, sites' linkage and ART initiation rates were markedly higher than in previous months.
Conclusions/Next steps: Our expert HDAs knew their catchment areas and were quickly and efficiently able to trace >95% of LTFU patients. The tracing exercise further revealed data challenges, specifically incom-

pleteness of patient data registers, client tracking processes, and patient referral systems. This necessitated mentoring on ART data collection tools and enhanced monitoring and evaluation training to reconcile HIV-positive and ART registers to ensure that all sites adhere to WHO's test and treat strategy.



[HTS_TST_POS to TX_NEW from 17 Zomba, Malawi Remediation Sites by Week: 1 Aug - 30 Oct 2017]

WEPEE617

Key populations leading the way: Innovative strategies for increasing HIV testing yield in high risk communities in Guyana

T. Hendricks[1], L. Thompson[1], S. Maher[2], M. Duffy[2], W. Proper[2]
[1]Advancing Partners & Communities - Guyana, Georgetown, Guyana, [2]John Snow, Inc., Washington DC, United States

Background: Guyana's 2014 Biological and Behavioural Surveillance Survey reports significantly higher HIV prevalence among KPs compared to 1.6% in general population. Transgender persons prevalence rate at 8.4%, sex workers at 5.5%, and men who have sex with men at 4.9%. There are persistent programmatic challenges to reaching and testing most at-risk KPs due to high levels of stigma and discrimination. Consequential, is low uptake of HIV testing services (HTS) and treatment services among KPs. This threatens Guyana's ability to help its people and achieve UNAIDS 90/90/90 targets.

Description: To address challenges, Advancing Partners and Communities (APC) Project in Guyana, a USAID funded programme led by JSI, introduced a personalized KP social network strategy. APC-supported peer educators, themselves KPs, belonging to social networks of most at-risk KPs reach them individually to encourage testing and linkage to treatment. KP peer educators provide HIV education in high risk communities for the most at-risk from their social networks and refer for HTS provided by KP-led NGOs. Efforts to improve HIV testing yield include personalized HTS and those testing HIV-positive are referred to a treatment site and accompanied if they choose.

Lessons learned: Identification of most at risk KPs, testing them and their partners, and linking positives to HIV care and treatment services yields the best outcomes. HTS quarter one results between 2017 and 2018 show a decrease of testing by 18% but an increase in HIV positive diagnosis by 14.2%. The results directly correlates to APC's strategy. In quarter one of 2017, 14.3% of newly diagnosed KPs linked to HIV treatment - 7% female sex workers (FSW), 7% men who have sex with men (MSM). In quarter one 2018, 43.8% KPs linked (12.5% FSW, 25% MSM & 6.3% transgender).

Conclusions/Next steps: The concept of a personalized approach for peer-led HTS and linkage is labour intensive but effective. Working in conjunction with KPs to develop tailored and flexible approaches that nimbly respond to challenges can lead to innovative strategies which achieve the best results to locate, diagnose and link most at-risk KPs.

WEPEE618

Community task forces making a difference: Increasing TB case notification rates through community-led TB campaigns (TBC) in 11 regions in Tanzania

G. Asuquo[1], Y. Ferguson[2], K. Achebe[3], M. Imran[3]
[1]Save the Children USA, Dar es Salaam, Tanzania, United Republic of, [2]Save the Children, Dar es Salaam, Tanzania, United Republic of, [3]Save the Children US, Washington, United States

Background: Tanzania ranks 15th among 22 TB high-burden countries and 6th in Africa. Since April 2016 Save the Children Tanzania has been implementing a Global Fund-supported TB /HIV program in partnership with four local sub-recipients in 14 high TB/HIV-burden regions. Despite reaching DoTs coverage of 100% and treatment success rate of 89%, TB case detection remains at 33%. Two thirds of people estimated to have TB are not reached by the health system. Challenges include poorly equipped diagnostic facilities; Low community awareness; distance from communities to diagnostic centres; break down in the referral supply chain with no mechanisms for escorted referrals. The program supports the Government of Tanzania's goals of increasing TB case detection efforts and reducing the incidence of TB by 25% and mortality by 50% of TB and Leprosy by 2020.

Description: A key intervention undertaken to achieve these goals are community-led TB Campaigns modelled along Combination HIV Prevention Campaigns aimed at increasing community TB awareness, strengthening active case-finding and community uptake of TB/HIV collaborative services. Using a campaign slogan dubbed, "I am a TB Case Hunter: How about you", 11 one-day TB campaigns were conducted from 14th November to 16th December 2017. This consists of community-friendly social mobilisation strategies and campaign actions including public education through mass-media, folk-media/theatre to mobilise communities to campaign grounds to receive TB Health Education, TB-screening and on-site sputum examination of presumptive cases in collaboration with District Laboratory technicians.

Lessons learned: In the 11 one-day campaign events, 2766 community members were screened for TB; specimens of 1298 (46%) presumptive TB cases were processed on-site; 376 (29%) were confirmed as TB cases. The results show that delivering TB services through community-taskforces using community-friendly campaign-actions generates community-demand for services and increases TB case-notification by combining leadership engagement/advocacy with service-delivery at community-doorsteps in a fun environment.

Conclusions/Next steps: By leveraging the visible participation/involvement of a broad spectrum of community stakeholders including Health-Care workers, EX-TB patients, CSOs and PLWHIV Networks, the TB campaigns validated the Engage-TB model. A targeted scale-up of this approach therefore has significant promise in ending the TB epidemic in Tanzania.

WEPEE619

The uptake of the PrePex and Shang Ring male circumcision devices among adolescent and adult males in sub-Saharan Africa, a systematic review

R. Kakaire[1,2]
[1]University of Cape Town, Public Health and Family Medicine, Cape Town, South Africa, [2]Clinton Health Access Initiative, Maseru, Lesotho

Background: Voluntary medical male circumcision (VMMC) programs have been implemented in fourteen countries in sub-Saharan Africa since 2007. The uptake of services has been suboptimal in some of these countries. Circumcision using device methods was postulated to increase the uptake of services. We conducted a systematic review to establish the uptake and acceptability of the PrePex and Shang Ring male circumcision devices in VMMC program countries.

Methods: A comprehensive literature search was carried out to identify studies reporting uptake or acceptability of either the PrePex or Shang Ring device methods. The search was limited to English language articles of studies among adolescents and adults in VMMC implementing

countries. Two reviewers independently reviewed and abstracted data from each article. Uptake was defined as selection of a device, either the PrePex or Shang Ring, when offered a choice between the device and another method of circumcision. Uptake estimates were pooled in a meta-analysis and stratified by device method and participant age. Acceptability of device methods among recipients was summarized using four criteria and presented as proportions.
Results: Of the 391 total articles retrieved, 25 studies met the inclusion criteria. Of these, 7 articles reported uptake of device method. The pooled uptake estimate was 75% (95% CI 62% to 89%). Prepex uptake was estimated to be 73% while the Shang ring estimates were 82%. By age group, uptake of device methods among adolescents was 82% compared to 72% by adults. Majority (21) of the studies reported at least one criteria used to assess acceptability. Acceptability of the two device methods was high: 95% of participants reported satisfaction with a device procedure. The devices were not associated with lengthy periods from work. Almost all (97%) participants circumcised with the device methods indicated they would recommend a device procedure to a friend or relative.
Conclusions: Our findings showed a high uptake and acceptability of the two circumcision devices methods that have been prequalified by WHO for use among adolescents and adults.
These findings support the likelihood that circumcision uptake could be assisted by introduction of the two device methods in countries where coverage remains suboptimal.

WEPEE620

From tokenism to concrete practice- the story of lived realities of PLHIV through MIPA forums in Zimbabwe

T. Magure[1], R. Yekeye[2], A. Mpofu[3], S. Mpofu[4]
[1]National AIDS Council (NAC), CEO, Harare, Zimbabwe, [2]National AIDS Council (NAC), Operations, Harare, Zimbabwe, [3]National AIDS Council (NAC), M&E, Harare, Zimbabwe, [4]National AIDS Council (NAC), Harare, Zimbabwe

Background: The 1994 Paris Declaration, the UNGASS Declarations of 2001, 2012 and 2015 all had a common thread that (PLHIV) are critical to an ethical response to HIV and AIDS and they should be meaningfully Involved in the HIV response. Greater/Meaningful Involvement of People Living with HIV and AIDS (GIPA/MIPA) was considered to be important because:

- HIV+ people bring a unique perspectives of their personal experiences, to the development and implementation of HIV and AIDS programmes.
- Reaffirms the protection and promotion of the rights of PLHIV to participate freely, without discrimination, in the development process.
- Helps to reduce stigma and discrimination, as they challenge the myths and misconceptions about HIV and AIDS.

Zimbabwe is one of the Countries that took this concept seriously and established a MIPA desk within the National AIDS Council. It is through this desk that MIPA Forums were stablished.
Description: MIPA Forums were established at districts, provincial and National levels. For and by PLHIV and meet quarterly to discuss issues affecting PLHIV such as availability of medicines, access to services and programmes and impacts of certain policies on PLHIV. The national MIPA Forum brings together PLHIV from Women, Adolescents, Religious Leaders , Key Populations and representatives who sit on national, International boards and Government officials to discuss how to achieve the three 90s.
Lessons learned:
· There is a very strong voice of PLHIV community from all sections of PLHIV guiding the planning of the national response at all levels.
· PLHIV have been empowered and have represented the country and region at various international boards.
· The health outcomes for PLHIV have greatly improved as indicated by 90% Viral Suppression at 12 months and 87,7% adults ART retention by December 2017.
· There has been mutual exchange of Information between PLHIV and key service providers

Conclusions/Next steps: PLHIV are critical in shaping the national response as they bring on board their lived experiences. MIPA Forums have proved to be the best vehicle of harnessing the knowledge and skill of PLHIV to shape the national response and they need to be strengthened to achieve the 90-90-90 goals.

WEPEE621

National mentorship to improve testing uptake for HIV-exposed children in Malawi

C. Stillson[1], G. Nyirenda[2], N. Nyambi[1], L. Berman[1], C. Banda[1], S. Jaidev[3], D. Midiani[4], M. Eliya[4], R. Nyirenda[4], A. Gunda[1]
[1]Clinton Health Access Initiative, Lilongwe, Malawi, [2]Right to Care, Lilongwe, Malawi, [3]Clinton Health Access Initiative, New York City, United States, [4]Ministry of Health, Dept of HIV/AIDS, Lilongwe, Malawi

Background: Malawi adopted Option B+ for the prevention of mother-to-child transmission (PMTCT) of HIV in 2011. Without treatment, fewer than half of HIV-positive children survive past two years, making early identification critical to reducing mortality. As such, known HIV-exposed children are routinely tested at 2 months, 12 months, and 24 months. However, by 2015 testing uptake for HIV-exposed children in Malawi was less than 50% at each of these milestones. In April 2016, the Malawi Department of HIV/AIDS and Clinton Health Access Initiative developed a half-day in-service guided mentorship for PMTCT service providers.
Methods: Mentorship focused on reviewing and strengthening patient flow, testing procedures, and documentation practices. Existing national PMTCT mentors were oriented to a mentorship checklist and deployed to public health facilities in teams of three. In addition to the checklist, mentors were provided with facility-specific data sheets to identify areas for improvement. The mentorship model was first piloted in 5 districts in southern Malawi, with 80 facilities receiving 2 rounds of mentorship over 6 months. In February 2017, this model was scaled nationally, reaching more than 400 facilities that collectively accounted for 95% of all exposed infant testing volume. National mentorship continued quarterly through 2017 and is expected to continue through Q2 of 2018.
Results: Compared to testing uptake prior to mentorship (Q1 2016), the most recently available data (Q3 2017) indicates that uptake increased substantially across exposed-child testing milestones. Uptake at 2 months increased by 100% (35% to 70%), uptake at 12 months increased by 38% (53% to 73%), and uptake at 24 months increased by 18% (56% to 66%).
Conclusions: The national mentorship program contributed to a substantial improvement in uptake across exposed-child testing milestones. This demonstrates that periodic on-site mentorship of PMTCT providers can be an effective, scalable means of improving testing uptake at key milestones. However, retaining mothers and children to the end of the testing cascade remains a challenge.
Additional efforts are needed to ensure that HIV-exposed children remain HIV-free, including efforts to retain HIV-positive mothers on treatment throughout breastfeeding and follow up with mothers and children who miss testing milestones.

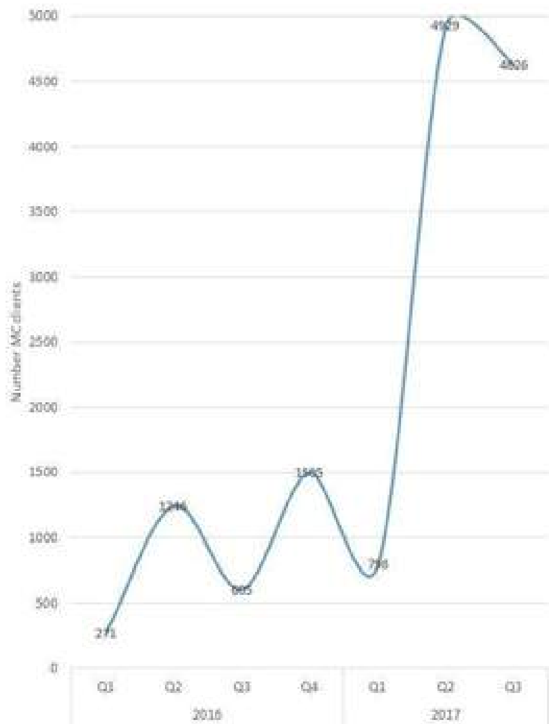
WEPEE622

Scaling up voluntary medical male circumcision services in Lusaka District of Zambia

H. Shasulwe[1], J. Banda[2], L. Aladesanmi[2], O. Chituwo[3], H. Chirwa[2], N. Kasonka[2], A. Chipukuma[2], F. Mulala[4], J. Zulu[4], K. Asiedu[2], Nashiol Nyirongo[1]
[1]Jhpiego - an affiliate of Johns Hopkins University, Health, Lusaka, Zambia, [2]Jhpiego - an affiliate of Johns Hopkins University, Lusaka, Zambia, [3]Centre for Disease Control, Lusaka, Zambia, [4]Ministry of Health Zambia, Lusaka, Zambia

Background: Male circumcision (MC) prevalence in Lusaka Province is 23% and HIV prevalence is 16%; the highest in the country. 80% of the population of the province reside in Lusaka District and has thus become a target for the scale up of HIV prevention services including MC. Historically MCs in Lusaka District have been dismal in comparison to its large population with only 33% of the annual target achieved in 2016.

Description: Jhpiego is implementing a 5-year CDC funded project under PEPFAR; providing MC services to reduce HIV transmission, thereby contributing to the control of the epidemic. The project plans to increase MC coverage to 80% in its supported districts which includes Lusaka. Services were scaled up through restructuring demand creation and service delivery strategies in 2017; this included: targeted demand creation using GIS mapping data; engagement of resident community mobilizers and facility environmental technician cadres; decentralization of services to health posts through regular outreaches; a roaster of service delivery providers for continuous deployment; as well as daily MC monitoring by program managers.
Lessons learned: This approach resulted in continuous client flows and seamless service provision. A review of MC uptake in Lusaka district from routine program data shows a dramatic improvement with over 4000 MCs done quarterly since April 2017 when this approach was implemented as compared to about 1000 MCs in the previous 5 quarters of the project. The project has contributed 15.3% of the MOH annual target for Lusaka district (67,566) after 3 quarters in 2017 as compared to only a 5.5% contribution in 2016. The project also exceeded its annual COP target by 15%.
Conclusions/Next steps: The project is now consolidating the principles of this approach as part of its standard implementation procedures and scaling this approach to its other districts of operation. These successes will also be shared with relevant stakeholder groups i.e. MOH, TWGs and other implementing partners for potential use across the country.



[Scaling up Voluntary Male Medical Circumcision in Lusaka District of zambia]

WEPEE623

Striking multiple ends: Access and use of female condoms reduce multiple reproductive health risks among female sex workers in an urban slum in Kampala City, Uganda

K. Buyinza[1], P. Ghaali[2]
[1]*Reproductive Health Uganda (RHU), Programs, Kampala, Uganda,*
[2]*Reproductive Health Uganda, Kampala, Uganda*

Background: With a prevalence of 7.3% in the general population, HIV/AIDS remains an important public health problem in Uganda, where the burden of HIV is higher among urban (8.5%) than the rural (6.5%) populations and much higher among sex workers (33%). However, access to comprehensive SRHR/HIV/AIDS information/services among sex workers and sexual minorities is still limited, associated with high mobility of key populations; a generally unfriendly SRHR service-delivery environment; and high levels social stigma/discrimination against SRHR for young people as well as sex-workers/sexual minorities. The above situation is compounded by the restrictive laws that limit commercial sex work, safe abortion and adolescent contraceptive use, resulting into many sex workers/sexual minorities operating *´under-cover´*; often abused (82%); and significantly excluded from critical SRHR services. As a result, sex workers face limitations in accessing appropriate information and services for their SRHR needs, which exposes them to disproportionately higher SRH risks e.g. HIV /AIDS (37%), STIs (42%), unsafe abortions 86%.
Description: Program Interventions: RHU/ IPPF implemented a peer-led SRHR program targeting FSWs and sexual minorities in urban slums of Kampala City; aimed at increased availability/access to quality rights-based SRHR information/services among vulnerable and often excluded young women/girls in urban slums of Kampala City.
Strategy/activities: Peer leaders were selected/trained as community-based SRHR agents, who in turn conducted targeted peer-to-peer mobilization, health education, provision of condoms, lubricants and FP methods; and referrals to health posts for services. Health facility capacities were enhanced to offer youth-friendly SRHR services, especially to SWs; and implementation of monthly integrated SRHR/HIV service outreaches in targeted sex-worker hot-spots.
Results: 1,530 FSWs were reached in two years (2016-2017); general condom use increased by >50%, while female-condom use increased by >39%; use of modern FP increased by >50%; STIs reduced by 59.5%%; while abortion-related cases reduced by >70%.
Lessons learned:

- The peer-to-peer approach and integration of HIV/AIDS and SRHR/FP interventions are effective for highly mobile KPs in resource-limited settings.
- Effective use of the female condom, empowers women and reduces multiple SRH risks.

Conclusions/Next steps: Participatory community-facility mechanisms should be designed, specifically target and collaborate with KPs to address the persistent SRH/HIV risks in resource-limited countries.

Methods to improve service quality, support and tailoring of services

WEPEE624

Implementing the Test and Treat policy: Increasing access to quality HIV care services at 11 USAID / Strengthening Uganda's Systems for Treating AIDS Nationally (SUSTAIN) supported hospitals

P. Donggo, G. Tugume, H. Alima, B. Tumusiime, M. Arinaitwe
URC University Research Co., LLC, Kampala, Uganda

Background: Uganda adopted the UNAIDS 90-90-90 strategy in 2015. The second and third 90s stipulate that 90% of people with diagnosed HIV infection should receive sustained antiretroviral therapy (ART), and 90% of these should achieve viral load suppression. However, only 46% of the 36.7 million people living with HIV (PLHIV) had received ART (World Health Organization [WHO] 2015), the majority initiating treatment with advanced HIV infection. Uganda's *Consolidated Guidelines for Prevention and Treatment of HIV (2016) recommend* that every HIV positive person should be started on lifelong ART despite their WHO clinical stage or CD4 count- "The Test and Treat" policy. Contrary to this guidance, staff at health facilities countrywide including 11 USAID SUSTAIN supported hospitals were not trained on the new guidelines. By December 2016 3,271 PLHIV in care were not on ART (pre-ART) at the 11 hospitals. Other barriers included *low ART stocks, poor client flow and low staff - patient ratio.*
Description: In February 2017 USAID SUSTAIN and the Ministry of health conducted a training of trainers followed by 3-day hospital-based trainings of medical, laboratory and data personnel, counselors, community

linkage coordinators, clinic volunteers and peer patients. We oriented them on the guidelines and gave them desk job aids, guideline booklets and standard operating procedures. We supported the ART clinic staff to establish quality improvement (QI) projects and assign roles to the QI team to implement the "Test and Treat" policy. Using a Ministry of health assessment tool, we reviewed implementation of the guidelines at one month and conducted mentorship and follow on assessments at three months post-training. We checked progress, identified gaps and made action plans to address them in the following month. Table 1 highlights these QI changes.

A multi-disciplinary team selected and assigned roles to accelerate new ART enrollment including conducting pre-ART counselling, forecasting and ordering adequate Anti retro-viral drugs for both new and old clients.
Continued Medical Education for all ART providers on the Test and Treat policy.
Generating a list of clients eligible for ART using the Uganda electronic medical records system.
Labeling HIV patient files with colored stickers that notify clinicians of clients who are not yet initiated on ART.
Data review meetings to assess progress on enrollment of pre- ART clients on ART
Daily health education sessions for clients on Test and Treat policy and referral of clients for adherence counselling.

[Table 1: Changes tested to increase initiation of HIV positive clients on ART at 11 USAID SUSTAIN supported sites]

[Chart 1: Total no. of adults and children receiving ART vs pre-ART at 11 SUSTAIN supported sites Oct'16 - Sept'17]

Lessons learned: Training and engagement of multidisciplinary teams increased enrollment on ART.
Post-training mentorships support adaptation to policy change.
Conclusions/Next steps: Systematic, implementation of quality improvement approaches through multidisciplinary teams enabled hospital teams to implement the Test and Treat policy.

WEPEE625

Modern response to modern living - addressing HIV service needs in spa and massage parlors for men having sex with men (MSM) in India

D. Kumar
India HIV/AIDS Alliance, Social Work, Noida, India

Background: HIV prevalence among MSM in India reported is at 4.3% in 2016. Despite of strategic HIV interventions from National AIDS Control Organisation (NACO), the prevalence among MSM remains significantly high. Punitive laws on homosexuality, stigma and taboo associated with MSM creates larger challenge on reaching to hidden MSM across India. The traditional sex sites have disappeared over times and the physical contacts have shifted to virtual contacts and sexual encounters are secretly done during spas and massage parlors in many countries including India.
Description: Samarth, (meaning 'empowered' in Indian language) is a programme based on the principle of 'test-treat-adhere-prevent' cascade for MSM and transgender population in India. The model aspires to establish strategies to support hard to reach clients for early testing to treatment linkages (after confirmatory test) for reactive clients and to repeat tests for people with negative results in every six months. Health camp approach has been taken to reach out to spas and parlors where MSM get door step services for HIV screening. People with positive screening results are then counseled and accompanied to government HIV testing centers and linked to treatment facilities if confirmed HIV positive.
Lessons learned: Confidentiality is extremely important for the population, they engaged in sex work as masseur. The Samarth clinic outreach is 'peer-base' and distributes condoms for safe sex and conducts health camps in nearby areas for them to access HIV services without apprehension. The spa owners and landlords of the rented space are the major stakeholders in the HIV prevention intervention.
Results: Samarth conducted 77 HIV screening tests in the intervention areas in three months. Nine people were screened positive, confirmatory test provide all nine positive who were then linked to treatment. Strategic events and activities needs to be planned on regular basis to engage these newly identified outreach sites for MSM activities.
Conclusions/Next steps: Samarth clinics have taken health camp approach by addressing HIV testing needs of the MSM community. Accompanied referrals were provided to test HIV is very important. Samarth is developing spa and massage parlor based male sex workers outreach guidelines to complement national HIV programme.

WEPEE626

Institutionalizing pharmacovigilance in an HIV treatment centre: Lessons from Baylor-Uganda

R. Sekabira, W. Mutabaazi, J. Tikabibamu, M. Kisekka, A. Kekitiinwa
Baylor College of Medicine Children's Foundation Uganda, Kampala, Uganda

Background: Pharmacovigilance augments patient safety and rational use of medications. Almost 50% of hospitalized patients in Uganda are prone to experience adverse drug reactions (ADR). The rate of ADR reporting to the national pharmacovigilance Centre is still low. This study aimed to assess interventions which would enhance and sustain ADR reporting in an HIV treatment Centre.
Description: The study took a Pharmacovigilance scope as prescribed by WHO; with emphasis on medication errors, ADRS and misuse of medicines.
To track medication errors, the facility established a quality control (QC) and Quality assurance (QA) in the pharmacy. Prior to medicine dispensation, a QC process was applied at recording of consumption, packing of prescribed medicines and medicine counselling all by different staff. QA or final review of both medicines and prescription was also done by a pharmacist or delegated staff. Identified errors were categorized, documented and client recalled for rectification if necessary.
For ADRs, a system to collect, report and effect preliminary analysis was established at the health facility. All filled Pharmacovigilance forms were collected by a focal person; who made submission to the Pharmacovigilance National Centre. Periodic feedback about individual Healthcare Provider (HCP) reporting rate was provided and response monitored overtime.
A perspective of product design was taken to assess *misuse of medication*. Piloting the capacity of HCP and clients to distinguish medicines with similar colour and packaging material in an HIV treatment centre.
Lessons learned: Between January and June 2017, the QC and QA unit averted 50% (2/4) errors due to sudden regimen switch, 79% (15/19) due to wrong doses and 61% (11/18) due to less or excess pills.
ADR reports increased from 7(2013) to 32(2014) and from 12 (2016) to 26(2017), all associated to HCP feedback. Product design contributed to 36% and 70% of medication misuse among HCP and clients respectively.
Conclusions/Next steps: A deliberate effort to strengthen pharmacovigilance among HIV treatment facilities is required because it will inform clinical practice and improve patient outcomes. Pharmaceutical manufacturers should also standardize their products in terms of color and packaging to mitigate medication misuse associated with product design.

WEPEE627

Advantages and challenges in providing medical & mentoring services through the pediatric HIV telemedicine initiative: A qualitative research

M.V. Manglani[1], M.M. Lala[1], Y. Gabhale[1], S. Balakrishnan[2], K. Bhuyan[2], B.B. Rewari[3], P. Singh[4], I. Kundan[4], M.S. Setia[5]
[1]Pediatric Center of Excellence for HIV Care, Lokamanya Tilak Municipal Medical College & General Hospital, Department of Pediatrics, Mumbai, India, [2]UNICEF, Mumbai, India, [3]NACO, New Delhi, India, [4]Maharashtra State AIDS Control Society, Mumbai, India, [5]The Pediatric Center of Excellence for HIV Care, Lokamanya Tilak Municipal Medical College & General Hospital, Epidemiology, Mumbai, India

Background: In October 2013, a pilot Pediatric-HIV Telemedicine Initiative was started at the Pediatric-Centre-of-Excellence-for-HIV-Care (PCoE) of Maharashtra state to provide video-linked delivery of expert medical and mentoring services as adjunct to existing services at peripheral ART-centers, as most are not manned by pediatricians/ HIV-specialists. Complicated patients are referred, but often do not reach higher centers due to several constraints. We assessed acceptability and feasibility of Telemedicine in patients, their caregivers & health-care providers.
Description: Scheduled and Need-based real-time video-conferences [VC] are conducted with patients, their caretakers along with the treating team at the Telemedicine-linked peripheral ART centers, so also mentoring sessions and mortality reviews for overall capacity building. The study period was October 2013 through June 2015.
We conducted 6 Focused-Group-Discussions [FGD] (48 participants) and 18 In-Depth-Interviews [IDI] with medical officers, counselors and pharmacists in 6 selected ART centers (3 Linked and 3 Non-linked).
Overall experience about care, problems faced, possible solutions were discussed; at Linked-centres, specifically about acceptability and challenges of telemedicine; at Non-linked centres, if telemedicine would be acceptable and beneficial, and if so, how. The data was analyzed using thematic frame work approach using NVivo software.
Lessons learned: Children and caregivers were comfortable communicating and found the technological aspects attractive; some reported it was as satisfying as being seen by a doctor in person. The reported advantages were: prompt consultation without having to travel to other cities saving time, money and effort. The challenges reported were: additional time spent and technical difficulties. The healthcare providers found it to be very useful.
The ´group counseling´ sessions wherein several children and caregivers interact, learn and motivate each other were particularly advantageous. Patients and healthcare-providers at Non-linked centres were aware of telemedicine from various sources and were eager to have it at their centres as well.
Conclusions/Next steps: We found that teleconsultation improved geographical and financial access to paediatric HIV care and was an effective, feasible, acceptable and desirable adjunct approach for patients, their caregivers as well as their healthcare providers. Healthcare providers wanted these services to not only continue in their centers, but also be initiated in the Non-linked centers.

WEPEE628

Differentiated service delivery: Harnessing the reach of faith-based organizations to deliver quality HIV services in Zambia

E. Mwila[1], K. Mwanda[1], M. Chikuba[1], P. Chungulo[1], I. Waddle[2], N. Daka[3]
[1]JSI Research & Training, Inc., International Division, Lusaka, Zambia, [2]United Church of Zambia (UCZ), Lusaka, Zambia, [3]Community Based TB/HIV/AIDS Organisation (CBTO), Lusaka, Zambia

Background: Zambia aims to reach HIV epidemic control by 2020, using the 90-90-90 yardstick[1]. However, the health system is currently over-extended with long wait-times for clients accessing HIV treatment services. In order to absorb and provide quality care for over 970,000 PLHIV who will be on ART for epidemic control, the country must institute differentiated service (DSD) to decongest the public sector.
Description: The USAID-funded USAID DISCOVER-Health Project implemented by JSI partners with the Ministry of Health (MOH) to take integrated HIV, reproductive health, family planning, and maternal and child health services into high-density under-served communities. The Project decongests over-burdened higher-level facilities through a network of 124 community-based newly established ART facilities. Finding the space to establish services was a big challenge - faith-based organizations offered their space, networks and reach, presenting a highly successful partnership, trusted by beneficiaries.
Through this partnership, services are provided through 32 newly-established prefabricated clinics at community level in Church grounds, offering free public-sector services. The Project also provides services through MOH health posts and community-based organizations for a total of 104 operational sites.
Lessons learned: A retrospective review of selected HIV indicators including quality of care indicators from inception of the project in 2015 to December 2017, revealed the following: Active clients 8,646 (90%), mortality 0.3%, LTFU 6.9%, Trans-outs 3.8%, viral suppression 90%. These indicators are better than the national mortality, LTFU and viral suppression estimates of 1.9%, 20%, and 77%, respectively. Strong church and community networks and partnerships (social capital) strongly facilitate service coverage and uptake, and influence good adherence to ART, and ultimately good health outcomes.
Conclusions/Next steps: DSD through leveraging faith-based platforms that have strong influence on and are trusted by community-members, has shown demonstrable effectiveness in addressing key barriers to accessing ART and other services.
Such partnerships take quality services where people live and respond to the expectations and needs of clients by reducing opportunity costs - distance, transport costs and travel-time. Importantly, this reduces the burden on higher-level facilities and contributes to quality HIV epidemic control.

WEPEE629

Responding to real needs - experiences from Wajood programme in India

S. Shaikh[1], A. Aher[2], S. Kundaswamy[2], V. Arumugam[2], H. Singh[2], S. Mehta[2]
[1]India HIV AIDS Alliance, Program and Policy, New Delhi, India, [2]India HIV AIDS Alliance, New Delhi, India

Background: In India, HIV prevalence among transgenders and hijras (TGH) is around 7.5% (NACO, 2016) which is manifold higher than the HIV prevalence among the general population (0.26%) (NACO 2016). While some progress has been made in responding to HIV in this population, a key issue for transgender women (TGW) still remains lack of sexual health services and enabling environment. India HIV/AIDS Alliance implemented "Wajood" programme in 5 states of India to increase the access to sexual health, violence mitigation and social welfare among transgender women and hijras.
Methods: Qualitative impact assessment study was conducted under Wajood programme and data were collected in 5 states where the programme was implemented. 12 focal group discussions (FGDs) (2 per site) and 10 in-depth interviews (IDIs) were conducted in these sites. Respondents for the study were selected purposively to maximise the validity and transferability of the data. Each FGD had 8-10 TGHs. The baseline survey was carried out in 2015 in the same states. Comparative content analyses were carried out using baseline and endline findings on the selected theme.
Results: Increased awareness on sexual and reproductive health (SRH) services including sex reassignment surgery (SRS) and availability of the SRH services in the Wajood implemented sites was seen.
Conclusions: Based on the findings from both qualitative study and secondary data analysis, Wajood is doing a commendable job of supporting the TGH community, however formulation of specific HIV guidelines or policy paper need to be developed for the community. Preparation of national clinical guidelines on gender transition and provision of services, especially SRS and hormonal therapy in government hospitals and provision of information and counselling on gender transition could be included through HIV prevention intervention.

Theme	Baseline	Midline
Crisis/ violence	- Extreme violence faced by TGHs verbally, physically and emotionally by family, police, community, clients, employers, partners and doctors. - Beating by police and goons was one of the frequently mentioned forms of violence. - Lack of help when faced with violence	- Violence is still there but reduced to a great extent. - There is more support from police who were one of the major perpetuators earlier. - They were confident of the support from Wajood who immediately came to rescue or resolve issues.
Human rights	- Faced insensitivity from everywhere - work, community, legal system, hospitals etc. - Not aware of identity documents even Aadhar card before Wajood - No support from police and lawyers to fight for the rights	- Wajood made lot of efforts to sensitize the society and organizations to help the TGH community access their rights - Very happy about the documents received due to Wajood - aware of their rights and could demand support from police and lawyers
SH services knowledge	- STIs and HIV were increasing because of unprotected sex work and other sexual violence. - Most seemed to opt only for castration and emasculation procedures through quacks. Not aware of SRS.	- Due to awareness and counselling from Wajood, they were very aware about the issues, prevention and treatments. - Aware of SRS and received counselling
SH services availability and accessibility	- Not aware about where to go and also hesitant to go due to stigma	- Aware of the options, increased availability to sexual health supplies from Wajood centers, camps by Wajood and linking with hospitals

WEPEE630

Supporting antiretroviral therapy multi-month scripting and dispensing at facilities in Zimbabwe: Effect on supply chain management

T.T. Fusire[1], M. Zvavahera[1], S. Murangandi[2], G. Fatti[3], N. Ngorima-Mabhena[4]
[1]Khethimpilo Aids Free Living, Programs, Harare, Zimbabwe, [2]Khethimpilo Aids Free Living, Programs, Bulawayo, Zimbabwe, [3]Khethimpilo Aids Free Living, Research, Cape Town, South Africa, [4]Khethimpilo Aids Free Living, Technical, Harare, Zimbabwe

Background: Treatment scale up has led to health facility congestion in high HIV burden countries due to monthly dispensing requiring frequent clinic visits. This practice has resulted in treatment interruptions and/or complete disengagement from care. Extending antiretroviral (ART) medicine refill intervals has successfully reduced frequency of clinic visits, in many settings.
The goal of multi-month scripting and dispensing (MMSD) is to reduce healthcare worker workload, improve long-term retention in care and enhance ART clients' participation in their health. This results in improved adherence and retention required to realize the benefits of ART which include optimum individual health and reduced transmission. Adequate medicine supply is a prerequisite for MMSD program scale up. The effect of strengthened support for MMSD on ART supply chain management was observed in Zimbabwe.
Description: Strengthened support was part of a cluster-randomized trial to assess the effectiveness of differentiated models of ART delivery for stable ART clients in 5 USAID-priority districts. MMSD was supported in 30 selected facilities from July-December 2017 to reduce congestion on the over-burdened facilities. MMSD was offered to stable clients who had been on treatment for more than six months, were free of opportunistic infections or serious drug side effects and responding well to therapy. Implementation was done in a systematic approach to ensure uninterrupted supply of ART. Quantification, forecasting, use of the pull system of ordering and stock control systems were strengthened to support ART MMSD.
Lessons learned: Through efficient medication quantification and stock forecasting, procurement was improved. Strengthening facilities on the use of the pull system of ordering resulted in improved stock management. The average stock levels of first-line ART in the facilities increased from 2.5 months' to above 3.6 months'. Frequent stock outs of second line ARVs observed before the support were eliminated. The proportion of clients on MMSD increased from 59%-76%. The biggest increase was observed in the proportion of clients receiving 6-month supply from 0.075%-3.4%.

Conclusions/Next steps: Strengthening of ART MMSD implementation resulted in an improved supply chain management system in the supported facilities. Systematic implementation of MMSD did not result in any medication stock-out but improved stock holding of the facilities.

WEPEE631

The use of the Clinical Monitoring System as a tool for monitoring the treatment gap in the State of Rio de Janeiro

J. Rebello Gomes, D. Ribeiro Franqueira Pires, P. Maria Sampaio Terra Monteiro, A. Vieira Tavares, J. Rodrigues Fagundes Neto, J. Maria Villas Bôas de Andrade, M. Maria Correia Zelaya, K. Regina Valente de Lemos
STD/AIDS Management, State of Rio de Janeiro Health Secretariat, Rio de Janeiro, Brazil

Background: The Clinical Monitoring System (SIMC) is an electronic tool built to cross-reference data from two databanks: the Laboratory Examination Control System (SISCEL), responsible for the storage of viral load test results and CD4 and CD8 T lymphocyte counts, and the Drug Logistic Control System (SICLOM), where antiretroviral drug dispensing is registered. The SIMC lists people who have already been linked to a public health service and have undergone HIV follow-up exams but have not started antiretroviral therapy.
The SIMC is a system for viewing and monitoring: 1. Treatment gap - people living with HIV (PLHA) who have not yet started antiretroviral therapy; 2. People who had their antiretroviral therapy (ART) initiated or modified 6 or more months prior and have detectable viral load; 3.People who abandoned treatment.
Methods: From the treatment gap list it is possible to identify people who could be in ART, subsequently look for them and offer treatment.
In July 2016, the STD/AIDS Management of the State of Rio de Janeiro in partnership with the Ministry of Health began monitoring the municipalities with the highest treatment gap.
The monitoring was initiated in partnership with the 08 municipalities that concentrated 82.2% of the treatment gap in the state.
During this period, municipalities were encouraged to use SIMC as a tool to improve the quality of care.
Each municipality designated a qualified professional to issue a SIMC treatment gap report with subsequent search for patients for ART initiation.
Results: The chart below shows the systematic reduction of GAP treatment that in the 18-month interval was about 50% of the number of people.

[GAP Treatment]

Conclusions: The data show a significant reduction of the treatment gap after the use of the tool. The next step is to expand its use to monitor treatment withdrawal and detectable viral load after 6 months of treatment.SIMC can contribute in a relevant way to and have a positive impact on the quality of life of PLWHA and AIDS mortality rate.

WEPEE632

Improvement collaboratives led by ministries of health to achieve global 90-90-90 targets: Examples from Namibia and Zimbabwe

B. Agins[1], A. Basenero[2], B. Khabo[3], D. Ikeda[4]
[1]University of California San Francisco, San Francisco, United States, [2]Ministry of Health and Social Services, Windhoek, Namibia, [3]Ministry of Health and Child Care, Harare, Zimbabwe, [4]HEALTHQUAL/UCSF, San Francisco, United States

Background: HEALTHQUAL with Ministries of Health (MOH) in Namibia and Zimbabwe have launched Quality Improvement (QI) collaboratives to improve gaps in the HIV treatment cascade to achieve 90-90-90 targets. Collaboratives are embedded within national MOH, and supported and co-led by local government. Each collaborative is led by MOH and layered onto existing structures, activities and programs, integrating into existing public health services.

Description:

1) a collaborative topic is selected;

2) a Design Meeting is convened to define collaborative aim, measures for monthly submission to track performance in run charts, select sites, draft the driver diagram, compile change ideas, define a timeline;

3) Pre-work is conducted to develop a readiness assessment tool, finalize data collection strategy, conduct site visits, identify site QI teams and focal people, finalize terms of reference, collect baseline data, finalize the driver diagram, and construct storyboards;

4) 3 Learning sessions (LS) occur during a 15-month collaborative each over 2-3 days, where teams share QI work.

5) During action periods, teams implement tests of change and submit data on Collaborative measures. Coaching is delivered by the QI team to guide and accelerate QI work.

6) After the final LS, summary work of the Collaborative is documented, shared with leadership, and disseminated.

Lessons learned: Improvements in HIV care and treatment outcomes have been achieved though QI Collaboratives. In Namibia, rates of viral load (VL) monitoring increased by 21%, rates of VL suppression increased by 8%, and loss to follow up rates decreased by 7% in 24 facilities over 7 months. In Zimbabwe, February to September 2017, the aggregate proportion of new-to-care clients who were initiated on ART on the same day of diagnosis increased by 13%; the proportion of previously-in-care clients who were initiated on ART on the same day of being brought back to care increased by 9%. A cumulative 1,238 previously-in-care clients were brought back to care across all of the 27 Collaborative sites, and 89% were initiated on ART on the same day.

Conclusions/Next steps: QI Collaboratives offer a fast-paced paradigm from which Ministries of Health can improve gaps in the HIV treatment cascade and achieve patient outcomes aligned with 90-90-90 targets.

WEPEE633

The continuum of HIV prevention and care among MSM and TW in Lima, Peru

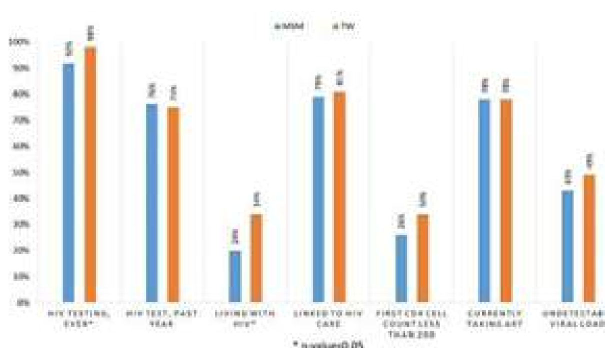
K. Konda[1,2], A. Maiorana[3], G.M. Calvo[2], A. Silva-Santiesteban[2], X. Salazar[2], E. Lugo[2], A. Nuñez-Curto Sifuentes[2], A. Motta[2], L. Price[3], P. Gonzales[4], C.F. Caceres[2], S. Kegeles[3]
[1]UCLA, Division of Medicine, Lima, Peru, [2]Center for Interdisciplinary Studies in Sexuality, AIDS and Society, Universidad Peruana Cayetano Heredia, Lima, Peru, [3]University of California San Francisco, Medicine, San Francisco, United States, [4]Hospital Maria Auxiliadora, HIV Program, Lima, Peru

Background: Key populations continue to face barriers (e.g. low access, stigma) that hinder their retention in various stages of the continuum of HIV prevention and care. Herein we explore this continuum among MSM and transgender women in Lima, Peru.

Methods: We conducted a survey with MSM/TW recruited via long chain peer referral; participation of individuals living with HIV was encouraged. HIV testing history was assessed among all participants, while those living with HIV were asked about engagement in care, quality of care, and experiences in care. Descriptive statistics are reported herein; differences between MSM and TW were explored using chi-square, t-tests and Wilcoxon ranksum tests, as required.

Results: Although significantly more TW reported living with HIV, the populations were similar in other aspects of the continuum of care. Both groups reported high rates of ever testing before, but only 75% tested in the last year. Many MSM/TW were diagnosed when they had low CD4 counts, and TW with HIV reach care with a greater delay, with 34% having CD4< 200 upon diagnosis vs. 26% among MSM; however, this figure was only available for a subset of the population as 20% did not know this information. Although 78% of both groups reported currently taking ART, there was only moderate adherence with 35% of MSM and 29% of TW reporting no missed doses of ART in the past 6 month. An undetectable viral load was found in less than 50% in both groups. Barriers to care were similar for MSM and TW, such as not having medical insurance, self-efficacy for ART use, interference of treatment with life, and burden of HIV treatment (all t-test p-values>0.05). Patient-provider communication with regard to HIV was slightly, though not significantly higher among MSM (median 26.5 vs. 21.0, p-value= 0.121).

Conclusions: The continuum of HIV prevention and care among MSM and TW in Peru remains far from the 90-90-90 goals, although figures were better than former estimates. Programs tailored to these key population groups could help increase testing, improve access to/engagement in care, understanding of HIV treatment, and adherence to ART.



[Cascade of HIV prevention and care Among MSM and TW in Lima, Peru]

WEPEE634

Feasibility of improving access to antiretroviral therapy (ART) through community pharmacies in Mozambique

A. Maranga[1], E. Seni[1], S. Chicuecue[2], E. Oliveras[2], I. Libombo[3], S. Chalufo[3]
[1]Howard University International Mozambique, Maputo, Mozambique, [2]Family Health International (FHI 360) Mozambique, Maputo, Mozambique, [3]Central de Medicamentos e Artigos Médicos (CMAM), Maputo, Mozambique

Background: High patient volume and human resource constraints affect the quality of care and services available to patients on ART especially those newly initiated on treatment or with treatment challenges. Long waiting times have social and economic effects on patients and affect their adherence and retention. Decongesting public ART facilities enables health providers to focus their time and effort on patients with the greatest need and subsequently contributes to improved quality of care. Community pharmacies present potential ARV dispensing sites that can help reduce public facility workloads and waiting time, contributing to better quality of care, and improved adherence and patient retention.

This study sought to establish the willingness of stable patients to pick up their ARV refills from community pharmacies while still accessing clinical care at public health facilities.

Methods: A cross-sectional study was conducted in four high volume urban health facilities providing ART in four provinces in Mozambique between October and November 2017. Structured interviews were conducted with 406 (254 male and 152 female) patients who had been on treatment for at least six months and were collecting their medicines from the health facility pharmacy; for patients under 5 years, the caregiver was interviewed. Descriptive data analysis was conducted using STATA; correlations were assessed using Fisher's exact tests.

Results: Most (84%) expressed willingness to pick up medicines from a community pharmacy. Willingness increased with education (Primary-47.6%; Secondary-59.0%; Tertiary-78.1%) and females were marginally more likely to express willingness to use community pharmacies than males (89.5% vs 81.1%). Although 69.2% of patients reported that the health facility pharmacy services were good, those who did not expressed higher willingness to use a community pharmacy (66.4% vs 52.0%). The leading reasons patients gave for willingness to use community pharmacies were saving time (32%) and increased flexibility (31%).
Conclusions: The acceptability of community pharmacies suggests that with the necessary infrastructural and policy support, they may be an effective strategy to decongest public ART facilities, provide information, and improve access to and quality of HIV treatment services. This study will be followed by a pilot of community pharmacy distribution to test their efficacy.

WEPEE635

Methadone dispensing systems in Medically Assisted Therapy for drug use harm reduction and linkage to HIV treatment and counselling: A case for secure, accurate and automated methadone dispensing

A.C. Kang'ethe[1], S. Abdallah[2], F. Sulliman[2], H. Manji[2], M. Hassan[3], M. Oloo[4], J. Njau[4], P. Ochieng[4], K. Shikely[5], F. Ibrahim[6], H. Musyoki[7], A.A. Baghazal[5], E. Mwamburi[8]
[1]*Jomo Kenyatta University of Agriculture and Technology, Mombasa, Kenya,* [2]*United Nations Office on Drugs and Crime, Nairobi, Kenya,* [3]*Kisauni MAT Clinic, Mombasa, Kenya,* [4]*Malindi Sub-County Hospital, Malindi, Kenya,* [5]*Mombasa County Health, Mombasa, Kenya,* [6]*Kilifi County Health, Malindi, Kenya,* [7]*National AIDS & STI Control Program (NASCOP), Nairobi, Kenya,* [8]*USAID, Nairobi, Kenya*

Background: Evidence shows Medically Assisted Therapy (MAT) is effective in reducing illicit drug use and HIV transmission among opioid dependent persons. However, the need to dispense methadone (a controlled drug) via observation daily to growing queues of clients on long term treatment is challenging for countries with human resource constraints. A user-friendly, affordable, efficient and secure automated dispensing system is essential for accurate dispensing since a wrong dose to a wrong patient may be fatal.
Description: Methameasure is a methadone dispensing system developed in the UK and piloted in UK, Canada and Australia. However, no country rolling out MAT in Africa has used Methameasure. Kenya rolled out MAT since 2014 in 4 counties, with support of UNODC, University of Maryland and ICAP. By mid-2017 six MAT sites had adopted Methameasure machines with variable ways of patient verification (Biometrics in Nairobi: 2, Kisumu: 1; Photo in Mombasa: 2, Malindi: 1). At least 2 pharmacy staff are trained on use at installation.
Lessons learned: By mid-June 2017 over 1900 clients were accessing methadone through Methameasure dispensing systems daily (Kisumu-50; Malindi-609; Mombasa-569; Nairobi-about 680). All sites confirm patient safety, ease of use, speed and precision in individual dispensing and MethaMeasure recording.
However, a key issue with the system is absence of standard specifications to assure smooth functionality amidst rising client load. Once the system records over 150,000 daily doses, dispensing time triples from 20 to 60 seconds/client or 5.5 to 8 hours per 500 clients, long queues, escalate conflict and stress among clients and staff.
Other challenges with Methameasure scale up include: high cost ($20,000 to $30,000 per machine); different software versions; partial bio-data; inaccurate missed dose alerts; deficient monthly reporting, calibrating for different methadone formulations, post-dated prescription entry; documentation for special days/Ramadhan dispensing; inconsistent data back-up; no integration with other electronic medical recording systems; internet and power outages; no decision-support.
Conclusions/Next steps: Urgent need for Kenya MAT implementers in Kenya to develop regulations and standards for a harmonised methadone dispensing system, that is open-source, integrates data with existing electronic medical record systems and generates the requisite reports for effective treatment monitoring, with consistent back up at subsidized cost.

WEPEE636

Strengthening linkage between the clinical, social and community sectors: Contribution of OVC collaborative platforms to an integrated offer of quality services to OVC and their families in Côte d´Ivoire

M.A.F. Ankotché Ahui[1], K.R. Koffi[1], T.S. N'guessan[2,3], C. Koua Diézou[4], M.A. Dohou Koulaté[5], S. Améthier[1]
[1]*PN-OEV (National OVC Program), Coordination, Abidjan, Cote D'Ivoire,* [2]*Université Nangui Abrogoua, UFR des Sciences de Gestion de l'Environnement, Abidjan, Cote D'Ivoire,* [3]*Centre Suisse de Recherche Scientifique (CSRS), Abidjan, Cote D'Ivoire,* [4]*PN-OEV (National OVC Program), Suivi Evaluation et Recherche Opérationelle, Abidjan, Cote D'Ivoire,* [5]*PN-OEV (National OVC Program), Formation, Abidjan, Cote D'Ivoire*

Background: In 2016, Côte d´Ivoire estimated 476,391 Orphans and other Vulnerable Children affected by HIV and AIDS (OVC). The national response has often remained sectoral, only partially covering the needs of OVC and their families. In order to facilitate a holistic offer of quality services, the OVC National Program (PN-OEV) joined forces with various public and community stakeholders to build OVC Collaborative Platform (PFC) strategy in 2005.
Description: Built around the Social Center (SC), PFC allows constructive interactions among local actors (public, private, and community) involved in the fight against HIV and for children's protection. Two approaches were adopted: (i) decentralization which led to a communal organization and facilitated the coordination of interventions, and (ii) multi-sectorality (all actors working in children protection field) for ownership of the policy. End of November 2017, 1,984 public structures (40 health districts, 1,592 educational structures, and 350 local authorities), 10 international organizations, and about 350 community organizations implemented 57 PFCs. To assess the effect of PFCs, a literature review was conducted, in addition to the primary data collected using individual interviews with the 56[HJ(1] PFCs (SC, member organizations) from February to December 2017.
Lessons learned:
- Linkage between sectors has been strengthened: improvement of the reference and counter-reference system between community actors and public sector (clinical and social) has optimized service delivery for OVC and their families.
- National tools developed under PN-OEV leadership have been integrated in organizations practices.
- Collaboration between public and community sectors helped recover cases of OVC and their mothers lost to follow-up in the Prevention of Mother-to-Child Transmission programs.
- PFC has contributed to the regular participation of SCs in Health District Team meetings thus facilitating the strengthening of linkage between social and health sectors.

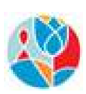
Conclusions/Next steps:
- Multi-sectoral approach and linkage between social, clinical, and community actors have made it possible to analyze the bottlenecks and provide an efficient and effective response to problems OVC and their families face.
- Extension of PFCs to other SCs, and strengthening of existing ones will help for better ownership and sustainability of a quality and sustainable response to the needs of OVC and their families.

WEPEE637

Exploring factors affecting the linkage to care of HIV positive young men who have sex with men in Hong Kong using focus group interview

T.F. Tong[1], S.P.Y. Ho[2], K. Chan[1], T.K.H. Lai[1]
[1]*Hong Kong Polytechnic University, School of Nursing, Hong Kong, Hong Kong,* [2]*Community Health Organisation for Intervention, Care and Empowerment, Hong Kong, Hong Kong*

Background: The HIV epidemics among men who have sex with men was not halted in the past decade with a growing number of Young men who have sex with men (YMSM) is infected in Hong Kong and neighboring cities in Shenzhen and Guangzhou.



Methods: YMSM and People living with HIV and AIDS (PLWHA) are marginalised and hidden population that is hard to reach. The understanding of the linkage to care will enable to success in the HIV care continuum. In-depth interview is used with a semi-structured questionnaires developed by an expert panel. 20 YMSM diagnosed with HIV were recruited using snowball sampling from drop in centre, HIV clinic and MSM communities of the social media. The interview was transcribed into verbatim and analyzed.

Results: YMSM were lost to follow up if they were not engaged to treatment after the initial testing. Various types of HIV test including self-test are available at present. The biggest leak was noted to be the testing of HIV status among high-risk population and the linkage to care in Hong Kong. YMSM failed to perform the test and to engage in the care continuum. The situation was worsen if they were tested at home or referred by general practitioners not familiarise with the HIV care and referral process. YMSM were more engaged in care if they attended a gay friendly non-government organisation for testing. The immediate psychosocial concerns in dealing with the diagnosis and treatment must be addressed in order to promote engagement of care. Prompt referral and shortening of the confirmation procedures would facilitate the engagement with treatment. As Hong Kong is providing free treatment to all PLWHA, the cost of the drug is less a concern. However, the HIV status may affect the employment and personal health insurance that deter some PLWHA fearing of disclosure of HIV status. More study is needed to review the structural barriers and its solutions.

Conclusions: To achieve the 90-90-90 goal treatment target to end the AIDS Epidemics by 2020. More efforts are needed to strengthen the treatment cascade through understanding the leakage.

WEPEE638

Implementing a performance based incentive system for outreach workers in a community based HIV care and treatment project in Zimbabwe

T. Tafuma[1], N. Mahachi[1], P. Mawora[1], T. Moga[1], T. Zulu[1], A. Muchedzi[1], T. Nyagura[2], M. Mpofu[3]

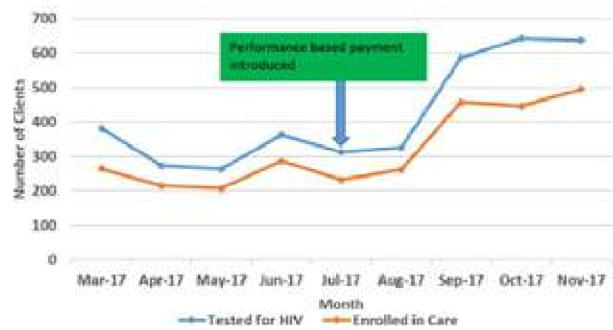
[1]FHI 360, Technical, Harare, Zimbabwe, [2]USAID, Technical, Harare, Zimbabwe, [3]FHI 360, Technical, Gaborone, Botswana

Background: FHI360-Zimbabwe's HIV Care and Treatment project implemented in 10 districts relies strongly on support from stable HIV patients on treatment called outreach workers (OWs) to identify index cases at facilities, obtain consent for home visit and peer support to linkage newly identified HIV positive clients. OWs are typically provided fixed monthly stipends ($25.00) for supporting the project. With the aim of increasing the number of newly identified HIV positive clients and linked to care, we report findings from a pilot of a performance-based payment initiative designed for OWs in two districts of Midlands, Zimbabwe for the period July to November 2017.

Description: The performance-based payment initiative was piloted in two high target districts namely Kwekwe and Gokwe South after sensitizing OWs. The performance of the system was assessed starting July 2017. During the pilot, an amount of $15 was paid to the OWs for index cases identified, and OWs received an additional $0.50 per every household tested that resulted in a newly identified person living with HIV, and an additional $1 for linking that client to care. Data was collected and analysed weekly, and monthly performance trends were produced for the two districts.

Lessons learned: A total of 51 outreach workers supported the districts. The project almost doubled the number of new positives identified from 312 to 586 in July and September, respectively reaching a peak of 642 in October. Performance was generally higher in sites located in urban areas than rural areas. District leads reported that rural areas have poor phone networks, bad roads and long distances resulting in some index cases not being reachable.

Conclusions/Next steps: Performance-based payment has demonstrated potential in increasing the number of HIV positives identified through the ZHCT project by motivating OWs. We recommend the project to roll-out this initiative while paying attention to area specific limitations such as transport and other communication constraints.



[Figure 1: Number of newly diagnosed HIV positive clients identified and Linked to care by month]

WEPEE639

Making a pivot to maximize impact: Age of clients at PEPFAR-supported voluntary medical male circumcision programs for HIV prevention, 2017

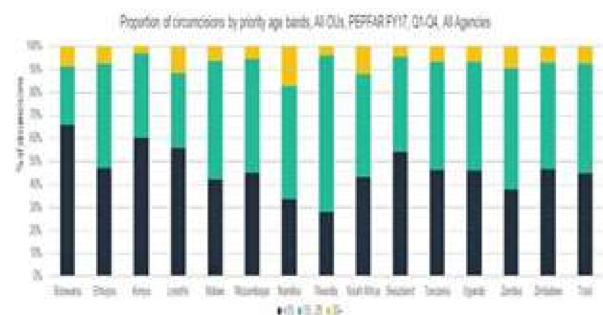
C. Toledo[1], S. Davis[2], A. Thomas[3], V. Kiggundu[4], C. Cooney[5], D.H. Watts[5]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, United States, [2]US CDC, Atlanta, United States, [3]US Department of Defense, Naval Health Research Center, San Diego, United States, [4]United States Agency for International Development, Washington, DC, United States, [5]Office of the US Global AIDS Coordinator, Washington, DC, United States

Background: Targeting voluntary medical male circumcision (VMMC) to males 15-29 years of age maximizes immediate HIV incidence reduction. Since 2016, PEPFAR has prioritized this age group for VMMC for HIV prevention in 14 southern and eastern African countries. However, uptake has historically been higher among 10-14-year-olds, and the new age focus has raised feasibility concerns.

Description: All PEPFAR-supported programs report numbers of men circumcised by standard age bands. Data are collapsed to less than 15, 15-29, and above 30 years of age.

Lessons learned: In 2017, over 3.4 million PEPFAR-supported VMMCs were conducted. Globally, 55% of clients were over the age of 15 (see Figure 1). Of these, 87% were aged 15-29 years. Rwanda had the greatest proportion of men over 15 years (73%) while Botswana had the lowest (26%). Tanzania conducted the highest number of VMMCs among men over 15 years (373,516 VMMCs). Globally, comparing 2017 to 2016, programs increased from 1.4 million to over 1.5 million clients aged 15-29 years; ten countries saw increases. Of these, four made considerable progress in increasing this age band in comparison to 2016; 5-10% more clients were aged 15-29 years in Malawi, South Africa, Swaziland and Tanzania. Seven countries had decreases in proportion 15-29 years of age, between 5 and 34% (absolute). Trend variations were noted between implementing partners operating in the same country.



[Proportion of Circumcisions by Priority Age Bands, PEPFAR, 2017]

Conclusions/Next steps: While some countries and implementing partners have successfully targeted and reached increasing absolute numbers of men in the 15-29 age group, many countries saw decreases in the proportion of priority men being circumcised in comparison to 2016. Successful strategies for reaching these males within and across country programs should be broadly shared as they may be valuable

to other HIV prevention interventions. As VMMC continues to scale up, countries with VMMC coverage gaps among men over 15 years will need to implement effective strategies to target these men, while countries with high coverage among this group will need to continue a shift towards younger men to maintain gains in VMMC coverage.

WEPEE640

Is MSM population effectively covered by HIV prevention services in high burden townships of Myanmar: Findings from programmatic mapping?

S. Hone[1], H.L. Oo[2], S. Phyu[3], Y.T.N. Oo[4], K.M. Htun[5], K.K.K. Nyunt[6], A.M. Soe[7], N.N. Myint[2], S.H. Aung[8]
[1]National AIDS Program, Department of Public Health, Yangon, Myanmar, [2]Alliance, Yangon, Myanmar, [3]UNAIDS, Yangon, Myanmar, [4]Department of Medical Research, Yangon, Myanmar, [5]ICAP, Yangon, Myanmar, [6]National AIDS Program, Department of Public Health, Nay Pyi Taw, Myanmar, [7]World Health Organization, Yangon, Myanmar, [8]FHI 360, Yangon, Myanmar

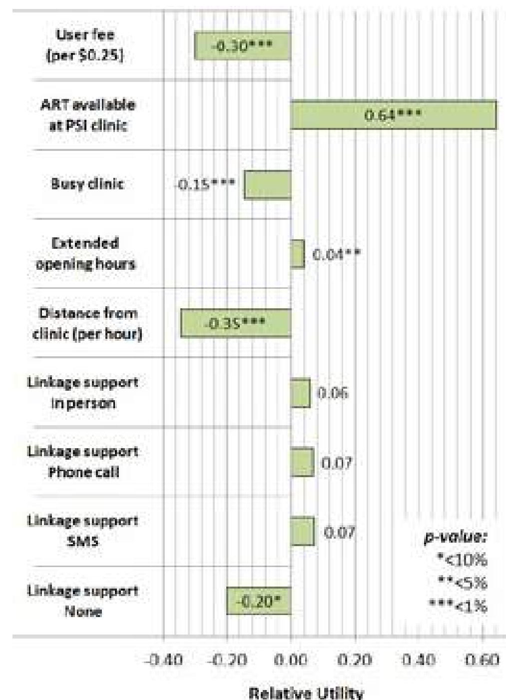
Background: In line with the Myanmar's National Strategic Plan for HIV/AIDS, programmatic mapping was conducted for men who have sex with men (MSM) to identify the characteristics of hotspots, barriers to access, service delivery gaps, and social networks in 46 high priority townships in 2016 to inform HIV prevention programming at sub-national level.
Methods: In each township, data collection was done through a field team consisting mainly of local MSM peers. It started with a list of known hotspots compiled with inputs from stakeholders, service providers and MSM representatives. On-site structured interviews, in-depth interviews and focus-group discussions with key informants were conducted.
Results: Hotspots were grouped into six categories: public spots, beauty salons, restaurants, entertainment sites, socializing spots and others. Of the total 1,538 MSM hotspots mapped: the largest proportions were beauty salons (27%), public spots (28%) and social spots (25%). Largest proportions of MSM were found in public spots (32%), social spots (23%) and beauty salons (21%). Most beauty salons were gathering sites for all MSM types, and owners of beauty salons were leaders in MSM communities/sub-communities. Sex took place in 45% of all hotspots. Outreach services covered 51% of all hotspots within one month before the mapping. Condoms were available at 62% of all hotspots. Prominent MSM community leaders, many of them respected by local MSM communities, were identified. The use of information technology for socializing and finding sex partners was common and growing, especially among hidden MSM. The most popular platforms were Beetalk, Facebook, Viber, Grindr and WeChat. There were exclusive MSM groups and local groupings on social media for easy networking among local MSM.
Conclusions: Findings highlighted the urgent needs to improve prevention service coverage and to design interventions deploying information technology. Service delivery modality channeling through less stigmatizing health programs and through networking with MSM community leaders should be considered in program design. In addition, prevention programs targeting specific hidden MSM subgroups, drama artists and migrants, should be established.

WEPEE641

Preferences for HIV self-testing distribution and linkage to care models: Results from discrete choice experiments in Zimbabwe

E. Sibanda[1], M. d'Elbée[2], G. Maringwa[1], N. Ruhode[1], M. Tumushime[1], C. Madanhire[1], P. Indravudh[3], C. Watadzaushe[1], C. Johnson[4], K. Hatzold[5], M. Taegtmeyer[6], J. Hargreaves[2], L. Corbett[2,3], F. Cowan[1,6], F. Terris-Presthol[2]
[1]Centre for Sexual Health & HIV AIDS Research, Harare, Zimbabwe, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Malawi-Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [4]World Health Organization, Geneva, Switzerland, [5]Population Services International, Johannesburg, South Africa, [6]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Background: New HIV testing strategies are needed to reach the UN's 90-90-90 target. HIV self-testing (HIVST) can increase uptake, but users' perspectives on optimal models of distribution and linkage to post-test services are uncertain. We explored preferences in rural Zimbabwe using discrete choice experiments (DCE).
Methods: DCEs are a quantitative survey method that present respondents with repeated choices between packages of service characteristics and allow the relative strength of preferences for each service characteristic to be estimated. Embedded within a population-based survey following door-to-door HIVST kits distribution by community volunteers (CVs) in Mazowe and Mberengwa districts, we administered two DCEs: one on distribution preferences and another on post-test/confirmatory testing preferences. Using the DCE, we simulated changes to confirmatory testing uptake at local public hospitals and Population Services International (PSI) outreach clinics attributable to hypothetical changes to service characteristics. Analysis among the general population and key groups used multinomial logit to identify subgroup heterogeneity in preferences.
Results: The distribution and linkage DCEs surveyed 296 and 496 participants, respectively, with 43% and 38% men in each. Free kits distribution by local CVs, and provision of multiple kits to whole households were strongest preferred attributes particularly relative to low user-fee (US$0.25 cents) and mobile clinic distribution. Men significantly preferred individual rather than whole household kit distribution. Testing support options (in-person or telephone) were less important, although never-testers valued phone helpline.
The strongest linkage preferences were for free services, within a short walking distance, with HIV treatment immediately available (Figure 1).



[Figure 1. "Linkage to care" DCE results. Service characteristics with a positive utility were preferred; those with a negative utility were disliked.]

Men reported higher willingness to link than women. Aversion to service fees increased with age.
Simulations suggested that antiretroviral therapy (ART) availability at PSI outreach clinics would increase linkage at this location, with lesser effects from extended opening hours and reduced congestion. Negative effects of service fees were strongest among men and the never-tested group.
Conclusions: Community-based approaches incorporating free distribution of HIVST by local volunteers, and convenient ART access were the strongest relative preferences identified. Accommodating linkage preferences to reach "resistant testers" with HIVST may maximise uptake of post-test services. Ensuring consistent ART at mobile PSI outreach clinics is likely to increase initial linkage rates.

WEPEE642

Bringing HIV care close to people, the experience of decentralization in Norilsk, Russia

I. Mukhratova[1], E. Tsareva[2], K. Kandlen[3], N. Mironova[4], A. Zacowicz[5], A. Chuykov[5]
[1]Norilsk State hospital #2, Norilsk, Russian Federation, [2]Norilsk State Hospital #2, Norilsk, Russian Federation, [3]AHF Russia, Moscow, Russian Federation, [4]AHF Russia, St.Petersburg, Russian Federation, [5]AHF Europe, Amsterdam, Netherlands

Background: Norilsk is a city with high HIV prevalence located far beyond the Arctic Circle. The most remote city districts, Kayerkan and Talnakh are located 30 and 40 kilometers from the AIDS clinic. Harsh weather conditions and remote location make medical services inaccessible for patients, leading to lower rates of HIV testing, challenges with retention in care and treatment adherence. The program intends to optimize service delivery by establishing access to HIV care at local clinics.
Methods: In 2015, AHF's program supported Norilsk hospital in their efforts to arrange the regular presence of HIV physicians at 2 local outpatient clinics in Talknakh and Kaierkan. The decentralization model includes onsite provision of ARV's by nurses, utilizing task shifting, providing social services such as patient follow up, bi-weekly blood sample collection, quick initiation of ARV treatment within 14 days from confirmation of eligibility. The analysis compares the situation prior to decentralization in 2015 with December 2017.
Results: The number of clients grew four times from 237 in 2015 to 840 in 2017 in both sites. Talnakh increased its number of patients to 597 and Kaierkan to 243 patients in December 2017. HIV treatment coverage increased from 30 clients in Talnakh in 2015 to 298 clients in 2017. Similar increase was noted in Kaierkan from 30 clients to 63. 169 clients who previously refused or interrupted treatment were returned to care by the social teams in Talnakh and Kaierkan. The number of patients who initiated ART in 14 days increased from 13 clients in 2015 to 161 in 2017. CD4 level at ART initiation increased from 230 in 2015, to 289 in 2017. Average travel time to the clinics reduced from 90 minutes to 10 minutes.
Conclusions: The approach of decentralization of HIV service delivery resulted in providing easy access to HIV services. The approach led to an increase of the number of patients who are using HIV treatment services, who started HIV treatment and helped with earlier ART initiation. The intervention has a potential to be used as an effective HIV service delivery model in remote locations.

WEPEE643

Improving HIV testing services at selected USAID-funded sites in Haiti: Strategies, lessons learned and implications for the National AIDS Control Program results from EQUIP

M.L. Excellent[1,2], D. Lauture[1], F. Jean Louis[1], E. Emmanuel[1], J.W. Domercant[1]
[1]EQUIP-MatCH Haiti, Petion-Ville, Haiti, [2]University of North Carolina at Chapel Hill, Public Health Leadership Programme (PHLP), Chapel Hill, United States

Background: *Targeting* high-risk populations for HIV testing services (HTS) can potentially increase yield. *Provider-initiated testing and counseling (PITC)* can foster uptake of HTS and facilitates access to HIV services. Barriers to *PITC program success,* include lack of training and mentorship for healthcare providers, and monitoring and evaluation. In Haiti, HTS are primarily reported as voluntary counseling and testing (VCT); PITC is underreported and capacity for data disaggregation by testing modalities is limited.
EQUIP-Haiti details the outcome of its combined interventions aiming at improving HTS yield at selected sites in support to Haitian Ministry of Health (MOH).
Description: EQUIP-Haiti assisted the MOH in revising the national HTS algorithm and in updating registers for data disaggregation into different HTS modalities: VCT, index case testing, and PITC. EQUIP-Haiti conducted a training needs assessment at 39 sites nationwide. The core competencies to strengthen included, standardized filling of registers, pre- and post-HIV test counseling; standardized filling of notification card, and a comprehensive HTS training package was developed. Two HTS training sessions were conducted for 54 providers and were innovative because HTS providers were never trained before on HIV national guidelines and registers' filling. Following the HTS trainings, EQUIP-Haiti conducted regular mentoring visits to enhance providers' skills and improve HTS data quality.
Lessons learned: The need assessment helped tailor HTS training package to provider's training needs. The revision of the national HTS algorithm and data collection tools facilitates monitoring and supervision. Training sessions to strengthen providers' competencies reported 30% increase of median score, which represented a milestone, while onsite mentoring is critical for standardized HTS implementation. Revision of HTS registers to integrate testing modalities led to improved data disaggregation.
The following results observed after the interventions were: VCT=37%, PITC=54%, and index case contacts testing=9% compared to 63%, 35% and 2%, respectively before the interventions. HTS yield increased as evidenced by a positivity rate of 4.10% compared to 3.23% before the interventions.

[Improvement in the implementation of all three categories of modalities for HIV Testing Services(HTS) reported by USAID funded health facilities(n=69)]

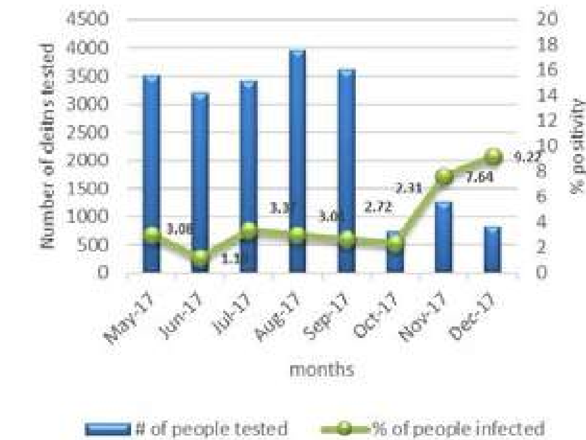
Conclusions/Next steps: Tailored trainings and on-site mentoring of providers markedly improved HTS yield. Improving HTS data quality and reporting will help the MOH in HTS strategic and programmatic decisions towards reaching the goal of testing 90% of people living with HIV in Haiti.

WEPEE644

Reaching the un-reached for achieving First 90 in the 90-90-90 cascade, family testing approach from Maharashtra, India

P. Deoraj[1], P. Singh[1], A. Phalake[1], H. Patel[2], K. Yewale[3], M.S. Setia[4]
[1]Maharashtra State AIDS Control Society, State Public Health Department, Mumbai, India, [2]World Health Organization (WHO), Strategic Information, Delhi, India, [3]World Health Organization (WHO), Strategic Information, Mumbai, India, [4]Consultant, Mumbai, India

Background: Disclosure of HIV status to the family members is a slow process. Though, the focus was on the individual client in the National programmes initially, since 2012, there is a greater emphasis on partner/spouse counselling and testing. Due to this about 85% of partners/spouses have been tested since 2012 at the testing centers; however, there was a backlog in testing of partners/spouses prior to 2012.
Thus, we initiated a community based programme to identify and test the spouses and children (in whom the female partner was found to be infected) in April 2017 in Maharashtra, India.
Description: The staff at the anti-retroviral treatment (ART) centres with support from PLHIV groups reviewed the records to identify family members that have not been tested. The data manager from each centre provided the list to the counsellor and the outreach workers (ORWs). The ORWs identified the PLHIV in the community and the counsellors counseled the index PLHIV about spouse testing. All the spouses came to the ART centre were counseled and tested for HIV. If the spouse was found to be positive, then the couple was counseled for child testing. The data manager maintained a record of the number of family members eligible and those who were tested. The doctor at each site monitored the progress every month and reported it to the State AIDS Control Society.
Lessons learned: We found that 125,621 family members (spouses/children) were eligible for HIV testing as of May 2017. Of these, 84,597 (67%) were already tested; thus, 41,024 family members needed to be counseled and tested. We had tested 20,527 (50%) of these till December 2017. Of these, 669 (3.3%) were found to be HIV infected (figure 1). From May to December 2017, we had successfully increased the family testing from 67% to 84% (p< 0.001).
Conclusions/Next steps: Intensive family tracking, counselling, and testing has helped in identifying and reaching out to individuals who are at-risk but have never been tested for HIV. Thus, these programme should be institutionalized in the existing ART programmes to reach out to the first 90 in the 90-90-90 cascade.



[Month wise testing Vs Positive in the family testing Drive]

WEPEE645

User-friendliness, accessibility, and confidentiality and privacy: How an interplay between these quality domains affects client satisfaction with HIV/AIDS services in Ukraine

A. Latypov[1], M.B. Hailemeskal[2], Y. Sereda[3], R. Dierst-Davies[4], T. Kiriazova[5], I. Pykalo[5], M. Duda[1], N. Avaliani[1]
[1]Deloitte Consulting LLP, The USAID HIV Reform in Action Project, Kyiv, Ukraine, [2]Deloitte Consulting LLP, Dallas, United States, [3]Independent Consultant, Kyiv, Ukraine, [4]Deloitte Consulting LLP, San Francisco, United States, [5]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine

Background: Ukraine has one of the most severe HIV epidemics in Europe and Central Asia, with an estimated 238,000 infected persons (population prevalence ~1.0%) in 2017. Globally, Ukraine is among 30 fast-track-strategy countries that generated more than 89% of new HIV infections in 2014. As retention in HIV care is related to client satisfaction with services, we evaluated the perceived quality of HIV services across three regions of Ukraine: Mykolayiv, Poltava, and Zhytomyr.
Methods: A mixed-methods proportional to size, cross-sectional design was used to recruit participants. In total 649 persons participated in an exit survey from across 47 health facilities in the three study regions. The study examined quality of HIV services along five domains:
(1) accessibility of services,
(2) user-friendliness,
(3) confidentiality and privacy,
(4) comprehensiveness of HIV testing and ARV treatment services, and
(5) overall client satisfaction.
Linkages between quality domains were measured by confirmatory factor analysis and structural equation modeling.
Results: Majority of participants were male (62%), unemployed or under-employed (60%), had low income (60%), and had a history of injecting drug use (68%). Overall, client satisfaction with HIV services was high (above 0.79 on a 0-1 scale), with clients from NGOs reporting the highest average satisfaction score of 0.93, while AIDS Center clients reported an average score of 0.73. Scores for the comprehensiveness of HIV counseling and testing and ART services were relatively low (0.64 and 0.77 respectively). Structural Equation Modeling revealed that satisfaction was both directly (=0.438; p< 0.001) and indirectly (=0.515; p< 0.001) positively related to user-friendliness. Accessibility (=0.213; p< 0.001) was directly associated with overall satisfaction, while confidentiality and privacy had indirect associations.
Conclusions: Results indicate that user-friendliness is the strongest predictor of client satisfaction, which in turn is primarily determined by perceptions of confidentiality and privacy, and overall quality of interaction with health providers. While training should be implemented to improve health providers' interactions with clients, task-shifting, staff augmentation, and innovative performance incentives should also be considered to improve client satisfaction. Decentralizing HIV services from AIDS Centers to primary healthcare facilities may also improve client access and satisfaction.

WEPEE646

Switching from the forceps-guided to the dorsal slit technique in a Voluntary Medical Male Circumcision (VMMC) program: Experience from Tanzania

A. Hellar[1], A. Christensen[1], J. Reed[2], A. Kapula[1], S. Mkungume[1], M. Machaku[1], K. Curran[2], P. Luvanda[3], G. Lija[4], E. Mlanga[5]
[1]Jhpiego, AIDSFree/VMMC, Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego, HIV ID Unit, Washington DC, United States, [3]President's Office Regional Authority and Local Goverment, Iringa RHMT, Iringa, Tanzania, United Republic of, [4]Ministry of Health Community Development Gender Elderly and Children, National AIDS Control Program (NACP), Dar es Salaam, Tanzania, United Republic of, [5]USAID, USAID/Tanzania, Dar es Salaam, Tanzania, United Republic of

Background: Prior to 2014, forceps-guided (FG) technique was the main method used in the scale-up of VMMC due to its time efficiency compared to sleeve resection (SR) or dorsal slit (DS) circumcision techniques. In July 2014, WHO recommended discontinuation of the FG technique among young adolescents due to an associated inherent risk of glans injury. Beginning in August 2014, the Strengthening High Impact Interventions for an AIDS-Free Generation (AIDSFree) Project, funded by PEPFAR and USAID, stopped using FG among those under 15 years and gradually phased out the FG technique among all VMMC clients. This action necessitated refresher training for all VMMC providers to ensure they had adequate skills to perform DS or SR techniques. We analyzed the impact of this change on client numbers and trends in reported adverse events (AEs).

Methods: De-identified VMMC client-level data were examined from October 2013 until September 2016. We analyzed the data according to the circumcision technique performed by age group each fiscal year and any adverse events during or following the procedure.

Results: There was a progressive switch to the DS technique, with a gradually higher proportion of clients circumcised by the DS technique at the end of fiscal year 2016 (Table 1). While FG was the most common technique used earlier in the program, DS became the method of choice for those under 15 beginning in 2014-2015, and the most frequently performed technique among all clients in 2015-2016. The moderate and severe AE rate per 100,000 procedures also declined across the analysis period from 5.3 in 2013-2014, 2 in 2014-2015, and 1.3 in 2015-2016. There were 2, 1, and zero instances of glans injuries in 2013-2014, 2014-2015, and 2015-2016, respectively.

VMMC Method	Oct 2013-Sept 2014				Oct 2014-Sept 2015				Oct 2015-Sept 2016			
	<15		15+		<15		15+		<15		15+	
	n	%	n	%	n	%	n	%	n	%	n	%
FG	76987	98.44	71075	97.95	372	0.70	41452	91.96	9	0.02	5239	13.01
DS	1164	1.49	470	0.65	53109	99.30	3618	8.03	38484	99.98	35044	86.99
SR	59	0.08	48	0.07	2	0.00	4	0.01	0	0.00	0	0.00
Total VMMCs	78210	100	72561	100	53483	100	45074	100	38493	100	40283	100

[Table 1: Analysis of VMMC techniques by Client Age from October 2013 to September 2016 in Tanzania]

Conclusions: The VMMC program in Tanzania has successfully transitioned from using the FG to the DS circumcision technique since the 2014 WHO recommendations. The data demonstrate that, with proper training, it is possible to completely change the surgical technique to enhance safety of the VMMC procedure. The reported number of AEs continued to decline over time, demonstrating increasing safety and quality of VMMC services.

WEPEE647

Lessons learned on improving the cascade of quality HIV/AIDS care through community and health system strengthening in Cambodia

S. Vanthuon[1], B.H. Leng[2], C. Sarath[1]
[1]AHF Cambodia, Phnom Penh, Cambodia, [2]National Center for HIV/AIDS, Dermatology and STD, Phnom Penh, Cambodia

Background: To extend and sustain a comprehensive continuum of care through correct adherence and compliance at both public and community healthcare facilities, we began providing four key interventions: building technical capacity, supporting quality assurance, supporting infrastructure and systems, and creating a community-enabling environment.

Methods: A qualitative method was used with different designs, a desk review and in-depth interviews with 15 key informants.

Results: Overall, more than 90% of clients who test positive for HIV within one month from any Voluntary Confidential Counselling and HIV testing (VCCT) site, had access to an ART site for continuum of care. All (100%) eligible clients with CD4 below 500/mm³ were initiated on ART. The ART coverage trend increased from 94% in 2011 to 99% in 2017. The proportion of clients who had a CD4 test in the past six months and the proportion with a viral load (VL) test was >90% and >95% respectively. Noticeably, the rate of undetectable VL increased from 91.7% in 2013 to 93.9% in 2017. Most importantly, the ART site returned on average 94% clients per month to care through the active mobilization of community participation and support.

Conclusions: The continuum of care and treatment for PLHIV at the sites we support appears to be successful in its effectiveness towards the goals and objectives (>90% of HIV positive receive ART, >90% have correct compliance and adherence, >90% have an undetectable viral load) and exceeds the set benchmark. Therefore, it is a good model for providing high-quality HIV/AIDS care to improve quality of life of PLHIV in Cambodia and could be replicated with significant confidence of meeting the "Three Zeros" in Cambodia by 2025.

WEPEE648

HIV performance measurement in correctional centres using a quality score: An example from Sierra Leone

W. Ameyan[1], J. Manley[2], E. Bunduka[3], M. Dumbuya[3], S. Diallo[4]
[1]Therapeutic Solidarity and Initiatives for Health (SOLTHIS), Freetown, Sierra Leone, [2]Male Correctional Centre, Regional Health Officer Wester Area, Freetown, Sierra Leone, [3]Male Correctional Centre, Freetown, Sierra Leone, [4]Therapeutic Solidarity and Initiatives for Health (SOLTHIS), Paris, France

Background: HIV service delivery in correctional facilities is an important part of the AIDS response in concentrated or mixed epidemics with under prioritized populations. Correctional services are often overlooked in performance monitoring, supervision and oversight. Part of the problems is generic as the criteria for performance measurement is often lacking. Solthis' Empower project in Sierra Leone devised and used a template to follow up the performance of critical process indicators in HIV service delivery to inmates at the main correctional facility in Sierra Leone to promote rights based services for inmates, while supporting health workers in adhering to processes that facilitate this right.

Methods: We implemented a HIV quality of care (QOC) score at a male correctional service with an inmate capacity of about 1,904. Project interventions included participatory needs assessments involving management staff, health workers and inmates; trainings and clinical mentoring. The QOC score comprises 15 indicators to monitor the quality of ART service delivery at the correctional facility and consists of the indicators, how indicator is to be measured and source of verification. The indicators include: Prescription of non-recommended ARV regimens; start of ART in line with national guidelines; CD4 monitoring before ART; clinical staging; use of registers; timely reporting; documentation; adherence assessment; TB screening; and retention in care. Each indicator is given a score of 0, 0.5 or 1 based on a defined criterion of measurement.

Results: The QOC score improved from 7% to 50% in the first 6 months. By the end of the second year, it had improved to 60%. Lack of resources in correctional facilities means that access to services like Hb, CD4 and viral load monitoring is still problematic for inmates. Privacy, stigma and confidentiality remain valid concerns affecting service delivery at correctional centres.

Conclusions: HIV service delivery at correctional facilities need an approach that combines results based monitoring with process supervision. Performance monitoring should include indicators that are context specific, easily measurable and verifiable. A HIV QOC score could be a valuable instrument in settings with similar contexts to highlight and fill gaps related to access and quality.

WEPEE649

Institutionalizing sustainable comprehensive sexuality education in a resource-limited setting: Lessons learned from teachers' sensitization

H. Bukola Yahaya[1], Y. Falola-Anoemuah[2], Y. Olaifa[3], T. Tokunyori Oladele[1], B. Olakunde[3], H. Aboki[1], A. Oluwatosin Ajiboye[1], E. Chime[4], N. Ifeayichukwu[5]
[1]National Agency for the Control of AIDS, Community Prevention, Treatment and Care Services, Abuja, Nigeria, [2]National Agency for the Control AIDS, Gender, Human Right and Care, Abuja, Nigeria, [3]National Agency for the Control of AIDS, NACA Project Implementation Unit, Abuja, Nigeria, [4]Federal Ministry of Education, Education Support Services Department, HIV/AIDS Unit, Abuja, Nigeria, [5]National Agency for the Contol of AIDS, Performance Management and Resources Mobilization, Abuja, Nigeria

Background: Comprehensive Sexuality Education (CSE) otherwise known as Family life and HIV/AIDS education (FLHE) programme was introduced in 2003 by the Nigerian Government to equip in-school youths with the requisite knowledge, values and skills to improve their reproductive health practices and prevent HIV. Though FLHE topics have been mainstreamed into school curriculum in the Federal Government Colleges (FGCs), the coverage of the programme were not being tracked by the teachers. Lack of adequate orientation of teachers on the delivery of CSE, its data capturing and reporting were identified as responsible.
Description: The World Bank HIV Prevention Development Project (HPDP II) through National agency of the Control of AIDS (NACA) supported the Federal Ministry of Education (FMoE) to scale up implementation of FLHE.
Teachers including vice principals, guidance and counsellors across 104 Federal Government Colleges were sensitized on FLHE for the 2015/2016 academic session. They were sensitized on the modalities for FLHE implementation such as curricular (classroom delivery), community awareness (modalities for central delivery of assembly talk) and peer education (songs, drama, dance) as well as data collation and reporting. Step down sensitization workshops were held for minimum of 18 Teachers and 2 Management staff in each school in order to dessemi-nate and deliberate on FLHE implementation strategies.
Lessons learned: **4,554** teachers and management staff (male: **2,261** and female: **2,293**) were sensitized. School managements adopted the FLHE implementation strategies and the use of school registers for reporting. About **97%** of the FGCs started reporting after sensitization workshop. **104,329** students (**37,752** male, **66,587** female) were reached with FLHE in the academic session.
Orientation is important for effective implementation, coordination and reporting of FLHE. The programme provided school management and teachers with understanding that FLHE can be implemented without additional resources for monitoring and record keeping.
Conclusions/Next steps: Strengthening FMoE for effective coordination FLHE implementation, data management on Education Management Information System and linkage with the National Health Management Information System. Advocacy to relevant stakeholders towards institutionalizing FLHE in Colleges of Education training curricula.

Prep: lessons learned from delivery

WEPEE650

Knowledge, attitudes and practices toward PrEP from MSM and transwomen in the largest suburban HIV epidemic in the United States

A.J. Santella[1], S.C. Cooper[2], A. Spieldenner[3], K. Rosales[4], H.E. Jones[4]
[1]Hofstra University, Health Professions, Hempstead, United States, [2]City University of New York School of Public Health, Community Health and Social Sciences, New York, United States, [3]Califrnia State University San Marcos, Communications, San Marcos, United States, [4]City University of New York School of Public Health, Epidemiology and Biostatistics, New York, United States

Background: Nassau and Suffolk Counties, home to 40% of New York State residents (subsequently referred to as Long Island), has the largest suburban HIV epidemic in the United States. Long Island, with its dense geography, inadequate public transportation, and racial segregation, is leaving vulnerable populations such as men who have sex with men (MSM) and transwomen isolated in poor communities with inadequate HIV prevention resources. HIV pre-exposure prophylaxis (PrEP) initiatives on Long Island have focused on MSM and transwomen as primary targets for prevention efforts.
Methods: We conducted a cross-sectional, online survey of MSM and transwomen between August and November 2017. Community members were recruited via medical and social service providers, LGBTQ community-based organizations, universities, social media, and word-of-mouth. The survey assessed knowledge, attitudes, and practices about PrEP. We present descriptive statistics on participants self-reports.
Results: 201 individuals who self-reported being HIV-negative participated in the survey. The sample was mostly MSM (90%), White (80%), with at least a high school diploma (97%): slightly over half were Hispanic (56%). Many reported both condomless insertive (80%) and receptive (72%) anal sex, being high or drunk during sex (70%), history of a sexually transmitted infection (59%), and diagnosis of depression (52%). While the majority had heard of PrEP (90%), only 87 (44%) persons had ever taken it. Participants indicated they strongly agreed/agreed on the following as main reasons for not taking PrEP: needing PrEP to be free/covered by insurance (95%) and not knowing how to obtain a PrEP prescription (82%). Many had sex partners (82%) and friends (77%) who had taken PrEP. 55% of those with concern about side effects versus 13% of those with no concern reported not being willing to take PrEP every day if they thought it worked ($p< 0.001$).
Conclusions: This data demonstrates that PrEP guidelines may need different strategies to increase uptake and usage among MSM and trans+ communities; especially those residing in suburban areas where there may be less PrEP providers. Additionally, addressing barriers by promoting patient assistance programs and building a larger network of PrEP providers may prove beneficial in increasing uptake.

WEPEE651

"*Now that PrEP reduces risk of transmission of HIV, why do you still insist that we use condoms?*" The condom quandary among PrEP users and health care providers in Kenya

E. Irungu[1], K. Ngure[2,3], K. Mugwanya[3], M. Awuor[1], A. Dollah[1], F. Ongolly[1], N. Mugo[1,3], E.A. Bukusi[1,3], E. Wamoni[1], J. Odoyo[1], J.F. Morton[3], G. Barnabee[3], J. Baeten[3], G. O'Malley[3], for the Partners Scale Up Project
[1]Kenya Medical Research Institute, Nairobi, Kenya, [2]Jomo Kenyatta University of Agriculture and Technology, Juja, Kenya, [3]University of Washington, Seattle, United States

Background: For decades, condoms have been the mainstay for HIV prevention. However, in 2015, the World Health Organization issued guidelines recommending use of pre-exposure prophylaxis (PrEP) by people with substantial HIV risk, in combination with other prevention interventions. With wide-scale implementation of PrEP, messaging on condom use by health care providers (HCP) is not well understood.

Methods: The Partners Scale-up Project is catalyzing PrEP delivery for HIV serodiscordant couples in HIV care clinics in Western and Central Kenya. We conducted in-depth interviews with 31 PrEP users and 37 HCPs to understand PrEP delivery processes. We used a combination of inductive and deductive approaches to identify themes relating to condom messaging and PrEP uptake.
Results: HCPs reported counseling PrEP initiators to use both PrEP and condoms in order to prevent unintended pregnancies and sexually transmitted infections. They counseled that PrEP would provide additional HIV protection if a condom breaks. HCPs asked PrEP users to be consistent with condom use especially during their first week of using PrEP. Few HCPs reported counseling that PrEP users could stop using condoms, outside of cases where conception was desired. However, HCPs were aware that many of their clients had did not use condoms consistently, either before or after starting PrEP.
Although all PrEP clients knew that condoms could prevent HIV before they started PrEP, many reported using condoms inconsistently due to desires for increased sexual pleasure, intimacy and conception. Some women also reported not using condoms to avoid conflict associated with asking their male partners to use them. Clients frequently reported starting PrEP as a welcome alternative to using condoms. However, some PrEP users reported getting confused by HCP insistence on continued condom use, in spite of the purported HIV protective factor of PrEP.
Conclusions: While HCP counseling on condom use in combination with PrEP sought to maximize prevention of all STIs, many PrEP users saw PrEP as an alternative to condoms. HCP insistence on continued condom use while taking PrEP may frustrate and discourage PrEP uptake amongst potential users. There is need for innovative ways to tailor messages around condom use in the context of PrEP use.

WEPEE652

Fewer than 1 in 6 gay/bisexual PrEP users receive comprehensive PrEP monitoring

J. Parsons[1], S. John[2], A. Talan[2], T. Whitfield[2], H.J. Rendina[1]
[1]Hunter College-CUNY, Psychology, New York, United States, [2]Center for HIV Educational Studies and Training, New York, United States

Background: Bacterial sexually transmitted infections (STIs) associated with decreasing condom use among PrEP users are a growing concern. In the US, guidelines for clinical follow-up and monitoring of PrEP users recommend ongoing STI screening every 6 months, with newer evidence suggesting every 3 months. In addition, quarterly HIV testing and assessment of sexual risk behaviors is recommended. Little, however, is known regarding fidelity to such comprehensive PrEP monitoring among GBM.
Methods: A US national sample of PrEP-using GBM (n=362; M_{age}=32.9 years; 53.4% White) were asked about their last PrEP visit. Comprehensive PrEP monitoring was defined as 1) blood-based testing for HIV and syphilis; 2) screening for chlamydia and gonorrhea via urine, rectal swab, and throat swab; and 3) assessment of sexual behavior and STI symptoms. Demographics (age, race/ethnicity, education, income, and health insurance status), any condomless anal sex (CAS; past 3 months), and healthcare provider type (specialty care/clinic versus primary care provider (PCP)) were regressed on having received comprehensive PrEP monitoring using fully-adjusted binary logistic regression.
Results: The majority of GBM had insurance (90.6%) and received PrEP-related care from a PCP (62.4%). Only 15.5% received comprehensive PrEP monitoring at their last visit. The majority (66.9%) reported being asked about sexual behavior, and 48.1% were asked about STI symptoms. Most (89.5%) received an HIV test, compared to only 47.8% who received a syphilis test. Urine, rectal, and throat STI testing were reported by 58.3%, 35.4%, and 35.4% of men, respectively. GBM who reported no CAS (AOR=3.81; 1.41-10.29, 95% CI) and those who received care from a specialty clinic/provider (AOR=3.51; 1.87-6.58, 95% CI) had higher odds of receiving comprehensive PrEP monitoring. There were no significant racial/ethnic differences in the adjusted model.
Conclusions: While most men had an HIV test and some discussion of sexual behavior at their last PrEP visit, most were not asked about STI symptoms, and only one-third reported rectal and pharyngeal STI testing. Fewer than one in six GBM received comprehensive PrEP monitoring at their last visit. Results indicate further efforts are needed to prepare healthcare providers, particularly PCPs, for managing patients on PrEP.

WEPEE653

Bridging the gap in accessing PrEP in Asia: Experience in the provider-assisted PrEP access (PrEP-PAPA) model in Taiwan

Y.-H. Chu[1], N. Yaemim[2], P. Phiphatkhunarnon[3], A. Charoen[3], W. Pumpradit[4], V.W. Tan[5], P. Huang[6], P.-C. Huang[7,8], F.-M. Jan[7], F. Hickson[1], S.W.-W. Ku[8,9]
[1]London School of Hygiene and Tropical Medicine, Department of Social and Environmental Health Research, London, United Kingdom, [2]Pulse Clinic, Bangkok, Thailand, [3]Love Foundation, Chiangmai, Thailand, [4]Bangkok Health Hub, Bangkok, Thailand, [5]Preptaiwan.org, Vensure Medical, Singapore, Singapore, [6]University of California San Diego, Department of Communication, San Diego, United States, [7]Taipei Veterans General Hospital, Division of Infectious Diseases, Department of Medicine, Taipei, Taiwan, Province of China, [8]Taipei Veterans General Hospital Hsinchu Branch, Division of Infectious Diseases, Department of Medicine, Hsinchu, Taiwan, Province of China, [9]HIV Education and Research Taiwan (HEART) Association, Taipei, Taiwan, Province of China

Background: Medication cost has been the main barrier to PrEP access for men who have sex with men (MSM) in Taiwan, where 77% are unable or unwilling to pay 340 USD per month for branded Truvada®. Similarly, one third of participants withdrew from Taiwan CDC's PrEP demonstration project because they could not afford the Truvada® they needed beyond the 105 tablets per year provided by the project. We present a provider-assisted model of PrEP delivery that aims to increase accessibility and affordability of PrEP among potential users in Taiwan.
Description: Since August 2017, the PrEP-PAPA model has been implemented through international collaborations between physicians in one public hospital providing PrEP in Taiwan (Taipei) and three private clinics in Thailand (two in Bangkok and one in Chiang Mai). Firstly, potential Taiwanese users visited PrEP providers in Taiwan for consultation and on-site laboratory tests (as per Taiwan National PrEP Guidelines). Next, Taiwanese PrEP providers confirmed users' eligibility and electronically sent prescriptions and laboratory results to private clinics in Thailand. Subsequently, Thai private clinics verified data and then delivered generic PrEP through online orders made by Taiwanese PrEP users at www.prepfirst.org/tw or www.preptaiwan.org. Taiwanese providers clinically monitored PrEP users every three months.
Lessons learned: By 17 January 2018, the PrEP-PAPA model had serviced 65 PrEP users. Pill costs were 14% of those in Taiwan CDC's demonstration project (NTD 1150 versus NTD 8110 monthly for daily regimen). 46% of users were formerly enrolled in the CDC demo project and continued to purchase generic PrEP after their subsidy ended. No participants were newly diagnosed with HIV infection after enrolment. 19% made orders within one week of consultations and 29% did not order PrEP online until three months after consultation.

[Table 1. Characteristics of participants of the PrEP-PAPA Model (N=65)]

Conclusions/Next steps: The PrEP-PAPA model increased affordability, drug quality assurance and convenience. It is a feasible alternative to escalate PrEP delivery in countries where generics are not yet available. Community-based education and raising awareness of PrEP services are necessary to increase the efficiency of provider-assisted PrEP services.

WEPEE654

Improving PrEP implementation through multilevel interventions: A synthesis of the literature

R. Pinto[1], K. Berringer[1], R. Meléndez[2]
[1]University of Michigan, Ann Arbor, United States, [2]San Francisco State University, San Francisco, United States

Background: Much research has emerged in the past decade on the myriad challenges to PrEP implementation worldwide. In the United States (US), this research has focused on barriers to effective PrEP implementation in communities disproportionately affected by HIV/AIDS, including gay and bisexual men and transgender women of color. While there is some agreement about what constitutes PrEP implementation challenges, this literature is disjointed and solutions to implementation challenges have been imprecise. This paper provides a comprehensive review of literature on PrEP implementation in the US and an analysis to support matching known challenges with precise solutions.
Methods: This integrative review summarizes research on PrEP implementation in the US between 2007-2017. Grounded in a socioecological framework, this review aims to identify and match patient-, provider-, and systems-level barriers to PrEP implementation with corresponding solutions. The review is focused on US-generated findings, but its analysis can inform PrEP implementation worldwide.
Results: Of 294 articles identified, 47 met our inclusion criteria. These papers reported barriers at three distinct domains: healthcare providers, individual patients, and the healthcare system. At the individual provider- and patient-level, articles frequently identified cognitive variables -- knowledge, attitudes and beliefs -- as barriers to effective PrEP implementation. At the healthcare systems-level, reported barriers included communication & awareness, funding, capacity & access, pharmaceutical barriers, and population-specific barriers & stigma. We found that proposed interventions in the literature often do not correspond to identified barriers. For instance, while a number of papers (n=18) focused exclusively on provider-level barriers, these papers often offered solutions exclusively targeting patient behavior. Moreover, frequently cited barriers to PrEP implementation often cut across all three levels, as in the case of the so-called "purview paradox" (i.e. the challenge that neither HIV specialists nor primary care providers consider PrEP implementation to be within their clinical domain) and structural barriers (e.g. patient mistrust based on historical legacies of structural racism and transphobia).
Conclusions: Given the interconnected nature of the barriers identified in the literature, we recommend that future interventions employ a unified approach that does not target providers, patients, and healthcare systems in isolation, but rather matches interventions to specific barriers across socioecological domains.

WEPEE655

Tracking oral PrEP globally: Using initiation trend data to inform product introduction

L. Fitch[1], J. Clancy[1], E. Donaldson[1], E. Gardiner[1], J. Reid[2], S. Jenkins[2], K. Callahan[2], M. Warren[1]
[1]AVAC, New York, United States, [2]Clinton Health Access Initiative, Boston, United States

Background: Oral pre-exposure prophylaxis (PrEP) has gained acceptability as a major tool for prevention since it was approved by the United States FDA in 2012. To date, 48 countries have begun offering PrEP through demonstration projects, implementation initiatives, and national programs. However, the decentralized nature of PrEP initiation data has proven detrimental for tracking progress. In order to address this challenge, AVAC began tracking global PrEP initiation in 2014 to generate new insights for product implementation and to inform advocacy efforts.
Methods: The global PrEP tracker includes a comprehensive database of information on ongoing and planned PrEP demonstration projects, implementation initiatives and national programs. Data is collected from projects through the dissemination of a quarterly survey covering PrEP initiation numbers, demographics, geography, funding, service delivery settings, program types, tools created and resistance testing. Regular updates from manufacturers and government partners are compiled to determine the number of individuals accessing PrEP through national health systems.
Results: December 2017 data indicates the number of people initiated on PrEP increased by more than 35% over the past year to total 189,170 globally. North America and sub-Saharan Africa currently have the highest overall number of initiations, accounting for 75% and 13% of the total number of users respectively. Regionally, Asia, Oceania and sub-Saharan Africa saw the greatest increases in PrEP initiation in 2017, with South America seeing the only regional decrease in initiations. Of the programs that disaggregate by population, the majority of reported enrollees are men who have sex with men, followed by female sex workers and adolescent girls and young women. These findings are estimated based on available data and may not include updated or disaggregated information from every project. Studies without confirmed initiation numbers were excluded.
Conclusions: The ability to track PrEP uptake globally is crucial for advocates, implementers and funders to discern where gaps exist and identify national, regional and global trends. The global PrEP tracker provides a baseline estimate for PrEP initiations and allows for dynamic assessment of initiation data. Increasing the visibility of this tracker and refining the data collection methods will increase the accuracy of the estimates and deliver actionable insights.

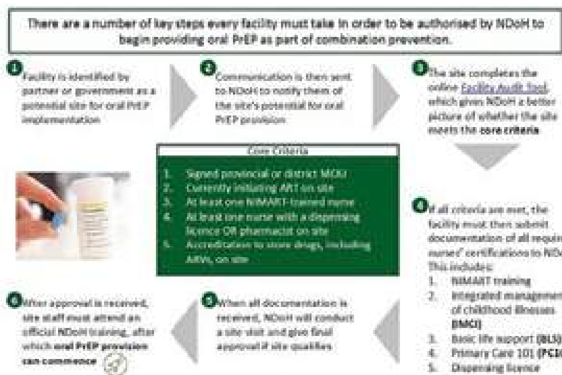
WEPEE656

Site-level process to oral PrEP implementation

N. Shoko[1], S.Y. Jenkins[1], S. Mullick[2], H. Subedar[3], Y. Pillay[3]
[1]Clinton Health Access Initiative, Pretoria, South Africa, [2]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [3]National Department of Health, Pretoria, South Africa

Background: The South African National Department of Health (NDoH) began a phased implementation of oral PrEP in 2016. Through partner and stakeholder engagement, implementation tools were developed to facilitate roll-out. A standardized approach to assessing and preparing implementation sites is a key component of this approach. This paper describes the implementation process of site readiness tools and discusses lessons learnt.
Description: A site assessment tool was designed through a consultative process led by NDoH and the National PrEP Technical Working Group (TWG) to assist with assessment of potential implementation sites. The assessment is a semi-structured tool consisting of closed- and open-ended questions on the following service delivery domains: human resources, drug and commodities procurement and supply chain, services delivered, including laboratory services and community engagement, and data management. The tool was administered through facility observations and interviews with clinic management staff.

Lessons learned: The tool was completed for 62 sites with a variety of target populations from March 2016 to December 2017. As of December 2017, 31 of the 62 (50%) assessed sites successfully fulfilled the criteria outlined and, following additional engagement, the sites began implementing oral PrEP. Eighteen sites are undergoing assessment. Sites assessed and not yet ready to implement are missing key assessment components. Of the 62 assessed sites, four (6%) lacked NIMART trained nurses and nine (15%) lacked professional nurses with dispensing licenses. Thirteen (21%) sites did not provide antiretroviral therapy (ART) on-site and twelve (19%) did not have signed Memorandums of Understanding (MOUs) with their respective Provinces and Districts.
Conclusions/Next steps: The assessment tool ensures a standardized readiness baseline, including services, personnel, systems, and funding, and clear understanding and expectations from NDoH for implementing and non-implementing partners engaged in oral PrEP implementation. The assessment tool allows for easy identification of potential implementation challenges, allowing for the development of tailored support plans and ongoing monitoring. Further, as additional HIV prevention options become available, NDoH can adapt the tool to ensure continued consistency for implementation readiness across varying sites.



[Figure 1 Steps to oral PrEP implementation]

WEPEE657

PrEP'ed for success? Lessons learned in PrEP implementation in New South Wales

J. Holden[1], C. Selvey[2], A. McNulty[3], R. Guy[4], H.-M. Schmidt[1], K. Price[5], D. Smith[6], B. Yeung[4], D. Halliday[1], G. Cabrera[4], E. Ogilvie[4], A. Grulich[4]
[1]NSW Ministry of Health, North Sydney, Australia, [2]Health Protection NSW, North Sydney, Australia, [3]Sydney Sexual Health Centre, Sydney, Australia, [4]The Kirby Institute, University of NSW, Kensington, Australia, [5]ACON, Surry Hills, Australia, [6]Lismore Sexual Health Centre, Lismore, Australia

Background: When New South Wales, Australia's most populous state, launched a HIV Strategy in 2012 government, community, clinicians and researchers reinvigorated their joint efforts to reduce HIV. The focus was on condom promotion, increased testing for earlier diagnosis and early treatment initiation to prevent transmission. By end 2015, testing had increased and 80% of people diagnosed with HIV were on treatment within six months of diagnosis. However, condomless anal intercourse among gay and bisexual men (GBM), the group at highest risk of HIV, had not declined. HIV diagnoses remained steady.
Description: In March 2016, a state-wide pre-exposure prophylaxis (PrEP) trial was implemented to rapidly achieve high PrEP coverage in GBM at high risk of HIV. It was anticipated that HIV incidence would fall within 12 months of enrolling around 4,000 participants. Nineteen publically funded, free sexual health clinics and three large HIV specialist general practices delivered PrEP free of charge to the client. Data were collected mainly through an existing system of automatic extraction of de-identified patient information from electronic medical records.
Lessons learned: Providing PrEP to over 8,000 people within existing services is achievable with clinical guidelines and streamlined models of care. This includes nurse-led counselling, care and dispensing, SMS messaging to confirm negative HIV and normal renal function test results to allow commencement of PrEP, and the use of peer educators. Creation of community demand via on-going social media and other platforms was very effective for Australian-born gay identified men, but less so for overseas-born men. Three-monthly STI screening resulted in large numbers of diagnosed STIs requiring efficient processes for recall and management. In parallel, condomless anal intercourse in GBM increased in the community, increasing the size of the target group for PrEP.
Conclusions/Next steps: Diagnoses of HIV with evidence of infection within 12 months of diagnosis have fallen in Australian-born men; but not in overseas-born GBM indicating the need for culturally appropriate strategies to engage this group. Federal funding of PrEP is expected, moving PrEP prescription to general practitioners (GPs) and necessitating rapid education of GPs about PrEP and effective STI management, targeted awareness campaigns for less engaged populations, and ongoing monitoring.

Testing and treatment at scale: issues and lessons

WEPEE658

Who does HIV viral load testing reach first? Lessons from Tanzania's first year of scaling up HIV viral load accessibility

G. Antelman[1], R. van de Ven[1], M. Mukaminega[1], D. Haule[1], J. van' t Pad Bosch[1], G. Somi[2]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Dar es Salaam, Tanzania, United Republic of, [2]Ministry of Health, Community Development, Gender, Elderly and Children, National AIDS Control Programme, Dar es Salaam, Tanzania, United Republic of

Background: Tanzania scaled-up HIV viral load (HVL) testing in 2016 through expanding laboratory capacity and specimen transport to processing hubs, with policies stating all ART patients should have HVL at 6, 12 and every 12 months after antiretroviral (ART) initiation. This analysis examines factors associated with HVL testing among eligible patients during early scale-up.
Methods: Electronic medical records from the national care/treatment database (n=198 clinics, six regions) were analyzed descriptively, and with logistic regression. 86,260 patients on ART visiting a clinic that provided HVL testing from October 2016-September 2017, and who were retained at least six months, were analyzed. Patients with their first HVL test during the study period were compared to patients who did not receive an HVL test. Independent variables included age, pregnancy, sex, CD4, ART regimen and duration on ART.
Results: HVL testing reached 22% of eligible ART patients overall: 17% of youth (15-24 years) received HVL testing, significantly less than the 23% in children < 15 and 22% in adults 25+ (p< .0001). Women recently or currently pregnant were more likely (33%, p< .0001) to receive HVL testing compared to non-pregnant women (22%) or men (21%). Patients with an unknown baseline CD4 were more likely to have an HVL test (23%), while patients with low baseline (< 200) CD4 were less likely (16%, p< .0001). HVL testing was more likely among patients on ART for more than one year (1-3 years: 19%, 4+ years: 26%) compared to those on ART 6-12 months only (14%; p< .0001), and patients on 2nd line ART were more likely to be tested (33%) compared to 1st line (22%). Selected adjusted odds ratios and 95% confidence intervals are presented in Table 1.
Conclusions: With HVL services still being scaled-up in Tanzania, these results describe how clinicians currently prioritize certain patients for HVL testing, such as those with a recent or current pregnancy, no baseline CD4 measure, on ART for longer, or on 2nd line ART already. As the program continues to scale-up, emphasis should be on ensuring adequate program support and clinician education to increase timely HVL monitoring for all eligible patients.

Variable	Category	Number HVL tested	%	p-value	Adjusted Odds Ratio	95% CI, lower	95% CI, upper
Recent or current pregnancy (<12m prior HVL)	no	12,696	22%	p<.0001	1.00		
	yes	772	33%		2.47	2.08	2.94
	male	5,498	21%		0.89	0.85	0.93
Baseline CD4 (ART imitation)	unknown	15,973	23%	p<.0001	1.16	1.07	1.24
	<200	762	16%		0.84	0.73	0.96
	200+	2,231	19%		1.00		
Duration on ART	6-12 mo	905	14%	p<.0001	1.00		
	1-3 yr	7109	19%		1.57	1.38	1.77
	4+ yr	10952	26%		2.04	1.74	2.40

A digital application for optimizing key population mobile testing in Jakarta's Fast-Track response

A. Human[1], S. Saifuddin[1], I. Afriyanto[1], M. Setyawan[1], E.R. Aditya[1], C. Francis[1], R. Ningsih[2]
[1]FHI 360, Jakarta, Indonesia, [2]Pact Inc, Jakarta, Indonesia

Background: Jakarta's Provincial Health Office articulated ambitious testing targets to reach a 2017 goal of diagnosing 9,292 people living with HIV (PLHIV). With more than 50 percent of new infections occurring among key populations (KP), impactful testing amplification strategies were needed to accelerate testing uptake among men who have sex with men, female sex workers, transgender women, and people who inject drugs. Test and triage modalities, including lay and self-testing, have not yet been integrated into Government policy and could not be comprehensively utilized to enhance coverage. Uptake of static voluntary testing and counseling (VCT) services has been constrained by restricted operating hours and human resources limitations, within a deteriorating political environment for KP programming. A Fast-Track approach for optimizing HIV testing across Jakarta was required.
Description: The USAID- and PEPFAR-supported LINKAGES Indonesia Project introduced DOKLING, an electronic HIV testing scheduler and tracking platform, in April 2017. Through a mobile phone or web browser, KP civil society organizations (CSOs) can directly request mobile testing visits from health facilities and receive immediate confirmation. Health facilities can plan for amplified testing coverage and dedicate appropriate technical, human and administrative resources for scale up purposes. When counseling resources are limited, facilities can use DOKLING to request counselors directly from CSOs. Mobile testing visit schedules can be shared with KP clients in advance - and across projects - to facilitate uptake. Fast-Track implementers can review DOKLING-generated encrypted testing data to assess testing coverage and case finding performance by CSO, facility, district and key sub-populations. Geo-location case-finding maps identify priority geographic areas for placement of impactful testing services.
Lessons learned: HIV testing among key populations increased by 86 percent between April and December with the introduction of DOKLING, and constituted 66 percent of VCT conducted at 21 facilities serving key populations. Reach-to-test ratios increased from 16% to 61% among three-quarters of PEPFAR-supported CSOs. Overall case finding rates averaged 590 KP PLHIV identified per quarter.
Conclusions/Next steps: Scalability of impactful interventions is aided by solutions that are easy to use, capitalize on the resources of diverse implementers, and use data for evidence-based planning and implementation.

WEPEE660

The surge: A targeted, multi-strategy approach to accelerate HIV case finding in Malawi

K. Simon[1,2], M. Hartig[1], E. Wetzel[1], E. Chester[1], C. Chembezi[1], A. Kabwinja[1], Z. Nkhono[1], E. Kavuta[1], R. Nyirenda[3], P. Kazembe[1,2], S. Ahmed[1,2], M. Kim[1,2]
[1]Baylor College of Medicine Children's Foundation-Malawi, Lilongwe, Malawi, [2]Baylor College of Medicine International Pediatric AIDS Initiative, Houston, United States, [3]Malawi Ministry of Health, Lilongwe, Malawi

Background: The WHO recommends a strategic combination of community- and facility-based HIV testing and Counseling (HTC) service models to improve the identification of people living with HIV (PLHIV). However, there is a paucity of literature describing the impact of an approach that simultaneously implements multiple HIV case finding strategies within routine program delivery. This study describes the impact of "The Surge", a targeted multi-strategy testing approach on HIV case finding in Malawi; where 27.3% of PLHIV are unaware of their status.
Methods: The Surge was a simultaneous implementation of six HTC strategies (enhanced outpatient department screening, index case testing, extended testing hours on weekends and evenings, testing during mobile outreach clinics, targeted community testing events, and scaled-up facility-based provider initiated testing) over a 6 week period at 19 health facilities in Malawi. The Surge also included increased supervision, infrastructural enhancements to provide additional testing space, and creation of a data feedback loop that provided weekly performance reports to facilitate real-time programming adjustments. Routinely collected, de-identified data from Ministry of Health HTC registers were used to determine number of tests performed and positive cases identified.
Results: In total, 29,533 HIV tests were conducted; 1,051 (3.6%) were positive. Of total tests conducted, 69.6% were amongst women and 77.0% were amongst those greater than 15 years. Yield was 3.3% amongst women, 4.2% amongst men, 1.5% amongst those 15 or younger, and 4.2% amongst those older than 15. The average weekly number of tests performed increased 51.6% during the surge from 3,337 to 6,896 (p=0.002). The average weekly number of positive cases identified increased 34.3% during the surge from 157.6 to 240.0 (p=0.017). The testing strategy resulting in highest yield was index case testing (5.7%). The strategy with the lowest yield was extended evening facility testing hours (1.2%). Yield for all strategies except index case testing was highest in adult men.
Conclusions: This study shows that a multi-strategy approach to HTC can be an effective means of accelerating HIV case finding; index case testing is particularly effective. Additionally, increased supervision, enhanced infrastructure, and real-time data feedback are critical factors in the success of a surge testing initiative.

WEPEE661

Can we achieve universal and annual HIV testing with home-based campaigns? Results from the ANRS 12249 TasP trial

M. Plazy[1], M.H. Diallo[2], M. Inghels[2], C. Iwuji[3,4,5], N. McGrath[4,6,7], D. Pillay[3,8], F. Dabis[1], J. Orne-Gliemann[1], J. Larmarange[2,3], ANRS 12249 TasP Trial
[1]Bordeaux University, School of Public Health (ISPED), Inserm, Bordeaux Population Health Research Center, UMR 1219, Bordeaux, France, [2]Centre Population et Développement, Institut de Recherche pour le Développement, Université Paris Descartes, Inserm, Paris, France, [3]Africa Health Research Institute, KwaZulu-Natal, Durban, South Africa, [4]Research Department of Infection and Population Health, University College London, London, United Kingdom, [5]Department of Global Health & Infection, Brighton and Sussex Medical School, Falmer, Brighton, United Kingdom, [6]Africa Health Research Institute, University of KwaZulu-Natal, School of Nursing and Public Health, KwaZulu-Natal, Durban, South Africa, [7]Academic Unit of Primary Care and Population sciences, and the Department of Social Statistics and Demography, University of Southampton, Southampton, United Kingdom, [8]University College London, Division of Infection and Immunity, London, United Kingdom

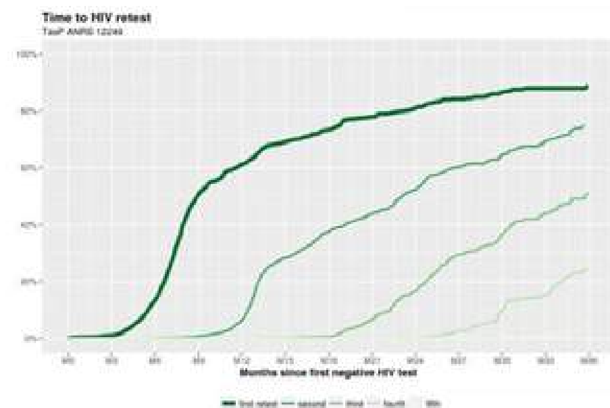
Background: Universal and regular HIV testing for early HIV-diagnosis is critical to reduce HIV incidence. Home-based HIV counselling and testing campaigns (HBHCT) have been shown acceptable and successful in high HIV prevalence setting, but little is known about the capacity of

such strategy to re-test people regularly. We aimed to describe time to, and factors associated with, repeat HIV testing through HBHCT in rural South Africa.

Methods: From March 2012 to June 2016, the ANRS 12249 TasP cluster-randomized trial aimed at evaluating the impact of a Universal Test and Treat (UTT) approach on population-based HIV incidence in a rural area of KwaZulu-Natal with about 30% HIV prevalence. In both arms, rapid HIV testing was offered at home every six month to all resident members aged ≥16 years old (about 1,000 individuals/cluster). Individuals who tested HIV-negative at first contact with TasP fieldworkers were included in the analysis. Times to HIV-retests since first HIV-negative test were described using Kaplan-Meier curves, with right censoring at the first positive rapid test, death, out-migration and end of observation. Factors associated with first HIV-retest were identified using Cox regression with time-dependant variables, and taking account of cluster effect.

Results: 16,372 individuals with a first HIV-negative test were included in the analysis. From the first HIV-negative test, the probability of one repeat HIV test after one year was 61.2%, the probability of two repeat HIV tests after two years and three repeat HIV tests after three years were 52.3% and 51.4%, respectively (Figure 1). Factors associated with first repeat HIV testing were female gender (HR=1.23; 95%CI=1.18-1.29), being 30-59 years old (HR=1.12; 95%CI=1.05-1.18) or >60 years old (HR=1.18, 95%CI=1.07-1.29) versus < 30 years old, being engaged but not married versus never engaged (HR=1.13; 95%CI=1.05-1.23), having low educational level (HR=1.20; 95%CI=1.12-1.28).

Conclusions: Home-based HIV testing campaigns could contribute to achieve the target of universal HIV testing and ultimately UTT but may not be sufficient considering the assumptions of the Granich's mathematical modelling (Lancet 2009). A combination of clinic-based and community-based strategies will be needed to maximise HIV testing coverage and specially reach men and youngest individuals.



[Time to HIV restest from first HIV-negative test in the ANRS 12249 TasP trial]

WEPEE662

How health workers motivated people living with HIV (PLHIV) to initiate antiretroviral treatment (ART) at high CD4 counts in three HPTN 071 (PopART) health facilities, Western Cape, South Africa

N. Peton[1], D. Wademan[2], P. Hendricks[2], C. Mubekapi-Musadaidzwa[2], G. Carolus[2], R. Mbaezue[3], G. Hoddinott[2], HPTN 071 (PopART)
[1]Western Cape Department of Health, Health, Cape Town, South Africa, [2]Stellenbosch University, Pediatrics and Child Health, Cape Town, South Africa, [3]City of Cape Town, Health, Cape Town, South Africa

Background: In 2016 South Africa adopted WHO recommendations of ART regardless of CD4 count for PLHIV. In 2016, ART coverage in South Africa was estimated at 56%. A shift toward increased uptake of ART at higher CD4 counts is required. Historically, health-messaging about starting ART have highlighted side effects, risks of acquired resistance, and triage of available treatment. CD4-count eligibility criteria and pre-ART counselling has reinforced a perception that PLHIV must be 'sick enough' to initiate ART. A shift in messaging is critical to increase uptake and ensure adherence. The study provides insight on ART messaging pre-national ART policy shift. How can we explain this policy shift to PLHIV and motivate them to initiate?

Methods: HPTN 071 (PopART) was a community-randomised trial in Zambia and South Africa. Patients at three health facilities in one arm of the trial in the Western Cape Province, were eligible for ART regardless of CD4 count outside of guidelines between June 2014 and September 2016. We conducted 134 randomly selected clinical patient folder reviews to characterise the sociodemographic profile of ART initiators under these conditions. We interviewed key informants (nurses, counsellors, post basic pharmacist assistants, data capturers and health management staff; n=12) about their experiences explaining initiating ART at high CD4 counts. The evaluation design was exploratory through case descriptions.

Results: The mean age of patients initiating ART at CD4 count >500 was 34.6 (range: 17-65; SD = 9.13) and most were women (74.7%), married (65.3%), and employed (42%). These sociodemographic characteristics were very similar to patients initiating ART at CD4 counts ≤500. Key informants indicated no radical shift was necessary to explain ART regardless of CD4 count. Rather, they (i) used a variety of metaphors to emphasize the importance of building a strong foundation and not waiting until HIV weakened the body, (ii) reiterated that ART prevents opportunistic infections, and (iii) emphasized that management of HIV through ART is comparable to other chronic diseases.

Conclusions: Motivating patients to initiate ART at high CD4 counts is possible even in high burden settings. Messaging about reduced risk of onward transmission was not a core component of health workers' narratives.

WEPEE663

Barriers and facilitators to improve antiretroviral therapy initiation among men who have sex with men and transgender women in Thailand

P. Saenyakul[1], C. Gregory[2], K. Sirisup[1], M. Avery[1], R. Vannakit[3]
[1]Family Health International 360, LINKAGES-Thailand, Bangkok, Thailand, [2]Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [3]United States Agency for International Development Regional Development Asia, Bangkok, Thailand

Background: There remain numerous policy, provider, and client barriers to immediate antiretroviral therapy (ART) uptake following HIV diagnosis in multiple countries. Thailand is no exception. Although between 2014 and 2017 ART coverage increased from 49 to 60 percent, many people living with HIV (PLHIV) have not received ART or received it long after diagnosis. In response to this challenge, the aim of this study was to collect PLHIV client experiences and perceptions about ART initiation and barriers to treatment uptake in both key population-led health services (KPLHS) and mainstream health services where clients are referred for ART.

Methods: The study was conducted in seven KPLHS in the four provinces in Thailand with the highest HIV burden among key populations (Bangkok, Chiang Mai, Chonburi and Songkhla). Focus group discussions (FGDs) and in-depth interviews (IDIs) were conducted from March to April 2017. A total of 40 PLHIV clients (28 on ART, 12 HIV treatment naïve) provided informed consent to participate in the IDIs (n=16 clients) and FGDs (n=24 clients).

Results: Barriers to ART initiation and retention in HIV care and treatment services included:
(a) service concerns, e.g., lack of privacy and confidentiality and readiness to disclose;
(b) concerns about health benefits, e.g., how to access universal ART;
(c) concerns about ART, e.g., antiretroviral side effects and ability to adhere to treatment;
(d) concerns about stigma and discrimination; and
(e) treatment literacy.
Facilitators to HIV care and treatment services identified included good provider-patient communication; high treatment literacy; guided referral to treatment services, including assistance in the transfer of treatment benefits; counseling on disclosure of HIV status; and effective interventions to reduce stigma.

Conclusions: Study results contribute to quality improvement of KPLHS by informing training of KPLHS staff on the importance of having trusting provider-patient relationships to help promote effective interventions to minimize stigma, improve self-efficacy, and promote adherence. These interventions are essential to reduce gaps in the HIV testing and treatment cascade and to maximize the individual and substantial public health benefits of universal ART in Thailand.

WEPEE664

Successful strategies to increase HIV case identification at public health facilities among males in Botswana

M. Ledikwe[1,2], N. Majingo[3], C. Petlo[3], O. Bakae[1], L. Tau[1], L. Seckel[2], S. Mawandia[1,2]
[1]International Training and Education Center for Health, Gaborone, Botswana, [2]University of Washington, Seattle, United States, [3]Botswana Ministry of Health, HIV Testing Services Unit, Gaborone, Botswana

Background: It is estimated that males account for a disproportionately high percentage of the undiagnosed HIV-positive individuals in Botswana. To achieve the UNAIDS 90-90-90 targets and reach epidemic control, innovative strategies are needed to increase HIV case identification among this priority population.

Description: Two strategies were employed to increase HIV case identification amongst men at 26 public health facilities in Botswana: extended hours testing, and use of a warm-line for scheduling testing appointments. Extended hours included evenings and weekends. The warmline was promoted through various traditional and social media outlets.

Lessons learned: Between June-December 2017, 73,258 HIV tests were administered, with 4,542 HIV cases identified in the supported facilities for a yield of 6.2%. The majority of tests (66,203, 90%) and cases (3,907, 86%) were identified during traditional facility hours (yield=5.9%). During extended hours, 7,055 tests were conducted with 635 cases identified (yield=9%). The percentage of males identified during extended hours testing was 63% compared to 37% during traditional testing hours. There were 642 HIV tests conducted following appointments through the warmline, with 86 HIV cases identified (Yield= 13.4%). Sixty percent were male. During standard-hours, it took approximately 20.6 Health Care Assistant (HCA)-hours to identify 1 HIV case. This increased to 31.3 HCA-hours per case during the weekend. This doubled to 62.8 HCA-hours per case during after-hours testing.

Conclusions/Next steps: Innovative strategies such as afterhours and weekend testing and implementation of a warmline are effective at increasing overall HIV case identification as well as case identification among males. While the absolute number of cases identified through these modalities were lower in comparison to HIV testing conducted during traditional hours, these modalities resulted in higher yield and a higher proportion of male cases. These data support the use of extended HIV testing hours and a warmline to supplement HIV testing services during traditional health facility working hours. Attention to linkage to care is a critical consideration for extended hours testing.

WEPEE665

Monthly baseline CD4 count trends of newly diagnosed HIV patients from 'test and treat' demonstration sites in Namibia

L. Bikinesi, A. Mengistu, N. Hamunime, S. Natanael, M. Kakubu, J. Kamangu, S. Mpariwa
Ministry of Health and Social Services, Special Programs, Windhoek, Namibia

Background: Before the fifth edition of the ART Guidelines was launched in November 2016 by the Ministry of Health and Social Services of Namibia, patients were initiated using a CD4 count threshold of below 500. An initial phase of 'test and treat' demonstration project was conducted where all HIV-infected individuals presenting to the selected ART sites were immediately offered treatment with TDF/XTC/EFV600 (tenofovir + [lamivudine or emtricitabine] + efavirenz 600mg) regardless of their CD4 cell counts or WHO clinical stages. The objectives included determining acceptability amongst patients and health care workers as well as evaluating the baseline CD4 count trends of newly diagnosed patients.

Description: 11 HIV care and treatment sites in three regions of Khomas, Ohangwena and Zambezi, were selected to implement this strategy. Patients were offered HIV treatment immediately after testing positive and comprehensive adherence counselling offered. Routine pre-treatment including baseline CD4 count data was collected from July 2016 to June 2017 using the electronic Patient Monitoring System (ePMS). This data was extracted from the ePMS, exported to excel and analysed using SPSS statistical software. Except for the immediate initiation of ART, the test and treat patients received the same standard of care that's being provided for all other patients in care and treatment in Namibia.

Lessons learned: There were a total of 2787 newly diagnosed HIV patients who were initiated on ART during the test and treat demonstration period of July 2016-June 2017 in all the 11 selected sites. The mean baseline CD4 count of the patients was 435.6 over the entire period. The mean CD4 count is lower than the 500 cut off used in the previous guidelines with no test and treat. Patients are still presenting themselves late for testing and treatment as demonstrated by low CD4 counts. The table below shows month on month mean baseline CD4 counts.

September 16	October 16	November 16	December 16	January 17	February 17	March 17	April 17	May 17	June 17
433.4	440.8	419.4	394.0	438.4	424.5	390.4	475.7	484.5	360.5

[Trends of Mean CD4 by month]

Conclusions/Next steps: 'Test and treat' alone will not result in patients being initiated at higher CD4 counts. Health education and routine HIV testing should be enhanced in order to diagnose HIV earlier thus initiate patients with CD4 counts higher than previous guidelines.

WEPEE666

Implementing the HIV "Treat All" Guidelines in Namibia: Patient and health provider perspectives

S. Tsang[1,2], B. Zieman[1], L. Stoman[3], L. Siluka[3], L. Vu[1]
[1]Population Council, Washington, United States, [2]Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States, [3]Survey Warehouse, Windhoek, Namibia

Background: In April 2017, the government of Namibia began a nationwide implementation of the World Health Organization's Treat All guidelines, which recommends immediate antiretroviral treatment (ART) for anyone who tests positive for HIV. This study sought to understand the perspectives of clients and providers regarding ART service delivery during the first three months of Namibia's implementation of the Treat All guidelines.

Methods: Three months after Treat All rollout began, research staff conducted 25 in-depth interviews with ART clients at ten health facilities in Northern Namibia. The team also facilitated six focus group discussions with 18 ART providers at these facilities. We double-coded and analyzed the IDIs and FGDs using ATLAS.ti 7 software.

Results: Most ART clients were satisfied with the knowledge of, interaction with, and treatment received from their main health provider. However, some expressed concern that their health provider was overburdened with a large case load. ART providers also commented that facility staff were generally overworked. Pharmacies, in particular, were a critical bottleneck. Although most ART clients were satisfied with individual interactions with pharmacists, many thought the pharmacies at their health clinic were significantly understaffed and caused long delays while clients waited for medication. Some clients suggested that facilities provide extended drug supplies to offset this problem.
Insufficient logistical support was also a concern among many health facility staff, who noticed shortages in HIV testing kits and medication. Most ART providers expressed a need for better job-specific training, more staff, and proper compensation—particularly with the additional workload that some facilities reported following the Treat All rollout. Finally, both ART clients and providers identified client transportation costs—including monetary costs and time—as a potential barrier to ART appointment attendance.

Conclusions: Although existing ART services provide a solid foundation for the rollout of the Treat All guidelines, numerous existing barriers may be exacerbated by expected increases in client load. As such, we recommend the following: expand implementation of community-level ART services, provide extended drug supplies to stable ART clients, evaluate the effects of the Treat All guidelines to understand implications for provider workloads and resource consumption, and expand human resources for health.

WEPEE667

Taking ART to the community to improve linkage to care of newly diagnosed HIV positive clients in a community based care and treatment project in Zimbabwe

P.W. Mawora[1], T.A. Tafuma[1], T. Zulu[1], T. Moga[2], L. Mangena[2], B. Basopo[1], A. Muchedzi[2], N. Mahachi[2]
[1]Family Health International (FHI 360), Monitoring and Evaluation, Harare, Zimbabwe, [2]Family Health International (FHI 360), Programs, HIV Care and Treatment, Harare, Zimbabwe

Background: The main challenge facing community-based HIV interventions is linkage to care for newly diagnosed HIV positive clients. By December 2016, 10 months into FHI360 Zimbabwe's 5-year USAID-funded HIV care and treatment project, month to month ART initiation rates averaged 53% against an 85% benchmark. Data from a linkage database introduced by the project in March 2016 cited time constraints and distance to the health facility as the two main reasons why clients were failing to initiate treatment in time.
Description: Starting in February 2017, the project piloted a new approach in Makoni District designed to increase diagnosis and treatment initiation in community settings. This was done in collaboration with facility based partners; Ministry of Health and Child Care and OPHID. The approach entailed transporting drugs to participating community locations, either on the day of testing to ensure same day initiation or on subsequent days based on appointments made with newly-diagnosed HIV positive clients. A WhatsApp platform was created to enhance coordination among partners. Clients initiated in the community were followed up for three months to ensure retention and adherence to treatment.
Lessons learned: · Community ART initiation is important towards plugging leakages in linkage to care for newly diagnosed HIV positive clients. The ART initiation rate in the project rose from 43.18% in February 2017 to 80% in March 2017 when community ART was rolled out. This was sustained such that by September 2017, the rate had reached 122%, which was a result of a mop up exercise done in the community to identify and initiate all clients with a pending initiation status from the previous months.
· 55% (444/805) of clients initiated on ART in the period February to December 2017 was through community ART initiation.
Conclusions/Next steps: · Community ART initiation improves linkage rates in community-based HIV interventions by addressing challenges faced by newly diagnosed HIV positive clients, including lack of time and long distances to health facilities for ART initiation.
· Scaling up community ART initiation to all project areas will help close leakages in linkage to care of newly diagnosed HIV positive clients.

[Figure 1 FHI360's improved ART initiation rates in Makoni District between February 2017 and December 2017]

WEPEE668

Impact of a universal test and treat strategy on retention in a public sector health system setting: Swaziland's *Max*ART trial, 2014-2017

S. Khan[1], D. Spiegelman[2], F. Walsh[3], S. Mazibuko[4], M. Pasi[4], B. Chai[2], E. Mafara[1], A. Hettema[1], C. Lejeune[1], T. Bärnighausen[2,5], V. Okello[4]
[1]Clinton Health Access Initiative (CHAI), Mbabane, Swaziland, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]Clinton Health Access Initiative (CHAI), Boston, United States, [4]Ministry of Health, Mbabane, Swaziland, [5]Heidelberg Institute of Public Health, University of Heidelberg, Heidelberg, Germany

Background: The World Health Organization (WHO) recommends offering antiretroviral treatment (ART) to all HIV-positive individuals regardless of CD4 count or disease stage, known as "universal test and treat" (UTT). In 2014, Swaziland launched the *Max*ART Early Access to ART for All trial to determine the "real world" implications of introducing UTT in its public sector health system. We report the retention outcomes from this health systems implementation trial.
Methods: We conducted a stepped-wedge trial from September 2014-August 2017 in fourteen public sector clinics in Swaziland. Clinics were paired and randomly assigned to transition from the current national guidelines (standard of care or SOC) to a UTT strategy (intervention) stage at each four-month step. All ART-naïve clients >18 years old who were not pregnant or breastfeeding were eligible for enrollment. Multivariable-adjusted Cox proportional models were used to compare retention at study completion. We carried out two analyses. In the first, patient assignment to the delay time until UTT access was fixed at the time of enrollment, depending on the clinic's intervention status at the time of the first patient visit, and the causal impact of the randomly assigned delay time was evaluated. In the second, exposure status varied according to the randomly assigned exposure sequence of the clinic at the first visit.
Results: A total of 3405 eligible clients were enrolled during the study period, of whom 1225 were ART-ineligible based on SOC at enrollment. The median age at enrollment was 33 years (IQR: 27-40) and 63% of the clients were women. For every additional six months of delay to UTT access, retention rates causally decreased by 7% (95% CI: 0.84-1.03, p=0.15). Similarly, when we treated the intervention as a time-varying exposure, clients enrolled in UTT were 60% more likely to be retained than those in SOC (RR 1.60, 95% CI: 1.20-2.14, p=0.001).
Conclusions: Retention in care was better among clients enrolled under a UTT strategy than under the standard of care. These results suggest UTT may have a beneficial impact on the overall performance of public sector ART programs.

WEPEE669

Tuberculosis preventive therapy in PEPFAR countries

J. Cavanaugh, J. Brown, A. Sanicki, H. Meri, G. Siberry
Office of the Global AIDS Coordinator, US State Department, Washington, United States

Background: TB preventive therapy (TPT) lowers mortality in persons living with HIV (PLHIV) and has long been a key WHO recommendation. Programmatic uptake has been limited, but data to inform programming are sparse and frequency of use of alternative regimens are largely unknown. We reviewed PEPFAR data to document programmatic uptake and completion of TPT, disaggregated by age and gender, and use of new regimens.
Methods: We conducted descriptive analyses of the number of PLHIV initiated on and scheduled to complete a course of TPT (or at least 6 months of isoniazid) and the number of people who completed such a course disaggregated by sex, age (< 15 vs 15+ years), and type of TPT. We restricted our analyses to PEPFAR-supported countries that reported TPT initiation in more than 5% of all PLHIV currently on antiretroviral therapy (ART).
Results: Eight countries reported initiating TPT in over 5% of the total number of PLHIV on ART; four countries reported TPT initiation in more than 10% (Table 1). Among those, TPT completion rates were highly variable, from 28% in Lesotho to 85% in Kenya and Swaziland. Democratic

Republic of Congo, Kenya and Mozambique initiated TPT in the highest proportions of PLHIV on ART; treatment completion rates, however, were reported as 53%, 85% and 49%, respectively. Use of alternative regimens was extremely limited, but continuous isoniazid preventive therapy was used in 15% of TPT in Mozambique (Table 1). Completion rates varied by age and gender and country, but there were no clear patterns in variability (Figure 1).

Conclusions: TPT was low across PEPFAR-supported countries. Completion rates were highly variable but there were no consistent differences by age or sex. Though completeness of reporting could not be verified, these data suggest gross underutilization and poor completion of TPT in many countries. PEPFAR has recently altered its indicator requirements to better track program progress in TPT initiation and completion. In countries which have a policy of one-time TPT, it will be most helpful to follow progress by tracking the clinical cascade, from screening to initiation and completion of TPT, in newly enrolling patients.

Country	TB Preventive Therapy Completion, % (numerator/ denominator)*	Number of PLHIV on ART	Proportion of PLHIV on ART that initiated TPT	Initiated Alternative Regimen	Initiated Continuous Isoniazid
Democratic Republic of the Congo	53% (10466/19845)	57704	34%	1	0
Haiti	67% (5082/7562)	85195	9%	0	0
Kenya	85% (165914/195319)	1011712	19%	2	678
Lesotho	28% (2324/8368)	140658	6%	0	0
Mozambique	49% (62503/128223)	909929	14%	36	18913
Nigeria	71% (43193/61161)	720272	8%	0	4
Swaziland	85% (13976/16381)	145891	11%	0	0
Vietnam	61% (2186/3590)	60113	6%	0	292

[Table 1. TB Preventive Therapy in Selected PEPFAR Countries]

WEPEE670

Are previously diagnosed HIV-positive patients returning to the clinic to initiate ART under UTT guidelines? A case study of ART management in the context of UTT

D. Onoya[1], C. Hendrickson[1], T. Sineke[1], M. Maskew[1], L. Long[1,2], M.P. Fox[1,2,3]
[1]*University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa,* [2]*Boston University, Department of Global Health, Boston, United States,* [3]*Boston University, Department of Epidemiology, Boston, South Africa*

Background: South Africa has adopted Universal Test-and-Treat (UTT) guidelines in order to reach the 90-90-90 targets set by UNAIDS. To achieve this, in addition to increasing HIV testing, all previously ineligible HIV-positive patients and those lost to follow up must be reengaged with care. We examine whether UTT implementation resulted in initiation of previously lost or pre-ART patients.

Methods: We conducted a prospective cohort study, enrolling newly diagnosed HIV-positive adults (≥18 years), regardless of CD4 count, at two primary health clinics in Johannesburg, South Africa between April and November 2015 while ART eligibility criteria were at CD4 < 500 cells/ mm³. Clinical information was collected from medical records up to 24 months following enrolment. We aimed to follow lost and previously ineligible HIV-positive patients through UTT implementation to assess whether these patients returned to initiate ART.

Results: We enrolled 148 adults (61.1% female) with a median age of 32.9 years (IQR: 27.4-37.8) at HIV diagnosis. Among those eligible for analysis (n=141), 27 (19.1%) did not return to receive their CD4 results, while 15 (10.6%) who received their CD4 results and were eligible were lost prior to ART initiation (Figure). Furthermore, 12 (8.5%) were not yet eligible to initiate ART and were considered to be in pre-ART care. Of those eligible and in care, 85.3% initiated treatment prior to UTT implementation, meaning that 54 (38.3%) were lost or ineligible by the time UTT was initiated in September 2016. Six months after removing the CD4 eligibility criteria, none of the pre-ART patients or previously lost had returned for ART initiation at these clinics and an additional 30 patients had been lost or transferred, resulting in an overall loss of 59.6%.

Conclusions: These results highlight a substantial gap in UTT policy implementation and the challenge to the 90-90-90 goals. This in-depth pilot study demonstrates that patients in the then pre-ART program or lost prior to ART initiation, are not returning for care at their diagnostic clinic under the new UTT guidelines. To achieve program success and the desired reduction in HIV transmission, it will be crucial to re-link this population to HIV care and treatment.

WEPEE671

Impact of universal test and treat policy on ART initiation among HIV positive patients in Johannesburg, South Africa

D. Onoya[1], T. Sineke[1], C. Hendrickson[1], M. Maskew[1], L. Long[1,2], M.P. Fox[1,2,3]
[1]*University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa,* [2]*Boston University, Department of Global Health, Boston, United States,* [3]*Boston University, Department of Epidemiology, Boston, South Africa*

Background: South Africa implemented Universal Test & Treat (UTT) guidelines in September 2016, eliminating the CD4< 500 cells/µl antiretroviral therapy (ART) eligibility threshold. We compare time to ART initiation pre- and post-UTT and examine predictors of ART initiation within 30 days of HIV diagnosis.

Methods: We conducted a prospective cohort study, enrolling newly diagnosed HIV-positive adults (≥18 years) at two primary health clinics in Johannesburg, South Africa. A baseline questionnaire on demographics and health seeking behaviour was administered at HIV diagnosis. Clinical information was collected from medical records up to 30 days after HIV diagnosis. We present crude risk ratios (cRR) for predictors of ART initiation within 30 days of HIV diagnosis, comparing patients diagnosed under the CD4≤500 cells/µl ART eligibility threshold to UTT using log-binomial regression.

Results: This analysis includes 258 adults (61.2% female; median age 32.9 years (IQR: 27.9-38.7) enrolled at HIV diagnosis, of which 115 (45.0%) enrolled under UTT. Overall, 166 (64.0%) initiated ART within 30 days (58.8% pre-UTT vs. 98.7% under UTT). The median time to ART initiation declined from 25 days (IQR: 17-37) to 8 days (IQR: 5-16) under UTT. UTT patients were 3.7 times more likely to initiate ART in the first month (RR 3.7; 95% CI: 2.7-5.2) compared with pre-UTT (Table 1). Compared to patients with CD4 count < 350cells/ul, patients with a CD4 count ≥500cells/ul were 40% less likely to initiate ART within 30 days (RR 0.6, 95% CI: 0.3-1.1). Among those who did initiate ART within 30 days, having a CD4 count >500 cells/ul increased the likelihood of ART initiation under UTT (cRR 26.3, 95%CI: 3.5-199.7) (Table 2). Patients living with parents/ relatives were 53% less likely to initiate ART under UTT compared with those living alone (cRR 0.5; 95% CI: 0.2 - 0.1) However, living with one additional adult in the household resulted in a 2.5 times increase in ART initiation under UTT compared with pre-UTT (cRR 2.5; 95% CI: 1.1 - 5.8).

Conclusions: We highlight a reduction in time to ART initiation after UTT implementation. However, our findings also identify important variables for further examination to close gaps in linkage to ART.

WEPEE672

Mobile and home testing identifies previously diagnosed HIV infected men and women who are not taking ART in Botswana

M. Roland[1], L. Block[2], P. Bachanas[2], M.G. Alwano[1], S. Lockman[3], W. Abrams[1], T. Gaolathe[4], E. Kadima[4], J. Makhema[4], S. El-Halabi[5], J. Moore[2]
[1]Centers for Disease Control & Prevention, Gaborone, Botswana, [2]Centers for Disease Control & Prevention, Division of Global HIV/AIDS & TB, Atlanta, United States, [3]Harvard T.H. Chan School of Public Health, Boston, United States, [4]Botswana Harvard Partnership, Gaborone, Botswana, [5]World Health Organization, Geneva, Switzerland

Background: Testing programs focus on identifying undiagnosed HIV positive individuals. Identifying and offering antiretroviral therapy (ART) to previously diagnosed individuals not on treatment ("legacy positives") may accelerate epidemic control.
Methods: The Botswana Combination Prevention Project (BCCP) is a randomized controlled trial in 30 matched rural or semi-urban communities. We describe legacy positive community residents by age, sex and testing strategy in the 15 intervention communities where mobile and home testing strategies were employed between October 2013 and September 2017.
Results: Among 61,129 participants whose HIV and ART status were assessed (documented results in prior 3 months or tested), BCPP identified 11,637 (19.0%) HIV positives, 3,252 (27.9%) of whom were not currently on ART. Of these, 1,874 (57.6%) were newly diagnosed and 1,378 (42.4%) were legacy positives. Of the legacy positives, 492 (35.7%) had previously taken ART (365 [74.2%] females). More female than male legacy positives, 960 and 418 respectively, were identified, with the majority identified with home testing (Table 1, Panel A). A larger proportion of female than male positives not on ART were legacy positives in all age bands and for both testing strategies (Panel B). Within the legacy positives (Panel C), the oldest age categories represented the largest proportion of legacy positives for both sexes. While fewer male legacy positives were identified, the oldest age group represented over two-thirds of the males identified with both mobile and home testing.

Panel A. Age and Sex of Legacy Positives

Sex	Age (years)			
	16-24	25-34	35-64	
	Number (percent)			Total
Female	124 (12.9)	350 (36.5)	486 (50.6)	960
Male	19 (4.5)	114 (27.3)	285 (68.2)	418

Panel B. Proportion of Total Positives not on ART that are Legacy Positives, Identified by Testing Modality

Testing Modality	Sex	Age (years)			
		16-24	25-34	35-64	Total
		Number Legacy/Total Positive (percent)			(percent)
Home	Female	80/179 (44.7)	249/390 (63.8)	379/605 (62.6)	708/1174 (60.3)
	Male	14/49 (28.6)	61/187 (32.6)	161/403 (40.0)	236/639 (36.9)
Mobile	Female	44/244 (18.0)	101/268 (37.7)	107/248 (43.1)	252/740 (34.1)
	Male	5/61 (8.2)	53/261 (20.3)	124/373 (33.2)	182/695 (26.2)

Panel C. Age and Sex Distribution of Legacy Positives Identified by Testing Modality

Testing Modality	Sex	Age (years)			
		16-24	25-34	35-64	
		Number Legacy/Total Legacy (percent)			Total
Home	Female	80/708 (11.3)	249/708 (35.2)	379/708 (53.5)	708
	Male	14/236 (5.9)	61/236 (25.8)	161/236 (68.2)	236
Mobile	Female	44/252 (17.5)	101/252 (40.1)	107/252 (42.5)	252
	Male	5/182 (2.7)	53/182 (29.1)	124/182 (68.1)	182

[Table 1. Legacy Positive Individuals Identified in 15 Rural and Semi-Urban Botswana Communities]

Conclusions: Legacy positives represented over 40% of HIV-infected individuals not on ART and are an important population to identify and support to initiate ART. Consistent with the HIV epidemiology in Botswana, more female than male legacy positives were identified and identification rates increased with age. Women represented a large proportion of participants who had previously taken ART, likely due to the pre-Option B+ PMTCT era. Home and mobile testing identified previously-diagnosed older men in need of ART in rural and peri-urban Botswana. Older men are drivers of HIV transmission and more difficult to identify and initiate on ART throughout Africa. Linkage to ART strategies for legacy positives should be implemented in all testing programs to support epidemic control goals.

WEPEE673

HIV-indexing: Identifying and linking children living with HIV to treatment through a community-based model in Zambia

K. Mwanda[1], M. Chikuba[1], H. O'Bra[2], E. Mwila[1], J. Chilongoshi[1], P. Chungulo[1], K. Chibesakunda[1], D. Phiri[1], D. Chikondi[1]
[1]JSI Research & Training, Inc., International Division, Lusaka, Zambia, [2]USAID/Zambia, Lusaka, Zambia

Background: In Zambia, HIV testing among children remains low. The Ministry of Health estimated that about 52% of the infected children 0-14 years were on ART, as compared with 67% of adults. Identifying children living with HIV (CLHIV) with traditional HTS strategies like VCT gives very low positivity yields at 1.7% and linkage ART and care are equally low at 81%.
Description: In order to address these disparities, the USAID-funded USAID DISCOVER-Health Project implemented by JSI introduced indexing and notification in Project-supported HIV treatment sites that offer community-based integrated HIV, reproductive health, family planning, and maternal and child health services, in August, 2017. The Project trained 237 experienced psychosocial counsellors from 58 ART sites to conduct targeted indexing, including eliciting information from adults on ART about biological children or OVC under their care aged 0-12 years, who had not had an HIV test. All adults on ART were targeted for indexing to identify CLHIV. Through their guardians, non-biological children on ART were equally treated as an indexing link to siblings under the age of 12 years.
Lessons learned: Between August and December 2017, 745 potentially HIV-exposed children under the age of 12 years were identified through their 861 female adult ART clients and 73 siblings on ART. Of the 745, 46 tested HIV positive for a positivity yield of 6%. Among the 318 males, the yield was 6.3%, while among the 427 females the yield was 5.9%. Linkage to ART was 91%.
Conclusions/Next steps: HIV indexing is an effective strategy for ensuring higher HTS yields and higher linkage rates to ART among CLHIV. Therefore, through this approach, children living with HIV have a better chance at diagnosis and linkage to treatment and most importantly a healthy life. The Project has since scaled-up this approach to 102 of its 124 community-based ART sites.

WEPEE674

Successes in the rapid implementation of the HIV test and treat approach in a high burden setting - a view from Nairobi, Kenya

M. Njagi[1], D. Nyukuri[2], S. Orina[1], D. Wendo[1], T. Simiyu[1], S. Byrne[3], S. Duberstein[3], C. Bennett[3]
[1]IMA World Health, Nairobi, Kenya, [2]The Christian Health Association of Kenya, Nairobi, Kenya, [3]IMA World Health, Washington, United States

Background: With a population of over 4 million and contributing over 11% of the country's HIV burden, the USAID-funded Afya Jijini program works in collaboration with the Nairobi City County Health Management Team to strengthen access to quality HIV services with an emphasis on health facilities located in Nairobi's informal settlements. Since 2016 the program has supported Nairobi County to roll-out Kenya's newly adopted Test and Treat guidelines, moving the country closer to achieving 90-90-90 treatment goals.
Description: From October-December 2016, Afya Jijini supported 22 high-volume facilities with over 500 clients on HIV treatment. A treatment preparation system and adherence counselors were trained and placed in facilities to ensure newly diagnosed patients were linked to treatment and provided with adherence and psychosocial support.

Newly diagnosed HIV clients were counseled on the importance of early ART initiation and where possible, immediately enrolled on ARTs on the same day. For individuals not ready to enroll, support was provided for initiation within 2 weeks. Standard operating procedures and quality improvement teams were established to identify gaps in adopting the new guidelines. The project also provided on-the-job training to staff to adopt the new guidelines, including promotion of the differentiated care model to fast-track stable ART patients.

Lessons learned: Data from 9 facilities found 519 clients were enrolled on treatment. 417 (80%) were initiated on treatment on the same day as their positive diagnosis, 51 (10%) were enrolled after one day but less than two weeks and 51 (10%) enrolled after 2 weeks. 12-month retention rates were higher with same day enrollment (90%) compared to those enrolled after 2 weeks (71%), a 19% difference, (95% CI 7.8847-32.8029; P≤0.0001). There was no statistically significant difference in 12-month retention rates in clients enrolled on the same day (90%) and those enrolled between one day and less than two weeks (86%), a 4% difference, (95% CI 3.7211-16.3067; P=0.3783).

Conclusions/Next steps: Same day initiation on treatment was associated with a higher number of patients retained on treatment at 12 months. These lessons can be applied to other countries seeking to rapidly adopt these new guidelines.

WEPEE675

A comparative analysis of expanded HIV testing and linkage interventions in PEPFAR pivot areas in Mozambique, Tanzania, and Zimbabwe from 2015-2017

L. Bonanno, K. Clark
United States Department of State, Office of the Global AIDS Coordinator and Health Diplomacy, Washington, DC, United States

Background: To assist host governments to achieve epidemic control, PEPFAR programs must find undiagnosed people living with HIV/AIDS (PLHIV), in order to provide HIV testing services and link PLHIV to health facilities for antiretroviral treatment (ART). Understanding data down to the facility level is essential, to make programmatic adjustments. In Mozambique, Tanzania, and Zimbabwe, there are defined geographic areas with large ART coverage gaps with large volumes of undiagnosed PLHIV. Additional efforts were needed in these areas to further progress toward epidemic control, specifically for testing and linkages. Interventions included provision of additional health care providers, increase of community based testing programs, and renewed programmatic focus on identification and linkages.

Description: Quarterly programmatic data for HIV testing services and enrollment onto ART were analyzed for Zambezia province, the city Dar es Salaam, and the city of Harare from September 2015 until September 2017.

Lessons learned: Zambezia, Dar es Salaam, and Harare all observed improvements in the numbers of people tested, PLHIV identified, and initiation onto ART, with variations among the different interventions and time periods. In Harare and Dar es Salaam, the additional interventions began in late 2015, and after a year of implementation, the percentage increases is more evident compared to the baseline.

The implementation of the interventions in Zambezia began in earnest in the last two quarters of 2017(April-September 2017). When comparing to the end of 2016, the improvements are much more apparent.

From 2015 to 2017, Harare saw a continuous improvement in linkage to treatment from testing positive, and Zambezia and Dar es Salaam both showed an uptick in linkage to treatment in the middle of 2017.

	Testing			Testing Positive			Treatment New		
	October 2015 to September 2017	October 2016 to September 2017	Q1 to Q4 2017	October 2015 to September 2017	October 2016 to September 2017	Q1 to Q4 2017	October 2015 to September 2017	October 2016 to September 2017	Q1 to Q4 2017
Zambezia Province	0.10%	49.49%	28.12%	-37.34%	-12.49%	199.41%	56.94%	35.68%	45.18%
City of Dar es Salaam	170.12%	53.94%	51.81%		69.78%	45.18%	88.15%	50.80%	24.78%
City of Harare	111.30%	32.57%	-4.92%	68.43%	17.84%	-14.79%	123.13%	43.43%	22.59%

[Percentage differences for testing, identification, and enrollment]

Conclusions/Next steps: Partnerships with the governments of Mozambique, Tanzania, and Zimbabwe were critical in the success of interventions to expand testing and linkages and focus resources where the HIV epidemic is greatest. National implementation of universal treatment policies was vital in ensuring that any PLHIV who was tested at the facility could receive ART. Even before additional financial and programmatic resources were made available, renewed urgency and emphasis on effective programmatic implementation can show dramatic improvements.

WEPEE676

Towards achieving the first and second 90 for children newly-diagnosed with HIV in North-Central Nigeria: Intensified case-finding and quality improvement collaborative approaches

R.I. Okonkwo[1], T.L. Jasper[1], J. Peterside[1], B. Adeyemo[2], F. Ifejika[2], O. Oriaku[2], R. Ejekam[3], N. Torbunde[3], A. Attah[1], E. Aiyenigba[4], D. Ikeda[5], B. Agins[5], N.A. Sam-Agudu[3,6]
[1]Institute of Human Virology Nigeria, Applied Health and Quality, Abuja, Nigeria, [2]Institute of Human Virology Nigeria, Abuja, Nigeria, [3]Institute of Human Virology Nigeria, Pediatric and Adolescent HIV Program, Abuja, Nigeria, [4]Institute for Health Improvement, Abuja, Nigeria, [5]University of Calfifornia, HEALTHQUAL, Institute for Global Health Sciences, San Francisco, United States, [6]University of Maryland School of Medicine, Institute of Human Virology, Baltimore, United States

Background: ART coverage for Nigeria´s estimated 270,000 children living with HIV (CLHIV) is only 21%, and identification of CLHIV in this relatively low HIV-prevalence (2.9%) setting has been challenging. We implemented pediatric intensified case-finding (PICF) and quality improvement collaborative (QIC) initiatives to improve numbers of CLHIV identified and linked to care in North-Central Nigeria.

Description: We piloted the initiatives at 15 primary, secondary and tertiary facilities in 5 peri-urban and rural communities in North-Central Nigeria. The PICF initiative established/expanded rapid HIV testing points at/to key points of service in each facility including tuberculosis, emergency, ART and inpatient units. Under the QIC, QI coaches guided Healthcare Workers (HCWs) to develop and share change ideas implemented in Plan-Do-Study-Act cycles. The pilot was implemented in April-December 2017; the first 3 months (April-June) and latter 6 months (July-December) were baseline and testing periods, respectively.

Lessons learned: During the pilot, 11,636 children 0-14 years old were tested, with testing coverage increasing from 25% to 93%. Compared to 1.1% at baseline, 0.9% (105 children) were found HIV-positive in the testing period. The highest-yield service delivery points were TB (3.6%), family index testing (1.6%) via ART clinic and inpatient wards (1.3%). Immunization (0.0%) and outpatient clinics (0.7%) had the lowest yields in spite of large numbers of children tested (1,152 and 8,044 respectively). ART linkage improved from 23% to 81%. The most impactful change ideas for linkage were treatment referral escorts from primary to higher-level care, reorganization of clinic for better testing point-to-ART clinic transfer, and sensitization of HCWs to provide prompt ART. Nearly 40% (38/105) of newly-diagnosed children were identified at rural primary facilities.

Conclusions/Next steps: Overall, the PICF and QIC strategies tested were effective for identifying and linking CLHIV to ART. However, positivity yield was essentially unchanged. As testing is scaled up to more facilities, innovative and efficient strategies are needed to continue targeting most at risk children in order to maximize yield. The most impactful and high-yield change ideas should be refined and scaled up, including at primary healthcare facilities in rural areas that have proven to be robust sources of as-yet unidentified CLHIV.

WEPEE677

Challenges in transitioning donor-supported health workers to build resilient local capacity for sustainable epidemic control in Uganda

V. Oketcho[1], A. Agaba[1], C. Brokenshire-Scott[2], J. Wesson[2]
[1]IntraHealth International, Kampala, Uganda, [2]IntraHealth International, Chapel Hill, United States

Background: PEPFAR has supported Uganda's gains in addressing HIV/AIDS through significant investments in hiring human resources for health (HRH) to reduce staff shortages in numbers and cadres. The increased workforce has contributed to improved outcomes—Government of Uganda (GOU) data show HIV prevalence declined to 6% (2016) from 7.3% (2011) and the number of children born with HIV declined by 86% between 2011-2015. However, the sustainability of the HRH investment faces challenges.
Description: With USAID funding, IntraHealth International conducted a longitudinal analysis using quantitative and qualitative methodologies to document HRH investments, absorption rates, retention rates, HIV service coverage and utilization trends.
IntraHealth deployed an online human resources information system (HRIS) to track, manage, deploy, and budget for absorption of PEPFAR-supported health workers. HRIS data were used to negotiate government absorption of critical PEPFAR-funded staff starting in 2015.
Of 3,154 health workers hired between 2012-2017; 693 (22%) have been absorbed. PEPFAR HRH recruitment was premised on GOU commitment to prioritize absorption of the workers but ensure gradual transition so services are not disrupted.
Lessons learned:

- One bottleneck impeding absorption is mismatch in salaries, with some PEPFAR contract staff earning four times more than GOU counterparts; 36% of non-absorbed PEPFAR staff have salaries not matched to GOU salary structure.
- Multi-stakeholder engagement within an accountability framework is critical to accelerate transition of contract staff to government. This outlines the roles and responsibilities of each party, transition targets and timelines, budget required for absorption and a framework to monitor progress of commitments.
- Alignment of cadres and job titles for health workers involved in HIV/AIDS services but not in existing government structures (e.g., sample transporters) is a key barrier and requires policy decisions for such cadres to be absorbed.
- Increase in wage budget allocation by government is critical to accelerate absorption of donor-supported HRH
- Transition of donor-supported HRH has potential to disrupt services and requires analysis of local capacity to sustain service provision after transition.

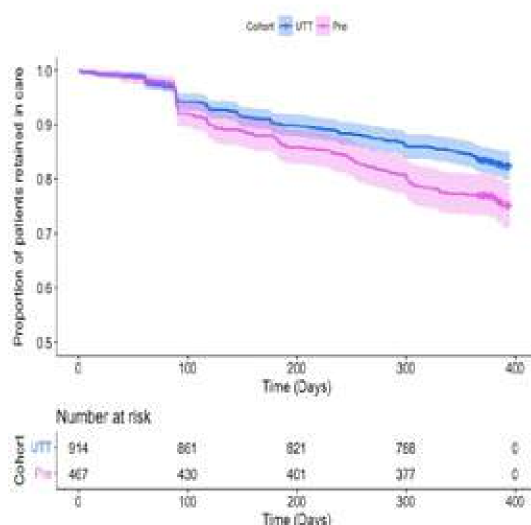
Conclusions/Next steps: Donor investments in HRH have had impact on AIDS epidemic control; however, it is difficult to sustain these gains if local capacity is not built through mainstreaming HRH into government.

WEPEE678

Retention on ART during Universal Test and Treat implementation in Zomba District, Malawi

M. Al Haj Mohammad[1,2,3], A. Amberbir[1,2], E. Singogo[2], V. Banda[2], M. van Lettow[2], A. Matengeni[2], G. Kawalazira[4], J. Theu[2], M. Raj Jagriti[2], A. K. Chan[2,5], J. J van Oosterhout[2,6]
[1]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [2]Dignitas International, Zomba, Malawi, [3]Canada International Scientific Exchange Program (CISEPO), Toronto, Canada, [4]Zomba District Health Office, Zomba, Malawi, [5]University of Toronto, Sunnybrook Health Sciences Centre, Division of Infectious Diseases, Toronto, Canada, [6]University of Malawi, College of Medicine, Blantyre, Malawi

Background: The national HIV programme in Malawi adopted Universal Test and Treat (UTT) in 2016: all persons who test HIV positive are immediately referred for initiation of antiretroviral therapy (ART).
Although there is strong evidence from clinical trials that early initiation of ART is associated with reduced morbidity and mortality, the impact of UTT on retention on ART in operational settings is not yet known.
Methods: We conducted a retrospective cohort study in 32 health facilities in Zomba district, Malawi. We compared standard programme outcomes of patients aged 10 years and older starting ART under the 2016 guidelines (UTT) to those prior to UTT roll out (Pre-UTT), with a follow up period of 12 months. Attrition from ART (the inverse of retention) was the composite of death, stop ART and lost to follow up. Patients who transferred to another clinic were excluded from the analysis. Multivariable Cox proportional hazards modeling was used to determine factors associated with attrition from ART at 12-months.
Results: Among 1,492 patients (mean age 34.4 years, 933 females, 63%) who initiated ART during the study period, 501 were in the Pre-UTT cohort, and 911 in the UTT cohort. At 12 months, retention on ART was 83.0% (95% CI: 81.0-85.0%) during UTT, significantly higher than in the Pre-UTT cohort 76.2% (95% CI 73.9-78.5%; p=0.002). Kaplan Meier analysis shows that the probability of attrition from ART was significantly higher in the Pre-UTT cohort than during UTT (figure). Younger age group (age 20-24; aHR 1.91, 95% CI 1.09-3.35) and being pregnant or breastfeeding when starting ART (aHR 1.86, 95% CI 1.30-2.66), but not BMI, TB status at ART initiation, or health facility type (urban/rural), were associated with attrition from ART in both cohorts.
Conclusions: Retention on ART may improve during implementation of UTT in Malawi. New retention strategies for young adults and pregnant and breastfeeding women are needed to achieve the UNAIDS 90-90-90 targets. Larger and longer studies using national and regional cohorts will be required to determine the full impact of UTT on clinical outcomes in real-life circumstances.



[Survival plots based on Kaplan Meier estimates comparing retention in-care in pre-UTT (pink) vs UTT (blue) cohorts. Shaded area represents the 95% CI]

WEPEE679

Identifying hard-to-reach men who have sex with men (MSM) for HIV services in Ghana: The use of social media

J.K. Ochill[1,2]
[1]CEPEHRG, Accra, Ghana, [2]Interfaith Diversity Network of West Africa, Accra, Ghana

Background: The use of social media platforms has become increasingly common in recent times among different populations. This has particularly been the case among MSM providing them with borderless communication and allowing them to keep their stigmatized behaviours hidden. Although targeted programmes provide services to MSM in Ghana, identifying and reaching MSM with targeted HIV services using conventional strategies remain a challenge.
I describe a social media approach, implemented by CEPEHRG under the USAID-funded Ghana Care Continuum Project/JSI, aiming to reach MSM who might particularly be concerned about being stigmatized when they access services.

Author Index

Description: A social media platform using the WhatsApp group application for smart phones was created by a peer educator (PE) in Greater Accra to reach hidden MSM for HIV testing services (HTS). WhatsApp groups deliver instant messaging to a group of people, and members can remain anonymous. Seeking full consent, members were recruited into the platform using their telephone numbers which were previously obtained by a PE. Additional MSM joined the group via the PE and existing members. Educational HIV information and issues were posted on the platform daily to encourage MSM to access HTS. Members could ask questions and prompt responses were given.
Lessons learned: The WhatsApp platform substantially helped in reaching MSM who may particularly be concerned about being stigmatized within a short period of time. The number of MSM reached over a 3-month period increased from an initial 45 to 82 members; 38 of these members tested for HIV over the period. Creating a virtual space for hard-to-reach MSM where they are comfortable to share their stories with other MSM and get tailored responses to their questions almost instantaneously has been key to the high uptake of HTS. Members most commonly asked questions related to HIV and STI prevention. If this approach can be scaled up, there is potential to reach a high number of MSM with HTS.
Conclusions/Next steps: Peer education programing should utilize innovative communication strategies using social media as a way of reaching or involving hard-to-reach MSM. There is potential to not only increase HIV testing but also linkage to care.

HIV self-testing for HIV and linkages to prevention and care

Successful implementation of HIV self-testing in the rural Shiselweni region of Swaziland

L. Pasipamire[1], L. Dube[2], E. Mabhena[1], M. Nzima[1], P. Lopez[3], M.L. Tombo[1], L.G. Abrego[1], S. Mthetwa[1], M. Dhlamini[1], R. Nesbitt[1], M. Pasipamire[2], S.M. Kabore[3], R. De la Tour[4], N. Lukhele[2], J. Goiri[4], I. Ciglenecki[4], B. Kerschberger[3]
[1]Medecins Sans Frontieres, Nhlangano, Swaziland, [2]Swaziland National AIDS Programme, Mbabane, Swaziland, [3]Medecins Sans Frontieres, Mbabane, Swaziland, [4]Medecins Sans Frontieres, Geneva, Switzerland

Background: Current healthcare worker led HIV testing approaches are failing to reach all people in need for HIV testing such as men, and young people. Although WHO recommends HIV self-testing (HIVST) as a complementary testing strategy, it is rarely applied in the public health sector.
Thus, Medecins Sans Frontieres (MSF) and the Ministry of Health (MOH) of Swaziland aimed to demonstrate the feasibility of HIVST as an innovative testing strategy under routine conditions.
Methods: From May to October 2017, HIVST kits have been provided through different targeted testing strategies at 9 government health facilities and at community sites in the rural Shiselweni region of Swaziland. In supervised HIVST, clients performed and interpreted the test in the presence of a health worker whilst in unsupervised HIVST, clients took 1-2 HIVST kits home for testing. We also provided tailored HIVST education and information material, established a toll-free hotline and performed structured follow-up calls to monitor possible adverse events, guide clients on interpreting the test results and advice on HIV services. Frequency statistics and proportions were used to describe the outcomes.
Results: A total of 1462 people (681 (47%) males, median age 29 (IQR 24-35) years) were reached through HIVST. 1817 HIVST kits (averaging 1.2 test kits per client) were distributed through 6 strategies (mutually not exclusive): 810(45%) at workplaces, 582(32%) and 191(11%) at targeted event-based testing for young people and men, 64(4%) in facility-based for pregnant/lactating women, 41(2%) at safe spaces for key populations, and 129(7%) undefined. Overall, 1615(89%) of tests were unsupervised and 202(11%) were supervised. Of 750(41%) HIVST results reported, 24(3%) were HIV-positive of whom 12(50%) had a confirmatory follow-up standard test done. All clients 12(100%) had concordant HIVST and standard HIV rapid test results, and 11(92%) were enrolled into HIV care. No adverse events were reported through 521 routine follow-up calls. The telephone hotline was used 167 times, mainly to disclose results and more often by men 95 (57%).
Conclusions: Implementation of HIVST was feasible in public health sector in rural Swaziland. This pilot informed national health policy and led to the adoption of HIVST as an additional national testing strategy in Swaziland.

Distributing HIV self-testing kit through internet-based pay-at-pickup at convenient stores: Experiences in Taiwan

Y.-F. Huang, H.-Y. Huang, H.-Y. Lo, C.-C. Lee
Centers for Disease Control, Taipei

Background: HIV self-testing is a novel and confidential way to help people know their HIV status. However, traditional venue-based access and delivery have limited its scale-up among vulnerable populations at risk. With permission of Taiwan Food and Drug Administration, Taiwan Centers for Disease Control launched a program to distribute self-testing kits through internet-based pay-at-pickup services provided by convenient stores and evaluate its acceptability.
Methods: The program was started on 11TH April, 2017, with collaborations of major chained convenient stores to deliver up to 7,000 HIV self-testing kits at pay-at- pickup services. Clients only needed to log their nickname, mobile phone number and designate which convenient store to pick up the testing kit. Then the contracted delivery company would deliver the HIV self-testing kit to the designated store. After the designated store received the package, its system would send text message to notify the client. At the counter of convenient stores, clients only need to tell the clerk the last 3 digit of phone number and paid 7 US dollars to get the kit. Clients could receive full redeem after logging their test results online, furthermore, they could join a lottery activity for coupons (3 US dollars) after completing questionnaires on testing experiences and about HIV self-testing.
Results: The kits were so popular that Taiwan CDC had to execute "one person one kit "policy and limit its max supply on every day, most of the time, the kits were booked out within 3 hours, then sold out in three months. In total, 6,863 kits were distributed through pay-at- pickup services provided by chained convenient stores. Of 3,121 (45.5%) who logged their test results anonymously on the website, 33 (1.1%) of respondents reported being newly tested HIV-positive. Of 1,986 who completed the questionnaire, 664(33.4%) reported that this was their first time to do HIV testing. Compared with the homosexuals (21.4%), the bisexual (31.8%) and the heterosexual (55.1%) are with higher percentage of never testing for HIV.
Conclusions: The novel delivery services with confidential assurance and providing through about 5,000 chained convenient stores around Taiwan were well-accepted and led to a substantial proportion of first-ever HIV testing.

WEPEE682

Facility-based HIV self-testing in Malawi: An assessment of characteristics and concerns among clients who opt-out of testing

F. Shaba[1], K.T. Balakasi[1], O.A. Offorjebe[2,3], M. Nyirenda[1], R. Hoffman[1,2], K. Dovel[1,2], EQUIP Innovation for Health
[1]Partners in Hope, Research, Lilongwe, Malawi, [2]University of California, Los Angeles, United States, [3]Charles R. Drew University of Medicine and Science, Los Angeles, United States

Background: HIV testing must increase to achieve UN 90/90/90 targets in sub-Saharan Africa. A recent cluster randomized trial demonstrates that facility-based HIV self-testing (HIVST) among outpatient clients dramatically increases testing. However, a portion of clients offered facility-based HIVST still opted-out of testing. To improve HIVST strategies, pro-

grams will require a greater understanding of why individuals refuse to test. We examined characteristics and concerns of outpatient clients in the trial who were offered and opted-out of HIVST in Malawi.

Methods: Exit surveys were conducted with outpatients ≥15 years at 15 facilities in Central/Southern Malawi. Surveys included sociodemographic information and reasons for opting-out of HIVST. We analyze survey data from clients who were offered HIVST and eligible for HIV testing (not tested HIV-positive and tested ≤ 3 months ago). Multivariate logistic regression models were used to assess factors associated with opt-out. We then explore the primary concerns listed by clients who opted-out of facility-based HIVST.

Results: A total of 1,418 outpatients were offered HIVST. Among those offered, 218 (15%) tested < 3 months ago and 81 (6%) previously tested HIV-positive. Both groups were excluded from analyses. Among those eligible for testing, 454 (34%) opted-out of facility-based HIVST (median age 29 and 39% men). Men (OR:1.41, p-value=0.004) and adolescents (OR:1.32, p-value=0.05) were more likely to refuse HIVST compared to women and adults, respectively. Among men, having fewer sexual partners was associated with opting-out of HIVST (OR:0.82, p-value 0.01). Primary reasons for opting-out were perceived low-risk of HIV-infection (42%), feeling unprepared to test (30%), not seeing the HIVST demonstration (14 %), and being too busy (9 %). Less than 2% did not understand HIVST instructions and only 1% wanted more privacy to preform HIVST. Men were more likely than women to report being too busy to use HIVST (OR:2.1, p=0.03).

Conclusions: Facility-based HIVST is largely acceptable - primary concerns are not related to characteristics of the intervention. Concerns regarding facility-based HIVST are similar to concerns for other testing strategies. Future testing strategies should include extensive community sensitization to increase client preparedness for testing and their awareness of HIV-risk. Targeted HIVST strategies for men and adolescents may be warranted.

	Total n (%)	Male n (%)	Female n (%)	p-value*
Among those offered HIVST				
Median age in years (IQR)	29 (21-41)	29 (21-44)	29 (21-40)	
Tested for HIV<12 months	560 (42)	183 (37)	377 (45)	0.010
Opted out	454 (34)	191 (39)	263 (31)	0.004
Among those who opted-out of HIVST:				
Median age in years (IQR)	27 (20-40)	28 (21-42)	26 (20-38)	
Tested for HIV<12months	199 (44)	71 (37)	128 (49)	0.020
Primary reasons for opting out of HIVST				
Low risk of HIV infection	192 (42)	83 (43)	109 (57)	0.670

Partner-delivered HIV self-testing increases the perceived acceptability of index partner testing among HIV-positive clients in Malawi

O.A. Offorjebe[1,2], F. Shaba[3], K. Balakasi[3], M. Nyrienda[3], R. Hoffman[1,3], K. Dovel[1,3], EQUIP Innovation for Health

[1]University of California, Los Angeles, United States, [2]Charles R. Drew University of Medicine and Science, Los Angeles, United States, [3]Partners in Hope, Lilongwe, Malawi

Background: Index partner testing is critical for reaching UN 90-90-90 goals. Partner referral slip (PRS) is the primary strategy for testing partners throughout sub-Saharan Africa, however, index testing remains low. HIV self-testing (HIVST) may overcome barriers to testing, however, there are no data on whether HIV-positive clients would be comfortable delivering HIVST kits to their partners. We examined HIV-positive clients' perceived acceptability of HIVST as a strategy for index partner testing in Malawi.

Methods: The study was nested within a cluster randomized trial examining HIVST distribution to outpatient clients within health-facilities. Exit surveys were conducted with outpatient clients ≥15 years of age at 15 facilities in Central/Southern Malawi. Clients who self-reported previously testing HIV-positive and having a sexual partner in the past 12-months completed a separate survey module on client perceptions of index partner testing strategies.

Results: 452 clients (8% of RCT participants) completed the index testing module. Clients' willingness to deliver index testing materials to partners increased by 11% when presented with the option to deliver HIVST kits over PRS. Overall, 65% of clients preferred delivering HIVST kits over PRS. Among those uncomfortable to deliver HIVST, common reasons include fear of partner responses (men:62%, women:60%) and feeling uncomfortable explaining HIVST to partners (men:24%, women:33%). When asked whether clients believed their partner would actually test for HIV through index testing, HIVST was associated with an 18% increase in anticipated testing compared to PRS. Overall, 69% of clients believed their partner would prefer testing with HIVST over PRS. HIVST was believed to decrease disparities in testing for male partners. HIV-positive women were less comfortable delivering PRS to their partners than HIV-positive men (AOR:1.86, p=0.03), however this gender-difference becomes insignificant when introducing HIVST (AOR:1.72, p=0.14). Similarly, male partners were believed to be less likely than female partners to actually test through PRS (AOR:1.60, p=0.04), and again, this gender-difference becomes insignificant when introducing HIVST (AOR:1.23, p=0.41).

Conclusions: Delivery of HIVST kits to sexual partners was perceived as acceptable among HIV-positive clients in Malawi. Importantly, HIVST may close gender-specific gaps in male partner testing. Additional studies are needed to assess actual use and linkage to care.

	Total	Men	Women	p-value*
Mean age, years (IQR)	37 (30-44)	42 (34-50)	36 (27-40)	<0.001
Mean number of children at home (IQR)	3.4 (2-5)	4.0 (2-5)	3 (2-4)	<0.001
Mean number of sexual partners (IQR)	1.8 (1-2)	2 (1-2)	1.7 (1-1)	0.37
Diagnosed HIV+ <3 months (%)	61 (14)	22 (13)	39 (14)	0.85
Comfortable distributing HIVST kit (%)	405 (90)	155 (92)	250 (88)	0.12
Comfortable distributing PRS (%)	366 (81)	147 (88)	219 (77)	0.007
Prefer distributing HIVST over PRS for index testing (%)	292 (65)	106 (63)	186 (66)	0.61

Performance and usability of OraQuick® oral fluid-based rapid HIV self-test among key populations in Vietnam

B. Vu Ngoc[1], M. Tran Hung[2], K. Green[1]
[1]PATH, Mekong Regional Program, Hanoi, Vietnam, [2]Center for Creative Initiatives in Health and Population, Hanoi, Vietnam

Background: Self-testing provides an opportunity to increase uptake of HIV testing, particularly among never or infrequent HIV testers. Studies in Vietnam have demonstrated interest in and acceptability of oral fluid-based self-testing, however the usability of an oral fluid HIV self-test by lay populations is unknown.
Methods: The practicability of HIV self-testing was assessed using OraQuick® Rapid HIV Self-Test, an oral fluid-based rapid HIVST, in 200 adults living in Hanoi and Ho Chi Minh City in Vietnam. The participants were inexperienced lay users from key populations including men who have sex with men, transgender women, female sex workers, and people who inject drugs, as defined by self-reported risk behaviors. Participants were observed performing the test, however, they did not report their results to site staff; they were provided mock devices to interpret a range of results. A post-test interview was conducted with participants to assess comprehension of the instructions and ease of use of the test.
Results: Nearly all participants (98.5%) read the instructions for use (IFU) and 100% were able to complete the test and read the result. Among those, 52% collected the sample correctly, and 79% waited for the appropriate time period prior to reading their test results. With the use of mock devices, 94% of participants correctly interpret a strong reactive test result, 55% correctly identified a weak reactive test result, 89.5% accurately identified a non-reactive test result and 43% incorrectly interpreted a weak reactive test result as non-reactive. Most participants (93.5%) understood the IFU, and 95.5% felt confident they would be able to perform this test again.
Conclusions: Participants read the IFU with ease, but were not able to correctly use the swab, or read the result within the recommended timeframe. Participants demonstrated strong confidence and acceptance of the OraQuick® self-test, indicating they would use it when available in the market, and would introduce it to others. The IFU can be improved to: stress the correct result read time; emphasize the correct sampling method, taking care not to swab the gums too many times; clearly denote differences between weak reactive and non-reactive test results.

WEPEE685

Assessing the feasibility of HIV self-screening in South Africa

L. Lebina[1], M. Milovanovic[1], N. Seatllholo[1], N. Taruberekera[2], M. Radebe[2], A. Kinghorn[1], T. Meyer[2], M. Mhazo[2], K. Otwombe[1], K. Hlongwane[1], A. Ringane[1], N. Koloane[1], M. [1]Perinatal HIV Research Unit - Wits, Wits Health Consortium, Johannesburg, South Africa, [2]Society for Family Life, Johannesburg, South Africa, [3]USAID, South Africa, Pretoria, South Africa, [4]Foundation for Professional Development, Pretoria, South Africa, [5]National Department of Health, HIV and AIDS Cluster, Pretoria, South Africa, [6]National Institute for Communicable Diseases, Johannesburg, South Africa, [7]Johns Hopkins University, Centre for TB Research, Baltimore, United States, [8]SA MRC, Soweto Matlosana Collaborating Center for HIV/AIDS and TB, Johannesburg, South Africa

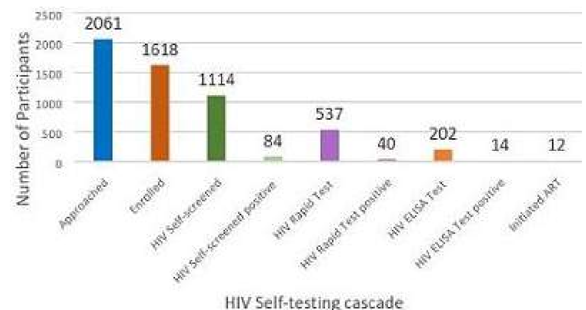
Background: HIV diagnosis is a critical step to linking HIV-infected individuals to care and treatment. However, HIV testing remains low in South Africa. The OraQuick HIV self-screening kit has been pre-qualified by the World Health Organization and recommended as one of the strategies to increase access to, and uptake of, HIV testing. This study aimed to evaluate the feasibility of HIV self-screening and obtain data to inform the HIV self-screening implementation programme in South Africa.
Methods: Mixed methods study involving prospective enrolment of participants from May-July 2017 in two townships in Johannesburg Metro: Diepsloot and Alexandra. Four recruitment strategies were used: home-based outreach, mobile site, workplace and sex worker programmes (SWP). Participants were offered three methods of administering the screening test: supervised clinician did the self-screen, semi-supervised clinician advised while participant did the self-screen, and unsupervised. Confirmatory HIV testing was done according to national guidelines and some participants received a laboratory based HIV ELISA test. Follow-ups were scheduled for linkages to care and confirmatory tests.
Results: In total, 2061 people were approached to receive information of which 78.5% (1618/2061) were enrolled and 68.8% (1114/1618) HIV self-screened. Median age was 28 (IQR:23-33) years with an even gender distribution. Across the four recruitment strategies: 43.0% (696/1618) were homebased outreach, 42.5% (687/1618) mobile sites, 7.3% (118/1618) workplace and 7.2% (117/1618) SWP. Unsupervised HIV self-screening was preferred across recruitment strategies, gender and age categorisation. Overall, HIV prevalence using the HIV self-screening kit was 7.6% (84/1109). Services accessed following HIV self-screening included counselling (5.8%, 94/1618), and for HIV infected: CD4 testing (3.6%, 3/84), initiation on HIV treatment (14.3%, 12/84). When compared to the confirmatory rapid test and laboratory ELISA the HIV self-screen sensitivity and specificity were 100% and 99.8%, 85.7% and 98.9% respectively.
Conclusions: HIV self-screening was feasible through homebased, mobile site, workplace and sex work programmes and unsupervised was the most preferred and utilised HIV self-screening method. Linkages to confirmatory testing and further care were low. Potential approaches to scale-up and acceleration of HIV self-screening integration need to consider distribution methods, increasing awareness, and strengthening linkages to confirmatory testing and further care.



[Figure 1. HIV self-screening cascade - Assessing the feasibility of HIV self-screening in South Africa]

WEPEE686

Characterizing implementation measures of HIV-self testing among people at risk for HIV to evaluate the potential impact of increasing HIV testing coverage in Senegal

C. Lyons[1], K. Coly[2], B. Liestman[2], D. Diouf[3], D. Castor[4], V. Wong[5], S. Geibel[6], O. Olawore[1], G. Turpin-Nunez[1], R. Amrita[1], S. Ketende[1], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Dakar, Senegal, [3]Enda Sante, Dakar, Senegal, [4]United States Agency for International Development, Crystal City, United States, [5]United States Agency for International Development, USAID Global Health Bureau; Office of HIV/AIDS - Prevention, Care and Treatment Division, Crystal City, United States, [6]Population Council, Washington, United States

Background: HIV Self Testing(HIVST) aims to address gaps in HIV testing coverage among people at risk, and can facilitate reaching the UNAIDS 90-90-90 targets. In Senegal, key populations bear a disproportionate burden of HIV, and report limited uptake of HIV testing given pervasive stigma and criminalization. In these contexts, HIVST provides a complimentary approach to reach populations reporting barriers to engagement with existing and routine HIV testing services.
Methods: OraQuick HIVST kits were distributed to 680 individuals in Dakar and Ziguinchor, Senegal through venue and network-based distribution. Pre-(N=680) and post-test(N=399) structured instruments were

administered to capture HIV risk behaviors, HIV testing history, motivation for testing, and acceptability of HIVST. Pretests were conducted at the distribution site, and post-test questionnaires were conducted two weeks after distribution.

Results: Of 680 participants, 68.1%(462/680) were from Ziguinchor and 32.0%(218/680) from Dakar. Mean age was 31.6 years(IQR:18-35) and 48.6%(330/679) of participants were male. Approximately 23.3%(77/330) of participants were men with a history of anal or oral sex with another man; 13.0%(81/625) reported engagement in sex work; and 3.7%(25/668) reported history of injection drug use. Overall, 45.3%(306/676) were first time testers. The main reason reported for HIVST was engagement in recent risky behavior(31.0%;197/636) and 78.8%(458/581) reported being worried about HIV. Among post-test survey respondents, 90.4%(358/396) used the HIVST and 80.2%(287/356) used it within 2 days. Majority(72.4%;259/358) used the HIVST at home compared to onsite; thought their friend/family would use the HIVST(92.7%;352/381); and would recommend HIVST to others(95.3%;341/357). In total, 3.7%(13/350) tested positive, and 3.7%(13/350) reported an invalid result. Since receiving the HIV self-tests, 32.5%(123/378) discussed HIV testing with a sexual partner or friend. 79.5%(283/356) reported feeling comfortable taking the HIVST; 62.7%(316/355) reported the HIVST was easy to use; and 87.9%(313/356) reported the instructions were easy to follow.

Conclusions: These data suggest the potential impact that HIVST could have in complementing existing HIV testing services by reaching a diverse group of first-time HIV-testers in Senegal. This small-scale implementation further suggested the importance of leveraging existing structures and programs for distribution, and sustained engagement with government and stakeholders are needed to strategize the implementation and scale-up of HIVST in Senegal.

Post-test Results (N=399)		%	n/N
Reported use of HIVST			
	Yes	90.4	358/396
	No	9.6	38/396
Place of HIVST use			
	Home	72.8	259/356
	At distribution site	27.0	96/356
Time of use after distribution			
	<2 days	80.2	287/356
	>2 days	19.8	69/356
Result of HIVST			
	Negative	92.6	324/350
	Positive	3.7	13/350
	Invalid	3.7	13/350
Would you recommend self-testing to others?			
	Yes	95.5	341/357
	No	4.5	16/357
Do you think your friends and/or family would use an HIVST?			
	Yes	92.7	352/381
	No	7.6	28/381
Since you receive the HIV self-tests, did you discuss HIV testing with any of your sexual partners or friends?			
	Yes	32.5	123/378
	No	67.5	255/378

Ensuring continuity of services for mobile populations

WEPEE687

Ensuring continuation of antiretroviral treatment in a Test & Treat programme in a rural conflict affected area of South Sudan, the experience of MSF Spain

C. Ferreyra[1], L. Moreto[2], B. Alonso[3], F. Temessadouno[4], A.J. Nyniyal[5], A. Harouna[6], M. Eltom[7]

[1]Médecins sans Frontières, Barcelona, Spain, [2]Médecins sans Frontières, Medical Department, Barcelona, Spain, [3]Mèdedins sans Frontières, Juba, South Sudan, [4]Médecins sans Frontières, Dakar, Senegal, [5]Ministry of Health Republic of South Sudan, HIV /AIDS STI, Juba, South Sudan, [6]Médecins sans Frontières, Juba, South Sudan, [7]Médecins sans Frontières, Nairobi, Kenya

Background: Access to antiretroviral treatment (ART) is limited in conflict affected settings, particularly in rural areas. In Yambio, ART coverage is estimated to be 10%. Innovative strategies are needed in these settings in order to increase access to HIV services while ensuring continuation of ART in case of security deterioration. Few data on the outcomes of HIV programs in security situations are available.

Description: In July 2015, MSF launched a Test & Treat (T&T) Pilot Project in rural areas of Yambio where the mobile teams provide HIV counselling and testing (HCT) and ART initiation at the same day. A contingency plan to continue these activities in case of security situations was developed including mapping of patients, key messages about "what to do in case of crisis" during counselling sessions, provision of a phone number to contact our team in case of drugs shortage and coordination with community health workers (CHW's) and PLWHA associations to provide ART refill for 2 month and "run-away bags" with 3 months of ART in case security context deteriorates to a higher level. Data on retention in care and viral load suppression was regularly recorded for patients affected by conflict situations.

Lessons learned: From September 2015 to December 2017, 8 security situations have affected Yambio area by limiting the access of our mobile clinics for drugs refilling and clinical follow up. The contingency plan was activated in every situation and a total of 90 patients in 6 different locations received drugs refill through contingency. Among them, 71 (79%) were active by January 2018, 2 (2.2%) were transferred out, 1 (1.1%) died and 15 (16.7%) defaulted. Among the active patients, 58 (81.7%) had a suppressed viral load.

Conclusions/Next steps: High rates of retention in care and virological suppression of patients affected by security situations show that community based Test & Treat services are feasible and suitable for conflict affected population when contingency plan is developed in advance.

Approaches to viral load monitoring at scale

WEPEE688

Analysis and proposals of strategies to reduce the turnaround time (TAT) of viral load samples in Nampula Province

J. Reis[1], M. Buene[2], M. Muloiua[3], I. Pinto[4], J. Massorel[2], M. de Freitas[2], B.G. Chilundo[5], E.P. de Gusmão[6], R. Sutton[7]

[1]ICAP at Columbia University, Maputo, Mozambique, [2]ICAP at Columbia University Mozambique, Maputo, Mozambique, [3]Nampula Central Hospital, DPS Nampula, Nampula, Mozambique, [4]Laboratory Central Department, Ministry of Health, Mozambique, Maputo, Mozambique, [5]ICAP at Columbia University Mozambique, Strategic Information, Maputo, Mozambique, [6]ICAP at Columbia University NY, New York, United States, [7]ICAP at Columbia University NY, SI Unit, new york, United States

Background: Mozambique implemented viral load (VL) testing in June 2015, with five referral laboratories serving 11 provinces. In December 2015, VL testing expanded nationwide to all health facilities (HF) through the creation of a sample referral network. This critical expansion of services increased demand for routine VL testing, but laboratory-processing capacity did not expand at the same rate. From January 2016 - September 2016, there was a backlog of 6,000 VL samples to be processed by the Nampula referral laboratory, with the mean TAT increasing from 28 to 43 days. To address this challenge, ICAP analyzed the existing systems within this laboratory to identify gaps and design strategies to reduce TAT and increase sustainability of VL testing services.

Description: Based on the results of a TAT analysis, ICAP in coordination with the Health Authorities and the VL laboratory at Nampula Central Hospital implemented the following interventions in January 2017: 1) creation of convergence points or "hubs" for samples and results at 10 high volume HF; 2) procurement of three motorbikes to strengthen sample referral network; 3) addition of four new data clerk positions to support data entry into the laboratory information system (DISA*LAB); and 4) increased length of shifts from two to four hours for lab technicians, with associated payment for additional hours worked. Turnaround time and laboratory processing capacity were analyzed before and after implementation of the strategies to evaluate the impact of these interventions.

Lessons learned: The synergistic implementation of these strategies contributed to improvements in VL sample processing. Following implementation, TAT for VL samples was reduced from 43 to 15 days, despite a 248% increase in the number of samples processed on a quarterly basis during that same time period (Oct - Dec 2016 = 3,654, Jan - Mar 2017 = 11,262, Apr- Jun 2017 = 12,715).

Conclusions/Next steps: Through analysis of the factors affecting TAT, ICAP was able to identify and implement a series of strategies, in conjunction with regular technical support, which significantly reduced VL sample TAT. However, challenges to prompt processing of VL testing remain, including the need to further increase the number of technical staff at referral laboratories.

WEPEE689

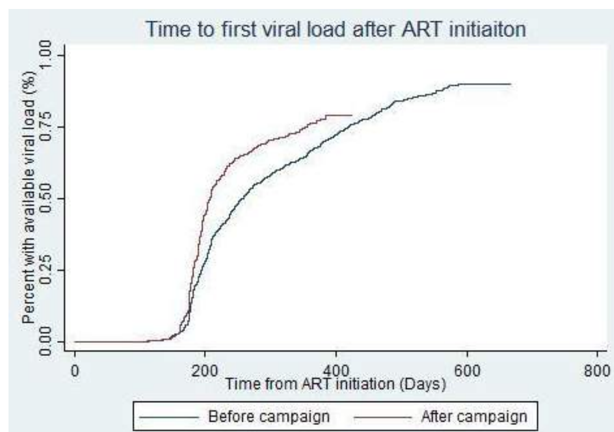
"Know your viral load": Impact of viral load demand creation on viral load monitoring in Swaziland

S. Khan[1], A. Hettema[1], K. Mngomezulu[1], B. Minsi[1], N. Ntshalintshali[1], G. Maphalala[2], N. Lukhele[2], D. Spiegelman[3], C. Lejeune[1], V. Okello[2], T. Bärnighausen[3,4]
[1]Clinton Health Access Initiative (CHAI), Mbabane, Swaziland, [2]Ministry of Health, Mbabane, Swaziland, [3]Harvard T.H. Chan School of Public Health, Boston, United States, [4]Heidelberg Institute of Public Health, University of Heidelberg, Heidelberg, Germany

Background: There is an ongoing effort from National ART Programs in low- middle-income countries to scale up access to viral load (VL) to determine the effectiveness of ART and improve early identification of VL failure. Access to VL, however, is being challenged by inefficiencies across the VL testing cascade resulting in delayed timing of first VL. Here we describe the impact of "Know your Viral Load" campaign launched in Swaziland on July 2016 to educate clients to actively demand VL testing—the first step in cascade of VL testing.

Methods: From September 2014-August 2017, 3,068 clients initiated ART under *Max*ART Universal Test and Treat (UTT) step-wedge implementation trial in 14 health facilities in Swaziland's public health sector. The "Know your VL" campaign in July 2016 included messaging on the importance of and time frame for VL monitoring for clients in order to create demand Reminder stickers were placed in appointment booklets, recording the expected month for repeat VL, actual test date, and VL results. This intervention was in addition to routine provider trainings. Secondary analysis was done to determine median times to first VL after 16 weeks on ART using Kaplan-Meier curves. The intervention effect was measured using a Cox proportional regression model with time-varying covariates.

Results: In clients initiating ART, median age was 34 years (IQR: 28-42) with 62% female. During the study follow-up, median time to first VL from ART initiation was significantly lower for the group exposed to the campaign than in control, 208 days (95% CI: 203-212) compared to 257 days (95% CI: 248-266). After adjusting for covariates at ART initiation, the hazard ratio for receiving first monitoring VL earlier in campaign group was 2.92 (95% CI: 1.62-5.27, p< 0.0001).



[Time to first viral load for clients before and after "Know your Viral Load" campaign]

Conclusions: There has been an increased effort to scale up the laboratory system capacity of Swaziland to provide VL, however, clients have not always had the information and encouragement needed to demand their VL. Empowering clients to demand VL monitoring in addition to routine provider trainings leads to earlier access to VL monitoring. Therefore, achieving the UNAIDS 90-90-90 targets would also require an informed and engaged patient.

WEPEE690

Routine viral load testing and enhanced adherence counseling for ART monitoring at a public ART centre in Mumbai, India

C. Laxmeshwar[1], S. Acharya[2], M. Das[1], P. Keskar[2], A. Pazare[3], N. Ingole[4], P. Mehta[4], M. Arago Galindo[1], P. Gori[5], H. Mansoor[1], S. Kalon[1], P. Isaakidis[6]
[1]Médecins Sans Frontières/Doctors Without Borders, Mumbai, India, [2]Mumbai Districts AIDS Control Society, Mumbai, India, [3]KEM Hospital and Seth GS Medical College, Department of Medicine, Mumbai, India, [4]KEM Hospital and Seth GS Medical College, Department of Microbiology, Mumbai, India, [5]KEM Hospital, ART Center, Mumbai, India, [6]Southern Africa Medical Unit, Médecins Sans Frontières, Cape Town, South Africa

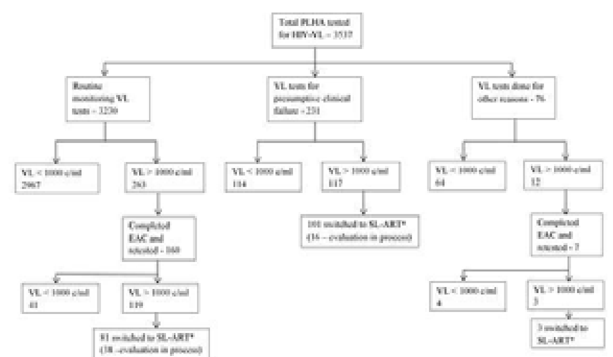
Background: WHO recommends viral-load (VL) testing as the preferred approach to monitor response to ART and diagnose treatment failure. However, India is yet to implement routine VL testing for people living with HIV/AIDS (PLHA). India being home to the third largest PLHA population in the world, urgently needs to initiate routine VL monitoring to achieve 90% VL-suppression as per UNAIDS 90-90-90 targets. Médecins Sans Frontières and Mumbai Districts AIDS Control Society are providing VL monitoring along with enhanced adherence counseling (EAC) for PLHA on ART at KEM hospital, Mumbai. This report documents findings of first Indian experience of routine VL monitoring and EAC in a high burden public ART-center.

Methods: This is a descriptive study of PLHA on ART who received routine HIV-VL testing and EAC during October 2016-December 2017. Logistic regression was used to identify factors associated with VL suppression (VL< 1000c/ml).

Results: Among 3537 PLHA who underwent VL testing, 1484 (42%) were female and median age was 42 years (IQR: 35-48). Of those tested, 3369 (95%) were on first-line ART, 32 (1%) were on alternate first-line ART and 136 (4%) were on second-line ART. Majority were referred for routine testing (3230 (91%)) and clinical failure (231 (7%)) (Figure).

Among 3230 tested for routine monitoring, 2967(92%) had VL suppressed. Of 263 with VL>1000c/ml, 160 completed EAC during the study period and after repeat VL 41 (26%) had VL< 1000c/ml. Among 119 with VL>1000c/ml, 81 were switched to 2nd line ART. Among 231 referred for clinical failure, 117 (51%) had VL>1000c/ml and 101 have been switched to second-line ART.

In unadjusted analysis using chi-square test, detectable VL was significantly associated with age (p< 0.001), duration on ART (p< 0.001) and CD4 count (p< 0.001). Overall, CD4 count < 500 (aOR 5.2 [95%CI 3.9-6.9]), on ART for< 5 years (aOR 1.4 [1.1-1.9]) and age < 45 years (aOR 1.5 [1.2-1.9]) were associated with VL>1000c/ml.



[Viral load cascade for PLHA tested at KEM Hospital ART Centre, Mumbai, India]

Conclusions: Results from the first routine VL program in public sector in India are encouraging and in line with UNAIDS 90-90-90 targets. Routine VL monitoring resulted in earlier switching to second line ART while preventing unnecessary switching. Use of routine VL for ART monitoring should be scaled up in India.

WEPEE691

Efficacy of intensive adherence counselling in reversing virologically-defined treatment failure in HIV-infected patients on long-term antiretroviral therapy in rural Uganda

R.S.A. Mazzola[1], J. Byawaka[2], J. Birungi[2], J.E. Sproule[1], M. Nanfuka[2], K. Mugisha[2], D. Kagimu[2], M. Etukoit[2], D.M. Moore[1,3]
[1]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [2]The AIDS Support Organization (TASO), Mulago Hospital Complex, Kampala, Uganda, [3]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada

Background: The WHO currently recommends patients with a viral load (VL) ≥1,000 copies/mL undergo three monthly intensive adherence counselling (IAC) sessions, before repeat VL testing can direct changes to therapy. We examined the efficacy of IAC among HIV positive adults receiving ART for ≥4 years without prior VL testing.

Methods: We conducted a retrospective cohort analysis on data collected from patient charts at seven centres of The AIDS Support Organization (TASO). Our sample included adults (>18 years) on ART for ≥4 years with a measured VL ≥1,000 copies/mL recorded between January 2014 and June 2016, without previous VL testing. Participants attended three IAC sessions and underwent repeat VL testing within 3-6 months of the initial test. Multivariate logistic regression analysis was used to ascertain independent factors associated with suppression.

Results: A total of 634 patients, 411(64.8%) women and 223(35.2%) men, had VLs ≥1,000 copies/mL during the study period. The mean age was 41.4 years (SD 11.8 years) and the mean duration on ART was 6.8 years (SD 2.3 years). Two hundred forty-nine (39.3%) patients achieved a VL of < 1,000 copies/mL on repeat testing, after IAC. Participants with baseline VLs of 1,000-10,000 copies/mL were more likely to achieve suppression than those with >10,000 copies/mL (49.0% vs. 30.8%; p< 0.01). Multivariate analysis confirmed that baseline VLs of 10,001-40,000 copies/mL (AOR=0.61, 95% CI[0.40-0.93]) or >40,000 copies/mL (AOR=0.60, 95% CI[0.39-0.91]) were associated with a reduced likelihood of suppression. Patients having adherence < 85% (AOR=0.05, 95% CI[0.03-0.08]) or 85-94% (AOR=0.27, 95% CI[0.17-0.43]) following IAC were less likely to suppress compared to those with ≥95% adherence. Being widowed increased likelihood of suppression (AOR=1.83, 95% CI[1.00-3.35]) relative to being divorced, while receiving HIV care at TASO Soroti (AOR=0.12, 95% CI[0.05-0.25]) or Masaka (AOR= 0.26, 95% CI[0.13-0.51]) decreased likelihood of suppression.

Conclusions: Only 40% of participants who were on ART for ≥4 years without prior VL monitoring and who received IAC were able to reverse virologically-defined treatment failure. Lower baseline VLs and higher adherence after IAC predicted suppression. Outcome variability between TASO centres suggests programmatic differences at sites with lower reversal rates may improve outcomes.

WEPEE692

Moving from CD4 counts to Viral load measures; policy, practice and patient experiences in rural Tanzania and Malawi: A mixed-methods case study

J. Songo[1], J. Renju[2], F. Hasan[3], E. McLean[1], A. Dube[1], T. Kalua[4], E. Geubbels[3], J. Todd[5], A. Crampin[1], A. Wringe[6]
[1]Malawi Epidemiology and Intervention Research Unit, Lilongwe, Malawi, [2]London School of Hygine and Tropical Medicine, Moshi, Tanzania, United Republic of, [3]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [4]Malawi Ministry of Health, HIV & AIDS Department, Lilongwe, Malawi, [5]London School of Hygine and Tropical Medicine, Mwanza, Tanzania, United Republic of, [6]London School of Hygine and Tropical Medicine, London, Malawi

Background: In 2014 the WHO suggested a changing role for CD4 monitoring in clinical care, recommending routine viral loads (VL) to monitor adherence, and using CD4 counts to screen for opportunistic infections. However, roll-out VL testing has been slow in many settings and little is known about how the switch from CD4 counts to VL monitoring is taking place in practice. We used mixed methods in Tanzania and Malawi to i) document the evolution of national policies, ii) assess health facility level implementation; and iii) understand health provider and patient perspectives on the utility of these tests.

Methods: Guidance on the use of CD4 and VL were extracted from National HIV policies covering the period 2013-17. A facility survey was conducted in 2017 in health facilities in Malawi (n=5) and Tanzania (n=11) within two health and demographic surveillance sites (HDSS). Eight indicators on CD4 counts and VL testing were extracted. In-depth interviews with 3-6 health workers and 7-11 PLHIV across countries explored understanding and experience of the tests. Interviews were recorded and transcribed. Thematic analysis was conducted and findings compared across settings.

Results: Unlike Tanzania, Malawi did not adopt a policy requiring CD4 testing for ART eligibility. However both countries adopted VL testing in 2014 (Malawi) and 2015 (Tanzania). The frequency for VL testing was well aligned with national policy. Turnaround times for VL testing were longer than government recommendations in both countries (30 days).
(Figure 1).
In-depth interviews suggested that health workers were aware of the guidance for VL testing and recognised its utility to give a "*better picture of the health of our patients*". However, in Tanzania health workers preferred CD4 counts, where available, reporting that the turnaround time was quicker. In both countries PLHIV that recalled having undergone tests generally referred to CD4 counts and valued it as a measure of their health status.

Conclusions: Although CD4 counts are being phased out, the coverage of VL testing has not matched national policy. The slow scale up of VL testing and corresponding health worker training and delays in processing test results may undermine PLHIV engagement in HIV care.

	Tanzania n (%)	Malawi n (%)
Facility details

WEPEE693

Can adult peer educators (Expert PLHIV) be utilized in HVL sample transportation to scale up HIV viral load testing in resource limited countries? THPS experience in Tanzania

H. Mwizanduru, I. Mtafya, A. Mwakyusa
THPS, Program, Dar es Salaam, Tanzania, United Republic of

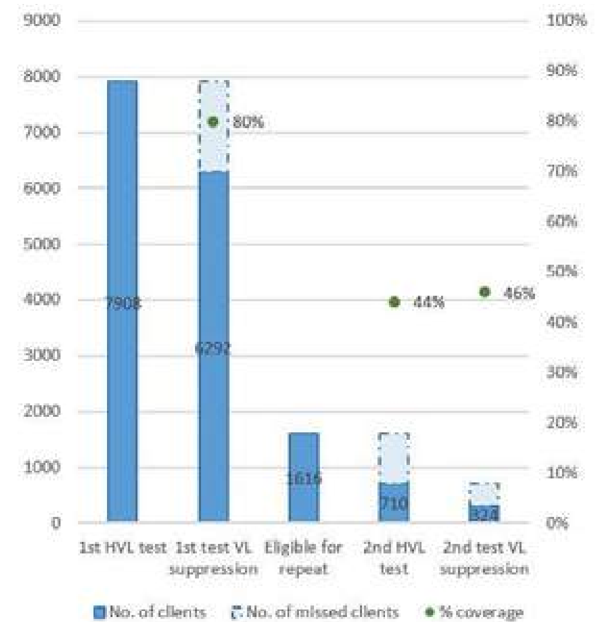
Background: HVL test remains the gold standard for monitoring patients on antiretroviral treatment. However paucity of HVL laboratories, human resource shortage and logistical challenges (sample storage and transportation) continue to be a barrier to access of HVL monitoring.
In addressing the above challenges THPS embarked on meaningfully engaging PLHIV in HVL sample transportation in all its catchment regions.PLHIV engaged also empowered to serve as Volunteers in supporting non-clinical tasks at care and treatment clinics e.g. counseling, group/individual education sessions, and facilitating disclosure and referrals of newly diagnosed PLHIV.
Description: In 2016 (123:72 female and 51 male) peer educators received three days training including practical's on sample management, documentation, biosafety issues and results feedback. Out of 123 Peer educators 102 (68 female and 34 Male) qualified and competent selected, provided with special ID cards, uniform and given the task of transporting samples using public Transport. National HVL monitoring tools were used in sample management. Data analysis conducted on weekly basis in the first month on total sample collected and transported, tested, rejected, results turnaround time and number of Peer Educators involved in sample logistics.
Lessons learned: A total of 14,534 HVL samples collected and transported between October2016 to Sept 2017 which made an achievement of 80% towards achieving the set target of 17588 HVL tests FY2016/2017. It was found that almost all rejected samples were due to technical operational/machine error. No rejections directly related to sample transportation. This proved that engaging expert PLHIV in sample transportation will fasten to reach UNAIDS third target before 2020.
Conclusions/Next steps: Trained PLHIV are capable of facilitating smooth running of HVL programs. And allows health providers to dedicate their time on clinical care; and because these Peer Educators are directly related with the consequence for this monitoring tests they serve as reliable agents. Adopting this practice in resource settings with limited numbers of HVL testing labs will facilitate scale up of HVL testing and hence reaching the UNAIDS global 3rd 90.

WEPEE694

Lessons from scaling-up HIV viral load testing in Tanzania: The importance of monitoring the HIV viral load cascade

R. van de Ven, G. Antelman, D. Haule, J. van 't Pad Bosch
Elizabeth Glaser Pediatric AIDS Foundation, Dar es Salaam, Tanzania, United Republic of

Background: Access to HIV viral load (HVL) testing in Tanzania has risen steeply in 2017 with the scale-up of testing laboratories and expansion of the hub-and-spokes model to transport and process samples. Within the regions supported by the Elizabeth Glaser Pediatric AIDS Foundation, HVL testing has increased three-fold within six months; from 4,157 tests between October 2016-March 2017 to 12,159 tests between April-September 2017. While the focus on scale-up has been to ensure all HIV clients receive a HVL test, follow-up results along the HVL cascade is equally important.
Methods: This retrospective analysis evaluates the HVL cascade (figure 1). Data from electronic medical records from the national HIV database at 71 sites were analyzed, for factors associated with uptake of repeat HVL testing among those identified with high viral load (>1,000 RNA copies per ml). Variables included age, sex, treatment regimen, and facility level.
Results: From October 2015 till March 2017, 7,908 clients received a first routine HVL test, with a viral load suppression rate of 80%. Out of 1,616 clients with a high viral load, 710 (44%) received a repeat HVL test and 46% of these clients were then found virally suppressed. Likelihood of repeat test was higher among patients seen at hospitals (46%) compared to lower-level facilities (25%, p< .0001), and patients on 2nd line regimen (55%) compared to 1st line (42%, p=.001). Children and adolescents/youths under 25 years were more likely to receive a repeat test (54%) compared to older patients (40%, p< .0001). The likelihood of receiving a repeat HVL did not vary by sex (p=.106).



[Figure 1: The HVL cascade at 71 sites across six regions in Tanzania, October 2015 - March 2017]

Conclusions: While the scale-up of HVL in Tanzania has improved, the follow-up of clients with high viral load lags. As many differentiated service delivery models are implemented for stable clients, these findings call for stronger focus on models for clients with high viral load. Follow-up along the HVL cascade also requires more investments in monitoring and evaluation systems to be able to track these at-risk clients and document the outcome of enhanced adherence counseling and potential treatment switch.

WEPEE695

Reaching the third 90 with a simple viral load quality improvement program in health facilities in Malawi

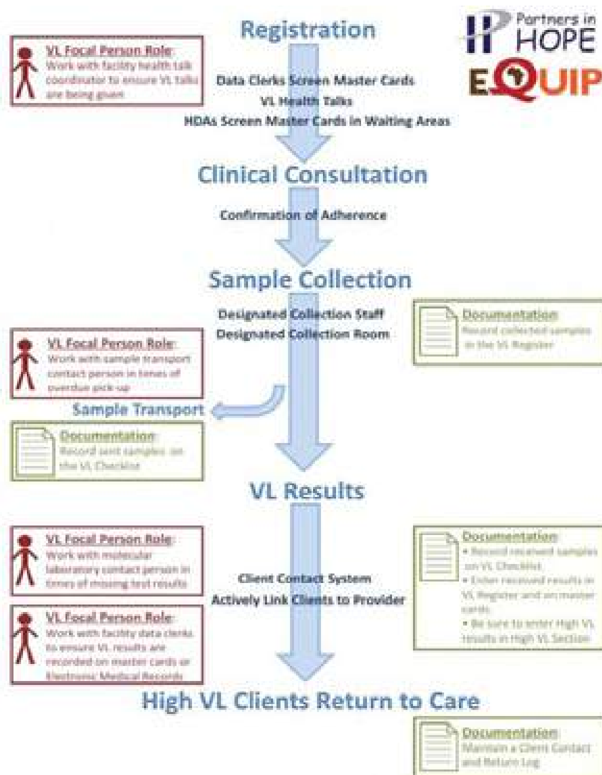
J. Hubbard[1,2], G. Kakwesa[3], J. Mwambene[4], K. Balakasi[2], T. Kalua[5], M. Nyirenda[3], K. Dovel[1,2], R. Hoffman[1,2], EQUIP Innovations for Health
[1]*University of California, Department of Medicine - Infectious Disease, Los Angeles, United States,* [2]*Partners in Hope-EQUIP, Research, Lilongwe, Malawi,* [3]*Partners in Hope-EQUIP, Technical Assistance, Lilongwe, Malawi,* [4]*Partners in Hope-EQUIP, Care and Treatment, Lilongwe, Malawi,* [5]*Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi*

Background: The UNAIDS 90-90-90 goals call for 90% of HIV-infected individuals on antiretroviral therapy (ART) to have a suppressed viral load (VL) by 2020. Scale-up efforts have largely focused on laboratory systems, with less attention on facility-level strengthening of staff who facilitate VL testing. To address this gap, we implemented a quality improvement (QI) program at 14 health facilities in Malawi supported by Partners in Hope-EQUIP, a PEPFAR/USAID mentorship program.
Description: In April 2016, we performed an assessment in health facilities in Central/Southern Malawi to identify facility-level barriers to VL testing. Findings informed the development of VL tools used in a QI program that focused on patient and provider VL knowledge and clarification of site-level roles and responsibilities, including the designation of a VL "Focal Person" to oversee all VL activities. Tools include: (1) standard operating procedures for VL testing that incorporate the Focal Person (Figure); (2) VL educational materials; and (3) job aids for the Focal Person. Orientations lasting 3-4 hours were conducted by clinical men-

tors in May 2017 in 14 health facilities representing both rural/urban hospitals and health centres. Monthly follow-up visits were preformed to provide mentoring. We compared the number of VL tests performed at these sites before (November 2016-April 2017) and after (May-November 2017) implementation of the QI program.

Lessons learned: The average number of VL tests performed significantly increased after implementation of the QI program (Table). Increased VL testing was sustained during the 6-months of follow-up. By mentoring facility staff on a monthly basis and appointing a Focal Person, VL procedures were optimized and streamlined, improving systems for client identification, sample collection, and results reporting. Increased education among patients allowed for "demand creation" while increased awareness among providers improved their ability to navigate the VL cascade.

Conclusions/Next steps: A simple QI program focused on improving VL knowledge among patients and providers and clarifying staff roles at a facility-level doubled VL testing over an extended period of time. Further investigation is needed on whether this program can be scaled in different settings across sub-Saharan Africa and on the duration of follow up required for sustained improvements in VL testing.



[Figure: Standard operating procedures for VL testing incorporating the Focal Person]

Facility Type	Mean number of monthly routine VL tests* before QI intervention (Nov 2016 -Apr 2017)	Mean number of monthly routine VL tests after QI intervention (May-Nov 2017)	**p-value
(n)	n(SD)	n(SD)	
District Hospitals (5)	96 (67)	187 (96)	<0.001
Mission Hospitals (4)	79 (31)	189 (86)	<0.001
Rural Hospitals (3)	71 (46)	168 (70)	<0.001
Health Centres (2)	23 (12)	90 (51)	<0.001
* Routine VL testing in Malawi is conducted 6 months after initiation, 24 months after initiation, and every 24 months thereafter			
** p-value calculated using t-tests			

[Table: Mean number of monthly routine viral loads taken before and after QI program, by facility type]

WEPEE696

Are adolescents and men the missing link? A review of viral suppression rates from a Kenya HIV program

M. Kitheka[1], S. Kelbert[2], S. Makunda[1], A. Gichangi[1], K. Curran[2]
[1]*Jhpiego, Nairobi, Kenya,* [2]*Jhpiego, Baltimore, United States*

Background: Kenya has made significant investments to fast track the 90:90:90 initiative towards HIV epidemic control. The Kenya AIDS Strategic Framework is the guiding policy document, and the country is investing heavily to achieve the 90:90:90 goals. The Ministry of Health has put in place an effective Viral Load (VL) surveillance system to monitor treatment success. The VLs are done for clients after 6 months and 12 months on ART then annually thereafter as per the national guidelines.

Description: APHIAPLUS KAMILI, a USAID funded project supports HIV care and treatment services in Eastern and Central Kenya since 2011. As of September 2017, there were 39,677 clients active on Antiretroviral Therapy (ART) across 140 sites. All clients on ART get at least one viral load test per year. The project has trained and mentored service providers on specimen collection, patient follow-up and assists on specimen referral through a lab networking system. Viral load results are posted online through a secure web system database and hard copies sent to facilities for client's clinical management. This review analyzed the viral load results database from all tests submitted from September 2016 to October 2017. Viral suppression is defined as VL results less than 1000 copies/ml.

Lessons learned: A total of 29,011 VL results were analyzed after all duplications and incomplete entries were removed. There were 23,973 (83%) clients who were virally suppressed. Viral suppression differed significantly by age, sex, region treatment regimen, and clinical indication on multivariate analysis. Male clients had lower viral suppression at 80% than female at 84% (P-value< 0.0001) and this was the same across most age groups. Adolescents had the lowest viral suppression across all counties. Viral suppression was at 90% (n=6,531) in age group 50 years+, with adolescents aged 15-19 (n=959) at 58% (P-value< 0.00001), 60% (n=1,280) in 10-14 years age band and 85 %(n=18,116) for 25-49 years.

Conclusions/Next steps: The region had made substantial progress in tracking viral suppression across regions and age groups. However, a lot needs to be done to improve viral suppression in adolescents and men. Close monitoring and adherence support is needed among these populations to improve treatment outcomes.

WEPEE697

"It helps us to help the patient earlier." A qualitative study from Zimbabwe exploring patient and health-care worker perceptions of receiving HIV viral load results by SMS

E. Venables[1,2], Z. Ndlovu[1], D. Munyaradzi[1], G. Martínez-Pérez[1,3], E. Mbofana[4], P. Nyika[5], H. Chidawanyika[6], D.B. Garone[4], H. Bygrave[1]
[1]*Medécins Sans Frontières, Southern Africa Medical Unit, Cape Town, South Africa,* [2]*University of Cape Town, Division of Social and Behavioural Sciences, School of Public Health and Family Medicine, Cape Town, South Africa,* [3]*African Women's Research Observatory, Barcelona, Spain,* [4]*Medécins Sans Frontières, Harare, Zimbabwe,* [5]*Ministry of Health and Child Care, Harare, Zimbabwe,* [6]*Research Triangle Institute International, Harare, Zimbabwe*

Background: HIV Viral Load monitoring is recommended by the WHO as a more accurate available measure of antiretroviral treatment response, and has been progressively adopted in many low and high HIV burden settings. Scale up of VL testing requires huge economic, laboratory and programmatic investments and significant challenges exist, including timely return of results to health facilities and patients; completion of adherence counselling and timeous switch to second line treatment for those eligible. Médecins Sans Frontières (MSF) introduced an mHealth intervention, where patients received a mobile phone SMS from the central laboratory to inform them that they should visit the clinic immediately to collect their VL results (if VL>1000copies/ml) or at their next scheduled visit (if VL< 1000copies/ml). The clinic received an SMS with the actual VL result.

Methods: A qualitative study was conducted in seven health-care facilities across the districts of Gutu and Buhera in rural Zimbabwe. In-depth interviews (n=32) and focus group discussions (n=5) were conducted to explore patient and health-care worker (HCW) perceptions and experiences of the mHealth SMS system intervention. Purposive sampling was used to select participants. Data were transcribed, coded and thematically analysed using NVivo.
Results: The VL SMS intervention was acceptable to patients and HCWs. HCWs perceived it to improve adherence and the well-being of patients by linking them to counselling services earlier and reducing the time taken to come to the clinic. Patients also appreciated the time they saved by not making unnecessary clinic visits. However, some participants were concerned about patient's challenges with understanding the purpose of the messages and the language of the SMSes. HCWs were more concerned about unintentional disclosure through the messages than patients were. Many participants believed future interventions could send the actual VL results to patients by SMS.
Conclusions: This was a unique and novel intervention in which an mHealth intervention was used to send SMSes to patients informing them about their VL results. Such interventions have the potential to empower patients and reduce unnecessary clinic visits, but need to be properly explained to patients before implementation, to ensure the purpose of the intervention is understood.

WEPEE698

Improving viral load test sample quality, coverage and suppression on antiretroviral therapy patients through quality improvement: A before-after study from south-western Uganda

A. Kwizera[1], J. Tumusiime[2], M. Namubiru[1], M. Walakira[3], E. Bitarakwate[3]
[1]*Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Health Systems Strengthening, Kampala, Uganda,* [2]*Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Knowledge Management, Kampala, Uganda,* [3]*Elizabeth Glaser Pediatric AIDS Foundation (EGPAF), Kampala, Uganda*

Background: To reach the ´third 90´ of viral suppression (VS), it will be essential to scale-up access to routine, quality viral load (VL) tests. One strategy anticipated to increase coverage of VL is with dried blood spot (DBS) testing and the quality of VL sample is essential for accurate results. To assess the impact of a comprehensive quality improvement (QI) intervention, we analyzed secondary routine program data before and after the intervention. Trends assessed were VL sample rejection rates, VL coverage, and VS.
Methods: National VL database was reviewed for our 264 supported sites in Southwest (SW) Uganda on key VL testing outcomes, January-September 2016 (before) and January-September 2017 (after) following implementation of QI activities to improve VL testing. This included: 5-day training Healthcare workers (HCWs) using National harmonized VL training module between October-December 2017; targeted VL mentorships; availing VL kits; continuous QI projects on identified VL cascade gaps. Aggregated data on samples rejected (rejection reasons), tests completed, and results extracted from VL dashboard, entered into Microsoft Excel for data analysis using descriptive statistics and assessed by gender and age. VL coverage defined as proportion of active ART clients eligible for VL with a VL test and VS as number of clients with a VL test result ≤1,000 copies/ml, as per national VL algorithm.
Results: Before intervention, 8.0% (n=2,786) of total samples were rejected commonly due to incomplete forms 59.3%, (n=1,652); poor sample quality 27.3%, (n=761); and non-eligibility (13.4%, n=373). VL coverage was 69% (n=34,825), 92.5% VS (94% women, 91% men). VS in adults (age≥19 years) was 95%, children and adolescents (5-10 years 75%, 10-15 years 80%, 15-19 years 75%). After implementation, samples rejected decreased to 2.4% (n=2,669), VL coverage increased to 85.0% (n=111,224), 93.8% VS (95.1% women, 92.5% men). VS in adults (≥19 years) was 95.0%, children and adolescents (5-10 years 78.0%, 10-15 years 81.0%, 15-19 years 82.0%).
Conclusions: In SW Uganda, following a multi-pronged QI intervention, we observed a decrease in proportion of rejected samples and increased VL coverage and VS. Investing in continuous QI and HCWs training may be important to maximize the impact of existing technologies to support VS.

Innovations and lessons for supporting adherence

WEPEE699

Empty exam rooms: Partnering with HIV consumer advisory board to improve medical appointment adherence, a New Jersey community health center experience

L. Kudryashova-Hernandez
Neighborhood Health Services Corporation, Ancillary/HIV, Plainfield, United States

Background: NHSC, a private, non-profit urban community-based health center in Plainfield NJ, USA, provides HIV care/treatment to approximately 360 patients under the umbrella of Early Intervention Services. NHSC has an enthusiastic, well-established Consumer Advisory Board (CAB) to offer valuable patient prospective on the EIS program development, implementation and evaluation, including quality improvement. Based on 2016 year-end data, HIV patient appointment adherence rates were sub-optimal (60%). Poor appointment adherence can be directly linked to virological failure and disease progression. NHSC determined *80% as its acceptable internal quality indicator* for medical appointment adherence.
Description: EIS program and CAB designed a quality improvement project around sub-optimal medical appointment adherence:
1. *Appointment Adherence Self-Assessment* tool was designed and administered to all patients to ascertain reasons for non-adherence.
2. Self-assessment responses were collected, analyzed and presented to CAB, EIS staff and leadership.
3. A 90-day **PDSA (Plan-Do-Study-Act)** cycle was developed to design a *process change* based on patients responses: a) Medical Case Managers (MCM) to make confidential reminder calls prior to appointments; b) MCM to identify barriers to appointment adherence (e.g. transportation) and make every efforts to resolve; c) MCM to provide patients with paper appointment slip and wall calendars to record appointments **(CAB suggestion)**, and d) MCM help patients schedule appointments of cell phone calendars **(CAB suggestion)**. Lists of missed appointments were generated weekly to contact patients on the same day to find out the reason for non-adherence and to reschedule.
4. Appointment adherence data was collected and analyzed on a monthly basis. It was further drilled down to identify specific patient sub-populations (gender, age, risk factor) that may require additional designated efforts to improve adherence.
Lessons learned: Based on the findings review/analysis at the end of the initial 90-days PDSA cycle: NHSC achieved 80% appointment adherence rate and was able **to sustain and surpass** it during the entire 2017. Furthermore, NHSC observed a 23% increase in viral suppression in previously unsuppressed patients.
Conclusions/Next steps: Implementation of a coordinated, patient-centered and patient-driven approach to appointment adherence monitoring and management allowed to achieve an overall *improvement of patient participation* in their care with the ultimate goal of achieving *sustained viral suppression*.

WEPEE700

"Qhubeka uthathe amapilisi": Solving the adherence challenge in antiretroviral treatment amongst women in the Ngqushwa district, Eastern Cape, South Africa. A user-developed programme

K. Pepper[1,2], N. Sibutha-Nodada[3]
[1]*University of KwaZulu Natal, College of Health Sciences, Durban, South Africa,* [2]*Ubunye Foundation, Health and Early Childhood Development, Grahamstown, South Africa,* [3]*Ubunye Foundation, Health, Grahamstown, South Africa*

Background: Blanket approaches to bolster ARV adherence have left significant gaps. An example is the case of newly-post-partum HIV+ women, whose ARV adherence shows a sharp drop after delivery.

Description: The objective of this programme is to address the challenge of long-term adherence by piloting a unique strategy: users become the researchers and programme developers, and photographs become the tools to achieve their goals.
Living in Nqushwa district, a rural, isolated region of the Eastern Cape of South Africa, ten women, newly post-partum, used photographs to record their struggles with ARV adherence after the birth of their baby. Taking photos of those barriers, they created a powerful portfolio of images. They then use this as a tool to communicate their challenges to local communities, health and social services, to open a discussion about their barriers, and to plan with these agencies how to manage their adherence together.
Lessons learned: This programme is on-going but already the photos are revealing a myriad of constantly-shifting barriers to adherence. These include: disparaging comments by relatives or friends; rumours around a local death; influence of bad spirits; physical and psychological impact of the drought; feelings of hopelessness and having 'paid' enough to have a child; purification by childbirth; exhaustion and a belief that others must take over.
Initial findings indicate that barriers to adherence are deeply personal, socially and culturally specific, and often related to the area in which people live. Using photos as tools, these women have been able to share a unique insight into their lives with others in their community. They are building an alliance between themselves and other community members and agencies to address these barriers together for the long term.
Conclusions/Next steps: This 'user-developed' programme - using photos as a vehicle - places the users in control of the collection, analysis and presentation of data, and puts them at the centre of support generated around them. In doing so it takes account of specific local and personal situations and resources, and ultimately moves adherence out of the medical sphere and away from a reliance on health services as the main support for those with HIV.

WEPEE701

Using peer-to-peer psychosocial support and active client follow-up to improve adherence: Lessons learnt from the mothers2mothers program in Southern Africa

M. Mbule[1], C. Hofmeyr[1], J. Igumbor[1,2], K. Schmitz[1]
[1]mothers2mothers, Cape Town, South Africa, [2]University of the Witwatersrand, Johannesburg, South Africa

Background: The ongoing scale-up of HIV treatment programs is undermined by poor treatment adherence challenges. Research has shown the use of reminders alone is not effective in promoting adherence and may even discourage clients who are struggling to adhere. mothers2mothers has developed an integrated service platform (ISP) that uses peer mentoring at both the health facility- and community-levels, combined with appointment-tracking and defaulter-tracing, to support women to stay on treatment during the first two years of her infant's life.
Description: mothers2mothers operates in urban and rural communities across eight southern and eastern African countries. The program employs lay health-workers, referred to as Mentor Mothers (MMs), to work in both facilities and their surrounding communities to deliver psychosocial support and education to pregnant women and new mothers. On a continuous basis, MMs track each client's ART pickups and follow up with text messages, phone calls and home visits when an appointment is missed. During each one-on-one interaction with a client, MMs conduct an adherence assessment as part of their standard package of services. Finally, when clients are identified to have poor adherence, MMs provide intensified education and support, and refer the client for additional social support services when appropriate.
Lessons learned: A multi-country internal evaluation of the mothers2mothers program conducted in 2017 revealed that the ISP model is associated with high rates of adherence. Measured as the number of days in the past week that the woman took her medication, 94.5% of the sample had an average adherence rate of >95% (n=326) over multiple measurements. In addition, over 95% displayed high levels of self-efficacy in remaining adherent. Low levels of adherence are often associated with lack of male partner support and partner violence.
Conclusions/Next steps: Rates of adherence in our evaluation did not vary significantly by country, suggesting that provision of peer support at both facility- and community-level in combination with appointment tracking is effective across different geographical and cultural settings. In order to address the challenges posed by minimal male partner engagement in remaining adherent, mothers2mothers is expanding the scope of the program to better include male partners in its package of services.

WEPEE702

Innovation & technology: Improving ARV access and adherence

F. Hendriksz
Right to Care, Right ePharmacy, Johannesburg, South Africa

Background: There are currently various initiatives in the South African health sector aimed at increasing patient access to medication and adherence. The most pioneering initiative is, an "ATM- like" innovation called a Pharmacy Dispensing Unit (PDU™) provides a differentiated and unconventional option for dispensing, counselling, and collection of medication. The pilot of this innovation in peri-urban communities in South Africa have uncovered benefits such as decongestion of overburdened facilities, freeing up healthcare practitioner capacity at primary healthcare facilities and the general quality of pharmaceutical services to patients.
Description: The PDU™ sites have been implemented in communities with high population densities, low Living Standard Measure (LSM) averages and located at community shopping centres which are within 15-minute travel time of the referring health facilities or clinics. PDUs™ provide the opportunity of alternate collection points for stable chronic outpatients; and convenience of accessibility, collection time flexibility as well as extended operating hours. PDUs™ utilises a cloud based dispensing software, barcode scanners, integrated medicine printer labellers, user interfaces and allows for tele-pharmacy access through audio-visual linking for remote counselling and dispensing capability.
Lessons learned: It is apparent that PDUs™ have the anticipated outcome of optimisation of limited pharmaceutical service resources through the increase in dispensing capacity and quality. The PDU™ sites allow patients to collect their medication at a time and location convenient to them; abating one of the common barriers to adherence in chronic stable patients. The most value derived comes from the trends identified from the analysis of demographic data and dispensing records. Other learning´s include referral health facility support, change management and continuous key stakeholder engagement.
Conclusions/Next steps: The success and challenges of this pilot implementation will be used to document "best practice standards" for this technology in the South African context., Opportunities will also be identified to optimize operations, inform policies and spread this solution locally and globally. Right ePharmacy intends to use its core competences in the domain of "Last Mile" dispensing and distribution technology to extend the application and functionality of the current technology to address other challenges in medicine access.

[AIDS 2018 PDU]

WEPEE703

A new patient-reported outcome measure to assess perceived barriers to antiretroviral therapy adherence: The PEDIA scale

C. Cardoso Almeida-Brasil, E. Nascimento, M. Rosa Silveira, P. Fátima Bonolo, M.D.G. Braga Ceccato
Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Perceived barriers are one of the strongest predictors of nonadherent behavior and a potentially modifiable construct. We sought to develop and validate a new patient-reported outcome measure to assess perceived barriers to antiretroviral therapy (ART) adherence.
Methods: Based on open-ended interview questions with HIV-infected adults from a national study, a pool of 47 items was created. After pilot-testing and content validity, scale revisions resulted in a 40-item version of the Perceived Barriers to Antiretroviral Therapy Adherence (PEDIA) scale. The PEDIA was administered to 415 HIV-infected adults receiving ART for a maximum of 180 days, recruited from three healthcare facilities that are a reference in HIV treatment in the city of Belo Horizonte, Brazil. Analyses included exploratory factor analysis, internal consistency, temporal stability, item response theory analysis, and criterion validity analysis.
Results: The final scale version contains 18 items distributed in three dimensions as follows: cognitive and routine problems (4 items); medication and health concerns (6 items); and patient`s fears and feelings (8 items). Results of the Cronbach's alpha (0.74) and temporal stability demonstrate that the PEDIA is internally consistent and yields stable scores over time. Test information functions suggested that the three dimensions were informative in assessing a broad range of the latent trait. Criterion validity was confirmed since a negative association was found between the total score of the PEDIA and adherence scores. Independently of other participants' characteristics, the odds of being non-adherent was significantly higher for participants who scored 1 point more in the total scale (aOR=1.18; 95%CI: 1.11, 1.23), and in each dimension: cognitive and routine problems (aOR=1.63; 95%CI: 1.40, 1.90); medication and health concerns (aOR=1.32; 95%CI: 1.15, 1.51); and patient`s fears and feelings (aOR=1.12; 95%CI: 1.05; 1.20).
Conclusions: Our findings suggest that the PEDIA is a psychometrically sound tool for evaluating perceived barriers in adult patients initiating ART. It can be utilized in both research and clinical practice settings for early identification of patients at risk for non-adherence and for the development of behavior change interventions. The PEDIA may ultimately narrow the gap between providers` and patients` realities and improve the quality of care from the patient's perspective.

WEPEE704

Improving HIV treatment uptake among HIV-positive female sex workers in Naivasha, Kenya

H. Nyongesa[1], C. Gathoni[2], L. Njeri[2], B.E. Ogwang'[1], N. Njuguna[1]
[1]*FHI 360, LINKAGES Program, Nairobi, Kenya,* [2]*Kenya National Outreach, Counselling and Training Program (K-NOTE), Naivasha DIC, Naivasha, Kenya*

Background: Stigma and discrimination (S&D), inadequate information on HIV treatment services, and inefficient key population (KP)-specific support mechanisms in the community negatively affect sex workers' ability and decision to access care and treatment services. To increase use of HIV treatment services, LINKAGES/Kenya — led by FHI 360 and supported by USAID and PEPFAR — implemented the *encounter initiative,* a personalized process for linking HIV-positive female sex workers (FSWs) to antiretroviral therapy (ART) in Naivasha, Kenya.
Description: The encounter initiative involves two strategies:
1) small, personalized group meetings dubbed *encounter groups* and
2) client feedback forums focused on addressing S&D against KPs living with HIV (KPLHIV).
Encounter groups comprise of three people: the client (a KPLHIV who has not begun or has stopped taking ART), a clinician, and a trained KPLHIV champion who has been on treatment for at least 24 months. Meetings involve talking with the client about benefits of treatment and factors that hinder their access to treatment, and formulating a plan to link them to care. Up to three encounter meetings are conducted. KPLHIV are linked to care at nearby government-run ART centers and supported by the KPLHIV champion. Feedback forums are held with the KPLHIV to understand if they face S&D at the ART centers; if stigma is reported, the clinician organizes a sensitization meeting at the facilities to highlight the importance of providing stigma-free services to KPs.
Lessons learned: In January 2017, there were 112 KPLHIV enrolled within the program, of whom 30 (27%) were on ART. From March to December 2017, 99 KPLHIV who were not yet on ART or had stopped treatment were engaged in encounter groups and followed up with feedback forums. Seventy (71%) of those KPLHIV initiated ART thus raising overall uptake to 100 (72%) (Figure 1). The most commonly cited reason (75%) for poor uptake of ART was S&D from healthcare workers. To address this, we conducted two sensitization meetings at two facilities commonly mentioned.
Conclusions/Next steps: Establishing community support for KPLHIV is key in their initiating antiretroviral therapy. Additionally, interventions to address S&D and accommodate KPs will encourage use of HIV treatment services by sex workers.

WEPEE705

Towards 95% completion rates of Isoniazid preventive therapy in resource limited setting; case of Amref Kibera community health centre, Nairobi, Kenya

Z. Muiruri Njogu[1], D. Wanyama[2], M. Mungai[2], S. Karanja[3], D. Dianga[1]
[1]*Amref Health Africa-Kenya, TB/HIV/Malaria Program, Nairobi, Kenya,* [2]*Amref Health Africa Kenya, TB/HIV Program, Nairobi, Kenya,* [3]*Amref Health Africa in Kenya, Country Programme, Nairobi, Kenya*

Background: Tuberculosis is the most frequent life-threatening opportunistic disease in people living with HIV (PLHIV). World Health Organization recommends the routine use of Isoniazid for 6 months to treat latent tuberculosis infection in PLHIV. Globally, many HIV programs have IPT completion rates lower than 90%. In year 2016, IPT completion rate was 84.72% among PLHIV attending Amref Kibera Community Health Centre. Failure to complete IPT was highly associated with Lost to follow up (5.09%) and self discontinuation (5.56%). This study aims to demonstrate how 6 months IPT completion rates can be improved through improvised pre-packing of Isoniazid and pyridoxine in resource limited setting in Amref Kibera Health centre.
Methods: This is a before and after study with PLHIV started on IPT before and after initiation of Isoniazid and pyridoxine pre-packaging intervention between December 2015 and May 2017. Baseline data on IPT completion rates was obtained from IPT register and generated into excel format. During intervention phase each client starting IPT was assigned a 6 months dose of IPT pre-pack. The number of drugs dispensed, date of collection and next refill date was documented on the packs. The packs were routinely monitored to detect treatment interruption. A customized tracking tool was used to document follow up outcomes. Prompt adherence counseling was done through phone calls and home visits. At the end of the 6 months therapy, all clients whose packs had drug remainders were traced back and interventions done as per the IPT national guidelines.

[Improvised IPT prepacks]

Outcome	Before Interventions (n=432) Number of patients	Rate	After Interventions (n=177) Number of patients	Rate
Completed IPT	366	84.72%	168	94.91%
Lost To Follow up	22	5.09%	2	1.13%
Died	5	1.16%	2	1.13%
Transferred out	13	3.01%	4	2.26%
Self discontinuation	24	5.56%	0	0.00%
Developed Adverse Drug Reaction (ADR)	2	0.46%	1	0.57%
Developed Active TB disease	0	0.00%	0	0.00%

[6 months Isoniazid Preventive Therapy (IPT) outcomes]

Results: During the intervention phase (September 2016 and May 2017), of the 177 patients started on IPT, 94.91% (168) successfully completed a full course of 6 months IPT in comparison to 84.72% (366) who completed IPT among 432 patients started on IPT between December 2015 and August 2016. The rate of self discontinuation and lost to follow up declined from 5.56% to 0% and 5.09% to 1.13% respectively.
Conclusions: IPT prepackaging offers individualized patient monitoring which significantly improved the 6 months IPT completion rates. We recommend for a global plan for IPT commodities to be pre-packed like the TB treatment drugs.

WEPEE706

Adherence patterns among patients enrolled in comprehensive HIV care programs in Kinshasa and Haut-Katanga provinces in the Democratic Republic of Congo

S. Dane[1], T. Tchissambou[2], A. Jha[3], F. Malele[2], D. Dibulundu[2], S. Matsumaini[2], B. Ngalamulume-Roberts[3], Y. Ilunga[2], J. Soares Linn[3]
[1]Columbia University Mailman School of Public Health, ICAP at Columbia University, New York, United States, [2]ICAP at Columbia University in DRC, Kinshasa, Congo, Democratic Republic of the, [3]ICAP at Columbia University, New York, United States

Background: The Democratic Republic of Congo (DRC) has committed to reaching 70% antiretroviral therapy (ART) coverage in 2018, but the effectiveness of lifesaving HIV treatment is dependent on patient adherence. Understanding adherence patterns, including sex differences, is critical to designing effective adherence support interventions as part of HIV treatment programs.
Methods: This analysis aimed to identify demographic and geographic correlates of ART adherence, and used aggregate data from 151 ICAP-supported sites in Kinshasa and Haut-Katanga provinces in DRC, collected from 2015-2017. The aggregate data was originally collected from ART registers at ICAP-supported sites. Adherence interventions in these facilities included adherence clubs, support groups, buddy systems using mobile apps, and adolescent groups that discuss barriers to adherence. Using logistic regression, we analyzed whether adherence is associated with sex, province, and age group in the first 12 months of treatment.
Results: Between January 1, 2015 and December 31, 2016, 7,346 adolescents (ages 15-19) and adults (ages 20 and over) newly initiated ART. Between March 1 2016 and December 31 2017, 4,405 (60%) patients had reached 12 months on treatment and self-reported as adherent. In an initial multivariable analysis, interaction was found between sex and province, and age group and province, so all further analyses were stratified by province. When controlling for age group, males in Kinshasa were less likely than females to be adherent in the first twelve months on treatment [adjusted odds ratio (AOR)=0.75, 95% CI=0.66-0.86)]. No difference was found between adolescents and adults (AOR=1.48, 95% CI=0.99-2.19). In Haut-Katanga, no difference was found between males and females (AOR=1.13, 95% CI=0.95-1.35). In Haut-Katanga, adolescents were more likely than adults to be adherent (AOR=4.58, 95% CI=2.22-9.47).
Conclusions: Differences between Haut-Katanga versus Kinshasa might be connected to overall higher socioeconomic status in Haut-Katanga, a result of the many precious stone mines in the region. Additionally, psychosocial support services targeted to adolescents in Haut-Katanga might explain age group differences in adherence. Option B+ for prevention of mother to child transmission of HIV provides an avenue for many newly initiated women to receive enhanced support, which might explain sex differences in Kinshasa.

Adolescent and youth programming

WEPEE708

Factors associated with transactional sex among adolescent girls and young women accessing community-based combination prevention services in Tanzania

G. Mbita[1], C. Casalini[2], A. Mwanamsangu[1], E. Esther Majani[2], T. Kipingili[3], A. Mongi[2], A. Akridge[4], W. Kafura[5], A. Komba[2], K. Curran[6]
[1]Jhpiego Tanzania, Monitoring Evaluation and Research, Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego Tanzania, Program, Dar es Salaam, Tanzania, United Republic of, [3]PACT Tanzania, Program, Dar es Salaam, Tanzania, United Republic of, [4]USAID Tanzania, Program, Dar es Salaam, Tanzania, United Republic of, [5]Tanzania Commission for AIDS (TACAIDS), Program, Dar es Salaam, Tanzania, United Republic of, [6]Jhpiego USA, Program, Baltimore, United States

Background: Sauti is a PEPFAR/USAID-funded HIV combination prevention project serving key and vulnerable populations, including adolescent girls and young women (AGYW); however, sex workers' programming targets only females ages 18 and above who exchange sex for cash or goods as their primary source of income. Trained biomedical providers offer services in the community at hot spots, which are defined as areas of high HIV transmission, or at home and resource centers.
Methods: We describe the characteristics of a population of out-of-school AGYW engaging in transactional sex, defined as self-reported exchange of sex for cash or goods (not as a primary source of income); vulnerable AGYW are defined as ages 15-24 who are out of school and sexually active; the analysis covers 12 regions in Tanzania, from August 2015 to September 2017. Factors associated with AGYW engagement in transactional sex were determined using multivariate logistic regression analysis on routinely collected project data.

Predictors	Multivariable OR [95% CI]	P-value

[Table 1. Multivariate logistic regression for transactional sex predictors among AGYW]

Results: Among 96,882 AGYW who accessed Sauti services over the 25-month period, 31.4% reported transactional sex. Among them: 64.6% were ages 15-19; 67.2% were single; 29.0% didn't use condom in the last month; 4.2% and 1.4% respectively used alcohol or drugs during sex within the last month; 56.9% didn't use a modern family planning method; 1.5% reported STI symptoms; 39.4% reported violence; and 2.5% tested HIV seropositive. At multivariate logistic regression, AGYW engaged in transactional sex were more likely to be young (OR 3.50 [3.36-3.65]; p< 0.001), married/cohabiting (OR 1.33[1.28-1.38]; p< 0.001) or divorced/sep-

arated (OR 2.14[1.92-2.38]; p< 0.001), to use condoms (OR 5.41[4.23-4.59]; p< 0.001), to use alcohol or drugs during sex within the last month (OR 3.22[2.97-3.50]; p< 0.001; OR 1.50[1.31-1.72]; p< 0.001; respectively), to use short acting FP methods (OR 3.86[3.71-4.00]; p< 0.001), report violence (OR 2.70[2.60-2.81]; p< 0.001), and be HIV infected (OR 1.79[1.62-2.0]; p< 0.001).

Conclusions: report violence, the project should intensify its efforts in reaching them with FP services and violence screening. In addition to ongoing structural and behavioral interventions, other biomedical interventions packages such as community-based ART and Pre Exposure Prophylaxis that target vulnerable AGYW engaged in transactional sex is necessary.

WEPEE709

Drug use, HIV, HCV infections among young people who use drugs (YPUD) in 3 cities of Vietnam

L. Nguyen[1], O. Khuat[1], L. Mitchel[2], O. Phan[2,3], C. Pham[1]
[1]Center for Supporting Community Development Initiatives, Hanoi, Vietnam, [2]Centre Pierre Nicole, Paris, France, [3]Unité INSERM, U1018, Maison des Adolescents, Paris, France

Background: In South East Asia, including Vietnam, amphetamine-type stimulants (ATS) is replacing heroin as the most popular drug. HIV programs, targeting PWID have most clients in their 30s and 40s. Little is known about actual drug use behaviors and HIV/HCV risks among younger generations.

"*Saving the Future project*" (funded by the French's 5% Initiative) implements innovative HIV prevention strategies among YPUD in Vietnam (16 to 24 y/o), regardless of their drug of choice and mode of use. An initial survey was conducted to learn about drug use and HIV/HCV risks and findings were used to develop packages mitigating the risks.

Methods: An RDS survey was conducted in 2016/2017 in Hanoi, Haiphong and Ho Chi Minh, 3 Vietnam biggest cities. Participants aged 16-24 y/o and urine test positive to at least one of the 4 most popular drugs in Vietnam: Methamphetamine, Cannabis, Heroin, Ecstasy. Participants responded to a questionnaire on demography, family, drug use, sexual behaviors, dependence. Blood sample was collected for HIV/HCV sero-status data. Study protocol was approved by a national IRB.

Results: 584 YPUD were enrolled, 42.1% were 16-18 y/o. 19.9% female, 1.2% transgender people, 61 self-identified as MSM, 84 reported selling sex (33 were male).

Polydrug use is common: 31.8% tested positive to more than 1 drug. Methamphetamine use reported by 83%, 71% tested positive; Cannabis 69.2% and 43.2%; Heroin 25.3% and 18%. Only 11% reported injecting and almost exclusively Heroin. Methamphetamine injection is rare, occurred only when YPUD need to hide their drug use or as an experiment.

Overall HIV/HCV prevalence was 6.3% and 9.4% (see table for details).

70.5% of YPUD reported ever had sex (80% reported at least one risky sex behaviors, 46% reported less likely using condom after consuming methamphetamine).

YPUD characteristics (n= 584, Hanoi: 168, Hai Phong: 213, HCMC: 203)	HIV prevalence	HCV prevalence
All participants	6.3%	9.4%
Methamphetamine user, never inject	5.9%	6.6%
Current heroin injector	17.8%	35%
Cannabis smoking only	0	0
MSM, never inject	16.4%	2%
Age 16 - 18	0.7%	0.7%
Age 19 - 22	6.5%	5.9%
Age 23 - 24	9.5%	14%

[HIV, HCV prevalence among YPUD in 3 cities in Vietnam by characteristics]

Conclusions: Methamphetamine is the most popular drug for YPUD, associated with HIV and HCV infection. Injecting is unpopular but associated with greatest risk for HIV and HCV. Being an MSM using drug is also associated with high HIV prevalence. Intervention should be differentiated for each segment of this population.

WEPEE710

Raising awareness of HIV status among learners through school-based testing in King Cetshwayo district, KwaZulu-Natal

E. Ford-Kamara[1], J. Hill[2], K. Duncan[2], G. Ngidi[1], R. Uenishi[2], N. Gcwensa[1], L. Ohler[1], A. Shroufi[2], S.J. Steele[2]
[1]Medecins Sans Frontieres - South Africa, Eshowe, South Africa, [2]Medecins Sans Frontieres - South Africa, Cape Town, South Africa

Background: Since 2011, Médecins Sans Frontières (MSF) has partnered with the Department of Health (DoH) in wards 1-14, uMlalazi, King Cetshwayo District, KwaZulu-Natal, to decrease HIV-related mortality and morbidity. A 2013 population survey by MSF estimated that new HIV infections were highest among those aged 15-29, with incidence among young women reaching a peak of 6.2% at age 19. To reach part of this population, MSF began working with the Department of Basic Education (DBE) in 2012 to provide health services at secondary schools.

Description: MSF conducts annual visits for grade 8-12 learners in 32 secondary schools commencing with DBE-approved age-appropriate health education sessions promoting behaviour which prevents HIV infection and the importance of knowing your HIV status. Following the education sessions voluntary HTS, pregnancy testing, condoms, and screening for STIs and TB are offered to learners in a mobile van. HIV-positive learners are referred to a DoH facility and linked to a Learner Support Agent or Life Orientation Educator, whom MSF has trained to be year-round focal points within schools. Additionally, young males are recruited for voluntary male medical circumcision.

Health promotion in schools has increased from reaching 11,088 learners in 2013 to 14,636 learners in 2017. Between 2013 and 2017, the number of HIV tests conducted increased from 4,474 to 6,591 while positivity rates declined (Figure 1). In 2017, 45% of learners (n=6591) accepted HTS, with 1% (n=65) testing positive. 71.4% (150/210) of HIV positive learners received a point of care CD4 between 2013-2015, with 58.0% being >500cells/μL, suggesting the program is accessing healthy HIV positive youth.

Lessons learned: Annual HTS with health promotion provides a safe space for learners to know their HIV status. HIV focal points in schools facilitate support and linkage to care for HIV-positive learners, and encourage healthy behavior.

Conclusions/Next steps: It is feasible to deliver these services in a mobile outreach model and a core element of implementing the National DBE policy should be that districts with high HIV burdens in South Africa should introduce annual HTS with Health Promotion on knowing HIV status, and train and establish HIV focal points among educators in schools.

[Figure 1: Numbers tested for HIV and proportion positive at schools, 2013-2017]

WEPEE711

Adolescent girls and young women as end users of HIV prevention in sub-Saharan Africa: Mapping ongoing and planned research along the HIV prevention journey to inform product introduction

E. Donaldson, A. Gomez, L. Fitch, E. Gardiner, M. Warren
AVAC, New York, United States

Background: New HIV prevention products are needed and existing ones need to be successfully introduced to address the disproportionate number of new infections among adolescent girls and young women (AGYW) in sub-Saharan Africa. For successful product introduction, a thorough understanding of factors that influence AGYW's awareness, acceptance, uptake, adherence and championing of HIV prevention is essential. The landscape of AGYW and HIV prevention research is highly saturated, and a mapping of research along the prevention journey framework is needed to discover what is known, will be known and what gaps exist.
Starting in 2017, the HIV Prevention Market Manager project began tracking ongoing and planned work. This mapping builds on a previously published analysis, identifying the full scope of work in this area and mapping research questions to the journey framework.
Methods: A review of ongoing and planned research on HIV prevention and AGYW ages 13-28 in sub-Saharan Africa was conducted. The review maps research by study type, country and questions along the prevention journey framework—awareness, acceptance, uptake, adherence and championing. Structured interviews with product developers, researchers, marketing agencies, program implementers and surveys informed the mapping.
Results: The review identifies 84 organizations working on 104 ongoing and planned projects in 18 countries across sub-Saharan Africa. Research focuses primarily on acceptability and adherence, with oral PrEP the main product under study. The mapping found that South Africa, Kenya and Zimbabwe are the primary locations for research. Only 14% of all projects in sub-Saharan Africa gather information on those who influence potential HIV prevention users, with 54% of these projects including a focus on male partners, and only 4% including a focus on the health provider as influencer.
Conclusions: The mapping brought to light several gaps in research on AGYW as end users of HIV prevention products, such as the lack of research focused on providers.
The mapping intends to be a living document, updated with new research on an ongoing basis, and can inform collaborations and act as a guide to funders and implementers when considering what is already happening, what gaps exist and what new work is needed to understand AGYW and HIV prevention.

WEPEE712

The SAGE-DREAMS project increases AGYW access to HIV testing services using school-based outreach: Evidence from Rakai district, Uganda

T. Odong[1], R. Laura Lulua[1], H. Achola[1], E. Omen[1], G. Ekpo[2], J. DeSoto[3,4], S. Waisswa[1]
[1]*World Vision, Kampala, Uganda,* [2]*World Vision, Washington, United States,* [3]*World Vision, Health, Program Quality and Impact, Washington, United States,* [4]*George Washington University School of Public Health, Washington, United States*

Background: Recent UNAIDS (2016) statistics indicate that in Uganda, 570 adolescent girls and young women (AGYW) aged 15-24 get infected with HIV each week. HIV prevalence is almost four times higher among AGYW than their male counterparts (UPHIA 2016-2017). The Strengthening School Community Accountability for Girls' Education (SAGE) is a two-year project (October 2016-September 2018) implemented by World Vision, Inc., funded by PEPFAR as part of the DREAMS Innovation Challenge, managed by John Snow, Inc. (JSI). It aims to keep 45,000 AGYW in 151 secondary schools across 10 districts in Uganda, which acts as a social vaccine to reduce new HIV infection.

Description: Rakai district in Uganda has one of the highest HIV prevalence (7.6%) compared to the national average (6%) (UPHIA 2016-2017). The SAGE-DREAMS addresses socio-economic risk factors for HIV infection among AGYW using adolescent girl-led school-community approaches.
To contribute to the national and UNAIDS 90-90-90 Global Strategy, the project adopted school-based HIV testing services (HTS) outreach strategies. The project mapped all health facilities providing HTS around target schools, supported health workers to conduct HTS in schools, and trained school administrators, teachers and adolescent girl leaders to mobilize students for HTS. After twelve school-based outreaches were conducted 2,363 out of the estimated 2,761 AGYW got tested for HIV and received their results, representing an 86% testing rate.
Lessons learned:
- School-based HTS enables AGYW to be reached in large numbers with support from the school administration, teachers and peer educators.
- Working with existing professional health workers eases the process of referral in case of AGYW found to be positive.
- School provides youth friendly spaces away from the health facilities as service points which reduces fear and encourages students to go for HTS.
- School-based HTS outreach approach strengthens relationships between health workers, schools and parents/caregivers.

Conclusions/Next steps: School-based outreach increases access to HTS for AGYW as per the findings in the twelve schools in the Rakai district in Uganda. The SAGE-DREAMS project will scale up this approach to reach more AGYW with HTS and these promising preliminary findings can be applied more broadly in Uganda and elsewhere.

Strategies to identify and reach high risk young women with DREAMS services in Zimbabwe

S.T. Chabata[1], B. Hensen[2], T. Chiyaka[1], P. Mushati[1], R. Makandwa[1], S. Floyd[2], J. Busza[2], I. Birdthistle[2], J.R. Hargreaves[2], F.M. Cowan[1,3]
[1]*Centre for Sexual Health and HIV/AIDS Research (CeSHHAR) Zimbabwe, Harare, Zimbabwe,* [2]*London School of Hygiene and Tropical Medicine, London, United Kingdom,* [3]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Background: Adolescence and sex work are independent risk factors for HIV. In many countries, including Zimbabwe, young women who sell sex (YWSS) are doubly criminalised as sex work and having sex below the age of consent are illegal. Consequently, they are particularly hidden and hard to reach with HIV prevention and care services. The DREAMS Partnership aims to reduce risk of HIV acquisition among the most vulnerable adolescent girls and young women, including YWSS, in 10 sub-Saharan African countries. We describe two methods used to identify and refer YWSS for DREAMS services (DREAMS) in Zimbabwe.
Description: DREAMS funds a 'Core Package' of evidence-informed approaches that go beyond the health sector, addressing structural drivers that increase girls' HIV risk, including poverty, gender inequality, sexual

violence, and lack of education. In Zimbabwe, a component of the core package for YWSS is the offer of oral pre-exposure prophylaxis. We used two approaches to identify hard to reach YWSS: 1) respondent-driven sampling surveys (RDS) and 2) peer outreach. For the RDS, we conducted detailed mapping to understand sex work typology and geography then purposively selected 20 participants to initiate RDS recruitment. Once recruited, YWSS underwent survey procedures and were referred for DREAMS. For peer outreach, we initiated recruitment through 18 trained and age-matched, supported peer educators using youth tailored community mobilisation and as with RDS, YWSS were referred for DREAMS. In both approaches we used unique identifier codes (UIC) to track YWSS across services provided by different implementing partners.
Lessons learned: From April-July 2017, RDS referred 1204 YWSS and from August-November 2017, the peer educators referred 2461 YWSS; 426 (35%) and 378 (15%) reached DREAMS, respectively (Table 1). There were challenges tracking YWSS across implementing partners because some YWSS intentionally altered information used to generate their UIC when accessing different DREAMS services. Also with these strategies, we couldn't capture or collect information on YWSS who refused participation.
Conclusions/Next steps: Peer referral whether through RDS or peer outreach is able to identify high risk young women and refer them to services. There is need to use robust UIC and other systems to facilitate tracking of individuals and avoid double counting.

Characteristic		Referred through RDS (N=426)		Referred through peer outreach (N=378)	
		n	% (RDS-2 weighted)	n	%
Age	≤19	144	34.9	174	46.0
	20-24	282	65.1	204	54.0

WEPEE714

Parenting programs a medium for addressing gender based violence and HIV risk reduction for DREAM girls

G.S. Nakabugo[1], C. Mungooma[2], F. Ayo[3], C. Agaba[4]
[1]TASO, Programs and Capacity Development, Kampala, Uganda, [2]TASO, Program Management and Capacity Development, Kampala, Uganda, [3]Catholic Relief Services, Program Management, Kampala, Uganda, [4]TASO, Research, Kampala, Uganda

Background: According to the Uganda Population Based HIV Impact Assessment (UPHIA 2016- 2017), the prevalence of HIV among adults aged 15 to 64 in Uganda is 6.2%: 7.6% among females and 4.7% among males. HIV prevalence is almost four times higher among females aged 15-24 years than their male counterparts. The AIDS Support Organization (TASO) is implementing a 2 year DREAMS (Determined, Resilient, Empowered, AIDS free, Mentored and Safe women) initiative targeting Adolescent Girls and Young women (AGYW) 10-24 years in three districts of Uganda. The goal is to reduce HIV incidence by 40% in two years. Strengthening families is one of the core packages offered through DREAMS. The interventions aim to strengthen the family economically as well as their ability to parent positively. Programs that involve parents and caregivers have shown to be effective in changing HIV related sexual behaviors among young people.
Description: The Sinovuyo Parenting intervention is a 14-week training program aimed at creating strong and positive relationships among teens and their caregivers. It helps families to get along better, reduces the risk of child abuse in families and helps teenagers to stay safe from HIV and AIDS. The teens who test HIV negative are enrolled into the program and those who test positive are linked to care. TASO has worked with the communities and formed 587 parenting groups composed of teens 10-17 years and their caregivers who meet in safe spaces. A total of 9,144 AGYW adolescent girls have benefited from the program.
Lessons learned: Risk reduction is evident; out of the 9,144 girls enrolled on the program and re tested; 99% are HIV negative and one (1) girl tested HIV + . Parenting interventions are addressing violence against children. Community facilitators have been empowered to support children report violence, 18 cases of abuse been reported and addressed. Community ownership of the program is crucial, all the 280 community safe spaces/ meeting spaces are provided by community members. Customization of the evidence based models is key in DREAMS implementation.
Conclusions/Next steps: DREAMS interventions have contributed to a decline in new infections among Adolescent Girls and empowered communities to address violence.

WEPEE715

A qualitative assessment of HIV risk and engagement in health services among adolescent girls who sell sex in Zimbabwe

S. Zitha[1], J. Busza[2], E. Fearon[3], F.M. Cowan[4], D. Hanisch[5], T. Mbengeranwa[6]
[1]CeSHHAR Zimbabwe, Key Populations, Harare, Zimbabwe, [2]WHO Ethiopia Country Office, Department of Population Health London School of Hygiene and Tropical Medicine, Addis Ababa, Ethiopia, [3]London School of Hygiene and Tropical Medicine, Department of Public Health, Environments and Society, London, United Kingdom, [4]CeSHHAR Zimbabwe, Research, Harare, Zimbabwe, [5]United Nations Population Fund, Technical Specialist HIV Prevention & SRH, Harare, Zimbabwe, [6]National Aids Council, Key Populations, Harare, Zimbabwe

Background: Adolescent girls and young women in Sub Saharan Africa remain at high risk of HIV. In Zimbabwe, little is known about adolescent girls (16-19 years) engaged in sex work, making it difficult to adapt programmes to meet the needs of this particularly vulnerable group. We conducted a study to understand the organisation of sex work among this age group and identify implications for targeted programming.
Methods: We collected qualitative data to understand how adolescent girls who sell sex (AGSS) operate, with whom they work, and the risks they face. In-depth interviews were conducted with 16 adolescent girls who self-reported having been actively involved in sex work in the last 30 days. Three focus group discussions were also conducted with 32 AGSS. Questions explored the AGSS' drivers of sex work, experiences, health knowledge and service use.
Results: AGSS reported financial shocks precipitated entry into sex work. Their stories indicated that poverty was a push factor, and most girls perceived their sex work to be temporary, something they were doing to cushion themselves during times of economic hardship. The girls lacked information on services available to them and were unaware of which sexual behaviours put them at risk of HIV. Even though respondents self-reported high and consistent condom use, they had all agreed to have unprotected sex at some point in their lives. AGSS reported being an insular group, preferring to remain in secrecy, which made them particularly vulnerable. They did not want to associate themselves with programmes already available for sex workers. AGSS reported they were in constant conflict with older sex workers for charging less and for their popularity with clients.
Conclusions: AGSS are vulnerable to HIV and lack important information on sexual and reproductive health and thus engage in behaviour detrimental to their general health. Programs tailored to their specific needs and vulnerabilities are required.

WEPEE716

State of the art diagnosis on the implementation of comprehensive sexuality education in the English and Dutch speaking Caribbean

M. Gunter, X. Edmund
United Nations Population Fund (UNFPA), HIV, Kingston, Jamaica

Background: While comprehensive Sexuality Education (CSE) is accepted as an effective strategy to control threats related to sexual and reproductive health of adolescents and youth and equip them with life skills which support healthy sexuality and inter-personal relationships, the concept of comprehensiveness, gives rise to differential implementation. A State of the Art Diagnosis was commissioned in an effort to generate evidence on the progress and effectiveness of CSE implementation in the Caribbean.
Methods: This 3 month mixed method study was conducted with 72 respondents from the Ministries of Education and Health in 8 countries. The study used evaluative research methodology to assess, determine and compare the strategies and factors influencing the effective implementation of CSE. The national programmes were assessed against good practice standards of UNFPA and UNESCO.
Results: The implementation of CSE programmes in the regions demonstrated varying levels of success as well as significant challenges in substance, form and delivery. The programme development stage was reported as the foremost predictor of implementation efficacy (83%). When assessed against the good practice standards using bidirectional bar-graphs, programme development and implementation was sub-optimum (-75%); Adherence to programme standards was moderate to low (-52%); Gender sensitive and rights-based approaches received the highest score (68%); Resourcing and resource mobilization the lowest (-77%); Acceptability and appropriateness standards received the highest favourable score (57%); and Fidelity and coverage the lowest (51%). Many respondents reported lack of evidence to support responses (34%) which may be tied to weak monitoring and evaluation frameworks. Specific weaknesses reported focused on supportive policy implementation, challenges with infusion and integration approaches, teacher preparation and instruction; and socio-religious influences on quality of delivery.
Conclusions: The study found that programme development and meso level issues were the main determinants of effective CSE implementation. The interrelationships between the macro, meso and micro levels of policy implementation, and the programme design and development phase are linchpins to realizing CSE implementation efficacy. Resulting action plans should aim to strengthen policy leadership and support, facilitate greater investment in CSE programme development and elevate capacity of CSE technicians to implement.

WEPEE717

PEPFAR partnership with girl effect; a branded approach to improving HIV outcomes among adolescent girls in Malawi

L. Marks[1], N. Bhandari[2], D. Jodrell[3], C. Gardner[3]
[1]Office of U.S. Global AIDS Coordinator and Health Diplomacy, Washington, United States, [2]Office of U.S. Global AIDS Coordinator and Health Diplomacy, G. Street, N.W. Suite #, United States, [3]Girl Effect, London, United Kingdom

Background: The power of brands to drive consumption and behaviour is widely recognised in the private sector. Leveraging its expertise in brand creation, Girl Effect launched Zathu in Malawi, a youth brand aiming to create behaviour change among adolescent girls and young women (AGYW) with regards to gender norms and HIV/AIDS prevention.
Description: As part of DREAMS, Girl Effect conducted extensive research which revealed that societal expectations of the relationship between boys and girls is a purely sexual one. This dynamic is unhealthy and puts girls at risk for HIV.
In response, Girl Effect created Zathu, a youth brand that encourages positive male-female relationships. Zathu uses the influence of music, radio, and drama to show positive platonic relationships, championing self-expression and challenging stereotypical gender roles. By improving the perceived value of girls, Zathu aims to help close the gender divide and in turn impact health and poverty indicators such as seeking out health services.
Almost 6.7 million Malawians aged 10 and over are aware of Zathu.
In the two DREAMS districts (Machinga and Zomba), there was an estimated 32% decrease in new HIV diagnoses among 15-24 year-old AGYW.
Lessons learned: This innovative partnership developed a measurement framework to demonstrate the influence of a youth brand for social change on improving girls' agency and driving health outcomes. PEPFAR provides the technical HIV expertise to inform programming and delivery; Girl Effect adds its technical expertise in girl-focused programmes, innovation, youth brands, and media to create perception change and improve the demand for health services. This partnership combines interventions that are effective when implemented individually and have the potential to be even more impactful when implemented as part of a package.
Conclusions/Next steps: Utilizing a partnership model where private sector expertise is adapted to solve social issues is effective. The impact of Zathu will be further evaluated, including how the brand affects relationships between boys and girls, and its impact on behaviour change with regards to HIV prevention. A baseline will be used to understand how Zathu is supporting the strides DREAMS has made in reducing HIV incidence among AGYW.

WEPEE718

Outcome evaluation of Grassroot Soccer-Zimbabwe SKILLZ for youth programmes (2011-2017)

C. Nombulelo Chaibva[1], F. Mantula[2], G. Mavondo[3], M. Mzingwane[4], C. Gwatiringa[1], C. Mapfumo[2], B. Moyo[5], P. Dube[5], H. Ncube[5], F. Govere[6]
[1]National University of Science and Technology, Department of Nursing and Midwifery Sciences, Faculty of Medicine, Bulawayo, Zimbabwe, [2]National University of Science and Technology, Faculty of Medicine, Bulawayo, Zimbabwe, [3]National University of Science and Technology, Pathology, Bulawayo, Zimbabwe, [4]National University of Science and Technology, Department of Pathology, Faculty of Medicine, Bulawayo, Zimbabwe, [5]Grassroot Soccer-Zimbabwe, Bulawayo, Zimbabwe, [6]Grassroot Soccer, Inc., Norwich, United States

Background: Zimbabwe is amongst the countries with the highest HIV infection rate. Young people continue being greatly affected by this epidemic with nearly 13.5% of young people aged 13-24 living with HIV in Zimbabwe. Grassroot Soccer, Zimbabwe (GRSZ) is an adolescent health organisation that leverages the power of soccer to educate, inspire and mobilize youth to overcome their greatest health challenges, live healthier, more productive lives and be agents of change in their communities. Since 2011, GRSZ in Bulawayo has been implementing three interventions in high schools which combine adolescent-friendly curricula, the power of soccer and local Coaches/Peer mentors to deliver HIV knowledge and prevention messages.
The purpose of the evaluation was to explore the outcomes of the three GRSZ SKILLZ Health programs; SKILLZ Generation, SKILLZ Holiday and SKILLZ Street. The evaluation was guided by specific elements that considered the scope and purpose of the evaluation namely; relevance, efficiency, effectiveness, utility and sustainability.
Description: The outcomes evaluation was conducted in Bulawayo, Zimbabwe from August 2017 to December 2017 for the three SKILLZ Health programmes implemented between 2011-2017. Quasi-experiment Design-Proxy Pre-Post Test design was used. Quantitative and qualitative data were collected using self-administered questionnaires on 392 randomly selected adolescents. Ten focus group discussions with adolescents and two with Coaches/Peer mentors were carried out while in-depth interviews were conducted with teachers, parents/guardians of the participants and partner organisations. Quantitative data was analysed using SPSS while qualitative analysis applied content analysis methods. Ethical approval was granted by the Medical Research Council of Zimbabwe (MRCZ).
Lessons learned: There was evidence of increased knowledge, behaviour change and attitudes on HIV and other reproductive health issues in both quantitative and qualitative analyses. Females scored 69.3% ("high")

on HIV and reproductive health knowledge when compared to males (30.7%). There was also a significant (p=< 0.001) increase in self-efficacy in resisting unwanted sex and negotiating for safer sex practices; 18.5% had had sex with 41.7% of them reporting male condom use in preventing STIs and pregnancy.
Conclusions/Next steps: Participation in GRSZ increased knowledge of HIV and self efficacy among adolescents suggesting that the programs/curricular are relevant, efficient, effective and sustainable.

WEPEE719

Reducing HIV vulnerability among adolescent girls and young women: Beneficiary and implementer perspectives of the DREAMS program in Zambia

M. Musheke[1], S. Mathur[2], N. Jani[2], L. Banda[1], D. Mulenga[1], J. Pulerwitz[2]
[1]Population Council, Lusaka, Zambia, [2]Population Council, Washington DC, United States

Background: The DREAMS program is being implemented in high-risk communities in Zambia, and aims to substantially reduce HIV-risk among adolescent girls and young women (AGYW). DREAMS' core intervention package, consists of a set of evidence-based interventions implemented by a range of implementing partners in each setting. We present beneficiary and implementing partner perspectives of the initiation and roll-out of this innovative comprehensive program in Zambia, and offer insights for strengthening program efforts.
Methods: In-depth interviews were conducted with 15-24 year old program beneficiaries (n=20) and DREAMS implementing partner staff (n=12), at 3 and 6 month intervals after program initiation in two sites in Lusaka and Ndola districts. Data was transcribed, coded and analyzed using thematic content analysis.
Results: Program implementation was initially characterized by delays due to weak coordination systems across program implementing partners. Poor understanding of the different roles of partners and how they complemented each other resulted in poor referral of AGYW among partners. Consequently, in part, this led to early loss of interest in the program by AGYW. Once the program was rolled-out, at beneficiary level, the program reportedly had a positive effect on HIV prevention knowledge and behaviors.
Some AGYW reported a reduction in the number of sexual partners, encouraging their partners to test for HIV, and insisting on condom use. For some girls, this assertiveness on HIV preventive behaviors even resulted in termination of relationships with non-yielding partners. AGYW also noted that joint parent-child sessions have helped break cultural sensitivities around discussions of sexual and reproductive health.
Other program components targeting structural risk factors, such as the loan and savings program, seemed to have had a tempered effect, due to limited access to the loan scheme and the inability by some girls to contribute funds hampered the intervention.
Conclusions: AGYW and their parents were actively engaged in HIV prevention efforts. Strong coordination systems, shared understanding of implementation roles, and frequent joint planning can support partners in implementing comprehensive programs. Additional targeted interventions to reach male partners of AGYW and structural efforts to alleviate household poverty may be needed to bolster AGYW in their HIV prevention efforts.

WEPEE720

Youth Care Clubs: Optimising clinic time, fostering peer support, improving adherence

M. Beery, R. Henwood, C.E. Martin, E. Dondolo, P. Ndlovu, M. Ngobeni, P. Onneile, T. Ziyane, S. Delany-Moretlwe, J. Imrie
Wits RHI, Research, Johannesburg, South Africa

Background: Long waiting times are common in South Africa's public health services. Peer support amongst adolescents living with HIV (ALHIV) positively effects emotional well-being and treatment adherence. We examined the efficiency gains, adherence and potential emotional benefits of a group model of ALHIV clinical and psychosocial care.
Methods: Wits RHI's USAID-funded Adolescent Innovations Project (AIP) implements 31 Youth Care Clubs (YCCs) in 18 clinics in two health sub-districts. YCCs are closed peer groups, comprising 20 ALHIV on antiretroviral therapy (ART). They are available to newly diagnosed, virally suppressed and un-suppressed patients. At each meeting, the club's facilitator conducts members' routine health screens (i.e. TB, STIs, nutrition, and psychosocial wellbeing), offers contraceptive services, facilitates an adolescent issues-focused conversation and distributes pre-packed ART. Coordinated annual viral load testing is conducted. Initially clubs meet monthly which fosters friendship development and encourages peer support. Club members keep in touch outside meetings through WhatsApp groups and online.
Time-motion observations were conducted assessing standard of care (SOC) clinic visits and YCCs. Retention and viral-load suppression data were extracted from YCC registers.
Results: Between August 2016 and December 2017, 542 ALHIV enroled in YCCs. Median age at enrolment was 18 years; 368 (68%) were female. Health screening was conducted at 96% of eligible in-person visits.
Retention in YCC care was 85% compared to 84% in SOC; 97% of YCC patients were virally suppressed after 12 months compared to 86% of patients in SOC. Each ALHIV attending an SOC visit spent an average of 86 minutes in the clinic of which 64 minutes was spent in "unengaged" waiting. YCC ALHIV spent 130 minutes for a YCC visit, however, "waiting" time was spent engaged in facilitated conversations with familiar peers and healthcare providers building supportive relationships. Despite overall longer clinic visits, YCCs reduced patients' total clinic visits by combining ART refills, contraceptive services and psychosocial support.
Conclusions: The YCC group model of clinical and psychosocial care provides efficient, comprehensive, convenient care for ALHIV without compromising retention or viral-load suppression, and fosters supportive social relationships between peers and healthcare workers.

WEPEE721

The power of peers: Multi-country analysis of adolescent viral suppression in sub-Saharan Africa

D. Mark[1,2], K. Bloch[1], L. Cluver[3,4], E. Toska[5], A. Ronan[1], L. Gittings[5], R. Hodes[5], S. Malunga[1], L. Hatane[1]
[1]PATA, Cape Town, South Africa, [2]University of Cape Town, Psychology, Cape Town, South Africa, [3]University of Oxford, Dept of Social Policy and Intervention, Oxford, United Kingdom, [4]University of Cape Town, Dept of Psychiatry and Mental Health, Cape Town, South Africa, [5]University of Cape Town, AIDS and Society Research Unit, Cape Town, South Africa

Background: UNAIDS fast-track targets require 90% of people on ART to be virally suppressed, but we are far from reaching this goal in adolescents and young people. Limited age-disaggregated data from sub-Saharan Africa reflect viral supression rates of 33-56% in these age groups. Health facility-based adolescent peer supporter programmes have gained recent attention as a promising scaleable intervention. However, we urgently need to examine their effectiveness in real-world settings in sub-Saharan Africa. This is the first known multi-country analysis of the impact of facility-based adolescent peer support on viral suppression.
Methods: In 2017, Paediatric-Adolescent Treatment Africa (PATA), a network of frontline health providers across sub-Saharan Africa, conducted cross-sectional surveys with 71 health facilities from 13 countries in Southern, Eastern, West and Central Africa to assess facility-level characteristics and past-year adolescent (10-19 years) viral suppression rates. Data were analysed using multivariate logistic regression to measure the impact of ≥1 facility-based adolescent peer supporter on adolescent viral suppression rate, controlling for: country, urban/rural location, public/private facility, level of facility (primary/secondary/tertiary) and physician/non-physician care. UNAIDS Eastern and Southern Africa (ESARO) 2017 data for all people living with HIV were used to define the regional viral suppression rate as 50%.
Results: Facility respondents were from Southern (35.2%), East (54.9%) and West/Central African (9.8%) regions. Two-thirds (74.7%) of facilities were urban/peri-urban and 57.8% public-only. Half (49.3%) provided primary care and 74.7% physican care. Controlling for these facility characteristics, provision of facility-based adolescent peer support was associated with an almost seven-fold increase in the likelihood of aggregate

adolescent viral suppression above that of the ESARO regional rate (adjusted OR 6.95, p=0.02, CI 1.28-37.59).
Conclusions: Findings suggest that peer support should be a key service component of the facility-based health response for adolescents living with HIV in sub-Saharan Africa, regardless of where facilities are located, their level of care or health provider profile. However, further operational research is needed to determine how best to implement and integrate peer support programmes. PATA will seek to identify a minimum package of peer-led services for low-resource settings to optimise the power of peers for the health and wellbeing of adolescents living with HIV.

WEPEE722

YouTube influencers support Dutch girls in making well informed, healthy SRHR choices

H. Roosjen[1], Y. Ohlrichs[2]
[1]Soa Aids Nederland, Amsterdam, Netherlands, [2]Rutgers, Utrecht, Netherlands

Background: Since 2009 Sense.info is the most frequently visited SRHR site for young people aged 12-25 in the Netherlands. In 2017 the website was visited more than 2 million times (the Netherlands has 17 million inhabitants).
In 2016 and 2017, 6 videos hosted by social influencer Britt Scholte were launched on Sense.info. These are the first vlogs in which Dutch social influencers cooperate with SRHR professionals. From previous projects we learned that social influencers are role models for teens. They speak each others language and share similar experiences using familiar references. Successful social influencers are trusted resources of information for a young audience. Therefore these vlogs are modern, unique and strong communication tools to reach teens.
Description: In each video, two Dutch social influencers (girls aged 17-23) discuss a particular contraceptive method. They exchange assumptions about and/or experiences with this method. As they realize that they have many questions the girls invite doctor Rosa in. She works at Sense, the Dutch SRHR center for young people. Doctor Rosa answers their questions and debunks popular myths about contraceptives.
Finally Britt and her guest invite viewers to anonymously share personal experiences with contraceptive use on Sense.info. All participating social influencers did likewise.
Within a year from the launch of the series the videos had more than 280.000 views.
Lessons learned: Cooperation with social influencers helped Sense.info to reach out effectively to a large audience of teens. With ease the vloggers translated SRHR messages in a language that appeals to a young audience. The videos come across as authentic, because the YouTubers have real questions themselves about contraceptives. It is very helpful to team with an agency that represents popular social influencers. This helped to find the most appealing spokespersons.
Conclusions/Next steps: Cooperation with social influencers on YouTube proves to be an effective strategy to empower young people in making well-informed decisions about their sexual and reproductive health. A good briefing of the influencers or involvement of an expert in the video is essential to avoid misinformation. Sense.info will continue this pioneering way of communicating to our audience.

[Social influencer Britt Scholte and Doctor Rosa]

What role do public libraries play in the fight against HIV/AIDS?: Lessons from Lubuto Library Partners in Lusaka, Zambia

E. Giles, M. Kasukumya
Lubuto Library Partners, Lusaka, Zambia

Background: As public institutions highly responsive to the information and service needs of their communities, public libraries have an especially critical role to play in the fight against HIV/AIDS: reaching vulnerable demographic groups (street children, adolescent mothers, and youth with disabilities) who are excluded from settings where HIV prevention programs are typically delivered. In Lusaka, Zambia, public libraries have reached more than 1,020 vulnerable youth with innovative HIV prevention programs.
Description: Lubuto Library Partners (LLP) is a development organisation that builds the capacity of public libraries to provide equitable education and poverty reduction, receiving an average of 2,400 of visits/week at its 2 Lusaka libraries in 2017. Beyond literacy and traditional library services, LLP runs a role-model mentoring program under a DREAMS Innovation Challenge grant to equip adolescent girls and young women aged 15-24 with HIV/SRH knowledge and access to services, and foster their determination to achieve.
Lessons learned:
1) Offering HTC services in a non-traditional yet trusted, inclusive, non-stigmatizing environment. By partnering with health service providers to offer testing at public libraries, LLP has held 6 HTC sessions at which 496 girls have been tested, maintaining a constant 100% referral completion rate.
2) Implementing an effective strategy to combat poverty-driven pressure towards transactional sex. Many girls in the program engage in transactional sex to earn up to USD $5/monthly to purchase essential toiletries, leading LLP to provide a graduation package of toiletries that reduces this pressure. This measure led to an average enrollment increase of 45% at two sites between Cohorts 1 and 2.
3) The value of cross-sectoral partnerships to offer holistic support for adolescents. LLP has taken 168 girls on horizon-broadening field trips to meet female leaders at institutions such as Parliament, universities, technology companies: trips that are unique among HIV prevention programs in Zambia, and which significantly drive program enrollment.
Conclusions/Next steps: These lessons suggest that HIV prevention programs can 1) benefit from partnerships to provide HTC at non-traditional community sites, such as public libraries and 2) drive enrollment by addressing factors that influence behavior, including poverty and lack of exposure to diverse female role models.

WEPEE724

"I feel brave and positive": Feasibility and acceptability of financial incentives for improving retention in care and adherence to anti-retroviral therapy amongst adolescents living with HIV in Rwanda

M. Bontempo[1,2], M. Osman[2], M. Sharma[2,3], S.P. Niyonsenga[4], R. Hope[2]
[1]University of California, School of Public Health, Berkeley, United States, [2]YLabs, Oakland, United States, [3]Harvard T.H. Chan School of Public Health, Boston, United States, [4]Rwanda Biomedical Center, Kigali, Rwanda

Background: Although antiretroviral therapy (ART) has shown to be critical in the treatment of HIV by suppressing HIV viral load and sustaining immune function, its adherence has been poorest in adolescents, especially in Sub-Saharan Africa. Financial incentive-based programs have shown early promise in motivating healthy behaviors, however concerns around acceptability remain. This study evaluated the feasibility and acceptability of a multipronged intervention ART adherence and care retention amongst HIV+ adolescents in Rwanda, to adapt the model for scale-up and policy uptake.
Description: Study participants were 72 adolescents (35 female, 37 male, aged 12-19), recruited through random stratified sampling from an urban (n=50) and a rural (n=22) clinic in Rwanda. Inclusion criteria were

adolescents aware of their HIV-positive status, enrolled in care at one site for >1 year, and prescribed ART for >1 year. The intervention, called YBank, consisted of:
a) short-term and long-term financial incentives for clinic attendance and suppressed viral load;
b) monthly life-skills training for financial literacy, and;
c) peer support from older HIV+ youth.
Data collection included:
a) baseline and endline survey data on demographic characteristics, clinic attendance, and viral load;
b) historical clinical data, and;
c) semi-structured interviews (30 adolescents, 20 caregivers, and 4 healthcare workers).
Lessons learned: All interviewees found the intervention highly acceptable, and reported emotional benefits associated with the incentive. Key themes expressed by adolescents were feeling rewarded and enhanced future planning. Few caregivers expressed concerns about adolescents accessing mobile money accounts independently. Overall, savings increased and we observed no increase in risky spending behaviors. Although there was no statistically significant reduction in viral load, early results indicate that the intervention may have greater impact on historically vulnerable groups including very young and out of school youth.
Conclusions/Next steps: Financial incentives, combined with a supportive environment and adequate skills-training, shows promise in motivating health behavior change in adolescents. The intervention was deemed acceptable to adolescents and caregivers, however its feasibility was limited by operational challenges, like access to mobile money accounts. The study indicated a need for mixed-methods in designing youth-targeted financial services, and evaluating their efficacy over time using large multi-site RCTs.

Mothers Matter! Ensuring young adolescents living with HIV adhere to treatment for improved health and wellbeing in high HIV counties of Kenya

N. Otwoma[1], G. Kerubo[1], L. Wangeci[2]
[1]*NEPHAK, Coordination, Nairobi, Kenya,* [2]*NEPHAK, Programmes, Nairobi, Kenya*

Background: Younger Adolescents 10 to 15 years living with HIV in Kenya continue to suffer from AIDS related illnesses despite having been enrolled on HIV treatment. Latest estimate show that only 61% of adolescents on HIV treatment have achieved viral suppression against the 90% target. There is also evidence that young people in Kenya are failing on the first line treatment and being put on 2nd line with adverse implications.
Description: With support of CIFF and EGPAF, NEPHAK in partnership with the Ministry of health has been implementing targeted interventions aimed at ensuring that children and adolescents are not left behind in the fast track plan to deliver on the 90.90.90 HIV treatment targets. The interventions start with a baseline assessment carried out by the Ministry of health on the Viral Load of the target adolescents. The adolescents are then introduced to targeted community focused interventions with the aim of ensuring they attend all clinics and adhere to treatment as advised by the clinicians. A post-intervention assessment through laboratory Viral Load monitoring is then done after one year. This is repeated at the end of 2 years.
Lessons learned: Of the 478 adolescents followed over a period of 2 years, 322 (67%) recorded undetectable Viral Load and were thriving well on the first line treatment. On further analysis, 90% (289) of those that had achieved viral suppression are under the care of biological mothers. On the contrary, 48% of the adolescents who were presenting with health challenges during the project period were living with older siblings with 7 living in households headed by adolescents.Parents and especially mothers play a critical role in ensuring that children and adolescents living with HIV adhere to treatment and good health.
Conclusions/Next steps: Interventions targeting younger adolescents living with HIV need to be family-centered and to ensure engagement of mothers. Fathers and other family members also need to be incapacitated, mentored and engaged in the interventions targeting younger adolescents to ease the burden on the mothers. NEPHAK will continue to advocate for family-centred interventions to improve the health and well-being of adolescents living with HIV.

WEPEE726

Assessment of adolescent HIV service delivery in Kenya: The PHASE study

K. Beima-Sofie[1], I. Mutisya[2], E. Begnel[1], P. Kohler[3], J. Itindi[4], E. Nyaboe[4], J. Stern[1], C. McGrath[1], J. Kinuthia[5], T.-H. Chen[2], B. Singa[4], E. Ngugi[2], A. Katana[2], G. John-Stewart[1,6,7], L. Ng'ang'a[2]
[1]*University of Washington, Department of Global Health, Seattle, United States,* [2]*U.S. Centers for Disease Control and Prevention, Division of Global HIV/AIDS & Tuberculosis, Nairobi, Kenya,* [3]*University of Washington, Department of Nursing, Seattle, United States,* [4]*Kenya Medical Research Institute, Centre for Clinical Research, Nairobi, Kenya,* [5]*Kenyatta National Hospital, Department of Research and Programs, Nairobi, Kenya,* [6]*University of Washington, Department of Pediatrics, Seattle, United States,* [7]*University of Washington, Department of Epidemiology, Seattle, United States*

Background: Inadequate provision of accessible and acceptable HIV services has been cited as a barrier to engagement and retention in HIV care among adolescents. We assessed provision of adolescent services at HIV treatment facilities throughout Kenya.
Methods: We conducted a survey at 102 large (≥500 HIV-infected patients) facilities in Kenya randomly selected among clinics using electronic medical records. Interviews were conducted with healthcare providers between February-May 2017. Respondents provided information on provision of adolescent (ages 10-19 years) care including: adolescent-dedicated services, workforce training, HIV treatment practices, and reproductive health services.
Results: Facilities reported an average of 110 adolescents (Range: 4-1462) ever enrolled in care with an average of 62 (Range: 3-508) in active follow-up. Forty-four percent of clinics had dedicated pediatric and adolescent clinic staff. Fifty-seven percent saw adolescents only on specific adolescent days rather than integrated into days for adults (23%), children (15%) or combined adult/pediatric days (9%). Most (72%) clinics reported having received training in adolescent HIV service provision while 59%) reported receiving training in providing adolescent sexual and reproductive health services. Only 64% of clinics identified themselves as providing "adolescent friendly services."
Most (81%) clinics offered peer support groups or teen clubs. Adolescents were most often given one month (51%) or three months (22%) of medication. Fifty-one clinics (50%) reported varying medication delivery based

on school schedules and/or medication adherence. Almost all clinics (99%) allowed a proxy to pick up medication for adolescents. One-third (34%) required a parent or primary caregiver to be present when providing HIV care to adolescent minors (ages 10-17) while 47% listed specifications for when care could be provided in the absence of a caregiver, including adolescent maturity and disease severity. Median age for initiating transition from pediatric to adult care was 15 years (IQR: 12-18), and for planned completion of transition was 19 years (IQR: 18-20). Most clinics reported providing condoms (65%), family planning services (60%) and STI screening (67%) to adolescents.
Conclusions: This study demonstrates the implementation landscape for adolescent HIV services in Kenyan clinics. Continued training on adolescent HIV service provision can ensure uniformly high quality of care across regions and facilities.

WEPEE727

A global review of condom availability programs in high schools

E. Algur[1], H.S. Friedman[2], X. Wang[3], B. Deperthes[2]
[1]Harvard University, Cambridge, United States, [2]UNFPA, New York City, United States, [3]Yale University, New Haven, United States

Background: High levels of HIV, STIs, and pregnancy among adolescents has motivated some countries to consider the implementation of condom availability programs (CAP) in high schools. However, this has been met in some countries with significant opposition from parents, religious leaders, and community members.
Opponents of CAP argue that the program would encourage sex and increase promiscuity among adolescents. In this present study, we analyzed the impact of CAP on students´ sexual behaviors and health outcomes.
Methods: We conducted a systematic global literature review of peer-reviewed articles published between 1990 and 2017. Criteria for inclusion in the full-text review were: condom distribution, availability, provision at schools, and studies related to male condoms only (as most of the articles did not address female condom). We organize the results based on three broad categories: initial attitudes of the community to CAP prior to implementation, impact of CAP on students' sexual behaviors, and impact of CAP on sexual health outcomes.
Results: 29 articles from seven countries were included in this review. We found that CAP does not increase sexual activity, nor lead to a greater number of sexual partners, nor lower the age of sexual initiation. A majority of the studies reported an increase in condom uptake and use at last sex among students with CAP. All of the studies that examined STI found a decrease of STI symptoms and rates for students with CAP compared to the control group. The data on HIV rates was inconclusive. There was no difference in pregnancy rates associated with participation in CAP programs.
Conclusions: This global literature review showed that the fears surrounding CAP and promiscuity are unfounded. Once CAP is in place, students utilize it, and condom use increases, which translates to improved sexual health outcomes.

WEPEE728

Camp and the third 90: HIV+ adolescents attending camp in Mbeya, Tanzania experienced no differences in viral suppression, mortality, or lost-to-follow compared to HIV+ adolescents not attending camp

J. Bacha[1,2,3], B. Makamong'oko[3], R. Mgimba[3], M. Chodota[3], L. Campbell[1,2,3]
[1]Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States, [2]Baylor College of Medicine, Houston, United States, [3]Baylor College of Medicine Children's Foundation - Tanzania, Pediatrics, Mbeya, Tanzania, United Republic of

Background: While camps for adolescents living with HIV (ALHIV) are well-received by adolescents and health care providers and have positive impact on psychosocial health, there is little literature examining impact of camp on virologic success and treatment outcomes. This abstracts compares HIV viral load results and treatment outcomes of ALHIV who attended "Salama Camp" in Mbeya, Tanzania to ALHIV not attending camp.
Methods: Salama Camp is a 5 day overnight camp targeting ALHIV ages 12-18yo, and aimed at improving psychosocial health, life skills, self care, and adherence to ART. Retrospective review was performed of Salama Camp reports and medical records of ALHIV who attended Salama Camp between 2012 and 2016. Most recent post-camp viral load and current chart status were extracted for all campers to determine virologic suppression (VL< 1000 copies/mL) and treatment outcomes. Age-matched ALHIV on ART at the HIV clinic between 2012 and 2016 who did not attend camp were used as a comparison group.
Results: 258 ALHIV attended Salama Camp, representing 39.2% (258/658) of all ALHIVs aged 12 to 18 years on ART at the clinic. 94.2% (243/258) Of those with post-camp VL results (94.2%, 243/258), 69.5% (169/243) had VL < 1000 copies/mL. Treatment outcomes of those who attended camp were 84.1% (217/258) active in care, 7.8% (20/258) transferred out, 4.3% (11/258) died, and 3.9% (10/258) LTFU.
In age-matched ALHIV on ART who did not attend camp (n=400): 72.5% (290/400) were virologically suppressed, 83.3% (333/400) active in care, 8.8% (35/400) transferred out, 4.5% (18/400) died, and 3.5% (14/400) LTFU.
There were no statistically significant difference in viral suppression (69.5% campers vs 72.5% non-campers, p=0.18), mortality rates (4.3% campers vs 4.5% non-campers, p=0.90), or LTFU rates (3.9% campers vs 3.5% non-campers, p=0.79) between the two groups.
Conclusions: No statistically differences in the key clinical outcomes of viral suppression, mortality, or LTFU were seen between ALHIV on ART attending camp and those not attending camp in Mbeya, Tanzania, despite the intensive and costly camp efforts. In resource limited settings, such resource intense programs must be continuously re-evaluated to ensure optimal use and maximal impact of scarce resources for ALHV.

WEPEE729

Youth participation: A way of achieving increased uptake of HIV prevention services among out-of school youths

A. Ajiboye[1], Y. Falola-Anoemuah[1], T. Oladele[1], H. Aboki[1], B. Olakunde[1], H. Yahaya[1], P. Odunlami[2], J. Garba[3], N. Ifeaiyichukwu[4]
[1]National Agency for the Control of AIDS, Community Prevention and Care Services, Abuja, Nigeria, [2]National Agency for the Control of AIDS, Strategic Knowledge and Monitoring, Abuja, Nigeria, [3]Federal Ministry of Youth and Social Development, Abuja, Nigeria, [4]National Agency for the Control of AIDS, Performance Management and Resource Mobilisation, Abuja, Nigeria

Background: In Nigeria, young people between 15-24 years make up 15% of the people living with HIV These young persons, which are either in-school or out-of-school account for about 36% of new HIV infection in Nigeria. While several HIV interventions such as family life and HIV/AIDS education, peer group sessions and anti HIV/AIDS club activities have targeted in-school youths, out of school youths are not adequately reached with HIV prevention programmes, largely because of their complex diversity and mobility. To address this gap, an outreach project was designed by Federal Ministry of Youth Social Development (FMYD) for out-of-school youths in Nigeria.
Description: The World Bank HIV Prevention Development Project (HPDP II), through National Agency for the Control of AIDS supported the FMYD to conduct HIV prevention outreaches in 12 states with high HIV prevalence in Nigeria. Youth-focused non-governmental organizations and community-based organizations working in each state were engaged to conduct HIV testing services (HTS) and distribute condoms to 2,000 out-of- school AYP per state. Furthermore, AYP living with HIV (AYPLHIV) from established support groups were also involved in the outreaches to facilitate linkage of positive persons to facilities for care. The venues of the outreaches included motor parks, automobile repair workshops, and markets. The out-of school youths targeted includes apprentices, artisans, food sellers, and street children (area boys).
Lessons learned: 31,000 out-of-school youths were reached with HIV prevention interventions across the states within 4 days. 260 HIV positive AYP were identified linked to care. Willingness to test for HIV is high among AYP out-of school youth. Young people's participation in plan-

ning and mobilization boosted the uptake of services. The presence of AYPLHIV provided immediate psychosocial support and ensured complete referrals. Engagement of AYPLHIV was critical for ensuring immediate psychosocial support and completed referrals. Workplace model for HIV service delivery favored out-of-school youth as most of them had little time to access facility based interventions.
Conclusions/Next steps: National Agency for the Control of AIDS (NACA) plans to develop guidelines for implementation of AYP focused HIV intervention in Nigeria. HIV programmes should be all inclusive to address specific needs of AYP in Nigeria including provision of mobile HTS.

WEPEE730

Addressing the needs of pregnant HIV-positive adolescent girls and young women: A growing need

E.A.J. Tumbare Machakaire, T. Lekhotsa, F. Mohai, V. Tukei, M. Mungati
Elizabeth Glaser Pediatric AIDS Foundation Lesotho, Technical, Maseru, Lesotho

Background: Lesotho's adult HIV prevalence is 25.7%. Elizabeth Glaser Pediatric AIDS Foundation (EGPAF) is a clinical implementing partner that provides technical assistance to Lesotho's Ministry of Health (MOH) and direct, comprehensive HIV/TB service delivery in 120 health facilities in five districts. In January 2017, EGPAF established adolescent and youth-friendly clinics in the Lesotho districts of Maseru, Berea, and Leribe. This abstract describes data collected at these clinics to increase a greater understanding of health needs among a population in sub-Saharan Africa with growing HIV infection and HIV-related mortality rates.
Description: The established youth-friendly clinics are focused on scaling-up provision of quality, comprehensive TB/HIV services, sexual and reproductive health (SRH) services (including antenatal care [ANC] and PMTCT), and primary health care for adolescents and young people (AYP) aged 10 to 24 years. Services are provided by specially trained staff (adolescent health-focused pediatricians, nurses, social workers, psychologists, and youth ambassadors) during non-traditional hours and weekends. Data from these clinics are collected routinely through MOH registers and entered into EGPAF electronic data collection tools. Summary statistics are calculated monthly and quarterly. Data for pregnant adolescent girls and young women (AGYW) at these clinics between June and October 2017 were collected and analyzed.
Lessons learned: Between June and October 2017, 99 (12.5%) of the 789 pregnant AGYW attending ANC at these centers came in with known HIV-positive status. Of these, 96% (95/99) were already on ART. Uptake of HIV testing for those with unknown status was 98.7% (681/690). Of those tested for the first time in ANC, 7.6% (52/681) were HIV-positive. Overall positivity (including known positives) was high, at 19.4%. (151/789). Overall ART uptake was high at 96.4% (54/56).
Conclusions/Next steps: The high HIV prevalence among pregnant AGYW at these clinics poses new challenges for addressing the needs of this population and their new-born infants. Offering testing, diagnosis and treatment services in non-school hour settings to AYP by specialized staff is a clear need and such services should be more widely implemented. EGPAF is currently expanding training of clinicians at all 120 supported health facilities to provide AYP health services, including PrEP to enable better epidemic control.

Indicator	Berea Hospital	Maluti Hospital	Motebang Hospital	Queen II Hospital	LPPA HC	Totals (%)
New in ANC	221	83	211	233	41	789
Known to be HIV-positive at presentation to ANC	33	11	26	26	3	99(12.5%)
Already on ART at presentation to ANC	33	11	26	22	3	95(96%)
Tested for HIV in ANC	188	72	176	207	38	681 (98.7%)
Tested HIV-positive in ANC	13	10	5	20	4	52(7.6%)
New on ART in ANC (known positive not on ART plus new positives initiated)	13	8	5	24	4	54 (96.4%)
Total HIV-positive in ANC	46	21	31	46	7	151 (19.4%)

[Summary for youth aged 10-24 accessing PMTCT and SRH services at five EGPAF-supported adolescent-friendly clinics in Lesotho (June-October 2017)]

WEPEE731

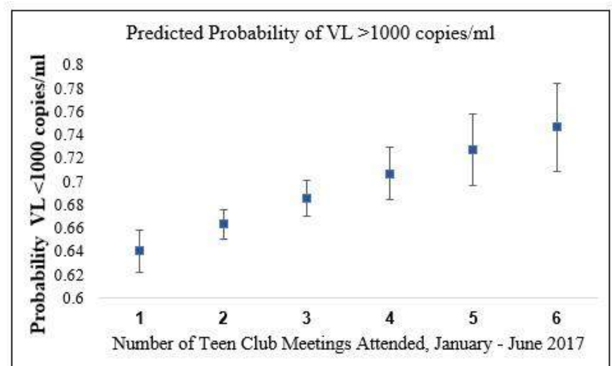
Teen Club uptake and viral load suppression among HIV-positive Malawian youth

K. McBride[1], J. Parent[2], K. Mmanga[2], M. Chivwala[2], M. Nyirenda[2], A. Schooley[2,3], J. Mwambene[2], K. Dovel[2,3], E. Lungu[2], K. Balakasi[2], R. Hoffman[3], C. Moucheraud[1], EQUIP Innovation for Health
[1]University of California, Fielding School of Public Health, Los Angeles, United States, [2]Partners In Hope, Lilongwe, Malawi, [3]University of California, David Geffen School of Medicine, Los Angeles, United States

Background: To improve outcomes among HIV-positive adolescents, the Malawi Ministry of Health is supporting scale-up of „Teen Clubs", a facility-based antiretroviral treatment (ART) delivery model. Teen Clubs are monthly ART clinics for youth that provide clinical services and peer psychosocial support.
We examined predictors of Teen Club uptake among youth, and factors associated with viral load suppression and adherence to ART among Teen Club participants.
Methods: We performed a retrospective analysis of medical records and Teen Club attendance data on 5,326 HIV-positive youth (10-19 years) at 21 PIH-EQUIP supported facilities across Malawi. In this sample, 1,175 youth were enrolled in Teen Club between January-June 2017. Multivariable logistic regression was performed to identify characteristics associated with Teen Club participation, and, among Teen Club enrollees with HIV viral load data (n=597), to identify factors associated with achieving suppressed viral load (< 1000 copies/ml). Predicted probabilities of being virologically suppressed were calculated. Multi-level logistic regression was used to explore moderating effects of ART adherence (≥95% based on pill count) among enrollees who attended at least 2 Teen Club meetings (n=589).
Results: Teen Club participants were younger than non-enrollees (p< 0.01) but there was no significant difference in uptake by sex (Table). Among participants, older adolescents (aged 15-19) were 38% less likely to achieve viral suppression compared to younger adolescents (aged 10-14) (adjusted odds ratio 0.62, 95% CI 0.39-0.98).The probability of viral suppression increased from 64% if participants attended 1 Teen Club meeting, to 74% if they attended 6 meetings (p< 0.05) (Figure).

	Enrolled in Teen Club	Not Enrolled in Teen Club	P-Value
	n=1,164	n=4,162	
Category			
Age, mean years (s.d)	13.8 (2.5)	14.2 (2.8)	p<0.001
Age, 10-14 years (%)	710 (61.0)	2256 (54.2)	p<0.001
15-19 years	454 (39.0)	1906 (45.8)	
Sex, male (%)	535 (45.9)	1956 (47.0)	p=0.532
Female	629 (54.4)	2206 (53.0)	
Two-sample t-tests for continuous variables and χ2 tests for categorical variables conducted to evaluate association between Teen Club status and covariates			

[Table: Characteristics of Sample by Teen Club Status; N= 5,326, 10-19 years]



Notes: Predicted probabilities of virologic suppression from logistic regression. Model adjusted for age, gender, number of meetings attended, district, and ART regimen. Estimates account for cluster-robust standard errors at the facility level.

[Figure: Predicted Probabilities of Viral Load (VL) < 1000 copies/ml with 95% CIs by Number of Monthly Teen Club Meetings Attended January - June 2017]

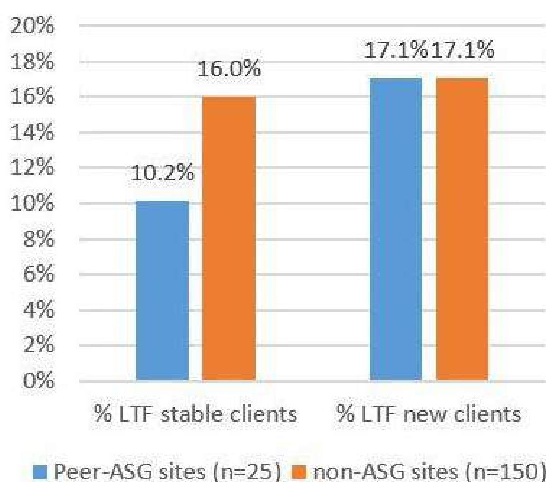
Males 15-19 years were 65% more likely to achieve ≥95% ART adherence (aOR 1.64, 95% CI 1.2-2.3) compared to younger (10-14 years) males.The moderated effect of age on adherence was smaller and not significant among females (aOR 1.36, 95% CI 0.96-1.9).
Conclusions: Youth with higher Teen Club attendance were more likely to achieve viral suppression compared to less-frequent attendees. Older Teen Club participants were less likely to achieve viral suppression, indicating the need for specialized programming for this group. Although our retrospective review found evidence in support of Teen Clubs, rigorously designed studies are needed to better characterize the benefits of Teen Club.

WEPEE732

Do peer-led adolescent support groups improve retention? Lessons learnt from Tanzania

R. van de Ven, G. Antelman, M. Mukaminega, C. Edward, J. van 't Pad Bosch
Elizabeth Glaser Pediatric AIDS Foundation, Dar es Salaam, Tanzania, United Republic of

Background: HIV-infected adolescents are a known risk group for poor antiretroviral therapy (ART) adherence and retention in care, which is one reason why programs have established various differentiated care models, including adolescent support groups (ASG). In Tanzania, the Elizabeth Glaser Pediatric AIDS Foundation established a unique model of peer-led adolescent clubs that combines psychosocial support led by peers with ART services on special Saturday clinic days.
Methods: This retrospective analysis was conducted to evaluate the role of peer-led adolescent clubs on the retention of adolescents (10-19 years) in HIV care. Data from electronic medical records from national HIV database at 175 sites were analyzed to measure the crude ART retention by September 2017 of adolescents already on ART for more than one year and adolescents newly initiated between October 2016 and September 2017, at health facilities with peer-led adolescent services (n=25) in comparison with facilities without any specific adolescent services (n=150).
Results: The overall crude retention rate by September 2017 was higher at clinics with peer-led adolescent clubs, 88% (1,623/1,845) versus 82% (1,233/1,501) (p< .0001); at sites with adolescent clubs, participation in the clubs was at 76% (1,238/1,623). The main improvement was seen among adolescent clients who were in care for longer than one year, with a significantly reduced lost-to-follow (LTF) rate; 10.2% compared to 16.0% (p< .0001). However, the LTF rate among new clients within the first year of ART did not show any difference, and remained high at 17.1% for both facilities with or without adolescent services (figure 1).



[Figure 1: Lost to follow rates by client type and service delivery model, October 2016 - September 2017]

Conclusions: Peer-led adolescent support services have a positive impact on retention. However, this was more pronounced for adolescents in care for more than one year; newly identified and ART-initiated clients still had a high LTF rate, comparable with sites without specific adolescent services. Adolescent clubs may benefit members, but in order to address the needs of newly identified adolescents living with HIV, a service delivery model with a more individualized role for adolescent peer educators, who could become involved as treatment supporter at ART initiation and offer follow-up at home as well, may be needed to achieve early adherence.

WEPEE733

Programmatic and treatment outcomes of HIV infected adolescents after transition into adult clinic in Myanmar

T. Htun[1], T.K. Aung[1], J. Moe[1], M.M. Oo[1], A.A. Mon[1], C.L. Htun[1], O. Mon[2], H.N. Oo[3]
[1]*International Union Against Tuberculosis and Lung Disease, HIV Unit, Mandalay, Myanmar,* [2]*Department of Medical Science, Ministry of Health and Sports, Mandalay, Myanmar,* [3]*National AIDS Programme, Ministry of Health and Sports, Naypyitaw, Myanmar*

Background: Since 2005, The Union, in collaboration with National AIDS Programme (NAP), is implementing Integrated HIV Care (IHC) Programme in 37 townships in Myanmar. Although transitional care for adolescents was started in May 2010, little is known on outcomes after transition to adult care. Primary objective of this study is to find out the post-transition outcomes of adolescents in adult clinics of IHC programme in Myanmar.
Methods: A Retrospective cohort study using routinely collected data among those adolescents who were transferred from pediatric to adult clinic between May 2010 and June 2016. Kaplan-Meier method was used to calculate the retention rate after transition and incidence rate of switch to second-line antiretroviral therapy (ART) after transition was estimated and described in 100 person-years (PYs). Poisson regression was used to assess risk factors for attrition (death and Loss-to-follow-up, LTFU) and switching to second line ART.
Results: Of 290 adolescents who were transitioned to adult clinics, 156 (53.7%) were female. Median age in years at transition was 14 [IQR, 12-15]. Retention rate in adult care at 12, 24 and 60 months after transition was 97.2%, 94.8%, 88.3% respectively. 24 (8%) adolescents undergo attrition in adult clinics. 12 (50%) patients died and the rest are LTFU. Eleven patients were switched to second line ART after transition and the rate of switching was 1.2 per 100 PYs. In multivariate analyses, the factors associated with attrition were those not taking ART and those taking second line ART at the time of transition. Transferring to facilities where both pediatric and adult services are not collocated was also found to be an independent risk factor for treatment failure.

	Total n (%)	Attrition n (%)	IRR (95% CI)	Switched to 2nd Line ART n (%)	IRR (95% CI)

Author Index

Conclusions: We found high retention rates among adolescents after transition into adult care in this setting. Counselling and LTFU tracing for adolescents with second line ART at the time of transition should be strengthen to reduce attrition among them. The study result suggests to consider initial transitional care in settings where both pediatric and adult services collocates. Strategies should be sought out to improve post transition outcomes by conducting qualitative studies in future.

WEPEE734

Using the power of football to get young people educated about and tested for HIV in rural Malawi

N. Khozomba[1], K. Kanjelo[1], J. Jere[1], E. Geoffroy[2], E. Schell[3,4], S. Miller[5], K. Nash[3]
[1]Global AIDS Interfaith Alliance, Blantyre, Malawi, [2]Global AIDS Interfaith Alliance, Marblehead, United States, [3]Global AIDS Interfaith Alliance, San Rafael, United States, [4]University of California, San Francisco, United States, [5]Grassroot Soccer, Cape Town, South Africa

Background: Grassroot Soccer (GRS) harnesses the power of football to connect adolescents with mentors and health information and services. In partnership with GRS, Global AIDS Interfaith Alliance (GAIA) has implemented "Skillz" programs in southern Malawi since 2015. Youth are particularly at risk with up to 50% of new HIV infections affecting youth 15-17, and adolescent (15-19) pregnancy rate of 35%, making prevention and access to services key to improving health.
Description: Through an evidence-based curriculum (Skillz GAIA and Skillz Girl), trained peer-educator "Coaches", and sports activities, the program provides sexual, reproductive and other health information as well as HIV testing. Skillz GAIA is a mixed-sex curricula, while Skillz Girl targets girls and adds empowerment and menstrual management information to the package. The program engages youth age 10-18 (mean participant age is 13). Children < 14 are offered testing with parental permission, while those 14-18 consent for themselves.
Lessons learned: From January 2014 through December 2017, nearly 14,000 youth were served and 2,028 at-risk youth and relatives have been tested for HIV. Twenty-three (1.1%) were HIV positive, including 10 children under 15. All HIV+ youth were linked to care, initiated on treatment, and offered adherence counseling, disclosure and peer support through HIV+ youth clubs. Staff reinforced the parent-child bonds that underlie successful treatment outcomes. Boys testing negative were referred for voluntary medical male circumcision and sexually active youth for contraception. The greatest changes from pre to post-implementation were related to youth's willingness to communicate about sensitive topics (26% increase for Skillz GAIA, 42% for Skillz Girl) and in HIV related stigma (25% improvement for Skillz GAIA, 42% for Skillz Girl).
Conclusions/Next steps: This program reaches youth with HIV prevention messages when they are becoming sexually active, and normalizes HIV testing. While HIV+ yields were low, youth found positive were linked to care and treatment early, increasing the likelihood of positive treatment outcomes. The program Coaches and HIV counselors helped HIV+ youth and their families cope with the diagnosis, linked them to care and strengthened family resilience. The opportunity to learn about and experience the testing process at an early age may reinforce life-long beneficial health seeking behaviors.

Delivering in services in and around conflict settings

WEPEE735

Community ART distribution center (*PODI*) as a differentiated service delivery measure in the Democratic Republic of Congo (DRC)

T. Tchissambou[1], A. Jha[2], S. Dane[2], D. Dibulundu[1], S. Matsumaini[1], C. Madevu-Matson[2], B. Ngalamulume-Roberts[2], Y. Ilunga[1], F. Malele[1], J. Soares Linn[2]
[1]ICAP at Columbia University in DRC, Kinshasa, Congo, Democratic Republic of the, [2]ICAP at Columbia University, Mailman School of Public Health, New York, United States

Background: Differentiated service delivery (DSD) is a patient-centered approach to HIV care that allows patients to receive services tailored to their individual needs. Aimed at increasing health systems efficiency, many DSD models let medically stable patients receive community-based healthcare services, reducing their need to travel to health facilities (HF). Since 2016, ICAP has supported DRC's National AIDS Control Program (NACP) in the scale-up of PODI, community-based ART distribution centers. The PODI model decentralizes ART refills to the community, separating refill visits from clinical appointments.
Description: In Kinshasa, ICAP has supported the establishment of two PODIs, PODI-East (January 2016) and PODI-West (July 2017). ICAP has trained and mentored to lay community health workers (CHW) responsible for the care of patients at PODIs. Eligible patients, those who are >15 years and on ART for 12 months and virally suppressed ("stable"), are referred to PODIs by providers at HFs where they receive care. Patients visit PODIs quarterly for ARV pickup and to receive adherence counselling, basic symptom screening, and index HIV testing for family members. Patients return to HFs annually for clinical check-ups and can be referred back to HFs if they require additional medical care.
Lessons learned: Since 2016, a total of 2,027 patients have enrolled at ICAP-supported PODIs. Of these, 80 (4.0%) were LTFU, which prompted tracing by CHW, 31 (1.5%) died, and 171 (8.0%) were referred back to a HF. Providing support to health care workers on eligibility criteria for PODIs and CHW for patient follow-up activities, and ensuring patients received adequate adherence counselling were critical to the success of this strategy.
Conclusions/Next steps: PODIs serve as a promising community-based model of care that addresses many of the health system challenges of providing lifelong treatment to stable HIV patients. Given that PODIs are co-located at community venues, patients are able to refill their ARVs close to home without having to visit a HF. Task-shifting ART monitoring and refilling to CHW allows providers at HF to spend more time with less stable patients. ICAP is working with NACP to expand the PODI model to Lubumbashi and plans to conduct an evaluation to inform the national scale-up plan.

WEPEE736

Implementing test & start program in a rural conflict affected area of South Sudan, the experience of MSF Spain

C. Ferreyra[1], L. Moreto[2], B. Alonso[3], F. Temessadouno[4], A.J. Nyniyal[5], A. Harouna[3], M. Eltom[6]
[1]Mèdedcins sans Frontières, Barcelona, Spain, [2]Médecins sans Frontières, Medical Department, Barcelona, Spain, [3]Médecins sans Frontières, Juba, South Sudan, [4]Médecins sans Frontières, Dakar, Senegal, [5]Ministry of Health Republic of South Sudan, HIV/AIDS/STI, Juba, South Sudan, [6]Médecins sans Frontières, Nairobi, Kenya

Background: Community-based HIV counselling and testing (CB-HCT) and early initiation of antiretroviral therapy (ART) can reduce HIV transmission and mortality. Access to HIV care in settings with low ART coverage and/or affected by conflict is still low; innovative strategies are needed to increase access and ensure continuation of ART in case of instability. Bringing HCT and ART closer to the community can be a suit-

able strategy in these settings. A pilot test and start project was implemented in rural areas of Yambio South Sudan, a chronically conflict-affected area. In a retrospective analysis, we aimed to determine the feasibility and acceptability of this pilot intervention.
Description: Programme data from July 2015 to December 2017 was analysed. The project involved five mobile teams offering HIV community sensitization, HCT and same day ART initiation at community level. A contingency plan including coordination with community health workers (CHWs) to distribute "run-away bags" with 3 months of ART was in place due to the setting.
Lessons learned: During the analysed period, 14800 people (31% of the population) were counselled and tested. 498 (3.3%) were found to be HIV positive and 395 (79.3%) accepted to start ART. 231 (61%) patients and 56 (15%) had CD4 count below 500cells/µl and 200 cells/µl, respectively. By December 2017, 95(24%) patients were loss of follow up, and 12 (3%) died. Retention in care at 6 and 12 months of follow up was respectively 283 (84%) and 241 (71%). 224 (out of 243) patients had an available VL at 12 months (92%) and in 179 (80%) it was suppressed. . At 30 months, 243 (71%) patients are still under follow up and on ART.
Conclusions/Next steps: Our program shows a high level of acceptance to HCT and early ART initiation despite of context. Results show rates of virological suppression comparable with HIV programs at clinic level and without security concerns, the same for retention in care at 6 and 12 months. We believe this strategy could be extrapolated to other similar contexts with low access to ART and where security situation is a concern.

WEPEE737

ART optimisation, plasma viral load and patient satisfaction in the conflict-affected setting of Donetsk, Ukraine

J. van der Meer[1], R. Malyuta[2], V. Pavlenko[3], T. Tarasova[4], N. Ferencic[5]
[1]PHESTA, Amsterdam, Netherlands, [2]United Nations Children Fund (UNICEF), Europe and Central Asia Regional Office Almaty Bureau, Almaty, Kazakhstan, [3]AIDS Centre Donetsk, Donetsk, Ukraine, [4]United Nations Children Fund (UNICEF), Ukraine Office, Kyiv, Ukraine, [5]UNICEF, CEE/CIS Regional Office, Almaty, Kazakhstan

Background: To what extent is it possible to maintain and improve antiretroviral treatment (ART) in settings affected by armed conflict? This study monitors an emergency delivery of ART to prevent stock rupture at the AIDS Centre in the city of Donetsk, a conflict-affected area in Eastern Ukraine, introducing a new regimen of a fixed-dose combination of tenofovir, emtricitabine and efavirenz (optimised regimen). The purpose of the study is to:

- Assess whether the change to optimised treatment in this setting was not harmful in terms of non-inferior outcomes compared to the prior treatment.
- Assess levels of satisfaction of patients on the optimised ART regimen compared to those on other regimens.

Methods: The monitoring study took place between April and June 2016. We took a random sample of 477 patients on ART at the Donetsk AIDS Centre and 13 surrounding ART sites. After consent, they filled out an ART patient satisfaction questionnaire, while their treating physician completed the medical details of the survey. We compared the patients put on optimised regimen (September 2015 - March 2016) with those who were not switched, with regards to plasma viral load (VL) and various patient satisfaction measures.
Results: There were 464 patients with complete data, 262 on optimised regimen and 212 patients who continued their previous regimen. In the optimised group 95.9% had an undetectable VL (< 40 copies/mm^3), in the non-optimised group this was 96.3%. Compared to non-optimised patients, a statistically significant (P< .05) higher proportion of patients on optimised ART reported effectiveness of their ART, were satisfied with requirements to adhere to ART, were satisfied about the timing to take their medication, they perceived less side-effects and discomfort of their medication, and a higher proportion planned to continue their treatment. Patterns among men and women were similar. There were no differences in self-reported adherence between the groups. Only 16 patients experienced treatment interruption.
Conclusions: Good viral suppression is possible in a conflict setting. It is possible to maintain and improve treatment quality and patient satisfaction in these settings. Humanitarian assistance can further improve the treatment cascade in conflict settings like those in Eastern Ukraine.

HIV service delivery in conflict affected and humanitarian settings

WEPEE738

Pediatric HIV care in conflict settings: Should we decentralize?

E. Vindu[1], J. Lusi[1], W. Bonane[1], D. Kamabu[1], J. Armas[2], J. Bress[2], G. Kashemwa Migabo[3]
[1]HEAL Africa, Goma, Congo, Democratic Republic of the, [2]Global Strategies, Albany, United States, [3]Global Strategies, Bukavu, Congo, Democratic Republic of the

Background: Current global policies advocate for integrating pediatric HIV care into primary maternal-child healthcare. This approach, while well-suited to high prevalence areas without major political instability, may not be the optimal strategy in low-prevalence conflict settings.
Description: The Children's AIDS Program at HEAL Africa Hospital is the only pediatric HIV center in the restive North Kivu Province of the Democratic Republic of Congo. The program was initiated in 2006 and provides care for 836 HIV-infected children. In this abstract, we describe an attempt to decentralize pediatric HIV care in North Kivu from our perspective as local leaders of a centralized pediatric HIV speciality center.
Lessons learned: Decentralization of pediatric HIV care out of speciality centers poses unique challenges in low HIV prevalence conflict settings. In North Kivu, lack of both maternal HIV care and early infant diagnosis leads to delayed recognition of HIV-infected children. As a result, care facilities must be able to treat life-threatening opportunistic infections and severe malnutrition. Active conflict can create inventory management crises, limit patient mobility and add safety risks for monitoring organizations. Low patient volumes at individual sites, coupled with interruptions in monitoring and evaluation, can reduce care quality. International non-governmental organizations are essential partners in providing pediatric HIV care in conflict settings. However, the high staff turnover and short grant cycles of international non-governmental organizations in conflict settings limit longitudinal planning, add artificial timelines that fail to account for dynamic field conditions and rarely allow for supporting recentralization efforts in the event that decentralization fails.
Conclusions/Next steps: Centers of excellence for pediatric HIV care, like pediatric oncology centers in developed settings, may be an acceptable short-term solution to treating HIV-infected children in politically unstable areas with low HIV prevalence. The same health system failures that lead to the continuous flow of newly infected children can stymie decentralization efforts, wasting precious energy and resources, while disrupting existing systems that provide pediatric HIV care in conflict settings.

WEPEE739

Can health be a bridge for peace? Health system convergence amid diversities: Lessons from prevention of mother to child transmission of HIV pilot services for equitable access

M.M. Khin[1], S.M. Lwin[2], S. Hone[3], B. Setiawan[2], H.N. Oo[3], E.M.M. Kyaw[4]
[1]UNICEF, Health and Nutrition Section, Hpa-an, Myanmar, [2]UNICEF, Health and Nutrition Section, Yangon, Myanmar, [3]Ministry of Health and Sports, Disease Control, Naypyitaw, Myanmar, [4]Karen Department of Health and Welfare, Health, Hpa-an, Myanmar

Background: Myanmar is ethnically diverse, perhaps one of the most diverse in the world. Ethnic health systems (EHS) - designed around ethnicity and the country's many ethnic groups for political reasons - have worked in parallel to the national system for a long time.

Description: The drive to eliminate mother-to-child transmission of HIV has served as an entry point to foster convergence of the two systems. It coalesces with the larger effort by the Ministry of Health and Sports (MoHS) to improve coordination mechanisms with EHS after the signing of the Nationwide Cease Fire Agreement in 2015.
The HIV sector also recognizes that this intervention will contribute to Myanmar's policy move towards Universal Health Coverage.
Lessons learned: HIV prevalence has been high among ethnic groups, especially among pregnant women and children who are, in general, the underserved population in HIV response. They are also the second largest group among those newly infected - 24% - followed by Injecting Drug Users (IDU), based on HIV transmission trend in 2016.
In Kayin State, 21% of pregnant women were not tested and only 64% of those detected HIV-positive received ARV prophylaxis treatment in 2014. The Karen Department of Health and Welfare (KDHW) has been responsible for the healthcare of approximately 450,000 Karen people, the largest ethnic minority group in this Kayin State, for over twenty years. Although KDHW provides health care to 12,150 pregnant women and 54,000 under-five children, PMTCT services are not fully scaled up.
A PMTCT convergence model was piloted in 15 villages between MoHS, the technical lead and KHDW, the implementer, with the support of UNICEF in March 2017. This convergence introduced standards, identity management and fostered greater data and resource sharing between the Ethnic Health Organization and MoHS. After 10 months of implementation, 89% of 568 underserved pregnant women from the pilot areas are being reached for PMTCT services, compared to none.
Conclusions/Next steps: The results yield important lessons in ensuring that no one is left behind, especially for the most deprived communities. Commitment and continued efforts from government and key stakeholders are essential for "Health as a bridge for peace".

Adapting HIV programmes to systems with severe resource constraints

WEPEE740

Nigeria ARV multimonth scripting: Impact on public health service delivery, infrastructure and supply chain management systems across "high volume" ART clinics

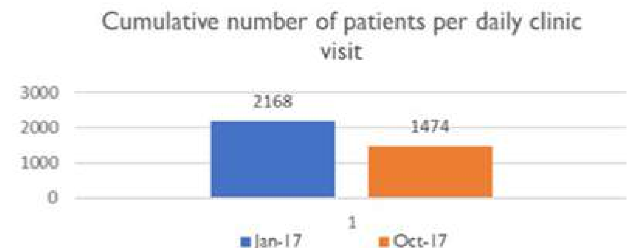
M. Attah[1], A. Mohammed[2], S. Hassan[1], F. Askederin[1], L. Osueke[3], I. Innocent[4], P.D. Haanongon[5], E. Esemokhai[6], V. Ajulo[2], M.L. Field-Nguer[7]
[1]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Deliver and Return, Abuja, Nigeria, [2]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Total Quality Management (Management Information Systems), Abuja, Nigeria, [3]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Field Logistics, Lagos, Nigeria, [4]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Supply Chain Operations, Abuja, Nigeria, [5]Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Deliver and Return, Makurdi, Nigeria, [6]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Deliver and Return, Benin City, Nigeria, [7]USAID Global Health Supply Chain Program - Procurement and Supply Management Project (GHSC-PSM), Task Order 1 HIV/AIDS, Arlington, United States

Background: Antiretroviral (ARV) multimonth scripting (MMS), which complements other antiretroviral therapy (ART) differentiated care, started January 2017 in Nigeria. Under MMS, stable ART patients receive at least three months of ARV refills and complete semiannual clinic visits. From research (Onwujekwe et al., 2016),
MMS can optimize service delivery and decongest clinics, resulting in improved patient care.
Description: MMS implementation required collaborative planning and implementation among stakeholders (program managers, clinicians, pharmacists, supply chain experts), including:

1. Eligibility and inclusion criteria for clinics and products
2. Quantification and supply of ARVs
3. Support to clinic personnel
4. Performance monitoring (stockout monitoring, patient per regimen numbers, provider feedback)

Clinic attendance records from nine high-volume clinics (>1,000 ART patients) were collected from January to October 2017. The records were analyzed to identify trends in ARV commodity dispensing and treatment numbers. The nine clinics support 12 percent of 414,000 patients on treatment across the 104 ART clinics implementing MMS in Nigeria. MMS is limited to adult first-line regimens of AZT/3TC/NVP 300/150/200mg and TDF/3TC/EFV 300/300/600mg, which make up 87 percent of the total regimens provided to ART clients in these clinics.
Lessons learned: Data from our analysis, and feedback from ART refill providers at the nine clinics, indicated reduced congestion with MMS implementation, as the number of patients per daily clinic visit dropped by 25 percent between January and October 2017. The drop was not related to attrition, as the total number of patients on treatment per period was consistent, averaging 42,000 and indicative of noninterruption of treatment with MMS.
The data did indicate that, at MMS initiation, the number of ARV issues to patients increased; these increased volumes resulted in a short-term supply risk that required a temporary slowdown in implementing MMS.
Conclusions/Next steps:

- MMS is an effective intervention to decongest clinics and optimize ART service delivery.
- Reduced workload resulting from MMS presents opportunities to expand service and enroll more ART patients.
- The convenience of decreased ARV refills and fewer clinic visits for stable patients reduces economic strain of multiple clinic visits.
- Collaborative planning prevents interruption of ARV supply during MMS implementation.



[Implementation of MMS results in reduced number of daily clinical visits]

WEPEE741

Mobilizing a multijurisdictional response to address alarming rates of HIV and Hepatitis C (HCV) in rural Saskatchewan (SK) Indigenous community (IC) in Canada

I. Mohammad Khan[1], D.S. Skinner[2], C.G. Cote[3], D. Bryant[3], A. Chhetri[4], B. Dow[5], L. Jagoe[5], A. Campbell[5], M. Andkhoie[5], D. Kupchanko[5], FNIHB, Infections Disease Dr Skinner and Cote First Nations Programs
[1]First Nations Inuit Health Branch, Department of Indigenous Service Canada, Regina, Canada, [2]University of Saskatchewan, Infectious Disease Department, Regina, Canada, [3]Cote First Nations, Regina, Canada, [4]Saskatchewan Health Authority, Yorkton, Canada, [5]FNIHB, Regina, Canada

Background: The Canadian Province of SK is roughly the size of France with the population of nearly 1.2 million. HIV and HCV rates in southern IC (108 and 323 per 100,000 in 2016 compared to Canadian HIV rates 6.4 respectively) are the highest in Canada. Kamsack is a rural town of approximately 2000 residents in Southeastern SK surrounded by three ICs (approximately 2000 population).
Description: An HIV outbreak relating to injection drug use was confirmed in the Kamsack area since mid 2016. 21 HIV cases diagnosed, over half of cases were new infections, 86% co infected with HCV, majority living in ICs. Poverty, homelessness, addictions, stigma and access to care were identified as major barriers to care. An integrated response

was initiated by a multidisciplinary team of federal, provincial and local partners. Majority of positive people were prescribed treatment and adhering to it. The mean time from diagnosis to treatment initiation was 14 days. HIV care was supported by IC leaders, First Nations Inuit Health Branch (FNIHB), Public health agency of Canada (PHAC), Saskatchewan Health Authority, laboratory, infectious disease docs, and local mental health / addiction programs. A new outreach center was established that provide food, transportation, family, referral and cultural support.
Lessons learned: Rapid mobilization of integrated response lead to timely, patient-centered and culturally safe care among all services that resulted in improved access to testing, care and treatment in rural communities. This has also established a precedence of delivering programs in rural setting (off reserve to IC) to people with the most complex socio economic and medical conditions.
Conclusions/Next steps: Similar efforts are needed to ensure response in other rural ICs in Canada to address the elevated rates of sexually transmitted blood born infections. Adding suboxone to the addiction program, access to Pre-Exposure Prophylaxis (PrEP) and more convenient ways of screening of at risk people.

WEPEE742

Test and start readiness evaluation: Phase 1 in Mozambique

A.M. Couto, N. Chicuecue, E. Paunde, J. Tique
Ministry of Health, STI/HIV National Program, Maputo, Mozambique

Background: The WHO guidelines on test and start have been adopted globally, which presents a significant context-specific challenge for developing countries. The strategy requires countries to ensure that a minimum of programmatic standards and criteria are in place before implementing test and start. Mozambique carried out an evaluation of health facilities to gauge their readiness for the implementation of test and start. The evaluation was carried out in June 2016 in the twelve districts (152 health facilities) with a high burden of HIV selected to be included in phase one of test and start roll out. The evaluation aimed to determine the readiness of the health facilities to implement test and start.
Methods: The evaluation measured readiness using a set of minimum criteria from the following thematic areas:
1. HIV Testing and Counselling (testing approaches, test kit management, linkage to care),
2. Care and Treatment (psychosocial support, positive prevention, retention),
3. Laboratorial monitoring (viral load),
4. Pharmacy (warehousing capacity, ARV drug management), and #
5. Human Resources (providers trained in testing and counselling, care and treatment, viral load, psychosocial support).
Weighted scores were calculated for each thematic area as follows: 0-65%= requires support in various areas, 66-85%= needs support on specific aspects, and >85%= prepared.
Results: The median score for the 152 health facilities evaluated was 55% overall, 64% for testing, 64% care and treatment, 50% lab monitoring, 60% pharmacy, and 59% human resources.
Conclusions: Mozambique faces substantial challenges in the transition to the WHO test and start policy recommendation, however, the country is working to overcome these challenges, recognizing the clinical and programmatic advantages of test and start. For developing countries such as Mozambique, we recommend a phased approach to the implementation of test and start, prioritizing high burden districts, while simultaneously carrying out baseline and follow-up readiness assessments to allow for programmatic adjustments during the implementation process.

Key populations in humanitarian settings and fragile contexts

WEPEE743

Right to health services

M.W. Mutonyi
Bar Hostess Empowerment and Support Programmes, Project Lead, Kitale, Kenya

Background: Kenya has made significant efforts towards achieving the UNAIDS 90 90 90 target. Despite this there is still high HIV prevalence among the key populations with the sex workers accounting for 29.3% than the general population of 5.9% (Kenya Aids Progress report 2013-2015).Stigma and discrimination and failure of integrating human rights norms and principles in health systems and programs designing, implementation, monitoring and evaluation have been identified as a major contributing factor to this.
Description: Bar Hostess Empowerment and Support Program, has more than 20 years of experience in working with the sex workers in Kenya. BHESP realized that the only way to achieve the 90 90 90 target and ending HIV pandemic by vision 2030 is through advocating for human right based approach in service delivery.
The organization has ensured this through creating awareness on human rights among the sex workers, influencing establishment of policies that are friendly to the sex workers at the national level, empowering the sex workers to take ownership and leadership of programs that targets them and participation in decision making process that is normally done by the national KP technical working groups.BHESP also monitors violation of human rights through conducting satisfaction surveys at service delivery point and documents findings and lesson learnt.
Lessons learned: It came out clearly that sex workers having gone through harsh terrains of discrimination and stigma, and human right violation they have solution for their own problems. In addition to this human right integration into service delivery and development strategies is key as it brings forth fully engagement sex workers and ownerships of this programs and finally Equality and freedom from stigma and discrimination is central, has benefits and no harms.
Conclusions/Next steps: Human right approaches should be adopted to ensure dignity and attention to the needs and rights of the key populations as this is the only way to ensure health services are available, acceptable, and accessible and of high quality just for them to enjoy services like any other human being. This will in deed avert HIV/STI.

WEPEE744

The role of AIDS councils in pushing the legal and human rights agenda for sex workers: Lessons from South Africa

K. Mangold, L. Malaka
SANAC, NSP Implementation, Pretoria, South Africa

Background: The South African Constitution protects its citizens from discrimination and safeguards their basic human rights. However, sex workers remain vulnerable to abuses including violence and exploitation, and secondary victimisation by police. The South African National AIDS Council (SANAC) developed the current sex worker HIV Plan and are uniquely placed to push for full implementation of the human rights package described therein.
Description: In 2017, SANAC spearheaded national efforts to connect with government on legal reform of sex work. SANAC partnered with a South African newspaper to host a critical dialogue on the decriminalisation of sex work. This was broadcast live and supplemented with a newspaper insert. SANAC advocated publicly for the decriminalisation of sex work and called for a holistic legal and human rights-based response to sex workers. SANAC further facilitated engagement between police and sex workers on the eve of World AIDS Day in the Eastern Cape in an effort to eliminate the police practice of using possession of condoms, lubricant, ARVs or any other legal commodity as evidence of sex work and grounds for confiscation or arrest.

Lessons learned: For the first time in South Africa, the National AIDS council is taking a lead in pushing the legal and human rights agenda for sex workers, with sex workers. SANAC's initiatives provide space for government officials, politicians and civil society to come together, engage and advocate for programme and policy change. This gives solid grounding to direct the legal and human rights agenda for sex workers in a way that is underlined by a national policy and which supports the public health response to HIV.
Conclusions/Next steps: The discussions facilitated by SANAC between civil society and government on legal and human rights of sex workers are critical to legitimise the influence of human rights violations on the country's HIV epidemic. SANAC leads by example in showing that even in a country where sex work is criminalised, a national AIDS council can take centre stage in the creation of an enabling environment to implement HIV programmes for sex workers.

WEPEE745

Utilisation of social media to reach key populations (men who have sex with men & transgender people) in challenging operating environments

I. Hove, P. Khambi
Right to Care, Johannesburg, South Africa

Background: Between 22% - 48% of HIV infections in South Africa are the result of men having sex with men and transgender people (MSM & TG) because of perceived barriers to health care, and sexual behaviours that facilitate transmission of HIV. Despite a progressive constitution, MSM & TG face high levels of social stigma and homophobic violence, thus find it difficult to disclose their sexuality to healthcare workers, limiting access to HIV services.
Description: The Global Fund against AIDS, TB and Malaria (GFATM) in partnership with Right to Care (RTC) and its sub-recipient (SR) community-based organisations are supporting implementation of combination prevention interventions for MSM & TG. RTC and SRs tested the use of social media to identify and link health services to unreached MSM & TG networks.
Social media sites like Facebook, Twitter, and Instagram were utilised in creating a platform to link clients to access primary health services between September - November 2017. A dedicated landing page was set up on the RTC website together with a booking form linked to sensitised partner clinics and SRs.
The content strategy was based on key messages and awareness objectives that promoted visits to linked centres and nearby sensitised clinics for regular HIV testing services, and any other primary health services.
The content strategy was based on key messages and awareness objectives that promoted visits to linked centres and nearby sensitised clinics for regular HIV testing services, support groups, and any other primary health services. A total of 298,917 users were reached. Out of these 379,850 impressions were recorded. 71,403 users engaged with the massages.In-post links to primary health service providers was generated by 1,926 users. The conversion rate was 3%.
Lessons learned: To effectively reach the targeted audience, social media messages should have a clear content strategy, careful planning of content calendar, targeted boosting of selected content and tailor the content to suit specific platforms (no one-size-fits-all approach).
Conclusions/Next steps: Social media is an important avenue for reaching MSM & TG not traditionally accessed by peer educators. It should be adopted as an integral outreach approach for HIV prevention interventions moving forward in challenging operating environments.

Integrating HIV and other health programming in migrant or refugee settings

WEPEE746

SANGJOG, a program for HIV vulnerable young key people in Cox's Bazar to address the emerging threat in the perspective of Rohingya influx in Bangladesh

M.M. Alam[1], N. Mohammad[1], S.T. Shimu[1], M.I. Hossain[2]
[1]*Population Services and Training Center (PSTC), Dhaka, Bangladesh,* [2]*Population Council, Dhaka, Bangladesh*

Background: The first HIV case was reported in Bangladesh in 1998, and since then till 2017 cumulatively 5,586 cases had been detected of whom 924 died. Among the general population of Bangladesh HIV prevalence is less than 0.01%. But the recent influx of Rohingya population and significant number (109) of HIV detected cases among them in a short period of time has become an emerging threat for Bangladesh.
Description: In this backdrop, SANGJOG program is initiated by Population Services and Training Center (PSTC) and funded through the Embassy of the Kingdom of the Netherlands in Bangladesh which focuses particularly on the needs of pavement dwellers, transport workers, floating sex workers, young people engaged in small trade and especially Rohingya Refugees in Balukhali and Kutupalang, Ukhiya, Cox's Bazar in Bangladesh.
SANGJOG increases knowledge of young key people vulnerable to HIV and AIDS through Peer Session on Comprehensive Sexuality Education. It provides health care services with counseling to the young people and increases the capacity of government's health services centers towards integration of sustainable SRH/HIV services and conducts advocacy with district level stakeholders and national decision makers to raise awareness and to promote monitoring and reporting of gender based violence.
Lessons learned: The Rohingya people, outnumbered the local people in Ukhia and Teknaf of Cox´s Bazar district. More than 0.4 million Bangladeshi people are living surrounding the Rohingya camps and its inhabitants now crosses 1 million and are connected with them also in different ways. Huge number of workers are traveling every day inside the camps to support the gigantic relief operations. There are evidences of sexual abuse and trafficking as common in any refugee situation. All these factors are influencing of HIV transmission among Rohingya Refugee as well as to the general people of Bangladesh.
Conclusions/Next steps: It is very much urgent to start comprehensive intervention targeting the Rohingya and Bangladeshi people living in Ukhia and Teknaf to prevent new HIV infections. And increasing program coverage and case detection, increased access to treatment, care and support services for the people living with HIV through a strengthened coordination mechanism will ensure to prevent further spread of HIV.

Delivering differentiated care

WEPEE747

Lessons learned from early implementation of the national adherence guidelines for HIV, TB and NCDs in South Africa

S. Pascoe[1], J. Murphy[1], A. Huber[1], M. Phokojoe[2], M. Gorgen[3], A. Moola[1], N. Scott[4], R. Fong[4], S. Rosen[4], D. Wilson[3], Y. Pillay[2], M. Fox[4], N. Fraser-Hurt[3]
[1]*University of Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa,* [2]*National Department of Health, Pretoria, South Africa,* [3]*The World Bank Group, Washington DC, United States,* [4]*Boston University School of Public Health, Global Health, Boston, United States*

Background: As countries implement treatment for all, they are confronted with how to best initiate and retain patients in HIV care. Differentiated models of care have been proposed to better serve pa-

tient needs, reduce unnecessary burden on the health system, and improve outcomes. In 2015, South Africa's National Department of Health (DOH) introduced National Adherence Guidelines (AGL) for Chronic Diseases, including Fast Track Initiation Counselling for newly diagnosed patients, Adherence Clubs and Decentralized Medication Delivery for stable patients, and Enhanced Adherence Counselling and Early Tracing for patients with elevated viral loads or lost to follow-up.
Description: As part of an ongoing cluster-randomized evaluation of early AGL implementation in 24 health facilities in 4 provinces, we used qualitative methods to gain insight into how to support AGL rollout and improve outcomes. We report here on lessons learned and insights from 24 focus groups (FGDs) with patients, 48 in-depth interviews (IDI) with healthcare providers, and 16 IDIs with DOH and implementing partners.
Lessons learned: The IDIs, FGDs and observations elicited the following key insights:
· Training of sufficient and appropriate staff and mentorship is a prerequisite to successful implementation.
· For stable patients, patients and providers greatly appreciate repeat prescription strategies that allow patients to collect medications outside facilities or in Adherence Clubs.
· Data flow within facilities and between external medication pick-up points is critical for patient management and monitoring retention
· An electronic medical record system for chronic conditions that includes decentralized service delivery is essential for integration and management of adherence interventions
· Patient file management must be addressed to prevent loss of patient information; a one-patient-one-file system facilitates patient management
· Efficient patient tracing relies on strong coordination and information flow between providers at facilities and in the community.
Recommendations based on these lessons are provided in Table 1.
Conclusions/Next steps: As we progress towards final outcomes within the evaluation, we have already gained insights into how to improve AGL rollout on a national scale based on provider and patient preferences and our observations of the early phase. Implementation of these recommendations should help improve outcomes as AGL scale up continues.

Area	Recommendation
Patient care forms and registers	Review format and use of forms that have proved complex/confusing and ensure that appropriate registers are in place for monitoring all patient interactions, especially for repeat prescription strategy interventions (e.g. Adherence Clubs and Decentralized Medication Delivery) and patient tracing.
Clinic barriers	Ensure site readiness with sufficient resources and engage with stakeholders to ensure buy in from providers and implementers so they feel engaged and empowered to deliver AGL interventions.
Training of staff	Engage with staff and ensure appropriate cadres are trained; provide ongoing mentorship and refresher training and retraining in areas with high staff turnover.
Decentralized medication delivery and reporting	Scripting, staffing and data issues all need to be resolved to ensure patients receive their medication and to prevent further congestion at facilities. In early implementation, it is critical that data on medication pick-up at external pick up points be fed back into clinic data collection systems.
Issues related to blood draws for viral load monitoring	It is critical that patients in repeat prescription strategy interventions continue to receive timely viral load monitoring. One way to help ensure this is by putting patients into cohorts based on viral load due date (e.g. set up Adherence Clubs in which all patients have the same monitoring schedule) and marking patient files for patients all due their viral load in the same month.
Patient tracing	There must be greater clarity on which patients need tracing, in order to maximize tracing resources: Patients with an elevated viral load who are not successfully recalled, and patients who have missed an appointment for 5-90 days.

[Table 1 - Recommendations for Improving Implementation of the Adherence Guidelines]

WEPEE748

Implementation of differentiated care model in Kenya´s private sector

C. Kanari[1], L. Maikweki[2], G. Mogaka[3], J. Andugosi[4]
[1]PSKenya, HIV, Nairobi, Kenya, [2]Population Services Kenya, HIV/TB, Nairobi, Kenya, [3]Gold Star Network Kenya, HIV/TB, Nairobi, Kenya, [4]Gold Star Kenya, Nairobi, Kenya

Background: In 2015 WHO released a recommendation that all PLHIV initiate ART irrespective of CD4 cell count or clinical stage dubbed "test and Treat". Successful implementation of Test and Treat led to a substantially increase in the number of patients starting ART and patient volume at ART sites. Kenyan government recognized this and adapted differentiated care model (DCM) in its new guidelines in 2016 which was also in line with WHO guidance. This translates to a client centred approach rationalizing fewer clinic visits for stable clients and options for community based ART distribution. PS Kenya implements HIV services uniquely and purely in the private sector which is fee for service approach, therefore an adapted approach was necessary as reduced visits may be perceived as reduced income by providers.
Description: The program sensitized its providers on the DCM approach. A Baseline survey was carried out in 13 facilities after sensitization of providers. The survey revealed that providers were implementing fast-track model. Appointment dates were set for the refill in 3 months and the clinical appointment in 6 months, this was recorded in the Appointment Diary for ART Refills. However the clients on long appointments were mostly not categorized as stable or unstable.
To start implementation of DCM, all patients were categorized and flagged. Provider willingness to implement the approach was also a consideration. The main intervention strategies were Sensitization on categorization of clients into stable and unstable to the providers, Mentorship to the service providers, Joint Support supervision with the sub-county teams, and line-listing of clients who had been on treatment for more than 1 year.
Lessons learned: DCM is a feasible model for ART provision even for Private sector providers despite it meaning less clinic visits. Some providers have proceeded to offer the service via a courier system and charge the clients for drug deliveries. One provider successfully implemented a concierge approach that led to him delivering drugs to his stable clients and taking the viral load sample for a fee and at a location of the client's preference.
Conclusions/Next steps: Implementation of client centred approaches for clients on Art is a feasible and scalable approach.

WEPEE749

Impact of offering differentiated HIV care on treatment retention and health facility workload: Results from Kenya health zone in the Democratic Republic of Congo

D. Kamerhe[1], C. Tendo[1], R. Mwamba[1], I. Thior[2], D. Canagasabey[2], J.-C. Kiluba[1], L. Mueller Scott[2]
[1]PATH, Lubumbashi, Congo, Democratic Republic of the, [2]PATH, Washington, United States

Background: Implementation of test-and-treat in the Democratic Republic of Congo (DRC) has resulted in more people living with HIV (PLHIV) accessing treatment services at health facilities, overwhelming facility workforce and increasing wait times for PLHIV, leading to weaker retention of PLHIV in treatment. PATH, through the USAID-funded Integrated HIV/AIDS Project in the DRC, piloted three differentiated models of care (DMC). We conducted an analysis to evaluate the impact of DMC on antiretroviral treatment (ART) retention and health facility workload.
Methods: Beginning October 2016, three DMC were implemented to decongest the Kenya General Reference Hospital (HGR):
1. ART distribution during monthly meetings at six PLHIV support groups
2. Community-based point of ART distribution (PoDi+)
3. Fast-track ART refill circuit at Kenya HGR
Stable PLHIV (older than 18 years; no opportunistic infections; not preg-

nant; undetectable viral load for at least six months) enrolled in a DMC of their choice and received a three-month ART supply. We used descriptive statistics to analyze patient medical records data.
Results: From October 2016 to December 2017, 938 PLHIV from Kenya HGR enrolled in a DMC: 576 in a PoDi+; 313 in the fast-track circuit; and 49 in support groups. The six-month retention rate observed at each DMC was 96% at the PoDi+, 96% at the fast-track circuit, and 94% among support groups, compared to 60% at Kenya HGR for the same period. The only model with 12 months of data (see table), the PoDi+, achieved a 12-month retention rate of 98%, as 22 of the 28 dropped from the PoDi+ were transferred back to Kenya HGR for treatment services due to pregnancy or opportunistic infections. There was a 47% reduction in provider workload at Kenya HGR, from 404 PLHIV/provider before DMC to 217 PLHIV/provider after DMC, and a decrease in wait time at Kenya HGR from two hours to 45 minutes.
Conclusions: Our analysis demonstrated that DMC were successful strategies for improving retention in treatment and reducing provider workload and wait times at Kenya HGR. Results suggest DMC are critical to increasing PLHIV retention in ART to contribute to epidemic control in the DRC.

Month of enrollment	Patients newly enrolled at PoDi+	Number retained after six months	Retention rate at six months (%)	Number retained after twelve months	Retention rate at twelve months (%)
October 2016	125	115	92%	110	88%
November 2016	87	86	99%	81	93%
December 2016	74	73	99%	68	92%
January 2017	38	36	95%	37	97%
	324	310	96%	296	91%

[12-month retention of patients enrolled at Kenya PoDi+ from October 2016 to January 2017.]

WEPEE750

ART behind bars: Differentiated service delivery results in high viral load suppression among prisoners in Zambia

K. Mwanda, M. Chikuba, E. Mwila, Y. Lungu, D. Phiri, L. Kawanga, M. Banda, K. Chibesakunda, D. Chikondi, J. Jose
JSI Research & Training, Inc., International Division, Lusaka, Zambia

Background: HIV prevalence among prison inmates in Zambia is 27%, twice that of the general adult population. The Zambia Correctional Service (ZCS) refers prisoners on ART to public sectors facilities outside prison. However, due to transport and manpower shortages, prisoners are often not able to keep appointments, resulting in ART interruption, with risk of poor viral suppression, ART resistance, and poor health outcomes.
Prisoners with poorly treated HIV, particularly those temporarily imprisoned, are also liable to transmit resistant HIV upon release, with negative consequences for HIV epidemic control.
Description: The USAID-funded USAID DISCOVER-Health Project implemented by JSI partnered with ZCS to bring ART within prison walls, to address challenges of access to regular HIV treatment, to improve treatment outcomes.
From October 2016, eight large correctional facilities are visited by project teams comprising one clinician, two nurses, and a psychosocial counsellor who provide ART and other services once a week or twice a month, inside prison walls. High-volume facilities with over 50 clients are visited weekly, while those with 50 or less are visited every two weeks.
At each visit, ART services including TB screening are provided, in addition to laboratory monitoring. Viral load testing is done in line with national HIV treatment guidelines.
Lessons learned: Of the 241 prisoners (234 males and 7 females) who were eligible for viral load monitoring, 221 (92%) were virally suppressed. 185 (84%) of the prisoners who were virally suppressed were initiated on ART at the time of imprisonment. Viral suppression among prisoners benefiting from this DSD model (92%) is higher than the viral suppression rate (77%) in the national HIV treatment program.
Conclusions/Next steps: By providing ART behind bars we reduced the barriers to ART adherence among prison inmates in eight correctional facilities in Zambia. Similar DSD models should be instituted in all prisons to improve adherence and health outcomes for PLHIV prisoners.

WEPEE751

A “quick pick-up” differentiated model of ART delivery shows good retention in care

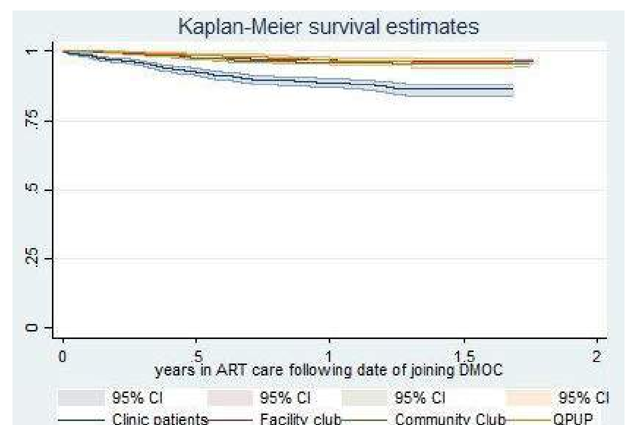
Background: In the context of ART scale-up, Differentiated Models of Care (DMOC) are a key strategy to improve efficiency and cater to patient needs. Available to clinic patients after confirmed viral suppression, DMOCs include facility- or community-based counselor-led adherence clubs. Since October 2015, a quick pick-up model (QPUP) has been running in one clinic in Khayelitsha, a low-income area in Cape Town, South Africa, with high HIV prevalence. QPUP, also known as fast-lane, allows patients to collect ART directly from pharmacy, without counselor review. All three DMOC models require an annual clinical visit and viral load. We describe patient characteristics and retention in QPUP, other DMOCs and those not in any DMOC.
Methods: We used routine clinical data of patients starting ART before July 2017 in three Khayelitsha clinics. QPUP patients are stable on ART prior to referral to QPUP. For comparability in terms of time on ART and viral suppression we matched each QPUP patient to two non-DMOC 'clinic' patients. Each QPUP patient was matched to two patients with the closest ART start date, from patients who were in care and virally suppressed at their last viral load when the QPUP patient joined QPUP. Follow-up time for both matched clinic patients began on the QPUP patient's QPUP start date. To compare QPUP with other DMOCs, only patients that joined facility or community clubs after QPUP began were included.
Results: Those in QPUP were more likely to initiate ART at WHO Stage 1(Table 1). A larger proportion of clinic patients are male but age is similar across groups. DMOC patients have higher retention in care compared to clinic patients (see also Figure 1) but a notable proportion return to clinic. At 12-months 96% of QPUP patients are still in ART care, but 85% remain in QPUP.
Conclusions: QPUP outcomes suggest that reduced healthcare contact time is feasible for stable patients, although return to clinic care is not uncommon across all differentiated models. A limitation of this data is incomplete viral load capturing and self-selection of DMOC patients. We aim to further develop the QPUP model, adapting to patient needs and health facility resources.



[Figure 1 Kaplan-Meier survival estimates of retention in any ART care of QPUP and Club patients compared to clinic controls]

	QPUP (N=976)	Clinic (N=1852)	Facility club (N=3138)	Community Club (N=3431)
median age (IQR)	37.3 (32.2-43)	38.3 (32.1-45.8)	36.3 (31-42.5)	39.6 (34.3-45)
Number male (%)	271 (28%)	641 (33%)	742 (24%)	926 (27%)
N (%) WHO stage 1 at initiation	451 (46%)	668 (34%)	1198 (38%)	889 (26%)
Median baseline CD4 Count (IQR)	208 (113-318)	204 (120-315.5)	224 (129-332)	181 (100-268)
Median months on ART at DMOC start* (IQR)	41.4 (21.6-70.4)	41.3 (20.1-68.8)	34.6 (18.1-63.2)	57.5 (33-87.7)
12 Month Retention in ART care after first DMOC visit*	96%	85%	93%	96%
12 Month Retention in DMOC care	85%		79%	85%
Viral load within first year after first DMOC visit* % complete (%suppressed)	33% (95%)	36% (91%)	43% (96%)	77% (96%)
*in the case of clinic patients, DMOC start refers to the DMOC start date of the patient they were matched to				

[Table 1: Baseline Characteristics and Outcomes of QPUP, Clinic and Club Patients]

WEPEE752

Early findings of an innovative, community-based antiretroviral therapy (ART) delivery program for female sex workers in Tanzania

L. Vu[1], W. Tun[1], L. Apicella[2], C. Casalini[3], D. Bikaru[4], N. Makyao[5], D. Michael[6], T. Koppenhaver[7], E. Mlanga[7]
[1]Population Council/Project SOAR, Washington DC, United States, [2]Populaton Council/ Project SOAR, Dar es Salaam, Tanzania, United Republic of, [3]Jhpiego, Dar es Salaam, Tanzania, United Republic of, [4]Jhpiego, Njombe, Tanzania, United Republic of, [5]National AIDS Control Program (NACP), Dar es Salaam, Tanzania, United Republic of, [6]National Institute for Medical Research (NIMR), Mwanza, Tanzania, United Republic of, [7]USAID, Dar es Salaam, Tanzania, United Republic of

Background: To increase linkages to and retention in ART care, we designed and piloted the delivery of community-based ART services to female sex workers (FSWs) using community-based HIV testing and counseling (HTC) platforms (mobile and home based).
Methods: This is a mixed-method implementation science research study, using a quasi-experimental design. Eligible participants in the intervention arm (Njombe Region) were enrolled into community-based ART, counselled on ART, and immediately received one month of ARV drug supply. At the first refill, each FSW receive 2 months of drug supply. Subsequently, FSWs receive 3 months of drug supply. FSWs in the comparison arm (Mbeya Region) were referred to public ART facilities, following national guidelines (at registered facility, fixed refill date, one month of ARVs). We collected data at baseline and will re-interview the cohort at 6 and 12 months. Viral load will be measured at 6 months and 12 months. This abstract describes baseline quantitative, and early qualitative and process data from the study.
Results: A cohort of 617 HIV-positive FSWs not currently on ART were established (June-July, 2017) and is being followed up (309 in Njombe; 308 in Mbeya). The median age is 30 years old; half were never married and a third were divorced. One-third of FSWs learned about their HIV positive status for the first time at study enrollment. Among a sub-sample who had known their status for more than a month before the study (n=97/617), half had not registered in HIV care. Condom use (at last sex) was low with paying (28%) and non-paying clients (25%), and internalized stigma was high (e.g. 46% felt guilty, 33% worthless; 39% ashamed because of living with HIV). In the intervention arm, 98% of participants came back on time for the first refill, and 95% came back on time for the second refill. Our 3-month qualitative interviews with providers and FSWs showed overwhelming support of this community-based ART model.
Conclusions: We found gaps in linking HIV+ FSWs with ART services. Early findings suggest that the community-based ART model is closing these gaps by being feasible, acceptable, and associated with increased linkages and retention in ART among FSWs.

WEPEE753

Barriers and facilitators to successful decentralized treatment provision for female sex workers living with HIV in Durban, South Africa

C. Comins[1], L. Parmley[1], S. Schwartz[1], H.T. Mkhize[2], V. Guddera[2], D.R. Phetlhu[3], K. Young[4], H. Hausler[4], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Key Populations Program, Center for Public Health and Human Rights, Department of Epidemiology, Baltimore, United States, [2]TB/HIV Care, Durban, South Africa, [3]University of Western Cape, School of Nursing, Cape Town, South Africa, [4]TB/HIV Care, Cape Town, South Africa

Background: Female sex workers (FSW) across sub-Saharan Africa are disproportionately affected by HIV and antiretroviral therapy (ART) coverage among FSW living with HIV remains low due to individual and structural-level barriers to care. Differentiated care models, including decentralized treatment programs (DTP), are being increasingly scaled for those that have already achieved viral suppression, but may also represent opportunities to better service marginalized populations including FSW. Here, we explore potential barriers and facilitators to decentralized HIV treatment initiation and care for FSW living with HIV in South Africa.
Methods: 38 semi-structured, in-depth interviews were conducted with FSW living with HIV in Durban, South Africa (n=24) and key informants (n=15) including implementing partners, clinic nurses, police, sex work advocates, brothel managers, and other key stakeholders. Participants were recruited using criterion-based sampling. Interviews were conducted in English or isiZulu between September-November, 2017 and transcribed, translated, and analyzed using grounded theory in Atlas.ti 8, based on deductive themes emerging from participants.
Results: DTP was seen to be particularly impactful in minimizing transport costs, time spent at the clinic (including wage loss), sex work-related stigma, and risks of inadvertent HIV disclosure. Advantages of mobile DTP emerged; Participants reported DTP would be more discrete, FSW-friendly, and less resource intensive than receiving care at facility-based clinics. Moreover, participants reported that DTP would provide a safety net for FSW who have missed ART pickup appointments and facilitate improved tracing of FSW, particularly those who are moving across venues within an urban area.
However, branding of mobile clinics, security and concerns around ART packaging may undermine DTP success.
Conclusions: Decentralization of HIV treatment services may represent a relevant differentiated treatment model to overcome occupational and non-occupational barriers among FSW living with HIV to engagement in ART. Studying determinants of who would most benefit from DTP and optimal implementation approaches for DTP will provide insight to the scalability of these approaches and utility in optimizing sustained treatment outcomes among FSW living with HIV in South Africa.

WEPEE754

Improving retention, viral suppression, and facility decongestion through community-based individual drug distribution (PODIs) in DRC

E. Mothibi[1], J. Mangoma[2], D. Kabamba[2], L. Monteith[2], F.X. N'siesi[3], J. Firth[4], J. Kiluba[5], D. Kamhere[6], F. Chirowa[7], B. Makumbe[2], A. Grimwood[2], G. Fatti[8]
[1]Khethimpilo, Health Systems Strengthening, Cape Town, South Africa, [2]Khethimpilo, EQUIP, Cape Town, South Africa, [3]USAID, Kinshasa, Congo, Democratic Republic of the, [4]EQUIP, Washington DC, United States, [5]IHAP, Lubumbashi, Congo, Democratic Republic of the, [6]IHAP, Kinshasa, Congo, Democratic Republic of the, [7]Khethimpilo, EQUIP, Harare, Zimbabwe, [8]Khethimpilo, Cape Town, South Africa

Background: Current estimates of PLHIV in the DRC is 370,000 with 33% (122,268) on ART (UNAIDS 2015). While scale-up is ongoing to increase patients on ART, strategies to achieve retention and viral load suppression are essential. Monthly patient visits, provider prescribing, and dispensing of medications creates congestion at clinics and pharmacies, additional time and economic burden on patients, and additional data collection and tracking burden on M&E systems. EQUIP is implementing

Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

an out-of-health facility, community-based individual drug distribution (PODI) point from which clients can pick-up their medication and receive psychosocial support and other additional services.
Description: With the support of EQUIP, PROVIC Plus (now IHAP) established PODIs in Lubumbashi, and Kinshasa. EQUIP trained local supporting partners, NGOs and MOH staff on PODI setup, created SOPs, tools and registers to use for performance tracking. PODI members are adults >18years who have been adherent to treatment for the last 6 months. At each PODI visit, lay NGO staff members, who are mostly PLWHIV, do a symptom screen, provide peer support and issue three months' ARV supply to the client. Symptomatic members are referred to the health facility for care. Annual, viral load tests are conducted. Monitoring tools track enrolment and missed appointment, retention, adherence and viral load suppression.
Lessons learned: In Lubumbashi PODI Kenya was set up in October 2016 and PODI Lubumbashi in January 2017. In Kinshasa, PODI Masina and PODI Kingasani were set up in 2017. By September 2017, a total of 1484 ART clients were enrolled at the 4 PODI houses resulting in decanting of linked facilities by 44%- 47% respectively. The four PODI houses show high retention rates of 92-100% at 3, 6 and 9 months and Viral Suppression above 90%. Some of the benefits of PODI houses include reduced costs to the patient and improved convenience for patients without compromising the quality of care.
Conclusions/Next steps: Shifting of ART delivery to Community Distribution points implemented as a differentiated model of ART provision for stable patients produces good retention and viral load suppression. This model can also provide benefits of decongesting facilities to enable rapid Test and Treat.

WEPEE755

Anticipated and lived experiences of stable patients on ART in urban adherence groups: A qualitative study from Zambia

P.C. Mwamba[1], S.M. Topp[2], C. Bolton-Moore[1], C. Cheelo[3], L. Jere[1], M. Mukumbwa-Mwenechanya[1], S. Nkwemu[1], W. Mutale[3], A. Sharma[1]
[1]Centre for Infectious Disease Research in Zambia, Research, Lusaka, Zambia, [2]College of Public Health Medical and Veterinary Sciences, James Cook University, Townsville, Australia, [3]The University of Zambia, School of Public Health, Lusaka, Zambia

Background: In Zambia, growing numbers of people on ART and health system constraints has spurred differentiated service delivery (DSD). Nested within a mixed methods study on DSD in three provinces in Zambia, we compared anticipated and lived experiences of patients and health care workers (HCWs) prior to and after six months of implementation of urban adherence groups (UAG). The acceptability, feasibility and appropriateness of UAGs, which consist of a group of 30 patients who collect ART at a facility-based meeting held every 2-3 months during off hours, has not been previously studied in Zambia.
Methods: At baseline, we conducted 34 focus group discussions (FGDs) with patients, family members, and HCWs and 26 in-depth interviews (IDIs) with government officials and local leaders. At mid-line evaluation, we conducted 15 FGDs with professional HCWs and patients and, 18 IDIs with lay and professional HCWs. Audio transcripts were translated, transcribed and uploaded to Nvivo QSR™. Using framework analysis, major themes from both evaluations were compared by type of respondent and exposure to UAGs.
Results: Prior to implementation, working patients found the off-hours drug collections times highly acceptable while HCWs considered them unacceptable given current workloads and clinic space. Both patients and HCWs raised concerns regarding the big group size which could expose patients to stigma and unintentional disclosure. HCWs expressed concerns about physical safety, record keeping, security of stored drugs and working off-hours. After six months of implementation, both patients and HCWs found UAGs acceptable albeit with concerns about staff shortage, compensation for HCWs working off-hours and ARV storage space. Contrary to expectations, patients found that UAGs reduced HIV-related stigma and created group support. There were no reported cases of theft and physical harm. On the contrary, documentation and records were described as well-kept and updated.
Conclusions: Most pre-implementation concerns were not reported at mid-line demonstrating the importance of mitigating foreseeable challenges. Implementing UAGs can result in reduced HIV-related stigma, freed-up time for patients and potentially decongest day-time clinics. To effectively implement UAGs, health services must be re-organised by increasing UAG-specific staffing and, adapting clinic operations to meet off hours and ARV storage requirements.

WEPEE756

Uptake of HIV differentiated care models for patients on antiretroviral therapy in South Africa

D. Joseph Davey[1,2], C. Serrao[3], T. Luthuli[4], E. Darkoh[2], BroadReach
[1]University of Californa, Los Angeles, Epidemiology, Hout Bay, South Africa, [2]BroadReach, Cape Town, South Africa, [3]BroadReach, Johannesburg, South Africa, [4]DOH, Mpumalanga, South Africa

Background: South Africa rolled out differentiated care to stable adult patients who were the same regimen for ≥12-months, ≥2 consecutive normal laboratory results (viral load <1000 copies/mL), and not currently on TB or other medication that requires clinical consultation. Differentiated care in South Africa includes: pharmacy, fast lanes, adherence clubs and decentralized, community-based drug distribution (CCMDD).
Methods: We conducted an analysis of national data from 307 facilities in five Districts in South Africa between September 2016 and December 2017 to evaluate demographic and clinical characteristics and treatment outcomes in patients on differentiated care vs. standard of care in multivariable logistic regression models.
Results: Of 433,249 patients on ART, 221,596 were eligible for differentiated care (51%) in 307 facilities. To date, 173,267 eligible patients were registered for differentiated care (78% of eligible patients) including: 34% CCMDD external pick up points (e.g. pharmacies), 27% clinic or community-based adherence clubs, 19% using internal CCMDD pick-up-points and 20% using clinic fast-lanes for ART delivery. There was a drop in use of external pick up points due to late deliveries, limited pick-up-points in rural areas and stock outs reported. Median age of patients in differentiated care was 39 (IQR=32-46), 71% were females. Median time on ART was 4.3 years (IQR=2.5-6.4 months). Median CD4 count was 488 (IQR=338-663), women had twice the odds of having a CD4 >450 (age-adjusted OR=2.06, 95% CI=1.98-2.16). Median last viral load was 124 (IQR=84-124) and men had increased risk of having a viral load >1000 copies/mL (age-adjusted OR=1.23, 95% CI=1.11-1.36). Loss to follow up and mortality were very low in this cohort at < 1%.
Conclusions: We found high uptake (78%) of differentiated care in stable patients on ART with most using external pick-up-points. Additional interventions are needed to improve treatment outcomes in patients not in differentiated care, mostly men and young people. Additional research is needed to evaluate the extent to which differentiated care decongests facilities, allowing for improved clinical management of complex cases, and initiation of new patients on ART.

WEPEE757

The first experience with ART adherence clubs in Maputo, Mozambique: An analysis of a second-line ART subcohort

I. Finci[1], A. Flores[1], A.G. Gutierrez Zamudio[1], E. de Abreu[1], S. Issufo[2], I. Gaspar[2], L. Molfino[1]
[1]Medecins sans Frontieres, Maputo, Mozambique, [2]Ministry of Health, Maputo, Mozambique

Background: The Adherence Club (AC) model of care was piloted by Medecins Sans Frontieres (MSF) starting in 2007 in South Africa. AC model offers patient-centred access to antiretroviral therapy (ART) to clinically stable patients and reduces the number of consultations in health-care facilities. In Maputo, MSF started to run AC in collaboration with Ministry of Health (MoH) in October 2015, at Centro de Referencia Alto Mae (CRAM), an MSF-supported health facility which assists complex HIV patients. Therefore, this is one of the first descriptions of an AC cohort of patients with a history of treatment failure.

Methods: A retrospective analysis of patients' data from CRAM enrolled in AC clubs and receiving second-line ART treatment was performed. The analysis spanned from October 2015 to January 2018. In addition to death, lost-to-follow-up (LFU) or coinfection with tuberculosis, reasons for exiting AC can be: unsuppressed viral load (VL) or skipping club session twice in succession. Kaplan-Meyer curve was used to analyse retention in AC (RIAC) and retention in care in health facility (RIC).
Results: The analysed cohort contains 687 patients on second-line ART, with median age at enrolment of 40 years [IQR:35-42] and 429 (63%) being female. All patients were stable and with VL< 400 copies/ml at enrolment in AC. During study period, 6 (0.9%) patients died and 5 (0.7%) were LFU. RIAC at months 12, 18 and 24 was 95% [CI:93-97%], 87% [CI:86-92%] and 83% [CI:78-87%], respectively. In the analysed period, 23 (3.4%) of patients exited AC due to unsuppressed VL, of which 6 (26%) successfully supressed VL afterwards and returned to AC. Additionally, 24 (3.5%) patients exited AC due to skipping club sessions. Patients who exited AC continued to be treated in the same facility, hence, the RIC of AC patients in our facility for the same period was 99% [98-100%], 98% [CI:96-99%] and 97% [CI:95-99%].
Conclusions: Patients with a history of treatment failure can have good outcomes in AC. Furthermore, by reinforcing counselling of patients who exit AC due to unsuppressed VL, patients can achieve VL re-suppression and return to AC. Finally, overall retention in care of AC second-line patients was encouragingly high.

WEPEE758

Challenges in providing patients centred care through community adherence groups in three provinces of Zambia

S. Nkwemu[1], C. Mwamba[1], C. Bolton-Moore[1], S.M. Topp[2], L. Jere[1], M. Mukumbwa-Mwenechanya[1], C. Cheelo[3], W. Mutale[3], A. Sharma[1]
[1]Centre for Infectious Disease Research in Zambia, Lusaka, Zambia, [2]College of Public Health Medical and Veterinary Sciences, James Cook University, Townsville, Australia, [3]The University of Zambia, School of Public Health, Lusaka, Zambia

Background: The Community Adherence Group (CAG) is a model adopted across resource-constrained facilities to improve ART retention. A CAG consists of approximately six stable patients who visit the clinic on a rotational basis for their clinical visit, during which they collect drugs for themselves and other CAG members. In anticipation of wider roll-out in Zambia, we piloted CAGs in five facilities in Lusaka, Eastern and Southern Province to identify unforeseen challenges faced by health service providers (HSP) and patients during implementation.
Methods: Using a qualitative exploratory study design, from August to November 2017, we conducted 12 focus group discussions with HSP and 16 in-depth interviews with CAG members to understand their experiences after approximately 6 months of implementation. Discussions and interviews were recorded on digital audio recorders and transcribed directly into English. Thematic analysis was conducted using inductive and deductive reasoning.
Results: Both HSP and patients favoured CAGs because of its ability to decongest the clinics and reduce work load but reported several health system issues that compromised intervention fidelity. CAG members had to return to the clinic more times than scheduled due to inadequate supply of anti-retroviral (ARV) drugs and specimen bottles to collect blood for CD4 testing as well as a malfunctioning CD4 machine. Patients reported challenges posed by eligibility criteria leading to, for example, exclusion of pregnant women. Lay healthcare workers (LHCWs) could not always cover the distances between clinic and CAG meeting venues or pick up attendance registers due to lack of transport. Additionally, they reported that some CAG members were keen to only pick up their drugs and did not participate in full CAG meetings that included health discussions and symptom checks. HSP reported lack of office space for document storage which could compromise patient confidentiality.
Conclusions: While CAGs have the potential to ease the health system, health systems must adapt to the needs of the CAG model. Supply chain management, laboratory services and management of patient and programme monitoring tools must be strengthened to allow LHCWs and HSP to perform their duties and to maintain fidelity to visit schedules.

WEPEE759

Acceptability of community differentiated models of care: A patient and service provider's perspective on community art refill groups in Zimbabwe

V. Mashungu[1], J. Munkuli[1], W. Khembo[1], B. Nkawu[1], B. Kumani[1], O. Mugurungi[2], N. Ngorima-Mabhena[3]
[1]Khethimpilo, Multi-Month Drug Dispensing Study, Harare, Zimbabwe, [2]Ministry of Health and Child Welfare, HIV/AIDS/TB, Harare, Zimbabwe, [3]Khethimpilo, Multi-Month Drug Dispensing Study, Pretoria, South Africa

Background: Public healthcare facilities are overburdened with large numbers of stable antiretroviral treatment (ART) patients resulting in poor management and long waiting time; community ART Refill Groups (CARGs) are postulated to decongest facilities improving care as one person collects ART at the facility for the whole group. This study explores patient and service provider's acceptability of CARGs in Zimbabwe.
Methods: As part of a cluster randomized trial to assess effectiveness of 3 and 6-monthly dispensing of ART for stable patients in CARGs, qualitative data were collected in Shona, Ndebele and Venda from October-December 2017 in Beitbridge, Chitungwiza, Gutu, Mberengwa and Zaka districts. Twenty key informant interviews from purposively selected service providers were conducted. 113 females and 42 males newly enrolled in CARGs were randomly selected and participated in focus group discussions from each of the 20 facilities. Translated-transcripts were analyzed for thematic content.
Results: Facility staff welcomed the formation of CARGs linked to their facilities as a solution to decongest facilities, improve care for unstable patients, increased time for patient data compilation and group viral load testing to improve monitoring (the third 90). New CARG members anticipate benefits that include saving on transport costs and reduction in facility visits thereby allowing increased focus on productive activities. Group support through livelihood projects, adherence and defaulter tracing were highlighted to improve retention, lifestyles, and psychological well-being.
Despite the general acceptability of CARGs, some members cited fear of stigma, discrimination and losing respect as reasons for not joining groups particularly for those unwilling to disclose HIV status. Young people and males preferred sending relatives for facility drug pick-ups than joining a CARG.
Some clients reported fear of *"huroyi"* (witchcraft) through someone else handling their medication as one of the reasons for not joining CARGs. Nurses expressed worry towards 6-month ART dispensing as monitoring occurs only twice yearly; patients may not seek needed care.
Conclusions: High acceptability of CARGS was shown by patients and service providers, however stigma and discrimination remain a challenge and need to be addressed at both individual and community-level. Group differentiated care may not be ideal for young people and men.

WEPEE760

Peer providers delivering differently: Installing young trained service providers (20-24 yrs) at service delivery points to increase access to adolescent and young people friendly SRH-HIV services in rural Kenya

A. Mwakalindo[1], J. Carter[2]
[1]Family Health Options Kenya, Youth Programs, Malindi, Kenya, [2]Family Health Options Kenya, Youth Programmes, Siaya, Kenya

Background: Siaya County has a 24.8% HIV prevalence, 4.2 times higher the national prevalence. Over 46% of new infections occurred amongst adolescents and young people (AYP), Kenya HIV estimates 2016. Policy documents like Adolescent SRH 2016 and the Fast track plan to end AIDS amongst adolescents have been adopted.
However Young people do not access SRH-HIV services including HIV testing services in public health facilities citing perceived or experienced health provider attitudes (IAS Young Lives, New Solutions Policy Brief). The Get Up, Speak Out (GUSO) project seeked to amplify the voices of young people and design service delivery models anchored on recommendations AYP in Family Health Options Kenya (FHOK) facilities.

Description: Supported by IPPF, FHOK, a leading service provider of SRH services in Kenya, with a special focus on youth, marginalized and socially-excluded people, initiated a nationwide 1 year project (Jan 1 - Dec 31, 2017). It seeked to ensure all AYP in Kenya enjoy there SRH rights. Through increasing access to rights based AYP friendly SRH-HIV services to 60,000 adolescents and young people nationally. Siaya County in Nyanza region was selected as a rural county where HIV stigma remains high. GUSO adopted the evidences and recommendations from the IAS Young Lives, New Solutions Policy Brief. GUSO recruited and trained 3 young graduates (Nursing officer, clinical officer and HTS provider 20-24 yrs) from Kenya Medical Training College in Bondo on AYP friendly services across different settings. Included 18 AYP in facility management teams. Trained 56 digital CSE peer facilitators.

Lessons learned: Young service providers recruited improved optics of the facility amongst AYP. More AYP accessed services at the facility due to referrals by peers who were satisfied clients. An unprecedented 67,196 (51,133F 16,063M) AYP accessed Contraceptive services while 16,612 (8,563F 8,049) tested for HIV.

Conclusions/Next steps: AYP has significant innovative solutions to barriers of accessing SRH-HIV services. Young people have the capacity to offer Clinical services. It is imperative that AYP friendly services training are institutionalised in the Kenya Medical Training College curriculum. Young graduates are place in AYP friendly centres. AYP are incorporated in hospital management committees.

WEPEE761

Characteristics and early clinical outcomes of key populations attending comprehensive community-based HIV care in Nigeria

O.J. Ibiloye[1,2], N. Eyona[1], T. Decroo[3], P. Agada[1], P. Eze[1], W. Fajemisin[1], A. Afolabi[1]
[1]Society for Family Health, Abuja, Nigeria, [2]APIN Public Health Initiatives, Clinical Services, Abuja, Nigeria, [3]Institute of Tropical Medicine, Antwerp, Belgium

Background: Despite a call for differentiated care, there is limited data from sub-Saharan Africa on comprehensive community-based HIV care for key populations (KP), including commercial sex workers (CSW), men who have sex with men (MSM), and people who inject drugs (PWID). In Nigeria, a programme was implemented that liaised with community-based organizations and offered HIV testing, same-day ART initiation, and ART follow-up to KP. Here we characterize KP and their partners enrolled on ART. Our objective is to assess the early treatment outcomes and to estimate predictors of attrition among KP.

Description: This is a retrospective cohort study of routinely collected data in a community-based HIV program for KP in Nasarawa state, Nigeria from August 2016 to November 2017. Variables of interest were socio-demographic, KP types, treatment outcomes, ART adherence, WHO stage, TB status and viral load. Summary statistics, logistic and Cox proportional hazard regression were used to describe the characteristics of KP and estimate predictors of attrition (patients either lost to follow-up (LTFU) or dead).

Lessons learned: Seven hundred and ten (710) KP and their partners were enrolled into this study, 77.3% (549) of study subjects were female and the median age was 30 years (IQR: 24-35). Respectively, 74.2%, 4.5%, 1.1% and 20% were FSW, MSM, PWID and their partners. Of 710 KP who started ART, 13.9% (99/710) discontinued after the first visit. After a median follow-up time of 7 months on ART 73.2% of patients were retained, 23.4% were LTFU, and 3.4% were dead. Lack of formal education (aHR 1.8; 95% CI 1.3-2.6) and unemployment (aHR 1.8; 95% CI 1.2-2.6) were significantly associated with attrition.

Conclusions/Next steps: Comprehensive community-based HIV care, including HIV testing and same-day ART is feasible. However, ART initiation on the same day of confirmatory HIV testing resulted in a high uptake of ART, but at the same time inflated attrition. To mitigate early attrition among KP after same-day ART initiation, the psychosocial readiness of clients should be assessed better. We strongly recommend further studies to understand factors contributing to high attrition among the KP.

WEPEE762

Rolling out a community differentiated care model: Lessons learned from a high-volume health facility in Taita Taveta County, Kenya

S. Konah
Pathfinder International, Watertown, United States

Background: Afya Pwani, a project funded by USAID and implemented by Pathfinder International, serves a population of more than 3 million and roughly 50,000 people living with HIV (PLHIV) on ART in five coastal counties in Kenya. The project has been supporting the rollout of differentiated service delivery for PLHIV in 19 high-volume facilities.

Description: In Taita Taveta County, since March 2017, Mwatate Hospital has been offering a community model of differentiated care through which ART patients who are virally suppressed, meeting predetermined clinical criteria for stable clients, and living in the same community are organized into groups of six to coordinate ART distribution and patient support. Each member takes turns picking up medication for the whole group and reports back on the progress of their group members to the clinician. A comprehensive care center (CCC) team visits the groups in the community quarterly for continuous medical education and to answer patient questions.

To identify eligible clients, 150 PLHIV patient files were reviewed from which 125 met the criteria of being stable; eighty-three patients (66% of eligible patients) agreed to participate and were organized into 13 ART groups based on proximity to other patients. After 10 months of implementation (March-December 2017), there has been no loss-to-follow-up, all patients have received viral load testing, and 81 patients (98%) remained virally suppressed.

Two patients (2%) that became unsuppressed were discharged from the community group and appropriate enhanced care was provided to them. Overall suppression rates for the hospital have increased from 81% in 2016 to 86% (395/460) in 2017.

Lessons learned: Mwatate Hospital has demonstrated how client-managed differentiated care can successfully be introduced without compromising overall suppression rates. This model provides an opportunity to reduce and prioritize healthcare provider workload, save client time and resources, and also enable PLHIVs to care for and support each other. The hospital continues to adapt the approach to maximize outcomes and quality of care, including increasing community-based CCC visits from quarterly to bi-monthly.

Conclusions/Next steps: The preliminary results from this community differentiated care approach are promising and lessons learned will inform rollout in all 19 Afya Pwani-supported high-volume facilities.

WEPEE763

Characteristics of adults in Malawi and Zambia eligible for 6-monthly antiretroviral therapy refills: The INTERVAL study

K. Balakasi[1], P. Pisa[2], A. Bardon[3], J. Hubbard[1,3], C. Moyo[4], Z. Siwale[4], G. Kakwesa[1], M. Haambokoma[4], J. Phiri[4], M. Fox[5], T. Kalua[6], T. Xulu[2], S. Rosen[7], I. Sanne[2], R. Hoffman[3], EQUIP Innovation for Health
[1]Partners in Hope Medical Center, Lilongwe, Malawi, [2]Right to Care EQUIP, Johannesburg, South Africa, [3]David Geffen School of Medicine at the University of California, Department of Medicine, Los Angeles, United States, [4]EQUIP Zambia, Lusaka, Zambia, [5]Boston University School of Public Health, Department of Epidemiology and Global Health, Boston, United States, [6]Malawi Ministry of Health, Lilongwe, Malawi, [7]Boston University School of Public Health, Department of Global Health and the Center for Global Health & Development, Boston, United States

Background: Differentiated models of care (DMOCs) are being adopted across Africa. Extending refills of antiretroviral therapy (ART) to 6 months is one such model, but little is known about the proportion or characteristics of patients who will qualify for and benefit from this DMOC. The INTERVAL study is a cluster-randomized evaluation of standard of care versus 3- and 6-month ART refills to determine whether a decreased frequency of facility visits for medication pickup improves retention in care and virologic suppression while reducing costs.

Methods: INTERVAL is being implemented in 30 facilities (10/arm) in Malawi and Zambia. Participants receive all clinical care at the assigned refill interval with no required interim visits. Participants are screened in waiting areas of adult, outpatient ART clinics and defined as "stable" if: ≥18 years, on first-line ART for ≥6 months; no active HIV-related complications/drug toxicities; no noncommunicable diseases (NCDs); not pregnant or breastfeeding; and have an undetectable viral load within the previous 6 months (Malawi: < 1,000 copies/mL, Zambia: < 20 copies/mL). We examined the characteristics of enrolled individuals to inform expectations for scaling up this model.

Results: 79% (N=6400, 65% female) of participants met the stability criteria. The most common reason for ineligibility was detectable viral load (7% Malawi, 19% Zambia). Only ~3% of women were excluded because of pregnancy or breastfeeding, as most ante/postnatal care is provided in antenatal and maternity clinics. Less than 1% were excluded for NCDs. Among individuals enrolled, the median age was 42.6 years. The median duration on ART (~5 years) reflects the transition in ART programs from newly initiated, younger patients to experienced, older patients. Women were slightly younger, had less formal education, and were less likely to miss work to come to ART clinic (Table). The gender breakdown reflects national populations on ART.

Conclusions: Roughly 4 out of 5 ART patients in outpatient clinics can be defined as "stable" for DMOC purposes. The low rate of NCDs in this older population suggests poor routine screening for these conditions. If DMOCs serve a relatively older population, other conditions of aging should be included in service delivery plans for these models of care.

	Overall n=6,400	Female n=4186 (65%)	Male n=2214 (35%)

WEPEE764

Overcoming barriers to access of HIV/AIDS services among female sex workers through differentiated service delivery models, TASO Entebbe experience

D. Kagimu, J. Egessa, L. Oucul, E. Senyonga
The AIDS Support Organisation (TASO), Program Management, Kampala, Uganda

Background: In 2014, there was an estimated 54,549 Female Sex Workers (FSW) in Uganda with HIV prevalence of 34.1% (UAC 2014).The combination of a restrictive legal environment and mobile nature of FSW are among the barriers that influence access of HIV/AIDS services, leading to poor retention in the continuum of care. TASO Entebbe, a model center of excellence, piloted the Community Client Led ART Delivery (CCLAD) Differentiated Services Delivery Model (DSDM) among 90 HIV positive FSWs in care to increase access to HIV/AIDS services and improve retention rates among FSWs in care.

Description: Following complaints from some FSWs, of long waiting time with loss of clients in lodges, inconvenient time drug refills time, and stigma & discrimination from the general population due to their dress code and appearance at the drug pick-up points, TASO Entebbe introduced the Community Client Led ART Delivery (CCLAD) model for stable FSWs living in the same community. This involved grouping FSWs according to a criteria of; being HIV positive, registered with TASO, having disclosed to peers, consented to join CCLAD and having suppressed VL. The group selected a leader whose roles included; taking members' parameters like weight and MUAC, distribution of condoms and lubricants, delivery of pre-packed ARVs to members and submission of the filled tools to the TASO technical staff.

Lessons learned: A total of 14 FSWs aged 20-29 years (3) and 30-35 years (11), were identified and 2 CCLAD of 7 members each were formed. All FSWs in each CCLAD group maintained a suppressed VL.100% retention rates in each group was achieved. ART adherence improved from 75% to 95%. The ripple effects of CCLAD caused other FSW in the same hotspots to request to join the CCLAD groups.

Conclusions/Next steps: Innovative ART delivery models like CCLAD among FSWs stimulates demand for HIV/AIDS services, mitigate effects of stigma and enhance treatment adherence and retention.

WEPEE765

Ensuring equitable access to HIV/AIDS care in rural Africa to meet the UNAIDS 90-90-90 targets: Achieving the second and third 90s through community based follow-up

N. Khozomba[1], J. Jere[1], L. Munthali[1], E. Geoffroy[2], E. Schell[3,4], T. Schafer[3], J. Goldman[5]
[1]Global AIDS Interfaith Alliance, Blantyre, Malawi, [2]Global AIDS Interfaith Alliance, Marblehead, United States, [3]Global AIDS Interfaith Alliance, San Rafael, United States, [4]University of California, San Francisco, United States, [5]Elizabeth Taylor AIDS Foundation, Beverly Hills, United States

Background: In southern Malawi 16% of the adult population is living with HIV. Ensuring that those found newly-positive through community based testing initiatives are quickly linked to care is critical to halting the spread of the disease and achieving the second and third 90s of the 90-90-90 UNAIDS treatment targets. Since 2014, Global AIDS Interfaith Alliance (GAIA) has implemented a program employing "follow-up nurse coordinators" (F/Cs) to make home visits to clients, encouraging adherence to co-trimoxazole preventive therapy (CPT) and for those eligible, anti-retroviral therapy ART initiation (or re-initiation) and adherence. With the advent of "test and treat" in September 2016, many clients needed to be notified of their eligibility for ART and linked to care.

Description: Well-known and trusted in this rural community, GAIA's trained nurses travel to clients' homes in remote villages by motorbike. They see each client a minimum of three times after diagnosis, first making sure the client has attended an ART clinic for group counseling and timely treatment initiation, and then assure the client is adherent and stable on ART. In addition, they provide index testing of family members (including at-risk children) and sexual partners as necessary.

Lessons learned: In 2017, five F/Cs provided individualized, holistic, confidential care to 367 clients living with or exposed to HIV across two districts. By the end of the year 92% (326/355) of HIV+ clients had enrolled in ART and 98% of those were adherent to treatment (verified by pill counts and refill records). Average time from diagnosis to treatment initiation was 13 days. Early initiation helped healthy clients stay healthy and productive and restored health to others. Counseling helped clients understand the importance of staying on lifelong treatment. Clients have cited the F/Cs' personal encouragement and "feeling that someone cared" as the main reason they either initiated or reinitiated treatment or remained adherent.

Conclusions/Next steps: Follow-up care can be resource and cost intensive but is important in assuring achievement the second two "90s." The investment may well pay off in terms of increased life-expectancy, economic productivity, and reductions in onward transmission. Studies testing scale up and cost/benefit analysis are needed.

Client and health worker perception to differentiated HIV care: A qualitative study from Kebbi State, North West Nigeria

U.I. Katchy[1], A. Etsetowaghan[2], S. Ibrahim[3], A.B. Usman[4], M.R. Magana[5], D. Ogundehin[6], J. Ezekiel[7]
[1]Management Sciences for Health, Clinical Care, Abuja, Nigeria, [2]Management Sciences for Health, Technical, Abuja, Nigeria, [3]Management Sciences for Health, Technical, Sokoto, Nigeria, [4]Sir Yahaya Memorial Hospital, Laboratory, Birnin Kebbi, Niger, [5]Management Sciences for Health, Laboratory, Birnin Kebbi, Nigeria, [6]USAID, PMTCT, Abuja, Nigeria, [7]USAID, HIV Care and Treatment, Abuja, Nigeria

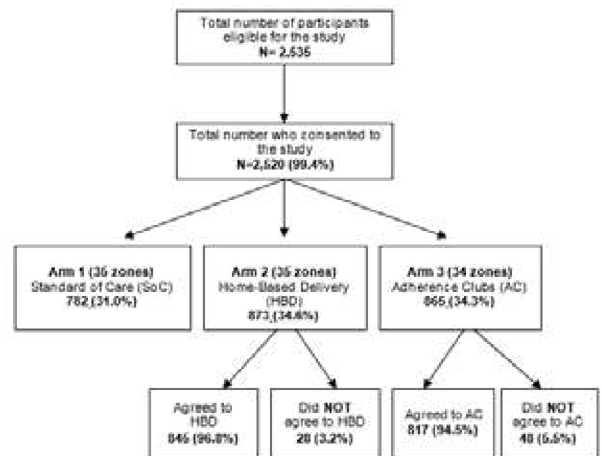
Background: The Differentiated Care Model (DCM) in HIV care is a patient centered approach to improve service delivery and supports meeting the UNAIDS 90-90-90 targets. Despite the potential impact of this model, it is imperative to establish client preferences and identify potential barriers. This will help in the development of feasible context specific DCM, which was the aim of this study.
Methods: The USAID-funded CaTSS project implemented by MSH conducted a qualitative study on perception of DCM among stakeholders involved in HIV care for at least one year between October-December 2017. Focus group discussions (FGD) were conducted among clients receiving ART treatment in six groups (6-8 people per group) using an FGD guide. Key informant interviews (KII) were conducted with 15 health care workers using a key informant guide. Participants were selected purposively from two large hospitals in Kebbi State (General Hospital Argungu and Sir Yahaya Memorial Hospital). Data transcription and familiarization were completed and data analysis done using mixed coding methods (predetermined codes [A-Priori] and use of emergent codes).
Results: Findings from FGD and KII were triangulated. Reducing the frequency of hospital visits (multiple-months prescriptions) was the most preferred approach for stable clients; HCW and clients desired three-monthly appointments to reduce travel related costs, stigmatization and improve adherence. Fast tracking, where stable clients collect medications without doctors' review, was desired, but HCWs were concerned that clients may pretend to be well to avoid reviews. Client managed groups were rejected by HCWs who believed this should be reserved for couples because it may affect patient monitoring, while clients worried that quarrels among group members may cause intentional disclosure of their status. A community distribution model was discarded by both groups; HCWs worried about fraudulent practices, documentation issues, and increased cost to providers, while clients feared stigmatization.
Conclusions: Reduction of the frequency of visits was the most preferred model in the hospitals in Kebbi State, because of perceived reduction in stigmatization and cost savings. Multiple-month prescriptions may improve adherence in this area. Scale up of this model in this resource-constrained area with high stigmatization is recommended.

WEPEE767

Acceptability and preferences of two different community models of ART delivery in a high prevalence urban setting in Zambia, nested within the HPTN 071 (PopART) trial

M. Limbada[1], S. Fidler[2], D. Macleod[3], O. Shibwela[1], S. Floyd[4], D. Nzara[1], V. Situmbeko[1], R. Hayes[4], H. Ayles[1,5], on behalf of the HPTN 071 (PopART) Study Team
[1]Zambart (Zambia AIDS-Related TB Project), Lusaka, Zambia, [2]Imperial College London, HIV Clinical Trials Unit, London, United Kingdom, [3]London School og Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [4]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom, [5]London School of Hygiene and Tropical Medicine, Department of Infectious and Tropical Diseases, London, United Kingdom

Background: In high HIV-prevalence resource-limited settings with overburdened health care facilities, retention on ART and viral suppression are key challenges. Community models of ART delivery have shown promising outcomes in relation to retention in care and adherence to treatment. Within the HPTN 071(PopART) trial, two models of non-facility based ART delivery, either home-based delivery (HBD) or adherence clubs (AC), were offered and compared to facility-based delivery (standard of care, SoC) for stable HIV+ patients. We describe acceptability of the different models of ART delivery, and preferences reported by eligible residents offered them.
Methods: This was a three-arm cluster randomized non-inferiority trial comparing outcomes, including virological suppression, among patients offered HBD of ART or AC in two HPTN 071(PopART) trial communities in Lusaka, Zambia. The communities were divided into zones and each zone was randomized to one of the three delivery arms:
1. SoC,
2. a choice between HBD or SoC, or
3. choice between AC or SoC.
Stable HIV+ patients (defined according to WHO classification) living within the community zones were invited to take part in the study. Irrespective of the trial arm, all participants at baseline were asked to state their preference for mode of ART delivery.
Results: Between May and December 2017, the study identified 2535 stable patients who were eligible for community models of ART delivery across both communities and 2520 (99.4%) consented to join the study. Initial preferences, regardless of randomization arm, were expressed by 32.2% of participants. Of those that stated a preference, 70.3% stated they preferred HBD, 15.5% AC and 14.2% SoC. (Table 1). Among participants randomized to the choice of non-facility method of ART delivery, overall 95.6% chose the non-facility method that they were randomized to receive [96.8% in the HBD arm and 94.5% in the AC arm] (Fig1).
Conclusions: In this urban Zambian setting, stable HIV+ patients who expressed a preference preferred home based delivery of ART compared to adherence clubs or receiving treatment at the clinic. Patient preference should be considered when developing differentiated care delivery models.



[Figure 1: Acceptability and Choices of Community Models of ART Delivery]

	Number (N)	Percentage (%)
Total number of participants who consented to the study	2520	99.4
Total number who did NOT state a model preference	1709	67.8
Total number who stated a model preference	811	32.2
• Preferred Standard of Care	115	14.2
• Preferred Home Based Delivery	570	70.3
• Preferred Adherence Clubs	126	15.5

[Table 1: Participants' stated Preferences for Models of ART Delivery]

WEPEE768

High acceptance and satisfaction of differentiated antiretroviral therapy service delivery among men who have sex with men, transgender women and healthcare workers in Thailand

T. Sungsing[1], R. Ramautarsing[1], J. Jantarapakde[1], S. Pengnonyang[1], R. Buajoom[2], H. Thiamkrathok[2], P. Panpet[3], F. Suwan[4], P. Pothasin[5], R. Faikhom[6], T. Jadwattanakul[7], P. Methajittiphan[7], P. Leenasirima[8], K. Traidej[8], A. Norchaiwong[9], A. Nilmanat[10], S. Chandrema[10], P. Phiayura[1], W. Sirisakyot[1], R. Meksena[1], P. Mingkwanrungruang[1], S. Charoenying[11], S. Mills[11], R. Vannakit[12], N. Phanuphak[1], P. Phanuphak[1]
[1]Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]Service Workers in Group Foundation, Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]Rainbow Sky Association of Thailand, Songkhla, Thailand, [5]Sisters Foundation, Chonburi, Thailand, [6]Caremat, Chiang Mai, Thailand, [7]Queen Savang Vadhana Memorial Hospital, Chonburi, Thailand, [8]Nakornping Hospital, Chiang Mai, Thailand, [9]Sarapee Hospital, Chiang Mai, Thailand, [10]Hatyai Hospital, Songkhla, Thailand, [11]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [12]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

Background: WHO recommends differentiated service delivery (DSD) for antiretroviral therapy (ART) to allow decentralization of ART-maintenance for stable patients. We studied feasibility and client and staff acceptance of and attitude towards key population (KP)-led DSD-ART for men who have sex with men (MSM) and transgender women (TGW) in Thailand.

Methods: We integrated DSD-ART into our Key Population-Led Health Services (KPLHS) model for MSM and TGW in 4 provinces in May 2017. Stable patients (ART for >1 year, 2 consecutive undetectable HIV-RNA, CD4>200 cells/mm^3, no adverse drug-reactions or current illnesses, and good understanding of lifelong ART-adherence) were eligible to receive ART-maintenance from KP community health-workers (KP-CHW) at KP-led clinics. KP-led clinics and public hospitals discussed and mutually agreed upon the building blocks of DSD-ART models (graph 1). Acceptance of and attitudes towards DSD-ART was evaluated among stable patients and staff.

Results: Between May 2015-October 2016, KP-led clinics tested 2,644 MSM and TGW, 453 (17.1%) were HIV-positive and 383 (84.6%) started ART. By September 2017, 95 patients were stable, 59 reached the visit when ART-maintenance by KP-HW at KP-led clinics was offered, and all agreed to be seen by KP-CHW. No adherence or clinical concerns which warranted referral back to hospitals have occurred. Among 157 patients on ART for >1 year, 95.5% were satisfied with the care at KP-led clinics, and 61.8% preferred ART-maintenance to happen at KP-led clinics. The most cited expectations from DSD-ART by clients were empowerment of individual responsibility for their health (91.7%), encouragement of their autonomy as a patient (88.5%) and enhancement of retention in care (86.6%). A positive attitude to DSD-ART was reported by 82.7% of 52 KP-CHW and 86.7% of 15 hospital-staff. The most reported expectation by KP-CHW and hospital staff was encouragement of patient autonomy (88.5% and 73.3%), while the biggest concern was regulatory barriers (28.8% and 40.0%).

Conclusions: DSD-ART models, mutually designed by KP-led clinics and hospitals, were feasible and highly acceptable by HIV-positive MSM, TGW and healthcare staff in Thailand. Longitudinal evaluations on adherence and virologic outcomes are needed. Policy support, legalization, and financing mechanisms are imperative to ensure scale-up and sustainability.

[Graph 1. Models for Key Population-Led Health Services for differentiated ART and care service delivery]

WEPEE769

Improving the identification of CAYPLHIV through index case testing across 14 districts in Zimbabwe

T. Chimbidzikai[1], T. Napei[2], N. Willis[3], K. Madzeke[3], S. Chimoko[4], T. Tapera[3], P. Manyanga[5]
[1]Africaid Zvandiri, Programmes, Harare, Zimbabwe, [2]Africaid Zvandiri, M&E, Harare, Zimbabwe, [3]Africaid Zvandiri, Harare, Zimbabwe, [4]Africaid, Harare, Zimbabwe, [5]I-TECH Zimbabwe, Harare, Zimbabwe

Background: Identifying and diagnosing children, adolescents and young people living with HIV (CALPLHIV) is the first step in the continuum of care and treatment. Yet, despite the availability of ART many CAYP are never offered an HIV diagnostic test (WHO 2013). CAYPLHIV who do receive an HIV test are often tested later than recommended, even though earlier testing is needed in order to facilitate treatment initiation. In Zimbabwe 34% of adolescents and young people, 15-24 have been tested and know their status compared to 74.2% amongst the adult population (ZIMPHIA 2015/16).

Description: Africaid is implementing a PEPFAR funded Game Changer project in partnership with I-TECH, the prime partner. The project aims to increase the availability and quality of care and treatment services for CAYPLHIV. HIV positive adolescents, 18-24 years, known as Community Adolescent Treatment Supporters, were trained and mentored in index case finding. During routine home visits to CAYP on ART, they identified undiagnosed siblings and sexual partners and referred them for HIV testing at either facility or linked them with I-TECH community-based testers. Those identified to be HIV positive were linked to care and confirmed through health facility ART register recording.

Lessons learned: 4,747 CAYP were mobilized through index case finding for HIV testing services with 4,180 getting tested and receiving their results. 628 were diagnosed HIV positive translating into a 15% yield rate with districts such as Marondera achieving a 24% yield rate. Out of the 628 who tested positive, 98% (613) were initiated on ART.

Conclusions/Next steps: Targeting undiagnosed siblings, sexual partners and immediate family members of CAYPLHIV index cases achieves an excellent yield. The role of AYPLHIV as peer experts has been a very successful innovation to improve HTS services and target those who are most unwilling to seek HTS at the facility level. CATS are therefore a critical community cadre to maximise the identification of new CAYPLHIV and link them into care peer-to-peer support.

Strategies to Increase Uptake of retention in HIV Services

WEPEE770

Positive links: Mobile technology to improve retention in care

C. Canan[1], M. Grabowski[1], A.L. Waldman[1], G. Reynolds[2], T. Flickinger[1], W. Cohn[1], K. Ingersoll[1], R. Dillingham[1]
[1]University of Virginia, Charlottesville, United States, [2]Health Decision Technologies, Oakland, United States

Background: PositiveLinks (PL) is a smartphone-based platform designed in partnership with people living with HIV (PLWH) to improve medication adherence and retention in care among PLWH. PL provides daily medication reminders, check-ins about mood and stress, educational resources, a community message board, and an ability to message providers. In this study, we evaluate the impact of up to 18 months of PL use on CD4 count, HIV viral suppression, and retention in care.

Methods: Between September 2013 and March 2017, providers at the UVA Ryan White HIV clinic referred patients to PL who were at risk of falling out of care. We assessed two measures of retention in care: attendance at ≥2 appointments ≥90 days apart within the past year (i.e. HRSA compliance) and visit constancy. CD4 and HIV viral load were assessed at 6 month intervals starting at enrollment. HRSA compliance, visit constancy, CD4, and viral suppression were compared between

study baseline and the 6-, 12-, and 18-month follow-up time periods using generalized estimating equations. We compared time to viral suppression (among those unsuppressed at baseline) and time to HRSA compliance (among those non-compliant at baseline) among patients with high vs. low PL use.
Results: Between September 2013 and March 2017, 127 patients enrolled in PL. Patients had a median age of 40, 65% were male, 53% were non-Hispanic Black, 52% earned < 50% of the federal poverty level, and 37% received education beyond high school. At baseline, 60% were virally suppressed and 59% met the HRSA metric for retention in care. All four outcomes improved significantly after 6 months of PL use and remained significantly improved after 18 months (see Table). Patients with high PL use were 1.51 (95% CI 0.70-3.26) times more likely to achieve viral suppression and 1.41 (95% CI 0.72-2.76) times more likely to attain HRSA compliance compared to those with low PL use.
Conclusions: Mobile technology, such as PL, can be effective in retaining patients in care and improving clinical outcomes. Our study demonstrates long-term acceptability of PL and provides preliminary evidence to support a long-term improvement in retention in care associated with PL use.

	Estimate (95% CI)			
	Baseline	6 months	12 months	18 months
HRSA compliance (proportion compliant)	0.59 (0.50-0.67)	0.86 (0.80-0.92)	0.81 (0.74-0.89)	0.72 (0.62-0.82)
Visit constancy (proportion 3 vs. ≤2)	0.27 (0.19-0.35)	0.36 (0.27-0.44)	0.45 (0.35-0.54)	0.40 (0.39-0.51)
CD4 count (cells/mm3)	569 (501-636)	628 (559-696)	654 (578-730)	598 (492-705)
Viral suppression (proportion <200)	0.62 (0.53-0.70)	0.87 (0.81-0.93)	0.83 (0.75-0.90)	0.84 (0.74-0.93)

[Estimated HRSA compliance, visit constancy, CD4, and viral suppression using generalized estimating equations]

WEPEE771

Mobile and tele-health: Scalable platforms for supporting efforts towards meeting the 90-90-90 targets in Uganda

J.M. Bwanika[1], D. Musinguzi[1], W. Lubega[1], L.H. Kamulegeya[1], J. Ssebwana[1], W. Abigaba[1], K. Horvath[2]
[1]The Medical Concierge Group Limited, Kampala, Uganda, [2]University of Minnesota, Minneapolis, United States

Background: Uganda has made tremendous strides towards achieving the UNAIDS 90-90-90 targets.
In order to beat the 2020 recommended target date; health ministries and HIV public health programs need to employ innovative ways of sustainably accelerating and scaling their activities.
We set out to explore the feasibility and role of mobile health (mHealth) and telehealth centre in improving HIV testing as well as treatment adherence and retention for eventual viral load suppression.
Description: Between January 2016 and July 2017, men and women from the Uganda Police, Private security guards, Uganda wildlife authority and Hotel owners' association consented to receive mobile health services through messaging and a 24/7 telehealth platform. This was under the USAID/Uganda HIV/AIDS and Health Initiatives in Workplaces Activity (HIWA) Project.
Through an open source SMS platform, voice calls and WhatsApp, beneficiaries were engaged with HIV prevention and testing information and how to access HIV services close to their locality. They also received individualized periodic reminders for treatment compliance and adherence as well as reminders for viral load testing. On-ground follow up based on the mHealth data was done by community linkage facilitators and health centre staff.
Lessons learned: Males contributed 73.4% of the users compared to 26.6% females overall; with a median age of 27 years (Interquartile range (IQR) 23, 33). 19,152 people received HIV prevention and behavioral change messages. 4.3% of those urged through the platforms to test for HIV were HIV positive.143 newly diagnosed HIV patients were successfully linked into care. 121 mothers joined the EMTCT mHealth campaign to be supported to adhere to treatment and complete diagnostic testing for their exposed babies.1241 HIV+ adults (M=532,42.8%; F=709,57.2%) signed up for the mHealth engagement on reminders for treatment adherence and clinic visits. All engaged HIV positive beneficiaries met their schedules for viral load repeat testing in the last 12 months.
Conclusions/Next steps: Mobile health services through a 24/7 telehealth centre are a feasible way to increase uptake of HIV testing services, improve retention in care as well as adherence and compliance to treatment guidelines. They should be considered as a way to scale up 90-90-90 efforts.

WEPEE772

Who understands viral load? Challenges for reaching the third 90 in South Africa

J. Michalow[1], M. Fineberg[2], S. Magni[2], A. Ismail[2]
[1]Genesis Analytics, Health, Johannesburg, South Africa, [2]Genesis Analytics, Johannesburg, South Africa

Background: Despite having the largest ART programme in the world, South Africa faces barriers to linkage and retention in HIV care. This threatens progress toward the 90-90-90 targets. One barrier is poor HIV treatment literacy. In line with the third-90, we assessed gaps in understanding and knowledge of viral load terminology.
Methods: We conducted 3,000 interviews across all nine provinces in South Africa with men and women aged 18-34 years using three-stage cluster sampling proportional to population size. To understand factors that contribute toward viral load knowledge we measured self-reported knowledge through the question "do you know what viral load is?" with response options "yes/no" and then asked respondents to define the term. Demographic information and self-reported HIV status were also measured. Multivariate analysis was performed in Stata v14. Results are reported using adjusted odds ratio (AOR) and 95% confidence intervals (CI).
Results: 10% (313/3,000) said they understood the term viral load and 8% (252/3,000) correctly defined viral load as "the number of HIV cells or copies in the blood of someone who is HIV-positive". Of those who self-reported as HIV-positive, 35% (65/184) said they understood the term viral load and 27% (50/184) defined it correctly.
Knowledge of viral load was: less likely in men (AOR 0.73, 95% CI 0.54-0.98, p=0.038), more likely in older respondents (AOR 1.06, 95% CI 1.03-1.09, p=0.000), more likely in respondents with higher socio-economic status (AOR 3.5, 95% CI 2.25-5.49, p=0.000), and less likely in self-reported HIV-negative respondents (AOR 0.19, 95% CI 0.14-0.28, p=0.000). Education level and employment status were not predictors of viral load knowledge.
Conclusions: Knowledge and understanding of viral load is low in South Africa. Understanding of viral load is concerningly low in PLHIV. This is an immediate issue with a direct bearing on achieving the third-90. Additionally, young, HIV-negative men of low socio-economic status are the least likely to know what viral load is. This group also displays poor testing behaviour.
Health system communication should be strengthened with a focus on PLHIV and other low-knowledge-high-risk groups to achieve the third-90 in South Africa.

WEPEE773

Need-based care to improve linkage to HIV services for female sex workers in Botswana

W. Dikobe[1], V. Ranebennur[2], M. Gilbert-Lephodisa[1], C. Akolo[2], M. Seretse[1]
[1]FHI 360, LINKAGES, Gaborone, Botswana, [2]FHI 360, LINKAGES, Washington, United States

Background: Antiretroviral therapy (ART) service delivery tailored for female sex workers (FSWs) helps improve retention and viral suppression by optimizing drug and care delivery. LINKAGES Botswana adopted a tailored approach for ART service delivery to enhance linkage to care and treatment for FSWs.
Description: From October 2016 to September 2017, LINKAGES Botswana has been providing integrated clinical services to FSWs through outreach at mobile clinics or drop-in centers using a one-stop-shop

approach. HIV testing services (HTS) and ART services were offered in the same location, making it easy for those newly diagnosed with HIV to be immediately initiated on care and treatment. Baseline laboratory tests were requested for newly diagnosed HIV-positive FSWs, but clients were initiated on ART immediately. Patients stable on treatment received multi-month prescriptions. Clinical visits were conducted every six months, with refills provided at the community level during outreach and at drop-in centers. Nonclinical staff at drop-in centers were trained to provide emergency refills for up to 14 days to anyone who had missed an appointment or traveled away from the base clinic. This allowed FSWs the flexibility of accessing treatment outside of normal working hours.

Lessons learned: By implementing the one-stop-shop approach and same-day initiation, there was a significant improvement in linkage to and initiation of ART among FSWs compared to the previous year. A total of 3,477 FSWs were reached with HIV prevention services October 2016-September 2017. More than 81 percent of those who were eligible for HIV testing and counseling were successfully linked to testing services (n=2,831), resulting in a 13 percent case-finding rate (n=358). Sixty-eight percent (n=242) of those who tested positive were successfully initiated on ART, demonstrating a 12 percent increase (p=.0003, CI 5.4-18.2) compared to the previous year (figure 1).

Conclusions/Next steps: Tailored HIV care and treatment services showed significant improvement in linking FSWs living with HIV to treatment. While this approach was highly successful among FSWs, efforts to link and retain key populations on treatment should be tailored by KP type. LINKAGES will expand this model across all Botswana sites in the remaining project period.

WEPEE774

Cut-off score of readiness to start antiviral therapy for patients newly diagnosis with HIV

Y.-I. Lai[1], C.-Y. Hsieh[2], Y.-C. Chen[3], C.-C. Lin[4], Y.-W. Tang[5], C.-P. Wu[6], H.-C. Ku[7], Y.-C. Kuo[8], L.-F. Liu[9], N.-Y. Ko[5,10]
[1]National Cheng Kung University Hospital, Department of Nursing, Tainan, Taiwan, Province of China, [2]Taichung Veterans General Hospital, Department of Nursing, Taichung, Taiwan, Province of China, [3]National Cheng Kung University, Institute of Allied Health Sciences, College of Medicine, Tainan, Taiwan, Province of China, [4]Chung Shan Medical University Hospital, Taichung, Taiwan, Province of China, [5]National Cheng Kung University Hospital, Tainan, Taiwan, Province of China, [6]Chain Medical University Hospital, Taichung, Taiwan, Province of China, [7]Chi Mei Medical Center Hospital, Tainan, Taiwan, Province of China, [8]EDA Hospital, Kaohsiung, Taiwan, Province of China, [9]Nurse AIDS Prevention Foundation, Taipei, Taiwan, Province of China, [10]National Cheng Kung University, Tainan, Taiwan, Province of China

Background: Since 2016, initiation of antiretroviral therapy (ART) after diagnosis regardless of CD4 counts is a global consensus. It is crucial to find an instrument to assess the readiness for early initiation of ART for people newly diagnosis with HIV. The study aims to compare the readiness between the patients receiving ART and those who have not yet on ART, to compare the readiness scores between two groups across 12 months, and to determine a cutoff value for medicine readiness with early initiation of ART.

Methods: A multicenter cohort study design was conducted and enrolled 297 newly diagnosed patients with HIV at four times: baseline, 1, 3-6, 9-12 months after ART initiation. Data collection included demographics, Chinese version of HIV Medication Readiness Scale (HMRS) and 2 items using 10-point Likert scale: readiness to take ART for a long time and confidence for adherence to ART.

Results: Overall, 224 (75.4%) patients with HIV initiated ART. The medicine readiness in patients with ART initiation was significantly increased across one year compared to non-ART user (*p*< .001). The mean scores of the 2-items self-rating readiness scale in patients with ART initiation were significantly higher than those without (*p*< .001). The cut off value in HMRS, self-rating readiness for ART, and confidence for adherence to ART were 23.5, 5.5, 6.5-score, respectively.

Conclusions: The optimal cut off value of Chinese version HMRS for evaluating HAART initiation among persons with HIV infection was 23.5. HIV health care professionals can apply the Chinese version HMRS and two simple self-rating questions as a rapid clinical tool for assessing readiness of ART initiation among people newly diagnosis with HIV.

Key Words: HIV, HAART initiation, HIV Medication Readiness Scale (HMRS).

WEPEE775

Retention on ART among HIV patients in Côte d'Ivoire and Swaziland

Y. Wu[1], T.G. Harris[1], H. Brou[2], H.N. Kamiru[3], S. Mazibuko[4], A. Kidane[3], G. Vandebriel[2], J.-J. M'Bea[2], A. Ekra[5], A.A. Howard[1], W.M. El-Sadr[1]
[1]Columbia University, ICAP, New York, United States, [2]Columbia University, ICAP, Abidjan, Cote D'Ivoire, [3]Columbia University, ICAP, Mbabane, Swaziland, [4]Center for Disease Control and Prevention, Center for Global Health, Division of Global HIV/AIDs and TB, Mbabane, Swaziland, [5]Center for Disease Control and Prevention, Center for Global Health, Division of Global HIV/AIDS and TB, Abidjan, Cote D'Ivoire

Background: The ultimate success of antiretroviral therapy (ART) initiation is dependent on achievement of high retention and adherence. Data are needed on factors that influence retention of ART patients in resource-limited settings.

Methods: We evaluated 12-month retention (PEPFAR MER indicator) among ART patients at PEPFAR-funded, ICAP-supported health facilities (HF) in Côte d'Ivoire (CI) and Swaziland (SW). By country, proportions of retained ART patients were calculated for quarterly cohorts initiating ART from January 2014-September 2015. Poisson regression models with generalized estimating equations (GEE) were used to examine time trends and significant demographic and HF factors associated with retention.

Results: Data from 6,923 HIV patients from CI (87 HF) and 19,118 from SW (93 HF) who initiated ART in this period were included in the analysis. In CI, 71.4% of patients were women and 94.2% were ≥15 years. Retention in CI at 12-months increased from 74.4% for the first cohort (January-March 2014) to 88.8% for the last cohort (July-September 2015), an average increase of 2.6 % per quarter after adjusting for sex, age and facility type (p_{trend}< 0.001). Men had lower retention than women (p< 0.0001). Patients at secondary (p< 0.0001) or tertiary (p=0.02) HF had lower retention than those at primary HF. In SW, 66.2% of patients were women and 94.3% were ≥15 years old. The 12-month retention was 92.7% for the first cohort and 88.2% for the last cohort, with no significant change over time (p_{trend}=0.34). Children 5-14 years old (p=0.001) had higher retention than adults ^{3}15 years but children < 5 years did not (p=0.69). Patients at semi-urban HF (p=0.02) had higher retention than urban HF, while those at tertiary HF (p=0.04) had lower retention compared to primary HF.

Conclusions: Retention on ART was high in both countries compared to earlier reports from sub-Saharan Africa, with differences noted by sex, age and HF location and type. Overall, these findings are encouraging and bode well for achieving the individual and societal benefits of ART. Viral load data are needed to confirm this potential.

WEPEE776

A descriptive analysis of call and text messaging communication between participants and healthcare providers

H.F. Adhiambo[1], M.A. Guze[2], J. Kulzer[3], E. Akama[4], Z. Kwena[4], T. Odeny[5], M. Petersen[6], E. Geng[2]
[1]Kenya Medical Research Insitute, Kisumu, Kenya, [2]University of California, San Francisco, United States, [3]University of California, San Fransisco, United States, [4]Kenya Medical Research Institute, Kisumu, Kenya, [5]University of Missouri, Kansas City, Kenya, [6]University of California, Berkeley, United States

Background: Mobile health (mHealth) is on the rise globally with recent research focused on use and outcomes. However, content and intensity analysis of SMS-based communication between patients and providers in resource-constrained settings is limited. We examined the frequency of call-backs, response time and duration, and reasons for calling in a sub-study of an ongoing randomized controlled trial on the effect of SMS on retention of persons living with HIV in Kenya.

Methods: We included five study sites in western Kenya between March 2015 and November 2017. Participants were ≥18 years with mobile phone access and randomized to the larger trial's SMS arm. Participants received scheduled health messages and appointment reminders, and could call or text back to a study phone. Study nurses responded to the calls/texts. Call times and content were recorded in a standardized phone log. We compared the demographic characteristics of callers versus non-callers using Chi-square tests. We analyzed and described reasons for participant call/text message and response time of the study nurse.

Results: Of 626 participants, 66% were female. The median age was 31 (inter-quartile range [IQR] 27, 37). A total of 292 calls/texts were sent by 170 (27%) participants, at a rate of 1.4 calls per person-year among callers. There were no significant demographic differences between participants who called/texted and those who did not. The broad reasons for calls were: social/behavioural (47%), medical (17%), logistical (17%), other (16%), and two or more reasons combined (2%), see figure 1 for more details. The study nurse responded to 99% of calls/texts, with a median response time of 29.0 (IQR 6.0, 76.0) minutes and a call length between nurse and participant of 1.0 (IQR 0.5, 1.4) minutes.

Conclusions: Over one-quarter of participants used the SMS call back feature, calling in 1-2 times a year. Nearly half called for social/behavioural reasons, primarily to appreciate message receipt. Provider response was rapid. This mHealth intervention appears to be well-received by patients utilizing it and response to patient needs was efficiently managed by providers. Further evaluation of communication content between the participants and providers would be helpful to understanding patient needs.

WEPEE777

'I hope I never have to go to the adult clinic': Clinic experiences of South African adolescents living with HIV

T.D. Ritchwood[1], A. Oduro[2], M. Atujuna[2], N. Ntlapo[2], S. Letoao[3], L.G. Bekker[2]
[1]Medical University of South Carolina, Public Health Sciences, North Charleston, United States, [2]University of Cape Town, Desmond Tutu HIV Centre, Observatory, South Africa, [3]Information Health Measurement, Mbabane, Swaziland

Background: While South Africa has the largest antiretroviral treatment (ART) program in the world, only 14% of adolescents living with HIV (ALWH) are on ART and only 10% are currently virally suppressed. These concerning figures emphasize the urgent need to identify socio-structural factors that contribute to poor retention in HIV care and low rates of treatment adherence within this group. One significantly under-studied factor that may impact treatment retention and adherence concerns the adolescent HIV clinic environment. The purpose of this study was to identify aspects of the clinic environment that either improve ALWH treatment retention and adherence, or that impede their ability to achieve positive healthcare outcomes.

Methods: Fifty-nine semi-structured, in-depth interviews were conducted to qualitatively determine how ALWHs' experiences at HIV clinics either support or hinder their treatment retention and adherence. Next, we inquired about best practices in ALWH treatment retention and adherence. Participants were ALWH (n=20; 13-19 years of age), their caregivers (n=19), and local stakeholders (n=20) from Cape Town, South Africa. Data were coded and analyzed using inductive content analyses. We then grouped codes into positive and negative HIV clinic experiences, and into suggestions on how clinic practices could be improved to facilitate ALWH treatment retention and adherence.

Results: Perceived positive aspects of adolescent-serving HIV clinics included: clinic co-location within one's community; familiarity with clinic staff; the benefits of adolescent-only clinics; and the availability of adolescent-friendly clinic spaces. Negative clinic aspects included: too many clinic visits that lead to missing school or work regularly; overcrowding and long wait times; HIV-related discrimination and stigma from staff and other patients; clinic practices that lead to involuntary status disclosure; no flexibility in appointment scheduling; and negative staff attitudes.

Conclusions: ALWHs' clinic experiences could impact their ability to remain in HIV care and adhere to their treatment regimens. Such realities call for innovative approaches to the provision of HIV services for ALWH, including precision-based medicine, differentiated care, and multi-level interventions that would enable stakeholders (e.g., private-sector, community, healthcare organizations) and ALWH to work together to support ALWH as they progress along the HIV treatment cascade.

WEPEE778

The sex worker virtual currency: Incentivizing peer educators to expand peer mobilization among female sex workers in Kisumu County, Kenya

B. Okaka[1], W. Odera[1], B.E. Ogwang'[1], M. Opili[2], N. Njuguna[1]
[1]FHI 360, LINKAGES Program, Nairobi, Kenya, [2]Keeping Alive Society's Hope, Kondele DIC, Kisumu, Kenya

Background: Though peer education has proven effective in promoting behaviour change among key populations (KPs), gaps remain in mobilizing KPs in Kenya to access HIV prevention interventions, a situation compounded by the decrease in global funding for HIV programming. We implemented a non-monetary incentive-based intervention—*Sex Worker Virtual Currency* (SWVC)—to motivate peer educators (PEs) to reach all peers in their cohort every quarter.

Methods: SWVC is a redeemable points system involving female sex worker (FSW) PEs at the Keeping Alive Societies' Hope (KASH) drop-in centre (DIC) in Kisumu, Kenya. PEs were oriented on SWVC, and an outreach worker appointed as the SWVC manager. Redeemable points were awarded based on the number of educators' peers who (i) registered their mobile numbers with the DIC to receive programmed health information messages via a bulk SMS platform, (ii) took an initial and repeat HIV test at the DIC, and (iii) enrolled in national health insurance. Uptake within the intervention was entirely voluntary. The SWVC manager awarded points daily based on uptake of services. At the end of the intervention, the three highest-scoring PEs redeemed their points for exchange visits to tourist beaches, shopping vouchers, and mobile phone airtime. Awards were based on discussions held with PEs. We used descriptive statistics to summarize SWVC outcomes.

Results: Twenty-one FSW PEs participated in SWVC from April to September 2017. Of the 1,748 FSW peers within their cohorts, 1,487 (85%) were enrolled into the bulk SMS system and thus received health information and communication from the DIC. A total of 1,099 (62%) tested for HIV for the first time within the year. Only 19 (< 1%) registered for the national health insurance program; the most commonly cited reason for poor uptake was the monthly insurance premium ($5). There was a 14% increase of FSWs reached with HIV prevention services by PEs during the SWVC compared to a similar time period the previous year.

Conclusions: Non-financial incentives to PEs improve their mobilization of hard-to-reach peers for uptake of HIV prevention services. Further education on benefits of insurance coverage for FSWs may increase uptake of enrollment into the national health program.

WEPEE779

Linkage to care among HIV-infected female sex workers participating in project Shikamana in Iringa, Tanzania: A long and winding road

W. Davis[1,2], A. Mantsios[2], C. Shembilu[2], J. Mbwambo[3], S. Likindikoki[3], N. Galai[2], S. Beckham[2], A. Mwampashi[3], D. Gitagno[3], A. Addesso[2], D. Kerrigan[1,2]

[1]American University, Department of Sociology, Washington DC, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [3]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of

Background: Implementation research to strengthen linkage to care, the foundation of test and treat approaches and the 90-90-90 goals, is urgently needed among key populations including female sex workers (FSW) who are less likely to access HIV care. Formative research conducted in Iringa, Tanzania identified multiple barriers to linkage including sex work-related stigma and discrimination. FSW led peer navigation was established to address such barriers within a Phase II trial of a community-based, combination HIV prevention intervention (Project Shikamana) with 496 FSW, (203 HIV+) in Iringa, Tanzania.

Methods: Ten peer navigators (PNs) were trained in supportive communication, disclosure, provider communication and motivational interviewing (MI) to address a mid-course lag in linkage. Each PN was assigned approximately 10 HIV+ FSW from the trial's intervention community (n=102). In weekly meetings, PNs problem-solved around linkage barriers on a case-by-case basis and developed responsive strategies. PNs aimed for weekly contact with participants including calls, text reminders, meetings and clinic visits. PNs also participated in sensitivity trainings with providers.

Results: At 18-month follow-up, of 99 HIV+ participants approached by PNs (3 participants died before PNs initiated contact), 88 were linked vs. 24 at baseline (see graph). In month 1, 33 were linked. Ten women were linked in 10 months and then with the introduction of MI 21 more women were linked. Linkage barriers included stigma, misinformation about the importance of immediate ART uptake, low social support, practical and logistical concerns (e.g., lack of clinic familiarity, how to hide pills). Linkage often took months to achieve given individual readiness and structural factors. PNs observed that persistence and trust were essential to successful linkage.

Conclusions: For FSW in Iringa, Tanzania, linkage to care is a delicate, complex process that must address individual and structural barriers. Ongoing, context-driven problem solving including a mid-course training in MI were central elements in our approach.

HIV genotyping and phylogenetics in the HPTN 071 (PopART) study: Validation of a high-throughput sequencing assay for viral load quantification, genotyping, resistance testing and high-resolution transmission networking

D. Bonsall[1,2], T. Golubchik[1], B. Kosloff[3,4], M. Limbada[3,4], M. de Cesare[2], A. Schaap[3,4], M. Hall[1], C. Wymant[1], G. Macintyre-Cockett[2], A. Brown[5], M.A. Ansari[5], S. Floyd[4], R. Hayes[4], H. Ayles[3,4], S. Fidler[6], C. Fraser[1], HPTN 071 (PopART) Study Group
[1]Big Data Institute, University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, [2]Wellcome Trust Centre for Human Genetics, University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, [3]The Zambia AIDS Related Tuberculosis (ZAMBART) Project, Lusaka, Zambia, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Peter Medawar Building for Pathogen Research, University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom, [6]Imperial College, Department of Clinical Medicine, London, United Kingdom

Background: Next-generation sequencing has been transformative to molecular epidemiology of viruses, though technical complexities have slowed adoption in clinical settings. We developed a quantitative genotyping method optimised for a large-scale HIV phylogenetic study linked to the HPTN 071 (PopART) cluster-randomised trial of antiretroviral treatment as prevention in Zambia.
Methods: To date, 4319 HIV-positive patients (ART-naive or >1 year since last ART) from 9 health care facilities have consented to viral sequencing using residual blood from CD4 testing collected at recruitment. Nucleic acid extracted from 0.5 ml plasma from 292 male and 357 female HIV-infected participants was used to produce sequencing libraries without virus-specific PCR. Oligonucleotide-baits, designed to capture the full HIV epidemic diversity enriched libraries for sequencing on MiSeq (Illumina) and portable MinION (Oxford Nanopore) sequencers. Optimizations focused on the simplest, most cost-effective means of maximizing numbers of unique viral RNA templates, including samples with low viral load, while preserving quantitative information and minimizing oversampling of short-RNA fragments. Merged paired-end reads were assembled using SHIVER, depleted of PCR-duplicates and contaminants, then submitted for high-resolution transmission-mapping (phyloscanner) and drug resistance profiling (HIVdb, Stanford). Quantitative sequencing controls were used to estimate viral load. Clinical viral loads were obtained for a random subset of samples (n=126) for cross validation.
Results: Whole genomes were obtained (with minimum depth of 5x) for 80% of all samples and for 97% of samples with clinical viral load >1,000 copies per ml (fig A). Sequence-based viral load correlated with clinical viral load (R2 = 88% and n=126, fig B). By minimizing PCR-amplification of short fragments, a median of 49% of inserts were longer than 350 b.p providing sufficient phylogenetic resolution to assess intrahost diversity, identify transmission pairs and potentially estimate recency of infection. The total processing time from RNA extraction to sequencing can be completed in 48 hours per batch of 90 samples.
Conclusions: Our novel laboratory and informatics pipeline provides robust viral genetic, viral load, and minority variant information. Processing times, cost and capabilities for handling low viral load samples are highly-competitive compared to routine viral load or polymerase drug resistance testing and suitable for clinical use.

High levels of adaptation to host cellular immunity in a concentrated North American HIV epidemic

N.N. Kinloch[1], S. Sanche[2], A. Wong[3], E. Martin[1], K.D. Cobarrubias[1], P. Sandstrom[4], P. Levett[5,6], P.R. Harrigan[7,8], J.B. Joy[7,8], Z.L. Brumme[1,7]
[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [2]University of Saskatchewan, College of Medicine, Saskatoon, Canada, [3]University of Saskatchewan, College of Medicine, Regina, Canada, [4]National HIV Retrovirology Laboratories, Public Health Agency of Canada, Winnipeg, Canada, [5]Saskatchewan Disease Control Laboratory, Regina, Canada, [6]University of Regina, Department of Biology, Regina, Canada, [7]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [8]University of British Columbia, Faculty of Medicine, Vancouver, Canada

Background: Globally, the spread of viral HLA-associated escape mutations in HIV epidemics has been linked to rapid disease progression and poor clinical outcomes. HIV diagnosis rates in the Canadian province of Saskatchewan are the highest nationwide, and reports of unusually rapid progression have also emerged from the province. Accelerated progression among individuals expressing certain HLA alleles, including the typically protective B*51, has also been reported in neighbouring areas; moreover, regional HLA surveys reveal HLA-B*51, B*35 and B*15 as the most frequently observed HLA-B alleles in at-risk populations in the region. Here, we tested the hypothesis that HIV adaptation to common HLA alleles, in particular B*51, is elevated in Saskatchewan.
Methods: We analyzed 1,144 partial HIV subtype B Pol sequences from unique Saskatchewan residents collected between 2000-2016 for drug resistance genotyping, alongside >6500 published Pol sequences from elsewhere in Canada and the USA from the same period, for the pres-

ence of 70 published HLA-associated Pol mutations. Overall HIV adaptation levels to 34 individual HLA alleles were also compared between these regions. Phylogenetic methods were used to identify putative HIV transmission clusters and the distribution of HLA-associated adaptations within and external to these clusters was investigated.

Results: HIV molecular epidemiology in Saskatchewan is unique: >75% of sequences resided within 26 large phylogenetic clusters (largest >200 sequences). HIV adaptation to numerous HLA alleles, notably B*51, B*15 and others, was also significantly elevated. For example, the Saskatchewan Pol consensus sequence differs from the North American consensus at 9 codons, 7 of which represent major HLA-associated escape mutations. Adaptation levels are also increasing over time. HLA-adapted HIV strains are significantly enriched in Saskatchewan transmission clusters, indicating that these are being widely and preferentially transmitted within the province.

Conclusions: Results indicate that a substantial proportion of at-risk individuals in Saskatchewan have a high probability of acquiring HIV that is pre-adapted to host immunity, providing a plausible explanation for reports of accelerated progression. Results also identify Saskatchewan as the first North American HIV epidemic featuring significant circulating HLA adaptation and highlight the urgent need to expand HIV prevention, testing and treatment in this region.

HIV-1 exposure enhances sexual transmission of hepatitis C virus by human mucosal Langerhans cells

B.M. Nijmeijer[1], R. Sarrami Forooshani[1], G.S. Steba[2], R.R.C.E. Scheurs[1], S.M. Koekkoek[2], R. Molenkamp[2], J. Schinkel[3], P. Reiss[4,5], M.L. Siegenbeek van Heukelom[5,6], M. van der Valk[5], C.M.S. Ribeiro[1], T.B.H. Geijtenbeek[1]
[1]Academic Medical Center- University of Amsterdam - Amsterdam Infection and Immunity Institute, Experimental Immunology, Amsterdam, Netherlands, [2]Academic Medical Center, University of Amsterdam, Department of Medical Microbiology, Clinical Virology Laboratory, Amsterdam, Netherlands, [3]Academic Medical Center, University of Amsterdam, Department of Medical Microbiology, Clinical Virology laboratory, Amsterdam, Netherlands, [4]Academic Medical Center - Amsterdam Institute for Global Health and Development, Department of Global Health, Amsterdam, Netherlands, [5]Amsterdam Infection and Immunity Institute, Academic Medical Center - University of Amsterdam, Department of Internal Medicine, Division of Infectious Diseases, Amsterdam, Netherlands, [6]Academic Medical Center - University of Amsterdam, Department of Dermatology, Amsterdam, Netherlands

Background: Sexual transmission of Hepatitis C virus (HCV), until recently, was thought to be rare. However, there has been a significant rise in the incidence of HCV infection among HIV-infected men-who-have-sex-with-men (MSM) and studies suggest that HCV can be sexually transmitted within this population. The mechanisms underlying this sexual transmission are unclear. Syndecans, a familiy of cell surface heparan sulfate proteoglycans have been shown to act as attachment receptors to transmit viruses.

In this study we investigated the role of Syndecans on LCs in HCV infection and transmission. We hypothesized that HIV-1 replication in HIV-1-infected MSM leads to mucosal changes that allow HCV entry and subsequent dissemination to hepatocytes via Syndecan-4 on activated LCs.

Methods: Therefore, we analyzed the immune cells within mucosal anal biopsies from HIV-1 infected MSM individuals as a potential entry route for HCV during sexual contact. We investigated the role of LCs in HCV infection and transmission using human primary isolated LCs and the *ex vivo* tissue transmission model.

Results: Notably, we detected Langerhans cells (LCs) within the mucosal anal tissue. Immature LCs were neither infected nor transmitted HCV to hepatocytes *in vitro* and *ex vivo*. As sexual transmission is mostly observed within HIV-1 infected individuals, we pre-exposed tissues with HIV-1 and, strikingly, HIV-1 pre-exposure significantly increased HCV transmission by LCs. Active HIV-1 replication is crucial for the increased HCV transmission as treating *ex vivo* tissue with HIV-1 replication inhibitors significantly decreased HIV-1-induced HCV transmission. Activation of LCs did not lead to infection by HCV but these activated LCs, in contrast to immature LCs from same donor, were efficient in transmitting HCV to hepatocytes. Notably, B cell-line expressing Syndecan-4 in contrast to other Syndecans was very efficient in transmitting HCV. Furthermore, silencing of Syndecan-4 on activated LCs decreased HCV transmission.

Conclusions: Thus, our data strongly suggest that HIV-1 replication in mucosal tissues in HIV-1 infected MSM, changes LC function, allowing Syndecan-4 to capture and subsequently transmit HCV to hepatocytes. This novel transmission mechanism by LCs implicates also that the activation state of LCs is an important determinant for HCV susceptibility after sexual contact.

Prophylactic and therapeutic efficacy of broadly neutralizing antibody PGDM1400 against HIV-1 in humanized mice

Y. van der Velden[1], J. Villaudy[1,2], E. Siteur - van Rijnstra[1], C. van der Linden[1], E. Frankin[1], M. Vink[1], P. van der Woude[1], E. Schermer[1], B. Berkhout[1], R.W. Sanders[1], M.J. van Gils[1]
[1]AMC, University of Amsterdam, Amsterdam, Netherlands, [2]AIMM Therapeutics, Amsterdam, Netherlands

Background: Broadly neutralizing antibodies (bNAbs) show promise as prophylactics and therapeutics against HIV-1 in macaques and humans. The introduction of new approaches in B cell isolation reinvigorated the field and led to identification of unusually broad and potent bNAbs. One example is PGDM1400, which neutralizes around 83% of virus strain, and at very low concentrations, making it a very attractive antibody for prophylactic and therapeutic applications.

Methods: A hu-HSC NSG mouse model, which has the complete human immune system, was used to study the protective and therapeutic efficacy of the bNAb PGDM1400. Mice were passively immunized (i.v.) with different concentration of PGDM1400 and challenged high dose i.p. with HIV-1_{JRCSF} 24 hours later. In a second experiment mice were infected with viruses from clades A, B or C (HIV-1_{BG505}, HIV-1_{REJO}, HIV-1_{AMC008}, or HIV-1_{MJ4}) and 12 weeks later, a high dose of PGDM1400 was given (i.v.) once a week for 4 weeks. Viral populations were sequenced before and after the administration of PGDM1400.

Results: In the passive immunization study, all animals in the 10 mg/kg and 3 mg/kg groups, and 4 out of 7 animals in the 1mg/kg group had undetectable levels of viral RNA, while all animals of the PBS group and the antibody control group had high levels of viral RNA 7 days after challenge. Subsequently, PGDM1400 administered during chronic infection, caused a modest decrease in viral load and also an increase in CD4+ T cell counts in the first 1-2 weeks of administration in some animals, however these levels did not persist, suggesting that the virus escaped from PGDM1400, quickly after administration of the antibody. This was confirmed by the sequence analysis of the viral population after PGDM1400 therapy.

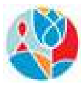
Conclusions: We showed that PGDM1400 is a promising component of a future prophylactic to prevent HIV-1 infection. In agreement with studies on other bNAbs, PGDM1400 monotherapy did not fully suppress chronic HIV-1 infection for a prolonged period, however considering that PGDM1400 is one of the most potent and broad bNAbs known, it can be an important component in therapeutic combination of different bNAbs.

THAA0105

A single dose of anti-HIV-1 antibodies can protect macaques from repeated mucosal SHIV exposures for 6 months

R. Gautam[1], Y. Nishimura[2], N. Gaughan[2], A. Gazumyan[3], T. Schoofs[3], A.-B. White[2], M. Seaman[4], B. Swihart[2], D. Follmann[2], M. Nussenzweig[3], M. Martin[2]
[1]NIH, Molecular Microbiology, Bethesda, United States, [2]NIH, Bethesda, United States, [3]Rockefeller University, New York, United States, [4]BIDMC, Boston, United States

Background: In the absence of an effective and safe vaccine against HIV-1, the administration of broadly neutralizing antibodies (bNAbs) represents a logical alternative approach to prevent virus transmission. bNAbs are capable of neutralizing most circulating strains, targeting different non-overlapping epitopes on the HIV-1 envelope spike.



Methods: We introduced two amino acid mutations (M428L and N434S [referred to as "LS"]) into the Fc domains of the highly potent HIV-specific 3BNC117 and 10-1074 bNAbs to increase their half-lives and evaluated their efficacy in blocking infections following repeated low dose mucosal challenges of rhesus macaques with the Tier 2 $SHIV_{AD8-EO}$.
The protective efficacy of 3BNC117-LS or 10-1074-LS was assessed following a single intravenous infusion of each mAb (20 mg/kg body weight) to 6 animals. The macaques were challenged beginning one-week after bNAb administration, and, in addition to viral RNA, we measured serum bNAb concentrations, anti SHIV-neutralizing titers, and anti-bNAb responses.
Results: The most striking result obtained in this study was the long period of protective efficacy conferred by a single injection of Fc modified human anti-HIV-1 neutralizing antibodies in macaques compared to the previous studies. A single intravenous infusion of 10-1074-LS mAb markedly delayed virus acquisition for 18 to 37 weeks (median = 27 weeks) whereas the protective effect of the 3BNC117-LS bNAb was more modest (protection for 11 to 23 weeks; median = 17 weeks). Serum concentrations of the 10-1074-LS mAb gradually declined and became undetectable in all recipients between weeks 26 to 41 whereas the 3BNC117-LS bNAb exhibited a shorter half-life. To model immunoprophylaxis against genetically diverse and/or neutralization resistant HIV-1 strains, a combination of the 3BNC117-LS plus 10-1074-LS mAbs was injected into macaques by the more clinically relevant subcutaneous route. Even though nearly 3-fold less of each bNAb in the mixture was administered, compared to the amount of single mAb injected in the intravenous infusions, the mAb combination still protected macaques for a median of 20 weeks.
Conclusions: The extended period of protection observed in macaques for the 3BNC117-LS plus 10-1074-LS combination could translate into an effective semi-annual or annual immunoprophylaxis regimen for preventing HIV-1 infections in humans.

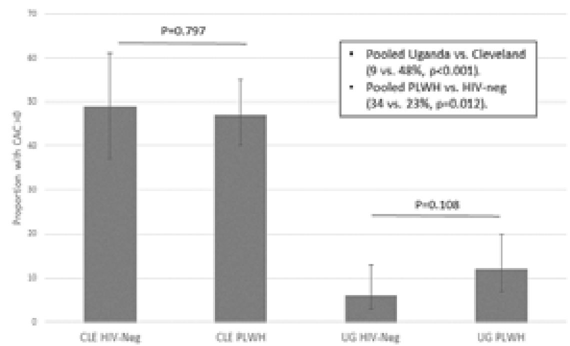
Low prevalence of calcified coronary plaque among Ugandans with and without HIV infection: Comparison with a United States cohort and associations with biomarkers of inflammation

C.T. Longenecker[1,2], B. Alencherry[2], G. Erem[3,4], G. Mirembe[5], J. Nansimbe[5], I. Ssinabulya[4,6], C.-H. Yun[7], C.-L. Hung[7], M.J. Siedner[8,9], C. Kityo[5], G.A. McComsey[1,2]
[1]*Case Western Reserve University School of Medicine, Cleveland, United States,* [2]*University Hospitals Cleveland Medical Center, Cleveland, United States,* [3]*Nsambya St. Francis Hospital, Kampala, Uganda,* [4]*Makerere University School of Medicine, Kampala, Uganda,* [5]*Joint Clinical Research Centre, Kampala, Uganda,* [6]*Uganda Heart Institute, Kampala, Uganda,* [7]*Mackay Memorial Hospital, Taipei, Taiwan, Province of China,* [8]*Massachusetts General Hospital, Boston, United States,* [9]*Harvard Medical School, Boston, United States*

Background: Little is known about subclinical coronary disease among people living with HIV (PLWH) in sub-Saharan Africa. We sought to compare prevalence of calcified coronary plaque between people with and without HIV in Uganda and the United States, and to explore associations with HIV-specific factors and biomarkers.
Methods: 100 Ugandan PLWH on antiretroviral therapy over 40 years old were prospectively age- and sex-matched to 100 HIV-uninfected controls. All had ≥1 major cardiovascular risk factor (hypertension, diabetes, smoking, or high cholesterol). Coronary artery calcium (CAC) scores were obtained from gated non-contrast computed tomography scans of the heart. Biomarkers were measured from cryopreserved plasma. Ugandan subjects were compared to PLWH on antiretroviral therapy (n=167) and uninfected controls (n=63) over 40 years old from a research database in Cleveland, USA.
Results: Compared to US subjects, Ugandans were older (mean age 56 vs. 52 years), had higher cholesterol (mean fasting cholesterol 216 vs. 176 mg/dL), more diabetes (36 vs. 3%), and more hypertension (85 vs. 36%); but were less likely to be male (38 vs. 74%), smokers (4 vs. 56%) or statin users (6 vs. 13%; all p< 0.01). Ugandan PLWH had lower current CD4+ (mean 570 vs 675, p=0.015), but similar nadir CD4+ compared to US PLWH. The unadjusted prevalence of CAC>0 was higher in the US vs. Uganda and among PLWH vs. uninfected controls (Figure). After adjustment for HIV serostatus, age, sex, and traditional risk factors, Ugandans had over 13x lower odds of CAC>0 (p< 0.001). In multivariable-adjusted models, soluble intercellular adhesion molecule (p=0.044), soluble CD163 (p=0.004), and oxidized LDL (p=0.043) were each associated with CAC>0 among Ugandans. Soluble CD163 and oxidized LDL remained associated (p< 0.025) in models of Ugandan PLWH that further adjusted for PI use and current CD4+. Among all PLWH (n=267), nadir CD4+ was the only HIV-specific variable associated with CAC>0 in adjusted models.
Conclusions: Despite a high burden of risk factors, this Ugandan cohort of PLWH and controls had substantially lower rates of calcified coronary plaque compared to a US cohort. Lower nadir CD4+ count and higher systemic levels of inflammation and immune activation were associated with CAC>0.



[Figure. Prevalence of calcified coronary plaque (coronary artery calcium score <0) among people living with HIV in Uganda and the United States. Error bars represent 95% confidence interval of the proportion, CLE, Cleveland; UG, Uganda; PLWH, people living with HIV]

THAB0102

Cardiac chamber abnormalities and left ventricular mass in people living with HIV and matched uninfected controls assessed by multidetector computed tomography

L. Demmer[1], A. Ronit[1], P.E. Sigvardsen[2], A.-M. Lebech[3], J. Gerstoft[1], A.D. Knudsen[1], A. Fuchs[2], J.T. Kühl[2], J. Lundgren[1], B.G. Nordestgaard[4], K.F. Kofoed[2], S.D. Nielsen[1]
[1]*Rigshospitalet, Viro-Immunology Research Unit, Copenhagen, Denmark,* [2]*Rigshospitalet, Heart Center, Copenhagen, Denmark,* [3]*University of Copenhagen, Department of Infectious Diseases, Hvidovre, Denmark,* [4]*Herlev Hospital, Copenhagen General Population Study, Herlev, Denmark*

Background: People living with HIV (PLWH) have increased risk of cardiovascular disease (CVD). Previous studies using echocardiography have reported higher prevalence of cardiac abnormalities including left atrial enlargement, left ventricle dysfunction, right ventricle dilatation and greater left ventricular mass in PLWH. Multidetector computed tomography (MDCT) allows a precise estimate of cardiac chamber volumes. We aimed to assess cardiac structural abnormalities and factors associated with cardiac abnormalities in PLWH and uninfected controls using MDCT.
Methods: A total of 592 PLWH from the Copenhagen co-morbidity in HIV-infection (COCOMO) study and 1184 age and sex matched uninfected controls from the Copenhagen General Population Study were included. Left atrial volume (LAV), left ventricular diastolic volume (LVDV), right ventricular diastolic volume (RVDV) and left ventricular mass (LVM) were assessed with semi-automated MDCT software and indexed by body surface area (LAVi, LVDVi, RVDVi and LVMi). Linear regression

models adjusted for demographic variables (model 1) and additionally for cardiac risk factors (model 2) were used to assess association between HIV and MDCT dimensions.

Results: Most PLWH were men (88.2%) with mean (SD) age 53.7 (8.8) years, and had undetectable viral replication (96.1%) and CD4 count > 500 cells/mL (77.0%). PLWH had smaller mean (SD) LAVi (40mL/m² (8) vs. 41mL/m² (9), p=0.002) and LVDVi (61mL/m² (13) vs. 65mL/m² (14), p< 0.0001). However, RVDVi was larger in PLWH (89mL/m² (18) vs. 86mL/m² (17), p< 0.001) than uninfected controls. After adjustment for age, sex, body mass index, ancestry, smoking pack-years, systolic blood pressure, high density lipoprotein, low density lipoprotein, triglyceride and non-fasting blood glucose, HIV was associated with -6mL (95%CI: -10;-3) lower LVDV, 11mL (95%CI: 7;16) larger RVDV, and 4g (95%CI: 1;7) larger LVM. Finally, CD4 nadir (per 100cells/mL) was associated with 2 mL larger LVDV (95%CI: 0;3) and 3mL larger RVDV (95%CI: 0;5).

Conclusions: HIV was independently associated with smaller LVDV, larger RVDV and greater LVM. However, absolute differences were small and no major structural cardiac abnormalities were found in a well-treated population of PLWH. Thus, the clinical impact is uncertain, and it is unlikely that structural cardiac abnormalities explain the increased risk of CVD previously observed in PLWH

CVD risk factors	Univariate β (95% CI)	P-value	Model 1 β (95% CI)	P-value	Model 2 β (95% CI)	P-value

THAB0103

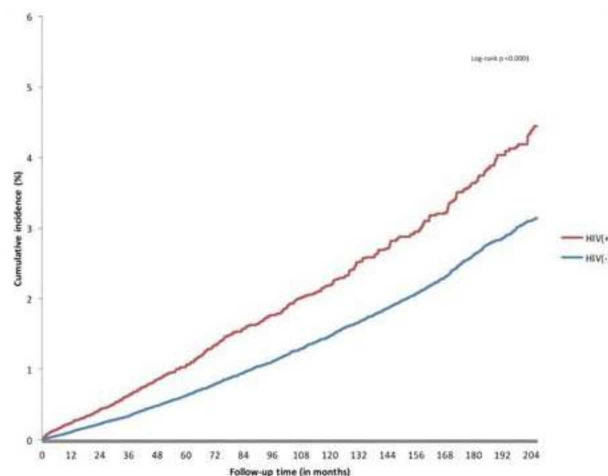
HIV infection independently increases the risk of developing heart failure: The HIV HEART study

A.S. Go[1], M. Horberg[2], K. Reynolds[3], W.J. Towner[3], H. Avula[1], R.C. Hechter[3], D. Klein[1], S. Vupputuri[2], K.K. Lee[1], T.K. Leong[1], W. Leyden[1], R. Neugebauer[1], S.H. Sung[1], M.J. Silverberg[1]
[1]Kaiser Permanente Northern California, Division of Research, Oakland, United States, [2]Kaiser Permanente Mid-Atlantic States, Mid-Atlantic Permanente Research Institute, Rockville, United States, [3]Kaiser Permanente Southern California, Department of Research and Evaluation, Pasadena, United States

Background: HIV infection has been associated with excess atherosclerotic events, but limited data exist about its link to developing heart failure (HF) and possible contributing factors. In a large, multi-institutional, community-based population, we evaluated the independent association of HIV infection with incident HF.

Methods: Within 3 large U.S. integrated healthcare delivery systems, we identified all eligible HIV(+) adults (≥21 years) between 2000-2016 without prior HF and frequency-matched up to 10:1 to HIV(-) subjects without prior HF based on entry year, age (±1 year), gender, race, and primary treating facility. Through 2016, we identified cases of incident HF based on validated algorithms using electronic health records (EHR). Demographic features, cardiovascular risk factors, pertinent medical history and medication use were ascertained from EHR and other health system databases. We evaluated the independent association of HIV infection with incident HF through a series of multivariable Cox regression models that sequentially adjusted for: health system and calendar era, demographics, lifestyle factors, cardiovascular history, other comorbidities, and cardiopreventive and other medication use. In the final model, we adjusted for acute coronary syndrome events during follow-up as a potential explanatory variable.

Results: We identified 38,868 HIV(+) and 386,586 matched HIV(-) adults during the study period. HIV(+) patients were more likely to have low neighborhood-level educational attainment and household income, prior cancer, dementia or depression but less likely to have prior cardiovascular conditions or cardiovascular risk factors. The rate (per 100 person-years) of incident HF was higher in HIV(+) (0.24, 95%CI:0.22-0.26) vs. matched HIV(-) (0.16, 95%CI:0.15-0.16) patients (P< 0.0001) (Figure). In multivariable analyses, HIV infection was associated with an increased rate of developing HF that strengthened after serial adjustment for demographic characteristics; cardiovascular and medical history; and cardiopreventive medication, antidiabetic therapy and NSAID use, with an 75% increased rate in the fully adjusted model (Table, Models 1-3). Further adjustment for acute coronary syndrome events during follow-up only modestly attenuated the association of HIV infection with incident HF (Model 4).



[Cumulative incidence of newly-diagnosed heart failure by HIV status]

	Model 1	Model 2	Model 3	Model 4
	Health System, Entry Year and Demographics	Model 1 + Cardiovascular and Non-Cardiovascular History	Model 2 + Cardiopreventive Medications, Antidiabetic therapy and NSAIDs	Model 3 + Acute Coronary Syndrome Events During Follow-Up
Adjusted Hazard Ratio (95% CI) for HIV(+) vs. HIV(-)	1.54 (1.40-1.69)	1.69 (1.54-1.86)	1.75 (1.59-1.93)	1.66 (1.50-1.83)

[Multivariable association of HIV infection with incident heart failure]

Conclusions: HIV infection independently increases the risk of developing HF and this excess risk does not appear to be mediated through atherosclerotic disease pathways or differential use of cardiopreventive therapies.

THAB0104

Malignancy and all-cause mortality: Incidence in teenage young adults living with perinatally acquired HIV

S. Chhabra[1], S. Fidler[1], M. Bower[2], S. Ayers[3], H. Lyall[3], C. Foster[3]
[1]Imperial College London, London, United Kingdom, [2]Chelsea and Westminster Hospital NHS Trust, London, United Kingdom, [3]Imperial College Healthcare NHS Trust, London, United Kingdom

Background: The incidence of malignancy between 10-24 years of age in the general UK population is 0.2/1000 person-years. Adults living with HIV have an increased risk of malignancy yet there is a paucity of data for teenage young adults (TYA) living with perinatally acquired HIV (PaHIV).

Methods: Retrospective cohort analysis of all-cause mortality and malignancies in TYAPaHIV aged 10-24 years attending a tertiary unit from 01.01.2004 to 31.12.2017, assessing mortality, cancer presentation, immunology, virology and comparing incidence and mortality to aged-matched UK general population rates.

Results: 290 TYAPaHIV contributed 2644 person-years of follow up. 2/290 (0.7%) were lost to follow-up, 14/290 (4.8%) transferred care and 6/290 (2.0%) died within the study period at a median age of 17 years

(inter-quartile range (IQR) 15-19). Cause of death; 3 with malignancy (non-Hodgkin's lymphoma, hepatocellular carcinoma (HCC), gastrointestinal adenocarcinoma), 2 with end stage HIV with poor adherence to antiretroviral therapy (ART) and 1 with cryptococcal meningitis. Overall mortality rate was 2.3/1000 person-years, 9.4 times the age-matched general population (incidence rate ratio (IRR) 9.4, 95% confidence interval (CI) 3.4-20.4, p < 0.0001). 8/290 (2.8%) were diagnosed with a malignancy aged 10-24 years; 7/8 males; 6 with lymphoma (3 Hodgkin's, 1 Burkitt's, 2 B-cell) and one each with HCC and gastrointestinal adenocarcinoma. At cancer diagnosis the median age was 19 years (IQR 14-23), median CD4 count 453 cells/uL (IQR 231-645) and 4/8 had undetectable HIV viral load (< 50 copies/mL). Median length of HIV viraemia pre-cancer diagnosis was 15 years (IQR 12-17). 4/6 lymphomas presented with advanced disease (Ann Arbor stage III/IV). The incidence of a malignancy was 3.0/1000 person-years in TYAPaHIV, IRR to the age-matched general population 12.9 (95% CI 5.6 - 25.5, p < 0.0001), driven by lymphomas (IRR 44.2, 95% CI 16.1 - 96.7, p < 0.0001).

Conclusions: In this cohort, TYA living with PaHIV had nearly a ten-fold increased risk of all-cause mortality and of malignancy compared to their uninfected peers, with the excess in malignancy driven by lymphomas. It is hoped that earlier access to antiretroviral therapy will mitigate some of the risk for future generations.

THAB0105

Increased risk of both mortality and incident comorbidity among frail HIV-positive and HIV-negative participants in the AGE$_h$IV Cohort Study, and increased risk of frailty progression in those with HIV

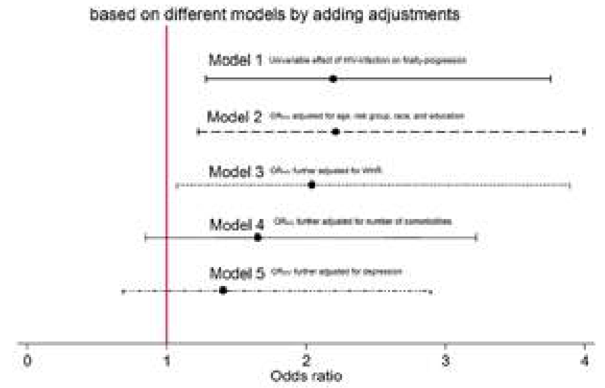
E. Verheij[1,2], G.D. Kirk[3], F.W. Wit[1,2,4], R.A. van Zoest[1,2], S.O. Verboeket[1,2], M.F. Schim van der Loeff[5], P. Reiss[1,2,4], AGEhIV Cohort Study
[1]Academic Medical Center, Department of Global Health and Division of Infectious Diseases", Amsterdam, Netherlands, [2]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, [3]Johns Hopkins University, Department of Epidemiology, Bloomberg School of Public Health, Baltimore, United States, [4]HIV Monitoring Foundation, Amsterdam, Netherlands, [5]Public Health Service of Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands

Background: Frailty is associated with morbidity and mortality in the general geriatric population. We assessed both the impact of frailty on mortality/incident comorbidity risk and factors associated with frailty progression.

Methods: Longitudinal data from 598 people living with HIV (PLWH) and 550 demographically comparable HIV-uninfected AGE$_h$IV Cohort Study participants were analyzed (Table). The presence of ≥3 criteria among 5 domains (weight loss, low physical activity, exhaustion, decreased grip strength, and slow gait speed), defined frailty. Impact of time-updated frailty status on all-cause-mortality in all, and on incident comorbidity among those (497 HIV-positive and 479 HIV-negative) contributing ≥1 consecutive visit pairs (n=1833 pairs) was assessed. Factors associated with frailty progression were analyzed among a subset of 488 participants with ≥2 consecutive biennial follow-up visits (Table). Kaplan-Meier plots, multivariable Cox or logistic regression models with generalized estimated equation were used, as appropriate.

Results: Among HIV-positive and HIV-negative participants respectively, 8.5 and 3.4 percent were frail, and during 4,423 person-years of follow-up (PYFU) 12 and 5 persons died, for an all-cause mortality rate of 5.2/1000 and 3.8/1000 PYFU. Time to death was shorter among frail persons. Adjusted for HIV-status, age and number of pre-existing comorbidities, frailty was independently associated with mortality (hazard ratio: 12.3, 95%CI 4.5-33). 342 incident comorbidities were diagnosed among 307 participants. Adjusted for HIV-status, age, gender, ethnicity, education and number of pre-existing comorbidities, frail participants had higher odds of developing ≥1 comorbidity (OR 1.93, 95%CI 1.15-3.322). No interaction was found between frailty and HIV-status on mortality or incident comorbidity risk.

In the subset of 488 participants, 60 demonstrated frailty progression. HIV-status was associated with frailty progression (OR 2.2, 95%CI 1.3-3.8), partly mediated by higher waist-to-hip ratio (WHR), comorbidity burden and depression.



[Showing the odds ratio and 95% CI of HIV-infection on frailty-progression based on different models]

Conclusions: Frailty was a strong predictor of mortality and incident comorbidity, regardless of HIV-status. Frailty was more prevalent among PLWH and HIV-status was associated with frailty progression, which was partly mediated by higher WHR and pre-existing comorbidity burden and depression. These results provide guidance to clinicians in recognizing patients at risk for developing frailty and associated adverse health outcomes, and the importance of maintaining physical and mental health.

Effectiveness of hepatitis A virus (HAV) vaccination among people living with HIV during an hepatitis A outbreak in Taiwan, 2015-2017

K.-Y. Lin[1,2], H.-Y. Sun[3], S.-M. Hsieh[3], H.-Y. Cheng[4], Y.-C. Lo[4], W.-H. Sheng[3], Y.-C. Chuang[3], A. Cheng[3], S.-C. Pan[3], G.-J. Chen[3], C.-T. Fang[2], C.-C. Hung[3], S.-C. Chang[3]
[1]*National Taiwan University Hospital Jin-Shan Branch, Department of Medicine, New Taipei City, Taiwan, Province of China,* [2]*Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan, Province of China,* [3]*National Taiwan University Hospital and National Taiwan University College of Medicine, Department of Internal Medicine, Taipei, Taiwan, Province of China,* [4]*Centers for Disease Control, Taipei, Taiwan, Province of China*

Background: Outbreaks of hepatitis A virus (HAV) infection have re-emerged among men who have sex with men (MSM) across the Asia-Pacific region, the United States, and several European countries since 2015. The suboptimal response to HAV vaccine among MSM living with HIV raises serious concerns about the personal-level and population-level effectiveness of HAV vaccination. We estimated the transmissibility of HAV during an hepatitis A outbreak among MSM living with HIV in Taiwan, 2015-2017, and measured the effectiveness of HAV vaccine in this population.

Methods: We developed a mathematical model of HAV transmission to estimate the basic reproductive number (R_0) of HAV in this outbreak. A case of acute hepatitis A was defined as a documented positive anti-HAV IgM in an HIV-positive patient who presented with clinical symptoms, elevated aminotransferases, or jaundice. We conducted a 1:4 nested case-control study to assess the effectiveness of HAV vaccine in MSM living with HIV.

Results: Given 30% of HIV-positive patients having mild symptoms after acquiring acute hepatitis A, we estimated the R_0 of HAV was as high as 6.37 in this outbreak. During study period (from June 1, 2015 to June 30, 2017), 55 cases of acute hepatitis A occurred among 1533 initially HAV seronegative HIV-positive patients. All case patients were MSM with a median age of 30 years and baseline CD4 count of 545 cells/µL, and 60% had recent syphilis within 6 months prior to the onset of acute hepatitis A. HAV vaccination protected recipients from acute hepatitis A (adjusted odds ratio, 0.03; 95% CI, 0.001-0.12), with an overall vaccine effectiveness of 97.4% (Table). The effectiveness of single dose and two doses of HAV vaccine was 96.1% and 99.7%, respectively. This high personal-level vaccine effectiveness in MSM living with HIV might explain the rapid control of this hepatitis A outbreak in Taiwan (Figure).

Conclusions: Our findings strongly support the implementation of HAV vaccination to control hepatitis A outbreak among MSM living with HIV.

	Univariable analysis		Multivariable analysis	
	Odds ratio (95% CI)	P value	Odds ratio (95% CI)	P value
At least one dose of HAV vaccination	0.04 (0.01-0.13)	<0.001	0.03 (0.001-0.12)	<0.001

Less severe but prolonged course of acute hepatitis A in HIV-positive patients than HIV-negative patients during an outbreak: A multicenter observational study

Y.-L. Li[1], C.-E. Liu[1], C.-C. Hung[2], P.-L. Lu[3], N.-Y. Chen[4], Taiwan HIV Study Group
[1]*Changhua Christian Hospital, Changhua, Taiwan, Province of China,*
[2]*National Taiwan University Hospital, Taipei, Taiwan, Province of China,*
[3]*Kaohsiung Medical University, Kaohsiung, Taiwan, Province of China,*
[4]*Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

Background: This multicenter retrospective cohort study aimed to compare the clinical presentations and evolution of acute hepatitis A (AHA) between HIV-positive patients and HIV-negative counterparts during the AHA outbreak.

Methods: Information on the demographics, clinical presentations, serial laboratory data, and abdominal imaging were collected from the medical records of the patients who received a diagnosis of AHA at the 14 designated hospitals for HIV care around Taiwan between May 2015 and May 2017.

Results: A total of 297 adult patients with AHA were included during the 2-year study period. With a mean age of 31.4 years (range, 19.0-76.1), 93.4% were males and 58.6% MSM. Of 265 patients with known HIV serostatus, 166 (62.6%) were HIV-positive. Compared with HIV-negative patients, HIV-positive patients had a lower peak alanine aminotransferase (ALT) level (median, 1312 vs 2014 IU/L, p=0.003), less coagulopathy (6.0% vs 16.2%, p=0.007), less hepatomegaly or splenomegaly on imaging studies, but delayed resolution of hepatitis (40.9% vs 21.3%, p=0.005). In the subgroup analysis, HIV-positive patients with good HIV viral suppression (plasma RNA load [PVL] < 1000 copies/ml) by combination antiretroviral therapy (cART) had a higher peak ALT level (median, 1420 vs 983 IU/L, p=0.012) and less delay in resolution of hepatitis (22.6% vs. 51.0%, p< 0.001) than patients without cART or with higher PVL.

Conclusions: During an AHA outbreak, we found that HIV-positive patients had a lower severity, but delayed resolution of AHA than HIV-negative patients. Receipt of cART with better viral suppression alleviated the impact of HIV infection on the clinical manifestations of AHA in HIV-positive patients.

Background: Infection of acute hepatitis C (AHC) among men having sex with men (MSM) has become an outbreak in several high-income countries from 2000. Several studies reported existence of specific HCV transmission network among MSM communities in Europe and especially a spread of HCV strains from HIV-HCV co-infected MSM toward HCV mono-infected MSM. We aimed to characterize HCV transmission clusters in HIV positive and HIV negative MSM communities in Parisian region by ultra-deep sequencing (UDS).

Methods: Illumina (Miseq) deep-sequencing of NS5B fragment was performed on plasma samples of 50 AHC HIV-positive and 18 AHC HIV-negative individuals including 13 from the Prep IPERGAY ANRS study. UDS data were analysed by Geneious (version 10.1.3). Phylogenetic trees were realized using Fasttree 2.1 and local support value of > 80% was chosen to define a robust tree. Trees were submitted to ClusterPicker (version 1.2.3) to determine transmission cluster at different thresholds of maximum genetic distance (MGD). We compared results of Sanger at 3%, UDS at 3%, and at 4.5% of MGD.

Results: Of 68 acute hepatitis C patients, 15 were cases of recontamination. HCV genotyping showed genotype 1a (47%), 4d (41%), 3a (9%), and 2k (3%). Sanger at 3%, UDS at 3% and at 4.5% of MGD allowed detection of 10, 17, and 18 clusters, respectively. By UDS, more clusters were detected but fewer subjects (median: 2 subjects) were identified within each cluster than Sanger did (median: 3 subjects). Furthermore, mixed clusters including HIV-positive and HIV-negative MSM were observed in 8/10 clusters by Sanger, in 10/17 by UDS at 3%, and in 10/18 by UDS at 4.5% of MGD. Overall, the number of HIV-negative individuals clustering with HIV-positive ones was 8/18 by Sanger, 8/18 by UDS at 3%, and 9/18 by UDS at 4.5% of MGD.

Conclusions: By Sanger or UDS, our study allowed the detection of HCV transmission clusters in MSM communities in Parisian region. Particularly in this population, the HIV-positive MSM shared the HCV transmission network with HIV-negative MSM, which in turn alerts the public health for surveillance and prevention measures in these communities, regardless of their HIV status.

THAB0204

Will hepatitis C transmission be eliminated by 2025 among HIV-positive men who have sex with men in Australia?

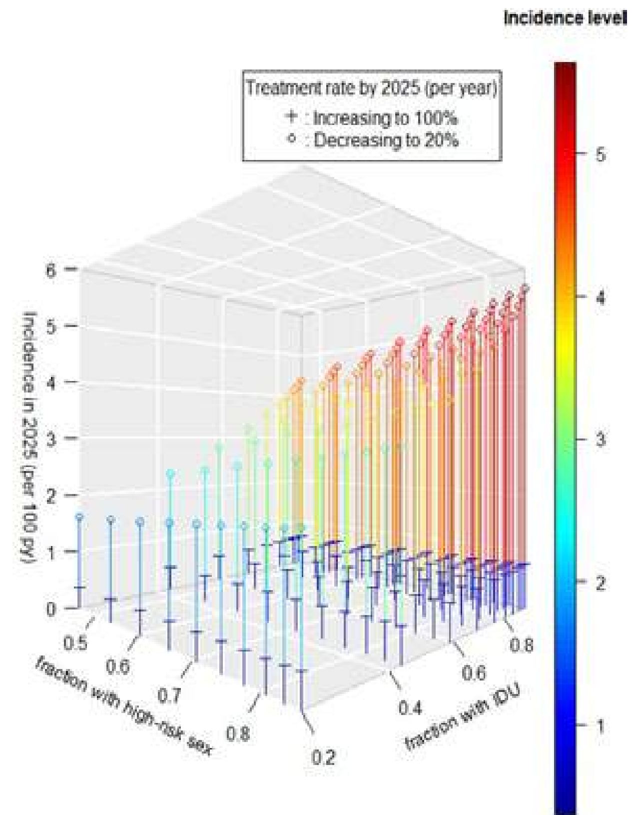
L. Salazar-Vizcaya[1], D.C. Boettiger[2], G.J. Dore[2], R. Gray[2], M. Law[2], A. Rauch[1], T. Lea[3], G. Matthews[2]
[1]University Hospital Bern, Inselspital, Department of infectious diseases, Bern, Switzerland, [2]Kirby Institute, UNSW, Sydney, Australia, [3]Centre for Social Research in Health, UNSW, Sydney, Australia

Background: Australia was among the first countries to offer universal access to direct-acting antiviral (DAA) therapy for hepatitis C virus (HCV) to HIV-positive men who have sex with men (MSM). Rapid scale-up of DAA therapy has been ongoing in Australia since 2016 and has the potential to interrupt HCV transmissions. However, concerns have been raised that behavioural changes may counterbalance the effect of treatment. We assessed the potential effect of treatment and risk behavioral changes on HCV incidence among HIV-positive MSM up to 2025.

Methods: Mathematical model of HCV transmission parameterized with Australian data collected between 2000 and 2016. The model was set to reproduce observed data and to assess the future impact of a range of changes in behavior that facilitate HCV transmission (i.e. high-risk sex and injecting drug use-IDU) in the context of increasing and decreasing rates of DAA use. Baseline DAA-treatment rate was based on data from the Control and Elimination within Australia of Hepatitis C from people living with HIV (CEASE) study.

Results: The Figure summarizes model outcomes. If the rate of DAA use increased from 65%/year among eligible patients in 2016 to 100%/year by 2025, HCV incidence would drop from 3.7/100 person-years (py) in 2016 to 0.4/100py by 2025 providing rates of risk behavior remained at current levels (20% and 45% for IDU and high-risk sex respectively). Even in the setting of substantial increases in the rates of high-risk sex and IDU (e.g. 90% and 85%) HCV incidence would drop to 0.8/100py. Moreover, if treatment rate remains stable after 2016, incidence would also drop regardless of risk behavior (results not shown in the Figure). Conversely, HCV incidence only increased from that in 2016 when rates of IDU also increased substantially (above 69%) alongside a drop in DAA use (to 20% by 2025).

Conclusions: The model suggests that HCV transmission among Australia's HIV-positive MSM population will continue, but decline substantially with DAA treatment upscale, even in the context of increased risk behaviour. If treatment rate continues to increase, by 2025 Australia could meet the 80% reduction goal formulated by the WHO.



[Projected incidence of HCV among HIV-positive men who have sex with men in Australia. Colors indicate incidence values as depicted in the coloured bar]

THAB0205

HIV infection is an independent risk factor for liver steatosis: A study in HIV mono-infected patients compared to uninfected paired controls and associated risk factors

A. Pacheco[1], H. Perazzo[2], S. Cardoso[2], M.J. Fonseca[3], R. Griep[4], P. Lotufo[5], I. Bensenor[5], J. Mill[6], R. Moreira[1,2], R. Moreira[2], R. Friedman[2], M. Santini-Oliveira[2], V. Veloso[2], D. Chor[3], B. Grinsztejn[2]
[1]Fundação Oswaldo Cruz (FIOCRUZ), PROCC, Rio de Janeiro, Brazil, [2]Fundação Oswaldo Cruz (FIOCRUZ), LAPCLIN-AIDS, Rio de Janeiro, Brazil, [3]Fundação Oswaldo Cruz (FIOCRUZ), Departamento de Epidemiologia e Métodos Quantitativos em Saúde, Rio de Janeiro, Brazil, [4]Fundação Oswaldo Cruz (FIOCRUZ), Laboratory of Health and Environment Education, Rio de Janeiro, Brazil, [5]University of São Paulo, School of Medicine, São Paulo, Brazil, [6]Federal University of Espírito Santo, Departamento de Ciências Fisiológicas, Vitoria, Brazil

Background: Several studies have been reporting the burden of metabolic liver disease in HIV-infected individuals. However, the impact of HIV infection on prevalence of liver steatosis and associated risk factors still lack. We aimed to evaluate the prevalence and factors associated with liver steatosis in HIV mono-infected patients compared to uninfected subjects paired for confounding factors.
Methods: 649 HIV mono-infected patients from the INI-ELSA cohort were eligible. To test the association of HIV infection with steatosis, non-infected subjects from the Brazilian Longitudinal Study of Adult Health (ELSA-Brasil) cohort (n=15,087) were paired by demographic, metabolic and inflammatory characteristics. Nearest neighbor matching with a 0.05 caliper on logistic regression-based scores were used for matching and balance was checked with usual procedures. The variables used for the matching and the ones used in the final model for risk factors for steatosis in HIV-infected individuals were selected through a genetic algorithm that searched for the best model fit. Fatty Liver Index (FLI) was calculated as previously validated [Bedogni BMC-Gastroenterology 2006] and liver steatosis was defined as FLI ≥ 60. Logistic regression analysis was performed to assess risk of steatosis in HIV-patients compared to controls and to identify factors associated with fatty liver in HIV-infected individuals.
Results: HIV-patients [58% male; median (IQR) age=44 (36-51) years; body mass index (BMI)=24.4 (21.9-27.5) Kg/m^2; 33% with metabolic syndrome] were paired with 333 uninfected controls, with good balance on demographic and clinical characteristics between patients and controls. HIV infection was an independent factor associated with liver steatosis [OR=2.1 (95%CI 1.49-2.95), p< 0.001]. In a multivariate analysis with all HIV patients included, the following variables were independently associated [OR (95%CI)] with presence of steatosis: male gender [5.36 (2.41-11.94)]; Black/*Pardo* ethnicity [0.22 (0.09-0.55)]; hypertension [2.56 (1.25-5.26)]; diabetes [5.79 (2.58-13)]; dyslipidemia [2.57 (1.27-5.21)]; BMI [1.91 (1.67-2.18)]; CD4 count [per cell/mm3, 1.13 (1.01-1.27)] and cumulative HIV viral load [1.25 (1.02-1.54)].
Conclusions: HIV-infected individuals had 2-fold higher odds for presence of steatosis compared to uninfected paired controls. Traditional and HIV-specific risk factors were also associated with steatosis. Prevention of metabolic factors should be integrated to HIV care to decrease the burden of liver diseases in HIV-infected individuals.

HIV mono-infected (n= 649)	OR (95%CI)	p-value
Male gender (yes vs no)	5.36 (2.41-11.94)	< 0.001
Black/Pardo ethnicity (yes vs no)	0.22 (0.09-0.55)	0.001

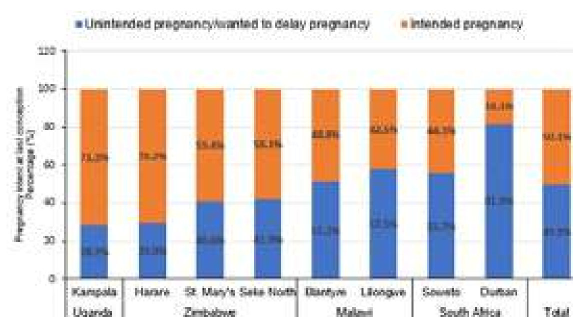
High frequency of unintended pregnancy and predictors of contraceptive choice among HIV-infected African women on life-long antiretroviral therapy (ART). The US-PEPFAR PROMOTE Cohort Study

J. Aizire[1], N. Yende[2], T. Nematadzira[3], M.E. Nyati[4], S. Dadabhai[1], L. Chinula[5], C. Nakaye[6], M. Naidoo[7], M.G. Fowler[8], T. Taha[1], US-PEPFAR PROMOTE Cohort Study
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Data Management Centre (DMC), Durban, South Africa, [3]University of Zimbabwe College of Health Sciences, Harare, Zimbabwe, [4]Perinatal HIV Research Unit (PHRU), Chris Hani Baragwanath Hospital University of the Witwatersrand, Johannesburg, South Africa, [5]University of North Carolina - Lilongwe, Lilongwe, Malawi, [6]Makerere University Johns Hopkins University (MUJHU), Kampala, Uganda, [7]Centre for The AIDS Research in South Africa (CAPRISA), Umlazi Clinical Research Site, Nelson R. Mandela School of Medicine, Durban, South Africa, [8]Johns Hopkins University, School of Medicine, Pathology-Medical Microbiology, Baltimore, United States

Background: About 90% of unintended pregnancies among African women are attributed to non-use of effective family planning (EFP) methods (injectable, oral, intra-uterine device (IUD), implant, or tubal-ligation). Long acting reversible contraceptives (LARC), which include implants or IUDs, are the most effective reversible contraception for an extended period without requiring user action. We report frequency of unintended pregnancy and determinants of contraceptive choice among African women on life-long ART.
Methods: The US-PEPFAR PROMOTE is a long-term cohort study of HIV-infected women (n=1,986) and their children, enrolled from December 2016 to June 2017, as an extension to a completed mother-to-child transmission prevention trial from eight sites in Malawi, South Africa, Uganda, and Zimbabwe. Standardized questionnaires were used to collect demographic and reproductive health data. Baseline enrollment data were analyzed using chi square and Wilcoxon Rank-Sum tests for group comparisons, and multivariable logistic regression to identify determinants of contraceptive choice.
Results: Overall, among 1,984 women included in this analysis, 49.9% (n=990) reported that their last pregnancy was unintended (figure 1), and >50% had no desire for more children.



[Fertility desire at last conception among HIV-infected women on Antiretroviral Therapy (ART) reported at study entry]

Among sexually-active, non-pregnant women, 81.6% (1,050/1,287) reported EFP use; while 19.0% (227/1,197) without permanent contraception reported LARC methods. Injectables were the commonest method (39%) - especially at the South African sites (>50%), followed by implant (14.4%). Oral pills were popular in Zimbabwe and tubal-ligations were common in Malawi and South Africa. Non-pregnant women whose last pregnancy was unintended versus intended were more likely to report current EFP use, adjusted odds ratio (95% CI), 1.44 (1.10 -1.96), p=0.02; but not LARC use, 1.25 (0.92-1.70), p=0.15. Women with no formal employment were less likely to report LARC use, 0.64 (0.43-0.96), p=0.03, but not EFP-use, 0.92 (0.62-1.35), p=0.60. All multivariable models included

age, marital-status, attained desired number of children, clinic travel-time, household water, and electricity, which were not associated with contraception choice.

Conclusions: Unintended pregnancy is common among HIV-infected African women. LARCs are acceptable contraceptive options in these settings, though under-utilized. Programmatic research should explore integrated ART and LARC delivery in consideration of the unique reproductive health challenges among HIV-infected African women on universal ART.

Tenofovir alafenamide pharmacokinetics with and without cobicistat in pregnancy

J.D. Momper[1], B. Best[1], J. Wang[2], A. Stek[3], T.R. Cressey[4], S. Burchett[5], R. Kreitchmann[6], D.E. Shapiro[2], E. Smith[7], N. Chakhtoura[8], E.V. Capparelli[1], M. Mirochnick[9], IMPAACT P1026s Protocol Team

[1]University of California, San Diego, La Jolla, United States, [2]Harvard University, Boston, United States, [3]University of Southern California, Los Angeles, United States, [4]Chiang Mai University, Chiang Mai, Thailand, [5]Boston Children's Hospital, Boston, United States, [6]Irmandade da Santa Casa de Misericordia de Porto Alegre, Porto Alegre, Brazil, [7]National Institute of Allergy and Infectious Diseases, Bethesda, United States, [8]National Institute of Child Health and Human Development, Bethesda, United States, [9]Boston University, Boston, United States

Background: Tenofovir alafenamide (TAF), a prodrug of tenofovir (TFV), has enhanced stability in plasma and improved safety compared to tenofovir disoproxil fumarate (TDF). TAF is administered as part of a fixed-dose combination either with or without the pharmacokinetic (PK) booster cobicistat (COBI). As COBI inhibits transporters involved in the disposition of TAF, co-administration of TAF with COBI results in higher TAF exposure. The PK of TAF have not been studied in pregnant women. This study described TAF exposure when administered with and without COBI during pregnancy and postpartum.

Methods: IMPAACT P1026s is an ongoing, nonrandomized, open-label, multi-center study of antiretroviral PK in HIV-infected pregnant women. Steady-state PK profiles of TAF following once-daily dosing of either TAF/FTC/RPV (25/200/25 mg, Odefsey®) or TAF/FTC/EVG/COBI (10/200/150/150 mg, Genvoya®) were obtained during the 2nd and 3rd trimesters (2T/3T) and 6-12 weeks postpartum (PP). TAF plasma concentrations were measured by a validated LC-MS/MS method. A two-tailed Wilcoxon signed rank test (=0.10) was employed for paired within-subject comparison of PK parameters.

Results: A total of 42 subjects from the US were enrolled with a median age at delivery of 30.4 years (range 19.1-38.8). For the TAF 25 mg arm, TAF exposure was lower and oral clearance was higher in 3T compared to PP (Table 1). For the TAF/COBI arm, no differences were seen between any ante-partum and post-partum PK parameters. HIV RNA at delivery was < 50 copies/mL for 10/11 women in the TAF 25 mg arm and 24/27 women in the TAF/COBI arm. Median infant gestational age and weight at birth were 38.9 weeks and 3.24kg, respectively. Congenital anomalies considered possibly related to study drugs included a ventral septal defect in one infant and congenital pseudoarthrosis of the left clavicle and neonatal compartment syndrome in another infant. Overall 27/41 infants were HIV-negative and 14 were indeterminate/pending.

Conclusions: In women taking TAF without COBI, TAF exposure was lower in 3T compared to PP, whereas no differences were seen between pregnancy and PP in women taking TAF with COBI. Before TAF can be recommended for use in pregnancy additional safety and outcome data as well as intracellular PK data are needed.

Effect of pregnancy on raltegravir free concentrations

Y. Zheng[1], D. Hirt[1], S. Benaboud[1], J. Lechedanec[2], J.-M. Tréluyer[1], S. Delmas[2], E. Arezes[2], J. Warszawski[2], J. Ghosn[3], ANRS 160 RalFe Study Group

[1]Hopital Cochin Laboratoire Pharmacologie, Paris, France, [2]Hôpital Kremlin-Bicêtre, Paris, France, [3]Hôpital Hôtel-Dieu, Infectious Diseases, Paris, France

Background: Raltegravir can be used for the prevention of mother-to-child HIV transmission, especially when a rapid decline of HIV RNA load is necessary. Physiological changes during pregnancy have an impact on raltegravir elimination. Indeed, exposure of total raltegravir were shown to decrease from 29 to 50% during the third trimester of pregnancy compared to postpartum. However albumin level is known to be lowered during pregnancy which could increase the active free fraction of the drug and reduce this effect. The objective of this study was to describe the unbound, total and glucuronide raltegravir pharmacokinetics during pregnancy.

Methods: The RalFe ANRS160 study was a non-randomized, open label, multicenter phase II trial in HIV-infected pregnant women receiving raltegravir 400 mg twice daily. Samples were collected during pregnancy (between 30 and 37 weeks of amenhorrea), at delivery and at postpartum (4 to 6 weeks after delivery). None of these women received an antiretroviral drug which could interact with raltegravir. Free raltegravir, total raltegravir and raltegravir glucuronide concentrations were measured using a validated liquid chromatography-tandem mass spectrometry and ultrafiltration methods. A population pharmacokinetic model was developed by using NONMEM software.

Results: A total of 414 samples were collected from 43 women, in which free, total and glucuronide raltegravir concentrations were measured. Free raltegravir was described by a one-compartment model with first order absorption and lag time, evolving either to bound raltegravir (by a linear binding to albumin), or metabolism to raltegravir glucuronide (through an additional compartment) or to a first order elimination. Pregnancy increased free raltegravir clearances : by 26% for glucuronide formation and 17% for other elimination. During pregnancy, trough concentrations and exposures decreased by 28 and 37% for total raltegravir and by 25 and 22% for free raltegravir. The decrease was low for the glucuronide form.

Conclusions: This is the first data reporting raltegravir free and glucuronide pharmacokinetics during pregnancy. Pregnancy effect is moderate on the active raltegravir free fraction, especially when compared to its intersubject variability. This effect is not considered to be of clinical importance; raltegravir doses do not need to be modified during pregnancy.

THAB0304

Lack of viral load testing in pregnancy is a barrier to breastfeeding among HIV-infected women in Botswana

G.K. Mayondi[1], R. Zash[1,2,3], S. Moyo[1,4], M. Diseko[1], J. Mabuta[1], G. Mogomotsi[5], E. Dintwa[5], J. Makhema[1], R. Falama[6], M. Mmalane[1], S. Lockman[1,2,7], M. Essex[1,2], R. Shapiro[1,2]

[1]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]Beth Israel Deaconess Medical Center, Boston, United States, [4]Harvard T.H. Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [5]Ministry of Health and Wellness, Gaborone, Botswana, [6]Kanye Seventh Adventist Hospital, Kanye, Botswana, [7]Brigham and Women's Hospital, Boston, United States

Background: Breastfeeding reduces child morbidity and mortality, including among HIV-infected women. Botswana updated its antiretroviral treatment (ART) guidelines in May 2016 to support breastfeeding for HIV-infected women on ART who have documented viral suppression during pregnancy. We describe infant feeding choices among HIV-infected mothers since new guidelines were implemented.

Methods: We abstracted data from obstetric records of all HIV-infected women discharged with a live infant from 8 government maternity wards from September 2016-December 2017. We validated the reported feed-

ing method using the PMTCT counselor report, formula dispensing log or direct observation. We evaluated obstetric card documentation of any viral load in pregnancy. All pregnant women were eligible to start ART and continue life-long, regardless of CD4 cell count.

Results: Among 6845 HIV-infected women with a live infant, 6473 had a validated feeding method at discharge from maternity and were included in the analysis. ART coverage was high (95%) among all women: 58% started ART prior to conception, 37% started in pregnancy, and 96% with a known ART start date had received at least 8 weeks of ART prior to delivery. At discharge, 2553(39%) of the HIV-infected women were confirmed to be breastfeeding (Table 1). Of 4573 records assessed, only 412(9%) women had viral load result (VL) documented at any time during pregnancy; of these, 400(97%) were suppressed to < 400 copies/ml. Among women with documented suppressed VL during pregnancy, 228(57%) chose breastfeeding compared with 1519(37%) of women without documented viral load testing in pregnancy (p< 0.0001). Four (33%) of 12 women with VL>400 copies/ml and 72(27%) of 270 women with no reported ART use in pregnancy, chose to breastfeed.

Conclusions: The low rate of breastfeeding among HIV-infected women in Botswana underscores the need to address barriers affecting feeding choices. Although the majority of pregnant women tested have a suppressed viral load and might be eligible for breastfeeding per Botswana guidelines, few women currently receive viral load testing in pregnancy. The viral load testing requirement in HIV-infected pregnant women is therefore unlikely to prevent a substantial amount of HIV transmission during breastfeeding, but likely contributes to low rates of breastfeeding in Botswana.

Chan School of Public Health, Boston, United States, [10]University of Liverpool, Department of Molecular & Clinical Pharmacology, Liverpool, United Kingdom

Background: Triple-drug antiretroviral prophylaxis of zidovudine (AZT) / lamivudine (3TC) / nevirapine (NVP) is preferred among HIV-exposed neonates with high-risk of transmission in many countries, including Thailand. This study aimed to assess safety of triple-drug neonatal prophylaxis and NVP trough concentrations (C_{24}) over the first 28 days of life.

Methods: A prospective cohort of 200 HIV-exposed infants was conducted at 5 clinical sites in Thailand. We enrolled 100 high-risk HIV-exposed neonates (maternal HIV RNA >50 copies/mL prior to delivery or received antiretroviral therapy (ART) < 12 weeks) who received AZT/3TC twice daily, plus NVP (4 mg/kg/dose) once daily, from birth for 6 weeks, and 100 standard-risk HIV-exposed neonates who received a 4-week regimen of AZT. Blood tests to assess hematologic and liver toxicities were performed at birth, 1, 2 and 4 months of life. Sparse plasma NVP concentrations were collected at day 1, 2, 7, 14, and 28 and assayed by a validated liquid chromatography-mass spectrometry assay.

Results: From October 2015 to November 2017, 200 infants were enrolled. Median (IQR) gestational age and birth weight were 38 (37-39) weeks and 2,873 (2,590-3,184) g, respectively. Common maternal ART regimens were TDF/3TC or FTC (58%), AZT/3TC(32%) in combination with EFV (45%), ritonavir boosted protease inhibitor (28%). There was no significant difference of adverse events between triple prophylaxis and AZT alone (Table 1). Median (IQR) hemoglobin level among infants who received triple prophylaxis were 9.9 (9.0-11.4) g/dL, 10.1 (9.3-11.0), and 11.7 (11.0-12.3) at aged 1, 2 and 4 months, respectively, which did not significantly differ between groups. No infants required blood transfusion. NVP concentrations were available from 48 infants (135 samples); median predicted NVP C_{24} were 1,336 ng/mL, 2,241, 2,782, 2,197, and 812 on days 1, 2, 7, 14, and 28 of life, respectively (Figure 1). All infants maintained NVP concentrations above the proposed prophylactic target threshold of 100 ng/mL during the first 4 weeks. Maternal EFV treatment did not affect infant NVP levels.

Conclusions: Six-weeks of AZT/3TC/NVP in HIV-exposed infants did not increase the risk of toxicity compared with an AZT regimen. Administration of 4 mg/kg of NVP from birth provided adequate NVP concentrations for prophylaxis during the first 4 weeks of life.

Adverse event rates+	6-week AZT/3TC/NVP prophylaxis (n=100)	4-week AZT prophylaxis (n=100)	p-value*

THAC01 New tools, old tricks: Innovative methods for understanding the epidemic

THAC0101

The identification of a micro-epidemic in a hyper-endemic HIV setting using molecular epidemiology

C. Coltart[1,2], F. Tanser[2], D. Gareta[2], S. Ntuli[2], T. de Oliveira[3], D. Pillay[2], A. Johnson[1], S. Hue[4]
[1]University College London, Institute for Global Health, London, United Kingdom, [2]Africa Health Research Institute, KwaZulu-Natal, South Africa, [3]University of KwaZulu-Natal, Durban, South Africa, [4]LSHTM, London, United Kingdom

Background: Understanding transmission dynamics of infectious diseases is critical in developing effective interventions. Traditional epidemiological analyses are the bedrock of many public health decisions, but can be resource-intensive and may be limited by incomplete/inaccurate datasets. Since HIV gene sequences can provide information not contained in traditional case data, considerable efforts are now invested in generating genomic data. However, the value of such data for epidemiological surveillance remains unclear. We illustrate how incorporating genomic data with traditional epidemiological analyses provides additional insight for surveillance, with potential to inform prevention strategies.

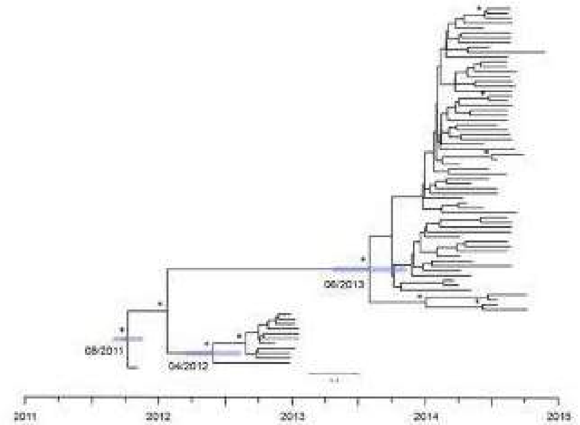
Methods: We used routinely-collected AHRI data to undertake a combined phylogenetic and epidemiological investigation.

A phylogeny of 2,179 HIV-1 subtype-C partial pol sequences was reconstructed by maximum-likelihood inference. This included 1,376 local sequences (2010-14, 15% of the HIV-positive population) and 803 publicly-available South African control sequences (2000-14). A dated phylogeny was inferred using Beast2 and reproduction numbers(R_e) estimated. We geo-located individuals to their residence and undertook space-time analyses to identify variations in HIV incidence.

Results: Phylogenetic reconstruction revealed a previously undetected distinct monophyletic cluster (75 local sequences; branch support>90%). The dated phylogeny suggests this outbreak emerged from a single common source, experienced two bursts of infection (2012&2013/4; R_e>1.8) and was still expanding at the time of sampling (2014)(Figure 1). Geo-locating individuals/sequences revealed over 40% resided within a rural area adjacent to a recent (2008) coal mine development. Baseline characteristics of the cluster suggest demographics compatible with those working in the mine (higher proportion of employed males). Space-time analysis confirmed the emergence of this rural cluster by identifying increased HIV incidence in the locality of the mine.

To our knowledge, this is the first time molecular methods have detected a micro-epidemic not identified via traditional epidemiological surveillance.

Conclusions: By uncovering a micro-epidemic our findings demonstrate that molecular epidemiology enhances traditional epidemiological analysis. Genomic data are a valuable addition to routine surveillance data, particularly in allowing detection of emerging micro-epidemics in a hyper-endemic region. Although, at present, implementation may be unrealistic in resource-poor settings, sequence data is becoming increasingly affordable, and molecular methods should be considered to enhance surveillance and guide the development of optimal intervention strategies.



[Figure 1.Dated Phylogeny of identified cluster.
This shows that the cluster emerged from a common single ancestral source in approximately August 2011 (confidence intervals between July and September) There appear to be two distinct (non-overlapping) outbursts of infections within this cluster - one in 2012 and one in 2013]

THAC0102

High prevalence fishing communities are not a major source of new HIV infections to the inland populations in Rakai District, Uganda: Implications for geo-spatially targeted HIV prevention interventions

O. Ratmann[1,2], M.K. Grabowski[3,4], M. Hall[5], T. Golubchik[5], C. Wymant[2,5], J. Kagaayi[4], G. Kigozi[4], T. Quinn[3,6], M. Wawer[4,7], O. Laeyendecker[3,6], D. Serwadda[4,8], R. Gray[3,4,7], C. Fraser[5], PANGEA-HIV Consortium and Rakai Health Sciences Program
[1]Imperial College London, Mathematics, London, United Kingdom, [2]Imperial College London, School of Public Health, London, United Kingdom, [3]Johns Hopkins Bloomberg School of Public Health, Medicine, Baltimore, United States, [4]Rakai Health Sciences Program, Entebbe, Uganda, [5]University of Oxford, Oxford Big Data Institute, Li Ka Shing Centre for Health Information and Discovery, Nuffield Department of Medicine, Oxford, United Kingdom, [6]National Institute of Allergy and Infectious Diseases, Division of Intramural Research, Bethesda, United States, [7]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [8]Makerere University School of Public Health, Kampala, Uganda

Background: Targeting combination HIV prevention (CHP) to areas of high HIV prevalence is considered a cost-efficient and essential strategy for reducing HIV incidence in sub-Saharan Africa. Since 2014, the Ugandan National Antiretroviral Therapy Guidelines recommend targeted CHP to fishing communities on Lake Victoria, with an estimated HIV prevalence 25%-40%, partly based on the assumption that fishing sites are a major source of HIV transmissions to the inland populations; however the validity of this assumption has not been empirically evaluated.

Methods: Between August 2011 and Oct 2014, individuals aged 15-49 years in 40 communities in Rakai District, Uganda, were tested for HIV and interviewed (sociodemographic, behavioral and health information).

Households were geocoded, and communities were classified as Lake Victoria fishing (n=4), agrarian (n=27), or main road trading (n=9) communities. Viral RNA from newly diagnosed participants was deep sequenced via *Illumina* instruments. The *phyloscanner* software package (https://github.com/BDI-pathogens/phyloscanner) was used to reconstruct HIV transmission networks, and to infer the direction of HIV transmission from deep sequence data. Transmission flows between fishing sites and agragrian/trading communities were estimated with Bayesian multi-level models.

Results: Of 23,719 individuals surveyed, 6205 were HIV-positive, 4309 (69%) were antiretroviral naive, of whom 2,803 (65%) were sequenced. 359 phylogenetically likely transmission events involving 676 individuals were reconstructed, with an estimated, expected 16% [11%-23%] of false reconstructions. Direction of transmission could be inferred in 241 likely transmission events, with an estimated, expected 14% [7%-26%] of false directions. Only 3/241 transmission events occurred from fishing sites to agrarian/trading communities. Adjusting for differences in participation and sequence sampling by age and community, an estimated 34.3% [28.6%-40.5%] of transmissions occurred within fishing sites, 58.0% [51.2%-64.6%] within agrarian/trading communities, 3.4% [1.7%-6%] from fishing sites to agrarian/trading communities, and 4.0% [2%-7.2%] from agrarian/trading communities to fishing sites.

Conclusions: HIV is infrequently transmitted from 4 high-prevalence fishing sites to the population in 36 agrarian/trading communities further inland, based on population-level NGS viral phylogenetic analysis. Our results suggest that targeted CHP to Lake Victoria fishing sites would not mitigate the broader HIV epidemic. Further studies in sub-Saharan Africa are needed to assess the strategy of targeting CHP to various high prevalence hotspots.

THAC0103

An RNA-seq gene expression signature identifies early HIV infection in rural Mozambique

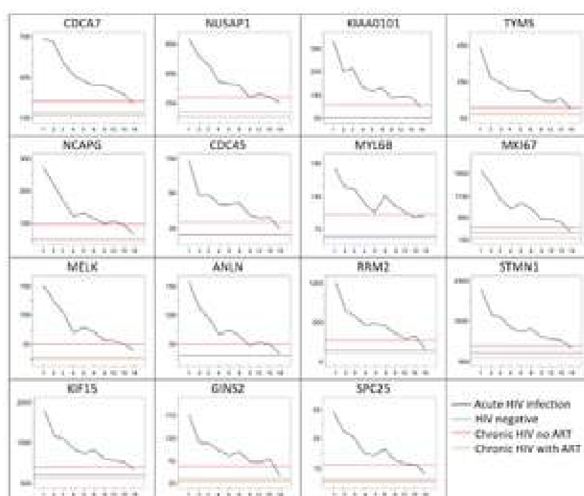
M. Judge[1], E. Parker[1], L. Pastor[2,3], L. Fuente-Soro[2], C. Jairoce[4], K. Carter[5], D. Anderson[5], D. Naniche[2,4], P. Le Souëf[1]

[1]University of Western Australia, School of Paediatrics and Child Health, Perth, Australia, [2]ISGlobal, Barcelona Centre for International Health Research (CRESIB), Barcelona, Spain, [3]AIDS Research Institute - IrsiCaixa, Barcelona, Spain, [4]Centro de Investigação em Saúde da Manhiça (CISM), Manhiça, Mozambique, [5]Telethon Kids Institute, Perth, Australia

Background: Accurate measurement of HIV incidence is crucial in determining the effectiveness of preventative and therapeutic interventions, yet remains a global challenge. This study employed RNA-seq to investigate changes in human gene expression during early HIV-1 infection with the objective of identifying a transcriptomic signature able to differentiate early from long-standing infection.

Methods: Individuals presenting to Manhiça District Hospital, Mozambique were screened for acute HIV infection (AHI), defined by positive viral load prior to seroconversion, with follow-up over 18 months. Uninfected subjects, plus those with longstanding HIV, with and without anti-retroviral therapy (ART), were recruited as controls. Peripheral blood mononuclear cells were collected and RNA extracted using RNeasy MinElute Clean-up kit (Qiagen). Illumina 50bp, single-end RNA-seq was performed. Read quality was assessed using FastQC. Reads were aligned to human reference genome hg19 using HISAT. Alignment quality was assessed using Samstat. Quantification and normalisation of read counts was performed using summarizeOverlaps (*GenomicAlignments* package) and voom (*limma* package), both from Bioconductor. Random Forest assessed the predictive accuracy of sample classification. Statistical analyses were performed using R version 3.2.0.

Results: Fifty-three AHI individuals had a median estimated time since infection of 9 weeks (IQR 7.8-19.3 weeks). RNA-seq was performed on 164 longitudinal samples from the AHI cohort, as well as 54 HIV negative, 24 chronic without ART, and 24 chronic with ART samples, resulting in an average of 23 million reads per sample, with 80% of reads mapped at high accuracy. All samples passed pre-and post-alignment QC. Fifteen genes were significantly differentially expressed during AHI compared with all controls (Figure 1). Random Forest analysis was able to predict biological group with a sample-level error rate of 0.26.



[Figure 1: Expression patterns of the fifteen gene that are differentially expressed during early HIV infection compared to all controls]

Conclusions: This exploratory transcriptomic analysis was able to identify a gene expression signature unique to early HIV infection, most effective at distinguishing the initial three months from longer-term infections. For individual samples, acute infections and chronic infections with ART had high identification accuracy, however chronic untreated infection samples were harder to distinguish from early infection. The gene candidates in Figure 1 are clearly differentially expressed during early infection, compared with all controls, indicating useful pathways for future incidence assay optimisation.

THAC0104

Size estimation of key populations for HIV in Singapore using the network scale-up method

A.K.J. Teo[1], K. Prem[1], M.I.-C. Chen[1,2], A. Roellin[3], M.L. Wong[1], H.H. La[4], A.R. Cook[1]

[1]Saw Swee Hock School of Public Health, National University of Singapore, Singapore, Singapore, [2]Tan Tock Seng Hospital, Department of Clinical Epidemiology, Singapore, Singapore, [3]National University of Singapore, Department of Statistics and Applied Probability, Singapore, Singapore, [4]Center for High Impact Philanthropy and Center for Public Health Initiatives, University of Pennsylvania, Philadelphia, United States

Background: The size of populations at-risk for HIV in Singapore has yet to be systematically estimated. Using the network scale-up (NSU) approach, we developed a localised instrument and Bayesian statistical method to generate size estimates—adjusted for transmission error—of at-risk populations in Singapore.

Methods: We conducted nine in-depth interviews and four focus groups discussions with key stakeholders to guide the development of the survey questionnaire. In total 199 participants recruited from the Singapore Population Health Studies cohort reported their socio-demographic information, opinions about certain behaviours and the social standing of different groups of people, and quantified the number of people whom they knew. We developed a Bayesian hierarchical NSU model to estimate the number of individuals in four hidden populations at-risk of HIV in Singapore. The method accounted for both transmission error and barrier effects using social acceptance measures and demographics.

Results: The adjusted size estimate of the population of male clients of female sex workers was 72 000 (95% CI: 51 000-100 000), of female sex workers 4 200 (95% CI: 1 600-10 000), of men who have sex with men 210 000 (95% CI: 140 000-300 000), and of intravenous drug users 11 000 (95% CI: 6 500-17 000). Average estimated personal network sizes were 140 (95% CI: 82-238).

Conclusions: The network scale-up method with adjustment for attitudes and demographics allows national-level estimates of multiple priority populations to be determined from simple surveys of the general population, even in relatively conservative societies.

THAC0105

Demographic transitions and the future of the HIV epidemic for children and adolescents

A. Khalifa[1], C. Lwamba[1], T. Porth[1], S. Essajee[2], D. Walker[2], L.D. Tsage[3], A. Bains[4], C. Luo[2]
[1]United Nations Children's Fund, Data, Research and Policy, New York, United States, [2]United Nations Children's Fund, Programme, New York, United States, [3]United Nations Children's Fund, West and Central Africa Regional Office, Dakar, Senegal, [4]United Nations Children's Fund, Eastern and Southern Africa Regional Office, Nairobi, Kenya

Background: Despite progress in the HIV response, new infections among adolescents and youth (AY) aged 15-24 in Sub-Saharan Africa (SSA) have only reduced by an average 3%/year since 2010. By 2050, the number of AY in SSA will increase by 85%. This demographic transition may impact the HIV epidemic and service needs for future generations. We used population statistics and recent epidemic trends to characterize the future of the HIV epidemic in SSA.
Methods: For 46 countries, we organized UNAIDS HIV estimates and UN population projections into five-year age groups by sex. HIV incidence and prevalence was calculated from 2010 to 2016. After analyzing trends, 2014-2016 data reflecting recent progress in disease control were selected to inform regression analyses by country, age and sex.
An exponential curve was applied for downward incidence trends and a linear curve for upward incidence trends and prevalence. From each regression, HIV incidence and prevalence was predicted until 2050. Incidence and prevalence were applied to projected populations in each year to determine new infection numbers.
Results were analysed to assess feasibility of epidemic control among AY 15-24, defined as 95% reduction in new infections since 2016.
Results: By 2050, new HIV infections will decrease by over 70% in Eastern and Southern Africa and by 2% in West and Central Africa. Overall, the SSA region will observe a 53% reduction in new HIV infections. None of 46 SSA countries will achieve epidemic control among AY by 2030. Botswana, Mozambique, Uganda, Zimbabwe, and Swaziland may reach epidemic control by 2050.
Of these five countries, Botswana, Swaziland, and Zimbabwe will reduce new infections among boys and men at least two years before they will in girls and young women.
Between 2017 and 2050, 9.6 million AY will become newly infected with HIV in SSA, 67% of which will occur among girls and young women.
Conclusions: While the world set a bold target of ending AIDS by 2030, epidemic control is unlikely among AY in SSA. Turning this demographic transition into a dividend will require better access to HIV prevention, sexual and reproductive health, and targeted testing services.

THAC02 Testing for 2030: Novel strategies for the home stretch

THAC0201

Delivering a high-quality comprehensive package of HIV prevention, care, and treatment for key populations is possible: Experience from two years of the FHI 360 LINKAGES Malawi project

G. Kamanga[1], L. Banda[1], L. Banda[1], C. Banda[1], M. Mkandawire[1], S. Kalyati[1], E. Mpunga[1], M. Gondwe[1], M. Ruberintwari[1], C. Akolo[2]
[1]FHI 360, Malawi, Global Health, Population and Nutrition, Lilongwe, Malawi, [2]FHI 360, Global Health, Population and Nutrition, Washington DC, United States

Background: In Malawi, HIV prevalence is 8.8 percent among the general population but higher among key populations (KPs): 62.7 percent among female sex workers (FSW) and 17.5 percent among men who have sex with men (MSM). FHI 360, through the USAID/PEPFAR-funded LINKAGES project, provides comprehensive HIV prevention, care, and treatment services for KPs. We present our experience implementing this project over a two-year period.
Description: We engaged government structures at all levels, KPs, and civil society organizations (CSOs) to get the project running. Programmatic mapping of hot spots and size estimation were conducted through engagement of KPs. Using a peer-led model, KPs were recruited to support others with HIV prevention services, linkage to care, antiretroviral therapy (ART), and retention. We built the capacity of peer leaders through trainings and microplanning, created safe spaces, and trained health care workers to mitigate stigma and discrimination.
Lessons learned: From October 2016 to June 2017, the project reached 9,601 FSWs, 3,609 (38 percent) of whom were already HIV positive, and 5,136 of whom were eligible for HIV testing; of the latter, 2,068 (40 percent) tested HIV positive and 1,862 (90 percent) were initiated on ART. The total number of HIV-positive cases detected, 5,677/9601 (59.1 percent), is close to the 62.7 percent estimated HIV prevalence among FSWs in Malawi. A total of 3,025 HIV-positive FSWs were enrolled in community care. We screened 13,827 FSWs for STIs, diagnosed 5,119 (37 percent) cases, and treated 5,108. Of 2,696 MSM reached with services, 2,561 were tested for HIV, 188 (7 percent) tested HIV positive, and 114 (61 percent) were initiated on ART. We screened 4,726 MSM for sexually transmitted infections, diagnosed 1,585 (34 percent) cases, and treated 1,507. Eighty-seven FSW and 39 MSM reported gender-based violence and received services. We identified 239 transgender women and are now receiving HIV prevention, care, and treatment.
Conclusions/Next steps: Empowered KP members positively contribute to their health. In addition, engagement with government, health care workers, and peer leaders is key to ensuring a successful KP program. Efforts are ongoing to document and scale up some of the best practices emanating from the program.

THAC0202

Key population-led health services: Community-based organizations and lay health workers transform HIV testing in Vietnam

H. Ngo[1], N.B. Vu[2], K. Green[2], H. Phan[3], H.S. Vo[3], M.T. Ngo[4], M.S. Le[5], T. Le[6], H.A. Doan[2], A. Bao[7]
[1]PATH, Healthy Markets, Ha Noi, Vietnam, [2]PATH, Ha Noi, Vietnam, [3]Ministry of Health, Ha Noi, Vietnam, [4]USAID, Ha Noi, Vietnam, [5]G3VN, Ho Chi Minh City, Vietnam, [6]G-LINK, Ho Chi Minh City, Vietnam, [7]PATH, Ho Chi Minh City, Vietnam

Background: Vietnam became the first Asian country to adopt global 90-90-90 targets, despite low annual uptake (~30%) of HIV testing among key populations (KPs). Up until late 2015, lay providers were not allowed to offer HIV testing, although studies indicated KP preference for community testing services.
Description: The USAID/PATH Healthy Markets project and Ministry of Health (MOH) piloted HIV lay provider testing in four provinces. From October 2015-September 2017, services were delivered by KP-led community-based organizations (CBOs) in urban areas and village health workers (VHWs) in rural areas, using blood- and oral fluid-based rapid diagnostic tests (RDTs). This was the first time CBOs were allowed to offer HIV services in Vietnam.
Trained CBOs/VHWs administered the RDT, interpreted results, provided post-test counseling supported those that were HIV-reactive to seek confirmation testing, and their enrollment in treatment. Coaching was provided to trained lay providers to reinforce service quality. 59,333 clients were HIV-tested, 2,503 (4.2%) were newly diagnosed HIV-positive and 90% enrolled in treatment.
Lessons learned: The pilot generated four key lessons: First, that CBOs/VHWs were capable of offering HIV testing with exceptional skills, and engagement in lay testing significantly boosted CBO confidence and pride in their work. Second, CBOs/VHWs were very effective in facilitating ART enrollment among those HIV-diagnosed. Third, among those tested by lay testers, more than half were first time testers, and 4.2% were newly HIV-diagnosed (compared to 1.6% among KPs testing in public sites). This suggests trust among KP for HIV lay provider services. Last, fostering close MOH engagement and observation of CBO/VHW testers rapidly translated into national trust and support for their work.
Conclusions/Next steps: Stepwise rollout of HIV lay provider testing positively disrupted the status quo, and has opened the door for KP-led HIV services. The pilot led to the development of national HIV commu-

nity testing guidelines and training package, and rapid adoption of the approach by the MOH, PEPFAR partners and Global Fund. For the future, it will be critical to target HIV lay testing to localities that need it most, and secure domestic financing sustained service delivery.

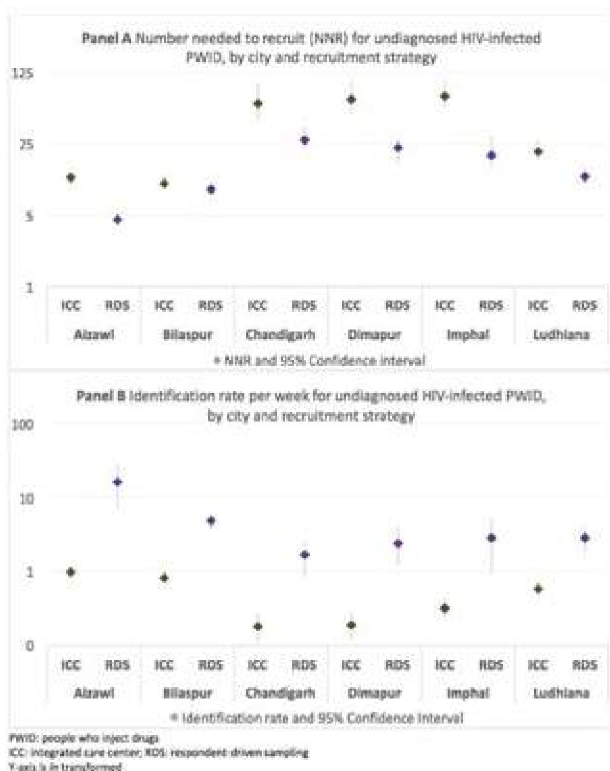
THAC0203

Respondent-driven sampling more efficiently identifies undiagnosed HIV-infected people who inject drugs (PWID) than PWID-targeted community integrated care centers in India

A.M. McFall[1], S.S. Solomon[2], A.K. Srikrishnan[3], S. Anand[3], C.K. Vasudevan[3], G.M. Lucas[2], S.H. Mehta[1]
[1]*Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States,* [2]*Johns Hopkins University School of Medicine, Baltimore, United States,* [3]*YR Gaitonde Centre for AIDS Research and Education, Chennai, India*

Background: Injection drug use drives HIV epidemics in many low-resource settings. Yet, many people who inject drugs (PWID) are inadequately engaged in HIV services, resulting in low awareness among HIV-infected PWID. Respondent-driven sampling (RDS), a method using peer connections, is widely used in research among key populations. We assessed the ability of RDS to identify undiagnosed HIV-infected PWID compared to integrated care centers (ICCs) in India.

Methods: In 6 Indian cities from 2014-2017, ICCs provided PWID-tailored services such as HIV counseling/testing and needle exchange; ICC utilization was voluntary. In these same cities from 2016-2017, an RDS sample of 1000 PWID/city was conducted; RDS participants were compensated for time and referrals. The number needed to recruit (NNR) (number of PWID screened in order to find one undiagnosed person living with HIV [PLWH]) and the identification rate (number of undiagnosed PLWH identified per week) assessed the efficiency of RDS vs. ICCs. Undiagnosed PLWH were individuals who tested positive and denied a prior diagnosis. Multinomial logistic regression was used to explore characteristics associated with identification by RDS only and RDS & ICC, both in comparison to ICC only.



[Figure: Number needed to recruit (NNR) and identification rate for undiagnosed HIV-infected PWID in India]

Results: Across the 6 cities, there were 10,759 ICC clients and 6,012 RDS participants; 40% of RDS participants were ICC clients (confirmed via biometrics) resulting in 14,397 unduplicated PWID, of which 753 (5%) were undiagnosed PLWH. The RDS NNR ranged from 5 to 27 and the ICC NNR ranged from 10 to 74. The NNR was lower for RDS versus the ICC in all but one city, Bilaspur (*Figure*). The RDS identification rate (1.7 to 2.8/week) was faster than the ICC identification rate (0.2 to 1.0/week) in all cities (*Figure*). PWID identified by RDS vs. the ICC only were more likely to be male (adjusted odds ratios [aOR] RDS only: 6.8, both: 2.7) and HIV-infected but undiagnosed (aOR RDS only: 2.5, both: 1.5).

Conclusions: In India, RDS required screening fewer PWID and more rapidly identified undiagnosed PLWH as compared to ICCs. Network-driven recruitment strategies with moderate compensation could be considered to identify and engage groups of PWID not currently visiting venues where HIV and harm reduction services are available.

THAC0204

Integrated gender affirmative hormone treatment services improve access to and retention in HIV testing, syphilis testing and pre-exposure prophylaxis (PrEP) service uptake among transgender women in Thailand

R. Janamnuaysook[1], K. Samitpol[1], P. Ketwongsa[1], A. Chancham[1], J. Kongkapan[1], P. Mingkwanrungruang[1], R. Meksena[1], P. Rattakitvijunnanakorn[1], N. Teachatanawat[1], S. Mills[2], S. Charoenying[2], S. Umasa[2], R. Vannakit[3], P. Phanuphak[1], N. Phanuphak[1]
[1]*Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand,* [2]*FHI 360 and USAID LINKAGES Project, Bangkok, Thailand,* [3]*United States Agency for International Development, Office of Public Health, Bangkok, Thailand*

Background: Despite the growing recognition of gender affirmative hormone treatment (GAHT) as an essential part of comprehensive health care for transgender women, evidence is limited on the roles of GAHT-services in HIV programming for transgender women. We examined the potential role of GAHT-services as an entry-point to facilitate uptake of HIV and other sexual health services.

Methods: Established in 2015, the Tangerine Community Health Center is the first clinic in Asia where fee-based GAHT-services are fully integrated with HIV services. Characteristics of transgender women clients and their access to GAHT-services and other health services were recorded. We compared the uptake of HIV and other sexual health services between transgender women who accessed or did not access GAHT-services.

Results: Of 972 transgender women who attended the clinic between November 2015-December 2017, median (IQR) age was 25.4 (22.5-30) years, 55% had education below bachelor's degree, 25% were unemployed, 56% used alcohol, and 10% used amphetamine-type stimulants. GAHT-services were used by 34% of transgender women. At baseline, 91% received HIV testing, and HIV prevalence was 12%. Antiretroviral therapy initiation was successful in 80%. Transgender women who did not use GAHT-services had lower income (65% vs. 45% earned < $571/month, p< 0.001), higher HIV prevalence
(13% vs. 3%, p< 0.001), and a trend toward higher HIV incidence than those who used GAHT-services. Compared to clients not accessing GAHT-services, GAHT-service clients were more likely to re-visit the clinic (50% vs. 34%, p< 0.001), had higher rates of repeat HIV testing (32% vs. 25%, p=0.019), repeat syphilis testing (14% vs. 9%, p=0.026), PrEP uptake (10% vs. 6%, p=0.015), and use of other sexual health services, including hepatitis B testing/vaccination and sexually transmitted infection treatment (50% vs. 34%, p< 0.001).

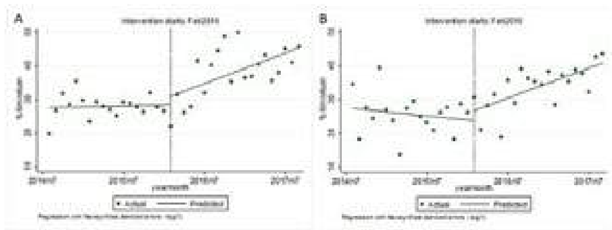
Conclusions: Integration of GAHT-services into HIV programming in this cohort showed improvement of retention in the program and subsequent increase of sexual health service utilization, including PrEP. Transgender women not accessing GAHT-services appeared to be highly vulnerable to HIV infection. HIV program managers, policymakers, and institutional donors should consider investing in well-tailored, subsidized, and comprehensive HIV and sexual health service packages that fully integrate GAHT-services for transgender women.

THAC0205

Continuing structural barriers to HIV/STI testing for migrants attending a community-based HIV testing service in Melbourne, Australia

K. Ryan[1], A. Wilkinson[2], D. Leitinger[3], P. Locke[3], A. Pedrana[1], M. Hellard[1], M. Stoove[1]
[1]Burnet Institute, Public Health Discipline, Melbourne, Australia, [2]Cancer Council Victoria, Centre for Behavioural Research in Cancer, Melbourne, Australia, [3]Victorian AIDS Council, Melbourne, Australia

Background: In February 2016 PRONTO!, a peer-led community-based rapid HIV testing service, introduced STI (gonorrhoea, chlamydia, syphilis) testing and SMS reminders to improve return HIV testing. HIV testing is free for all clients. Clients eligible for Australia's universal healthcare system, including Australian, New Zealand and UK citizens (eligible), receive free STI testing. Citizens of other countries (ineligible) pay up to $158AUD upfront. We determined changes to return-HIV testing pre- and post-service changes among eligible and ineligible clients to explore ongoing barriers to accessing sexual healthcare among migrants.
Methods: All HIV tests conducted between February 2014 and September 2017 with country of birth recorded were included in the analysis (February-July2014 allowed lead time to assess returning). We describe STI testing uptake and HIV/STI positivity among eligible and ineligible clients. Return HIV testing was compared between pre-intervention (August 2014-January 2016) and post-intervention (February 2016-September 2017) periods. Segmented linear regression of monthly aggregate data assessed changes in the percentage of tests that returned within 183 days (six month return testing) among eligible and ineligible clients across pre- and post-intervention periods. We report changes in six month return testing pre- to post-intervention (change in slope, 3), p< 0.05 was considered significant.
Results: This analysis included 2679 eligible and 1619 ineligible clients. Post intervention there was a significant difference in the proportion of HIV tests accompanied by STI tests among eligible clients (82%) and ineligible clients (49%; p< 0.01); however among those accessing testing, STI positivity was similar (12% and 12%, respectively). Four (0.3%) eligible and nine (1.1%) ineligible clients were diagnosed with HIV. Post-intervention, six month HIV return testing increased significantly among eligible (3 0.7% per month, 95%CI:0.1-1.3, p=0.02) clients from 22%-50% and ineligible (3 0.9% per month, 95%CI:0.4-1.5, p< 0.01) clients from 19%-44% (Figure 1).



[Figure 1. Six month return testing among eligible (A) & ineligible (B) clients pre (Aug 2014-Jan 2016) & post (Feb 2016-Sept 2016) service level changes]

Conclusions: Increases in six month HIV return testing were observed among eligible and ineligible clients following the introduction of STI testing and SMS reminders. However, the significantly lower uptake of fee-for-service STI tests among overseas-born clients compared to uptake of free STI tests among eligible clients suggests ongoing financial barriers to comprehensive HIV and STI testing in this group.

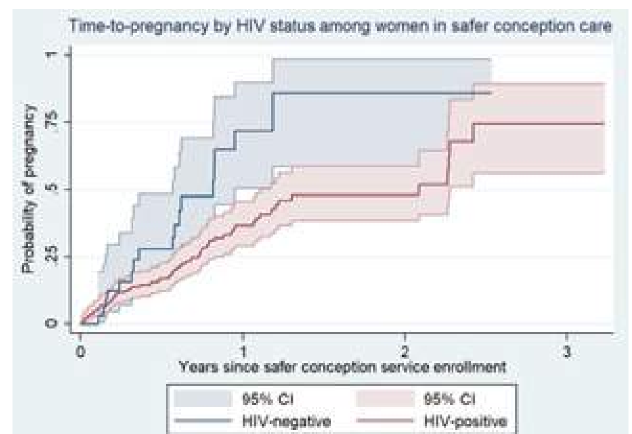
THAC03 Better care: Enhancing mother and child outcomes

THAC0301

HIV and pregnancy outcomes from the Sakh'umndeni Safer Conception Clinic

S. Schwartz[1], J. Bassett[2], M. Mudavanhu[2], N. Yende[2], R. Phofa[2], L. Mutunga[2], I. Sanne[3], A. Van Rie[4]
[1]Johns Hopkins University, Epidemiology, Baltimore, United States, [2]Witkoppen Health and Welfare Centre, Johannesburg, South Africa, [3]Clinical HIV Research Unit, University of the Witwatersrand, Johannesburg, South Africa, [4]University of Antwerp, Antwerp, Belgium

Background: Safer conception strategies--ART for HIV-positive partners, PrEP for HIV-negative partners, timed condomless sex, self-insemination and male medical circumcision--empower couples affected by HIV trying to conceive to minimize HIV transmission risk to partners and potential children. We report outcomes from the Sakh'umndeni demonstration project, one of the first safer conception clinics in sub-Saharan Africa.
Methods: Adults trying to conceive and in relationships in which at least one partner was HIV-positive were enrolled into safer conception care at Witkoppen Clinic in Johannesburg, South Africa, between July 2013-July 2017. Patients were provided tailored safer conception care by a nurse. Time-to-first pregnancy was estimated using Kaplan-Meier curves; women who did not conceive were censored at date of termination or last follow-up visit.
Results: 526 individuals (334 women/192 men) from 334 partnerships participated. Couples were serodifferent (n=164, 49%), seroconcordant (n=147, 44%) or in relationships with one unknown status partner (n=23, 7%). Median ages of women and men were 34 [IQR:30-38] and 37 [IQR:33-42] respectively. At baseline, 64% of HIV-positive women and 45% of HIV-positive men were virally suppressed (< 50copies/ml). It took couples a median of 4.0 months [IQR:1.7-7.7] to be given the go-ahead to start trying to conceive. In total, 98 pregnancies among 88 women were observed. Pregnancy incidence was 47.9/100 person-years (95%CI:38.9,59.1). HIV-positive women were 52% less likely to conceive as HIV-negative women (IRR:0.48, 95%CI:0.28,0.87). Median time-to-pregnancy was 0.8 years for HIV-negative and 2.1 years for HIV-positive women (Figure). At time of pregnancy, most HIV-positive women were virally suppressed (63/75 [84%] < 50 copies/ml and 74/75 [99%] < 1000 copies/ml]. Of the 98 pregnancies, 66 (67%) delivered a baby, 24 (25%) had a miscarriage or ectopic pregnancy, 5 (5%) were still pregnant and 3 (3%) unknown. No horizontal or vertical HIV transmissions were observed.
Conclusions: HIV-positive women were less likely to conceive than HIV-negative women and risk of miscarriage was high. Prolonged attempted conception highlights the need for approaches to reduce onward transmission risks, particularly as viral suppression among patients trying to conceive on ART cannot be assumed. Safer conception strategies can help couples successfully conceive an HIV-free child without jeopardizing their own or partner's health.



[Time-to-pregnancy among women enrolled in safer conception care, Johannesburg, South Africa]

THAC0302

HIV mother-to-child transmission in Cameroon: Early infant diagnosis positivity rates by entry point and key risk factors

P. Tchendjou[1], S. Lekeumo[1], T. Binde[1], A.C. Bissek[2], G. Dongmo[1], J. Cohn[3], E. Sacks[4], C. Kengne[5], A. Beng Amougou[5], V. Nzima[1]
[1]*Elizabeth Glaser Pediatric AIDS Foundation, Yaounde, Cameroon,*
[2]*Ministry of Health/Division of Operational Research, Yaounde, Cameroon,*
[3]*Elizabeth Glaser Pediatric AIDS Foundation, Geneva, Switzerland,*
[4]*Elizabeth Glaser Pediatric AIDS Foundation, Washington D.C., Cameroon,*
[5]*National AIDS Control Committee, Yaounde, Cameroon*

Background: Prevention of mother-to-child transmission (PMTCT) programs aimed at reducing pediatric HIV infections are frequently assessed by the MTCT rate collected from PMTCT entry points, but this misses positivity rates in other entry points. Using the opportunity of the introduction of point of care early infant diagnosis (POC EID) in Cameroon, we extended infant HIV testing to several entry points of health facilities. We assessed HIV positivity by entry point and key risk factors.
Methods: A cross-sectional study nested within the POC EID project implemented in four regions was conducted in 58 health facilities of varying levels. Clinical history of the mother-baby pair, assessment of HIV status of the mother were used as eligibility criteria of infants. In each health facility, all entry points were considered and categorized as either a PMTCT entry point or a non-PMTCT entry point. Eligible infants presenting to these facilities between December 2016 and December 2017 were tested by POC EID. Variables including demographics, antiretroviral use, and breastfeeding history were extracted from the EID request form. Data were analyzed using multivariate analysis with backward elimination ($p>0.20$).
Results: Overall, 2,254 HIV-exposed infants were tested using POC EID as first HIV diagnosis. The median age at sample collection was 7.3 weeks (IQR [6.3;19.0]). The main entry points were PMTCT (48.7%), immunization unit (14.3%), Pediatric ward (13.8%). Of the 2,254 infants tested, 8.7% (197/2,254) were HIV-positive. This rate varied according to entry points (outpatient department, 19.2%; emergency/pediatric ward, 17.7%; PMTCT/antiretroviral treatment (ART), 5.7%). In univariate analysis, positive cases were more likely to be found at non-PMTCT entry point, among females, and infants delivered to HIV-positive women who received incomplete ARVs for PMTCT. In multivariate analysis, risk of being HIV-positive was higher when the infant was found at non-PMTCT entry point (OR:2.09; 95%CI: 1.47-2.99; $p< 0{,}001$), was on mixed feeding mode (OR: 3.74; 95%CI: 2.43-3.47; $p< 0{,}001$).
Conclusions: Only 48% of infected infants came from PMTCT-entry point. EID positivity rates were highest in non-PMTCT entry points. Strengthening testing in non-PMTCT entry points help to address missed opportunities of PMTCT programs and link more children into ART care.

THAC0303

Prevention of mother to child transmission and early infant diagnosis in Malawi: Accomplishments of a mature Option B+ program in a resource-limited setting

E. Kim[1], J. Cuervo-Rojas[2], T. Kalua[3], A. Jahn[3], D. Payne[4], C. West[4], M. Nzima[5], N. Wadonda-Kabondo[4], S. Jonnalagadda[6], MPHIA Study Team
[1]*Centers for Disease Control and Prevention, Division of Global HIV and TB, Lilongwe, Malawi,* [2]*ICAP at Columbia University, New York, United States,* [3]*Ministry of Health, Lilongwe, Malawi,* [4]*Centers for Disease Control and Prevention, Lilongwe, Malawi,* [5]*UNAIDS, Lilongwe, Malawi,* [6]*Centers for Disease Control and Prevention, Atlanta, United States*

Background: Malawi spearheaded the development and implementation of the Option B+ policy for prevention of mother to child transmission of HIV (PMTCT). From mid-2011, all HIV-infected pregnant and breastfeeding women were eligible for life-long ART. Routine aggregate program data indicated successful rapid scale-up, but some concerns about uptake and retention remained. We measured PMTCT and early infant diagnosis (EID) coverage in the 2015-16 Malawi Population-based HIV Impact Assessment (MPHIA).
Methods: MPHIA was a nationally representative household survey; eligible women were consented and interviewed on pregnancies and outcomes, including self-reported HIV status during their most recent pregnancy, uptake of PMTCT, and EID testing. Women aged 15-49 years reporting a live birth in the 36 months before the survey were included in this analysis. Descriptive and multivariable logistic regression analyses were weighted to account for the complex survey design.
Results: A total of 3,598 women reported a live birth in the 36 months before the survey; mean age was 26.9 years and mean parity was 3.0. Of these, 96.2% (95% confidence intervals (CI): 95.5-97.0) reported being tested for HIV and receiving their results or knowing their HIV status during their last pregnancy; 7.4% (95% CI: 6.5-8.4) self-reported their HIV-positive status during pregnancy. Of the 302 women self-reporting their HIV-positive status, 98.1% (95% CI: 96.5-99.6) reported being on ART during pregnancy and 81.0% (95% CI: 75.6-86.4) reported that their child was tested for HIV; 50.6% (95% CI: 43.1-58.1) reported EID testing within two months of birth. Of those reporting that their child was tested for HIV, 3.1% (95% CI: 0.5-5.7) reported a HIV-positive result.
Adjusting for age and urban/rural residence, EID testing within 2 months of birth was associated with secondary or higher education (adjusted odds ratio (aOR) 3.1, 95% CI: 1.5-6.2), disclosure of mother´s HIV-positive status to family (aOR 2.4, 95% CI: 1.3-4.6), and uptake of cotrimoxazole (aOR 6.2, 95% CI: 2.7-14.2).
Conclusions: Data from the 2015-16 MPHIA demonstrate the success of Malawi´s PMTCT Option B+ program at a population level, with high uptake across the PMTCT cascade. However, challenges remain in the timeliness of EID testing for HIV-exposed infants according to recommended guidelines.

THAC0304

Birth outcomes and HIV-free survival with Option B+ in Lesotho: Results from an observational prospective cohort study

A. Tiam[1,2], S. Kassaye[3], R. Machekano[1], V. Tukei[4], M. Gill[1], M. Mokone[4], S. Mohale[4], M. Letsie[5], M. Tsietso[6], I. Seipati[7], J. Barisa[4], A. Isavwa[8], L. Guay[1,9]
[1]*Elizabeth Glaser Pediatric AIDS Foundation, Research, Washington, United States,* [2]*University of Bergen, Centre for International Health, Bergen, Norway,* [3]*George Town University, Medicine and Infectious Disease, Washington, United States,* [4]*Elizabeth Glaser Pediatric AIDS Foundation, Research, Maseru, Lesotho,* [5]*Ministry of Health, Disease Control, Maseru, Lesotho,* [6]*Ministry of Health, Laboratory Services, Maseru, Lesotho,* [7]*Ministry of Health, Family Health, Maseru, Lesotho,* [8]*Elizabeth Glaser Pediatric AIDS Foundation, SI & E, Maseru, Lesotho,* [9]*George Washington University, Milken Institute School of Public Health, Washington, United States*

Background: Combination antiretroviral therapy (cART) reduces mother-to-child transmission of HIV and improves maternal health. Since introduction of option B+, there are scant data on birth outcomes of HIV-exposed compared to unexposed infants. We assessed birth outcomes and six-week HIV free survival among HIV-exposed infants (HEI) and HIV-unexposed infants (HUI).
Methods: 941 HIV-negative and 653 HIV-positive pregnant women were enrolled in an observational cohort to evaluate effectiveness of universal maternal cART (Option B+) rolled out within routine programs in 13 health facilities in Lesotho. Birth outcomes included infant birth weight (IBW), maturity, congenital anomalies, and mortality. Infant HIV birth testing by DNA PCR within two weeks of birth was introduced at study sites alongside routine six-week testing. Data were analysed to determine birth outcomes, HIV transmission, and HIV-free survival rates at six weeks.
Results: : HIV-positive women were older, 28.7 vs. 24.4 years ($p<0.001$) and presented for antenatal care earlier at 23 weeks vs. 25.3 weeks gestation ($p<0.001$). Mean IBWs were similar: 3.0 kgs for HEIs vs 3.1 kgs for HUI. HEI were more likely to be premature, 8.3% vs. 4.0% ($p=0.001$). Neither Age (median age: 26 vs 25) nor parity (median: 1 vs 1) was associated with prematurity. No differences in stillbirths or congenital anomalies were noted. Six infants were HIV-infected by six weeks: cumulative HIV transmission was 0.9% (N=4) at birth (95%CI: 0.25%-2.36%) and 1.03% (N=6) (95%CI: 0.38%-2.23%) by six weeks. Infant mortality was 4.4% and 4.3% for HUI and HEI respectively ($p=0.93$). The estimated six-week HIV

free survival was 91.5% [95%CI: 89.1% - 93.6%] for HEI. Survival for HUI was 94.1% [95% CI: 92.4% - 95.6%]. Excluding stillbirths, six-week HIV free survival for HEI was 95.2% [95% CI: 93.2% - 96.8%] compared to survival rate of 97.5% [95% CI: 96.2% - 98.4%] among HUI (p=0.02).
Conclusions: A low HIV transmission rate by six weeks was found among mother-infant pairs enrolled in a universal cART prevention of mother-to-child transmission program, though there were higher rates of pre-maturity; six-week survival among HIV-exposed infants was comparable to HIV-unexposed infants. It will be important to explore if this trend continues at 12 months and 24 months.

THAC0305

Cohort study of HIV+ children in Southern Africa returning to care after being lost to follow up: Effect of interrupting care on mortality

C. Davies[1], S. Sawry[2], C. Chimbetete[3], B. Eley[4], M. Vinikoor[5], K. Technau[6], J. Ehmer[7], H. Rabie[8], S. Phiri[9], F. Tanser[10], K. Malisita[11], G. Fatti[12], M. Osler[1], R. Wood[13], M.-A. Davies[1]

Background: Although patients initiating antiretroviral therapy (ART) should ideally have sustained engagement in care after ART start, it is increasingly recognized that a large proportion of patients experience care interruptions for a range of reasons. However, few studies have assessed the long-term outcomes of children with a care interruption (CI), during which the child's health status and use of medication is unknown. We evaluated the characteristics and outcomes of HIV-infected children that have care interruptions (i.e. >180 days without a clinic visit).
Methods: We included data on children < 16 years old initiating antiretroviral therapy (ART) since 2004 at an International Epidemiologic Databases to Evaluate AIDS (IeDEA) Southern Africa (IeDEA-SA) cohort with >180 days potential follow-up. Children who died within 180 days of ART start were excluded. A CI was defined as a >180 days without a clinic visit and loss to follow-up (LTFU) was defined as no visit within 180 days of database closure. The main outcome was all cause mortality. Two exposed groups were considered: those with a first CI within the first 6 months on ART, and those with a first CI after >6 months on ART. Adjusted rate ratios were determined using a Poisson regression model with robust standard errors.

Variable	ARR* (95% CI)	P-value
Care Interruption status		
No Care Interruption	1.00	<0.001
Care Interruption before 6 months	2.70 (2.13 to 3.43)	
Care Interruption after 6 months	1.01 (0.77 to 1.31)	
Age at ART initiation		
<2 years	1.00	<0.001
2-5 years	0.98 (0.75 to 1.27)	
6-9 years	1.83 (1.26 to 2.66)	
>=10 years	4.18 (2.71 to 6.45)	

[Adjusted rate ratios for the effect of a care interruption on mortality using a Poisson model]

Results: Among 46,356 children included, 24,280 (52%) had a CI, of which 10,998 (45%) had a first CI within 6 months on ART and 13,282 (55%) had a first CI after 6 months on ART. Having a CI within the first 6 months on ART was associated with increased mortality (adjusted rate ratio (ARR) = 2.70, 95% CI 2.13- 3.43), but there was no association between a first CI after 6 months on ART and mortality (ARR = 1.01, 95% CI 0.77- 1.31)
ARR adjusted for variables in the table, and also adjusted for gender, current age, year of ART initiation, time in/ out of care, CD4% at ART initiation.
Conclusions: The findings suggest that strengthening retention of children in care in the early period after ART initiation is critical to improving paediatric ART outcomes.

Rapid ART initiation and index client testing outcomes of commlink, a community-based, HIV testing, mobile HIV care, and peer-delivered, Linkage Case Management Program - Swaziland, 2017

D. Williams[1], D. Mackellar[1], M. Dlamini[2], N. Simelane[2], S. Mlambo[2], P. Mamba[2], J. Byrd[3], S. Mazibuko[4], I. Pathmanathan[1], N. Lukhele[5], L. Dube[5], M. Pasipamire[5], V. Nxumalo[2], A. Beyer[2], C. Ryan[4]
[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV/ AIDS and Tuberculosis, Atlanta, United States, [2]Population Services International Country Program, Mbabane, Swaziland, [3]ICF International, Atlanta, United States, [4]U.S. Centers for Disease Control and Prevention Country Office, Mbabane, Swaziland, [5]Swaziland Ministry of Health, Swaziland National AIDS Programme, Mbabane, Swaziland

Background: Few persons diagnosed in community settings receive antiretroviral therapy within seven days of diagnosis (rapid ART) in accordance with World Health Organization recommendations. To improve rapid ART for clients diagnosed in community settings in Swaziland, we implemented CommLink, an integrated community-based HIV testing (CBHTS), mobile HIV care, and peer-delivered linkage case management (LCM) program.
Description: In urban and rural settings in three regions of Swaziland, consenting HIV-positive, out-of-care clients identified through CBHTS receive mobile-unit CD4 testing, baseline clinical assessment, and cotrimoxazole. Medical charts and test results are transferred to referral HIV care facilities. ART-adherent, expert-client counselors provide LCM for up to 90 days. Services include escort and treatment navigation at referral facilities, regular telephone contact for psychosocial support, and counseling on HIV care and disclosure. Beginning in April 2017, index-client testing services (IDTS) were initiated for partners, family members, and associates (PFAs) of CommLink clients.
Lessons learned: From April through December 2017, of 498 eligible clients aged ≥15 years, 488 (98%) participated in LCM. Of 361 (74%) closed cases (completed program/discontinued participation/timed-out), from the date of diagnosis, 351 (97%) clients enrolled in facility-based care within a median (IQR) of 2 days (1-6) and 349 (97%) were initiated on ART within a median (IQR) of 2.5 days (1-6); 276 (76%) clients received rapid ART. At least 95% of clients in all gender and age groups were initiated on ART (Table). During LCM, 94% of clients disclosed their HIV status to at least one partner or family member, and 42% had at least one PFA tested. Of 209 PFAs tested, 128 (61%) tested HIV positive (40% of 128 newly diagnosed), and 117 subsequently participated in CommLink. Disclosure of HIV status and participation in IDTS was similar across demographic groups.
Conclusions/Next steps: CommLink achieved near-universal early and >70% rapid ART initiation among all persons diagnosed in community settings in Swaziland, including men and young adults. As an integral component of LCM, index client testing was pivotal for active case finding. In 2018, CommLink has been approved by the Swaziland Ministry of Health to pilot community-based point-of-diagnosis ART initiation and is being scaled-up nationally.

THAC0402

Community-based HIV testing and assessment for same-day ART reaches men for HIV care

S. Asiimwe[1], H. van Rooyen[2], T. Schaafsma[3], A. van Heerden[2], B. Turyamureeba[1], M. Krows[3], A. Szpiro[4], J. Baeten[3], C. Celum[3], R. Barnabas[3], The Delivery Optimization of Antiretroviral Therapy (DO ART) Study
[1]Integrated Community Based Initiatives, Kabwohe, Uganda, [2]Human Sciences Research Council, Sweetwaters, South Africa, [3]University of Washington, Department of Global Health, International Clinical Research Center, Seattle, United States, [4]University of Washington, Biostatistics, Seattle, United States

Background: Integrating same-day ART start into community-based HIV testing has the potential to increase ART coverage, particularly among hard to reach priority populations, such as men. The coverage and feasibility of community-based same-day ART initiation requires evaluation.
Methods: The Delivery Optimization for ART (DO ART) Study is an ongoing randomized study of community-based compared to clinic-based ART initiation and monitoring in the Sheema District, Uganda and KwaZulu Natal, South Africa. Lay counselors conduct community-based HIV testing and counseling at home or through a mobile van. To reach men, testing was conducted at trading posts and in the evenings. HIV-positive persons are assessed for same-day ART by a clinical questionnaire and point-of-care testing for CD4 count, pregnancy, and creatinine. Nurses received standardized government training on ART initiation and HIV care, and assess ART eligibility. Participants are eligible for same-day ART start if they are clinically stable (have a CD4 count >100 cell/mL and no evidence of current or past WHO stage 3 or 4 HIV conditions), have no symptoms of active TB, are not pregnant, and have normal renal function. Eligibility results are presented for Uganda, where enrollment is complete.
Results: Between June 2016 and November 2017, 398 HIV-positive persons were identified by community-based HIV testing in Uganda, of whom 320 (80%) were eligible for same-day ART start. Among the 98 participants who were not eligible for same-day ART start, the leading reasons were CD4 count >500 cells/mL (46%, who were not eligible by the Ugandan national guidelines for ART initiation at the time), CD4 count < 100 cells/mL (17%), any of 4 symptoms suggestive of TB (14%), and a positive pregnancy test (9%). One participant had a creatinine >1.5 mg/dL and was not eligible. Of those eligible for same-day ART start, 169 (53%) were men.
Conclusions: Among HIV-positive persons identified through community-based HIV testing in a rural setting in Uganda, 80% were eligible for same-day ART start. Notably, men accounted for more than half the persons eligible for same-day ART start. Community-based HIV testing and counseling and same-day ART start has the potential to increase coverage of ART among priority populations.

THAC0403

Same-day ART initiation in HIV/STI testing center in Bangkok, Thailand: Initial results from an implementation research

P. Seekaew[1], N. Teeratakulpisarn[1], P. Surapuchong[1], S. Teeratakulpisarn[1], S. Amatavete[1], P. Jomja[1], C. Prabjunteuk[1], C. Hanaree[1], W. Chaison[1], P. Plodgratoke[1], K. Singhaseni[1], D. Lingjongrat[2], S. Janyam[3], P. Na Nakorn[1], S. Charoenying[4], S. Mills[4], R. Vannakit[5], P. Phanuphak[1], N. Phanuphak[1]
[1]Thai Red Cross AIDS Research Centre, Prevention, Bangkok, Thailand, [2]Rainbow Sky Association of Thailand, Bangkok, Thailand, [3]Service Workers in Group Foundation, Bangkok, Thailand, [4]FHI 360 and USAID LINKAGES Project, Bangkok, Thailand, [5]Office of Public Health, U.S. Agency for International Development Regional Development Mission Asia, Bangkok, Thailand

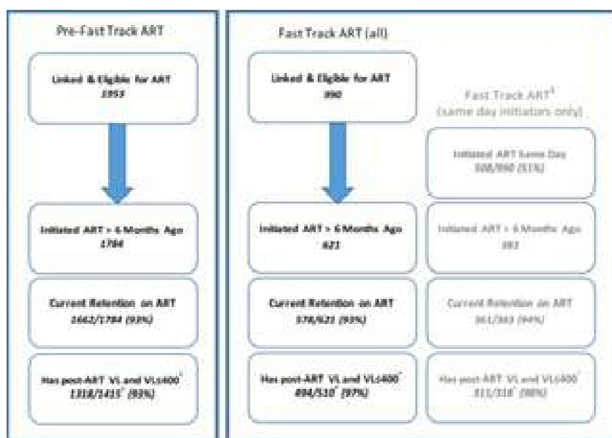
Background: Despite WHO's recommendation on Universal ART, one-third of persons living with HIV in Thailand are without antiretroviral therapy (ART). Attrition from care due to delays in initiating treatment may contribute to this gap. There is strong evidence to suggest clinical and practical benefits of rapid ART initiation, including Same-Day ART. However, data on safety and feasibility in real-world settings is limited.
Methods: Data was collected among HIV-seropositive Thai clients at Thai Red Cross Anonymous Clinic in Bangkok, Thailand. Clients were categorized as newly diagnosed or reengaged. Assessment of acceptability, logistical eligibility (no previous ART and could return for follow-up visits), and first date of known HIV-seropositive status were self-reported. Baseline laboratory tests (creatinine/ALT/syphilis/HBsAg/anti-HCV/CD4/CrAg if CD4< 100) and chest x-ray were performed according to national guidelines. Physicians determined clinical eligibility of Same-Day ART based on signs/symptoms and only results of CD4 and chest x-ray to rule out tuberculosis, cryptococcal meningitis, and serious illnesses. Mean days from HIV diagnosis/reengagement to ART initiation were calculated. Referral rate to long-term ART continuation site, after 10 weeks of ART, was also determined.
Results: From July-December 2017, 86.8% of 1,062 HIV-seropositive clients were logistically eligible for Same-Day ART service and 90% (95% newly diagnosed; 85% reengaged) accepted the service. Median (IQR) CD4 was 295.5 (203-415) cells/mm^3. 82% of those who accepted the service were clinically eligible and initiated ART. Among these, 79% received ART on the day of HIV diagnosis/reengagement. Mean (SD) days from HIV diagnosis/reengagement to ART initiation was 1.4 (5.2) days for newly diagnosed clients and was 1.1 (4.0) days for reengaged clients. Immune reconstitution inflammatory syndrome was not seen. Referral to long-term ART site was successful among 88.2%. Virologic suppression was achieved by 100% of 12 clients who reached month six after ART.
Conclusions: Same-Day ART initiation in an HIV/STI testing center in Thailand is highly feasible and safe, with high rates of client eligibility and acceptability. Preliminary data on referral to long-term ART site and short-term virologic suppression are encouraging. Same-Day ART should be immediately scaled-up, with rigorous and longitudinal evaluations to further inform HIV guidelines.

THAC0404

Fast-track ART initiation in Botswana is associated with high rates of ART initiation, retention in care, and virological suppression

R. Lebelonyane[1], P. Bachanas[2], W. Abrams[3], M. Roland[3], J. Theu[1], M. Kapanda[1], S. Matambo[3], S. Lockman[4], J. Moore[2], L. Block[5], T. Gaolathe[6], J. Makhema[6], J.N. Jarvis[6,7]
[1]Botswana Ministry of Health and Wellness, Gaborone, Botswana, [2]Centers for Disease Control and Prevention, Division of Global HIV/ AIDS and TB, Atlanta, United States, [3]Centers for Disease Control and Prevention, Gaborone, Botswana, [4]Harvard T.H. Chan School of Public Health, Boston, United States, [5]Intellectual Concepts, Atlanta, United States, [6]Botswana Harvard Partnership, Gaborone, Botswana, [7]Botswana-UPenn Partnership, Gaborone, Botswana

Background: The Botswana Combination Prevention Project (BCPP) started in 2013 and has offered "fast-track" ART initiation at the first clinic visit since June 2016. We examined treatment outcomes pre- and post-fast-track ART initiation.
Methods: BCPP is a cluster-randomized trial evaluating a combination HIV prevention package in 15 intervention and 15 control communities. In the intervention communities, we compared the cumulative proportion of individuals initiating ART (using Kaplan Meier estimates), as well as retention in care and viral suppression in patients, comparing outcomes in two periods: following the introduction of fast-track ART (June 2016-November 2017), versus pre- fast track ART initiation (October 2013-May 2016).
Results: Overall 3622 HIV-infected individuals not on ART were identified through community testing activities and referred for treatment, and 3315 (92%) linked to care. At data censoring in November 2017, 91% (2682/2943) of linked, eligible individuals had initiated ART. The cumulative probability of initiating ART within one year of linkage was 84% and 87% in pre- and post-fast track groups respectively. ART initiations occurred more quickly after implementation of fast-track ART with 63% (626/990) initiating ART within 7 days of linkage and 73% (723/990) initiating within 30 days, compared to 12% (237/1953) and 44% (851/1953) prior to fast-track. Retention in care after 6 months on ART was 93% in both groups. However, viral suppression rates within the first year of ART were higher in the fast-track group; 82% of those on ART for at least 6 months (510/621) had a viral load (VL) performed of whom 97% (494/510) were suppressed. In the pre fast-track group, 80% (1415/1784) had a VL performed of whom 93% (1318/1415) were suppressed (p=0.04). Median time from linkage to first viral suppression was significantly shorter following introduction of fast track ART (108 days vs 288 days, p< 0.001).



*Within First Year of ART initiation
†Viral loads were available for 1415/1784 (79%), 510/621 (82%),and 318/383 (83%) of individuals initiating in the pre-fast track, fast track, and same day cohorts respectively.
‡A sub-analysis was performed limited to just those individuals who initiated ART within one day of linkage (results not shown in text)

[Retention in Care and Viral Suppression in the Botswana Combination Prevention Project]

Conclusions: ART initiation, retention in care and viral suppression rates were high in HIV-infected individuals who initiated fast track ART. Time from linkage to viral suppression was significantly shorter with fast-track ART, reducing the period of potential HIV-transmission risk. These data support programmatic ART initiation efforts designed at starting ART quickly in stable patients.

THAC0405

Towards the third 90: Factors associated with adolescent antiretroviral adherence and viral suppression

P. Wekesa[1], L. Nyabiage[2], K. Owuor[1], J. Kataka[1], J. Oliech[1], A. Bisera[1], E. Ouma[1], S. Omondi[3]
[1]Centre for Health Solutions - Kenya (CHS), Nairobi, Kenya, [2]Division of Global HIV & TB (DGHT), US Centers for Disease Control and Prevention (CDC), Nairobi, Kenya, [3]Ministry of Health, County Department of Health, Siaya, Kenya

Background: Globally, adolescents have lower rates of adherence to antiretroviral therapy (ART) and viral suppression (VS) compared to adults and children. We sought to understand predictors of adherence and VS among adolescents in Siaya County, western Kenya.
Methods: We conducted a retrospective analysis of patient files for adolescents aged 10-19 years initiated on ART between 2000 and 2017 at 119 sites. Outcomes were self-reported adherence (SRA) to ART and VS (< 1000 copies/ml) based on the latest 2017 VL results. Adherence was based on missed doses per month (good < 2, fair 2-4, poor >4). Variables were: age, sex, ART regimen, VS, SRA, school attendance, and frequency of clinic visits. Caregiver variables included HIV status, VS, SRA, stable caregiver and support group (SG) attendance within the last 3 months. Descriptive, bivariate and multivariable binary logistic regression analyses were done. Unadjusted and adjusted odds ratios (OR) and 95% confidence intervals (CI) were calculated to assess associations at the 5% level.
Results: Records of 2,814 adolescents were included in the analysis; of these 1,389 (49%) were female and the mean age was 13.3 years (SD ±2.7). Good adherence was reported among 2,192 (78.8%), while 389 (14%) had fair and 201 (7.2%) poor adherence. In total, 1,615 (61.6%) achieved VS. Among caregivers 1,568 (55.7%) attended SG, 1,440 (51%) had HIV, 1,425 (99%) were on ART, and of these, 1,087 (88%) reported good adherence. Factors associated with good SRA were: caregiver good SRA (aOR= 9.05 [95% CI: 4.96-16.52]), caregiver VS (aOR=11.11 [95% CI 8.33 -14.28]), caregiver attendance of SG (aOR=1.38 [95% CI: 0.97-1.98]) and clinic visit intervals of 2 months or more (aOR=3.76 [95% CI: 1.72-8.22]). Viral suppression was associated with good SRA (aOR= 11.34 [95% CI: 8.56-15.01]), clinic visit intervals of 2 months or more (aOR=2.82 [95% CI: 1.75-4.53]) and Tenofovir-based ART regimen versus an Abacavir (aOR=0.64 [95% CI: 0.48-0.85]) or Zidovudine (aOR=0.65 [95% CI: 0.5-0.86])-based regimen.
Conclusions: Caregiver factors were associated with good SRA to ART among adolescents. Regimen type was a significant predictor of VS. The potential role of these factors in improving adolescent adherence to ART and VS should be explored.

THAC05 I want your sex: Sexual health in the PrEP era

THAC0501

The post-intervention effects of conditional cash transfers for HIV/STI prevention: A randomized trial in rural Tanzania

D. de Walque[1], W.H. Dow[2], R. Nathan[3], The RESPECT Study Team
[1]The World Bank, Development Research Group, Washington, United States, [2]University of California, School of Public Health, Berkeley, United States, [3]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of

Background: Incentive-based policies have been shown to be powerful in many areas of behavior, but have rarely been tested in the sexual domain. The Rewarding Sexually Transmitted Infection Prevention and

Control in Tanzania (RESPECT) study is a randomized controlled trial testing the hypothesis that a system of rapid feedback and positive reinforcement that uses cash as the primary incentive can be used to reduce risky sexual activity among young people, male and female, who are at high risk of HIV infection. Recognizing that such an intervention would be difficult to sustain over the length of individuals' sexual lives, we evaluated its long-term effects using a post-intervention follow-up survey conducted one year after discontinuing the intervention.
Methods: The study enrolled 2,399 participants in 10 villages in rural southwest Tanzania. The intervention arm received conditional cash transfers ($10 or $20 every four months) that depended on negative results of periodic screenings for sexually transmitted infections, an objectively measured marker for risky sexual behavior. One year after discontinuing the CCT intervention, at month 24, we revisited the 10 study villages and retested and re-interviewed study participants to assess the long-term impacts of the intervention.
Results: Overall, the CCT interventions seemed to have had a sustained impact in reducing the STI prevalence among the study population: when we combine all 7 STIs tested, both the high and the low value CCT intervention have relative risks significantly lower than 1, corresponding to 18 (p< 0.1) to 20% (p< 0.01) risk reduction compared to the control group, respectively. These effects are stronger among males than among females.
Conclusions: Those results from the one-year post intervention follow-up indicate that the CCT interventions might have sustained effect even after the cash payments have been discontinued and suggest a learning effect. They do not suggest that CCTs might destroy the intrinsic motivation to adopt safe sexual practices since no increased risk was reported in the intervention groups. Those are important results when considering the potential feasibility at scale and sustainability of our CCT intervention.

Changes, patterns and predictors of sexually transmitted infections in gay and bisexual men using PrEP; interim analysis from the PrEPX demonstration study

M. Traeger[1], J. Asselin[1], B. Price[2], V. Cornelisse[3,4], N. Roth[4], J. Wilcox[5], B.K. Tee[6], C. Fairley[3], C. Chang[2], J. Armishaw[2], O. Vujovic[2], M. Penn[7], P. Cundill[7], G. Forgan-Smith[8], J. Gall[8], C. Pickett[9], L. Lal[2], A. Mak[2], T. Spelman[1,10,11], L. Nguyen[1], D. Murphy[12], K. Ryan[1], C. El-Hayek[1], S. Ruth[13], C. Batrouney[13], J. Lockwood[2], J. Hoy[10], R.M. Grant[14], M. Hellard[1,2,10], M. Stoové[1,10], E. Wright[1,2,10], PrEPX Study Team
[1]Burnet Institute, Disease Elimination Program, Melbourne, Australia, [2]Alfred Health, Melbourne, Australia, [3]Melbourne Sexual Health Centre, Melbourne, Australia, [4]Prahran Market Clinic, Melbourne, Australia, [5]Northside Clinic, Melbourne, Australia, [6]Centre Clinic, Melbourne, Australia, [7]PRONTO! clinic, Melbourne, Australia, [8]ERA Health, Melbourne, Australia, [9]Ballarat Community Health Centre, Ballarat, Australia, [10]Monash University, School of Public Health and Preventative Medicine, Melbourne, Australia, [11]Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [12]University of New South Wales, Centre for Social Research in Health, Sydney, Australia, [13]Victorian AIDS Council, Melbourne, Australia, [14]Gladstone Institute for Virology and Immunology, San Francisco, United States

Background: While there is growing evidence of increasing sexually transmitted infections (STIs) among gay and bisexual men (GBM) using PrEP, few studies have been able to measure STI incidence before PrEP commencement. We compare STI incidence among GBM before and after enrolment in the Pre-exposure Prophylaxis Expanded (PrEPX) study, a population-level, multi-site, PrEP implementation project in Melbourne, Australia, and predictors of STI diagnoses while taking PrEP.
Methods: STI testing and behavioural data from PrEPX participants attending five clinics specializing in GBM health were extracted prior to study enrolment and at scheduled three-monthly PrEP visits between July 2016-December 2017 through the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance (ACCESS). We calculated participants' gonorrhea, chlamydia and syphilis incidence in the year before PrEPX enrolment and during PrEPX follow-up. Incidence comparisons were calculated overall and by participants' pre-enrolment testing frequency and self-reported pre-study PrEP use. Kaplan-Meier estimating methods and Cox proportional hazards regression explored associations between baseline and longitudinal behaviours and STI diagnosis after PrEP commencement.
Results: 2,490 participants contributed 1040.3 person-years (PY) pre-PrEPX and 1899.7 PY during PrEPX. During PrEPX, 41% of participants were diagnosed with ≥1 STI and 455 (18%) participants with multiple STIs accounted for 68% of all infections. Rectal infections were commonest (62.4/100PY). STI incidence among all participants increased significantly from 78.4/100PY pre-PrEPX to 96.1/100PY during PrEPX. Significantly elevated STI incidence was detected among participants with ≥3 test visits in the year preceding enrolment, but not among participants with ≥4 visits. STI incidence increased most among participants reporting no pre-study PrEP use. STI diagnosis and condomless receptive anal intercourse prior to enrolment were associated with increased STI risk during PrEPX (p< 0.001). Younger age (aHR=1.02/year, 95%CI=1.01-1.03), >10 casual anal sex partners (aHR=1.76, 95%CI=1.30-2.39) and group sex (aHR=1.49, 95%CI=1.10-2.03) in the past six months were associated with increased STI risk.
Conclusions: STI incidence increased among GBM in PrEPX following PrEP initiation, driven largely by GBM experiencing repeat infections. High partner turnover and group sex elevated STI risk. Our findings support ongoing and frequent STI screening alongside education on early identification of STI symptoms for PrEP users, especially among those exhibiting multiple STIs and high-risk behaviours.

	1 Year Before Enrolment		During Follow-up			
	Median Follow-up (months)	Incidence Rate (per 100 person-years)	Median Follow-up (months)	Incidence Rate (per 100 person-years)	IRR (95% CI)	p-value

How can programmes better support female sex workers to avoid HIV infection in Zimbabwe? A prevention cascade analysis

E. Fearon[1], A. Phillips[2], S. Mtetwa[3], S. Chabata[3], P. Mushati[3], V. Cambiano[2], J. Busza[1], S. Napierala[4], B. Hensen[5], S. Baral[6], S.S. Weir[7], B. Rice[1], F.M. Cowan[3,8], J.R. Hargreaves[1]
[1]London School of Hygiene and Tropical Medicine, Department of Public Health, Environments and Society, London, United Kingdom, [2]University College London, Institute for Global Health, London, United Kingdom, [3]Centre for Sexual Health and HIV AIDS Research Zimbabwe, Harare, Zimbabwe, [4]RTI International, Women's Global Health Imperative, San Francisco, United States, [5]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [6]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [7]University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [8]Liverpool School of Tropical Medicine, Department of International Public Health, Liverpool, United Kingdom

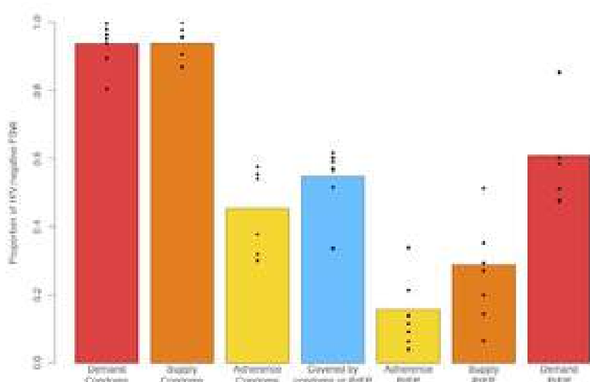
Background: The 'HIV prevention cascade' has been proposed as a tool to measure prevention coverage and guide programming by identifying gaps in demand, supply and capability to adhere to HIV prevention tools. Here, we use a prevention cascade framework to explore coverage of

condom use and Pre-Exposure Prophylaxis (PrEP) among female sex workers (FSW) in Zimbabwe, and make recommendations for programming.

Methods: We conducted secondary analysis of seven respondent-driven sampling (RDS) surveys from the intervention sites of a cluster-randomised trial in Zimbabwe in 2016. Women were tested for HIV, and completed a questionnaire detailing their socio-demographic and sex work characteristics, their experience of PrEP (available during the trial 2014-2016) and reported condom use with clients and partners. We operationalised measures of 'demand', 'supply' and 'adherence' to using condoms and PrEP. We used logistic regression to identify determinants of adherence. Differences were examined across sites and data then pooled. We weighted by site-normalised inverse degree and dropped seeds.

Results: There were 611 HIV-negative women included in our analysis. Approximately half of these women (54.7%) reported adherence to condoms and/or to PrEP. While women knew that condoms prevented HIV and reported good access (both 94.0%), only 45.5% reported no episodes of condomless sex in the previous month. For PrEP, there were gaps across all three domains of demand, supply and adherence (Fig 1). Alcohol use of women and of their clients was associated with lower condom adherence (among women drinking alcohol 4+ times per week, 38/115 28.9% adhered, compared to no alcohol, among whom 139/262 50.9% adhered, aOR=0.34 95% CI 0.08-0.41, adjusted for socio-demographic and sex work characteristics). Newer entrants to sex work, and younger women were less likely to report taking PrEP every day (aOR=1.05, 95% CI 1.01-1.10 for each year of age).

Conclusions: After 21 months of intensive community mobilisation for PrEP and condoms during the trial intervention, almost half of HIV-negative FSW reported inadequate prevention coverage, worse in the context of heavy alcohol use, which programmes could address. Interventions aimed at younger women are important. HIV prevention cascades should consider different prevention tools together, not in isolation.



[Figure 1. Demand, Supply, Adherence and Coverage by Condoms and/or PrEP amongst 611 HIV-negative FSW from seven sites]

THAC0504

HIV "condom cascade" to monitor prevention among female sex workers in Uganda

S. Weir[1], F. Ssengooba[2], L. Ayutambe[3], S. Kasasa[2], G. Mulholland[1]
[1]*University of North Carolina, Epidemiology, School of Public Health, Chapel Hill, United States,* [2]*Makerere University, School of Public Health, Kampala, Uganda,* [3]*Makerere University, Kampala, Uganda*

Background: Recently there has been interest in HIV prevention cascades. We applied a proposed prevention cascade framework (*Garnett, 2016, Lancet*) to data collected for a PLACE mapping and biobehavioral survey in 30 districts in Uganda.

Description: The client-centric and program centric cascades were measured for condom use among 9,207 HIV-negative female sex workers from 30 districts. The client centric cascade showed that over half of the female sex workers did not perceive themselves to be at risk for HIV acquisition. Most of those who perceived themselves at risk had ever used condoms but only 64 of the 9,207 female sex workers reported consistent use. The program centric prevention cascade found that only two-thirds of the female sex workers who are at risk have access to condoms. But of those who have ever used condoms, consistent use is very poor. Estimating the condom cascade led us to estimate the number of condoms that would be required per month in order to protect female sex workers. We estimated that 110,889 condoms would be required to for 10,417 female sex workers. We estimated that 1677 acts in the past 4 weeks were among HIV infected sex workers who did not use a condom. Anal sex was also often not protected.

Lessons learned: Both the program centric and the client centric cascades provided compelling evidence of the lack of availability of condoms, the poor uptake of condoms, and the almost negligible consistent use of condoms in this population. It is striking that 4,736 of 9207 female sex workers did not perceive they were at risk for HIV acquisition. It is also striking that 2853 female sex workers reported that condoms were not readily available to them. The cascade helped document the condom programming needs for this key population.

Conclusions/Next steps: These findings have already been used to advocate to increase cthe accessibility of condoms to those who most need it. Additionally, there is interest in developing HIV prevention cascades at the venue level to characterize venues that have been adequately reached by prevention programs and those where there remain gaps.

THAC0505

Making markets work for HIV prevention: A total market approach to condom security in Vietnam

Y. Vu, K. Green
PATH, USAID-PATH/Healthy Markets, Hanoi, Vietnam

Background: Donor-funded free and partially subsidized condoms for key populations (KPs) artificially suppressed a domestic commercial condom market in Vietnam. With significant declines in free/socially marketed condoms from 2014 on, market management was needed to ensure a sustained supply of affordable commercial condoms capable of meeting the needs of populations at-risk of HIV.

Description: From 2015 on, the USAID/PATH Healthy Markets project initiated a condom total market approach (TMA) effort:

1) Generating condom market volume, sales and growth projections that were used to engage local condoms manufacturers and encourage local production of quality, low-cost condoms that appealed to KP; identify new distribution channels; and increase demand among key populations;

2) Developing a sustainable KP-focused condom value chain, bringing together the private sector, social enterprises, and KP-led community-based organizations (CBOs); and

3) Working with the Ministry of Health to use market data to shape annual condom planning and budgeting.

As a result, four KP-market segmented brands were developed, and commercial condom sales volume in KP hotspots/outlets increased 400% from 5,125,984 in 2015 to 22,823,447 in 2017. Commercial condom market-share in KP-preferred outlets, i.e. hotels and guesthouses, significantly increased from 25% in 2013 to 74% in 2016.

Lessons learned: Key lessons learned include:

1) market and consumer insights and brokering relationships with new distributors and retailers were invaluable to engaging and securing commitment from local condom manufacturers to invest in the local market;

2) increasing the capabilities of KP-led CBOs and social enterprises to engage in commercial condom sales was essential to developing a sustainable KP-targeted market;

3) partnering closely with the MOH from the start increased their ownership and stewardship of more nuanced condom commodity planning.

Conclusions/Next steps: The TMA has been a driving force for growing a sustainable condom market that meets the needs of KP in Vietnam. The TMA needs to be extended to other HIV-commodities, and the MOH will need to take an increasing role as a market manager, not only for condoms, but also for needles and syringes and other critical HIV-related commodities, as donor funds further decline and domestic financing of all HIV-commodities must be secured.

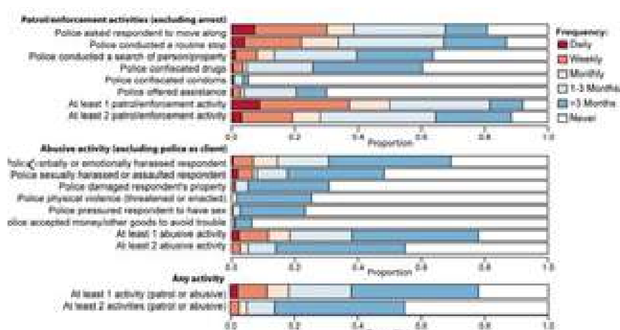
THAD01 Creating danger: Impact of end-demand laws and policing of sex work

THAD0101

Police related correlates of client violence among female sex workers in a U.S. city

K.H.A. Footer[1], J. Park[2], S.T. Allen[1], M.R. Decker[3], B.E. Silberzahn[1], S. Huettner[4], N. Galai[2], S.G. Sherman[1], the SAPPHIRE Study
[1]Johns Hopkins Bloomberg School of Public Health, Health Behavior and Society, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [3]Johns Hopkins Bloomberg School of Public Health, Population,Family and Reproductive Health, Baltimore, United States, [4]Johns Hopkins School of Medicine, Baltimore, United States

Background: Globally, rates of HIV among female sex workers (FSW) remain high. A more nuanced understanding of the role of structural factors is of paramount importance. Law enforcement practices have been identified as an important factor in the HIV risk environment of FSW. This study looks to characterize the frequency and type of interactions that FSW have with the police and explore the implications of cumulative police exposures on experiences of client violence.
Methods: Cross-sectional baseline data examined from a cohort study of 250 street-based FSW recruited between 04/2016- 01/2017 using targeted sampling in Baltimore City, Maryland, U.S. Questionnaires captured a range of patrol/enforcement (e.g., routine stops) and abusive (e.g., verbal/sexual harassment) police encounters, experiences of client violence and other HIV risk factors, including drug use. All women were tested for HIV. Pearson's chi-square tests and logistic regression models were used to test frequency and type of police interactions experienced by FSW, and the association between police interactions and client violence, accounting for daily heroin use.
Results: 78% of participants (n= 195) reported lifetime abusive police encounters, 41% reported daily/weekly encounters of any type. 22% of participants experienced client violence in the prior three months. FSW that reported heroin use (70%; n= 175) reported more abusive encounters (2.5 vs 1.6, p<0.001) and more client violence (26% vs 12%, p=0.02) than their non-heroin using counterparts. In multivariable analysis, each additional type of abusive interaction was associated with 1.3 times (95%CI: 1.1-1.5) increased odds of client violence. For patrol/enforcement encounters this value was 1.3 (95%CI: 1.0-1.7).
Conclusions: Our findings point to high levels of routine and abusive police exposure experienced by FSW contributing to a layering of risk that promotes an environment in which FSW are at a heightened risk of client perpetrated violence. For FSW who inject drugs, risk of both police exposure and client violence appear amplified. Our results demonstrate the need for greater attention to better understanding the nature and impact of these forms of intersectional risk on FSW HIV risk environment. Structural interventions that seek to address police-FSW interactions and promote FSW safety are critical to alleviating police's impact on FSW health.



[Figure 1]

THAD0102

"They should protect us because that is their job": An assessment of sex workers' experiences with police abuse in Lusaka, Zambia

T.K. Esterhuizen
Southern Africa Litigation Centre (SALC), LGBTI and Sex workers Rights Programme, Johannesburg, South Africa

Background: In Lusaka, police officials often perpetrate violence and abuse against sex workers and target them with the arbitrary and subjective enforcement of overly broad laws. This abuse increases the vulnerability of sex workers pushes them away from important health services and limits their access to information about their sexual and reproductive health needs. This study assesses the challenges faced by Lusaka's sex workers. It is aimed at developing advocacy and litigation strategies to address the systemic abuse of sex workers by the police in Lusaka. It also highlights mechanisms that activists and lawyers can use to hold officials accountable.
Description: This study is based on a combination of desk research and limited qualitative research. The desk research focused on the legal framework within which the police interact with sex workers in Zambia. In addition to this, focus group discussions were held with 39 self-identified female sex works (FSW) in two local languages, Nyanja and Bemba. The FSW, aged between twenty and forty, represented five different geographic districts across Lusaka. The purpose of the focus group discussions was to develop an understanding of the relationship between sex workers and police authorities.
Lessons learned: While the act of selling sex for reward is not criminalised in Zambia, police officials often use vagrancy and nuisance laws to arbitrarily arrest and detain sex workers. These offences are overbroad and subjectively applied, which creates a culture of impunity - in which both the clients and police officials can abuse sex workers without consequences. Often, police officials request sex from sex workers in exchange for not arresting, detaining, or fining them. Eighty seven percent (87%) of participants in the study reported that the police have harassed them because they engage in sex work. Sex workers' experiences with police affect their willingness to open cases at the police station, and therefore, often directly affect the extent to which they can access healthcare services post-rape, including post-exposure prophylaxis and emergency contraception.
Conclusions/Next steps: In order to protect the fundamental rights and dignity of sex workers, the Zambian Penal Code must be revised to repeal offences that are vague and overly broad.

THAD0103

Violence towards sex workers in the Netherlands

M. Kloek[1], M. Dijkstra[1], M. Jonker[1], D. Bons[2], L. Dekker[1], S. Hendriks[1], Study Group Consisting of Research Assistents from Sex Worker Led Organisation
[1]Aids Fonds, Sex Work Program, Amsterdam, Netherlands, [2]PROUD, Dutch Union for Sex Workers, Amsterdam, Netherlands

Background: Violence is one of the most important factors affecting the risk for sex workers around the world to HIV/AIDS. Due to their position in society and criminalising laws, sex workers are at risk for physical, sexual, economic and emotional violence from clients, co-workers, managers, institutions and others. This may cause inconsistent condom use and prevents sex workers globally from accessing necessary support and health care. This study assesses the current state of violence among sex workers in the Netherlands.
Methods: In this mixed methods study (including surveys, in-depth interviews and FGDs) sex workers were trained as research assistants and were part of the design and roll-out of the study. A very diverse group of 308 sex workers from all over the Netherlands was included.
Results: Overall violence experienced by sex workers in the Netherlands is high (physical violence 60%, sexual violence 78%, economic violence 58%, emotional violence 93%). Logistic regression analysis shows among others that male sex workers have 2.3 (p< .05) more odds for sexual violence and transgender sex workers have 4.9 (p< .05) more odds for emo-

Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

tional violence compared to their female peers. Young sex workers were found to have (e.g. 2,4 (p< .05) more odds for sexual violence). Sex workers who do not work in a licenced venue have 3,2 (p< .0001) more odds for sexual violence. Sex workers who work at massage salons have 8,5 (p< .01) more odds for sexual violence where as sex workers who work in hotel rooms have 4,6 (p< .05) more odds for emotional violence. Working in a window venue is a strong protective factor (3.1 (p< .05) less odds for sexual violence). Despite high levels of violence experienced by sex workers in this study most sex workers (79%) did not report any incident of violence to the police in the last 12 months.
Conclusions: Even though sex work is legal in the Netherlands, sex workers experience high levels of violence. Most sex workers do not report incidents to the police, which leaves them at higher risk. Decriminalization of sex work is necessary to increase access to justice for sex workers and reduce violence.

THAD0104

The impact of end-demand legislation on sex workers' utilization of HIV care, health and community-led support services in a Canadian setting

E. Argento[1,2], S.M. Goldenberg[1,3], M. Braschel[1], S. Moreheart[1], S.A. Strathdee[4], K. Shannon[1,5]
[1]BC Centre for Excellence in HIV/AIDS, Gender and Sexual Health Initiative, Vancouver, Canada, [2]University of British Columbia, Interdisciplinary Studies, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [4]University of California San Diego, Medicine, San Diego, United States, [5]University of British Columbia, Faculty of Medicine, Vancouver, Canada

Background: Despite scientific and legal evidence on the harms of criminalization of sex work, Canada adopted new end-demand legislation - the Protection of Communities and Exploited Persons Act (PCEPA) - in 2014 that criminalizes new aspects of sex work (e.g., clients, third party advertising). One of the explicit goals of end-demand approaches is to increase access to services and supports for sex workers, despite substantial evidence that criminalization impedes access. This study aimed to longitudinally evaluate the impact of the PCEPA on sex workers' access to HIV care, primary care, and community/sex worker-led services in Vancouver, Canada.
Methods: Data were drawn from a prospective community-based cohort of women sex workers, known as AESHA (An Evaluation of Sex Workers Health Access) represented by experiential team members. Multivariable logistic regression with generalized estimating equations (GEE) examined the independent effect of the post-PCEPA period (2015-2017) versus the pre-PCEPA period (2010-2013) on sex workers' utilization of HIV care and community-driven services and supports, using time-updated data.
Results: In separate multivariable confounding models, the post-PCEPA period was independently correlated with significantly reduced odds of utilizing community-driven (e.g., sex worker-led, Indigenous, migrant/refugee, women or youth-specific) services and supports (AOR 0.60; 95%CI: 0.49-0.73). There was no evidence of increased access to HIV-specific services among sex workers living with HIV following implementation of the new laws (AOR 1.30; 95%CI: 0.85-2.00). The post-PCEPA period was also correlated with significantly reduced odds of accessing health services when needed (AOR 0.59; 95%CI: 0.45-0.78).
Conclusions: Findings show no increase in utilization of HIV care or other health services post-PCEPA, and rather a reduction in odds of accessing community-driven supports and health services when needed. Findings demonstrate that end-demand approaches to criminalize sex work may not only reproduce the harms of previous criminalized approaches to sex work in Canada, but may further exacerbate barriers to accessing health and community-led services that have been proven to be key contributors of better health outcomes. There is a critical evidence-based need to move away from criminalized approaches to sex work to ensure full labor and human rights for sex workers, including access to health, social, and legal support services.

THAD0105

"Ending demand" in France: The impact of the criminalisation of sexworkers´ clients on sexworkers' health, security and exposure to HIV

H. Lebail[1], T. Leicester[2], C. Giametta[3]
[1]CNRS - Sciences Po, Centre de Recherches Internationales, Paris, France, [2]Médecins du Monde [Doctors of the World], France Fieldwork Operations, Paris, France, [3]Aix-Marseille University, Laboratory or Mediterranean Sociology, Marseille, France

Background: As of April 2016 France criminalized sexworkers' clients as part of new legislation aimed at "Fighting against the prostitutional system" inspired by the so-called "Swedish model". Detractors of the new legislation have cited the risks that the new law increases sexworkers' vulnerability and exposure to stigma and violence, hinders their access to health and legal services and increases risks of exploitation in the sex industry. Based on these arguments, Médecins du Monde (Doctors of the World) initiated a survey aimed at evaluating the impact of the law on sexworkers' health, rights and well-being.
Methods: Research was conducted between April 2016 and January 2018 based on mixed-methodology including qualitative semi-directive interviews and a questionnaire-based quantitative survey. Two researchers in social sciences oversaw research methodology and data analysis, and data collection was undertaken with a strong involvement of 13 civil-society organisations (health NGOs, community-based health NPOs and sex worker groups). 70 semi-directive interviews with sex workers, 28 interviews with outreach service-providers and 583 questionnaires completed by sexworkers were collected in 9 different cities and overseas territories.
Results: The most direct effect of the 2016 law on sex workers has been an acute increase in their socio-economic vulnerability. This vulnerability is interconnected with a multiplicity of factors including: the increase of violence; degrading working conditions; negative impact on sexworkers' health. Our research also highlights the decrease in condom use and the increasing difficulty for sex workers to negotiate safe-sex practices as well as the difficulty of accessing treatment for HIV+ sexworkers. Whilst it is still too early to evaluate the impact in terms of HIV infections, the research points to an increase in some STIs, notably of syphilis, amongst sexworkers in France.
Conclusions: Sexworkers are a key population in the fight against HIV. Our research clearly demonstrates the negative consequences of the criminalisation of clients on sexworkers' ability to practice safe sex and prevent HIV infection. The results have far-reaching implications for policy-makers considering the legal framework around sexwork and are highly relevant to health workers, activists and sex-worker groups advocating to improve the rights of sexworkers and mitigate the negative impacts of repressive policy.

THAD02 Dignity has no nationality: HIV and migrants' rights

THAD0201

Criminal justice involvement as a social determinant of sexual risk among male migrant and non-migrant market vendors in Kazakhstan: Implications for HIV prevention and human rights

P. Marotta[1,2,3], A. Terlikbayeva[1,2,3], S. Primbetova[1,2,3], A. Mandavia[1], T. Hunt[1,2,3], L. Gilbert[1,2,3], L. Beletsky[4], G. Mergenova[1,2,3], E. Wu[1,2,3], N. El-Bassel[1,2,3]
[1]Columbia University, New York City, United States, [2]Social Intervention Group, New York City, United States, [3]Global Health Research Center of Central Asia, New York City, United States, [4]Northeastern University, Boston, United States

Background: This longitudinal study assessed associations between criminal justice involvement (CJI) and sexual risk behaviors in a sample of male migrant and non-migrant vendors in the largest open-air marketplace in Central Asia. We hypothesized that questioning by market officials and migration police, experiencing arrest and incarceration would be associated with greater likelihood of sex under the influence of drugs or alcohol, more than one sexual partner, condomless sex, transactional sex, condomless sex while traveling, and more than one sexual partner while traveling.
Methods: We employed respondent driven sampling (RDS) to recruit 1,342 male vendors consisting of external migrants from Tajikistan, Uzbekistan, and Kyrgyzstan, internal migrants and a non-migrant comparison group from Kazakhstan. Multiple imputation with chained equations (ICE) adjusted for bias introduced from missing data at baseline and 3, 6, and 12-month assessments (5,863 observations). Multi-level logistic regression with time period fixed effects and random intercepts estimated odds ratios (OR) of associations between CJI and sexual risk behaviors overall and by non-migrant and migrant groups.
Results: Table 1 provides CJI, and sexual risk behaviors stratified by migration status. In multivariate models, questioning by market officials predicted increased risk of condomless sex (OR=1.02, SE=0.01, p<0.05), sex under the influence of drugs/alcohol (OR=1.03, SE=0.01, p<0.01), transactional sex (OR=1.05, SE=0.01, p<0.001) and more than one sexual partner while traveling (OR=1.06, SE=0.02, p<0.001). Contacts with migration police predicted increased risk of sex under the influence of drugs/alcohol (OR=1.02, SE=0.008, p<0.01). Arrest predicted increased risk of sex under the influence of drugs/alcohol (OR=1.91, SE=0.31, p<0.001), more than one sexual partner (OR=1.33, SE=.20, p<0.10), condomless sex (OR=1.42, SE=0.16, p<0.01), transactional sex (OR=1.96, SE=0.44, p<0.01) and more than one sexual partner while traveling (OR=2.62, SE=0.60, p<0.001). Incarceration predicted increased risk of sex under the influence of drugs (OR=3.79, SE=1.08, p<0.001), sex with more than one partner (OR=1.71, SE=0.44, p<0.05) and transactional sex (OR=4.16, SE=1.70, p<0.001).

	External migrant %(obs.)	Internal migrant %(obs.)	Non-migrant %(obs.)	Overall %(obs.)
Sex under the influence of drugs/alcohol	11.47(143)	15.08(141)	11.60(219)	12.49(503)
Transactional sex	7.31(72)	6.76(66)	5.99(101)	6.47(239)
Unprotected sex	35.53(609)	32.54(321)	34.66(585)	34.28(1515)
>1 sex partner while traveling	3.16(31)	7.37(55)	4.24(59)	4.84(145)
Questioning by market officials	1.05(.21)	.50(.11)	.51(.11)	.62(.08)
Questioning by migration police	3.10(.50)	.86(.27)	1.13(.28)	1.47(.18)
Arrest	26.58(711)	10.37(120)	7.69(190)	12.37(1021)
Incarceration	4.27(125)	2.48(23)	1.83(34)	2.51(182)

[Table 1. Population estimates of CJI and sexual risk by migration status (obs. 5868)]

Conclusions: Findings underscore the need for structural interventions that target law enforcement and other criminal justice policies to facilitate HIV prevention interventions with key populations including male labor migrant market vendors in Kazakhstan.

THAD0202

Harms of workplace inspections for im/migrant sex workers in indoor establishments: Enhanced barriers to health access in a Canadian setting

B. McBride, K. Shannon, P. Duff, M. Braschel, S.M. Goldenberg, AESHA Study Team
BC Centre for Excellence in HIV/AIDS, Gender and Sexual Health Initiative, Vancouver, Canada

Background: New end-demand sex work legislation (PCEPA) was passed in Canada in 2014, the enforcement of which may disproportionately impact im/migrant women in indoor venues due to its focus on third party advertising and conflation of sex work with sex trafficking (forced sexual labour). Im/migrant sex workers face intersecting concerns regarding criminalization, restrictive immigration policies, and poor health access, yet evidence is limited regarding how experiences and perceptions of criminalized enforcement impact health access. This study examined correlates of worrying about workplace inspections by authorities and modeled the independent effect of worrying about inspections on health access amongst indoor sex workers over a 2.5-year period (2014-2017).
Methods: Longitudinal data were drawn from AESHA, a community-based prospective open cohort involving 900+ sex workers across Metro Vancouver. Experiential (current/former sex workers) and non-experiential staff guided participants through interviewer-administered semi-annual questionnaires. Bivariate and multivariable logistic regression with generalized estimating equations (GEE) were used to investigate factors correlated with worrying about workplace inspections, using time-updated data at each semi-annual visit. A separate confounder model was used to examine the independent impact of worrying about inspections on barriers to health access.
Results: Across the 2.5-year study, of 397 indoor sex workers, 23.9% experienced workplace inspections and 51.6% worried about legal, economic or social consequences of inspections. In multivariable GEE analyses, worry about inspections was correlated with recent im/migration (adjusted odds ratio[AOR] 3.13; 95% confidence interval[CI] 1.77-5.53), police harassment (AOR 3.49; 95%CI 1.92-6.34), workplace violence (AOR 1.66, 95%CI 1.09-2.51), and enhanced work stress (AOR 1.05 per additional point on work stress scale, 95%CI 1.01-1.09). In a multivariable GEE confounder model adjusted for key confounders, worry about inspections had an independent effect on enhanced barriers to health access (AOR 1.45, 95%CI 1.06-1.98).
Conclusions: Im/migrant sex workers had higher odds of worrying about inspections and their consequences, and worrying about inspections was linked to enhanced barriers to health access. Findings suggest that enforcement-based approaches to sex work may exacerbate poor health access amongst sex workers in indoor venues, particularly recent im/migrants. Legal reforms that decriminalize sex work, avoid conflation of sex work and sex trafficking, and enable safer indoor workspaces are recommended.

THAD0203

The influence of immigration law concerns on drug use and HIV risk

B. Suro Maldonado[1], C. Galletly[2], J. Lechuga[3]
[1]Lehigh University, Education, Bethlehem, United States, [2]The Medical College of Wisconsin, Milwaukee, United States, [3]Lehigh University, Bethlehem, United States

Background: Hispanic immigrants are disproportionately impacted by health disparities in many domains. For example, they have the second highest rate of Human Immunodeficiency virus (HIV) infection of any racial or ethnic minority group in the United States (U.S). Although past research has documented the impact of the existence of immigration laws that criminalize immigration on access to health care none of the aforementioned studies examined participants' perceptions and understanding of the immigration laws that lead them to avoid and the effect of such perception on accessing health care services and HIV testing.

The purpose of the present study is to investigate the impact of fear of deportation and perceived enforcement of immigration law on Hispanic immigration law related concerns, access to health care and HIV testing.
Methods: Three hundred and thirty-nine U.S Hispanic immigrants between the ages of 18 to 74 years (*M*=34.08 years, *SD* = 9.12) were recruited primarily through Spanish radio ads and referrals from a network of community based organizations serving Hispanics in metropolitan areas in Virginia and North Carolina. The inclusion criteria included the following: be at least 18 years old, engaged in sexual risk behavior in the past 12 months, reported negative or unknown HIV status, and lived in the U.S for at least 6 months. Data analysis consisted of descriptive statistics to describe the sample and blocked logistic and linear regression analysis.
Results: Results indicated that concern with being a public charge, which refers to concern that seeking publicly funded health services will present a barrier for adjusting one's or a family member's immigration status is associated with reduced HIV testing OR = .07 [.02,.28] $p < .01$, fear of seeking healthcare services due to immigration status = .22, $p < .01$, and more logistical barriers seeking health care services = .15, $p < .01$.
Conclusions: Our findings indicate that immigrant's perceptions of immigration law consequences are significantly associated with health behaviors. In light of the present negative political rhetoric towards immigrants around the world it is important to research the potential negative impact that such climate may have in willingness to seek health care services.

THAD0204

Ensuring access to primary care for undocumented migrants in England

Y. Azad, C. Hicks, K. Smithson, D. Gold
NAT (National AIDS Trust), London, United Kingdom

Background: In the UK, the National Health Service (NHS) is a comprehensive health service providing free healthcare to all UK residents. It is funded by taxation i.e it is not an insurance-based or contributory system. However, in England undocumented migrants are not eligible for free care and are charged for accessing certain services.
Description: Migrants, especially from sub-Saharan Africa, are amongst the most affected by HIV in the UK. Black African men and women living in the UK making up 1.8% of the UK population but 31% of all people accessing HIV care.
Despite securing free HIV treatment for migrants in 2012, we continued to be concerned about charging migrants for other elements of healthcare, which would deter migrants from accessing healthcare and reduce opportunities for migrants to be tested and diagnosed. Primary care is a key site for HIV diagnosis and in England migrants are more likely to be diagnosed with HIV in primary care than in a sexual health clinic.
The Government has looked to implement primary care charging for a number of years. Most recently, in the Government's 2015-16 consultation on further extensions of charging, the Government canvassed views of stakeholders on charging in primary care. We submitted a consultation response detailing the public health impact of such a move. We also supported a coalition of other NGOs to respond making the case for access to primary care. In early 2017, the Government announced that they were putting off immediate plans to charge in primary care.
Lessons learned: We have ensured that, despite the current anti-immigration policy context in England, primary care remains free for everyone irrespective of residency status. The public health argument, in a political climate where migrants are a marginalised and politically unpopular group, is an argument that policy-makers have particularly taken note of. Important to the success of our campaigning has been; a united voice from the HIV sector including clinicians, strategic coalitions with health and migration organisations, mobilising parliamentarians, and utilising the evidence base.
Conclusions/Next steps: Advocacy will continue to ensure that migrants can continue to access primary care and other vital parts of the health service.

THAD0205

Migrant's perspective on TB and HIV in relation to healthcare services: A qualitative study in Stockholm, Sweden

V. Tirado[1], J. Shedrawy[1], S. Strömdahl[1,2], C. Hanson[1], K. Lönnorth[1], A.M. Ekström[1,3]
[1]*Karolinska Institutet, Public Health Sciences, Stockholm, Sweden,* [2]*Uppsala University, Uppsala, Sweden,* [3]*Karolinska Hospital, Stockholm, Sweden*

Background: While most refugees are young adults in relatively good physical health, the unprecedented stress and trauma that most are exposed to on-route affects their mental well-being and also favors the spread of infectious diseases, such as HIV and tuberculosis (TB) and challenges their health. In Sweden, newly arrived migrants are offered a free-of-charge examination to identify and provide treatment of infectious diseases, including HIV and TB. However, little is known about the migrants' knowledge and attitude towards HIV and TB screening in the host country. We aim to explore the knowledge and attitudes about HIV and TB in relation to the healthcare services through migrant's perspective in Stockholm.
Methods: Focus group discussions (FGD) and in-depth interviews (IDI) with migrants were conducted during late 2017 and early 2018 in various settings; specialized health clinics for migrants and civil societal organizations meeting newly arrived migrants in Stockholm, Sweden. The FGD were organized with homogenous groups of 7 individuals based on gender, age range and language. The IDI with 6 migrant men and women were utilized to allow for sensitive thoughts to emerge. The interviews were done with migrants with latent TB, and migrants have that not tested for HIV since arrived to Sweden. We conducted latent content analysis.
Results: In Sweden, migrants reported the following: experience stigma associated with testing for HIV and TB; fear of positive diagnosis for TB and HIV infection: limited knowledge about available services to screen and treat for HIV/TB; delay timely healthcare seeking due to fear of and stigma; and fear of losing social and family support in the case of HIV/TB diagnosis.
Conclusions: HIV and TB screening are perceived as a necessity for newly migrants and receive information upon arrival to Sweden. Crowded living conditions, language barriers, stigma, myths about HIV and TB, as well as fear of deportation also add to reluctance of migrants to seek for screening, delaying diagnosis and treatment. It can be seen as an opportunity to critically evaluate actions taken for newly arrived migrants, and to learn from and to share experiences between policy-makers and service providers concerning migrant's health in Sweden.

THAD03 Community system strengthening = Sustainable HIV response

THAD0301

Community monitoring in HIV prevention programs with sex workers in Kyrgyzstan

S. Radchenko, A. Myrzabekova
Tais Plus, Bishkek, Kyrgyzstan

Background: The goal is to regularly monitor the quality of services and legal barriers that prevent sex workers from participating in HIV programs, including monitoring of:
- approaches to working with sex workers
- adequacy of services in terms of needs and context
- work of state agencies
Monitoring in the field is accompanied with technical assistance to NGO.
Description: Tais Plus conducted monitoring by the community during 2016-2017 in the framework of the Global Fund program, the components "Community Systems Strengthening" and "Removing Legal Barriers" (CSS and RLB).

Monitoring tools have been developed for conducting focus groups with NGOs in the following areas: VCT, STI services, capacity of NGOs to work on CSS and RLB.
For 2 years, Tais Plus staff has visited 6 NGOs on a quarterly basis, which implement HIV prevention programs with sex workers in Kyrgyzstan. During each visit, focus groups were held with NGO staff, as well as meetings with sex workers, during which participants shared their concerns and feedback on the work of NGOs, and also discussed their barriers and opportunities to actively participate in HIV and rights programs. Conclusions&recommendations from each visit were agreed with NGOs, and then sent to the principal donors funding HIV and rights programs to inform them about the need to make changes in current activities.
Technical assistance was based on the SWIT.
Lessons learned: For two years:
- 10 Tais Plus staff participated in monitoring visits, 8 of them - on a voluntary basis.
- 5 visits were made to most of the NGOs
- 47 employees from 6 NGOs participated in monitoring, including focus groups discussions and on-the-job trainings
- The proposals to improve the following program areas with sex workers were developed and agreed with NGOs: information work, VCT, legal barriers, community strengthening, STI&SRHR services, and increasing NGO capacity. These proposals are addressed to both NGOs and donors.

Conclusions/Next steps:
- Monitoring through community should be an integral part of HIV programs, and its results should be used to plan and adjust programs
- Ensure training employees who are sex workers of visited organizations to monitor and then form mixed monitoring teams.

THAD0302

When situations go from bad to worse: Strengthening collective action during periods of crisis through concrete guidance and principles for engagement

R. Dayton[1], M. Sundararaj[2], S. Mellors[3], J. Keatley[4], J. Chang[5], G.T. Brighton[6]
[1]FHI 360, LINKAGES, Durham, United States, [2]Global Forum on Men who have Sex with Men and HIV, Oakland, United States, [3]International HIV/AIDS Alliance, Brighton, United Kingdom, [4]Innovative Response Globally for Trans Women and HIV, Oakland, United States, [5]International Network of People Who Use Drugs, London, United Kingdom, [6]Network of Sex Work Projects, Bulawayo, Zimbabwe

Background: Acute violence, defined as periods of increased severe emotional, physical, sexual, and economic abuse, against key populations—men who have sex with men, people who inject drugs, sex workers, and transgender women—is increasing, including in East Africa. Recent examples include the torture of peer educators, the arrest of mobile outreach teams, and the ransacking of key population-led community-based organizations (CBOs)—all of which disregard human rights and undermine efforts to curb the HIV epidemic. While local actors lead the response to acute violence, international and regional stakeholders—such as global and regional key population networks, international non-governmental organizations (NGOs), and donors—must be able to play an effective role if requested.
Methods: In 2017, the Technical Advisory Group on Violence, Stigma, and Discrimination Against Key Populations supported by the PEPFAR and USAID-funded LINKAGES project, convened CBOs, NGOs, United Nations agencies, donors, security experts, and global and regional key population networks working in East Africa to identify current challenges in acute violence responses, articulate principles for local engagement, and generate recommendations for international and regional actors.
Results: Barriers to appropriate and effective responses by international and regional stakeholders' include: acting without guidance from those most affected, causing added stress and danger for local actors; a failure to adequately resource program staff most at risk, increasing their vulnerability; and support to individual local partners instead of collectives, resulting in duplicative investments and fractured coalitions. Recommendations include deference to local actors, appropriate resourcing, and pre-emptively forming local collectives and international and regional coordinating bodies that can act in a unified immediate way. Principles to guide international or regional actors' engagement reinforce the importance of: embracing "first, do no harm" in every aspect of key population programming, avoiding false dichotomies between human rights and HIV objectives, and striving to take a long-term view even during a crisis.
Conclusions: International and regional actors operating in East Africa and beyond can strengthen their responses to acute violence by taking concrete steps, grounded in principles for engagement, thereby protecting key population members' human rights and removing barriers to the effective implementation of HIV programs.

THAD0303

Monitoring and evaluating technical assistance to key populations and HIV projects in Russia: Removing legal barriers and community systems strengthening

S. Ka Hon Chu[1], M. Golichenko[1], A. Bidordinova[2], R. Elliott[3]
[1]Canadian HIV/AIDS Legal Network, Research and Policy, Toronto, Canada, [2]Canadian HIV/AIDS Legal Network, Consultant, Toronto, Canada, [3]Canadian HIV Legal Network, Research and Development, Toronto, Canada

Background: In 2015-2017, non-governmental organizations in Russia delivered HIV services for people who use drugs, sex workers and men who have sex with men with the support of the Global Fund to Fight AIDS, Tuberculosis and Malaria. The service component was aligned with an advocacy component, which included community systems strengthening activities (CSS) to empower and mobilize key affected populations (KPs) to engage in meaningful dialogue with authorities, and activities to educate KPs and provide them with tools to challenge discrimination and remove legal barriers (RLB) for HIV services. In 2016 the Canadian HIV/AIDS Legal Network provided legal technical assistance (TA) for the advocacy component.
Description: A Monitoring, Evaluation and Learning framework was designed to collect and analyze quantitative and qualitative data to assess (1) how staff of HIV projects and KP representatives rated the TA; and (2) how the access to legal aid changed as a result of the TA.
Lessons learned: Through the TA, access to legal aid significantly improved. Over 500 community legal workers (CLWs) and KPs participated in CSS/RLB capacity-building and networking activities. CLWs consulted with 7,683 clients and the TA team provided direct legal support for 950 clients. Of 1,195 documented cases, 929 were partially or fully resolved, including through formal complaint and court procedures (580 cases) and legal mediation. Two shadow reports to two UN treaty bodies resulted in strong recommendations to Russia regarding the discrimination and HIV prevention among SW and PWUD. CLWs and project managers rated the TA as a very important component in vitalising legal advocacy and integrating human rights promotion and protection into national, community- based programs.
Conclusions/Next steps: Legal TA is important to help CLWs and KPs navigate complex legal environments, encourage and empower them to address discrimination and human rights violations, thus reducing the risks of HIV. With the support of the Elton John AIDS Foundation, the Legal Network will implement the "best practices" of the 2016 TA project in its current 2017-2020 legal TA project in St. Petersburg to help people who use drugs access a continuum of HIV care services.

The Caribbean civil society shared incident database: A monitoring and reporting mechanism to strengthen community activism to address human rights violations

M. Thompson, K. Mena, I. Cruickshank
Caribbean Vulnerable Communities Coalition, Programme Department, Kingston, Jamaica

Background: People living with HIV and key populations in the Caribbean frequently experience human rights violations including denial of access to health, housing, employment, as well as social exclusion and violence.
Description: In 2016, the Caribbean Vulnerable Communities Coalition (CVC) established the Shared Incident Database (SID), the first regional civil society-led human rights monitoring mechanism which records, analyses and exchanges information on rights violations. It facilitates comprehensive data collection through standardised intake procedures which enhance the capacity of KPs and CSOs to document rights breaches and enables data sharing to support redress or engagement with policy, public health and legal decision-makers.Clients identifiable details are only visible at an organizational level and there are varied data access levels within an organization profile. At an organizational, national and regional level the database generates non-identifiable aggregated data with geographic identifiers. The database is linked to redress opportunities such as Cari-bono which is a network of lawyers around the Caribbean who will be offering pro-bono services to cases documented. Technical assistance was provided to civil society organizations to build capacity in the community monitoring of legal rights and use of SID.
Lessons learned: As a result of improved community monitoring of legal rights, there have been five legal challenges filed before the courts in Jamaica, Guyana and Trinidad & Tobago respectively.
The database has support the building of CSO capacity to carry out redress for their clients. While CSOs engage their clients around redress, it provides capacity building opportunity for community members to take on self-advocacy.
For instances where persons are not aware of the official patient complaint mechanism, SID has proven to be viable substitute once there is an understanding between the CSOs documenting the right violations and the health care officials.
Conclusions/Next steps: Use one of the incidents entered into SID to undertake strategic litigation for the improvement of the legal enabling environment for PLHIV and key populations. To have CSOs documenting rights violations in all the Caribbean countries and territory
Increase awareness.

THAD0305

Strengthening HIV-related community organizations: Evidence from a large-scale program in India

M. Battala, S. Patel, M. Walia, S. Mukherjee, B. Mahapatra, N. Saggurti
Population Council, HIV/AIDS, New Delhi, India

Background: Community-organizations (COs) are at the front lines of combating the AIDS epidemic, particularly among marginalized populations. Yet they often have institutional weaknesses that make their stability uncertain. The Bill and Melinda Gates Foundation, through its Avahan program in India, supported the development and strengthening of COs in high HIV prevalence states to help reduce socioeconomic vulnerabilities among key populations. We assessed the capacities of the COs over a three-year period in program implementation, resource mobilization, networking, and advocacy.
Methods: The training of the COs to deliver quality services was based on four pillars:
(i) strengthening institutional capacity,
(ii) improving access to social protection schemes,
(iii) enhancing financial security and
(iv) providing effective social justice and security efforts.
Further COs' capacities were strengthened in resource mobilization, advocacy, networking, etc. Data collected in two survey rounds during 2015 and 2017 from 48 COs have been used in the analysis, that includes descriptive statistics, frequencies and bivariate techniques.
Results: More than 42,000 new members were enrolled across the COs in the last three years. A three-fold increase was found in their corpus fund from an average of US$ 2,961 per CO in 2014 to US$ 8,844 in 2017. Similarly, the COs have been immensely successful in raising funds from various sources; 71% of COs have generated funds in 2017 as compared to 46% in 2014. COs generated on average US$ 3,604 in the last three years, 56% of which was raised in the program's last year. COs engagement with different district level forums, government officials and institutions increased significantly over time; Police (35% vs 75%), Social welfare department (32% vs 81%), Judiciary (31% vs 79%) and with formal financial institutions (37% vs 77%).
Conclusions: Most of the COs demonstrated significant improvement in increasing their corpus fund through resource mobilization, establishing networks with a wide range of stakeholders, and taking up various income generating activities. Strengthening COs to implement focused interventions inculcates ownership among members and an increased probability of organizational sustainability.

THAE01 Confronting violence against women

THAE0101

What do we know about interventions to prevent and reduce gender-based violence among young people living with, or most affected by, HIV in low- and middle-income countries? A systematic review

F. Meinck[1,2], M.T. Little[1], V. Nittas[3], V. Picker[1], A. Bustamam[4], L. Orza[5], M. Pantelic[5], H. Stöckl[6]
[1]University of Oxford, Social Policy and Intervention, Oxford, United Kingdom, [2]North-West University, School of Behavioural Sciences, Vanderbeijlpark, South Africa, [3]University of Zurich, Epidemiology, Biostatistics and Prevention Institute, Zurich, Switzerland, [4]McMaster University, Department of Health Research Methods, Evidence, and Impact, Hamilton, Canada, [5]International HIV/AIDS Aliance, Brighton, United Kingdom, [6]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom

Background: Adolescents and young people are disproportionately affected by gender-based violence (GBV). GBV is associated with an increased risk of HIV acquisition and can disrupt access to treatment and retention in care, resulting in worse HIV outcomes. This systematic review aims to assess effectiveness of existing GBV interventions evaluated among young people vulnerable to HIV aged 10-24 in low-and middle income countries (LMICs).
Methods: Studies were identified by searching databases, grey literature, trial registries, back referencing and contact with researchers and program implementers. Abstracts were screened by two researchers according to the inclusion criteria pre-specified in the review protocol. Randomized, cluster-randomized and quasi-experimental studies with control group were included if they assessed GBV or attitudes towards GBV as an outcome. Data were extracted using a form adapted from the Cochrane Collaboration and narratively synthesized. Study quality was assessed using the Cochrane Risk of Bias tool.
Results: Thirteen studies with 35,322 participants were included. Interventions were structural (5), school-based (4), community-based (2), and individual-focused (2). Interventions aimed to empower young women (5), change behaviors (4), remove economic barriers among young women (2) or change gender norms (2). All interventions had multiple components (e.g. life-skills and health education, micro-grants, or social support). ONE intervention specifically included a key population (sex-workers); the remaining included young people in high HIV-prevalence settings. No interventions for HIV+ adolescents were found.
Overall, the studies had a median risk reduction of 15% (range: 4-60%) in self-reported GBV exposure favoring the intervention, and TWO studies reported a median risk reduction of 7% (range: 1-12%) in self-reported

GBV perpetration favoring the intervention. SIX studies reported reductions in physical/emotional intimate partner violence, THREE studies reported reductions in physical coercion/violence, ONE study reported reduction of verbal assault by opposite sex, and FOUR studies reported reduction of any sexual assault/forced sex. No harmful effects could be observed. Structural and school-based interventions were most effective.
Conclusions: Structural and school-based interventions targeting behaviors, economic barriers, negative gender norms and promoting empowerment may help to substantially reduce and prevent GBV among young people vulnerable to HIV in LMICs. Evidence on effective GBV interventions for young key populations is urgently needed.

WINGS of hope: Evaluating effects of integrating a brief gender-based violence prevention intervention with HIV counseling and testing among women who use drugs in Kyrgyzstan

T. Musagalieva[1], D. Nikitin[2], A. Pugachev[2], L. Gilbert[3], T. Hunt[3], T. Jiwatram-Negron[3], O. Rychkova[4], A. Mukambetov[5], I. Sadykov[5], I. Ermolaeva[6], R. Bayazitova[7], M. Atabekova[6], N. Sharonova[8], M. Akmatova[8], M. Abduraupova[9], S. Nazarova[9], E. Tkacheva[10], R. Mazhitov[11]
[1]ASTERIA Foundation, Bishkek, Kyrgyzstan, [2]GLORI Foundation, Bishkek, Kyrgyzstan, [3]Columbia University Social Intervention Group, New York, United States, [4]Previously Open Society Foundations, New York, United States, [5]Soros Foundation Kyrgyzstan, Bishkek, Kyrgyzstan, [6]Asteria Foundation, Bishkek, Kyrgyzstan, [7]Asteria Foundation & Ganesha Foundation, Bishkek, Kyrgyzstan, [8]Podruga Foundation, Osh, Kyrgyzstan, [9]Positive Dialogue Foundation, Osh, Kyrgyzstan, [10]Chance Crisis Center, Bishkek, Kyrgyzstan, [11]Plus Center, Osh, Kyrgyzstan

Background: Gender-based violence (GBV) negatively impacts access of women who use drugs (WWUD) to HIV prevention and to drug treatment. Collaboratively with consultants at Columbia University Social Intervention Group, partner Kyrgyz-based NGOs and GLORI Foundation, we developed WINGS of Hope intervention that includes GBV screening, brief intervention and referral to treatment service (SBIRT) with HIV counseling, testing and linkage to care. We evaluated the feasibility and acceptability of WINGS (Women Initiating New Goals for Safety) GBV-prevention model adapted for helping WWUD in Kyrgyzstan to access HIV prevention and harm reduction services.
Methods: In 2013-2016, 213 WWUD in Kyrgyzstan participated in WINGS of Hope intervention study. Each participant attended the 2-session GBV SBIRT intervention that included raising awareness about different types of GBV and how GBV increases risk for substance misuse and HIV, screening for GBV, safety planning, and identifying goals to increase safety. Women participants were offered voluntary HIV rapid testing and linkage to HIV care when necessary (Gilbert et al., 2016). We used a pre-post design to evaluate the effects of the intervention.
Results: At 3-month follow-up assessment, participants experienced 11% fewer intimate partner and 39% fewer gender-based violence incidents of any kind than what they had experienced at baseline. Also, there was a 38% increase in women who experienced neither IPV nor GBV "in the past 3 months". The number of women who completed the gender-specific HIV testing, increased from 37 to 61%, from 14 to 29% increased number of women who received counseling or group support to deal with GBV. All 10 women who tested positive for HIV, including 3 new cases, were referred to HIV treatment at the AIDS Centers.
Conclusions: The high rates of participation, attendance, and retention, as well as significant reductions in GBV victimization suggest the feasibility and promising effects of this WINGS SBIRT-based intervention to help WWUD who experience GBV, and link them to appropriate HIV services. The GBV services for WWUD should be integrated into and coordinated with social, medical and legal services. The project findings underscore the need for gender-sensitive harm reduction services for WWUD.

THAE0103

Integrating gender-based violence screening and support into HIV counselling and testing for adolescent girls and young women accessing PrEP in South Africa and Tanzania - experiences from the EMPOWER study

M.B. Colombini[1], L. Ramskin[2], N. Khoza[2], A. Stangl[3], F. Scorgie[2], S. Harvey[4], C. Manyamba[2], C. Watts[4], S. Kapiga[5], S. Delany-Moretlwe[2], EMPOPOWER Study group
[1]London School of Hygiene and Tropical Medicine, Public Health and Policy, Pretoria, South Africa, [2]Wits Reproductive Health Institute, Johannesburg, South Africa, [3]International Center for Research on Women, Washington DC, United States, [4]London School of Hygiene and Tropical Medicine, Public Health and Policy, London, United Kingdom, [5]Mwanza Intervention Trials Unit, Mwanza, Tanzania, United Republic of

Background: Partner violence may undermine oral PrEP use, yet evidence is scarce on how to best to support PrEP use while decreasing vulnerability to violence. We assessed the feasibility and acceptability of integrating gender-based violence (GBV) screening and support into HIV counselling for adolescent girls and young women (AGYW) accessing oral PrEP.
Methods: EMPOWER is an open-label PrEP demonstration project for AGYW (16-24 years) in South Africa and Tanzania. We adapted HIV counselling and testing guidelines for lay counsellors to include five questions about exposure to gender-based violence (GBV), recommended by the World Health Organisation. Participants were screened at baseline and at each follow-up visit. We analysed data from counselling session observations (n=10 in SA only) and in-depth interviews with participants (n=39, SA = 25, Tz =14) and clinical staff (n=13, SA = 10, Tz =3). Themes explored included: comfort with GBV screening sessions, usefulness of risk assessment and safety planning, and appropriateness of referrals to GBV support services.
Results: We screened 619 and enrolled 431 HIV negative AGYW (SA=379; Tz=52). 141 (SA=119; Tz= 22) reported lifetime experiences of violence at baseline. Including GBV screening within HIV counselling sessions was feasible, provided continuous training and staff support was available. Overall, study participants were amenable to GBV screening, provided that the basic principles of confidentiality, staff empathy, and absence of judgment were observed. Participants who reported abuse said that it was reassuring and helpful to talk to friendly, non-judgemental counsellors. Challenges reported by HIV counsellors included: initial discomfort in asking about violence; facilitating disclosure of suspected cases; length of time taken to complete the sessions; and offering help when participants did not want any referrals. Staff felt supported by regular debriefings, a directory of referral services for GBV, and an on-site social worker.
Conclusions: Overall, our study suggests that integrating GBV screening into HIV counselling and testing for AGYW is acceptable and feasible when appropriate referral, staff debriefing and technical support are offered, and basic principles of empathetic listening and confidentiality are respected. It is essential that counselling for this group is adolescent-friendly and non-judgmental.

THAE0105

Group therapy for gender-based violence (GBV): Reducing HIV and GBV risk among adolescent girls and young women in Nairobi's informal settlements

M. Muia[1], B. Odero[1], M. Nderitu[2], T. Simiyu[3], C. Bennett[4], M. Kariuki[2], D. Wendo[5]
[1]National Organization of Peer Educators, Nairobi, Kenya, [2]IMA World Health, Nairobi, Kenya, [3]USAID, Nairobi, Kenya, [4]IMA World Health, Washington, United States, [5]IMA World Heatlh, Nairobi, Kenya

Background: The 2015-2018 USAID/Kenya and East Africa funded Afya Jijini program is implementing the Determined, Resilient, Empowered, AIDS free, Mentored and Safe (DREAMS) intervention to help empower adolescent girls and young women (AGYW) and reduce their HIV risk in Nairobi, Kenya's informal settlements. Five in every 10 Kenyan wom-

en (about 47%) between ages 15 to 49 have experienced at least one form of violence in their lifetime. Adolescent girls and young women in Nairobi's informal settlements are uniquely vulnerable to HIV. Their vulnerability cuts across behavioral, social and biological factors. AGYW often engage in age-disparate and/or transactional relationships as a result of poverty and unemployment, putting them at increased HIV risk. The perception that AGYW can negotiate monogamy, condom use, as well as request their male sexual partners (MSPs) to get circumcised, is still largely unheard of for most AGYW living in the project's catchment areas.

Methods: Group therapy for GBV, facilitated by a trained trauma counselor allows AGYW to cultivate trust and share GBV experiences during group sessions. This therapy includes recognition of emotional self-awareness, followed by cognitive autonomy sessions that enable AGYW to take responsibility for their own change. The therapy sessions provided post violence counseling support to 2,452 enrolled AGYW at 12 safe spaces across Mukuru Kwa Njenga Ward. Ninety-five percent (n=2,320) of AGYW accessed counseling for physical violence, with 5% (n=124) reached with emotional counseling. Afya Jijini worked with the girls and formed post GBV support groups with over 1,050 (43%) AGYW.

Results: The need for trauma counseling support and information sharing on GBV-related matters is pivotal to AGYW transformation. The earlier the AGYW are exposed to GBV prevention information, the increased likelihood of reporting GBV cases. Multiple platforms for GBV prevention awareness is key for communities to shun negative gender norms. Post GBV therapy groups offer a base for advocacy and networking for collective voice against the social issue.

Conclusions: Discussing GBV is a taboo issue in Kenya. Through group GBV therapy sessions, AGYW find a platform to discuss these issues. Furthermore, AGYW are able to recognize their roles in mitigating GBV.

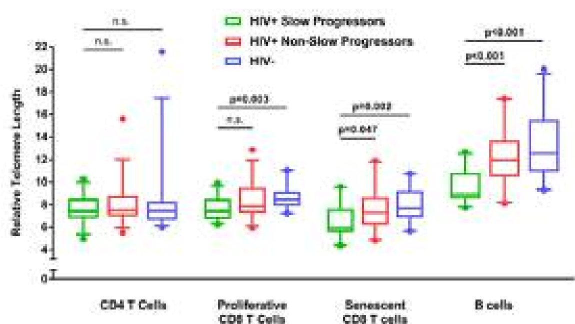
THPDA0102

Shorter cell subset telomeres in HIV slow progressors than in HIV non-slow progressor women

A. Hsieh[1], B. Sattha[1], N. Bernard[2], C. Tremblay[3], H. Côté[1,4],
for the CIHR Team on Cellular Aging and HIV Comorbidities in Women and Children (CARMA)
[1]University of British Columbia, Pathology and Laboratory Medicine, Vancouver, Canada, [2]McGill University Health Centre Research Institute, Montreal, Canada, [3]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montreal, Canada, [4]Centre for Blood Research, Vancouver, Canada

Background: Although shorter leukocyte telomere lengths (TL) of people living with HIV have been reported, TL investigations in HIV-relevant immune subsets remain scarce. Immune aging, including subset-specific TL attrition and imbalance in senescent/proliferative CD8 T cell distributions, likely link HIV with premature age-related comorbidities among people on stable cART. It is unknown whether this link exists for HIV slow progressors (SP). Our objective was to characterize immune subset TL in SP to determine whether their ability to control HIV protects against HIV-modulated immune aging. We hypothesized that TL shortening and senescent CD8 T cell subset expansion would be mitigated in SP compared to cART-controlled HIV+ non-slow progressors (NSP).
Methods: Live PBMCs were obtained from cART-controlled NSP and HIV- women enrolled in the CARMA cohort, and SP from the Canadian Cohort of HIV+ Slow Progressors. Groups were matched 1:1:1 for age. CD4 T cells, proliferative (CD28+), senescent (CD28-) CD8 T cells, and (CD19+) B cells were sorted by FACS, and their relative TL measured by multiplex qPCR. Groups were compared using Mann-Whitney or χ^2 tests.
Results: Women (n=35/group) 27-60y were well-balanced for age and ethnicity, and CD4 counts were similar between SP/NSP. All NSP were undetectable, while 15/35 SP were ART-experienced, including 2 on cART at visit. Cells were sorted from all matched groups and TL data were available for n=20-31, as matched trios with insufficient sorted cells were excluded. Shorter TL was observed in SP proliferative CD8, senescent CD8, and B, but not CD4 T cell subsets, compared to both NSP (p<0.047, n=20-31) and HIV- (p=0.002) participants (Figure 1). TL was shorter in senescent compared to proliferative CD8 T cells among SP (n=34, p<0.001) and NSP (n=27, p=0.027) but not HIV- controls (n=22, p=0.13). The senescent CD8 compartment was expanded in SP (median CD28-:CD28+ ratio=1.67) compared to NSP (0.66, p<0.001) and HIV- (0.45, p<0.001) participants.



[Relative telomere lengths of immune subsets between HIV+ Slow Progressor, HIV+ Non-Slow Progressor, and HIV- groups]

Conclusions: Contrary to our hypothesis, these data strongly suggest that cellular aging, at least within CD8 T and B subsets, may be accelerated among SP compared to HIV+ NSP and HIV- women. These results stress the importance of cART treatment and viral suppression in SP.

THPDA0103

Does HIV-seroconversion affect the serum N-glycans profile, one possible biomarker of ageing? Insights from a longitudinal study

C. Pirazzini[1], P. Garagnani[2], E. Giampieri[3], C. Sala[3], V. Borelli[2], M.G. Bacalini[1], D. De Francesco[4], C.A. Sabin[4], M. Prins[5,6], F.N.M.W. Wit[7,8], N.A. Kootstra[9], C. Libert[10,11], C. Franceschi[1], P. Reiss[7,8], The Co-morBidity in Relation to AIDS (COBRA) Collaboration and the Amsterdam Cohort Studies on HIV
[1]IRCCS Institute of Neurological Sciences, Bologna, Italy, [2]Alma Mater Studiorum Università di Bologna, Department of Experimental, Diagnostic and Specialty Medicine, Bologna, Italy, [3]Alma Mater Studiorum University of Bologna, Department of Physics and Astronomy, Bologna, Italy, [4]Institute for Global Health, University College London, London, United Kingdom, [5]Public Health Service of Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, [6]Academic Medical Center, Department of Internal Medicine, Amsterdam, Netherlands, [7]Academic Medical Center and Amsterdam Institute for Global Health and Development, Department of Global Health and Amsterdam Infection and Immunity Institute, Amsterdam, Netherlands, [8]Stichting HIV Monitoring, Amsterdam, Netherlands, [9]Department of Experimental Immunology, Amsterdam, Netherlands, [10]Ghent University, Department of Biomedical Molecular Biology, Ghent, Belgium, [11]Center for Inflammation Research, Flanders Institute for Biotechnology, Ghent, Belgium

Background: Persons living with HIV (PLWH) who are successfully treated with combination antiretroviral therapy can survive to older ages but have an increased risk of age-related conditions compared to HIV-negative individuals. Whether HIV infection per sé affects the ageing process and contributes to PLWH's susceptibility to age-related conditions remains unclear. To address this question, we determined the serum profile of N-glycans, which are powerful and reliable biomarkers of ageing, in cryopreserved longitudinal serum samples from Amsterdam Cohort Studies on HIV/AIDS (ACS) participants, from before and after HIV-seroconversion (SC).
Methods: The N-glycans profile was analyzed using longitudinal serum samples from 73 ACS participants (all males, with a mean [SD] age at time of first pre-seroconversion sampling of 34.8 [7.5] years). For each subject, 3 samples were obtained between 12 and 6 months *before* SC and 3 samples were obtained between 6 and 60 months *after* SC. None of the participants were receiving antiretroviral treatment during the time of sampling. Serum glycoproteins were analyzed using DSA-FACE technology. Ten N-glycan peaks were detected; a combination of the ten peaks was derived using measurements before SC. This combination was then applied to measurements after SC to estimate the age advancement (difference between chronological and estimated age). The effect of SC on each N-glycan peak was evaluated using a multivariate linear model including age, SC event and length of time after SC.
Results: We found a significant mean age advancement (sem) after SC of 2.61 (0.16) years. SC was significantly associated with a significant increase in peaks 1 (p< 0.001), 2 (p< 0.001) and 3 (p< 0.001) and a significant decrease in peaks 5 (p< 0.001), 7 (p< 0.001) (Table 1). The changes in peaks 2, 5 and 7 were influenced also by the length of time after SC.

	Regression coefficient for SC event	p-value for SC event
logP1	0.80	p<0.001
logP2	0.66	p<0.001
logP3	0.73	p<0.001
logP5	-0.55	p<0.001
logP7	-0.40	p<0.001

[Table. Regression coefficient and p-value for SC event (after vs before) adjusted for age and time after SC.]

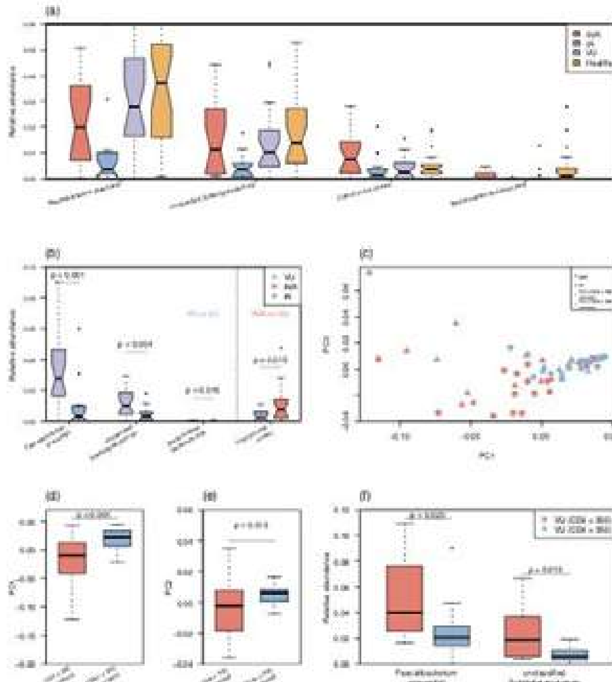
Conclusions: We confirmed the well-known dependency with age for N-glycan peaks 1 and 6. Our results suggest that both SC and the length of time after SC may affect the aging process by acting on the glycan profile, including on peaks that thus far have not been routinely used for age prediction.

THPDA0104

Association between gut microbiota and CD4 recovery in HIV-1 infected patients

W. Lu[1,2], Y. Feng[3,4,5], F. Jing[1,2], Y. Han[1,2], Z. Qiu[1,2], T. Li[1,2], B. Zhu[3,4,5]
[1]Peking Union Medical College Hospital, Division of Infectious Diseases, Beijing, China, [2]Chinese Academy of Medical Sciences and Peking Union Medical College, Center for AIDS Research, Beijing, China, [3]Chinese Academy of Science, Institute of Microbiology, Beijing, China, [4]University of Chinese Academy of Science, Beijing, China, [5]Beijing Key Laboratory of Microbial Drug Resistance and Resistome, Beijing, China

Background: Changes in gut microbial compositions have been described in human immuno-deficiency virus (HIV)-infected patients on antiretroviral therapy (ART). Evidences suggest that ART-treated patients with poor $CD4^+$ T-cell recovery have higher levels of immune activation and microbial translocation. However, the association between gut microbiota and immune recovery remains unclear.
Methods: We performed a cross-sectional study on 30 healthy controls (HC) and 61 HIV-infected individuals, including 15 immunological ART responders (IRs), 20 immunological ART non-responders (INRs) (IRs and INRs, $CD4^+$ T-cell counts ≥350 cells/mm³ and < 350 cells/mm³ after 2 years of ART, respectively), and 26 untreated individuals (VU). Each subject's microbiota composition was analyzed by metagenomics sequencing. Levels of $CD4^+$ T cells, $CD8^+HLA\text{-}DR^+$ T cells and $CD8^+CD38^+$ T cells were measured by flow cytometry.
Results: We identified more *Prevotella* and fewer *Bacteroides* in HIV-infected individuals than in healthy controls. Patients in INR group were enriched in *Faecalibacterium prausnitzii*, unclassified *Subdoligranulum sp.* and *Coprococcus comes* when compared with those in IR group. *F. prausnitzii* and unclassified *Subdoligranulum sp.* were overrepresented in individuals in VU group with $CD4^+$ T-cell counts< 350 cells/mm³. Moreover, we found that the relative abundances of unclassified *Subdoligranulum sp.* and *C. comes* were positively correlated with $CD8^+HLA\text{-}DR^+$ T-cell count and $CD38^+HLA\text{-}DR^+/CD8^+$ percentage.
Conclusions: Our study has shown that gut microbiota changes were associated with CD4 T cells and immune activation in HIV-infected subjects. Interventions to reverse gut dysbiosis and inhibit immune activation could be new strategies for immune reconstitution in HIV infected individuals.



[Differentially abundant species in the IR and INR groups and correlation with CD4 T cells.]

Polymorphism rs1385129 within Glut1 gene SLC2A1 is linked to poor CD4+ T cell recovery in antiretroviral-treated HIV+ individuals

[1]Burnet Institute, Life Sciences, Melbourne, Australia, [2]Monash University, Department of Infectious Diseases, Melbiurne, Australia, [3]Monash University, Melbourne, Australia, [4]Monash IVF, Melbourne, Australia, [5]Unidad de Investigación Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico, [6]Rush University Medical Centre, Department of Immunology-Microbiology, Chicago, United States

Background: HIV infection is associated with progressive $CD4^+$ T cell depletion, which is generally recovered with combination antiretroviral therapy (cART). However, a signification proportion of cART-treated individuals have poor $CD4^+$ T cell reconstitution. Abnormal glycolytic activation marked by increased $CD4^+$ T cell Glucose transporter-1 (Glut1) expression is associated with low CD4 T cell count in treated HIV infection. We investigated the association between the frequency of circulating $CD4^+Glut1^+$ T cell, specific single nucleotide polymorphisms (SNPs) within the Glut1 gene, and those regulating Glut, and HIV disease progression in treatment naïve patients and immunological response to cART.
Methods: Glut1 levels on $CD4^+$ T cells was determined by flow cytometry. Study groups comprise 17 HIV-positive treatment naïve individuals with favourable disease progression (>200 $CD4^+$ cells/μL within 3-7 years, or the loss of < 80 $CD4^+$ cells/μL/year) and 11 with non-favourable progression (< 200 $CD4^+$ cells/μL within 3 years of diagnosis, or a loss of >80 $CD4^+$ cells/μL/year). Treated groups comprise 25 treatment responders (>500 $CD4^+$ cells/μL; >3 years on cART), and 14 non-responders (< 500 $CD4^+$ cells/μL; >3 years on cART). SNP was evaluated in the Glut1 gene SLC2A1 (rs1385129, and rs841853), Glut1 regulatory AKT (rs1130214, rs2494732, rs1130233 and rs3730358), and the antisense RNA 1 region SLC2A1-AS1 (rs710218).
Results: High $CD4^+Glut1^+$ T cell percentage is associated with rapid $CD4^+$ T cell decline in HIV-positive treatment-naïve individuals and non-favourable $CD4^+$ T cell recovery in HIV-positive individuals on cART. Poor $CD4^+$ T cell recovery in HIV+/cART individuals is linked to the homozygous genotype (GG) of SLC2A1 SNP rs1385129 when compared to those with a recessive allele (GA/AA) (OR: 4.67; P: 0.04; Univariable logistic regression). $CD4^+Glut1^+$ T cell percentage is elevated among those with a homozygous dominant genotype for SNPs rs1385129 (GG) and rs710218 (AA) when compared to those with a recessive allele (GA/AA and AT/TT respectively) (P: 0.04; Mann-Whitney). The heterozygous genotype of AKT SNP 1130214 (GT) has a higher $CD4^+Glut1^+$ T cell percentage when compared to the dominant homozygous genotype (GG) (P: 0.0068; Mann-Whitney).
Conclusions: SNPs within genes that regulate glycolysis offer new insights into HIV pathogenesis and factors controlling HIV disease outcomes.

Background: Doravirine (DOR) is a novel human immunodeficiency type 1 virus (HIV-1) non-nucleoside reverse transcriptase inhibitor (NNRTI), with improved potency against prevalent NNRTI resistance-associated mutations, including RT K103N, Y181C, G190A, and E138K, at clinically relevant concentrations. This study aimed to characterize the mutant viruses selected in treatment-naïve participants through Week 48 from DRIVE-FORWARD and DRIVE-AHEAD, and to assess the impact of selected mutations on NNRTI susceptibility and viral fitness.
Methods: Plasma samples from the trials were tested for genotypic and phenotypic NNRTI susceptibility using a Monogram Biosciences resistance assay. Additionally, laboratory mutant isolates were generated via a site-directed mutagenesis (SDM) method with gene synthesis and subcloning into plasmid RT112. The resulting mutants were tested for their susceptibility to DOR and other NNRTIs in MT4-GFP cells to assess potential cross-resistance. The relative replication capacity of the mutants was measured by mixing various ratios of wild-type (WT) and mutant infected cells. The resulting cultures were incubated for 4 weeks with medium change every 3-4 days. At each passage, supernatant was harvested for clonal sequencing analysis to quantitate the relative abundance of WT and mutant viruses.
Results: Seven of 747 (0.9%) participants developed NNRTI resistance-associated mutations from 2 DOR phase 3 clinical trials (Table 1). SDMs were generated for the substitutions Y188L, V106I/F227C, A98G/F227C, V106I/H221Y/F227C, A98G/V106I/H221Y/F227C, V106A/P225H/Y318F, and V106M/F227C and their susceptibility to NNRTIs was evaluated. Most of the mutants conferred high level of resistance to DOR with a fold change (FC) >100 (FC: mutant$_{EC50}$ versus WT$_{EC50}$). Among the 7 mutants, V106I/F227C, V106I/H221Y/F227C, V106M/F227C, and Y188L mutants displayed FC < 10 against etravirine and rilpivirine, which is consistent with the phenotypic data from Monogram Biosciences. In addition, mutants containing F227C substitution were shown to be hypersensitive to some NRTIs such as AZT, TDF/TAF, and d4T. The replication capacity (RC) of Y188L, V106I/F227C, and A98G/V106I/H221Y/F227C was < 10% of WT virus and the RC of A98G/F227C and V106M/F227C was approximately 20% of WT virus.
Conclusions: The majority of DOR-selected viruses identified in the treatment-naive participants in clinical trials to date may retain susceptibility to etravirine and hypersensitivity to some NRTIs with low replication capacity.

Background: Next-generation (deep) sequencing provides a sensitive and cost-effective assay for low-frequency variants in diverse HIV-1 infections, but historically has been underutilized for non-subtype B HIV-1 infections in resource-limited settings. Here, we use deep sequencing to analyze samples from treatment-naïve individuals and individuals experiencing virological failure on combination antiretroviral treatment in Uganda.
Our objective was to detect associations between low-frequency mutations in HIV-1 integrase and treatment outcomes in Uganda.
Methods: We retrieved a total of 362 archived plasma samples from patients at the Joint Clinical Research Centre (Kampala) with non-B infections, of which 85 were treatment-naive and 277 had experienced virological failure (VF) on first- (N=129), second-line (N=116) or raltegravir (RAL)-based (N=32) regimens. For each sample, we extracted HIV-1 plasma RNA and generated amplicon libraries for two overlapping regions spanning HIV-1 integrase for sequencing on an Illumina MiSeq. Sequencing reads were iteratively aligned with bowtie2 and subtypes were classified with SCUEAL. Amino acid presence/absence matrices were generated at a 1% frequency cutoff and multiple imputations (n=50) were analyzed by L1-norm support vector machine (SVM) classification with 5-fold cross-validation.
Results: Overall, HIV-1 subtype A (47%) was the most frequent, followed by subtype D (21%). More importantly, we detected several polymorphisms associated with integrase inhibitor resistance (*e.g.*, E138K, G140A, Y143R, S147G, Q148K) in a small number of VF samples, although none of these polymorphisms were significantly associated with treatment outcomes. Our SVM analysis determined that the mutations T93A and V126M were the most strongly associated with first-line VF; T174A and K211T with second-line VF; and V165I and V151I with RAL-based VF.
Conclusions: Detecting minority HIV-1 variants with deep sequencing is important in settings where patients frequently discontinue treatment following VF, often leading to reversion to wild-type genotype by the follow-up visit. Our method describes a general strategy for detecting potential associations between the residual polymorphisms and treatment outcomes.

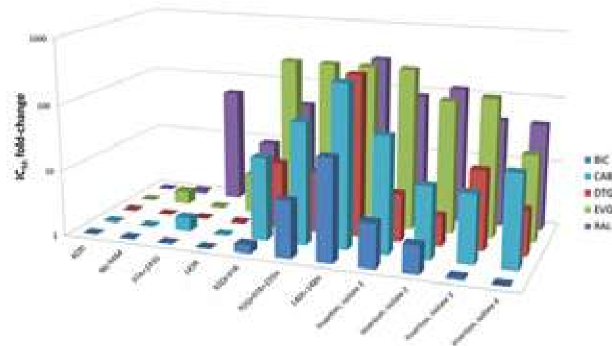
termined on HIV-2 clinical isolates. We aimed to assess phenotypic susceptibility to five INSTI on integrase clinical isolates.

Methods: Phenotypic susceptibility assays were performed on 10 HIV-2 isolates (3 group A and 7 group B) and the ROD reference strain using peripheral blood mononuclear cells method for bictegravir (BIC), cabotegravir (CAB), dolutegravir (DTG), elvitegravir (EVG) and raltegravir (RAL). Viruses were cultured without antiretroviral and with five 10-fold dilutions of drug, ranging from 1000 to 0.1 nM. At days 3 or 4, supernatant was withdrawn to assess viral replication (Biocentric HIV-2 RNA®). Phenotypic susceptibility was expressed in fold-changes of the IC_{50} between the isolate and the HIV-2 ROD reference strain.

Results: Ten clinical isolates were obtained from patients included in the ANRS CO5 HIV-2 cohort, exhibiting virological failure (VF) under an INSTI-based regimen (RAL=6, EVG=1 and DTG=3). Five isolates displayed integrase resistance-associated mutations (RAM) (97A+143G, 143R, 92Q+97A, 92Q+97A+155H and 140S+148). Five had no RAM but four of them presented a similar 5 amino-acids insertion in the integrase N-terminal region (S/Y-R-E-G-R/K), selected under RAL-based regimen.

On the 5 isolates with RAM, BIC and DTG exhibited lower fold-changes than RAL and EVG. On the 92Q+97A and 140S+148H combinations, BIC had lower fold-changes than DTG (1.4 and 35-fold for BIC versus 10 and >300-fold for DTG, respectively).

Regarding the 4 isolates with integrase insertion, they all presented high fold-changes to RAL and EVG ranging from 20 to >300-fold and intermediate fold-changes to DTG and CAB ranging from 3 to 17-fold and 11 to 58-fold, respectively. Fold-changes of BIC on those isolates were unmodified (0.4 and 1.1-fold) or moderate (3 and 5-fold).



[Figure. Phenotypic susceptibility of HIV-2 isolates to integrase inhibitors For each isolate, RAM in the integrase region are indicated.]

Conclusions: We describe for the first-time, a new INSTI-resistance pathway in HIV-2-infected patients with an insertion of 5 amino-acids in the integrase. This insertion, selected under RAL-based regimen, severely impacts RAL and EVG but might also compromises CAB, DTG and BIC susceptibility. Phenotypic susceptibility to BIC was less impacted than other INSTI by the presence of INSTI-RAM.

THPDB0104

Accumulation of mutations in vivo confer cross-resistance to new integrase inhibitors

W.W. Zhang[1], P.K. Cheung[2], N.S. Oliveira[2], M. Robbins[2], P.R. Harrigan[3], A. Shahid[2]
[1]*University of British Columbia, Medicine, Vancouver, Canada,* [2]*British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada,* [3]*University of British Columbia, Vancouver, Canada*

Background: Bictegravir (BIC) and cabotegravir (CAB) are novel HIV integrase inhibitors currently in clinical trials. Descriptions of clinically relevant resistance to these newest inhibitors are still relatively limited. Dolutegravir (DTG) response in vivo in the VIKING study was reduced in patient viruses with Q148H±G140S and/or additional mutations, with 2-fold increases in IC50 considered clinically relevant. Reduced in vitro susceptibility to viruses with these mutations has also been observed with BIC and CAB. Here, we compare the phenotypic susceptibility to all five available HIV integrase inhibitors of a panel of fourteen viruses derived from patients having integrase inhibitor resistance.

Methods: Initially clonal recombinant viruses were produced by PCR amplification under conditions where single copies of integrase were amplified. This was followed by co-transfection of integrase amplicons and linearized integrase-deleted pNL4.3 plasmid into CEM-GXR cells. Subsequent titering and phenotyping were performed in MT4-LTR-EGFP cells, where infectivity data was collected using a Spectra-max i3 Minimax 300 microplate reader. Recombinant viruses were grown under a range of concentrations of raltegravir, elvitegravir, DTG, BIC and CAB. EC50 fold-changes (FC) relative to a NL4.3 control were determined on day 3 post-infection.

Results: Viruses with the combination of G140S and Q148H substitutions alone had >100-fold increases in EC50 to raltegravir and elvitegravir, but relatively small changes (2-4-fold) in DTG, BIC or CAB susceptibility (Table 1). Viruses with progressively more substitutions showed extensive high level cross resistance to all five drugs (increases >50-fold). Viruses with T97A and L74M substitutions exhibited 6-fold greater increases in IC50 (67 to 456-fold change to DTG, BIC or CAB) compared to viruses which had only a T97A substitution (11 to 80-fold change). Phenotypic resistance values were strongly correlated between DTG, BIC, and CAB, with correlation coefficients ranging from 0.96 to 0.98.

Conclusions: Accumulation of multiple mutations in HIV integrase led to high level phenotypic resistance to all five HIV integrase inhibitors in patient-derived samples. Increases in phenotypic resistance values for DTG, BIC and CAB were almost co-linear.

Key Mutations (Stanford HIV DB)	G140S + Q148H	G140S + Q148H	G140S + Q148H

Baseline resistance testing in the current treatment era - no longer cost-effective?

E. Hyle[1], J. Scott[1], P. Sax[2], L. Millham[1], T. Hou[1], M. Weinstein[3], K. Freedberg[1], R. Walensky[1]
[1]*Massachusetts General Hospital, Boston, United States,* [2]*Brigham and Women's Hospital, Boston, United States,* [3]*Harvard T.H. Chan School of Public Health, Boston, United States*

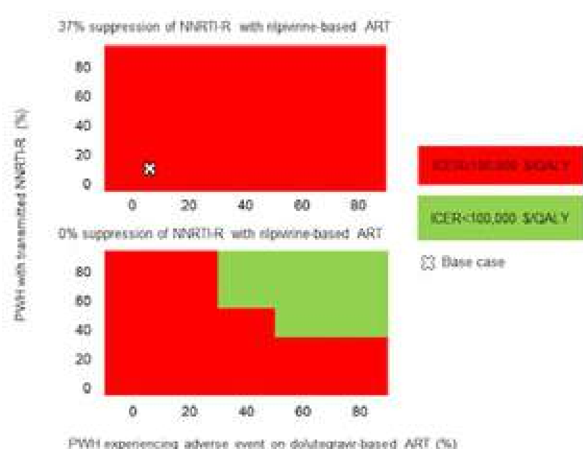
Background: For people newly diagnosed with HIV, US guidelines recommend standard genotype testing to detect transmitted resistance to NNRTI, NRTI, and PIs, but not INSTIs. With INSTI-based regimens as preferred first-line therapy, results of a standard genotype at HIV diagnosis will influence only second-line ART selection for people who experience an adverse event (AE) on INSTIs and require an ART switch.

Methods: We used the Cost-effectiveness of Preventing AIDS Complications (CEPAC) model to examine the value of standard genotype at HIV diagnosis for people starting dolutegravir, comparing: 1) *No Genotype* and 2) *Genotype*. In both strategies (Table), patients with an AE to dolutegravir switch to rilpivirine, except those with known NNRTI-resistance in *Genotype* who instead transition to darunavir. In *No Genotype*, patients with undiagnosed NNRTI-resistance have lower viral suppression with second-line rilpivirine. In both strategies, patients with virologic failure then have genotypes to guide subsequent ART. Standard genotype costs $350; ART costs $3000-3700/month. In sensitivity analysis, we varied the prevalence of transmitted NNRTI-resistance (base case, 8%), prevalence of AEs on dolutegravir (base case, 14%), and suppression of NNRTI-resistant virus with rilpivirine. Model outcomes (discounted 3%/year) included quality-adjusted life years (QALYs), costs, and incremental cost-effectiveness ratios (ICERs). We considered ICERs< $100,000/QALY cost-effective.

	No Genotype		*Genotype*	
	NNRTI-susceptible	NNRTI -resistant	NNRTI-susceptible	NNRTI -resistant
1st-line ART	Dolutegravir		Dolutegravir	
48-week suppression	93%		93%	
Monthly cost	$3,700		$3,700	
2nd-line ART	Rilpivirine	Rilpivirine	Rilpivirine	Darunavir
48-week suppression	83%	37%	83%	83%
Monthly cost	$3,000	$3,000	$3,000	$3,700

[Table. Strategy-specific response to adverse events on first-line dolutegravir.]

Results: Among all newly-diagnosed patients, *No Genotype* resulted in 15.3043 QALYs and cost $730,240/person; *Genotype* gained 0.0003 QALYs and cost $850/person more (ICER, $2.8 million/QALY gained). Among patients with transmitted NNRTI-resistance, *Genotype* resulted in 0.0039 additional QALYs compared to *No Genotype* and cost $6,590/person more (ICER, $1.6 million/QALY gained). At base case assumptions, 1.1% of newly diagnosed people with HIV would benefit clinically from *Genotype*, but it would cost $114,510 to test 100 patients for a maximum gain of 2.6 quality-adjusted days for one person. *Genotype* was not cost-effective compared to *No Genotype* unless prevalence of transmitted NNRTI-resistance >40% and AEs on dolutegravir >40%, with no suppression of NNRTI-resistant virus on rilpivirine-based ART (Figure).
Conclusions: With INSTI-based regimens as first-line treatment in the US, the standard genotype test at HIV diagnosis offers minimal clinical benefit, is more expensive, and is not cost-effective. Practice guidelines should consider removing genotypes from the recommended baseline evaluation.



[Figure. Multi-way sensitivity analysis: Genotype is cost-effective compared to No Genotype only extremely high prevalence of transmitted NNRTI-R and adverse events while on dolutegravir, as well as poor suppression of NNRTI-R with rilpivirine-based ART

Dispensing HIV self-tests in pharmacies in France: The pharmacists' point of view

T. Greacen, A. Simon, A. Troisoeufs, K. Champenois
EPS Maison Blanche, Laboratoire de Recherche, Paris, France

Background: HIV self-test kits have been available in pharmacies and on pharmacy websites in France since September 2015. What are the principle obstacles and facilitators that pharmacists themselves have encountered providing self-tests and information and support for self-test clients?
Methods: From February to December 2016, 22 interviews were conducted with pharmacists in three high HIV prevalence areas (a gay neighbourhood in central Paris; Guadeloupe/French Guyana; Paris suburbs with large sub-Saharan migrant communities) and one low HIV prevalence area in Northern France.
Results: Although pharmacists saw HIV self-test provision in pharmacies as a step forward with regard to engaging their profession in a key public health issue in France, most professionals interviewed had sold relatively few self-tests, and significantly less than expected. The major concern of pharmacists was the risk associated with individuals discovering positive test results alone at home and the issue of linkage to care. The current price of self-test kits was generally considered to be too high, even for pharmacists making minimal profit. Discretion and anonymity were clearly major issues. Few clients actually asked any direct questions. Clients interested in HIV self-tests were generally not their habitual clientele. A number of pharmacists reported clients purchasing two tests at a time, and hypothesized that this might be for their partners. The positioning of the HIV self-test kits in the pharmacy was a key indicator of pharmacists' attitudes with regard to self-testing. Although the law specifically states that the HIV self-test should be kept behind the counter, some pharmacists provided off-the-shelf access to ensure convenience and privacy to clients. In other pharmacies, typically in gay areas in central Paris, the self-test kits were stored behind the counter but visible to the public, with the aim of facilitating discussion with clients. Finally, in a not insignificant number of cases, no self-test kits or information on HIV self-testing were visible at all.
Conclusions: Although pharmacists see HIV self-testing as part of a significant trend in France towards facilitating access to screening for health conditions in general, price, anonymity, discretion and linkage to care remain crucial issues.

THPDC0102
Linkage to HIV care following HIV self-testing: A cluster randomised trial of community-based distribution of oral HIV self-test kits nested in four HPTN 071 communities in Zambia

S. Floyd[1], K. Shanaube[2], A. Schaap[1,2], M. Phiri[2], B. Hensen[1], C. Mulubwa[2], V. Bond[1,2], B. Chiti[2], M. Simwinga[2], R. Hayes[1], S. Fidler[3], A. Mwinga[2], H. Ayles[1,2]

Background: HIV self-testing (HIVST) has the potential to help achieve the UNAIDS 90-90-90 targets. However, evidence is limited about how to ensure linkage to care (LTC) among individuals with HIV-positive results. We report LTC findings from a HIVST cluster-randomised trial nested within the HPTN071 (PopART) trial in Zambia. The PopART intervention was delivered in "annual rounds" from 1/12/2013-31/12/2017, during which community-HIV-care-providers (CHiPs) visited all households, and offered home-based HIV testing with a rapid diagnostic test using fingerprick blood (RDT), referral to routine clinic services, and support (including follow-up visits) for LTC.
Methods: In December 2016, 4 of the PopART intervention communities in Zambia, comprising 66 zones, were included in a cluster-randomised trial of adding oral HIVST to the standard intervention. Self-testing was offered in-person, supervised or unsupervised, and to absent partners via secondary distribution. We estimated the time from CHiP referral to LTC among individuals who were (re-)enumerated as a household member during 1/2/2017-30/4/2017, aged ≥16 years, and diagnosed HIV-positive based on initial or confirmatory (following HIVST) RDT. We used the Kaplan-Meier method for "time-to-event" analysis, and follow-up information to 30/9/2017.
Results: Among 13,267 individuals in 33 HIVST zones, 195 were diagnosed HIV-positive; additionally 20 tested HIV-positive with supervised/unsupervised self-testing but did not have confirmatory RDT, and 13 tested HIV-positive following secondary distribution but were not contacted in-person by CHiPs. Among 13,706 individuals in 33 non-HIVST zones, 204 were diagnosed HIV-positive. Among those diagnosed, 94% (184/195) in HIVST and 98% (199/204) in non-HIVST zones were referred to care. We estimated that 65% in HIVST, and 64% in non-HIVST, zones were LTC by 3

months after referral (hazard ratio 1.11, 95%CI 0.78-1.58; Figure 1, Table 1). In HIVST zones, there was a suggestion that LTC was slower for individuals who tested with unsupervised self-testing or via secondary distribution, compared with those who tested with RDT (Table 1).

Conclusions: LTC following an HIV-positive diagnosis and CHiP referral was not undermined by offering HIVST as a testing option, in the context of LTC support. Strategies to facilitate confirmatory RDT following an initial HIVST, and LTC following unsupervised self-testing and secondary distribution, may be important.

		Referred to HIV care (n/N, %)	Linked to HIV care, by months after referral (%)			
			1	3	6	Hazard ratio, 95% confidence interval
Overall	Non-HIVST	199/204, 98%	50.3	63.8	76.6	1 (ref)
	HIVST	184/195, 94%	52.6	64.8	78.2	1.11 [0.78-1.58]
Overall, HIVST zones	RDT	85/88, 97%	51.2	71.4	78.9	1 (ref)
	Supervised	80/86, 93%	57.5	68.1	80.8	1.04 [0.66-1.63]
	Unsupervised	14/16, 87%	45.6	45.6	45.6	0.47 [0.19-1.14]
	Secondary distribution	5/5, 100%	25.0	25.0	25.0	0.24 [0.03-1.76]
"Minimum estimate" of linkage to HIV care	Non-HIVST	199/204, 98%		82/199 41.2%

Increasing knowledge of HIV status and demand for antiretroviral therapy using community-based HIV self-testing in rural communities: A cluster randomised trial in Malawi

P. Indravudh[1,2], K. Fielding[1], M. Neuman[1], R. Chilongosi[3], P. Mkandawire[3], E. Nyondo[3], R. Nzawa[2], L. Magombo[3], D. Chalira[2], M. Kumwenda[2], R. Nyirenda[4], C. Johnson[5], C. Nkhoma[3], N. Desmond[2,6], K. Hatzold[7], E.L. Corbett[1,2]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [3]Population Services International, Blantyre, Malawi, [4]Ministry of Health, Lilongwe, Malawi, [5]World Health Organisation, Geneva, Switzerland, [6]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [7]Population Services International, Washington, United States

Background: HIV self-testing (HIVST) has potential to reach populations poorly served by facility-based HIV testing services. We used a cluster-randomised trial design to investigate the impact of community-based HIVST distribution on recent HIV testing and antiretroviral therapy (ART) uptake in rural Malawi.

Methods: Government clinics (n=22) and their defined rural catchment areas were allocated using restricted 1:1 randomisation to either (i) door-to-door distribution of HIVST kits by resident community-based distributors (CBD) or (ii) the standard of care (SOC). Distributors provided continuous HIVST access and option of post-test support and assisted referral to routine confirmatory testing and ART services. Social harm monitoring was also established.

The primary outcome compared recent HIV testing (previous 12 months) across arms, ascertained through population-based surveys conducted 12 months after the cluster start date in pre-defined evaluation villages. Analysis used logistic regression with adjustment for imbalance between arms. For the secondary outcome, we used generalized estimating equations to analyse cluster-level ART initiations that were recorded in clinic registers in the 12 months after cluster enrolment, adjusting for ART initiations in the preceding 12 months.

Results: A total of 83 CBDs delivered 79,349 HIVST kits over a 12 to 15-month period, with three reported social harms. Of 5,504 adults in the post-intervention survey, 42.6% were men and 15.4% were adolescents aged 16-19 years. Coverage was significantly higher in the HIVST than SOC clusters for both recent testing (64.1% versus 45.6%, adjusted risk ratio [aRR] 1.38, 95%CI 1.14-1.68) and lifetime testing (87.3% versus 78.7%, aRR 1.12, 95%CI 1.05-1.16). Differences between arms were more pronounced for adolescents (aRR 1.99, 95%CI 1.35-2.92) and men (aRR 1.55, 95%CI 1.19-2.01).

Among 93,640 adults living in the defined study area, the proportion of ART initiations per 1000 adult clinic population increased in the HIVST versus SOC arm in the intervention period, adjusting for pre-intervention ART uptake (adjusted initiation risk ratio 1.36, 95%CI 0.95-1.94, p=0.09).

Conclusions: CBD-delivered HIVST increased HIV testing coverage in rural populations, especially among men and adolescents, and population-level demand for ART. This approach can rapidly improve knowledge of HIV status in underserved populations and have a measurable impact on ART uptake.

I. Recent and lifetime HIV testing					
	HIVST arm No. (%)	SOC arm No. (%)	Unadjusted risk ratio (95% CI)	Adjusted risk ratio[1] (95% CI)	p-value
Recent testing in past 12 months	1,660 (64.1)	1,328 (45.6)	1.42 (1.19-1.68)	1.38 (1.14-1.68)	0.002
Men	659 (61.1)	511 (40.4)	1.55 (1.23-1.95)	1.55 (1.19-2.01)	0.002
Adolescents	255 (64.3)	182 (40.4)	1.74 (1.21-2.51)	1.99 (1.35-2.92)	0.005
Lifetime testing	2,262 (87.3)	2,293 (78.7)	1.11 (1.06-1.16)	1.0 (1.05-1.16)	<0.001
Men	900 (83.5)	908 (71.8)	1.15 (1.07-1.26)	1.16 (1.06-1.28)	0.003
Adolescents	306 (77.3)	248 (55.0)	1.40 (1.16-1.77)	1.53 (1.21-1.92)	0.001

II. Facility-level ART uptake				
	HIVST arm Rate per 1000	SOC arm Rate per 1000	Adjusted initiation risk ratio[2] (95% CI)	p-value
ART initiation in 12-month intervention period	10.2	7.3	1.36 (0.95-1.94)	0.09

HIVST, HIV self-testing; SOC, standard of care; NA, not applicable; NS, not significant
[1] Adjusted for age, sex and cluster-level recent testing rates at baseline
[2] Adjusted for ART uptake in the 12-month pre-intervention period

[Effect of community-based HIVST self-testing on testing coverage and ART demand]

THPDC0104

Secondary distribution of HIV self-tests as a way to promote HIV testing among male partners of young women: Subgroup analysis from a randomized trial

K. Agot[1], B. Obonyo[1], J. Ambia[1], G.-N. Wango[2], H. Thirumurthy[3]
[1]*Impact Research and Development Organization, Kisumu, Kenya,* [2]*Nyanza Initiative for Girls' Education and Empowerment, Kisumu, Kenya,* [3]*University of Pennsylvania, Department of Medical Ethics and Health Policy, Philadelphia, United States*

Background: HIV risk among young women in eastern and southern Africa remains extremely high and age-disparate sexual relationships are widely believed to be a contributing factor. Interventions that promote HIV testing among male partners of young women are essential for reducing HIV risk. Given compelling evidence on the acceptability of HIV self-testing (HIVST), we assessed whether provision of multiple self-tests to young women can result in higher male partner testing.

Methods: This sub-study analyzed data among a subgroup of young women aged 18-24 years who participated in a larger randomized trial conducted at clinics in Kisumu, Kenya (NCT02386215). The trial enrolled women seeking antenatal and postpartum care and randomized them to receive two HIV self-tests (HIVST group) or a comparison group in which invitation cards were given to encourage clinic-based HIV testing. Women in the HIVST group also received a brief demonstration of how to use self-tests along with pictorial use instructions. Follow-up interviews were conducted with women at 3 months to assess whether partner and couples testing occurred. The primary outcome was partner testing and the secondary outcome was couples testing. Logistic regression analyses were used to compare outcomes in the two study groups.

Results: Of 599 women enrolled in the trial in 2015, 367 (61.2%) were aged 18-24 years. Eighty-eight percent of the young women were married. A total of 179 and 188 women were randomized to the HIVST and comparison groups, respectively. Follow-up interviews were completed by 347 women (94.5%). Male partner testing uptake was 92.4% in the HIVST group and 55.7% in the comparison group (odds ratio 9.7, 95% CI 5.1-18.3). Couples testing was also significantly more likely in the HIVST group than the comparison group (77.8% vs. 38.1%, odds ratio 5.7, 95% CI 3.6-9.1).

Conclusions: Provision of multiple HIV self-tests to young women seeking pregnant and postpartum care was very effective in increasing male partner and couples testing. Although not generalizable to unmarried young women, the findings suggest that HIVST can play a prominent role in facilitating testing among their male partners. As countries begin to scale-up HIVST, further investigation of secondary distribution interventions among young women is warranted.

THPDC0105

Effective promotion of HIV Self-testing among MSM in Russia in the context of growing stigma and discrimination

E. Pisemskiy
Orlovskaya Regional Non-Profit Organization against AIDS Phoenix PLUS (NGO Phoenix PLUS), Orel, Russian Federation

Background: This project provided for free and easy access for gays and other MSM and TG to self-testing for HIV. They could get a free self-testing kit in various places: community organizations, friendly clinics, friendly commercial pharmacies, clubs and saunas, as well as by limited courier delivery and from volunteers. The project was implemented in 5 cities
The project answers 3 major questions:
1. How to increase testing coverage?
2. What methods of self-testing kits distribution are the most convenient for MSM and TG and are cost effective for an NGO?
3. How can we make MSM and TG come to AIDS centers for confirmation testing and linkage to care?

Methods: Throughout the project, users could contact the organizers via the free 8-800 hotline or a friendly doctor at the AIDS center (whose business card was included into the self-test kit) or a peer consultant by the phone and any social media. When receiving a self-testing kit, the users were also encouraged to give feedback on the gaytest.info website using an individual code.

Results: The project supported by EJAF allowed to perform roughly the same number of HIV tests among MSM as 5 large projects supported by the Global Fund in 5 Russian cities.
Over 10,000 tests were conducted within a year. Self-reports show that **28%** of users leave feedback on the result of the test, **15%** of them reporting a reactive result**.** As a result of case management, 230 confirmation tests were performed in AIDS centers (registered) and 186 people were enrolled in care at AIDS centers.

Conclusions: The HIV self-testing project significantly increases testing coverage of MSM and TG. Since most MSM do not turn to community organizations for services, self-testing allows to reach the groups of MSM and TG people that were not covered by testing programs earlier. We recommend self-testing as a method that can be effectively used for such key populations as MSM, SW and DU even under high levels of stigma and discrimination.

THPDC0106

An intervention to teach young MSM and transgender women of color how to HIV self-test with a friend: Lessons learned in project TRUST

M.Q. Paige[1], L. Wilton[2], D. Lucy[1], G. Ortiz[1], V. Nandi[1], B. Koblin[1], V. Frye[1,3]
[1]*New York Blood Center, Project ACHIEVE, New York, United States,* [2]*Binghamton University, Binghamton, United States,* [3]*City University of New York, New York, United States*

Background: Increasing consistent HIV testing among high-risk populations such as men who have sex with men (MSM) and transgender women (TW) can lead to earlier treatment and uptake of PEP/PrEP, reducing HIV transmission. HIV self-testing is a relatively novel method that may increase consistent testing by reducing the travel and time burdens, HIV stigma, and/or increasing client control.

Description: TRUST tested a behavioral intervention to increase consistent HIV self-testing among Black/African-American and Latino MSM and TW aged 18-34. The experimental arm randomized friend pairs to taking 4th generation HIV rapid tests together and a 30-minute, facilitated session designed to: increase motivation to test consistently, master HIV self-testing skills, and commit to consistent HIV testing. Here we describe participant experiences of the experimental arm.

Lessons learned: Correct knowledge of HIV transmission is fundamental to increasing testing motivation, yet many participants had low knowledge (e.g., the "window period," status certainty, PEP/PrEP, etc.), indicating that HIV/sex education is lacking in primary/secondary US education. HIV testing is an anxiety-producing experience, with stigma an important driver of testing fear. "TRUST" was appropriately named, as participants chose the study friend based primarily on whether they "trusted" them. Increasing trust within the friend pair was facilitated by concrete discussion of testing plans, specifying and practicing support acts, and integrating familiarity and levity into testing. Participants reported high levels of satisfaction with the session, particularly learning how to self-test and with a friend. Increased self-efficacy and control were reported and attributed to mastering test mechanics and the realization that participants could control the setting, timing of and people present via self-testing. This last finding was consistent with the theoretical bases for the intervention, which emphasized self-determination and agentic control.

Conclusions/Next steps: Teaching friend pairs of MSM and TW of color to HIV self-test may increase consistent HIV testing among this higher risk group. Our experimental arm implementation assessment suggests that the intervention hit many of the theoretical targets and was highly acceptable to participants. Results of the trial will determine if the experimental arm outperformed the control arm on study outcomes.

THPDD01 Knowing and resolving stigma

THPDD0101

Social-structural correlates of HIV stigma among women living with HIV in Metro Vancouver

K. Deering[1,2], C. Logie[3], A. Krusi[4], F. Ranville[2], M. Braschel[2], P. Duff[4], K. Shannon[2,4], on Behalf of the SHAWNA Project (Sexual Health and HIV/AIDS: Women's Longitudinal Needs Assessment)
[1]University of British Columbia, Vancouver, Canada, [2]Gender and Sexual Health Initiative, Vancouver, Canada, [3]University of Toronto, Actor-Inwentash Faculty of Social Work, Toronto, Canada, [4]University of British Columbia, Medicine, Vancouver, Canada

Background: HIV stigma is widely known as a substantial barrier to access to and use of HIV treatment and care services. Less is known about the social and structural factors that produce HIV stigma. The objective of this study was therefore to understand the social and structural correlates of HIV stigma among women living with HIV (WLWH) in Vancouver, Canada.

Methods: Data were drawn from two years of follow-up from a longitudinal community-based participatory open cohort of 318 cis or trans WLWH who lived and/or accessed care in Metro Vancouver, Canada (2014-present)(Sexual Health and HIV/AIDS: Women´s Longitudinal Needs Assessment "*SHAWNA*"). Participants completed semi-annual interviewer-administered questionnaires by trained peer researchers/community interviewers and clinical questions by a sexual health research nurse. Stigma outcomes included three dimensions:

1) Disclosure Concerns;
2) Personalized Stigma;
3) Internalized Stigma; and an additional question measuring
4) Social Attitudes Stigma.

Sexual orientation, gender identity, immigrant status and ethnic/racial identity were all measured at the initial interview; remaining social-structural variables were time-updated and measured in the last six months, including stigma outcomes. Bivariate and multivariable linear regression using generalized estimating equations for repeated measures were used to examine correlates of the four stigma measures.

Results: Overall, 215 women responded to >=1 follow-up survey with 509 total observations. In multivariable analysis, HIV disclosure without consent was significantly associated with Disclosure Concerns (estimate:0.84, 95%CIs:0.30-1.37;p=0.002); Personalized Stigma (estimate:2.17, 95%CIs:1.35-2.98;p< 0.001); Internalized Stigma (estimate:1.04, 95%CIs:0.31-1.76;p=0.005); and Social Attitudes Stigma (estimate:0.44, 95%CIs:0.11-0.76;p=0.008). Time since first diagnosed with HIV (estimate:-0.04 p/year, 95%CIs:-0.08- -0.01;p=0.016) was negatively associated with Disclosure Concerns. Physical violence by any perpetrator (estimate:0.90, 95%CIs:0.13-1.67;p=0.022); poor treatment by health professionals (estimate:0.98, 95%CIs:0.10-1.86;p=0.030); and physical/verbal violence associated with the participant's HIV-positive status (estimate:1.43, 95%CIs:0.49-2.38;p=0.003) were associated with Personalized Stigma. Physical violence from any perpetrator (estimate:0.41, 95%CIs:0.15-0.68;p=0.002); and physical/verbal violence associated with participant's HIV-positive status (estimate:0.38, 95%CIs:0.11-0.66;p=0.006) were significantly associated with Social Attitudes Stigma.

Conclusions: Study results strongly suggest a critical need to develop strategies to address social and structural violence against WLWH, including amending Canada's restrictive HIV disclosure laws as a structural intervention to reduce HIV stigma and promote safe disclosure for WLWH.

THPDD0102

HIV-related stigma and discrimination among health care personnel in Thailand: Results of the 2017 national surveillance survey

K. Srithanaviboonchai[1,2], P. Khemngern[3], N. Pudpong[4], J. Chueayen[1], T. Siraprapasiri[3]
[1]Chiang Mai University, Research Institute for Health Sciences, Chiang Mai, Thailand, [2]Chiang Mai University, Faculty of Medicine, Chiang Mai, Thailand, [3]Ministry of Public Health, Department of Disease Control, Nonthaburi, Thailand, [4]International Health Policy Program (IHPP), Nonthaburi, Thailand

Background: HIV-related stigma and discrimination (S&D) is a major obstacle in the attempt to end the AIDS epidemic. Stigma and discrimination that occur within health facilities are of particular concern. To monitor this issue, Thailand developed a national surveillance system to monitor S&D in government health facilities.

Methods: Thirteen provinces, 12 provinces that serve as the centers for Thailand´s 12 health regions as well as the capital city Bangkok, were selected as national surveillance sites. All government hospitals with antiretroviral treatment clinics in each province served as survey venues. Both health staff and supportive staff providing services directly to the patients (regardless of patient's HIV status) were eligible to participate in the survey. The sample size at each health facility was determined proportional to the size of health staff of the whole province. Simple random sampling was used to identify potential participants. The participants completed a standardized questionnaire capturing actionable drivers and manifestations of HIV-related S&D in health care facilities online using a smartphone or tablet. The composite indicators, defined as the percentage of positive responses with at least one question within a particular domain, were computed and reported as the main outcomes.

Results: Of the 2,615 participants, 78.2% were females and 51.2% were professional health staff. The average age was 38.6 years old. The most frequently reported composite indicators of the drivers of HIV-related S&D were negative attitudes toward people living with HIV (PLHIV) (82.1%), followed by fear of acquiring HIV while caring for PLHIV (50.5%). The most frequently reported composite indicators of the manifestations of stigma were over-protecting oneself while caring for PLHIV (56.7%), followed by observed discrimination towards PLHIV during the last 12 months (25.8%). Compared to non-professional staff, professional staff were more fearful acquiring HIV while caring for PLHIV (OR=1.53; 95%CI 1.24-1.88), but had fewer negative attitudes toward PLHIV (OR=0.50; 95%CI 0.40-0.63).

Conclusions: The survey provided evidence of HIV-related S&D in Thai health facilities. The information could be used as an advocacy tool for policy change and to tailor stigma reducing interventions at the local level.

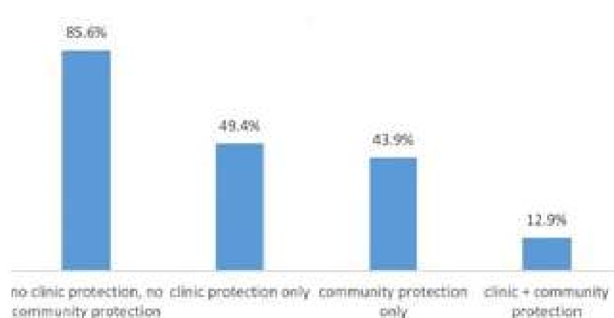
THPDD0103

Socio-structural protection from internalized HIV stigma among South African adolescents living with HIV: The potential of clinic-community collaborations for stigma reduction

M. Pantelic[1,2], M. Moshabela[3], E. Toska[2,4], L. Cluver[2,4], G. Caswell[5], A. Ronan[6]
[1]International HIV/AIDS Alliance, Secretariat, Brighton, United Kingdom, [2]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [3]University of KwaZulu-Natal, Durban, South Africa, [4]Cape Town University, Cape Town, South Africa, [5]International HIV/AIDS Alliance, Cape Town, South Africa, [6]Pediatric-Adolescent Treatment Africa, Cape Town, South Africa

Background: Southern Africa is home to 2 million adolescents living with HIV (ALHIV), who struggle to adhere to HIV treatment and care partly due to exceptionally high levels of self-stigma. South Africa's new National Strategic Plan HIV, TB and STIs includes a key objective to halve HIV-related self-stigma by 2022 but there is no evidence of scalable interventions to achieve this. This study examined protective factors in both clinics and communities that could reduce self-stigma among ALHIV.

Methods: Total population sampling of ALHIV (aged 10-19) from 53 public health facilities in the Eastern Cape, South Africa was used. Self-stigma was measured via the adolescents living with HIV stigma scale (ALHIV-SS). Community protection was measured via adolescent report of:
1) no experiences of discrimination and
2) no perceived stigma in the community.
Clinic protection was measured via five key adolescent-reported indicators:
1) No past-year ART stockouts,
2) Flexible clinic appointments that prevented excessive school truancy,
3) Adolescent-sensitive healthcare providers,
4) Perceived data confidentiality and
5) Access to a regular HIV support group.
A multivariate logistic regression tested associations between clinic and community protection and self-stigma controlling for age, gender and knowledge of HIV status. A marginal effects model tested potential additive effects of combining clinic and community protection.
Results: 90.1% of eligible ALHIV were interviewed (n=1060, 55% female, mean age = 13.8, 21% living in rural locations and 67% vertically infected). Prevalence of self-stigma was 26.5%. At the community level, protection from discrimination (OR:.38; CI:.22-.63) and non-stigmatizing perceptions (OR:.40; CI:.29-.64) decreased odds of self-stigma. At the clinic level, reliable ART stocks (OR:.40; CI:.23-.72), flexible appointment times (OR:.78; CI:.50-.93) and kind healthcare providers (OR:.58; CI:.41-.93) decreased odds of self-stigma among ALHIV. Age, gender, HIV status awareness, clinic confidentiality and support group access were not associated with self-stigma. Prevalence of self-stigma dropped from 85.8% among ALHIV without clinic or community protection to 12.9% among ALHIV with both clinic and community protection (Figure 1).
Conclusions: Findings suggest that a combination of clinic and community interventions hold promise for adolescent-centred HIV care. Self-stigma among ALHIV can be substantially reduced by addressing stigma in communities and strengthening health systems.



[Figure 1. Predicted probabilities of self-stigma by clinic and community protection]

THPDD0104

Pathways from sexual stigma to incident HIV and sexually transmitted infections among Nigerian MSM

E. Okporo[1], C. Rodrguez-Hart[2], TRUST Study Group
[1]Hyacinth AIDS Foundation, Prevention, Jersey, United States, [2]New York State Department of Health and Mental Hygiene, New York, United States

Background: Sexual stigma is the co-occurrence of the following four components within a power imbalance: labeling, stereotyping, separation, and status loss and discrimination specific to sexual minorities because of same-sex practices. Although sexual stigma has been found to be associated with HIV prevalence and with avoidance of seeking health care, it remains unknown whether sexual stigma drives onward transmission of HIV and sexually transmitted infections (STIs) among Nigerian MSM. Sexual stigma has also been found to be associated with condom less sex among MSM across a variety of settings outside of Nigeria.
Methods: The Network-Based Recruitment of MSM into HCT, Care, Treatment and Prevention Services at Trusted Community-based Venues (TRUST/RV368) study utilizes respondent-driven sampling to recruit MSM into a prospective cohort at ICARH site in Abuja Nigeria, Eligibility criteria included male sex assigned at birth and at least 16 years of age in Abuja. total of 1480 participants.
Results: The sample consisted of participants who were primarily under 25 years of age (60%), had completed high school or less education (70%), identified their sex as male (82%), had never disclosed their same-sex practices to a family member (83%), engaged in both insertive and receptive anal sex with male partners in the past 12 months (53%), and approximately half had a female sex partner in the past 12 months. Bivariate analysis revealed that in creasing sexual stigma was associated with increasing incident HIV and/or STI infections in a dose-response association (low: 10.6%, medium: 14.2%, high 19.0%, P¼0.008.
Conclusions: The path analysis model revealed that MSM who were in higher stigma classes at baseline were more likely to contract HIV/STIs over the course of the study, and this was partially explained by stigma's association with suicidal ideation, suicidal ideation's association with condomless sex with casual sex partners, and condomless sex's association with HIV/STI acquisition. Therefore, our findings highlight the need to incorporate mental health issues of MSM in HIV and STI programming in Nigeria. One option would be to adopt WHO's Mental Health Gap Action Programme intervention.

THPDD0105

Project on HIV destigmatization in the marriage equality movement in Taiwan

S.-C. Du, C.-L. Peng, M.-Y. Juan
Taiwan Tongzhi (LGBTQ+) Hotline Association, Taipei City, Taiwan, Province of China

Background: In 2016-17, the marriage equality debate was heated in Taiwan, and certain anti-LGBTQ+ groups have used HIV-related issues to attack the LGBTQ+ community, spreading false information about LGBTQ+ and HIV/AIDS via mass and social media. Gay and bisexual men, especially those living with HIV/AIDS (PLWHA), have become a major target of rumors and slanders. This presentation aims to introduce how Taiwan Tongzhi (LGBTQ+) Hotline Association tackled the HIV stigma incurred in the marriage equality movement, and how we destigmatize the disease and reflect on the issue.
Description: This project adopts two strategies of destigmatizing HIV while promoting marriage equality:
1. Analyzing and responding to false information regarding LGBTQ+ and HIV/AIDS: We designed an easy-to-understand version of "HIV/AIDS for Dummies," and have distributed the correct information to the general public via social media.
2. HIV+OK Campaign: We have invited people to express their support for PLWHA with actions through organizing public events, campaigning on social media, and taking actions on Taiwan LGBT Pride Parade.

Lessons learned: The "HIV/AIDS for Dummies" has attracted 107,353 views and public discussions. Our targeted audience is not limited to the LGBTQ+ community but also their parents and LGBTQ+-friendly heterosexuals. Meanwhile, the HIV+OK Campaign has encouraged people to express their support for PLWHA. More than 30 people, including PLWHA, their family members and friends shared their stories. More than 100 people joined Hotline's procession in Taiwan LGBT Pride Parade that promoted the concept of "HIV+OK," and more than 2,000 social media users changed their profile picture to openly show their support.
Conclusions/Next steps: Examining the implementation and outcomes of this project, we found that:
1. This project is the first time for LGBTQ+ group to initiate large-scale, broad-scope public dialogues about HIV related issues, not just focusing on LGBTQ+ community.
2. There is an obvious lack of anti-discrimination HIV/AIDS education that targets adults in Taiwan, enabling the false information about HIV/AIDS to be spread rapidly. We urge that the government devote more state resources to this issue.
3. The fight for equal rights for PLWHA cannot be independent from LGBTQ+ movements and the marriage equality movement. They have to ally with one another to move forward.

THPDD0106

Stigma as a barrier to obtaining quality VCT services: Monitoring outcomes from the Zaporizhzhia region of Ukraine

R. Milevskyi[1], O. Vytvitskyi[1], D. Kalinin[1], S. Maltabar[1], Y. Radchenko[2], O. German[2]
[1]Gender Z, Zaporizhzhia, Ukraine, [2]ECOM, Tallinn, Estonia

Background: Due to the pervasiveness of homophobia and transphobia in Ukrainian society, we decided to research the prevalence of stigma towards MSM and LGBT people by health professionals and NGO social workers providing VCT services in the Zaporizhzhia region. Additionally, we examined providers' awareness levels in regards to the specifics of MSM/LGBT counselling.

Description: With support from ECOM, we piloted an advocacy project, which included the monitoring of VCT providers in both NGO and public health care settings. The program also included training elements, as well as the development and regional-level approval of an Algorithm and practical recommendations for the consultation of MSM/LGBT people. During field research our "test clients" visited 95 service centers to assess their comprehensiveness and suitability, as well as providers' tolerance and professionalism upon disclosures of non-heterosexual sexual orientations and practices.

Based on our findings, we organized a training on SOGI and MSM/LGBT counselling for 100 representatives from every VCT point in the region.

After having jointly analysed the problems that we uncovered with local authorities, the Zaporizhzhia Department of Health adopted an Algorithm for counselling MSM and LGBT people and approved our recommendations on the prevention of stigma and discrimination in the provision of health care services.

Lessons learned: The monitoring visits revealed a range of shortcomings and gaps in the health care sector, including: inadequate accessibility to HIV testing, violations of VCT principles, homophobia and transphobia, and a widespread lack of knowledge of key populations' issues. Our follow-up advocacy activities were designed to decrease the number of rights violations experienced by MSM/LGBT people accessing health care in our region and to reduce the overall level of stigma and discrimination.

The project confirmed that:

- Provider-based stigma and inadequate knowledge of LGBT issues remain salient barriers to obtaining quality services;
- The initiative and meaningful involvement of affected communities is essential in order to promote any positive changes.

Conclusions/Next steps: Raising tolerance levels towards MSM/LGBT significantly decreases stigmatization within professional circles and, subsequently, helps fight the HIV epidemic. Our positive experience using the methodology of "test clients" suggests that this research method can be applied to future projects aimed at other key populations.

THPDD02 Falling off the HIV cascade: Autonomy as a determinant of ART retention among sex workers

THPDD0201

Multi-level barriers to antiretroviral therapy initiation, retention, and adherence for female sex workers living with HIV in South Africa

C. Comins[1], L. Parmley[1], S. Schwartz[1], H.T. Mkhize[2], V. Guddera[2], D.R. Phetlhu[3], K. Young[4], H. Hausler[4], S. Baral[1]
[1]Johns Hopkins Bloomberg School of Public Health, Key Populations Program, Center for Public Health and Human Rights, Department of Epidemiology, Baltimore, United States, [2]TB/HIV Care, Durban, South Africa, [3]University of Western Cape, School of Nursing, Cape Town, South Africa, [4]TB/HIV Care, Cape Town, South Africa

Background: South Africa has a generalized HIV epidemic that disproportionately affects female sex workers (FSW). FSW experience individual, network, and structural barriers to initiation and sustained engagement in antiretroviral therapy (ART). Here, we use a modified socio-ecological model (SEM) to map ART initiation, retention and adherence barriers among FSW in South Africa.

Methods: FSW living with HIV (n=24) and key informants (n=15) participated in semi-structured, in-depth interviews from September-November 2017 in Durban, South Africa. FSW participants were sampled using maximum-variation sampling, ensuring variations in sex work and ART experiences. Key informants included providers at various levels, brothel managers, and police. Qualitative data were coded using a grounded theory approach in Atlas.ti 8. Matrices were used as a post-coding technique to map emergent themes at each level of the SEM including individual, network, community, and public policy levels.

Results: Each level of the SEM presented specific barriers to initiation, retention, and adherence for FSW living with HIV (Figure 1). Diagnosis prior to universal test and treat, lack of clinic card, and incarceration were policy-level challenges among FSW and related to ART initiation, retention and adherence, respectively. Initiation and retention in care was affected at all levels, with emphasis on individual-level barriers, while network- and individual- level barriers predominately affected ART adherence. At the network- and community- levels, FSW experienced unique barriers generally and based on their sex work venue (indoor v. outdoor) and primary work time (nighttime v. daytime) respectively. FSW identified no community-level barriers related to ART adherence.

Conclusions: While ART is well known to improve clinical outcomes, and decrease onward HIV transmission, these data highlight the sustained barriers to ART initiation and retention among FSW living with HIV in South Africa. Moving forward necessitates tailored yet scalable interventions to address level-specific barriers among FSW and ultimately optimize sustained treatment outcomes.

[Figure 1. Challenges engaging in HIV Treatment among female sex workers living with HIV in Durban, South Africa]

THPDD0203

"They must understand us as sex workers": Health service perspectives among female sex workers in the context of PrEP and early ART introduction in the TAPS Demonstration Project, South Africa

R. Eakle[1], A. Bourne[2], R. Bothma[1], G. Gomez[3], F. Venter[1], H. Rees[1]
[1]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [2]LaTrobe University, Melbourne, Australia, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Female sex workers (FSWs) are a key population and could greatly benefit from HIV prevention methods such as pre-exposure prophylaxis (PrEP). However, FSWs often experience difficulties accessing health services which could pose a barrier to PrEP uptake and retention. We explored previous health service experiences and suggestions for best practices with FSWs in focus group discussions (FGDs) as part of designing the TAPS Demonstration Project.
Methods: FGDs were conducted in Johannesburg and Pretoria, and examined opportunities and barriers for safe and efficient PrEP delivery within the context of TAPS. Sex worker peer educators recruited participants through social networks using snowball sampling. Facilitation was in English with adaptation by facilitators into local languages as needed. Transcripts were translated and transcribed into English. Data were subject to a thematic analysis.
Results: Four FGDs were conducted in each of the two sites engaging 69 participants, ages 20-60. Overwhelmingly, participants voiced concerns about stigma and negative treatment of FSW in public health facilities. This was seen as a major potential barrier to successful provision of PrEP and early ART as FSWs would not attend clinics where they had been negatively treated. "Feeling free" to openly discuss health issues, such as burst condoms, STIs, or even sexual assault, was critically important, as was accessibility. Some FSWs felt that getting to the clinic when they lived some distance away would be challenging for monthly clinic visits. Mobile delivery was highly recommended. Consistency and flexibility in service provision (e.g. aligning clinic times, regular mobile clinics) were recurring themes as part of effective, quality care. Peer-driven education, navigation, and service were highlighted as an important best practice.
Conclusions: Service provision sensitised and tailored to sex workers needs will be critical to successful delivery of PrEP and early ART. Stigmatization of sex workers in clinic environments is well-documented, yet little has been published from FSW perspectives about how to address these issues. Involving FSWs will help to build relevant services especially when implementing new interventions.

THPDD0204

Occupational barriers to antiretroviral therapy adherence, sources of support, and coping strategies for female sex workers living with HIV in South Africa

L. Parmley[1], C. Comins[1], S. Baral[1], H.T. Mkhize[2], V. Guddera[2], D.R. Phetlhu[3], K. Young[4], H. Hausler[4], S. Schwartz[1]
[1]Johns Hopkins Bloomberg School of Public Health, Center for Public Health and Human Rights, Baltimore, United States, [2]TB/HIV Care, Durban, South Africa, [3]University of Western Cape, School of Nursing, Cape Town, South Africa, [4]TB/HIV Care, Cape Town, South Africa

Background: Despite advances in antiretroviral therapy (ART) globally, achieving sustained viral suppression among persons living with HIV continues to be a major challenge in the HIV response. Social and structural barriers impede ART adherence and are heightened among marginalized and key populations including female sex workers (FSW) in South Africa. The objective of these analyses is to characterize FSW-specific barriers and facilitators to ART adherence affecting clinical outcomes and HIV prevention goals.
Methods: Semi-structured, in-depth and key informant interviews were conducted with 24 FSW living with HIV and 15 key informants in Durban, South Africa from September-November 2017. FSW and key informants were recruited using maximum-variation and snowball sampling respectively. FSW were recruited on key variants including: type of sex work venue, primary work time, and ART-naivety and use. Data collection and analysis were iterative; transcripts were coded and analyzed using grounded theory in Atlas.ti 8.
Results: Multiple relevant themes were reported that included sex work venues dismissing FSW known to be living with HIV based on ART use, theft of clinic cards and ART by clients, and concerns of wage loss if HIV status were disclosed to clients, colleagues, and pimps/managers either by being seen at an HIV clinic or by carrying ART. Occupational pressures including short term or seasonal migration for work further challenged engagement in treatment programs while pressures to use drugs and alcohol from clients or the use of similar substances to desensitize themselves challenged adherence to ART. Support systems to optimize ART included FSW receiving HIV treatment support from peers. In addition, many FSW reported individual coping strategies to overcome adherence barriers including sharing and purchasing ART from peers, planning for spontaneous client demands and approaches to facilitate taking medications at work while limiting unwanted disclosure of status.
Conclusions: Taken together, these data highlight the occupational barriers to accessing and taking ART among FSW living with HIV. While coping strategies included social cohesion among FSW, ART sharing and purchasing may be associated with suboptimal treatment outcomes. Considering these occupational pressures on FSW is important when designing and implementing HIV treatment programs to support sustained ART engagement.

THPDD0205

The sociability of risk: Sex work, criminalization and HIV/AIDS in Kampala, Uganda

S. Cruz
University of Amsterdam, Research Center for Gender & Sexuality, Amsterdam, Netherlands

Background: In Kampala, Uganda women engaging in "high risk" sexual practices, like commercial sex work, have an estimated 33-37% HIV seroprevalence (Vandepitte et al. 2011; Hladik et al. 2017). In response to this statistic I set out to investigate how women manage daily risks associated with sex work, criminalization, and HIV/AIDS.
Methods: Primary ethnographic data collection occurred over fifteen months within two Kampala Divisions (Rubaga and Makindye), involving participant observation, group discussions, and informal, unstructured interviews with female commercial sex workers. Research insights then informed policy analysis.
Results: The study reveals that women's social networks have the greatest impact on their ability to manage daily risks. However, three important variables intervene with women's risk management:
(1) the sex work environment,
(2) divergence in women's social relationships, and
(3) the current policy approach guiding HIV healthcare.
The study reveals that a woman's physical sex work environment, such as the room she rents in a brothel, impacts her ability to safeguard private property (e.g., condoms, cash, medications, clothing, shoes, etc.). In turn, a woman with fewer personal belongings is perceived by other women in the brothel as less capable of minimizing risks, such as police abuse, arrest, client violence, and/or contracting HIV, and therefore less deserving of social relationships in the brothel. Alternatively, women deemed more capable of maintaining their social ties are far more likely to develop cash reserves in order to purchase medications, improve their brothel working and living conditions, receive and retain condom supplies, and/or frequently travel outside the brothel to receive healthcare and/or improve their commercial sex work prospects. Data furthermore reveals how current HIV interventions, prioritizing individualized behavior, undermine women's social resources (i.e., their social networks and social capital). The study documents women's struggles to adhere to recommended HIV/AIDS treatment protocols when they believe they must choose between their individualized HIV healthcare plan and demands from their social network (i.e. the social practices minimizing daily risks associated with sex work and criminalization).
Conclusions: In conclusion, this research underscores the sociability of women's HIV risk, risk management, and the implications of these social processes on current HIV/AIDS prevention and treatment protocols.

THPDD0206

Differentiated ART delivery model for female sex workers in Uganda: Community client led ART delivery to improve outcomes

L. Oucul[1], J. Birungi[2], K. David[3]
[1]*The AIDS Support Organization (TASO), Programs and Capacity Development, Kampala, Uganda,* [2]*Medical Research Council, Kampala, Uganda,* [3]*The AIDS Support Organization (TASO), Kampala, Uganda*

Background: In 2013, Uganda National ART guidelines recommended test and start for all key populations. The AIDS Support Organization (TASO) started implementing these guidelines in 2014. In 2016, TASO ART data showed16% ART retention of FSW. To support improved outcomes, TASO expanded differentiated ART delivery model and adapted it for FSWs.

Description: TASO has been implementing a client-managed group model of differentiated ART delivery called Community Client Led ART Delivery (CCLAD) since 2012. In 2017, this was expanded and adapted for FSWs. Eligible FSWs who consent to be on group model, were grouped by geographical area into a peer support group of five to ten members. The group selected a peer leader who is responsible for collecting 3 monthly ART refills. All group members attend 6- monthly clinical reviews and annual viral load monitoring at TASO clinic.

Lessons learned: Between October 2016 and June 2017, more than 7,000 FSWs were reached with a behavior change campaign. A total of 5,775 HIV tests were completed and 525 people living with HIV were identified (positivity rate = 9.1%). Of those identified as HIV%, 81.5% were linked to care and 23.6% of those linked to care were initiated on ART. Over the same time period, a cumulative number of 215 FWs were in care with 89.8% being on ART of which 90.9% were virally suppressed. All 24 FSW in CCLAD group had viral suppression above 95%.

Conclusions/Next steps: Key populations can benefit from having access to differentiated ART delivery models. In Uganda, FSWs with access to a differentiated ART delivery model with community ART distribution and less frequency clinical consultations had good client outcomes. This model supported retention in care by tailoring services for a highly mobile population.

THPDE01 #NextGeneration: Programming for adolescents

THPDE0101

Integrated youth-friendly health services lead to substantial improvements in uptake of HIV testing, condoms, and hormonal contraception among adolescent girls and young women in Malawi

N. Rosenberg[1], N. Bhushan[1], D. Vansia[2], T. Phanga[2], B. Maseko[2], A. Kachigamba[3], J. Tang[1], M. Hosseinipour[1,2], A. Pettifor[1], L.-G. Bekker[4]
[1]*University of North Carolina at Chapel Hill, Chapel Hill, United States,* [2]*University of North Carolina Project, Lilongwe, Malawi,* [3]*District Health Office, Lilongwe, Malawi,* [4]*Desmond Tutu HIV Foundation, Cape Town, South Africa*

Background: Adolescent girls and young women (AGYW) in sub-Saharan Africa (SSA) experience high incidence of HIV, pregnancy, and sexually transmitted infections (STIs), but face numerous barriers to HIV and sexual and reproductive health (SRH) care-seeking. In this analysis, we assessed whether a model of integrated youth-friendly health services (YFHS) for AGYW led to increased uptake of condoms, HIV testing, and hormonal contraception, compared to standard of care (SOC).

Methods: Through the Girl Power study, four comparable public sector health centers were selected in Lilongwe, Malawi and randomly assigned to either the SOC or YFHS. The SOC offered vertical HIV testing, STI management, and family planning in 3 separate areas with providers who received no additional training. The other three health centers offered YFHS, which consisted of these same services in an integrated fashion, in youth-dedicated spaces, with peers and providers trained in youth-friendly approaches. In each health center, AGYW 15-24 years old were enrolled and followed for one year for uptake and frequency of HIV testing, condoms, and hormonal contraception. The SOC and YFHS models were compared using adjusted risk differences and incidence rate ratios and ninety-five percent confidence intervals.

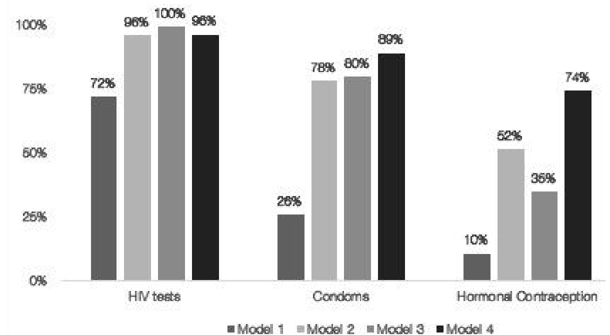
Results: One thousand AGYW enrolled (N=250/health center). Median age was 19 years (inter-quartile range 17-21 years). Compared to AGYW in the SOC health center, those in the YFHS health centers were 23% (CI: 17%-29%) more likely to ever receive HIV testing, 57% (CI: 51%-63%) more likely to ever receive condoms, and 39% (CI: 34%-45%) more likely to ever receive hormonal contraception. Compared to AGYW in the SOC, AGYW in the YFHS models accessed HIV testing 2.4 (CI: 1.9-2.9) times more often, condoms 7.9 (CI: 6.0-10.5) times more often, and hormonal contraception 6.0 (CI: 4.2-8.7) times more often. Each of the three YFHS health centers performed better than the SOC on each indicator.

Conclusions: In public sector health centers an integrated model of YFHS that included brief provider training and modest clinical modifications lead to considerably higher SRH and HIV service utilization for AGYW. Implementation science is needed to guide scale-up of this highly promising service delivery model.

	Proportion of Participants Who Ever Received the Service Over One Year				Mean Number of Times Service Received Per Participant Per Year			
	SOC (N=250)	YFHS (N=750)	Adjusted Risk Difference*	p-value	SOC (N=250)	YFHS (N=750)	Adjusted Incidence Rate* Ratio	p-value
Condoms‡	26%	83%	57%	< 0.001	0.3	2.3	7.9	< 0.001
HIV Testing†	72%	97%	23%	< 0.001	1.1	2.7	2.4	< 0.001
Hormonal Contraception§	10%	54%	39%	< 0.001	0.2	1.0	6.0	< 0.001

*All models control for age, number of children, and marital status measured at baseline. Some models also controlled for baseline HIV testing†, condom use‡, and hormonal contraceptive use§

[Table 1. Comparison of the SOC Clinic (Model 1) to the YFHS Clinics (Models 2-4)]



[Figure 1. Proportion of AGYW who Received Each Service by Arm]

THPDE0102

Meaningful engagement of schools and school-based advocates in promoting education on HIV and supporting adolescents living with HIV in Kenya

E. Ruria[1], M. Sayo Muandale[2], J. Odionyi[3], J. Kose[3], L. Matu[3], E. Mwangi[3], R. Otieno-Masaba[3], G. Woelk[4], N. Rakhmanina[4,5,6]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Homa Bay, Kenya, [2]Ministry of Education, Homa Bay County, Homa Bay, Kenya, [3]Elizabeth Glaser Pediatric AIDS Foundation, Nairobi, Kenya, [4]Elizabeth Glaser Pediatric AIDS Foundation, Washington, United States, [5]Children's National Health System, Washington, United States, [6]George Washington University, Washington, United States

Background: Adolescents living with HIV (ALHIV) spend a significant proportion of their daily lives in schools. In 2016, with support from ViiV Healthcare, the Elizabeth Glaser Pediatric AIDS Foundation implemented the innovative peer-designed fast-track linkage-to-care and early retention Red Carpet Program (RCP) throughout public health care facilities (HCFs) and schools in Kenya. RCP worked closely with the Ministry of Education (MOE) and Ministry of Health (MOH) to design and implement school-based interventions to promote HIV education and support for ALHIV. The aim of this analysis was to evaluate the implementation of RCP school-based interventions conducted in 2017.

Description: RCP conducted two main interventions in the Homa Bay County boarding schools:

a) enhanced partnership between schools and 50 RCP HCFs;

b) built capacity of adolescent health advocates (counselling teachers, school matrons, nurses and boarding in-charge managers).

A sensitization meeting was held with 70 secondary boarding school in-charge managers, principals and MOE officials in August 2017. During August-September 2017, RCP conducted a two-day capacity building workshop for 90 school-based adolescent health advocates from 44 high volume local secondary boarding schools.

Lessons learned: By November 2017, 50 boarding schools in Homa Bay County developed key HIV strategies including: a) fostering direct linkages with HCFs; b) formation of School Health Committees (SHC); c) training of adolescent health advocates; and d) support of ALHIV. By December 2017, 50 SHC were formed and >3000 students (both HIV+ and HIV-) were reached with education on HIV, HIV stigma, antiretroviral treatment, pre-exposure prophylaxis, and sexual and reproductive health. Fifty schools implemented activities targeting ALHIV, parent representatives and linked RCP HCFs teams. All 50 schools implemented adherence counselling, confidential storage and access to HIV medications for ALHIV.

Conclusions/Next steps: Schools provided daily support to ALHIV from accessing care, medications to retention in care. The uptake of the general HIV education and support services for ALHIV was high in schools of Homa Bay County, Kenya. Going forward, RCP works to expand collaboration between HCFs and schools with the goal to increase long-term retention in care and on treatment, and achieve high levels of virologic suppression among ALHIV.

THPDE0103

Cash+Care: Parenting support and violence reduction programme associated with reductions in adolescent HIV-risks in South Africa: A cluster randomized trial of a DREAMS and 4Children-implemented programme 'Parenting for Lifelong Health'

L. Cluver[1,2], F. Meinck[1], J. Doubt[1,3], C. Ward[2], C. Lombard[4,5], Y. Shenderovich[1,6], J. Steinert[1], R. Herrero Romero[1], S. Medley[1], A. Redfern[1], N. Salah[7], S. De Stone[8], L. Ncobo[9], J. McLaren Lachman[1,9], S. Tsoanyane[9], H. Loening[3], J. Byrne[3], L. Sherr[10], M. Casale[1,11], F. Gardner[1], C. Wittesaele[1], R. Catanho[1], S. Hoeksma[1], C. Mikton[12], J. van der Wal[1], M. Nocuza[1], M. Pancoast[1,13], M. Danisa[9], I. Wessels[2,9], N. Masuku-Mukadah[9], M. Boyes[14], D. Nzima[15,16], N. Sibanda[17]
[1]Oxford University, Department of Social Policy & Intervention, Oxford, United Kingdom, [2]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [3]UNICEF Innocenti Office of Research, Florence, Italy, [4]South African Medical Research Council, Biostatistics Unit, Cape Town, South Africa, [5]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, [6]University of Cambridge, Institute of Criminology, Cambridge, United Kingdom, [7]London School of Hygiene & Tropical Medicine, London, United Kingdom, [8]University of Warwick, Warwick Medical School, Warwick, United Kingdom, [9]Clowns Without Borders South Africa, Durban, South Africa, [10]University College London, London, United Kingdom, [11]University of the Western Cape, School of Public Health and Family Medicine, Cape Town, South Africa, [12]WHO, Department of Violence and Injury Prevention and Disability, Geneva, Switzerland, [13]The Beans, San Francisco, United States, [14]Curtin University, Faculty of Health Sciences, School of Psychology and Speech Pathology, Perth, Australia, [15]University of Fort Hare, Department of Sociology & Anthropology, Alice, South Africa, [16]Ali Douglas Research Network, Bulawayo, Zimbabwe, [17]London School of Economics and Political Science, Department of International Development, London, United Kingdom

Background: Adolescent HIV-risk behaviors are increased by family violence, low parental supervision, substance use and poverty. 'Cash + care' structural approaches can reduce adolescent HIV-risks, but parenting a teenager is complex and challenging. WHO, UNICEF, USAID-PEPFAR and academics developed and tested a parenting support and violence reduction program for low-resource settings, to be used as part of structural prevention programs.

Methods: Pragmatic cluster randomized trial (n=1100 participants, 40 clusters) in South Africa's rural and urban Eastern Cape. Adolescents and caregivers participated in 14 evidence-based sessions

(i.e. conflict reduction, protection from sexual abuse in the community, family budgeting), implemented by local community members with NGOs Clowns Without Borders, REPSSI, UNICEF South Africa and the Department of Social Development. Analyses used intention-to-treat with hierarchical negative binomial or Poisson regression for counts and hierarchical linear mixed effects regression for continuous outcomes.

Results: Retention was 97% at 5-9 months post-intervention. The intervention did not impact all parenting outcomes (i.e. neglect), but had significant impact on six key HIV risk reduction factors: lower family violence (caregiver report IRR 0.55 (95% CI 0.40-0.75, P< 0.001); improved involved parenting (caregiver report d=0.86 (95% CI 0.64-1.08, P< 0.001; adolescent report d=0.28 (95% CI 0.08-0.48, P=0.006) and less poor supervision (caregiver report d=−0.50 (95% CI −0.70- −0.29, P< 0.001; adolescent report d=−0.34 (95% CI −0.55- −0.12, P=0.002), and improved family economic welfare, including sustained food availability (caregiver report d=−0.62, 95%CI −0.84– -0.40, P< 0.001; adolescent report d=−0.28, 95%CI −0.52- −0.05, P=0.017). It was also associated with lower alcohol and drug use amongst adolescents (IRR=0.55, 95% CI 0.33-0.93, P=0.026) and amongst caregivers (IRR=0.67, 95%CI 0.49-0.99, P=0.041), and with improved planning for protection against sexual predators (caregiver report d=0.48, 95% CI 0.24-0.72, P< 0.001; adolescent report d=0.33, 95% CI 0.06-0.59, P=0.017).

Conclusions: This cluster RCT in South Africa shows that an intervention to support families can reduce direct risks for adolescent HIV-acquisition: violence, low supervision, food insecurity and substance use. The programme is being adapted and scaled in 8 countries in the region through DREAMS, 4Children, USAID, UNICEF and by national governments. Strengthening families may be an essential component of adolescent HIV prevention in Africa.

Improving timely linkage to care among newly diagnosed HIV-infected adolescents: Results of SMILE

R. Miller[1], D. Chiaramonte[1], C. Banerjee[2], D. Sharma[2], J.D. Fortenberry[3], Adolescent Medicine Trials Network for HIV/AIDS Interventions
[1]*Michigan State University, Psychology, East Lansing, United States,* [2]*Michigan State University, CSTAT, East Lansing, United States,* [3]*University of Indiana, Adolescent Medicine, Indianapolis, United States*

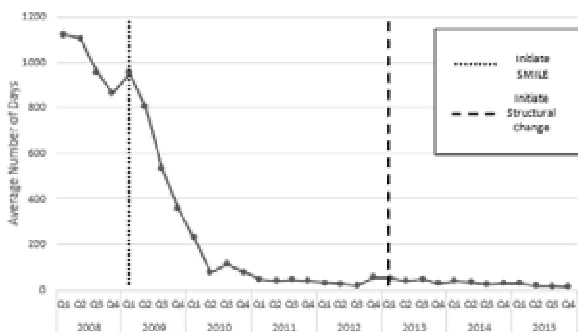
Background: In the U.S., youth are the least likely among people of all age groups to link to HIV medical care quickly following a positive HIV-test result. Delayed linkage to care deprives youth of the benefits of HIV treatment and risks increased HIV transmission. Interventions to improve the rates of timely linkage to care for youth represent an urgent national priority.

In 2009, we initiated the Strategic Multisite Initiative for Identification, Linkage and Engagement (SMILE) program to improve timely linkage to care among newly diagnosed HIV-infected youth in 8 urban U. S. adolescent medicine clinical trials units (AMTU). We deployed a dedicated linkage-to-care specialist to link youth to an infectious disease physician within 42 days of a positive test result.

In 2013, we additionally pursued local organizational, institutional, community, and policy changes to address structural barriers to youth's timely access to care through coalitions convened by each AMTU.

Methods: We collected anonymized clinical patient records from 2008 to 2015. Data included demographics and dates of HIV testing and medical care linkage events for 1695 newly diagnosed HIV-positive youth ages of 12-24. We plotted the linkage-to-care interval in days for each quarter from the start of 2008, prior to the start of SMILE, through 2015.

Results: At the start of SMILE, the average number of days between HIV test result and linkage was 951. This reflects, in part, that youth who had HIV tests long before the program's initiation ultimately linked to care during its start-up phase. By end of 2012, the average number of days to linkage had decreased to 55 (Figure 1). By the end of the initiative (2015), the average number of days to linkage had fallen to 16.



[Figure 1. Average number of days between HIV test and linkage-to-care.]

Conclusions: Integrated, multi-level interventions that draw on existing community resources can dramatically improve timely linkage to care among high-risk youth.

THPDE0105

90-90-48: The reality of viral suppression among ART-initiated adolescents in South Africa

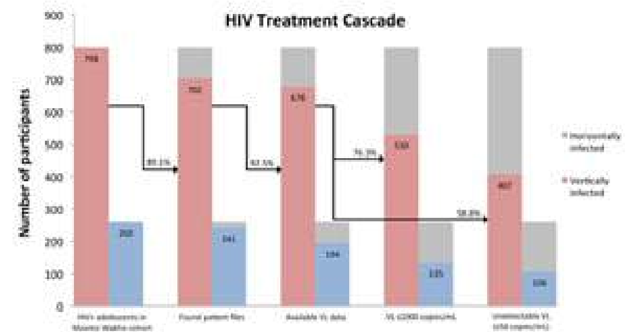
R. Haghighat[1], L. Cluver[1], N. Bungane[2], E. Toska[3]
[1]*University of Oxford, Social Policy and Intervention, Oxford, United Kingdom,* [2]*Mzantsi Wakho, East London, South Africa,* [3]*University of Cape Town, AIDS and Society Research Unit, Cape Town, South Africa*

Background: Global fast-track targets include 90% viral suppression among all ART-initiated persons. Data suggests adolescents have worse viral suppression rates than children and adults, but little is known on adolescent progression through the HIV treatment cascade. This study examines the HIV treatment cascade for a large sample of HIV+ adolescents in South Africa.

Methods: 1,058 ART-initiated adolescents (10-19 years) from 52 urban and rural healthcare facilities in the Eastern Cape were interviewed (March 2014-September 2015). Data were extracted from paper-based medical records from all facilities (including records in multiple facilities) through January 2018. Predictors of progression through cascade were identified using sequential multivariate logistic regressions, with age (10-14/15-19 years), sex, urban/rural residence, mode of infection, decentralised/centralised ART care, and time on ART entered simultaneously. Interactive effects and moderating effects of gender and mode of infection were tested with regressions, corrected with the Benjamini-Hochberg procedure.

Results: 92.5% of adolescents had viral loads available in clinic files. 63.1% had viral loads recorded in the past 2 years. At most recent viral load, 78.5% of measurements were ≤1000 copies/mL, but only 58.8% were undetectable (≤50 copies/mL). Participants were female (54.0%), median age 13 years (IQR 11-16), urban-living (76.8%); and 30.0% attended ≥2 healthcare facilities.

Adolescents on ART for < 2 years were more likely to lack viral loads from the past 2 years (OR 5.73 [95%CI 1.82-18.08], *p*< 0.003), and decentralised care was protective only for females (OR 2.56 [95%CI 1.40-4.64], *p*=0.002). Viral load >1000 copies/mL was associated with older age and rural-living (OR 2.18 [95%CI 1.58-3.00], *p*< 0.001; OR 1.48 [95%CI 1.06-2.12], *p*=0.031). Older adolescents, those on ART for < 2 years, and decentralised adolescents were less likely to have undetectable viral loads (OR 0.65 [95%CI 0.49-0.87], *p*=0.003; OR 0.36 [95%CI 0.13-0.91], *p*=0.047; OR 0.74 [95%CI 0.57-0.98], *p*=0.035).



[HIV treatment cascade for ART-initiated adolescents in the Eastern Cape, South Africa]

Conclusions: Viral suppression rates remain low among adolescents in South Africa. Older, recently initiated, and decentralised adolescents were least likely to be virally suppressed—potentially due to down-referrals from tertiary paediatric facilities to generalised primary clinics. With 30% of adolescents receiving care in multiple facilities, interventions supporting patient linkages to care may be essential for adolescents transitioning across multiple forms of care.

THPDE0106

A randomized, controlled trial of a patient-centered disclosure counseling intervention for Kenyan children living with HIV

R. Vreeman[1,2,3], W. Nyandiko[2,3], I. Marete[2,3], A. Mwangi[3,4], C. McAteer[1,3], A. Keter[3,4], M. Scanlon[3,5], S. Ayaya[2,3], J. Aluoch[3], J. Hogan[3,6]
[1]*Indiana University School of Medicine, Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indianapolis, United States,* [2]*College of Health Science, Moi University, Department of Child Health and Paediatrics, Eldoret, Kenya,* [3]*Academic Model Providing Access to Healthcare, Eldoret, Kenya,* [4]*College of Health Science, Moi University, Department of Behavioral Sciences, Eldoret, Kenya,* [5]*University of Massachusetts Boston, John W McCormack Graduate School of Policy and Global Studies, Boston, United States,* [6]*Brown University, Department of Biostatistics, Providence, United States*

Background: For children living with HIV, learning about their HIV status ("disclosure") is a critical process within their transition to adulthood. Caregivers of perinatally HIV-infected children frequently worry about the impact of disclosure, while also reporting delayed disclosure can

hurt medication adherence. We evaluated the impact of a patient-centered, culturally- and age-appropriate disclosure counseling intervention among Kenyan children and their caregivers.

Methods: We conducted a prospective, clinic-cluster randomized trial in which we followed child-caregiver dyads (children ages 10-14) attending eight clinics (randomized to intervention or control) at a large HIV treatment program in Kenya. All patients at the intervention clinics had access to intensive counseling (family, one-on-one, and peer group sessions) with trained disclosure counselors and culturally-tailored materials, compared to control clinics with standard care. Disclosure was treated as a time-to-event outcome, measured on a discrete time scale, with assessments at 0, 6, 12, 18, and 24 months. Mental health and psychosocial outcomes were assessed using standardized questionnaires.

Results: The 285 children were mean age 12.3 years, 52% female, with average time-on-treatment of 4.4 years. At baseline, 32% of the children reported that they knew their HIV status already (no difference between control and intervention groups). Disclosures in both control and intervention arms increased over follow-up, but the intervention arm had significantly more disclosures. Using child-reported disclosure, the prevalence of disclosure increased significantly between the baseline and 24 months of follow-up from 29.2% to 58.5% in the control arm and from 33.2% to 74.0% in the intervention arm (difference of 15.5%, 95% confidence interval: 3.7, 27.3). Overall, there were not significant differences in mental and behavioral health outcomes, although trends suggested mental and behavioral distress increased at month 6 in the intervention group as disclosures increased, and then decreased compared to controls thereafter.

Conclusions: This study provides evidence for an effective, clinic-based intervention to increase disclosure of HIV status to children living with HIV. Making counseling support available throughout the disclosure process may be particularly important to navigate increased psychological distress immediately after disclosure and move towards resilience.

THPDE02 Meeting the challenge: Community financing for a sustained response

THPDE0201

Empirical cost of community mobilization activities to support the scale-up of Universal Test and Treat in Swaziland

S. Khan[1], C. Wong[1], T. Maziya[1], F. Walsh[2], C. Lejeune[1], Y. Fleming[3], G. Khumalo[4], M. Zwane[5], V. Okello[6], T. Bärnighausen[7,8]

[1]Clinton Health Access Initiative (CHAI), Mbabane, Swaziland, [2]Clinton Health Access Initiative (CHAI), Boston, United States, [3]aidsfonds, Amsterdam, Netherlands, [4]Swaziland National Network of People Living with HIV/AIDS (SWANNEPHA), Mbabane, Swaziland, [5]SAfAIDS, Mbabane, Swaziland, [6]Ministry of Health, Mbabane, Swaziland, [7]Harvard T.H. Chan School of Public Health, Boston, United States, [8]Heidelberg Institute of Public Health, University of Heidelberg, Heidelberg, Germany

Background: Swaziland and many other countries in sub-Saharan Africa are adopting the 2015 World Health Organization (WHO) antiretroviral therapy (ART) guidelines and implementing universal test and treat (UTT). However, it has become increasingly clear that without successful community mobilization activities and demand generation, UTT will not lead to substantial increases in ART coverage. Here we present for the first time empirical cost estimates of community mobilization implemented as part of UTT in Swaziland.

Methods: From September 2014-August 2017, we collected comprehensive data from community partners supporting the transition of fourteen public health facilities from the previous standard-of-care (SOC) to UTT as part of a stepped-wedge implementation trial. The activities included community dialogues and mobilization events to educate both targeted and broader community as facilities introduced UTT. We carried out bottom-up costing of sub-activities for total unit cost estimation. The mean costs of each activity type are presented in USD ($).

Results: During the observation period, 311 events were carried out at a total combined cost of $90,448. Of this total, 54% were associated with community mobilization activities with mean cost of $348 (95% CI: 137,559) for activities ranging from dialogue with people living with HIV (PLHIV) to broader community. The cost of Information, Education and Communication (IEC) production and printing was $4,404 (95% CI: -7217, 16024) or 15% of total, while the cost of running a community advisory board (CAB) to ensure rights of clients was $348 (95% CI: 137,559) or 23% of total. Remaining costs were associated with orientation of the media and community leaders as well as monitoring and evaluation activities.

Conclusions: We present one of the first comprehensive set of estimates of the costs of community related activities carried outside the healthcare facilities to support UTT. The costs vary widely across broad categories due to mix of fixed (equipment rental) and variable costs (distance traveled, food), while CAB costs were high due to initial capital investment needed in training support. Future funding and planning should use these cost estimates to ensure that scarce resources for community mobilization are used to largest possible health and social benefit.

Events	Mean cost per event (USD) (95%CI)
General Orientation	$1,267
Media Orientation Workshop	$933
Information, Education and Communication (IEC) material	$4,404 (-7217, 16025))
Community Mobilization Events	$231 (198-265)
M&E	$145 (98-192)
Community Advisory Board (CAB)	$348 (137-559)

[Average cost of community events in support of UTT policy in Swaziland]

THPDE0202

Increased domestic financing of key population-led health services (KP-LHS): Lessons from Thailand's transition planning and response

K. Rungtanatada[1], S. Janyam[2], D. Linjongrat[3], S. Charoenying[4], K. Benjamaneepairjoj[4], M. Kim[5], M. Sanguankwamdee[5], S. Mills[4]

[1]National Health Security Office (NHSO), Bangkok, Thailand, [2]Ministry of Public Health (MoPH), Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]LINKAGES/Thailand, FHI 360, Bangkok, Thailand, [5]United States Agency for International Development Regional Development Asia, Bangkok, Thailand

Background: As international donors such as The Global Fund (GFATM) and PEPFAR transition out of middle-income countries, there is an urgent need for domestic budgets of countries to increase their financial commitments to the HIV response. In Thailand, nowhere is this more urgent than with HIV cascade interventions for key populations (KPs) most successfully delivered by civil society organizations (CSOs) uniquely able to reach these often-marginalized persons affected and infected by HIV. Yet these critical KP-LHS have thus far failed to attract increased domestic financing because of poor targeting of scarce resources, pervasive stigma and discrimination towards KPs, and a lack of contracting mechanisms to fund CSOs providing KP-LHS.

Description: The Thailand National Health Security Office (NHSO) committed approximately $6 million starting in 2016 for initiatives to increase access to HIV testing and antiretroviral treatment among KPs. The initiative was designed to tap the expertise of KP-led organizations, many of whom have been traditionally financed by GFATM and PEPFAR. NHSO developed reimbursement schemes based on cost estimates of "reach-recruit-test-treat-prevention-retain" activities which vary for each KP group. These amounts were made available to organizations such as CSOs, hospitals, and provincial health offices providing services for KPs through contracts with NHSO.

Lessons learned: Despite the increases in government budgetary support for KP-LHS, certain gaps remain. An estimated 60% of the total were funds provided to CSOs and 40% were provided to hospitals. NHSO identified the following gaps and needs: strengthening of systematic management of funding and service monitoring; accreditation system

to ensure organizational and service capacity of CSOs; ensuring that unit cost reflects appropriate operational costs of CSOs; funds integration with other funding sources for greater coverage.
Conclusions/Next steps: NHSO will work with stakeholders to address these challenges through establishment of an accreditation process to ensure organizational capacity to manage funds and provide services, conducting of costing studies to ensure alignment of service reimbursement for KP-LHS under models applicable to each KP group and local epidemic contexts, and strengthening local fund management entities to manage and monitor NHSO funding.

THPDE0203

Last to be funded, first to be cut: An analysis of current funding trends to local community organisations in the Positive Action Network

N. Spicer[1], D. Kemps[2], S. Demellweek[3]
[1]ViiV Healthcare, Positive Action, London, United Kingdom, [2]ViiV Healthcare, Brentford, United Kingdom, [3]ViiV Healthcare, Positive Action, Brentford, United Kingdom

Background: To enable the global community to meet its own Fast Track targets, UNAIDS estimates that approximately US$ 26.2 billion will need to be spent on HIV responses in 2020. Despite this, there was a $51 million reduction in donor Government funding for HIV between 2015 and 2016. The critical role of community-based interventions in the fight against HIV has never been in question, but if funding squeezes are affecting these small groups in equivalent proportions, we could see transmission rates and HIV-related deaths rise as a result.
Description: ViiV Healthcare is conducting a comprehensive survey of organisations engaged in our Positive Action for Children Fund (PACF) and Positive Action for Girls and Women (PAGW) online communities. The survey of 350 current and former grantees and over 2000 community members seeks to understand funding trends since 2015, how grant durations are spread, and in what proportions different funder types are contributing to community HIV interventions in low resource settings.
Lessons learned: Preliminary findings from community based organisations (CBOs) indicate that funding opportunities are unchanged (less than 20% change) in the past two years, with commentary that the number of international funders funding local CBOs has also remained unchanged. This is despite the High Level Meeting in 2016 proposing increased funding to local communities to optimise investments in health services.
Offering a rare insight into funding levels in communities, these results are valuable in allowing us to quantify the recent funding trends for grassroots CBOs for the first time, and determine whether the globally reported percentages for funding to CBOs are reflected in the experiences of respondents on the ground.
Conclusions/Next steps: The results point to the urgency in prioritising funding to local communities if we are to meet funding commitments and ensure that investments in health systems are optimised. Further research will be needed to assess the intensity of fundraising required to achieve the current level of funding versus previous years.

THPDE0204

Post-global fund HIV financing: A promising transitioning model and the implementation of plan from the SHIFT (Sustainable HIV Financing in Transition) program in Thailand

R. Jommaroeng[1,2], Y. Somphoh[1], K. Uppakaew[1], A. Karakit[1], D. Linjonrut[2], C. Thongbai[3], P. Panitchpakdi[4], CSO Resource Mobilization (CRM) Coalition
[1]Thai National AIDS Foundation, Bangkok, Thailand, [2]Rainbow Sky Association of Thailand, Bangkok, Thailand, [3]Pink Monkey Organization, Lopburi, Thailand, [4]Raks Thai Foundation, Bangkok, Thailand

Background: Thailand has been a recipient country of the Global Fund to Fight against AIDS, Tuberculosis and Malaria (GFATM) since 2004 with the accumulative amount of US$287.4 million which sustains 95.0% of the programs implemented by civil society organisations(CSO) 5.0% is supported by the Subsidiary Fund of the Thai government. The country has been categorised as an upper-middle income country in 2011, partly resulting in the out-transitioning of GFATM, negatively affecting sustainability of CSO-implemented HIV programs.
Description: The initial of 30 CSOs, including MSM, transgender women, sex workers, PWID organizations, gathered in late 2015 to form CSO Resource Mobilization(CRM) under 'AIDS-Almost Zero' program to address HIV financing sustainability and currently supported by the SHIFT program to ensure increased fiscal space, allocative efficiency, effective transitioning plan and funding mechanisms for CSOs. We have been advocating the National Health Security Office(NHSO) for a regular annual scheme for CSOs working with key populations. The goal is to reach US$14.7 million/year and US$5.9 million has been successful allocated in 2018 and with the Disease Control Department to increase the Subsidiary Fund from US$1.5 million to US$ 3 million. To minimize the risks of sole government funding, the CRM have initiated a public-private partnership program to raise funds for US$1.5 million with an exponentially annual increase for five consecutive years.

[Thailand's Model of CSO Resource Mobilization on HIV Financing for Post-GFATM]

Lessons learned: Collaboration and partnership across all key stakeholders is essential for an effective HIV response. Formal dialogues help convey strategic information to the government but informal dialogues help change their perception towards CSOs, influencing favorable policy outcomes. Consistency in engaging with the government is crucial since government staff rotation is to be expected and trust cannot be earned over a few meetings. Instant messaging applications such as Facebook and LINE™ are used as informal but effective communication means, eventually leading to improved trust.
Conclusions/Next steps: We are fostering strengthened partnership with both central and local governments with a key message "Get yourselves invited in all policy dialogues, seen in all festive occasions, and perceived as highly reliable partners. In addition, a development of national CSO accreditation is in progress to ensure our effective management, accountability and that we deliver results.

Policies/ Mechanisms	Policy target	Themes	Achievements	Challenges
The US$14.7M Scheme for Key Populations	The National Health Security Office	Increased fiscal space, Allocative efficiency, CSO funding mechanism	US$5.9M is allocated annually in 2018. 15 CSOs working with MSM and SW receive direct funding and 9 CSOs through local government agencies	This challenges the Public Administration Reform in Thailand, hence this is innovative. More standardization on allocative efficiency is yet to be strengthened.
The US$3M Subsidiary Fund	The Ministry of Public Health Department of Disease Control	Increased fiscal space, Allocative efficiency	US$1.5M is allocated to CSOs in 2018. 500 projects are financed.	More strategic allocation is needed to increase fiscal space as the MoPH promises 500 projects to be funded as the only indicator.
The US$3M Public-Private Partnership Fund	Public Sector (Corporate and Individual)	CSO funding mechanism	US$0.79M has been raised so far.	HIV is no longer an appealing to the public.

[HIV financing policy progress monitoring]

THPDE0205

A sustainable approach to providing HIV services and information at the community level: A longitudinal exploration of female community health entrepreneurs' performances

R.A.J. Borst[1], M.O. Kok[1,2], F. Bucker[3], D. Muhangi[4]
[1]Erasmus University Rotterdam, Erasmus School of Health Policy & Management, Rotterdam, Netherlands, [2]Amsterdam Public Health, Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands, [3]Vrije Universiteit Amsterdam, Health Sciences (Student), Amsterdam, Netherlands, [4]Makerere University, Social Work and Social Administration, Kampala, Uganda

Background: Community health entrepreneurship is an innovative way of providing rural communities access to primary healthcare by harnessing the entrepreneurial skills of lay health workers. Previous research shows that community health entrepreneurs have a highly beneficial impact on communities' knowledge of HIV prevention. However, it remains unclear how the performance of these entrepreneurs evolve over time. Hence, this study aimed to longitudinally compare the performances of lay health workers and community health entrepreneurs. The findings of this study aim to contribute to the construction of a sustainable primary sexual and reproductive healthcare model.

Methods: Data were collected using a tablet-based performance survey in a six-month quasi-experimental study. The study aimed to sample 500 female lay health workers from two rural districts in East and Central Uganda who were recruited to become a community health entrepreneur. A random sample of 150 participants would receive their training directly, whereas the other 350 would start six months later. Mixed models were used to longitudinally asses the difference in performance indicators between the two groups. These indicators included their income, self-esteem, and availability of essential medicines and equipment.

Results: A group of 56 female community health entrepreneurs successfully completed their training directly, followed by a second group 77 six months later. After six months, the entrepreneurs showed sustained performance over the lay health workers. The community health entrepreneurs proved to have a key role in providing rural populations with basic services and products for sexual and reproductive health. The entrepreneurs had a higher availability of essential medicines (OR: 3.39, 95%-CI: 2.03; 5.65) and key equipment (OR: 1.87, 95%-CI: 1.03; 3.37). In addition, their Rosenberg self-esteem score increased with 1.24 points (95%-CI: 0.09; 2.39) more than that of lay health workers, whereas their weekly overall income increased with $8.96 (95%-CI: $3.59; $14.32) more than that of lay health workers.

Conclusions: Female lay health workers who were trained to become a community health entrepreneur showed an increased and sustained performance in the medium-term. This study provides the first evidence that community health entrepreneurship may be a sustainable and lasting model through which to organise sexual and reproductive healthcare.

THPDE0206

Building a constituency of advocates for sustainability: Identifying the capacity needs of HIV CSOs and key populations to advocate for HIV financing and sustainability in Indonesia, Malaysia, Philippines and Thailand

J. Bagas
APCASO, Bangkok, Thailand

Background: In response to declining donor funding for HIV, the Sustainable HIV Financing in Transition (SHIFT) Programme is supporting HIV financing advocacy for CSOs in four middle-income countries in Southeast Asia through capacity building and strategic information.

APCASO, a regional sub-recipient of SHIFT, conducted a needs assessment for CSOs and key population (KP) groups in Indonesia, Malaysia, Philippines and Thailand in 2017 to identify their capacity needs in relation to HIV financing advocacy.

Description: APCASO developed a tool for a two-day focus group discussion where participants representing SHIFT SRs, HIV CSOs, and KP groups scored or assessed their capacities in five areas: programmatic capacity; organisational capacity; individual capacity; linkages to HIV financing stakeholders; and enabling environment.

48 participants from 28 CSOs and KPs took part of the FGDs: Philippines = 5 groups; Malaysia = 8; Indonesia = 8; and Thailand = 7. They represented the following communities and KPs: PLHIV (5 groups); MSM (10); TGs (8); SWs (3); PWUDs (5); women PLHIV (1), and YKPs (1). 7 organisations reported representing broad constituencies or all KPs.

Lessons learned: Here are some of the major findings of the needs assessment:

- Almost all groups reported moderate to weak capacity on key HIV financing topics, such as transition policies, UHC, and budget cycles.
- Advocacy is perceived as an add-on to service delivery despite prevailing notion that advocacy is their core mandate.
- There is limited or no engagement with critical government decision-makers, such as the Finance ministry, treasury, or major political leaders.
- Spaces for HIV financing advocacy presented by decentralisation are not maximised. Existing government funding mechanisms for CSOs are not fully understood.
- HIV networks present a means to mitigate KP-specific barriers (such as criminalisation). However, capacity to advocate for KP-specific programmes varies across groups.

Conclusions/Next steps: To address these gaps, APCASO worked with the SRs and SHIFT regional partners to design in-country advocacy trainings that covered national HIV funding landscapes, UHC, budget cycles, CSO funding mechanisms, as well as advocacy skills on HIV financing. APCASO also developed a set of tailored technical assistance activities for the four countries to continue enhancing capacities on HIV financing.

Eliminating/Silencing latency

THPEA001

The Mitochondrial Antiviral Signaling protein plays an essential role in the activity of several latency-reversing agents

I. Sarabia[1], C. Novis[2], A.B. Macedo[1], R. Nell[3], B. Shakya[4], H.L. Schubert[4], C.P. Hill[4], A.B. De Paula-Silva[2], A.M. Spivak[3], V. Planelles[2], A. Bosque[1]
[1]George Washington University, Microbiology, Immunology and Tropical Medicine, Washington, United States, [2]University of Utah, Department of Pathology, Division of Microbiology and Immunology, Salt Lake City, United States, [3]University of Utah, Department of Medicine, Division of Infectious Diseases, Salt Lake City, United States, [4]Univerisity of Utah, Department of Biochemistry, Salt Lake City, United States

Background: The Mitochondrial Antiviral Signaling protein (MAVS) is part of the cell's innate immune mechanism of defense. MAVS plays an important role in activating NF-B after the cytosolic RNA sensors retinoic acid-inducible gene I (RIG-I) and melanoma differentiation-associated protein 5 (MDA5) recognize viral infections. MAVS can also sense cellular stress and activate an anti-oxidative stress (AOS) response through the activation of NF-B. Because NF-B is a main transcription factor for HIV, we wanted to address what role MAVS and the AOS response plays in HIV reactivation from latency.
Methods: We first tested whether activation of the AOS response reactivates latent HIV using a tumoral latency model, a primary cell model of latency, and cells from aviremic participants. Next, we generated a clone lacking MAVS in the tumoral cell model of latency JLAT using CRISPR/Cas9. Using this system, we further characterized the role of MAVS in viral reactivation mediated by the AOS response. We then addressed whether MAVS plays a role in viral reactivation mediated by several known latency-reversing agents (LRAs). Finally, complementation studies were performed to demonstrate the requirement of MAVS for the activity of several LRAs.
Results: Our results indicate that the AOS response can reactivate latent HIV through the activation of NF-B in a MAVS dependent manner. Interestingly, several LRAs with different putative mechanisms of action, such as HDAC inhibitors and PKC agonists, exert part of their anti-latency activity by inducing an AOS response and require MAVS to fully reactivate latent HIV.
Conclusions: Our results indicate that the activity of many clinically relevant LRAs is partially due to their induction of an AOS response and NF-B activation and suggest a central role of the mitochondria and MAVS in controlling HIV transcription in response to cellular stress.

THPEA002

Potency of latency-reversing agents and CTL exhaustion balance the killing of HIV inducible provirus

A. Ruiz de Andrés[1], O. Blanch-Lombarte[1], E. Jimenez-Moyano[1], R. Peña[1], M. Genescà[2], B. Mothe[1,3], P. Goulder[4], B. Clotet[1,3], J.G. Prado[1]
[1]AIDS Research Institute IrsiCaixa, Hospital Universitari Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, Spain, [2]Hospital Universitari Vall d'Hebrón, Institut de Recerca (VHIR), Universitat Autònoma de Barcelona, Department of Infectious Diseases, Barcelona, Spain, [3]Universitat de Vic-Universitat Central de Catalunya, Vic, Spain, [4]University of Oxford, Peter Medawar Building, Department of Paediatrics, Oxford, United Kingdom

Background: The clinical use of Latency-reversing agents (LRA) in HIV cure interventions has demonstrated detectable perturbations on the viral reservoir with no measurable reductions. Thus, many questions regarding immune surveillance of HIV-reactivated cells continue unanswered. Here, we aim to determine magnitude and kinetics of recognition of HIV-reactivated cells by CTL, and to evaluate the impact of CTL exhaustion as a balancing factor of the magnitude of the killing of inducible provirus.
Methods: We developed an HIV "Resting-Like cell model" (RELI) that allowed simultaneous monitoring of "HIV shock and CTL kill". Briefly, RELI cells were treated with LRA for 48h. After that, cells were washed and co-cultured for 20h with CTL clones or bulk CD8+ T-cells from HIV-infected patients. We monitored the potency of LRA-inducible HIV reactivation by intracellular p24 staining and assessed the magnitude of CTL killing by differences in frequency of p24+ cells in the absence or presence of CTL/CD8+. We measured the kinetics of CTL recognition and killing of reactivated cells at 3, 6 and 20h post co-culture. We evaluated exhaustion of CTL/CD8+ by PD-1, LAG3, TIM3 and CD39 expression.
Results: We demonstrated an increase in the magnitude of the killing of HIV-infected cells by CTL through reactivation with SAHA or Panobinostat ($p< 0.01$). Our findings were confirmed in co-cultures of bulk CD8+ from HIV-infected patients ($p< 0.05$, $n=7$). The kinetics experiment revealed early recognition of HIV-inducible provirus by CTL starting at 3h, where the speed of killing correlated with the magnitude of reactivation ($r2=0.82$, $p< 0.005$ at 3h; $r2=0.93$, $p< 0.0005$ at 6h). Besides, magnitude of CTL killing in response to HIV-reactivation was reduced upon the co-expression of three or more exhaustion markers ($p< 0.05$). In bulk CD8+, we observed a correlation between the magnitude of killing and the lack of exhaustion markers.
Conclusions: Our results support the contribution of CTL responses to the clearance of HIV-inducible provirus upon LRA treatment. Moreover, our findings indicate the importance to maximize LRA potency for the rapid recognition and killing of HIV-reactivated cells by CTL, together with the evaluation of CTL exhaustion in HIV-infected patients to optimize "shock & CTL kill" strategies.

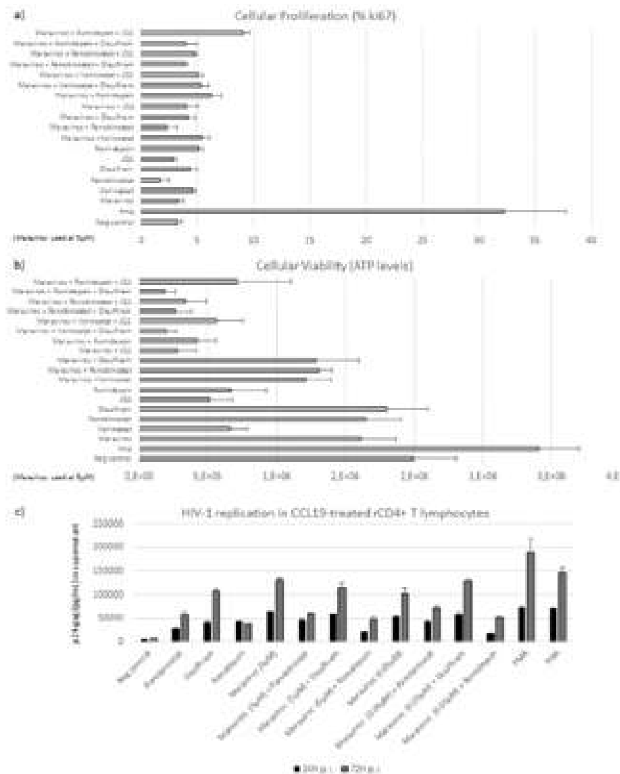
THPEA003

Combinations of maraviroc with other latency reversing agents to activate latent HIV-1 in rCD4+ T lymphocytes

M.R. López-Huertas, L. Jimenez-Tormo, L. Luna, S. Moreno
Hospital Universitario Ramón y Cajal - Instituto Ramón y Cajal de Investigación Sanitaria, Infectious Diseases Service, Madrid, Spain

Background: HIV-1 remains incurable due to latent reservoirs established in non-activated CD4+ T cells. Current efforts to achieve a functional cure rely on immunomodulatory strategies focused on enhancing the functions of cytotoxic cells. Implementation of these actions required a coordinated activation of the viral transcription in latently infected cells so that the reservoir became visible and accessible to cytotoxic cells. As no latency-reversing agent (LRA) has been shown to be completely effective so far, new combinations are of increasing importance. Recent data show that maraviroc, the CCR5 antagonist with clinic use, is a new LRA due to its ability to activate NF-B and to induce viral replication in latently infected cells. Our objective was to find combinations of maraviroc with other LRAs that potently reactivate HIV-1.
Methods: rCD4+ T cells were stimulated with maraviroc (0.05, 0.5 μM) alone or combination with other LRAs including vorinostat (335 nM), panobinostat (30 nM), romidepsin (40 nM), JQ1 (0.5 mM) and disulfiram (500 nM). PMA or PHA were used as positive control. Cellular viability and proliferation were measured by quantifying ATP and ki67 levels, respectively. Then, a latently model based on treating primary resting CD4+ (rCD4+) T cells with CCL19 (29nM) before in vitro HIV-1 infection with X4-NL4.3 was used. HIV-1 replication was assessed by quantifying p24 antigen in the culture supernatant 24h and 72h post-stimulation.
Results: Cell cycling was not detected in any of the double or triple combinations tested except for maraviroc+romidepsin+JQ1 (Fig. 1a). However, most of the triple combinations reduced cellular viability and were rejected (Fig. 1b). Maraviroc 5 and 0.05 μM were both efficient in reactivating HIV-1 replication but 5 μM was slightly superior. Maraviroc (5 μM) reactivates HIV-1 replication with the same potency as positive controls after 24h and 72h stimulation, which was around 10- and 18-fold, respectively (Fig. 1c). Maraviroc plus disulfiram is the only combination maintaining these levels.

Conclusions: Maraviroc reactivates HIV-1 replication in vitro. A combination of maraviroc plus disulfiram maintains the effect without resulting in cellular toxicity or proliferation. Ex vivo studies are required to highlight the importance of this combination before moving into in vivo assays.



[Figure 1. HIV-1 replication in CCL19-treated rCD4+ T cells after stimulation with maraviroc]

THPEA004

Getting the "kill" into "shock and kill": The role of PI3K inhibitors

Y. Kim[1], J.L. Anderson[2,3], A. Solomon[1], J. Ali[4], P.U. Cameron[1,5], S.R. Lewin[1,5]
[1]The Peter Doherty Institute for Infection and Immunity, The University of Melbourne and Royal Melbourne Hospital, Melbourne, Melbourne, Australia, [2]The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [3]The University of Melbourne, Microbiology and Immunology, Melbourne, Australia, [4]Infinity Pharmaceuticals, Cambridge, United States, [5]Dept Infectious Diseases, Monash University, The Alfred Hospital, Melbourne, Australia

Background: One strategy to eliminate latently infected CD4+ T cells in HIV+ individuals on antiretroviral therapy (ART) is to use latency reversing agents (LRAs) to reactivate virus expression. However, additional strategies to kill reactivated cells are needed. Phosphoinositide 3-kinases (PI3K) promote cell survival by preventing apoptosis. We hypothesised that PI3K inhibitors in combination with LRAs will increase the sensitivity of latently infected cells to apoptosis.

Methods: Using the latently infected cells line JLat6.3 and CD4+ T cells from HIV-infected individuals on ART, we evaluated virus expression and cell death following administration of isoform-specific PI3K inhibitors (IPI-XXXX, IPI-3063: Infinity Pharmaceuticals), a panPI3K inhibitor (Wortmannin) and a Bcl-2 inhibitor (Venetoclax), together with a panel of LRAs including vorinostat, panobinostat, romidepsin, bryostatin, JQ1 or disulfiram or T cell activation with PMA/PHA. Toxicity was evaluated by a violet cell death stain. HIV expression was quantified by flow cytometry for EGFP in J-Lat6.3 cells, and HIV integrated DNA was measured by qPCR.

Results: In J-Lat6.3 T cells, PI3Ki alone or combined with LRAs did not enhance cell death. Contrary to our hypothesis, there was a reduction in cell death with bryostatin+IPI-XXXX (68% decline relative to DMSO) and panobinostat+IPI-XXXX (21% decline relative to panobinostat alone). Given that activity of PI3Ki may be different in an immortalised cell line, we also evaluated these drugs in CD4+ T cells from HIV-infected individuals on ART (n=4). In one of four participants, compared to DMSO or either drug alone, there was a reduction in HIV integrated DNA *with* IPI-XXXX and romidepsin (5% decline) and Wortmannin and PMA/PHA (24% decline). Venetoclax induced a decline in HIV DNA alone and this was not increased by the addition of RMD or PMA/PHA.

Conclusions: PI3K inhibitors together with LRAs have minimal effects on apoptosis in the J-Lat6.3 cell line while in CD4+ T-cells from HIV-infected individuals on ART, a reduction in HIV DNA in one individual was observed. Further work is needed to define the optimal combination of LRAs with PI3K inhibitors to reduce latently infected cells.

Immunotherapy

THPEA005

Use of the immunomodulatory activity of tyrosine kinase inhibitors to elicit cytotoxicity against HIV-1 infection

S. Rodriguez-Mora[1], G. Bautista[2], M.R. Lopez-Huertas[3], E. Mateos[1], V. Garcia-Gutierrez[3], J.L. Steegmann[4], J. Ambrosioni[5], N. Climent[5], F. Cervantes[5], J.M. Miro[5], M. Plana[5], V. Planelles[6], J. Alcami[1], M. Coiras[1]
[1]Instituto de Salud Carlos III, AIDS Immunopathology, Madrid, Spain, [2]Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, [3]Hospital Ramon y Cajal, Madrid, Spain, [4]Hospital Universitario de La Princesa, Madrid, Spain, [5]Hospital Clinic, IDIBAPS, Barcelona, Spain, [6]University of Utah, Salt Lake City, United States

Background: Due to reservoirs, HIV-1 infection cannot be cured with current ART, even in the presence of latency reversal agents (LRAs). Cytotoxic cells such as NK and CD8+ T lymphocytes should be activated to destroy latently infected cells. However, attempts to reactivate the reservoir with LRAs cannot be effective in the absence of a potent cytotoxic response. We previously described that tyrosine kinase inhibitors (TKIs) imatinib and dasatinib, successfully used for treating chronic myeloid leukemia (CML), impede HIV-1 replication. TKIs also increase populations of NK (CD3-CD56+), NK-LGL (CD56+CD57+), and T-LGLs (CD3+CD57+) cells in CML patients. In this work, we analyzed whether TKIs may promote cytotoxicity to destroy HIV-infected cells.

Methods: CD4+ T-cells isolated from PBMCs of healthy donors (n=6) and activated with PHA/IL-2 for 3 days were cocultured with autologous NK and CTLs, previously treated with imatinib 10mM or dasatinib 37.5nM, and then infected with NL4-3_Renilla. Same procedure was performed with PBMCs from patients with CML treated with dasatinib (n=6) or imatinib (n=6), except for TKI treatment in vitro.

Results:

1) CD8+ T-cells and NKs isolated from healthy donors and treated in vitro with imatinib or dasatinib showed an average cytotoxic potential >2-fold against HIV-1 infection, regarding the same cells untreated, when cocultured with autologous CD4+ T-cells infected with HIV-1.

2) CD8+ T-cells and NKs isolated from CML patients on treatment with imatinib or dasatinib for more than 6 months showed cytotoxic potential >5-fold against autologous CD4+ T-cells infected ex vivo.

3) These PBMCs from CML patients treated with dasatinib showed 4.1-, 1.5-, 4.9-, and 5.6-fold increase of CD56+/CD16+, CD56+/CD57+, CD56+/NKG2D+ and CD56+/CD158f+ cells, respectively. PBMCs from CML patients treated with imatinib showed 2.7-, 2.0-, and 2.0-fold increase of CD56+/CD16+, CD56+/CD57+, and CD56+/NKG2D+, respectively, with no changes in CD56+/CD158f+ population, regarding healthy controls.

4) Synthesis of IFNg in response to CEF peptides was 5.1- and 2.0-fold increased in PBMCs of CML patients treated with dasatinib or imatinib, respectively.

Conclusions: TKIs such as imatinib and dasatinib may act as immunomodulators, increasing cytotoxicity of NK and CTLs in vivo. Once the provirus is activated by LRAs, co-treatment with TKIs may destroy latently HIV-infected CD4+ T-cells.

Administration of rhIL-15 in combination with anti-PDL1 (Avelumab) in SIV-infected RM

P. Chen[1], H. Chen[2], M. Moussa[1], T. Li[1], J. Chen[1], J. Lifson[3], M.C. Sneller[2], L. Krymskaya[4], S. Godin[5], H.C. Lane[2], M. Catalfamo[1]
[1]*Georgetown University School of Medicine, Washington, United States,* [2]*CMRS/Laboratory of Immunoregulation, NIAID, NIH, Bethesda, United States,* [3]*AIDS and Cancer Virus Program, Retroviral Pathogenesis Section, Leidos Biomedical Research, Frederick National Laboratory, Fredrick, United States,* [4]*Laboratory of Human Retrovirology, Leidos Biomedical Research, Inc., Federick, United States,* [5]*Smithers Avanza Toxicology Services, Gaithersburg, United States*

Background: During chronic HIV/SIV infection, there is persistent immune activation accompanied by accumulation of virus-specific cells with terminally differentiated phenotypes and expression of down-regulatory immune modulatory receptors such as PD1. These observations led to the hypothesis that blockade of this pathway may restore the immune system leading to control/elimination of the viral reservoir. In addition, previous studies from our group had established that continuous infusion of IL-15 leads to expansion of CD8 T cells with effector memory phenotype. In the present study, we hypothesized that expansion of CD8 T cells with IL-15 in combination of anti-PD-L1 may be a potential therapeutic strategy to control viral replication in SIV-infected rhesus macaques (RM).
Methods: We investigated the effects of administration of recombinant human IL-15 in combination with a fully human anti-PD-L1 mAb (SB0010718C, Avelumab, EMD-Serono, Inc., Rockland, Massachusetts, USA) in SIV_{mac239}-infected RM receiving cART with suppressed viremia. The treatment group (n=6) received cART for 11 weeks followed by 2 x 10-day cycles of continuous infusion of rhIL-15 at a dose of 10µg/kg/day and weekly administration of 20 mg/kg of Avelumab. cART was interrupted at 8 weeks and administration of Avelumab continued for an additional 16 weeks. Viral load, CD4 counts, lymphocyte subsets and chemistry were monitored during the study.
Results: Administration of IL-15 and anti-PDL1 was well tolerated, and no clinically significant changes in body weights, hematologic, or chemistry parameters were observed during the study. There was no impact of the experimental interventions on CD4 count or viral load. In contrast to previous studies of IL-15 alone, no expansion of the CD8 T cell pool was observed although an increase in the proportion Ki67+ effector memory phenotype CD8 was noted at the time of the IL-15 cycles (compare controls and treatment groups). A reduction of the proportion of PD1+ effector memory phenotype CD8 T cells was accompanied by an increase in the proportion of CXCR3+ CD8 T cells.
Conclusions: Administration of IL-15 and anti-PD-L1 in chronic SIV-infected RM was well tolerated. The failure to observe the same substantial CD8 T cell expansions seen with IL-15 alone highlight the challenges encountered in evaluating combinations of immunomodulatory therapies.

Vaccines

THPEA007

Impact of a dendritic cell based therapeutic vaccine on microRNA expression profile

R. Pastor[1], C. Feher[1,2], O. Tort[1], T. Escribà[1], P. Aloy[2], H. van den Ham[3], R. Guters[3], A. Andeweg[3], M. Arnedo[1], F. García[1]
[1]*Group of Genomics and Pharmacogenomics, Laboratory of Retrovirology and Viral Immunopathogenesis. IDIBAPS. Infectious Disease Department, Hospital Clinic de Barcelona, Barcelona, Spain,* [2]*Institut de Recerca Biomèdica de Barcelona, Barcelona, Spain,* [3]*Department of Virology, Erasmus MC, Rotterdam, Viroscience, The Netherlands, Rotterdam, Netherlands*

Background: We have reported a monocyte-derived dendritic cell (MD-DC) based vaccine elicits T-cell responses associated with a reduction of viral load set-point around 94% in chronic HIV-1 infected patients after 12 weeks of an analytical therapy interruption (ATI). To better understand the efficacy of this vaccine, we assessed the impact on differential expression of microRNA.
Methods: 35 chronically -HIV-1 infected patients on ART were randomized 1:1:1 to receive: 3 doses of MD-DCs pulsed with inactivated autologous HIV-1 separated by two weeks interval (weeks 0,2,4) and ATI w0 (ATIw0-DC-HIV-1, n=12) vs the same immunogen and ATI w4 (ATIw4-DC-HIV-1, n=12) vs 3 doses of non-pulsed MD-DCs and ATI w4 (DC-control, n=12). Total RNA from frozen PBMC was used to perform the *Affymetrix 4.1 Array Strips*. Differential miRNA (DEmiRNA) expression and enrichment analisys was performed using t-test as implemented in the Bioconductor. MiRwalk v2.0 and DAVID softwares were used to identify validated gene targets and functional annotation pathways respectively.
Results: After normalization, 45 differential expressed DEmiRNA were found in ATIw0-DC-HIV-1 and 66 DEmiRNA in ATIw4-DC-HIV-1 groups, respectively, as compared with the DC-control group. Fourteen of these DEmiRNAs were shared by both DC-vaccine groups (ATIw0-DC-HIV-1 and ATIw4-DC-HIV-1) (p-value< 0.05; -0.5>FC>0.5). 4/14 DEmiRNA had the highest significance (p-value< 0.005; -0.5>FC>0.5) and were selected for the enrichment analysis (hsa-miR-4708-5p;hsa-miR-4731-5p;hsa-miR-767-5p;hsa-miR-6770-5p). These DEmiRNA target a total of 378 validated genes that are involved mainly in the humoral immune response and in the regulation of regulatory T-cell differentiation pathways.
Conclusions: The vaccination with a MD-DC based immunogen against HIV-1 infection was associated with the expression of 4 miRNA involved in the in the humoral immune response and in the regulation of regulatory T-cell differentiation pathways.

Genetherapy

THPEA008

Differences in antiviral efficacy and expression profile of anti-HIV RNAs expressed from the RNA polymerase III promoters U6, 7SK and H1

R. Goguen[1,2], O. Del Corpo[2,3], C. Malard[1,2], A. Daher[2], S. Colby Germinario[2], R. J. Scarborough[1,2], A. Gatignol[1,2,3]
[1]*McGill University, Microbiology and Immunology, Montreal, Canada,* [2]*Lady Davis Institute, Montreal, Canada,* [3]*McGill University, Experimental Medicine, Montreal, Canada*

Background: AIDS remains a globally distributed disease, despite the various drugs available to treat HIV infection. An alternative approach to classical treatments is to use gene therapy vectors to deliver antiviral molecules to hematopoietic stem cells (HSCs) and make all major HIV producing cells resistant to HIV replication. This could be achieved by engineering HSCs to permanently produce antiviral RNAs and eliminate the need for daily medication.
While clinical trials are already in progress with this approach, there are conflicting results reported in the literature as to the optimal promoter for expression of anti-HIV RNAs. We hypothesize there will be an optimal promoter for each RNA candidate to ensure maximal antiviral efficacy and minimal toxic effects.
In this study, two anti-HIV short hairpin (sh) RNA were compared for their effects on HIV production, cellular toxicity and metabolite profile, when expressed from different RNA polymerase (Pol) III promoters.
Methods: Co-transfections were performed in HEK293T cells with an HIV-1 molecular clone (pNL4-3) and a plasmid expressing shRNAs from modified H1, 7SK or U6 RNA Pol III promoters. Viral production was quantified by HIV-1 reverse transcriptase activity in co-transfected cell supernatants. Cellular toxicity was measured by metabolic enzyme activity and the metabolic profile of shRNAs was evaluated by RNA sequencing in shRNA transfected cells.
Results: For both shRNA candidates, the U6 and 7SK promoters produced more effective anti-HIV RNAs. Changing the sequence of the U6 and H1 promoter to their natural sequences resulted in the expression of less effective shRNAs. Transfection of shRNAs expressed from different RNA Pol III promoters did not change effects on cellular toxicity but had major effects on their metabolite profile.

Conclusions: Our results suggest that RNA Pol III 7SK and U6 promoters express more effective anti-HIV shRNAs compared to H1 promoters with no further improvement when changing the promoters to their natural sequence. We also demonstrate the metabolite profile of anti-HIV shRNAs is variable when expressed from the different promoters. Combination anti-HIV RNA gene therapy is among the top approaches to cure HIV infection and our results will help in the selection of optimal promoters for the expression of anti-viral RNAs.

THPEA009

Cell-based gene therapy to treat HIV-1/AIDS

E. Herrera-Carrillo, B. Berkhout
Academic Medical Center of the University of Amsterdam, Department of Medical Microbiology, Amsterdam, Netherlands

Background: HIV-1 drug therapies are effective at suppressing the viral load in patients to block disease progression, but drugs cannot eradicate HIV-1 from an infected individual and therefore have to be taken life-long. Because there is also no protective vaccine available, it remains important to develop more durable therapeutic approaches against HIV-1. A gene therapy to protect cells against HIV-1 would seem ideal as it requires only a single treatment. The gene therapy can be based on diverse methods for gene silencing (e.g. RNAi) or gene disruption (e.g. CRISPR-Cas) and we have tested such anti-HIV genes that act in a strictly sequence-specific manner. However, these antivirals do not block infection by the virus particle and do not prevent integration of the viral DNA genome into that of the host cell.
Methods: In order to realize an early block, we designed a gene therapy based on anti-HIV-1 peptides that block the membrane fusion process during virus infection. We evaluated the efficacy of three generations of anti-HIV peptides (C46, T1249 and T2635), which were produced by the engineered cells either as membrane-anchored or secreted protein.
Results: Both peptide forms exhibit robust and broad spectrum anti-HIV activity and the third generation peptide was more active than the first and second generations. Under HIV-1 pressure, the membrane-anchored peptides conferred a profound selective survival over control cells. The secreted peptides also demonstrated potent antiviral activity and were in addition able to protect non-modified bystander cells.
Conclusions: The anti-HIV-1 peptides block virus infection at the virus entry step. A small percentage of modified cells may suffice to stop virus replication and disease progression because the survival advantage is predicted to lead - over time - to a majority of HIV-resistant cells. Secreted peptides have the additional advantage of protecting bystander cells. In conclusion, anti-HIV-1 peptide-based gene therapeutics may provide a strong benefit to AIDS patients and could present an attractive alternative to current antiretroviral drug regimens.

HIV controllers (including post-treatment controllers) and long term non-progressors

THPEA010

HLA-B*57+ HIV controllers demonstrate an efficient antibody profile

Background: Current HIV vaccination strategies strive to induce anti-HIV antibodies (Abs), of which several types are of interest. Among them, neutralizing Abs are able to protect macaques against experimental infection but are difficult to induce by vaccination.
HIV Controllers (HICs; undetectable viral load without treatment) constitute an interesting cohort for Ab profiling. Indeed, the polyfunctional activities of IgG1s and IgG3s and the induction of anti-gp41 IgG2s were associated with HIV control and slower disease progression. Recently, HIV-Env-specific memory B cells frequency was found to correlate with neutralization breadth in HICs positive for the HLA-B*57 protective allele. This suggests that a specific Ab profile participating in the control of HIV might have been induced in HICs.
Methods: Our study aims to characterize Ab isotypes and their functional responses in the sera of 37 HICs (separated in HLA-B*57+ and HLA-B*57-), compared to 21 chronic progressors (evolving to disease). We analyzed isotype distribution in the different cohorts by ELISA and neutralization activities using TZM-bl neutralization assays. The correlation between anti-HIV Ab detection and functional activities was analyzed by a Spearman rank correlation.
Results: We found no differences between the induction of anti-HIV IgAs in HICs and chronic progressors. Chronic progressors induce more anti-HIV IgGs and anti-HIV-IgG2s while HICs induce higher proportions of anti-HIV IgG3s. Notably, HICs display neutralizing activities against several HIV strains including transmitted/founder viruses, despite low antigen detection. Remarkably, these neutralizing activities positively correlate with IgG subtype detection in HLA-B*57+ HIC subgroup, but not in HLA-B*57- HICs or chronic progressors.
Study of Ab function according to their isotypes is in progress.
Conclusions: These results demonstrate that HIC patients display an unexpected Ab isotype profile. Anti-HIV Ab detection is associated with neutralizing activity in HLA B*57+ HICs, suggesting that neutralization may contribute to HIV control in this patient subgroup. Conversely, the absence of correlation between Ab profile and neutralization in HLA B*57- HICs further suggests that additional Ab functions may be involved. An in-depth characterization of said Ab profile will guide the design of new immunogens for a future vaccine.

Founder viruses/transmission bottleneck

THPEA011

Envelope biological properties of early and late HIV-1 variants issued from a same transmission cluster

M. Beretta[1], A. Moreau[1], A. Essat[2], C. Goujard[2], M.-L. Chaix[3], L. Meyer[2], F. Barin[1], M. Braibant[1], on behalf of the ANRS 06 Primo Cohort
[1]*INSERM - U 966, Tours, France,* [2]*INSERM - U 1018, Paris, France,* [3]*INSERM - U 941, Paris, France*

Background: Recent studies suggested that during the sexual transmission of HIV-1, a single transmitted/founder (T/F) virus among the numerous viral variants present in the donor is transmitted most often. This results in a genetically restricted viral population at the beginning of infection. The aim of our study was to compare the biological properties of envelope glycoproteins of HIV-1 variants circulating during the early and late phase of infection within a transmission cluster. Our hypothesis was that, if transmitted variants have a selective advantage, envelopes of viruses found at the early stage of infection should share some biological properties.
Methods: A transmission cluster of 4 patients infected by subtype B viruses was included in the ANRS Primo cohort, with available early (< 3 months) and late (18/24 months after infection) plasma samples for each patient. We produced Env-pseudotyped viruses expressing the envelope glycoproteins representative of the viral population infecting each patient at the early (early viruses) and late (chronic viruses) stage of infection, and compared their sensitivity to a panel of broadly neutralizing antibodies (bNAbs) and entry inhibitors.
Results: We observed that early viruses of the 4 patients used exclusively the CCR5 coeceptor, whereas chronic viruses of 2 subjects were able to use the 2 co-receptors CCR5 and CXCR4. Early viruses were more sensitive than chronic viruses to bNAbs PGT121 and 10-1074 targeting the V3 region, as well as to the mini-CD4 M48U1. Conversely, they were more resistant to the fusion inhibitor T20. This observation may reflect a better ability of early viruses to fuse with their target cells. Interestingly, differences in sensitivity/resistance between early and late viruses were associated with identical envelope amino acids changes in all four patients.
Conclusions: The analysis of early and late variants of HIV-1 circulating within a transmission cluster allowed us to compare the evolution of closely related viral variants in 4 different patients. We observed that envelopes of early and late viruses of all 4 patients shared similar biological properties, associated with identical molecular features, suggesting a common viral evolution in the 4 patients.

THPEA012

Chronic binge alcohol consumption influences the establishment of founder virus populations in rhesus macaques mucosally-inoculated with SIV_{mac251}

S. Robichaux[1], N. Lacour[1], A.M. Amedee[2]
[1]*Louisiana State University Health Sciences Center, Microbiology, Immunology, & Parasitology, New Orleans, United States,* [2]*Louisiana State University Health Sciences Center, Microbiology, Immunology, & Parasitology, and Alcohol and Drug Abuse Center of Excellence, New Orleans, United States*

Background: Alcohol abuse is highly prevalent among HIV-infected and at-risk people, resulting in increased risk of HIV transmission and adverse effects on disease. Using SIV-infected rhesus macaques exposed to chronic binge alcohol (CBA), our studies have shown that CBA enhances susceptibility to rectal mucosal SIV challenge and increases set-point viremia. We hypothesized that CBA altered early virus:host interactions, affecting the establishment of transmitted/founder virus populations and their subsequent replication dynamics to impact disease progression.
Methods: To address our hypothesis, alcohol was delivered daily via gastric catheters to 13 male rhesus macaques beginning 3 months prior to SIV-inoculation. Peak blood alcohol levels of 50-60mM were obtained following administration, while sucrose was administered to 11 controls. Following rectal infection with SIVmac251, founder virus populations in animals were characterized using single genome amplification (SGA) of SIV-gp160 and compared to inoculum genotypes. To more thoroughly assess viral populations and monitor evolution, we utilized a novel next generation deep sequencing assay targeting envelope V1-V2. De novo cluster and principal coordinate tools in *Mothur*, were used to analyze and compare virus populations, with a mean of 7500 sequences from each animal. Viral RNA levels in plasma and lymph node cells were measured by qPCR.
Results: Within the SIV inoculum, 17 unique V1-V2 genotypes which clustered into three main genotypes (G1, G2, G3) were identified by SGA. Analysis of founder virus populations revealed that CBA animals expressed a more diverse founder virus population when compared to controls ($p < 0.001$), with a predominance of G1 and a significant reduction in G3 sequences observed in CBA animals. At 10 weeks SIV, we observed a small increase in viral diversity among control animals, while CBA animals showed a significant reduction in diversity ($p < 0.001$) and selection for G1 sequences. Concomitantly, CBA animals showed significantly higher levels of viral RNA in both plasma and lymph node cells ($p < 0.05$).
Conclusions: These observations suggest that CBA mitigates early innate host selective pressures to establish more diverse virus population in tissues of CBA animals. The establishment of genotypes that are expressed at higher levels plays an important role in accelerating disease progression in CBA animals.

Preclinical drug development, including prophylactic drug and microbicide development

THPEA013

Pharmacokinetics of VM1500A long acting injectable formulations for HIV-1 infections treatment and prevention after repeat-dose administration in dogs

A. Koryakova[1], R. Karapetyan[1], A. Khvat[2], B. Rogovoy[2], I. Nikoulin[3], S. Sankar[3], G. Yakatan[3], N. Trankova[2], I. Ivashchenko[2], K. Klumpp[4], N. Savchuk[2], V. Bichko[2]
[1]*Chemical Diversity Research Institute, Moscow, Russian Federation,* [2]*Viriom, Inc, San Diego, United States,* [3]*IriSys, LLC, San Diego, United States,* [4]*Riboscience, LLC, Sunnivale, CA, United States*

Background: VM1500A is a new, potent non-nucleoside HIV-1 reverse transcriptase inhibitor (NNRTI). Its orally-bioavailable prodrug, Elsulfavirine (Elpida®, VM1500), is currently marketed in Eastern Europe as an oral QD regimen for HIV/AIDS treatment. Unique pharmacokinetic properties ($T_{1/2}$ ~ 9 days) of VM1500A suggest a possibility for long-acting formulation development.
Methods: VM1500A was subjected to polymorph analysis *via* generation of corresponding amorphous forms and evaporative/low-temperature crystallization from 50 different solvents. Two aqueous nanosuspensions of VM1500A polymorph I with particle size distribution (PSD d90) of 306 or 411 nm were prepared by wet milling. Formulation safety and pharmacokinetics (PK) were studied in beagle dogs, following three once-monthly 10 mg/kg dose administration by intramuscular (IM) injection. Three animals were studied per formulation. Blood samples were collected frequently up to 72 h after administration and every week up to 3 months after last administration. VM1500A plasma concentrations were measured using LC-MS/MS.
Results: A total of twenty morphoforms of VM1500A were identified. Out of those, two (morphoforms I and X), were found to be stable. Morphoform I was selected for further studies. All studied formulations were well-tolerated, no adverse reactions were observed, including at the injection site. Dosing with 306 nm-formulation provided more stable drug plasma concentrations than dosing with that of 411 nm. Following three once-monthly 10 mg/kg IM injections of 306 nm VM1500A formulation, drug plasma levels were maintained above 40 ng/ml for at least for 4 month. These levels exceeded the clinically-efficacious VM1500A plasma concentrations.
Conclusions: This study supports further development of VM1500A long-acting injectable formulations to enable infrequent dosing.

THPEA014

Membrane cholesterol maintains structural stability of the HIV-1 envelope glycoproteins and their resistance to antibody neutralization

J. Johnson, H. Salimi, M. Flores, H. Haim
University of Iowa, Iowa City, United States

Background: Diverse strains of HIV-1 differ in their sensitivity to neutralization by patient sera. Tier-1 isolates and lab adapted strains are globally sensitive whereas Tier-2 and Tier-3 isolates are more resistant. We have recently shown that global sensitivity to antibody neutralization is associated with structural stability of the Env trimer. Multiple interactions in the ectodomain of Env control its resistance to structure-perturbing treatments. We hypothesized that interactions between Env and the lipid membrane may also affect stability of Env. Specifically, we examined the effects of membrane cholesterol on Env structure, function and neutralization sensitivity.
Methods: Diverse Tier-2-like strains of HIV-1 were treated with the cholesterol-depleting agent methyl beta cyclodextrin. To quantify changes in Env conformation we measured the effect of cholesterol depletion on binding of monoclonal antibodies to virus particles using a luminescence-based assay. We also examined the effects of cholesterol depletion on virus sensitivity to structure-perturbing treatments, including exposure to 0°C and antibodies.
Results: Depletion of cholesterol from viruses enhances exposure of multiple partially-cryptic epitopes, including the coreceptor-binding site (CoR-BS) and membrane-proximal ectodomain region (MPER) of gp41. Conformational effects were isolate-specific and corresponded well with measured changes in virus infectivity. Structurally-unstable Env variants that assume a CD4-bound conformation were highly sensitive to depletion of cholesterol. Similarly, cholesterol depletion acted in synergy with cold, which also induces an "open" form of the trimer, to effectively inactivate the virus. Importantly, we found that mild depletion of cholesterol from viruses enhanced their sensitivity to neutralization by antibodies that target the CoR-BS, V3 loop of gp120 and MPER at concentrations that are otherwise non-inhibitory.
Conclusions: Resistance of Tier-2 HIV-1 isolates to antibody neutralization is associated with stability of the Env trimer. Depletion of cholesterol from Tier-2-like viruses destabilizes the trimer and sensitizes the virus to host antibodies. This destabilization-based approach can be combined with microbicides or vaccine strategies to reduce mucosal transmission of HIV-1.

THPEA015

Release and safety profile of drug loaded innovative bioadhesive vaginal microbicide gels to prevent HIV and HSV infections

G. Shankar
SRI International, Pharmaceutical Sciences, Menlo Park, United States

Background: Epidemiological studies have demonstrated that there is a strong synergy between HSV and HIV; HSV infection also increases the risk of HIV acquisition. A combination of antiretroviral tenofovir along with antiherpetic acyclovir for vaginal mucosal delivery is an attractive prophylaxis. Further a bioadhesive gel requiring fewer applications can increase the adherence of microbicide; and help in prevention of both HIV and HSV.
Methods: Drug loaded polymeric gel formulations were characterized for pH, osmolality, viscosity and mucoadhesion to porcine vaginal mucosal tissue. The release profile study of drugs from the gels were carried out using porcine vaginal mucosa. In the current study we have also screened for vaginal toxicity of drug loaded gel after intravaginal administration in mice and compared with Nonoxynol-9 (N9) gel, a positive control agent for tissue toxicity and safety.
Results: The pH and osmolality of drug-loaded vaginal gel was found to be 4.82 ± 0.011 and 55 ± 5.3 mOsm/kg respectively. Ideally, it is recommended that the osmolality of a personal lubricant not exceed 380 mOsm/kg in order to minimize any risk of epithelial damage. Mucoadhesive strength of the drug-loaded vaginal gel measured by texture analyzer using porcine tissue with and without mucin disc was found to be 561.4 ± 56.43 dynes/cm² and 368.09 ± 50.80 dyne/cm² respectively. In-vitro drug release in phosphate buffered saline of pH 7 resulted in about 5.0 ± 1.18% (53.36 ± 12.67 µg) of tenofovir and 0.5 ± 0.14% (23.54 ± 6.88 µg) of acyclovir released in 6 h from a 100 µl of drug-loaded vaginal gel. Further about 3.33 ± 1.19% (35.67± 12.76 µg) of tenofovir and 2.01± 1.35% (95.53± 64.21 µg) of acyclovir was retained in the porcine vaginal mucosa after 24 h of release study. From our biomarker analysis of both vaginal brush and tissue samples, we have determined that drug loaded SR-2P gel demonstrates a significantly improved toxicity profile compared to N9 gel when administered intravaginally.
Conclusions: We conclude that this gel prototype is well tolerated and is capable of delivering both acyclovir and tenofovir in vaginal tissues at levels that could provide protection against both HSV and HIV infection.

Immunotherapy (including broadly neutralizing antibodies)

THPEA016

Bovine monoclonal antibodies with human CDRH3 size neutralize heterologous HIV viruses

B. Heydarchi[1], N. Salazar Quiroz[1], C. Mackenzie[1], C. Gonelli[1], M. van Gils[2], R. Sanders[2], D. Purcell[3]
[1]*University of Melbourne at Peter Doherty Institute, Melbourne, Australia,* [2]*University of Amsterdam, Academic Medical Center, Amsterdam, Netherlands,* [3]*University of Melbourne at Peter Doherty Institute, Microbiology and Immunology, Melbourne, Australia*

Background: Cloned immunoglobulin (Ig) genes from HIV-1 infected patients with elite antibody responses yield potent and broad HIV neutralizing antibodies (bnAb) with unusually long and highly mutated CDRH3 domains. Passive infusions with these bnAb give sterilising protection against lentiviral infection in animal transmission models. A vaccinated cow with HIV Env-gp140 produced antibodies that neutralised 90% of 27 Env-pseudotyped reporter viruses including Env from clade A, B and C reference panels. The antibodies from this cow inhibited human broadly neutralizing antibody VRC01 and PGT121 binding to CD4bs epitope.
Methods: In this study, we used HIV Env antigen scaffold and trimer proteins to isolate anti-HIV memory B cells. The Cells were FACS sorted and variable heavy (VH) and light (VL) genes were amplified and cloned into human constant region expression vector. The antibodies were expressed and characterised for envelope binding and neutralisation activity.
Results: In total, 52 monoclonal antibodies were isolated belonging to 4 main clonal families. The antibodies in each clonal family had the same VH but different VL genes. The antibodies had VH size of between 121 a.a (CDRH3: 13 a.a) and 134 a.a (CDRH3: 26 a.a). Out of all expressed antibodies, nine monoclonal antibodies were selected for further characterisation. Five antibodies were able to bind RSC3 but not RSC3 Δ373I/P363N but only one of these antibodies (124b) with a short CDRH3 (13 a.a) could neutralise AD8 pseudovirus specifically. This antibody also showed heterologous neutralization against tier 1 pseudoviruses (MN and SF162), so far. The antibody was specific for CD4bs of HIV Env protein.
Conclusions: Though it is shown in a previous study that an Env immunogen with a native-like structure (SOSIP) is more efficient in eliciting heterologous neutralising antibodies than other forms of Env, we showed that cows vaccinated with AD8 soluble gp140 were alsoable to elicit neutralising antibodies. Interestingly, we also showed that bovine antibodies with even a human-sized short CDRH3 could neutralise different HIV viruses.

THPEA017

IL-7 as an adjuvant for mucosal vaccine development

M. Rancez[1], S. Logerot[1], S. Figueiredo[1], B. Charmeteau-de-Muylder[1], I. Bourgault-Villada[1], A. Couëdel-Courteille[2], R. Cheynier[1]
[1]Institut Cochin - INSERM U 1016 - CNRS UMR 8104 - Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [2]Institut Cochin - INSERM U 1016 - CNRS UMR 8104 - Université Paris Descartes, Sorbonne Paris Cité - Université Paris Diderot, Paris, France

Background: Despite considerable research efforts, mucosal immunity remains particularly difficult to stimulate through vaccines. Systemic injection of IL-7 stimulates chemokines-induced recruitment of circulating T-cells into mucosae.
Methods: The optimal dose of IL-7 to be sprayed on mucosal surface was defined on 14 rhesus macaques. On mucosal biopsies collected after IL-7 administration, we quantified local transcription of 19 chemokines by qRT-PCR and cell infiltration by immunochemistry plus image analysis. Six macaques were immunized with antigens (DT and the HIV-1 gp41-P1 peptide) applied directly on the vaginal mucosa, two days after either IL-7 or PBS administration. The immunizations were repeated thrice, four months apart, and the macaques were euthanized 2 weeks after the last immunization. Antigen-specific IgA and IgG productions were quantified in vaginal secretions by ELISA. Antigen-specific plasma cells were detected by reverse immunohistochemistry in tissue, and by B-cell ELISPOT in PBMCs.
Results: A significant overexpression of twelve chemokines was observed 48 hours after mucosal administration of 10µg of IL-7. Subsequently, mDC, macrophage, NK, B- and T-cell numbers significantly raised in the IL-7-treated mucosae, suggesting massive chemokine-driven infiltration. Administration of antigens led to a stronger mucosal immune response in the IL-7-treated macaques as compared to animals immunized with antigens alone. Robust production of antigen-specific IgAs and IgGs was detected in vaginal secretions. The immunizations repeated thrice sustained mucosal specific immune responses. Antigen-specific-antibody secreting cells were recovered from PBMC and more DT-specific plasma cells were found in the vaginal mucosae (IgA isotype) and the draining lymph nodes (IgG isotype) of IL-7-treated macaques. Tertiary lymphoid organs were observed in vaginal mucosae from IL-7-treated macaques only.
Conclusions: Pre-treatment by non-traumatic vaginal administration of IL-7 (10µg by spray), allows for the development of a strong mucosal immune response in macaques following subsequent mucosal vaccination, through local chemokine expression and the recruitment of immune cells in the vaginal mucosa. The mucosal localization of IgA-specific plasma cells argues for their main contribution in the high levels of specific-IgAs evidenced in the vaginal secretions. These data suggest that IL-7 could be used as a mucosal adjuvant to elicit vaginal antibody response, the most promising way to confer protection to numerous STD.

Novel vectors and strategies

THPEA018

A novel vaccine platform using Env-incorporated particles for induction of broader anti-HIV antibody responses

H. Ishii[1], M. Nakamura-Hoshi[1,2], M. Inoue[3], T. Hironaka[3], T. Shu[3], T. Matano[1,2]
[1]National Institute of Infectious Diseases, AIDS Research Center, Tokyo, Japan, [2]University of Tokyo, Institute of Medical Science, Tokyo, Japan, [3]ID Pharma CO., Ltd., Ibaraki, Japan

Background: Efficient antibody induction is a principal strategy for the development of effective vaccines toward global HIV-1 control. Virus particles carrying Env trimers may be a promising immunogen for effective anti-HIV antibody induction, but inactivated HIV virions that carry only 10-20 molecules of Env trimers are not good for immunogen. In the present study, we developed novel vaccine using Sendai virus (SeV)-based particles carrying Env trimer antigen for efficient anti-Env antibody induction.
Methods: We designed a novel chimeric HIV Env antigen, HIV EnvF, consisting of the extracellular region (gp140) of HIV Env and the transmembrane/cytoplasmic tail region of SeV F. By using HIV BG505 (Clade A) and AD8-EO (Clade B) strains, we obtained BG505 EnvF and AD8EO EnvF, respectively. We constructed F-deleted SeV vector expressing EnvF (SeV-EnvF) and non-infectious SeV particles carrying EnvF (NVP-EnvF). BALB/c mice received the first vaccination with SeV-BG505 EnvF, the second with NVP-BG505 EnvF, and the third with NVP-BG505 EnvF or NVP-AD8EO EnvF. Anti-HIV-1 Env gp120 antibodies in plasma after vaccination were examined by ELISA using BG505 and BaL (Clade B) gp120 antigens.
Results: EnvF was shown to form trimers and be efficiently incorporated into SeV-based particles.
Anti-BG505 gp120 antibody responses were efficiently induced after the first vaccination with SeV-BG505 EnvF and boosted after the second with NVP-BG505 EnvF in mice. Comparison of two groups receiving NVP-BG505 EnvF and NVP-AD8EO EnvF at the third vaccination indicated more efficient induction of antibodies specific to Clade B (BaL) gp120 than those specific to Clade A (BG505) gp120 by NVP-AD8EO EnvF immunization, implying the multiple immunization with NVP-EnvFs derived from varieties of HIV strains to induce broader antibody responses.
Conclusions: Our vaccine system may provide a novel vaccine platform using Env-incorporated particles for induction of broader anti-HIV antibody responses.

Antibodies

THPEA019

HIV-1 lineage envelope proteins based on viral sequences from elite neutralizers

A. Schorcht[1], T. van den Kerkhof[1], T. Rijkhold Meesters[1], G. Ozorowski[2], J. Burger[1], E. Schermer[1], S. de Taeye[1], A. Torrents de la Peña[1], J. Torres[2], C. Cottrell[2], A. Yasmeen[3], A.-J. Behrens[4], P.J. Klasse[3], M. Crispin[4], A. Ward[2], J. Moore[3], M. van Gils[1], R. Sanders[1,3]
[1]Academic Medical Center Amsterdam, Amsterdam, Netherlands, [2]The Scripps Research Institute, La Jolla, United States, [3]Weill Medical College of Cornell University, New York, United States, [4]University of Oxford, Oxford, United Kingdom

Background: Cleaved, native-like Env trimers can induce autologous Tier 2 neutralizing antibody responses in animals. The challenge now is to broaden these responses to target heterologous Tier 2 isolates by inducing broadly neutralizing antibodies (bNAbs). The evolving envelope trimers in individuals that are naturally infected with HIV and that develop bNAbs can be taken as blueprints for vaccine design.
Methods: We generated recombinant envelope trimers based on early viral sequences from two elite neutralizers participating in the Amsterdam Cohort Studies on HIV/AIDS and infected with subtype B viruses, termed AMC009 and AMC011. The introduction of SOSIP and additional stabilizing mutations allowed for the generation of stable native-like trimers with desirable antigenic properties.
Results: Rabbits immunized with AMC011 trimer or a trivalent cocktail of Env trimers developed autologous as well as sporadic heterologous Tier 2 neutralizing antibody responses. Heterologous neutralization could be depleted by the corresponding Env trimers, proving that the neutralization stemmed from trimer-directed antibodies. We also generated recombinant trimers based on viral sequences from subsequent time points to generate lineage immunogens.
Analysis of the AMC009 lineage proteins suggests viral escape from multiple antibody specificities, whereas the AMC011 lineage was under pressure from the recently isolated bNAb ACS202 targeting the gp120-gp41 interface including the fusion peptide.
Conclusions: Lineage immunogens based on the evolving Env sequences in elite neutralizers might be attractive vaccine candidates.

THPEA020

Characterization of serum- and colostrum-derived antibodies in dairy cows vaccinated with HIV-1 gp140 envelope proteins

N. Salazar-Quiroz[1], B. Heydarchi[1], J. Edwards[2], C. Mackenzie[1], M. van Gils[3], R. Sanders[3], D. Macinnes[4], B. Muller[4], B. Wales[5], C. Gonelli[1], G. Khoury[1], D.F.J. Purcell[1]
[1]The Peter Doherty Institute for Infection and Immunity / The University of Melbourne, Microbiology and Immunology, Melbourne, Australia, [2]The University of Melbourne, Microbiology and Immunology, Melbourne, Australia, [3]University of Amsterdam, Academic Medical Center, Amsterdam, Netherlands, [4]Reef Pharmaceuticals, Victoria, Australia, [5]Department of Agriculture, Melbourne, Australia

Background: Dairy cows can produce antibodies with neutralizing activity against heterologous tier 2 viruses from different clades. Previously we have shown that these antibodies have high affinity for clade B envelope proteins and compete with the monoclonal antibodies b12 and VRC01, indicating they target CD4 binding site (CD4bs), a feature of neutralizing antibodies. We assessed the reproducibility of these high quality vaccine responses in a larger number of cows, and tested whether other Env gp140 trimer immunogens could increase the breadth or potency of the bovine antibodies.
Methods: 32 cows were vaccinated with recombinant HIV-1 gp140 envelope uncleaved trimers (clade B AD8, clade B PSC89, clade C MW) and clade A KNH1-SOSIP cleaved trimer. A first dose was given several weeks before conception, followed by 3 boosts during pregnancy in a period of 52 weeks. Sera and colostral milk were collected from each cow and their immune response was evaluated for gp140 binding breadth, binding site analysis, neutralizing activity and antibody-dependent immunity.
Results: The fully glycosylated chronic B-clade AD8 Env gp140 elicited the highest binding potency and breadth against different envelope proteins. These cows generated antibodies that compete with neutralizing antibodies such as VRC01, B12 (CDbs-specific) and PGT121 (V3 glycan), and display neutralizing activity against a panel of HIV-1 pseudoviruses. Moreover, a boost with the modified Env BG505 SOSIP gp140 enhanced the neutralizing activity of bovine serum, while the same modification in the AD8 protein (AD8 SOSIP gp140) only increased binding breadth. Finally, the Fc portion of these bovine antibodies bind to the cellular receptor FcgRIIa, allotype R131 and interact with different cell types.
Conclusions: The vaccine formulated with AD8 gp140 generated antibodies with the highes titre and affinity and broadest binding for envelope proteins of different clades. The neutralizing activity correlates with the presence of antibodies that bind to CD4bs and V3-glycan neutralizing epitopes. Binding to FcgRIIa associates with the generation of antibody-dependent cellular phagocytosis (ADCP). All these features are applicable to produce a topic microbicide that can be used when other preventive treatments, such as PREP drugs, are less effective in preventing HIV transmission.

THPEA021

Similar antibody responses elicited in BG505 SHIV infected and BG505 SOSIP trimer immunized non-human primates

J. van Schooten[1], M. van Haaren[1], C. Cottrell[2], D. Sok[2], G. Shaw[3], D. Burton[2], A. Ward[2], R. Sanders[1], M. van Gils[1]
[1]Academic Medical Center (AMC), Medical Microbiology, Amsterdam, Netherlands, [2]The Scripps Research Institute, San Diego, United States, [3]Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States

Background: The human immunodeficiency virus (HIV) remains a global health threat and the development of an effective vaccine is highly desirable to eradicate the HIV/AIDS pandemic completely. The major focus of HIV vaccine development is to induce potent immunity that protect against infection. However, vaccines against HIV have not yet been able to induce such protective immune responses. Broadly neutralizing antibodies isolated from HIV-1 infected individuals have revealed that the human immune system is capable of eliciting responses that can protect against infection. Recently, soluble native-like HIV envelope glycoproteins (BG505 SOSIP.664 trimers) were developed, which induced neutralizing serum responses against the homologous virus in both macaques and rabbits. However, it is still unclear if these native-like trimers are capable of eliciting similar responses compared to natural infection.
Methods: Non-human primates (NHP) were immunized with BG505 SOSIP.v.5 trimers or infected with the homologous BG505 SHIV. Immunogen-specific IgG+ B cells from 2 BG505 SOSIP immunized and 4 BG505 SHIV infected NHP were single cell sorted to obtain monoclonal antibodies (mAbs). These antibodies were further characterized for their binding and neutralization characteristics using Enzyme-Linked Immuno Sorbent Assay (ELISA), Negative Stain Electron Microscopy and neutralization assays. The viral population from the BG505 SHIV infected NHP were sequenced over time as well.
Results: We were able to isolate over 50 mAbs with a diverse set of characteristics from 5 of the 6 NHP. Both neutralizing and non-neutralizing mAbs were isolated with distinct epitopes such as the fusion peptide and strain-specific glycan holes. mAbs elicited by the BG505 SOSIP trimer showed similar characteristics compared to the mAbs from the BG505 SHIV infected NHP, however mAbs from the SHIV infected NHP showed more neutralization and no mAbs that target the base of the trimer.
Conclusions: The results suggest that immunizing with the BG505 SOSIP trimer mimics infection correctly, however the BG505 trimers also elicit non-neutralizing mAbs to the base of the trimer in addition to neutralizing mAbs to more relevant epitopes, such as the fusion peptide. The knowledge obtained in this study will help design immunization strategies to broaden the response after vaccination.

THPEA022

Monoclonal antibodies from vaccinated rabbits reveal an immunodominant epitope at the gp41 subunit of soluble HIV-1 envelope trimers

M.M. van Haaren[1], C. Cottrell[2], L.E. McCoy[2], P. Van der woude[1], A. Yasmeen[3], S. de Taeye[1], A. Torrents de la Pena[1], P.J. Klasse[3], D.R. Burton[3], A.B. Ward[2], R.W. Sanders[1], M.J. van Gils[1]
[1]AMC, Amsterdam, Netherlands, [2]The Scripps Research Institute, San Diego, United States, [3]Weill Medical College of Cornell University, New York, United States

Background: To overcome HIV-1 viral diversity a vaccine needs to induce broadly neutralizing antibodies (bNAbs). Although bNAbs can be found during natural infection, they are generally not elicited by vaccination. Characterizing the immune responses elicited by soluble antigenic mimics of the surface expressed Envelope (Env) trimer will provide a better understanding which epitopes are targeted and why there is limited breadth.
Methods: Monoclonal antibodies (mAbs) were isolated from four AMC008 SOSIP.v4.2 protein immunized rabbits. AMC008 SOSIP.v4.2 is a subtype B based, stabilized, soluble Env trimer. mAb were isolated by single-cell sorting of B cells and subsequent amplification and cloning of the heavy and light chain variable regions of the expressed antibody. mAb characteristics were determined by neutralization assay, ELISA, and negative stain-electron microscopy (NS-EM).
Results: We isolated 21 HIV-specific mAbs, of which 16 bound heterologous Env trimers. Four mAbs from two rabbits showed homologous neutralization and cross-neutralization of another subtype B virus. Three of these mAbs were clonal family members. Varying ELISAs revealed that the four mAbs targeted the same epitope on the gp41 subunit of the Env trimer.
Deeper analysis by NS-EM indicated an upward angle of approach for the clonal family members as well as binding near a strain specific glycan hole. Interestingly, mutant and competition ELISAs showed that several non-neutralizing mAbs isolated from the same rabbits target the gp41 subunit in a comparable fashion, although with slightly different approach angles and glycan dependencies.
This region might be less accessible on viruses with all glycans in place, explaining the lack of cross-neutralization. In addition, the Fc part of mAbs with such approach angles is expected to clash with the viral membrane. However, these mAbs show neutralizing capacity suggesting that Env trimers on the viral surface have remarkable flexibility.

Conclusions: Thus, AMC008 SOSIP.4.2 Env trimer immunization induced NAbs and non-NAbs targeting the gp41 subunit of the Env trimer. Viral variability of this region and the suboptimal angle of approach, provide an insight in the lack of neutralization breadth and will guide future immunogen design.

Correlates of immune protection

THPEA023

DNA+protein co-immunization regimens combined with TLR-4 based adjuvants induce immune responses controlling infection of tier 1 SIV_{smE660}

S. Singh[1], E. Ramirez[1], R. Doueiri[1], A. Valentin[1], M. Rosati[1], F. Dayton[1], J. Bear[1], X. Hu[1], B. Chowdhury[1], C. Alicea[1], B. Keele[2], S. Shen[3], G. Tomaras[3], G. Ferrari[3], C. Pavlakis[1], B.K. Felber[1]
[1]National Cancer Institute at Frederick, Frederick, United States, [2]AIDS and Cancer Virus Program, Leidos Biomedical Research, Inc., FNLCR, Frederick, United States, [3]Duke Human Vaccine Institute, Durhum, United States, [4]Ragon Institute of MGH, MIT and Harvard University, Cambridge, United States, [5]US Military HIV Research Program, Walter Reed Institute of Research, Silver Spring, United States, [6]Inovio Pharmaceuticals, Inc., Plymouth Meeting, United States, [7]Infectious Disease Research Institute, Seattle, United States, [8]Biostatistics and Data Management Section, CCR, NCI, Rockville, United States, [9]Laboratory of Molecular Microbiology, NIAID, Bethesda, United States

Background: We developed a method of simultaneous vaccination with DNA and protein resulting in high and durable cellular and humoral immune responses with efficient dissemination to mucosal sites and protection against SIV infection in macaques. To further optimize vaccine-induced immunity and efficacy of the DNA+protein co-immunization vaccine regimen, a SIV_{mac251} based vaccine was tested using two TLR-4-based liposomal formulations as adjuvants (TLR-4+TLR-7 or TLR-4+QS21) in macaques.
Methods: Macaques were vaccinated with DNA plasmids expressing SIV_{mac251} derived mac239 and M766 env gp120 and membrane-bound gp120, SIV gag and macaque IL-12, administered by in vivo electroporation. The DNA vaccine was co-administered into the same muscle with HEK293-produced soluble monomeric SIV M766 gp120 Env protein, adjuvanted with liposomal formulations of a combination of TLR-4 and TLR-7 agonists or with a combination of TLR-4 agonist and QS21. The animals received 3 vaccinations (0, 2, 6 months) and were challenge 5 months later with heterologous SIV_{smE660} via the rectal mucosal route.
Results: The vaccines induced similar robust levels of immune responses to vaccine-matched SIV_{mac251} and heterologous SIV_{smE660}, including responses recognizing V2. Upon heterologous SIV_{smE660} challenge, a trend of delayed viral acquisition was found in the vaccinees, which reached statistical significance in animals with the TRIM-5a resistant genotype. Vaccinees were preferentially infected by SIV_{smE660} transmitted founder T/F virus carrying the neutralization resistant A/K mutation, demonstrating a strong vaccine-induced sieve effect. Delay in virus acquisition was directly correlated with SIV_{smE660}-specific systemic neutralizing antibody to the neutralization-sensitive virus, mucosal gp70-V1V2 binding antibodies. These data support contributions of immune responses and genetic make-up to protection efficacy. Reduction of viremia inversely correlated with humoral responses targeting V2 (cyclic V2, gp70-scaffolded V1V2) and with SIV-specific cellular responses. Although both DNA+protein vaccine groups show delay of virus acquisition, the TLR4+7 adjuvanted vaccine induced stronger protective responses (lower number of T/F; SIV_{smE660}-specific bAb and NAb, association with ADCP effector function and Env glycosylation structure G2S2FB; lower peak and chronic viremia).
Conclusions: Combination of DNA and gp120 Env protein vaccine regimens using two different protein adjuvants induced high, durable and potent cellular and humoral responses contributing to controlling heterologous challenge.

Co-infection: TB and other mycobacteria

THPEA024

Factors associated with the occurrence of deaths in patients co-infected with HIV and TB at the three health districts of Casamance (Senegal)

K. Diallo[1], N.M. Manga[2], A. Diatta[3]
[1]Hopital de la Paix de Ziguinchor, Infectious Diseases, Ziguichor, Senegal, [2]Assane Seck University of Ziguinchor, Infectious Diseases, Ziguinchor, Senegal, [3]Assane Seck University, Pneumology, Ziguinchor, Senegal

Background: HIV infection remains the leading cause of increased incidence of tuberculosis. We performed this work to describe socio-demographic characteristics and identify factors associated with death in patients coinfected with TB and HIV.
Methods: This was a descriptive and analytical retrospective cohort study. It concerned all HIV-infected patients with all forms of tuberculosis confirmed by bacteriology and / or the Xpert-MTB / Rif test and who were included and monitored at the services of the health districts of Bignona, Ziguinchor and Oussouye from 1 January 2014 to 31 December 2016.
Results: A total of 126 cases were collected during the study period. The mean age of patients was 41.77 ± 12.16 years with extremes ranging from 19 to 87 years. Females were predominant (53.1%) with a sex ratio of x, x. Clinically, 88% (n =.) Of patients were in severe immunosuppression (CD4 < 200 / mm3). The isolated lung form accounted for 91.26% (n = 115) followed by the multifocal 4.8% (n = 6) and the extra-pulmonary form 4.0% (n = 5). The mean CD4 + T cell count was 262 ± 243 / mm3 with extremes of 2 to 989 / mm3. Twenty-three percent (23%) of the patients had severe immunosuppression (CD4 < 200 / mm3). All patients had received antituberculous treatment and 96% of them had started ARV treatment. The overall cure rate was 74.34%. In multivariate analysis with binomial regression, four (4) factors were significantly associated with the occurrence of death: WHO clinical stage 3 and 4 at baseline (OR = 3.12, 95% CI: 1.44 at 6.76), late delay> 3 weeks of ARV treatment after the start of antituberculous treatment (OR = 3.12, 95% CI: 1.44 to 6.76), male sex (OR = 3) , 59, 95% CI: 1.100 to 11.735).
Conclusions: This study has shown that the high case-fatality rate in co-infected patients, when the discovery of HIV infection is late (WHO stage III and IV) and / or when the ARV treatment delay is greater than 3 weeks. It is therefore necessary to strengthen HIV testing of TB patients and to provide early treatment for HIV infection.

Co-infection: Viral hepatitis

THPEA025

HIV and hepatitis B virus (HBV) co-infection leads to an increase in intracellular hepatitis B surface antigen and HBV DNA in hepatocytes: A potential mechanism for adverse liver outcomes

W. Zhao[1], K. Singh[2,3], V. Sozzi[4], P. Revill[4], S. Lewin[1,3]
[1]The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [2]The Peter Doherty Institute for Infection and Immunity at Royal Melbourne Hospital, Victorian Infectious Diseases Service, Melbourne, Australia, [3]Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia, [4]The Peter Doherty Institute for Infection and Immunity, Victorian Infectious Diseases Reference Laboratory, Melbourne, Australia

Background: HIV infection significantly alters the natural history of chronic hepatitis B (HBV). Compared to HBV mono-infection, HIV-HBV infected individuals experience accelerated progression of liver disease and increased liver-related mortality. HBV-active antiretroviral therapy (ART) including tenofovir has improved rates of virological control, however liver related mortality and morbidity remains increased.

We hypothesized that direct interactions between HIV and HBV in the hepatocyte, in the presence and absence of HBV-active ART, drives adverse liver outcomes.
Methods: The hepatocyte cell lines HepG2.2.15 and AD38 (expressing HBV) or HepG2 cells (not expressing HBV) were infected with laboratory strains of wild-type (WT) HIV (NL4-3) or vesicular stomatitis virus (VSV)-pseudotyped HIV expressing enhanced green fluorescent protein (EGFP). Sodium taurocholate co-transporting polypeptide (NTCP)-expressing HepG2 cells were infected with HBV inoculum derived from AD38 and subsequently with HIV. EGFP expression was quantified by flow cytometry; integrated HIV DNA and mRNA level of HBV-related transcription factors by qPCR; intracellular HBsAg by western blotting; and HBV DNA by southern blotting. Comparisons between conditions were made using a student t-test.
Results: VSV-pseudotyped HIV infection of hepatocytes resulted in 70% of cells expressing EGFP after 4 days. The administration of raltegravir and efavirenz prior to infection led to a reduction and elimination of EGFP expression respectively. Both drugs results in elimination of integrated DNA. No EGFP expression was observed following infection of hepatocytes with WT. VSV-pseudotyped HIV infection resulted in a significant increase in intracellular HBsAg, HBs RNA and HBV DNA.
Conclusions: HIV-HBV co-infection of hepatocytes significantly increased intracellular HBsAg, HBs RNA and HBV DNA. Therefore, these adverse effects on HBV replication may contribute to accelerated liver disease in individuals with HIV-HBV co-infection.

Novel assays of immune responses

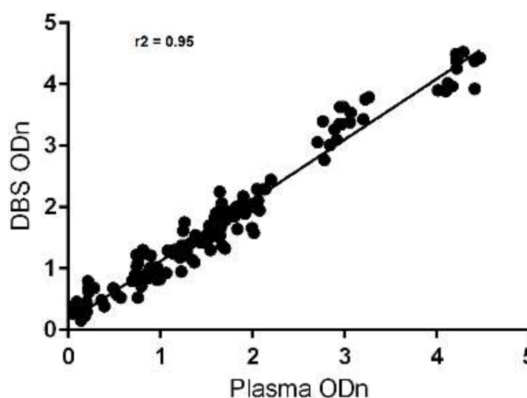
THPEA026

Could DBS specimens reduce overestimation of HIV incidence using BED CEIA assay?

H. Syed Iqbal[1], M. Selvakumar[1], P. Nandagopal[1], S.S. Solomon[1,2], P. Balakrishnan[1]
[1]YRG CARE, Infectious Diseases Laboratory, Chennai, India, [2]Johns Hopkins University, Baltimore, United States

Background: The established algorithm for HIV incidence estimation is screening HIV positive specimens with BED™ CEIA assay followed by Avidity assay. The 'Aware™ BED™ CEIA HIV-1 incidence test (IgG-Capture HIV-EIA)' is reported to overestimate HIV incidence. Also shipping to developing countries, logistic issues and cold-chain maintenance of plasma specimens from remote areas is major disadvantage. The efficacy of dried blood spots (DBS) must be studied, which can serve as better alternative for plasma specimens. Use of DBS provides minimally invasive specimen collection and simple processing steps when compared to plasma specimens. In this study, we compared matched plasma and DBS specimens on BED™ CEIA assay and the results were confirmed with modified BioRad GS HIV-1/2 Plus O Avidity based Assay.
Methods: Parallel DBS and plasma specimens were collected from 152 HIV infected injecting drug users across 7 different sites from north India. Both these plasma and DBS specimens were run on BED™ CEIA. Quantitative values (i.e) normalized optical density (Specimen/Calibrator = OD-n) obtained from plasma and DBS specimens in BED™ CEIA assay were compared to derive r^2 values and mean difference. The categorical results between plasma and DBS were compared to derive Cohen's kappa co-efficient (). Apart from this, specimens with discrepant results between plasma and DBS were run on BioRad Avidity assay using plasma specimens.
Results: The co-efficient of determination (r^2) (Figure 1) and mean difference for quantitative OD-n values between plasma and DBS specimens was 0.95 and -0.11, respectively. A higher OD-n values were obtained from DBS specimens compared to plasma specimens. The Cohen's kappa co-efficient () value derived between plasma BED and DBS BED was 0.9. Six specimens are classified recent using plasma specimens were marked long term (LT) in DBS specimens. These results were confirmed to be LT in BioRad Avidity assay.

Conclusions: Plasma and DBS specimen OD-n values were highly correlated, However, plasma specimens were found to be overestimating HIV incidence than DBS specimens using BED™ CEIA assay. The DBS specimens could be a better alternative method for estimating HIV incidence in resource-limited settings. Added advantage with the DBS specimen is sample collection procedure with finger prick.



[Correlation graph obtained from results of matched plasma and DBS specimens tested with BED-CEIA assay]

THPEA027

The clinical performance and diagnostic accuracy of an instrument-free low-cost point-of-care CD4 test (VISITECT® CD4) as performed by nurses, counsellors and laboratory staff among pregnant women in South Africa

S. Luchters[1,2,3], K. Technau[4], Y. Mohamed[1,3], M.F. Chersich[2,5], S. Khan[4], P.A. Agius[1,3], M.D. Pham[1], M.L. Garcia[1], J. Forbes[6], A. Shepherd[6], B.A. Haile[1], A. Coovadia[4], S.M. Crowe[1,7], D.A. Anderson[1]
[1]Burnet Institute, Melbourne, Australia, [2]Ghent University, International Centre for Reproductive Health, Department of Obstetrics and Gynaecology, Ghent, Belgium, [3]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia, [4]University of the Witwatersrand, Empilweni Services and Research Unit, Department of Paediatrics & Child Health, Rahima Moosa Mother and Child Hospital, Faculty of Health Sciences, Johannesburg, South Africa, [5]University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Faculty of Health Sciences, Johannesburg, South Africa, [6]Omega Diagnostics, Alva, United Kingdom, [7]Monash University, The Alfred Hospital and Department of Infectious Diseases, Melbourne, Australia

Background: CD4 testing continues to be important for triaging care after an HIV diagnosis and during treatment. The VISITECT® CD4 is the first-ever instrument-free low-cost point-of-care CD4 test. The test is semi-quantitative, providing a result of above or below 350 CD4+ve Tcells/mm^3. Results are interpreted visually after 40 minutes by comparing the intensity of the test line with the reference line.
Methods: We assessed the clinical performance and diagnostic accuracy of the VISITECT CD4® test among HIV-infected pregnant women in South Africa. Nurses performed testing at the point-of-care using both venous and finger-prick blood, and counsellors and laboratory staff tested venous blood in the clinic laboratory (four tests/participant). Staff attended three days training. Performance was compared to mean CD4 count from duplicate CD4 flow cytometry tests (FACSCalibur Trucount).
Results: At Rahima Moosa Mother and Child Hospital, 156 patients were enrolled between March and June 2017, providing a total of 624 VISITECT® CD4 tests (468 venous and 156 finger-prick). Of 624 tests, 28 (4.5%) were inconclusive (eight invalid results and 20 incorrectly performed). A Generalised Linear Mixed Model performed on 539 valid reference results and VISITECT® CD4 results showed a better diagnostic performance of the VISITECT® CD4 on venous blood (sensitivity=81.7%, 95%CI=72.3-91.1; and specificity=82.6%, 95%CI=77.1-88.1) as compared to finger-prick blood (sensitivity=60.7%, 95%CI=45.0-76.3; and specificity=89.5%, 95%CI=83.2-95.8; p=0.001). Importantly, there was no difference in the performance of the VISITECT® CD4 by cadre of health workers

(p=0.113). Inter-observer reliability between the first read-out and the second read-out of the same test-strip by two health workers showed excellent agreement (kappa statistic=100%).
Conclusions: Consistently good performance of the VISITECT® CD4 with different operators and at the point-of-care, in combination with the fact that no electricity and no instrument is required for conducting the test, shows the potential utility of this device. It may especially be useful for decentralization of CD4 testing services in rural areas. Considerable clinical and financial benefits associated with obtaining an immediate test result at the point-of-care may outweigh the risks associated with a proportion of false negative results.

THPEA028

Dried blood spots stored at room temperature should not be used for incidence testing

A.L. Eisenberg[1], Z. Packman[2], R. Fernandez[2], E. Piwowar-Manning[2], Y. Agyei[2], E.L. Hamilton[3], J. Wang[4], K. Kahn[5], A. Selin[6], F.X. Gomez-Olive[7], C. MacPhail[8], J. Hughes[9], A. Pettifor[6], S. Eshleman[2], O. Laeyendecker[10]
[1]National Institute of Health, NIAID, Bethesda, United States, [2]Johns Hopkins University, Baltimore, United States, [3]FHI 360, Durham, United States, [4]SCHARP, Seattle, United States, [5]University of the Witwatersrand, Johannesburg, Johannesburg, South Africa, [6]University of North Carolina at Chapel Hill, Chapel Hill, United States, [7]University of the Witwatersrand, Johannesburg, Mpumalanga, South Africa, [8]University of Wollongong, Wollongong, NSW, Australia, [9]University of Washington, Seattle, United States, [10]National Institute of Health, NIAID, Baltimore, United States

Background: We investigated the effectiveness of using dried blood spots (DBS) stored at room temperature (18-25°C) for cross-sectional HIV incidence testing using two serologic assays. DBS results were compared to results obtained with plasma samples.
Methods: Matched DBS and plasma samples (306 paired samples) were collected in the HPTN 068 trial in South Africa (2012 to 2014). Samples were shipped to the United States and were stored with desiccant at room temperature prior to testing. Two assays were evaluated: the Maxim HIV-1 Limiting Antigen Avidity EIA (LAg-Avidity, measured in normalized optical density [OD-n]) and a modified BioRad HIV-1/2 Plus O Avidity-based assay (BioRad, measured in percent avidity). The following assay cutoffs were used to indicate recent HIV infection: BioRad < 40%; LAg-Avidity < 1.5 OD-n. The performance of stored plasma and DBS specimens was compared for each assay. In addition, the effect of storage time at room temperature was assessed for DBS.
Results: Compared to plasma, the median absolute percent difference in avidity obtained with DBS samples was -47.0% (IQR: -13.5, -75.0) for the BioRad assay and -62.2% (IQR: -30.3, -73.3) for the LAg-Avidity assay. A higher percentage of samples had results below the assay cutoffs when DBS samples were used for testing compared to plasma: 53% (160/306) vs. 17.3% (53/306) for BioRad; 63.1% (193/306) vs. 18% (55/306) for LAg-Avidity. The percentage of samples with results below the assay cutoffs was also higher using DBS samples for individuals who were HIV-infected for >1 year: 38.8% (47/121) vs. 0.8% (1/121) for BioRad; 46.3% (56/121) vs. 5.0% (6/121) for LAg-Avidity. For the LAg-Avidity assay, for each log increase in viral load there was a 21% increase in the absolute difference between DBS to plasma OD-n values; no such effect was seen with the BioRad assay. For the DBS BioRad assay, there was a significant increase in false-recent misclassification for individuals infected >1 year with each additional year of sample storage (yearly Prevalence Ratio: 1.67 [95% CI: 1.18, 2.37]).[JH3] This was not seen with the plasma samples.
Conclusions: DBS samples stored at room temperature should not be used for cross-sectional HIV incidence estimation using serologic incidence assays.

Novel approaches to assess viral load and ARV resistance/tropism

THPEA029

Pooled nucleic acid testing strategy for monitoring HIV-1 treatment in resource limited settings

J. Boobalan[1], T. Dinesha[1], S. Gomathi[1], S. Sivamalar[1], S. Poongulali[1], A. Pradeep[1], K.G. Murugavel[1], S. S. Solomon[1,2], N. Kumarasamy[1], P. Balakrishnan[1], D. Smith[3], S. Saravanan[1]
[1]Y.R. Gaitonde Centre for AIDS Research and Education (YRG CARE), Chennai, India, [2]John Hopkins Univesity school of Medicine, Baltimore, United States, [3]University of Califfonia, San Diego, United States

Background: In treated HIV-1 infected patients, quantification of the viral burden and identification of drug-resistant mutations are important tools to monitor the outcomes. However, in resource-limited settings like India viral load quantification and drug resistance assay is still hampered by the high cost. Here we standardized a more efficient combined pooled nucleic acid amplification (NAT) test and drug resistance (DR) assay to monitor patients receiving ART.
Methods: 325 participants on first line ART with virologically suppressed at wk-24 were followed up until wk-48. Participants were screened for suppressed plasma viral load (PVL) using Abbott RealTime HIV-1 assay (40-1000000 copies). All the plasma samples were pooled by combining five samples of 200µL each for a total of 1mL in each pool were subjected to quantitative PCR to amplify HIV-1 RT region and positive minipool were deconvuluted by individually testing forquantitative PCRfollowed by genotyping.
Results: Of these 325 participants, 277 (55.4%) were females with the median age of 39 (IQR 33-44) and majority of the patients were on Tenofovir+ Lamuvidine+ Efavirenz regimen with the median PVL of 4369 (IQR 179-67155). Out of 65 pools,13 were positive. Testing of all samples individually revealed that one of the pool contained two positive samples. All positive samples had viral load > 1000 copies/mL; thereby meeting the definition of failing ART (4.3%). Altogether, the NAT pools had a negative predictive value and positive predictive value of 100%. Similarly, the sensitivity for detecting patients failing therapy was 100% (95% CI 76.84% to 100%), with a specificity of 100% (95%CI 98.82% to 100%) and there would have been 3 times cost saving with pooling NAT PCR compared to individual PCR. Of the patients failing first-line ART, 28.5% had NRTI and 71.4% had NNRTI resistance mutations and K103N (57.14%) was the predominantly found NNRTI mutation.
Conclusions: Pooled NAT+DR assay is a reliable strategy to drastically reduce the cost and sustainability of the virologic monitoring and can thereby facilitate the scale-up of successful HIV treatment programs in resource-limited settings.

THPEA030

Diagnostic accuracy of Filtered Dried Plasma Spot (FDPS) for HIV viral load testing using a newly developed plasma separator device

M. Pham[1,2], B. Haile[1,3], I. Azwa[4], N. Raman[4], A. Saeidi[4], M. Kahar Bador[4], M. Tan[4], Y. Feng[5], J. Zhu[5], J. Elliot[3], M. Garcia[1], F. Li[1], S. Luchters[1,3,6], D. Anderson[1,5]
[1]Burnet Institute, Melbourne, Australia, [2]Hanoi Medical University, Institute for Preventive Medicine and Public Health, Hanoi, Vietnam, [3]Monash University, Melbourne, Australia, [4]University of Malaya Medical Centre, Kuala Lumpur, Malaysia, [5]Nanjing BioPoint Diagnostics, Nanjing, China, [6]Ghent University, International Centre for Reproductive Health, Department of Obstetrics and Gynaecology, Ghent, Belgium

Background: Dried blood spot (DBS) is a recommended sampling method to improve patients' access to HIV viral load (VL) testing in resource-constrained settings where only centralised laboratory services are available. However, DBS suffers significant decrease in VL test accuracy as compared to plasma, particularly at 1,000 copies/ml cut-off, the recommended threshold for diagnosis of treatment failure. We assessed diagnostic performance (sensitivity and specificity to identify VL>1,000 copies/ml) of the newly developed "VL-Plasma" device, a simple, afford-

able and equipment-free lateral flow strip in a cartridge for the separation of plasma from whole blood, resulting in a Filtered Dried Plasma Spot (FDPS).

Methods: The "VL-Plasma" device uses specific membranes for the sequential removal of red and white blood cells, and a Whatman 903 membrane for plasma collection. HIV-infected patients attending the infectious disease clinic, University of Malaya, were enrolled. Each patient provided 100µl, 70µl and 1ml of whole blood for preparation of FDPS, DBS, and fresh plasma samples, respectively. Dried blood samples (FDPS & DBS) were dried overnight and stored in plastic bags with desiccants for 3-4 weeks at ambient temperature before testing. All samples were run on the Roche COBAS AmpliPrep/TaqMan 48 system.

Results: Reference fresh plasma identified treatment failure in 20/132 patients (15%). Sensitivity of FDPS for detection of treatment failure was 100% (95% confidence interval (95%CI=83.2%-100%) and specificity 100% (95%CI=96.8%-100%). In contrast, sensitivity and specificity for DBS were 100% (95%CI=96.8%-100%) and 34.8% (95%CI=26.1-44.4%), respectively. Positive predictive value and negative predictive value for treatment failure were 100% (95%CI=83.2%-100%) and 100% (95%CI=96.8%-100%) for FPDS, and 21.5% (95%CI=13.7%-31.2%) and 100% (95%CI=91%-100%) for DBS, respectively. Two DBS samples and one FDPS sample failed to provide VL results. Positive predictive value of DBS was only marginally improved by using higher thresholds for treatment failure, 37.7% (95%CI=24.8%-52.1%) at 3,000 copies/ml and 57.6% (95%CI=39.2%-74.5%) at 5,000 copies/ml.

Conclusions: Compared to DBS, FDPS from the "VL-plasma" device can significantly improve identification of virologic failure at 1,000 copies/ml, and minimize unnecessary switching to second-line ART and/or compliance interventions. The "VL-plasma" device will increase patients' access to VL testing, improving the effectiveness of HIV treatment in resource-constrained settings.

THPEA031

A compelling alternative to dried blood spots - Pplasma separation card for the quantification of HIV-1 RNA viral load

S. Carmona[1,2], B. Seiverth[3], D. Magubane[2], L. Hans[1,2], M. Hoppler[3]
[1]University of the Witwatersrand, Molecular Medicine and Haematology, Johannesburg, South Africa, [2]National Health Laboratory Service, Johannesburg, South Africa, [3]Roche Diagnostics International AG, Rotkreuz, Switzerland

Background: Plasma HIV viral load (VL) testing is the preferred means of monitoring response to antiretroviral treatment (ART) and programme performance. While Dried Blood Spots (DBS) hold considerable logistical advantages over plasma-based VL, performance based limitations still remain. DBS VL can lead to misclassifications of virological failure at 1000 cp/mL and have higher limits of detection (LOD) than plasma assays. We aim to evaluate the usability by health care workers (HCW) and analytical performance of a novel plasma separation card (PSC) versus plasma for the quantification of HIV-1 RNA.

Methods: HCW collected 140µL of finger-prick capillary blood from ~50 HIV-infected patients and transferred to the PSC, immediately after, venous EDTA whole blood was drawn by venipuncture. In addition, residual venous EDTA whole blood from ~400 adult HIV-infected patients was spotted onto PSC. We determined LOD using WHO International-Standard, specificity and sensitivity at 1000 cp/mL and specimen stability at a range of temperatures and storage durations in both COBAS® Ampliprep COBAS TaqMan® (CAP/CTM) and cobas® 8800 systems using the PSC. PSC performance was assessed in relation to EDTA plasma in both assays.

Results: Overall HCW rated sample collection positively, the lancet was considered easy to use, as were the capillary tube and blood transfer to PSC. Of ~100 specimens with quantitative values in both PSC and plasma, the mean log_{10} difference between EDTA-plasma and PSC was 0.05 cp/mL (95%CI = -0.01 to 0.11). The LOD for cobas® HIV-1 was determined at 790.2 cp/mL and for CAP/CTM HIV-1 v2 737.9 cp/mL. At 1000 copies/mL, the sensitivity of PSC samples was 97.0% (128/132) and specificity 97.2% (343/353) for cobas® HIV-1 and showed an excellent correlation to plasma (Deming R^2 = 0.90) over the linear range. PSC results were unaffected by different temperature and storage conditions (table1).

Conclusions: PSC collected samples are easy to prepare, correlate well with plasma VL and have demonstrated adequate sensitivity and specificity in a real world/clinical setting. The card provides an alternative sample collection to DBSs and, by minimising cell-associated viral nucleic acid contamination, leads to more accurate result. This PSC supports the 90-90-90 VL scale-up.

	CAP/CTM HIV-1 v2	cobas® HIV-1
Sample type	Dried plasma spot	Dried plasma spot
Input volume	1 spot with 140 µL	1 spot with 140 µL
Limit of detection	737.9 cp/mL	790.2 cp/mL
	(95% CI: 614.3 – 938.5)	(95% CI: 658.9 - 1003.6)
Correlation to EDTA plasma	Correlation: 0.05 log10	Correlation: 0.05 log10
Specificity (at 1000 cp/mL)	99%(95% CI: 98-100%)	97% (95% CI: 95-99%)
Sensitivity (at 1000 cp/mL)	91% (95% CI: 84-96%)	97% (95% CI: 93-99%)
	(n=325)	(n=485)
Specimen stability	28 d @ 45°C & 85% rH	28 d @ 45°C & 85% rH
	56 d frozen or @ 2°-30°C	56 d frozen or @ 2°-30°C

THPEA032

Provision of a clinical HIV-1 drug-resistance service by Next-Generation Sequencing (NGS) - assay development and full validation

L. McCrae[1], H. Wu[1], O. Lancaster[1], S. Wilson[1], R. Myers[2], S. Graham[1], J. Workman[1], E. Smit[1]
[1]PHE Public Health Birmingham Laboratory, Birmingham, United Kingdom, [2]PHE Infectious Disease Informatics, London, United Kingdom

Background: Sanger population sequencing is the current standard methodology for routine clinical HIV drug resistance testing. Using this method, a single consensus sequence is generated representing the predominant HIV quasispecies within the sample. In contrast, Next-Generation Sequencing (NGS) is capable of sequencing diverse HIV quasispecies and potentially achieving the early detection of emerging minority drug-resistant variants.

Over the past two years, progress has been made to bring forward the vision of an NGS-based HIV-1 resistance testing clinical service.

Methods: RNA extracts from 58 retrospective clinical samples were randomly selected.

The *Pol* genes of the samples were sequenced in parallel twice (batch A & B) by both Sanger and MiSeq. Sanger data were compared with NGS at 20%, 10%, 5% and 2% minority detection levels.

A further 386 clinical samples were also sequenced in parallel during the validation process.

Sequence concordance and resistance interpretations were analyzed and any difference in nucleotide base calls that resulted in amino acid changes, including complete and partial differences in mixture calling, were recorded as mismatches.

Results: All (22) MiSeq runs were successful and quality metrics were consistent with more than 80% passing filters; Q scores ³ Q30 were also well above the required 80%. All key mutation sites associated with Protease, NRTI and NNRTI resistance were represented by more than 100,000 reads.

A total of 3,712 amino acids (64 mutation codons each from 58 samples) were analysed. A total of 4 amino acid mismatches (4 samples at 3 codons in batch A and 4 samples at 4 codons in batch B) were identified (20% level) with a concordance of 99.9%.

With one exception, all 368 additional samples were successfully sequenced by MiSeq. A total of 32 amino acid mismatches in 29 samples at 15 codons were identified. Of these 15 codons, one PI (I54VTALM), two NNRTI (Y181CIV and E138KAGQR) and four NRTI (K65R, T215FY, T69SAIE and M184VI) mutations conferred major drug resistance. The concordance between NGS (at the 20% level) and Sanger was 99.9%.

Conclusions: An NGS-based HIV resistance-testing assay has been developed, fully validated and is considered ready for implementation into routine clinical service.

In-vitro activity

THPEA033

Efficacy of a novel entry inhibitor in combination with neutralizing antibodies against HIV-1 infection

S. Harada[1], M. Yokoyama[2], Y. Hikichi[1,3], H. Sato[2], T. Matano[1,3], K. Yoshimura[1]
[1]National Institute of Infectious Diseases, AIDS Research Center, Shinjuku, Japan, [2]National Institute of Infectious Diseases, Pathogen Genomics Center, Musashimurayama, Japan, [3]University of Tokyo, Institute of Medical Science, Minato, Japan

Background: Both neutralizing antibodies (NAbs) and entry inhibitors can inhibit HIV-1 infection by acting at different stages of the entry process. The combination of NAbs with entry inhibitor(s) may offer a therapeutic advantage and may be advantageous in overcoming resistance to them. Recently, we performed structure-based *in silico* screening of a chemical library to identify novel entry inhibitors (NEIs). In this study, we evaluated the *in vitro* anti-HIV-1 activity of NEI as a single agent or in combination with various classes of NAbs.
Methods: All entry inhibitors were docked into the CD4 binding site of HIV-1 Env gp120 using the MOE Dock tool, and ranked by London dG scoring. The susceptibility of infectious HIV-1 clones to NEIs and neutralization sensitivity to NAbs were determined using the TZM-bl assay. Additionally, we investigated the combined effect of NAbs with NEIs, by Combination Indexes (CIs) using the Chow and Talalay method.
Results: The TZM-bl assays revealed that NEIs 50b, 16b and 01c exhibited significant activity against HIV-1 with IC_{50} values ranging from 0.80 to 45 μM, and the most potent inhibitor was 50b, with IC_{50} value of 0.80, 1.2, 1.2 and 45 μM for HIV-1 NL4-3, 89.6, JR-FL and the primary isolate, KP-5mvcR, respectively. All three NEIs interfered with viral infection at the entry step. We further examined the combined effect of NEIs and NAbs targeting different domains in Env (VRC01, b12, PG9, PG16, 2G12 and 2F5). Synergistic anti-HIV activity (CI = 0.31 to 0.90) was demonstrated with a large number of combinations. In particular, potent synergy was observed for 50b in combination with either 2G12 or 2F5. These results suggest that combination of NEI with NAb can result in increased sensitivity to NAbs.
Conclusions: Novel entry inhibitors 50b, 16b and 01c can inhibit HIV-1 entry and combinations of a NEI with NAbs are efficacious against HIV-1. Our results support further investigation into NAb-based therapeutics and the HIV-1 entry process.

Tissue penetration

THPEA034

Plasma, CSF and brain tissue concentrations of raltegravir in ABCB1 and/or ABCG2 knockout rats

K. Tsuchiya[1], M. Ohuchi[2], A. Hamada[2,3], S. Oka[1,4], H. Gatanaga[1,4]
[1]National Center for Global Health and Medicine, AIDS Clinical Center, Tokyo, Japan, [2]National Cancer Center Research Institute, Division of Molecular Pharmacology, Tokyo, Japan, [3]Kumamoto University Graduate School of Medical Sciences, Department of Medical Oncology and Translational Research, Kumamoto, Japan, [4]Kumamoto University, Center for AIDS Research, Kumamoto, Japan

Background: HIV-1 infection in brain is associated with long-term neuronal damage and neurocognitive disorders. Raltegravir (RAL), one of the preferred integrase strand transfer inhibitors in the current antiretroviral therapy guidelines, is highly effective in penetrating the central nervous system. The ATP-binding cassette transporter B1 (ABCB1) and G2 (ABCG2) are both expressed at the blood-brain barrier and the blood-cerebrospinal fluid (CSF) barrier, and contribute to active transport of drugs. Recently, RAL was identified to be a substrate of both transporters. In the present study, we analyzed the relations between plasma, CSF and brain tissue concentrations of RAL in Abcb1 and/or Abcg2 knockout (KO) rats.
Methods: Wild-type (WT) male Sprague-Dawley (SD) rats (n=8), Abcb1-KO male SD rats (n=8), Abcg2-KO male SD rats (n=8), and Abcb1/Abcg2-KO male SD rats (n=8) were administered an intravenous dose of RAL 100 mg/kg. Plasma, CSF and brains were taken 10 min after RAL intravenous dosing. Plasma, CSF and sliced brain tissue concentrations of RAL were measured by the liquid chromatography-tandem mass spectrometry (LC-MS/MS). Localization of RAL in sliced brains were analyzed using matrix-assisted laser desorption ionization mass spectrometry imaging (MALDI-MSI).
Results: Mean plasma RAL concentrations±standard error (SE) of WT, Abcb1-KO, Abcg2-KO, and Abcb1/Abcg2-KO rats were 79.6±17.6, 117.9±13.9, 118.1±26.6, and 120.2±7.7 μg/ml, respectively. Mean CSF RAL concentrations±SE were 2666.5±806.4, 5864.7±1003, 2836.5±826.9, and 6719.2±362.1 ng/ml, respectively. Mean brain tissue RAL concentrations±SE were 0.033±0.007, 0.105±0.02, 0.071±0.023, and 0.144±0.014 ng/μg of protein, respectively. MALDI-MSI data showed that RAL were localized around the choroid plexus in Abcb1-KO, Abcg2-KO, and Abcb1/Abcg2-KO rat brains.
Conclusions: Mean CSF and brain tissue RAL concentrations of Abcb1-KO and Abcb1/Abcg2-KO rats were significantly higher than WT rats. The observed association between high CSF and brain tissue concentrations of RAL and Abcb1-KO and Abcb1/Abcg2-KO may be explained by increased RAL flow in the blood-brain barrier as the result of reduced expression of ABCB1. Then, localization of RAL in each KO rat brains are observed in the choroid plexus. These results suggest that choroid plexus may work as a barrier for RAL transport between capillary blood and CSF, and there may be a transporter for RAL at the choroid plexus.

ART in acute infection

THPEB035

Outcomes of expedited initiation of antiretroviral therapy (ART) in individuals with acute HIV infection, British Columbia, Canada

M. Hull[1], T. Grennan[2], J. Wong[2], S. Guillemi[1], W. Zhang[1], V. Lima[1], T. Consalacion[2], P. Sereda[1], M. Gilbert[2], M. Krajden[2], J. Montaner[1], R. Hogg[3], G. Ogilvie[2]
[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]BC Centre for Disease Control, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada

Background: Diagnosis of acute HIV infection may allow for interventions to reduce risk of transmission. British Columbia has implemented pooled HIV NAT testing and individual NAT testing for weakly positive EIA samples, with expedited linkage to care for acute HIV diagnoses. Outcomes of individuals with acute infection were evaluated.
Methods: Individuals with HIV diagnosis April 2009 - June 2016 were assessed to determine stage at diagnosis. Individuals classified as acute HIV infection using Fiebig staging (Stage I-IV) were included in the analysis. Baseline variables included risk group (men who have sex with men [MSM] vs. not, and regimen type (standard 3 drug regimen or intensified 4 drug regimen [IR]) was ascertained through linkage with the BC HIV Drug Treatment Program. Factors associated with time to ART uptake from diagnosis were determined using an adjusted Cox proportional hazards model.
Results: Overall 247 individuals with acute HIV infection initiated ART; n=50 (20%) were Fiebig I/II, n=58 (23%) were Fiebig III and139 (57%) Fiebig IV. Median age was 33 years, 1st-3rd quartile [Q1Q3] 27 - 44 years, 89% were male, 73% were MSM. Median time to ART initiation was 28 days (Q1Q3 15 - 67) for Fiebig I/II and 51 days (Q1Q3 15 - 124) for Feiibig III/IV (p = 0.115). Overall n=39 (16%) individuals received an IR at median 7 days (Q1Q3 6 - 11 days) and achieved suppression at 55 days (Q1Q3 32 - 95 days) vs. n= 208 (84%) who received standard ART at median 55 days (Q1Q3 26 - 139 days) and achieved suppression at 127 days (Q1Q3 80 - 183 days), p < 0.001. Faster time to ART uptake was associated with being Fiebig I/II and receiving IR (aHR 14.09; 95% CI 6.13 - 32.36), Fiebig III/IV and receiving IR (aHR 7.93; 95% CI 5.10 - 12.33) and being MSM (aHR 1.60; 95% CI 1.09 - 2.35).

Conclusions: One fifth of acute HIV infections were identified early at Fiebig stages I/II, and initiated immediate ART. The combination of systematically identifying acute HIV cases and expedited linkage to treatment results in rapid control of HIV viraemia which can reduce risk of onward transmission.

ART in first- and second-line therapies

THPEB036

Prezent - pilot study of darunavir boosted by cobicistat in combination with rilpivirine in HIV+ treatment naïve subjects - final 96 week results

J. Gathe Jr[1], S. Letendre[2], Q. Ma[3], S. Woods[4], C. Mayberry[5], V. Davis[5], C. Swindle[5], E. Diejomaoh[6]
[1]Therapeutic Concepts, PA, Houston, United States, [2]University of California at San Diego, Department of Medicine, San Diego, United States, [3]University at Buffalo, Department of Pharmacy Practice, Buffalo, United States, [4]University of Houston, Department of Psychiatry, Houston, United States, [5]Therapeutic Concepts, P.A., Houston, United States, [6]Therapeutic Concepts, P.A., Research, Houston, United States

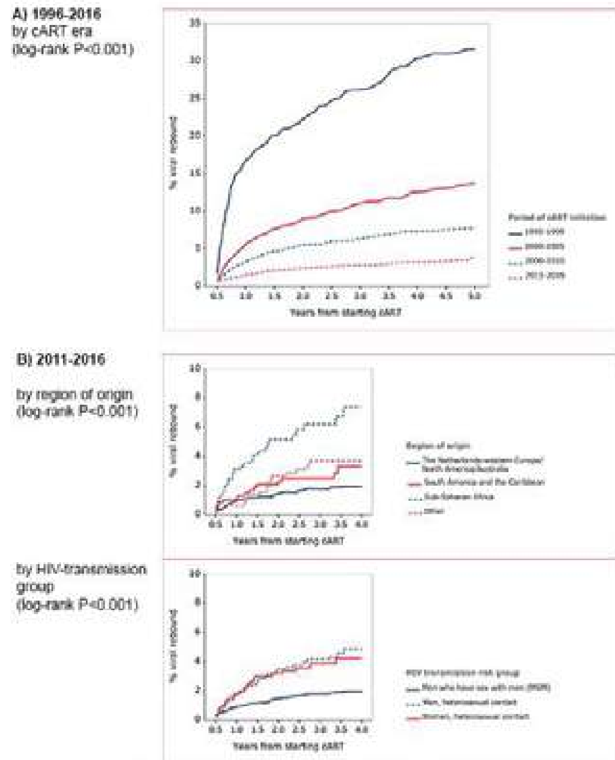
Background: Treatment strategies with two drug regimens are being studied in an effort to control viral replication for less cost and potentially less toxicity. Prezent, the first study of the novel two drug combination of darunavir boosted by cobicistat and rilpivirine in ARV naïve subjects demonstrated virologic control both in plasma (93%) VL ≤ 50 and the CNS (100%) VL < 20 at 48 weeks. Further, CSF concentration of both DRV and RPV exceeded IC90 in all subjects studied and was associated with significant neurocognitive improvement by MOCA score.
This study assess the durability of the regimen to 96 weeks.
Methods: Extension to 96 weeks of a Phase IV open/label pilot study of HIV positive, ARV naïve subjects age ≥ 18 years VL ≥ 5000 with any CD4 count at baseline. Exclusions included hepatitis B co-infection, active AIDS defining illness or baseline resistance to study drugs. Extension eligible subjects were all with VL ≤ 50 at 48 weeks. Primary endpoint was % subjects VL ≤ 50 at 96 weeks (ITT M=F). Secondary endpoints included change in CD4 counts and MOCA scores.
Results: At week 48, 28/30 subjects had VL ≤ 50 and were eligible for the extension phase. All 28 enrolled and completed the 96 week study. 28/28 (100%) had VL ≤ 50 by the end of the study with increased CD4 counts (median 258 cells). MOCA scores were ≥ 26 in 93% of subjects and there were no significant AE reports.
Conclusions: The novel combination of DRV/Cobi and RPV demonstrated durable control of virologic replication with 100% of eligible subjects VL ≤ 50 at week 96. CD4 counts continued to increase and cognitive improvement as measured by MOCA scores were sustained. The regimen remained well tolerated without significant AE. Based on this successful pilot study, this durable, cost effective treatment strategy warrants larger clinical trials.

THPEB037

Substantial decline in virological failure after combination antiretroviral treatment (cART) initiation in treatment-naïve HIV-positive adults in the Netherlands from 1996 to 2016

T.S. Boender[1], F.W.N.M. Wit[1,2,3], A. van Sighem[1], K. Brinkman[4], C. van Nieuwkoop[5], A.M.J. Wensing[6], P. Reiss[1,2,3],
on behalf of the ATHENA National Observational HIV Cohort
[1]Stichting HIV Monitoring, Amsterdam, Netherlands, [2]Academic Medical Center, and Amsterdam Center for Infection and Immunity, Department of Internal Medicine, Division of Infectious Diseases, Amsterdam, Netherlands, [3]Academic Medical Center, and Amsterdam Institute for Global Health and Development, Department of Global Health, Amsterdam, Netherlands, [4]OLVG, Department of Internal Medicine, Amsterdam, Netherlands, [5]Haga Teaching Hospital, Department of Internal Medicine, The Hague, Netherlands, [6]University Medical Center Utrecht, Department of Virology, Utrecht, Netherlands

Background: We evaluated the incidence of, and factors associated with, virological failure (VF) after combination antiretroviral therapy (cART) initiation in adults in the Netherlands, since the introduction of cART in 1996.
Methods: We assessed the incidence of VF (i.e. the first of two consecutive viral load measurements ≥200 copies/ml after >6 months of cART) among HIV-1 positive, ART-naïve, non-pregnant adults in the ATHENA-cohort between 1996-2016. Time was censored at the date of last contact with HIV-care, or at the last date of cART when cART was interrupted for >2 weeks. We assessed the incidence of VF since cART initiation, and assessed socio-demographic and clinical factors associated with time-to-VF specifically for cART initiation between 2011-2016 using Cox regression.



[Kaplan-Meier estimates of time-to-virological failure]

Results: During 1996-2016, 1,807 (10.6%) out of 17,044 adults experienced VF after a median of 1.4 [IQR 0.7-3.4] years since cART initiation. The likelihood of VF decreased substantially by year of cART initiation: unadjusted hazard ratio (uHR) 12.6 (95%CI 10.4-15.2) in 1996-1999, 5.2 (4.3-6.3) in 2000-2005, and 2.6 (2.1-3.2) in 2006-2010, respectively compared to 2011-2016 (*Figure A*).

During 2011-2016, 133 (2.1%) out of 6,228 people who initiated cART experienced VF after a median of 1.6 (IQR 0.7-2.0) years. Before VF, 106 out of 133 people had ≥1 VL measurement available, of whom 66 had an undetectable VL. HIV-transmission risk group and region of origin were independently associated with VF: adjusted hazard ratio (aHR) 1.7 (95%CI 1.0-2.7) for men with heterosexual acquired HIV-1 compared to men who have sex with men (MSM), and aHR 2.3 (1.3-4.1) for people originating from sub-Saharan Africa compared to Western Europe/North America/Australia (*Figure B*).

Additionally, a higher VL (aHR 1.5 [95%CI 1.2-2.0] per $\log_{10}$ cps/ml) and lower CD4-cell count (aHR 2.3 [1.0-5.1] for < 50 cells/mm³, and aHR 2.1 [1.0-4.5] for 50-199 cells/mm³, compared to >500 cells/mm³) at cART initiation were independently associated with VF.

Conclusions: VF after cART initiation has decreased substantially over the last two decades in the Netherlands. While the risk of VF continues to decline, additional support for non-MSM, late-presenters, and those originating from sub-Saharan Africa is warranted to further optimize cART outcomes.

THPEB038

B/F/TAF versus ABC/DTG/3TC or DTG + F/TAF in treatment-naïve adults with high baseline viral load or low baseline CD4 count in 2 Phase 3 randomized, controlled clinical trials

D. Podzamczer[1], H.-J. Stellbrink[2], C. Orkin[3], A. Pozniak[4], J.R. Arribas[5], E. Koenig[6], M. Ramgopal[7], A. Baumgarten[8], X. Wei[9], A. Cheng[9], D. Sengupta[9], H. Martin[9], E. Quirk[9]
[1]*Hospital Universitari de Bellvitge, HIV and STD Unit Infectious Disease Department, Barcelona, Spain,* [2]*ICH Study Center, Hamburg, Germany,* [3]*Barts Health NHS Trust, Royal London Hospital, Ambrose King Centre, London, United Kingdom,* [4]*Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom,* [5]*Hospital Universitari de Bellvitge, Barcelona, Spain,* [6]*Instituto Dominicano de Estudios Virologicos IDEV, Santo Domingo, Dominican Republic,* [7]*Midway Immunology and Research Center, Fort Pierce, United States,* [8]*Zibp Zentrum fur Infektiologie Berlin Prenzlauer Berg, Berlin, Germany,* [9]*Gilead Sciences Inc., Foster City, United States*

Background: Treatment-naïve, HIV-1-infected individuals with high viral load and/or low CD4 count may be difficult to treat. In two Phase 3 studies of fixed-dose combination bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) vs. dolutegravir comparators, there were no treatment differences between arms for subgroups with HIV-1 RNA >100,000 copies (c)/mL or CD4 < 200 cells/ µL at baseline. No participant failed with resistance. To further characterize efficacy of B/F/TAF, we analyzed pooled results from these trials for those with high HIV-1 RNA or low CD4 count at baseline.

Methods: Treatment-naïve, HIV-1-infected adults were randomized 1:1 to receive blinded treatment with B/F/TAF (50/200/25 mg) vs. dolutegravir/abacavir/lamivudine (DTG/ABC/3TC) (study 1489) or DTG (50 mg) + F/TAF (200/25 mg) (study 1490). Participants were recruited in North America, Europe, and Australia.

To evaluate the efficacy of B/F/TAF specifically in these populations, we conducted a per-protocol (PP) analysis, which included participants randomized who received ≥1 dose of study medication but excluded those without on-treatment results in the week (W) 48 window (unless discontinued for lack of efficacy) or who had low medication adherence (< 2.5th percentile).

We present W48 virologic responses by FDA snapshot algorithm for participants with baseline HIV-1 RNA >100,000 c/mL or CD4 count < 200 cells/µL using the PP analysis set.

Results: 629 adults were randomized in study 1489 (B/F/TAF n=314, DTG/ABC/3TC n=315) and 645 in study 1490 (B/F/TAF n=320, DTG+F/TAF n=325). Pooled, 198 participants (PP analysis set) had baseline HIV-1 RNA >100,000 copies/mL (B/F/TAF n=103/634 [16%], DTG/ABC/3TC n=46/315 [15%], DTG+F/TAF n=49/325 [15%]), and 132 (B/F/TAF n=73/634 [12%], DTG/ABC/3TC n=27/315 [9%], DTG+F/TAF n=32/325 [10%]) had baseline CD4 count < 200 cells/µL. For both high VL and low CD4 subgroups, rates of participants with HIV-1 RNA < 50 c/mL at W48 were similarly high for B/F/TAF, DTG/ABC/3TC, and DTG+F/TAF (table). No participant failed with resistance to any components of study drug.

Conclusions: B/F/TAF demonstrated potent viral suppression with no treatment-emergent resistance in treatment-naïve adults with high baseline HIV-1 RNA or low CD4 count. These data provide further evidence that B/F/TAF is an appropriate treatment for a wide range of patients, including late presenters who have been historically more difficult to treat.

Baseline HIV-1 RNA >100,000 c/mL	B/F/TAF (n=103)	DTG/ABC/3TC (n=46)	DTG + F/TAF (n=49)

THPEB039

Virologic outcomes among treatment naïve HIV+ patients initiating common first antiretroviral therapy core agents in the OPERA observational database

A. Mills[1], L. Brunet[2], J. Fusco[2], M. Wohlfeiler[3], C. Garris[4], A. Oglesby[4], J. Mrus[4], P. Lackey[5], G. Fusco[2]
[1]*Southern California Men's Medical Group, Los Angeles, United States,* [2]*Epividian, Durham, United States,* [3]*AIDS Healthcare Foundation, Miami, United States,* [4]*ViiV Healthcare, Inc., Research Triangle Park, United States,* [5]*Carolinas Healthcare System, Charlotte, United States*

Background: The efficacy of the commonly used core agents dolutegravir (DTG), elvitegravir (EVG), raltegravir (RAL) and darunavir (DRV) has been evaluated in clinical trials, but assessments of clinical effectiveness in real-world settings are needed. Virologic failure (VF) following core agent initiation was compared in ART-naïve patients in the Observational Pharmaco-Epidemiology Research and Analysis (OPERA) cohort.

Methods: The study population consisted of ART-naïve OPERA patients initiating DTG, EVG, RAL, or DRV between 08/12/2013 and 07/31/2016, with follow-up to 07/31/2017. VF was defined as (i) 2 consecutive HIV viral load (VL) ≥200 copies/mL after 36 weeks of ART, or (ii) 1 VL ≥200 copies/mL with core agent discontinuation after 36 weeks, or (iii) 2 consecutive VL ≥200 copies/mL after suppression (VL ≤50 copies/mL) before 36 weeks, or (iv) 1 VL ≥200 copies/mL with discontinuation after suppression before 36 weeks. Patient characteristics including baseline mortality index and VF frequency during follow-up were described. Survival analyses were conducted with Kaplan Meier methods and multivariate Cox Proportional Hazards modeling (covariates described in Figure 1).

Results: There were 5,561 ART-naïve patients who initiated DTG (35%), EVG (48%), DRV (14%) or RAL (3%). Median follow-up time was 18.4 months (IQR: 12.6-27.4). Compared to DTG, EVG users were younger, more likely to be male or from the southern U.S. and had lower baseline mortality index; DRV and RAL users were older, less likely to be male or Hispanic, more likely to be African American and had lower baseline CD4 cell count or mortality index; RAL users were also more likely to be from the southern U.S. and had higher baseline VL (Table 1). VF was experienced by 7.7% DTG, 9.8% EVG, 16.8% DRV and 27.0% RAL users (Figure 1). Compared to DTG, the 47-month adjusted hazard ratio for VF was 1.20 (95% CI: 0.97, 1.49) for EVG, 2.12 (1.65, 2.74) for DRV, and 3.75 (2.61, 5.38) for RAL (Figure 1).

Conclusions: In this assessment of ART-naïve patients in a real-world clinical setting, DTG users were statistically significantly less likely to experience VF compared to RAL and DRV users, and marginally less likely to experience VF compared to EVG users.

	Dolutegravir, n=1970 (35.4%)	Elvitegravir, n=2654 (47.7%)	Darunavir, n=781 (14.0%)	Raltegravir, n=163 (2.9%)

THPEB040

Superior efficacy of dolutegravir (DTG) plus 2 nucleoside reverse transcriptase inhibitors (NRTIs) compared with lopinavir/ritonavir (LPV/r) plus 2 NRTIs in second-line treatment - 48-week data from the DAWNING Study

M. Aboud[1], R. Kaplan[2], J. Lombaard[3], F. Zhang[4], J. Hidalgo[5], E. Mamedova[6], M. Losso[7], P. Chetchotisakd[8], C. Brites[9], J. Sievers[1], D. Brown[10], J. Hopking[11], M. Underwood[12], M.C. Nascimento[1], M. Gartland[12], K. Smith[12]

[1]ViiV Healthcare, Brentford, United Kingdom, [2]Desmond Tutu HIV Foundation, Cape Town, South Africa, [3]Josha Research, Bloemfontein, South Africa, [4]Beijing Ditan Hospital, Beijing, China, [5]VÍA LIBRE, Lima, Peru, [6]Kiev AIDS Centre, Kiev, Ukraine, [7]Hospital J M Ramos Mejia, Buenos Aires, Argentina, [8]Srinagarind Hospital, Khon Kaen University, Khon Kaen, Thailand, [9]Federal University of Bahia, Salvador, Brazil, [10]ViiV Healthcare, Abbotsford, Australia, [11]GlaxoSmithKline, Uxbridge, United Kingdom, [12]ViiV Healthcare, Research Triangle Park, United States

Background: DAWNING is a non-inferiority study comparing DTG+2NRTIs with a current WHO-recommended regimen of LPV/r+2NRTIs in HIV-1 infected adults failing first-line therapy (HIV-1 RNA ≥400 copies [c]/mL) of a non-nucleoside reverse transcriptase inhibitor + 2 NRTIs (ClinicalTrials.gov: NCT02227238). Prior to a 24-week interim analysis, the Independent Data Monitoring Committee (IDMC) recommended discontinuation of the LPV/r arm due to superior efficacy of DTG+2NRTIs based on available data; the study protocol was amended to allow ongoing LPV/r subjects to switch to the DTG arm.

Methods: Subjects were randomised (1:1, stratified by Screening plasma HIV-1 RNA and number of fully active NRTIs) to 52 weeks of open-label treatment with DTG or LPV/r combined with 2 investigator-selected NRTIs, including at least one fully active NRTI based on Screening resistance testing. The primary endpoint was the proportion of subjects achieving HIV-1 RNA < 50 c/mL at Week 48 (Snapshot algorithm).

Results: 624 adults were randomized and treated. Subjects were well matched for demographic and baseline characteristics. The IDMC decision had limited impact on the primary endpoint as all LPV/r subjects who switched or discontinued due to the IDMC decision had a viral load value at Week 48/52. At Week 48, 84% (261/312) of subjects on DTG versus 70% (219/312) on LPV/r achieved HIV-1 RNA < 50 c/mL (adjusted difference 13.8%, 95% CI: 7.3% to 20.3%, p < 0.001 for superiority). The difference was primarily driven by lower rates of Snapshot virologic non-response (VL ≥50 c/mL) in subjects on DTG. The overall safety profile of DTG+2NRTIs was favourable compared to LPV/r+2NRTIs with more drug-related adverse events reported in the LPV/r group. Of 11 DTG subjects who met protocol-defined virologic withdrawal criteria through Week 52, one had treatment-emergent primary integrase-strand transfer inhibitor (INSTI) and NRTI resistance mutations while another had INSTI mutations only; in comparison, 30 LPV/r subjects met virologic withdrawal criteria, and 3 had emergent NRTI but no protease inhibitor mutations.

Week 48 outcomes	DTG (N=312)	LPV/r (N=312)
Snapshot virologic success	261 (84%)	219 (70%)
Snapshot virologic non-response	30 (10%)	68 (22%)
Data in window not <50 c/mL	18 (6%)	34 (11%)
Discontinued for lack of efficacy	6 (2%)	20 (6%)
Discontinued for other reason while not <50 c/mL or change in ART	6 (2%)	14 (4%)
Snapshot no virologic data	21 (7%)	25 (8%)
Discontinued due to AE or death	7 (2%)	17 (5%)
Discontinued for other reasons or missing data during window but on study	14 (4%)	8 (3%)
Drug-related AEs	50/314 (16%)	119/310 (38%)

[Week 48 outcomes]

Conclusions: In DAWNING, DTG+2NRTIs demonstrated superior efficacy at Week 48 and a favourable safety profile compared with LPV/r+2NRTIs confirming interim 24-week results. The study provides important information to help guide second-line treatment decisions in resource-limited settings.

THPEB041

Virological failure through the R263K pathway to a first line Doluegravir containing regimen

M.J. Pena[1], N. Chueca[2], M. Hernández-Febles[1], J.A. Fernandez Caballero[2], F. Garcia[2], J.M. Zarzalejos[1]

[1]Hospital Universitario de Gran Canaria Dr Negrin, Las Palmas, Spain, [2]Hospital Universitario San Cecilio, Granada, Spain

Background: Virological failure to Dolutegravir (DTG) containing regimens is a rare event. So far only a few cases have been reported in treatment-experienced individuals, commonly associated with emergence of R263K in the integrase, a substitution that confers low-level resistance against DTG and disminishes HIV DNA integration and viral fitness. In first line therapy, DTG shows a higher barrier to resistance with no reported mutations at 96 or 148 weeks. Here we report a case of early virological failure in an antiretroviral naïve patient that started a DTG based first line therapy.

Methods: A 49 year old woman was diagnosed of HIV-1 infection while admission in June 19th 2017 for lumbar spine surgery. At diagnosis CD4+ count was 39 cells/µl and plasma HIV-1 RNA was 457.000 copies/ml. ART was started one week later with TDF/FTC and DTG 50 mg BID, as she was taking rifampicin,. On July 23th, VL was 3461 copies/ml and CD4+ increased to 113 cells/µl. On August 22nd, rifampicin was removed due

to a cutaneous adverse reaction and DTG was given QD. On September 14th, CD4+ count was 42 cells/µl and VL had increased to 126.393 copies/ml. Adherence was confirmed both by hospital records and patient interview, and virological failure was confirmed in a second sample (VL 208.518 c/ml).

Results: Sanger sequencing in RT and Integrase genes was performed at all time points, showing the sequential emergence of M184I (replaced by M184V), R263K, E157Q and K70E. Treatment was changed to TDF, darunavir/cobicistat (DRV/cob) and rilpivirine (RPV), with a VL decrease to 25 copies/ml and a CD4+ increase to 302 cells/µl. A summary of resistance findings is shown in table 1. Deep sequencing of *pol* and *env* revealed infection by a recombinant CRF14_BG form.

Conclusions: To our knowledge, this is the first report of first-line treatment failure with DTG with the selection of mutations in the integrase. Using deep sequencing we were able to trace the development and replacement of mutations. Interestingly we have shown, for the first time in vivo, the restoration of viral fitness that E157Q exerts on R263K containing viruses.

THPEB042

Patient satisfaction, tolerability and acceptability of Cabotegravir (CAB) and Rilpivirine (RPV) Long-Acting (LA) therapy in HIV-1 infected adults: LATTE-2 week 96 results

M. Murray[1], F. Pulido[2], A. Mills[3], R. Moti[4], R. Leblanc[5], H. Jaegar[6], V. Chounta[1], D. Dorey[7], S. Griffith[8], J. Mrus[8], V. Cannon[9], D. Margolis[8], W. Spreen[8]

[1]ViiV Healthcare, Brentford, United Kingdom, [2]Hospital Universitario 12 de Octube, Madrid, Spain, [3]Anthony M. Mills Internal Medicine, West Hollywood, United States, [4]Midway Immunology and Research Center, Fort Pierce, United Kingdom, [5]Royal Victoria Hospital, McGill University Health Centre, Immunodeficiency Service Division of Hematology, Montreal, Canada, [6]MUC Research GmbH, Munich, Germany, [7]GlaxoSmithKline, Mississauga, Canada, [8]ViiV Healthcare, Research Triangle Park, United States, [9]Janssen Pharmaceutica, Beerse, Belgium

Background: The objective of the LATTE-2 study was to assess the long-term efficacy and safety of the intramuscular IM combination therapy of Cabotegravir LA + Rilpivirine LA every 4 weeks (Q4W) or every 8 weeks (Q8W) for maintenance of HIV-1 viral suppression through 96 weeks compared to oral CAB + abacavir/lamivudine (ABC/3TC). Secondary objectives include satisfaction, tolerability and acceptability of Cabotegravir LA + Rilpivirine LA.

Methods: LATTE-2 is an open-label study in ART-naïve HIV-1 infected adults. Patients who were virally suppressed with oral CAB+ABC/3TC during the 20-week Induction Period were randomized 2:2:1 to IM CAB LA + RPV LA Q4W, Q8W, or to remain on daily oral CAB + ABC/3TC (PO) in the Maintenance Period (MP). Tolerability and acceptability were self-assessed with the HIV-Medication Questionnaire (HIV-MQ) while satisfaction was measured with the adapted HIV-Treatment Satisfaction Questionnaire (HIV-TSQ).

Results: LATTE-2 randomized 286 patients into MP. At week 96, 87% (Q4W) and 94% (Q8W) of patients maintained HIV-1 RNA < 50 c/mL compared to 84% on PO (ITT-ME). Drug-related AEs included injection site pain which was the most frequently reported adverse event in the IM groups (97% in Q4W, 95% in Q8W). Patients in the Q8W group reported the highest and patients in the PO group reported the lowest levels of satisfaction with their HIV Treatment through Wk96 (HIVTSQs mean total score for Wk96 was 62.9 in the Q8W group (p=0.001) and 61.7 in the Q4W group (p=0.02) versus 58.1 [from a possible 66] in the PO group; p-values calculated as post-hoc analyses). In the HIVMQ, 37% of patients in the PO group did not find the treatment inconvenient or difficult to adhere, versus 72% of patients in the Q8W and Q4W groups.

Conclusions: Within the MP up to 96 weeks, patients receiving the IM combination therapy of Cabotegravir LA + Rilpivirine LA consistently demonstrated higher levels of satisfaction, tolerability and acceptability in both the Q4W and Q8W groups compared to patients on the PO group. Patients on the Q8W group demonstrated numerically higher levels of satisfaction compared to those in the Q4W group.

[1]Northwestern University, Chicago, United States, [2]Russia AIDS Federal Center, Moscow, Russian Federation, [3]Moscow Region AIDS Center, Moscow, Russian Federation, [4]Republic Tatarstan AIDS Center, Kazan, Russian Federation, [5]Volgograd Region AIDS Center, Volgograd, Russian Federation, [6]Moscow City AIDS Center, Moscow, Russian Federation, [7]IPHARMA LLC, Moscow, Russia, Moscow, Russian Federation, [8]Viriom Inc, San Diego, United States

Background: Elpida® / Elsulfavirine (VM1500) is the prodrug of VM1500A, a new potent non-nucleoside reverse transcriptase inhibitor with unique pharmacokinetic properties ($T_{1/2}$ ~ 9 days). A 20 mg once daily dosing was chosen for further study based on 12-week efficacy, pharmacology and safety data; 48 week data comparing Elpida 20 mg to Efavirenz-based therapy plus tenofovir/emtracitabine (TDF/FTC) has been reported effective and safe. The objective of this study was to assess the efficacy and safety of an ART regimen including Elpida 20 mg plus two NRTI during 96 weeks.

Methods: In the parent Phase IIb randomized, double-blind, multicenter study, ART-naïve HIV-1-infected patients, treated initially for 48 weeks with Elpida plus TDF/FTC, continued the study treatment for up to 96 weeks. During this period they received Elpida 20 mg and various two NRTI regimens.

Results: After initial 48 weeks of treatment, 81% of patients on Elpida 20 mg and 73.7% patients on Efavirenz had VL < 50 c/mL (MITT). A total of 81out of 87 (93%) patients, treated with Elpida in the main study, continued in the follow-up study for additional 48 weeks. A total of 73 out of 87 (84%) patients had VL < 50 c/mL and 79/87 (91%) had < 400 c/mL at week 96. 3 patients receiving Elpida had VL >1000 c/mL during the study, presumably due to poor compliance; none had NNRTI resistance mutations. A CD4+ T-lymphocyte count increased by 246 ± 175.3 cells/mm³ during 96 weeks of treatment. Median CD4/CD8 ratio increased from 0.40 to 0.82. There were no new significant AEs, related to Elpida, after 48 weeks of treatment. New AE were mainly related to the changes of two NRTI regimen, including 2/89 (2.2%) patients with Grade 3 events (i.e. decreased appetite, irritability, dyspnea and rash). No drug-related SAE were reported. Total exposure to Elpida was 151.7 patient-years.

Conclusions: This study demonstrated that Elpida was safe and well tolerated to 96 weeks, with continued virologic efficacy, immunologic improvement and favorable resistance profile. Elpida-based therapy is a safe and effective long term strategy with many potential advantages over current therapies.

ART in highly treatment-experienced persons

THPEB044

Identifying heavily treatment experienced patients in the OPERA cohort

R. Hsu[1,2], C. Henegar[3], J. Fusco[4], V. Vannappagari[3], C. Llamoso[5], P. Lackey[6], G. Pierone[7], G. Fusco[4]
[1]New York University School of Medicine, Internal Medicine, New York, United States, [2]AIDS Healthcare Foundation, New York, United States, [3]ViiV Healthcare, Research Triangle Park, United States, [4]Epividian, Inc., Durham, United States, [5]ViiV Healthcare, Branford, United States, [6]Carolinas Healthcare System, Charlotte, United States, [7]Whole Family Health Center, Fort Pierce, United States

Background: Despite the availability of highly effective combination ART, a subset of HIV+ patients have had exposure to multiple different treatments and have limited future treatment options remaining due to development of resistance and/or intolerance. It is important to identify the prevalence of heavily treatment-experienced (HTE) patients and associated clinical characteristics to support and guide development of new therapies for this unique and under-served patient population.
Methods: Adult HIV+ patients actively followed in the OPERA care network were identified. Patients with ≥1 visit(s) in the year prior to 12/31/2016 were considered active in care. From this population, prevalence of HTE was estimated using three separate definitions; definition 1: currently on 4th line of ART, definition 2: exposure to ≥3 ART core agent classes prior to current regimen, definition 3: currently on core agents suggestive of HTE. Drugs from non-NRTI drug classes were considered core agents. Point prevalence (PP) and 95% confidence intervals (CI) were calculated for each definition. Overlap between definitions was explored and patient demographic and clinical characteristics were described for each definition.
Results: Of the 41,939 patients alive and in care, 1,972 (PP=4.7%; 95% CI: 4.5%, 4.9%) met definition 1, 1,784 (PP=1.9%; 95% CI: 1.7%, 2.0%) met definition 2, and 1401 (PP=3.3%; 95% CI: 3.2%, 3.5%) met definition 3. A total of 3,908 (9.3%) OPERA patients were captured by at least one definition for HTE; 239 (0.6%) patients were included in more than one definition and 10 (0.02%) patients met all three definitions. [Figure 1] The patients defined by these definitions were similar in age and sex but differed substantially in race, ethnicity, and route of infection. History of AIDS-defining illness and time since ART initiation were greatest for the patients in Definition 2 with far more initiating therapy more than 10 years ago and experiencing AIDS. [Table 1]
Conclusions: Three proposed definitions for identifying HTE patients in an observational database resulted in a prevalence of 1.9-4.7% of patients active in care. Minimal overlap of patients identified as HTE by these criteria suggests multiple definitions may be required to fully capture this complex and varied population in need of new therapeutic approaches.

	Definition 1: On 4th line of ART[3] N=1,972	Definition 2: ≥3 core agent classes[4] N=784	Definition 3: ART regimens of interest[5] N=1,401
Prevalence (95% CI)	4.7% (4.5, 4.9)	1.9% (1.7, 2.0)	3.3% (3.2, 3.5)
Age, median years (IQR)[6]	48.9 (41.8, 55.1)	50.9 (44.8, 57.2)	48.3 (39.5, 54.5)
Female, n (%)	351 (17.8%)	139 (17.7%)	258 (18.4%)
African American, n (%)	666 (33.8%)	256 (32.7%)	655 (46.8%)
Hispanic, n (%)	578 (29.3%)	259 (33.0%)	298 (21.3%)

Phase 3 study of fostemsavir in heavily treatment-experienced HIV-1-infected participants: BRIGHTE week 24 subgroup analysis in randomized cohort subjects

G. Pialoux[1], M. Kozal[2], J. Aberg[3], P. Cahn[4], M. Thompson[5], J.-M. Molina[6], B. Grinsztejn[7], R. Diaz[8], A. Lazzarin[9], G. Latiff[10], M. Gummel[11], A. Pierce[12], C. Llamoso[13], M. Lataillade[13], P. Ackerman[13]
[1]Hopital Tenon, Paris, France, [2]Yale University School of Medicine, New Haven, United States, [3]Icahn School of Medicine at Mount Sinai, New York, United States, [4]Fundación Huesped, Buenos Aires, Argentina, [5]AIDS Research Consortium of Atlanta, Atlanta, United States, [6]Hôpital Saint Louis, Paris, France, [7]Instituto de Pesquisa Clínica Evandro Chagas FIOCRUZ, Rio de Janeiro, Brazil, [8]Federal University of São Paulo, São Paulo, Brazil, [9]Ospedale San Raffaele, Milan, Italy, [10]Maxwell Centre, Durban, South Africa, [11]GlaxoSmithKline, Biostatistics, Upper Providence, United States, [12]ViiV Healthcare, Clinical Development, Research Triangle Park, United States, [13]ViiV Healthcare, Clinical Development, Branford, United States

Background: The BRIGHTE study evaluates fostemsavir (FTR), a first-in-class attachment inhibitor, in HIV-1 infected heavily treatment-experienced (HTE) patients with limited treatment options (≤2 antiretroviral [ARV] classes remaining) and who are failing their current ARV therapy. Fostemsavir demonstrated superior efficacy relative to placebo (0.79 $\log_{10}$ c/mL for FTR vs 0.17 $\log_{10}$ c/mL for placebo; p< 0.0001) after 8 days of functional monotherapy.
Fifty-four percent of subjects in the Randomized Cohort (1-2 remaining ARV classes at baseline), receiving FTR plus optimized background therapy (OBT), achieved virologic suppression (HIV-1 RNA < 40 c/mL) at Week 24 (W24). The mean CD4+ T-cell count increased by 90 cells/μL from baseline at W24.
Methods: Here we present a subgroup analysis of immunologic response (observed mean change in CD4+ count at W24) and of virologic efficacy (adjusted mean change in $\log_{10}$ HIV-1 RNA at Day 8 and percent with HIV-1 RNA < 40 c/mL at W24 by snapshot algorithm) in participants within the Randomized Cohort.
Results: Increase in mean CD4+ counts at W24 was similar regardless of subgroup, including baseline CD4+ category. Participants with baseline CD4+ counts < 20 cells/μL averaged an increase of 97 cells/μL at W24, which is comparable in magnitude to mean change in all other baseline CD4+ categories. Reduction in baseline viral (VL) at Day 8 of FTR monotherapy was also similar across all subgroups. A lower virologic response rate at WK24 was observed in participants with a baseline VL ≥100,000 c/mL (38%) vs. VL < 100,000 c/mL (60%) and in participants with a baseline CD4+ < 50 cells/μL (37%) vs. CD4+ ≥50 cells/μL (63%).
Conclusions: In fostemsavir-treated HTE participants with 1 or 2 remaining ARV classes, improvement in CD4+ count through W24 was clinically significant and similar for all subgroups; including participants with very low incoming CD4+ counts at baseline (< 20 cells/μL). Virologic response at W24 was similar across subgroups except high baseline VL (≥100,000 c/mL) and low baseline CD4+ count (< 50 cells/μL); two well-recognized determinants of virologic response.

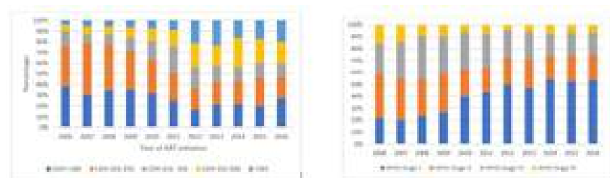
THPEB046

Impact of improved baseline immune status on early mortality after initiating anti-retroviral therapy among HIV-infected adults in Uganda

V. Ssempijja[1], E. Namulema[2], R. Ankunda[2], M. Kayiso[2], S.J. Reynolds[3,4]
[1]Leidos Biomedical Research Inc, 1. Clinical Research Directorate/Clinical Monitoring Research Program, Frederick, United States, [2]Mengo Hospital, HIV Counseling and Home Care Clinic, Kampala, Uganda, [3]Johns Hopkins University, Johns Hopkins School of Medicine, Baltimore, United States, [4]National Institutes of Health, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, Bethesda, United States

Background: In Uganda, criteria for anti-retroviral therapy (ART) initiation among HIV-infected persons has progressed from prioritizing AIDS patients with pre-ART CD4+ T-cell count (CD4) ≤200 cells/ul and/or WHO stage IV in 2004, increasing to ≤350 cells/ul in 2010, then to ≤500 cells/ul in 2013, and treating all HIV-infected persons regardless of CD4 in 2017. In addition, option B+ for pregnant mothers and ART initiation for all HIV/TB patients were adopted beginning 2011. Low CD4 count and/or AIDS defining illness are associated with higher mortality after ART initiation.
We assessed changes in baseline CD4 and WHO stage over time as ART initiation guidelines changed, and examined their impact on mortality in the first 12 months after ART initiation.
Methods: We retrospectively identified HIV-infected adults aged 18+ years who started ART between 2005 and 2014 at the urban Mengo Hospital HIV clinic. We estimated trends in mortality rates during the first 12 months after ART initiation and identified risk factors associated with mortality using cox proportional regressions methods.
Results: We identified 7314 HIV infected adults who initiated ART between 2005 to 2016, including 5101 (70%) females; the majority (45%) were aged 25-34 years. Between 2005 and 2016, median CD4 at ART initiation increased from 136 (IQR=55-250) to 274 (IQR=95-450), proportion of patients initiating ART with WHO stage III or IV significantly decreased from 42% to 26%, and mortality rates 12 months after ART initiation significantly decreased from 8.4 deaths/100 pys to 4.0 deaths/100pys. Adjusted hazard ratio of death was 0.84(0.4-1.7) in 2006 and 0.45(0.2-1.1) in 2016 when compared to 2005. Compared to clients with CD4≤100 cell/ul, clients with CD4=101-250 cells/ul had a death adjusted hazard ratio (aHR)=0.38(0.2-0.6), with CD4=251-350 cells/ul aHR=0.13(0.0-0.3), with CD4=350-500 cells/ul aHR=0.09(0.0-0.3) and with CD4≥501 cells/ul aHR=0.12(0.0-0.4).
Conclusions: Baseline immune status of patients initiated on ART has improved with time, and early mortality has reduced substantially, however a substantial proportion of HIV patients still initiate ART with CD4< 100 cells/ul, even in 2016. Strategies to implement timely ART initiation before advanced immune suppression occurs should be prioritized to reduce early mortality and improve survival.



[Distribution of baseline CD4 count and WHO stage by year of ART initiation]

Regimen simplification and switch studies

THPEB047

Durable suppression 2 years after switch to DTG+RPV 2-drug regimen: SWORD 1&2 studies

M. Aboud[1], C. Orkin[2], D. Podzamczer[3], J. Bogner[4], D. Baker[5], M.-A. Khuong-Josses[6], D. Parks[7], K. Angelis[8], L. Kahl[1], E. Blair[9], M. Underwood[9], B. Wynne[9], K. Vandermeulen[10], M. Gartland[9], K. Smith[9]
[1]ViiV Healthcare, Brentford, United Kingdom, [2]Royal London Hospital, London, United Kingdom, [3]Ciudad Sanitaria y Universitaria de Bellvitge, Barcelona, Spain, [4]Leiter der Sektion Klinische Infektiologie, Munich, Germany, [5]East Sydney Doctors, Sydney, Australia, [6]CHG - Hôpital Delafontaine, Saint Denis Cedex, France, [7]Central West Clinical Research, St Louis, United States, [8]GlaxoSmithKline, Stockley Park, United Kingdom, [9]ViiV Healthcare, Research Triangle Park, United States, [10]Janssen Pharmaceutica, Beerse, Belgium

Background: Reducing long-term cumulative toxicity becomes more important in an era of near normal life expectancy for PLWHIV. Treatment modalities that reduce long term cumulative ARV exposure in the form of 2-drug regimens (2DR) are an area of active research. At 48 weeks, efficacy of DTG+RPV as a 2DR for maintenance of virologic suppression was non-inferior to 3DRs in SWORD 1&2. Improvements in bone, renal biomarkers and neutral effects on inflammatory biomarkers were demonstrated. We summarize outcomes through week 100.
Methods: Two identical open-label, global, phase III, non-inferiority studies evaluated efficacy and safety of switching from CAR to DTG+RPV once daily in HIV-1-infected adults, with HIV-1 RNA< 50c/mL (VL< 50c/mL) for ≥6 months and no history of virologic failure. Participants were randomized 1:1 to switch immediately to DTG+RPV (Early Switch group) or continue CAR. Participants randomised to CAR with confirmed suppression at Week (Wk)48 switched to DTG+RPV at Wk52 (Late Switch group). Secondary endpoints included proportion of participants with VL< 50c/mL at Wk100 using Snapshot algorithm for ITT exposed (ITTe) population and safety evaluations.
Results: 1024 participants were randomized and exposed (DTG+RPV 513; CAR 511), across both studies. At Wk100 in the Early Switch group, 456 (89%) had VL < 50c/mL; low rate of snapshot virologic non-response was observed (3%); 6 (1.2%) participants met Confirmed Virologic Withdrawal (CVW) criterion. The Early Switch group demonstrated a stable safety profile consistent with each individual component; 34 participants (7%) experienced AEs leading to withdrawal. At Wk100 in Late Switch group, 444 (93%) had VL < 50c/mL; 2 (< 1%) participants met CVW criterion. Safety profile of the Late Switch group was comparable to the Early Switch group at Wk48 (Table 1). One participant with RPV resistance at CVW (Early Switch group, Wk100) had pre-existing NNRTI mutations at baseline. No participants developed INSTI resistance.
Conclusions: The novel once daily 2DR of DTG+RPV demonstrated durable maintenance of HIV suppression through Week 100, following switch from 3DR in virologically suppressed HIV-1-infected adults. The safety profile of DTG+RPV was consistent with their respective labels. A DTG+RPV 2DR offers potential for reduction in cumulative ARV exposure, without increased risk of virologic failure.

	Early Switch Group		Late Switch Group
Outcomes	DTG + RPV (N=513) n (%) Day 1 to Week 48	DTG + RPV (N=513) n (%) Day 1 to Week 100	DTG + RPV (N=477) n (%) Week 52 to Week 100

THPEB048

Genital HIV-1 shedding with Dolutegravir (DTG) plus Lamivudine (3TC) dual therapy

S. Gianella[1], T. Wilkin[2], B. Berzins[3], P.E. Sax[4], C. Moser[4], V. Marconi[5], C.J. Fichtenbaum[6], C.A. Benson[1], M. Vargas[1], M.F. Oliveira[1], B.O. Taiwo[3]
[1]*University of California San Diego, La Jolla, United States,* [2]*Weill Cornell Medicine, New York, United States,* [3]*Northwestern University, Chicago, United States,* [4]*Harvard Medical School, Boston, United States,* [5]*Emory University, Atlanta, United States,* [6]*University of Cincinnati Medical Center, Cincinnati, United States*

Background: Antiretroviral therapy (ART) suppresses HIV RNA and prevents viral transmission. Genital HIV RNA shedding occurs in 2-20% of individuals on standard 3-drug ART. The incidence of genital HIV RNA shedding with the novel two-drug regimen of DTG+3TC is unknown.
Methods: Virologically suppressed participants randomized to either arm of the ASPIRE study (switch to DTG+3TC versus continue standard 3-drug ART) and ART-naïve participants who initiated DTG+3TC in the single-arm ACTG A5353 study were eligible for this genital substudy. Participants provided genital samples (semen or vaginal swabs) at week 24 and/or later timepoints through 48 weeks after study initiation to quantify genital HIV RNA, herpes simplex virus (HSV) and cytomegalovirus (CMV) DNA by real-time PCR. HIV genotyping and urine analysis for Gonorrhea and Chlamydia were performed in genital HIV shedders. Plasma HIV RNA results were obtained from parent studies.
Results: Fifty-one participants (ASPIRE DTG+3TC arm (N=16); ASPIRE 3-drug ART arm (N=22); and A5353 (N=13)) contributed 90 samples (77 semen, 13 vaginal swabs) at weeks 24-36 (N=41) and 48 (N=49). Median (range) time on ART before ASPIRE entry was 5.8 (1.3-17.6) years, and the pre-randomization regimens included a protease inhibitor (32%), non-nucleoside reverse transcriptase (RT) inhibitor (26%) or integrase inhibitor (42%). HIV RNA was not detected in any of the vaginal swabs.
During the 48 weeks of follow-up, three participants had seminal HIV shedding: 1/22 (4.5% [95%CI:0.1%,22.8%]) in the ASPIRE 3-drug ART arm, 1/16 (6.3% [0.2,30.2]) in the ASPIRE DTG+3TC arm and 1/13 (7.7% [0.2,36.3]) in the A5353 study (table 1).
For participant #2, no integrase drug-resistance mutation was detected in seminal HIV RNA (RT sequencing unsuccessful). Genital HSV and bacterial infection were not detected in the three participants with seminal HIV RNA shedding, while high CMV levels were detected in participant #2 at both assayed time-points.
Overall, genital CMV was detected in 17/51 (33%) and HSV was detected in 5/51 (9.8%) participants.
Conclusions: In this study, we detected genital HIV RNA shedding in virologically suppressed individuals who switched to DTG+3TC and ART-naïve participants treated with DTG+3TC at similar rates as 3-drug ART. Dual-drug regimen appears to be safe to use but more testing is needed.

PID	Parent Study	Study week	ART regimen	Genital HIV RNA (copies/ml)	Plasma HIV RNA (copies/ml)	CMV DNA (copies/ml)	HSV DNA (copies/ml)	Gonorrhea RNA	Chlamydia RNA
1	ASPIRE	48	RPV, TDF, FTC	42	179	Not detected	Not detected	Not detected	Not detected

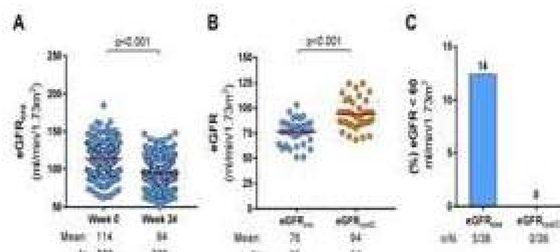
THPEB049

Renal function after switching to dolutegravir in an acute HIV cohort in Thailand

C. Sacdalan[1], C. Austin[2], S. Pinyakorn[3,4], E. Kroon[1], D. Colby[1], P. Chan[1], O. Goh[1], J. Intasan[1], T. Luekasemsuk[1], M. Robb[3,4], N. Chomchey[1], N. Phanuphak[1], J. Ananworanich[1,4,5], SEARCH010/RV254 Study Group
[1]*The Thai Red Cross AIDS Research Centre, SEARCH, Bangkok, Thailand,* [2]*Washington University School of Medicine at St. Louis, St. Louis, United States,* [3]*The Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States,* [4]*United States Military HIV Research Program, WRAIR, Silver Spring, United States,* [5]*University of Amsterdam, Department of Global Health, Amsterdam, Netherlands*

Background: There are limited data on dolutegravir-based antiretroviral therapy (ART) from Asia. Dolutegravir (DTG) prescribing information reports a 9% decrease in estimated renal function on people taking DTG 50mg once a day. DTG inhibits organic cation transporter 2 leading to elevated creatinine and reduced estimated glomerular filtration rate ($eGFR_{cre}$), but does not affect cystatin C ($eGFR_{cystC}$). We describe changes in $eGFR_{cre}$ after switching to DTG in an Asian cohort, and $eGFR_{cystC}$ in those with low $eGFR_{cre}$.
Methods: Participants in the SEARCH010/RV254 cohort who had started ART during acute HIV infection (AHI) were switched to DTG and had $eGFR_{cre}$ pre- and 24 weeks post-switch. $eGFR_{cre}$ was calculated using the MDRD equation adjusted for Thais. Those with grade 3 low $eGFR_{cre}$ (< 60 ml/min/1.73m^2 or decrease of >30%) using DAIDS adverse event grading table were tested by $eGFR_{cystC}$. Paired t-test and McNemar's exact test were used to compare continuous and binary variables respectively.
Results: 328 AHI participants were included. At time of DTG switch, most participants were on efavirenz (>95%) with median (IQR) ART duration of 124 (71-195) weeks, CD4 of 640 (523-729) cells/mm^3 and 307/328 (94%) had VL< 50 copies/ml. Mean $eGFR_{cre}$ significantly decreased by 17% from 114 to 94.2 ml/min/1.73m^2 24 weeks after switching to DTG (p< 0.001) (Figure1A).
Thirty-six (11%) of 328 participants had grade 3 $eGFR_{cre}$ decline at 24 weeks post-switch. Mean renal function as measured by $eGFR_{cystC}$ was in the normal range for all participants and was significantly higher than $eGFR_{cre}$ (p< 0.001) (Figure1B). Furthermore, eGFR < 60 ml/min/1.73m^2 was observed in 5/36 using $eGFR_{cre}$ but in none when measured by GFR_{cystC} (Figure 1C).
Conclusions: In this cohort of predominantly young Thai MSM, estimated renal function by $eGFR_{cre}$ decreased greater than stated in prescribing information. Low eGFR 24 weeks after switching to DTG was common when calculated by serum creatinine but was not observed with cystatin C measurements, indicating no true renal function deterioration. Therefore, the use of cystatin C for those with marked $eGFR_{cre}$ declines might be of clinical importance in evaluating renal function in Asian individuals taking DTG and in mitigating unnecessary ART modifications.



[Figure 1A. $eGFR_{cre}$ pre and 24 weeks post DTG switch, 1B. Comparison of $eGFR_{cre}$ and $eGFR_{cystC}$ 24 weeks after DTG switch, 1C. Participants with eGFR <60 24 weeks after (DTG) switch using $eGFR_{cre}$ and $eGFR_{cystC}$]

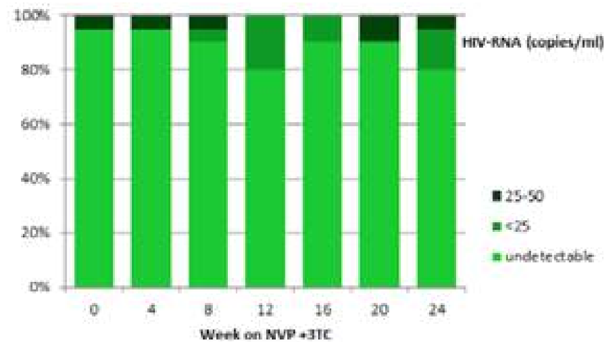
Nevirapine plus Lamivudine maintain HIV-1 suppression through week 24

C.R. Kahlert[1,2], M. Cipriani[1], P. Schmid[1], P. Vernazza[1]
[1]Cantonal Hospital St. Gallen, Clinic for Infectious Diseases & Hospital Epidemiology, St. Gallen, Switzerland, [2]Children's Hospital of Eastern Switzerland, Infectious Diseases and Hospital Epidemiology, St. Gallen, Switzerland

Background: Simplification of HIV maintenance therapy may reduce adverse events and cost. The effect of boosted protease-inhibitor monotherapy is limited as shown by increased rates of viral blips and HIV-RNA detection in cerebrospinal fluids, most likely due to insufficient compartment penetration. For 80% of the patients with no hypersensitivity reaction at treatment initiation, Nevirapine (NVP) is characterized by an excellent long-term tolerance. For this single center pilot study we hypothesized, that a combination of NVP and Lamivudine (3TC), two active compounds with excellent compartment activity may provide an optimal HIV maintenance therapy. The aim of this pilot study is testing feasibility and efficacy of this strategy before evaluation in a larger trial.
Methods: Patients with fully suppressed HIV plasma viral load (pVL) >24 months whereof >6 months on a NVP containing regimen and without previous failure of any non-nucleoside reverse transcriptase inhibitor regimen were switched to NVP and 3TC. HIV pVL was monitored monthly until week 24. The primary outcome was confirmed viral failure (RNA >100 copies/ml). The frequency of low level detection of HIV- RNA in plasma (< 20, 20-50, >50 cp/ml) was compared in each patient with pre-study viral load measurements.
Results: Twenty patients (15 male) were included and reached week 24. After a total of 480 observation weeks, none of the 20 patients experienced HIV pVL >50 copies/ml (figure 1).



[Figure 1. Frequency of low HIV-RNA detection w0-w24]

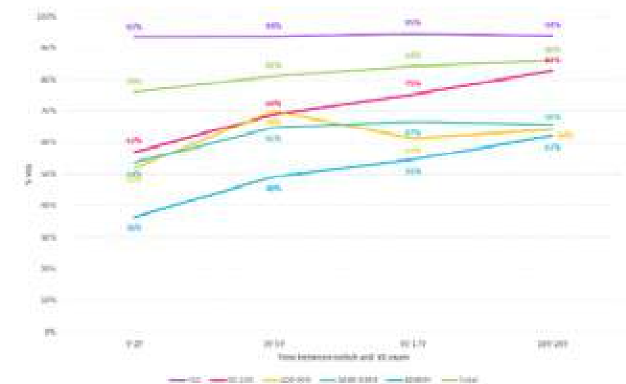
The frequency of low level HIV-RNA detection < 20 copies/ml (10/120) and 20-50 copies/ml (5/120) was not different from the period before randomization.
Conclusions: Our findings do not falsify the study hypothesis. This indicates that dual-treatment with NVP and 3TC warrants further evaluation as a potentially interesting maintenance strategy. A properly sized study to investigate non-inferiority of NVP/3TC bi-therapy to standard triple therapy is planned. If successful, this would result in a maintenance strategy with significant benefits in cost and reduced long-term side effects.

THPEB051

Virological monitor of the switch from RAL-containing to DTG-containing regimens in Brazil: Data from a real-world cohort

G. Mosimann Júnior[1], A.R. Pati Pascom[2], F. Rick[2], F. Barros Perini[2], M. Veloso[2], A. Benzaken[2], F. Fernandes Fonseca[3]
[1]MOH Brazil, HIV Department, Brasilia, Brazil, [2]MOH Brazil, Brasilia, Brazil, [3]MOH Brazil, HIV, STI, Viral Hepatitis, Brasilia, Brazil

Background: In January 2017, Brazilian MoH recommended switch to Dolutegravir-containing (DTG-C) from Raltegravir- containing (RAL-C) regimens for cases of people living with HIV (PLWHIV).
This study aimed to assess virological effectiveness of switch from RAL-C to DTG-C regimens in a real life cohort from Brazilian public health system and to investigate factors associated with viral load suppression (VLS) after the switch.
Methods: We used programmatic individual-level information on viral load (VL), CD4 and antiretroviral therapy (ART) from PLWHIV, aged 18+, with RAL-C regimen who switched to DTG-C, in 2017. We assessed VLS comparing VL up to one year after the switch and time between the switch and VL from zero to 270 days. Furthermore, was conducted uni and multivariable logistic regression to assess the association of demographics and clinical factors with VLS, among those who presented at least one VL done after switch.
Results: A total of 8,790 PLWHIV presented previous VL up to one year before the switch, and of those 5,970 regimen presented previous VL up to one year before the switch and have a VL measure at least one month after the switch and were included in the analysis. Overall, median age of 49yo (IQR=14), 62% men; 42% non-black; and median of 10 years on ART. Among those who switched with VL< 50 copies/mL, 94% maintained VLS during follow-up period. The longer the time using DTG-C regimen, the higher VLS rates, even among those who switched with higher pre-switch VL (Figure 1).
Despite the association observed in the univariate analysis for all variables, the multivariable analysis showed the following variables were positively associated with VLS: increasing age (60+ aOR 3.3 95%CI=2.47-4.49, compared with 15-24); non-black race/color (aOR 1.36 95%CI=1.17-1.58, compared with black); and high CD4 at baseline (500+ aOR 6.65 95%CI=5.32-8.39, compared with < 100).
Conclusions: DTG-C regimen showed early VLS at switch on those with detectable VL and VLS was maintained on those with undetectable pre-switch VL. Hence, DTG- C is an effective choice for switch on PLWHIV using RAL-C regimen. Finally, this switch might be reproduced in other low middle-income settings.



[Percentage (%) of PLWHIV aged 18+ with viral load suppression after the switch from RAL-containing to DTG-containing regimens according to the time (i)]

THPEB052

Uptake and effectiveness of two-drug compared to three-drug antiretroviral regimens among HIV-positive individuals in Europe

A. Pelchen-Matthews[1], B. Neesgaard[2], on behalf of the EuroSIDA Study in RESPOND
[1]University College London, Centre for Clinical Research, Epidemiology, Modelling and Evaluation (CREME), Institute for Global Health, London, United Kingdom, [2]University of Copenhagen, CHIP, Department of Infectious Diseases, Copenhagen, Denmark

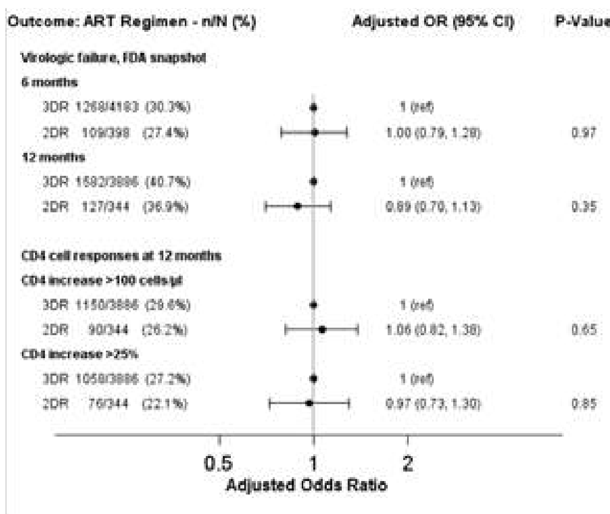
Background: Although two-drug antiretroviral regimens (2DR) have been assessed in several randomized controlled trials, there is little information on uptake and outcomes of these regimens in routine clinical practice.
Methods: Logistic regression was used to analyse the uptake and outcomes among persons in the EuroSIDA cohort who started a 2DR with a boosted protease inhibitor (bPI), integrase inhibitor (INSTI) or bPI+INSTI,

compared to those on a 3-drug regimen (3DR) with one of these antiretrovirals (ARVs) between 1/7/2010 and 31/12/2016. Virologic failure was defined using the FDA snapshot algorithm at 6 or 12 months after starting (treatment failure: viral load (VL) ≥400 copies/ml or no VL at 6 or 12 months ±16 weeks, change of ARV regimen, AIDS or death). Immunologic response was defined as a 100 cell/µl increase in CD4 count at 12 months ±16 weeks in those with available data.

Results: 423 (9%, 8 ARV-naïve) individuals started a 2DR and 4347 (91%, 566 ARV-naïve) started 3DR. Compared to those starting 3DR, those on 2DR tended to be older (median age 52 (IQR 46, 58) versus 46 (38, 53)), have higher CD4 counts (median 552 (381, 788) versus 536 (341, 743) cells/µl) and controlled VL(< 400 copies/ml, 87.5% versus 74.4%). 98% of those on 2DR were treatment-experienced, with higher cumulative exposure to all the main ARV classes. Those on 2DR also had higher levels of comorbidities including diabetes, cardiovascular disease, liver-related events and chronic kidney disease(p< 0.001 for all).

After adjustment, there was no significant difference in the odds of virologic failure comparing 2DR and 3DR at 6 or 12 months (adjusted odds ratio [aOR] 1.00 (95% CI 0.79-1.28) and 0.89 (0.70-1.13) respectively; Figure). Likewise, there were no differences in the odds of immunologic response at 12 months (aOR 1.06 (0.82-1.38)). Similar results were seen when immunologic response was defined as a 25% increase in CD4 counts (Figure).

Conclusions: 2DR were largely used by individuals with well-controlled viremia and high CD4 counts. Virologic and immunologic outcomes were in line with results from clinical trials and suggest immunologic and virologic responses to 2DR were similar to 3DR, although confounding by indication cannot be excluded.



Proportions of individuals failing the FDA snapshot or with improved CD4 cell counts (n) as a fraction of all participants in EuroSIDA on 2DR or 3DR ART (N), and odds ratios (OR) for virologic failure or CD4 cell response, adjusted for age group (<50 or ≥50 years), gender, race (Caucasian vs. other), region of Europe (South, Central, North or East), HIV risk group (MSM, intravenous drug user, heterosexual contact or other), recent HIV diagnosis (prior 2 years), baseline CD4 cell counts (<200, 200-350, 350-500 or ≥500 cells/µl), baseline viral load (<400 or ≥400 RNA copies/ml), prior ART (vs. treatment naive), liver-related events and chronic kidney disease.

[Figure: Virologic failure and immunologic responses for individuals on 2DR versus 3DR ART]

THPEB053

Immediate vs. deferred switching from a boosted Protease Inhibitor (PI/r) to Dolutegravir (DTG) suppressed patients with high cardiovascular risk or age ≥50 years: Final 96 weeks results of NEAT 022

J.M. Gatell[1], L. Assoumou[2], G. Moyle[3], L. Waters[4], M. Johnson[5], P. Domingo[6], J. Fox[7], E. Martinez[8], H.-J. Stellbrink[9], G. Guaraldi[10], M. Masia[11], M. Gompels[12], S. de Wit[13], E. Florence[14], S. Esser[15], F. Raffi[16], A. Pozniak[3], on Behalf of NEAT 022 Study Group

[1]Hospital Clinic. University of Barcelona, Infectious Diseases, Barcelona, Spain, [2]INSERM. UPMC, Institute Pierre Louis, Paris, France, [3]Chelsea & Westminster Hospital, London, United Kingdom, [4]Mortimer Market Center, London, United Kingdom, [5]Royal Free Hospital, London, United Kingdom, [6]Hospital de Sant Pau, Barcelona, Spain, [7]Guys and St Thomas Hospital, London, United Kingdom, [8]Hospital Clinic. University of Barcelona, Barcelona, Spain, [9]ICH Study Centrum, Hamburg, Germany, [10]University of Modena, Modena, Italy, [11]Hospital de Elche, Elche, Spain, [12]Southmead Hospital, Bristol, United Kingdom, [13]St. Pierre Hospital, Brussels, Belgium, [14]Institute of Tropical Medicine, Antwerp, Belgium, [15]Universitatklinikum, Essen, Germany, [16]University Hospital de Nantes, Nates, France

Background: Switching from a PI/r to DTG may improve convenience, lipids and cardiovascular risk.

Methods: NEAT022-NCT02098837 is a European, open label, randomized, non-inferiority trial. Adults ≥ 50 years or with Framingham score ≥10% were eligible if HIV RNA < 50 copies/mL for at least 24 weeks. Patients were randomized (1:1) to switch the PI/r component to DTG immediately (DTG-I) or to deferred switch at week 48 (DTG-D) . Week 96 end-points were: proportion of patients with HIV RNA < 50 copies/ml, percentage change of total plasma cholesterol and other lipid fractions and adverse events.

Results: 415 patients were randomized: 205 to DTG-I and 210 to continue PI/r plus a deferred switch (DTG-D) at week 48 . 89% were men, 87 % were ≥50 years, 74 % had a baseline Framingham score >10%, and suppressed viremia for a median of 5 years. At week 96, in the ITT analysis, treatment success rate was 92.2 % in DTG-I arm and 87% in DTG-D arm (difference 5.2%, 95%CI -0.6 to 11, non-inferiority demonstrated). There were 5 virological failures in the DTG-I arm (range 51 to 130 copies/mL) and 5 (1 while on PI/r and 4 after switching to DTG) in the DTG-D arm (range 64 to 3373 copies/mL) without selection of resistance. There was no significant difference in terms of grade 3 or 4 AE´s or treatment modifying AE´s (8 in DTG-I arm - 6 were due to mood disturbances or insomnia- and 12 in the DTG-D arm of whom 9 occurred after switching to DTG with 7 of the 9 due to mood disturbances or insomnia). Total cholesterol and other lipid fractions (except HDL) significantly (p< 0.001) improved both after immediate and deferred switching to DTG overall (See Fig 1) and regardless of baseline PI/r strata. Between 30% and 34% were on lipid lowering agents at weeks 0, 48 and 96 in both arms.

Conclusions: Both immediate and deferred switching from a PI/r to a DTG regimen in suppressed HIV patients ≥ 50 years old or with a Framingham score ≥10% was highly efficacious, well tolerated and significantly improved the lipid profile.

THPEB054

Switching tenofovir/emtricitabine/efavirenz (TDF/FTC/EFV) to TDF/FTC/rilpivirine (RPV) versus continuing TDF/FTC/EFV in HIV-infected patients with complete virological suppression: A randomized controlled trial

S. Wiriyatanakorn[1], S. Sungkanuparph[2]
[1]Ramathibodi Hospital, Mahidol University, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, [2]Chakri Naruebodindra Medical Institute, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Samut Prakan, Thailand

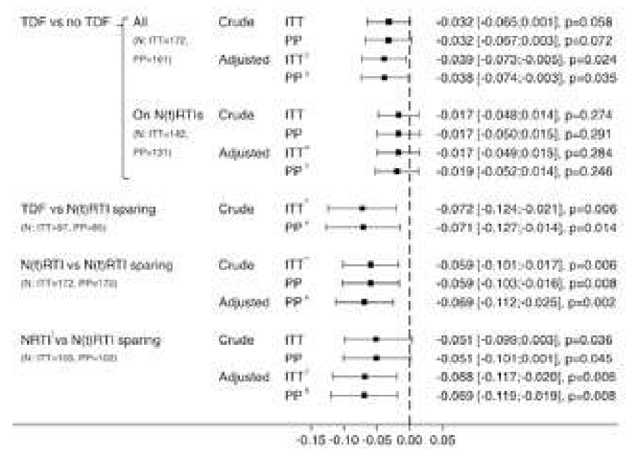
Background: Tenofovir/emtricitabine/efavirenz (TDF/FTC/EFV) is currently recommended as the preferred first-line antiretroviral therapy (ART) in resource-limited countries. Central nervous system (CNS) side effects and dyslipidemia are commonly associated with EFV use. Rilpivirine (RPV) has shown non-inferiority to EFV in treatment-naïve patients. This study aimed to compare the efficacy and adverse effects between switching from TDF/FTC/EFV to TDF/FTC/RPV and continuing TDF/FTC/EFV in patients with complete viral suppression.
Methods: A randomized controlled non-inferiority trial was conducted in HIV-infected patients currently on TDF/FTC/EFV with undetectable HIV RNA (< 50 copies/ml). Patients were randomized to switch from TDF/FTC/EFV to TDF/FTC/RPV (Group A) or continue TDF/FTC/EFV (Group B), and were followed up for 24 weeks. The primary endpoint was the proportion of patients with undetectable HIV RNA (non-inferiority margin of 12%). Changes in CD4 cell count, lipid profiles, and adverse events were also analyzed. (ClinicalTrials.gov NCT03251690)
Results: 246 patients were enrolled, 124 in Group A and 122 in Group B. Mean age was 44.6 years and 63.0% were males. Mean baseline CD4 cell count was 565 cells/mm³. Baseline characteristics including age, sex, CD4 cell count, lipid profiles, duration of ART and CNS side effects between the two groups were similar (p>0.05). Mean baseline values for total cholesterol (TC), LDL, HDL, and triglycerides (TG) were 196, 117, 47, and 148 mg/dl, respectively. At 24 weeks, 95.9% of patients in Group A and 97.6% of Group B had maintained HIV RNA < 50 copies/ml (difference -1.68%; 95%CI, -7.06 to 3.35), showing non-inferiority of switching to TDF/FTC/RPV. Mean CD4 cell count was 564 and 581 cells/mm³ in Group A and B, respectively (p=0.604). Mean change in lipid profiles (Group A vs B) were: TC, -22.4 vs -1.8; HDL, -4.2 vs +0.5; LDL, -6.4 vs +3.2; and TG, -29.4 vs +0.3 mg/dl (all p< 0.05). CNS side effects persisted in 0% and 6.5% of patients in group A and B, respectively (p< 0.001).
Conclusions: Switching TDF/FTC/EFV to TDF/FTC/RPV is non-inferior to continuing TDF/FTC/EFV in maintaining viral suppression at 24 weeks, and provides better lipid profiles and CNS side effects. Switching to TDF/FTC/RPV should be considered in HIV-infected patients on TDF/FTC/EFV with complete viral suppression.

THPEB055

Antiretroviral treatment maintenance strategies and blood telomere length change

R. Montejano[1], N. Stella-Ascariz[1], S. Monge[1], J.I. Bernardino[1], I. Pérez-Valero[1], M. Montes[1], L. Martín-Carbonero[1], J. González-García[1], J. Rodriguez-Centeno[1], B. Rodes[1], B. Alejos[2], R. de Miguel[1], A. Esteban-Cantos[1], R. Perona[3], J. Arribas[1]
[1]Hospital La Paz Institute for Health Research, Madrid, Spain, [2]Institute of Health Carlos III, Madrid, Spain, [3]Institute of Biomed Research Alberto Sols, Madrid, Spain

Background: We have evaluated the impact of Nucleoside Reverse Transcriptase Inhibitors (NRTI) and/or tenofovir disoproxil fumarate [N(t)RTIs] on blood telomere length (TL) in aviremic HIV infected persons.
Methods: Prospective cohort of HIV-1 infected participants with suppressed virological replication on a stable antiretroviral treatment for at least one year, comparing participants with current exposure to tenofovir disoproxil fumarate (TDF group) versus those never exposed to TDF (non TDF group) and receiving other antiretrovirals [NRTI containing and N(t)RTI sparing]. TL was measured in whole blood by monochrome quantitative multiplex PCR. We estimated change in TL during follow-up (both by intention to treat and by per protocol analysis) using a multivariable estimative linear regression adjusted by baseline TL and significant confounders and a predictive model to identify independent predictors.
Results: 172 participants: 67 in the TDF-group (64 TDF/FTC, 2TDF-3TC, 1 TDF-FTC-D4T) and 105 in the non-TDF group [75 receiving NRTI (71 ABC, 3 AZT, 1 ddI, 74 3TC), 30 receiving N(t)RTI sparing (25 without any N(t)RTI and 5 with 3TC as the only N(t)RTI]. Mean baseline age, % of females, years since HIV diagnosis, CD4 and years with viral load ∠ 50 copies/mL (TDF/non-TDF): 49/50, 30/25,18/16, 744/846, 7.2/6.7 After two years of follow-up mean TL increased 0.042 units in the whole cohort (p = 0.030). The N(t)RTI group had significantly smaller gains in TL than the N(t)RTIs sparing group. The TDF group had significantly smaller gains in TL than the non-TDF group and the N(t)RTI sparing group. The NRTI group had significantly smaller gains in TL than the the N(t)RTIs sparing group. When analysis was restricted to participants receiving N(t)RTIs, TDF exposure was not associated with an independent negative effect (Figure). In the predictive model, factors significantly associated with blood TL changes were N(t)RTIs at baseline (difference -0.070, p=0.001) female gender (0.042, p=0.019), and time since HIV diagnosis (-0.018 , p=0.006)
Conclusions: Our results reflect in vivo the in vitro inhibitory capacity of TDF and abacavir upon telomerase. After two years, N(t)RTI sparing ART, compared to TDF and/or abacavir containing ART, had greater gains in blood TL suggesting enhanced recovery from immunosenescence.



[Mean difference in TL (adjusted by baseline telomere length) after two years]

THPEB056

Efficacy and safety of switching from boosted protease inhibitor-based regimens to darunavir/cobicistat/emtricitabine/tenofovir alafenamide for treatment of HIV-1 infection: Subgroups analysis by baseline regimen

P.-M. Girard[1], G. Huhn[2], E. DeJesus[3], D. Luo[4], R. Petrovic[5], K. Brown[6], E.Y. Wong[6]
[1]University Pierre and Marie Curie, Paris, France, [2]The Ruth M. Rothstein CORE Center, Chicago, United States, [3]Orlando Immunology Center, Orlando, United States, [4]Janssen Research & Development, LLC, Titusville, United States, [5]Janssen Research & Development, Beerse, Belgium, [6]Janssen Scientific Affairs, LLC, Titusville, United States

Background: Darunavir/cobicistat/emtricitabine/tenofovir alafenamide (D/C/F/TAF) 800/150/200/10 mg is a once-daily, single-tablet regimen approved in Europe and under regulatory review in the US for the treatment of HIV-1 infection. In the pivotal EMERALD trial of HIV-1-infected adults, switching to D/C/F/TAF led to non-inferior cumulative virologic rebound at Week 48 compared to continuing use of a boosted protease inhibitor (bPI)+emtricitabine/tenofovir disoproxil fumarate (control); favorable renal/bone safety was seen with D/C/F/TAF versus control. Results were consistent across age, gender, and race subgroups. Here we report Week 48 results in subgroups based on baseline bPI and boosting agent.

Methods: The phase 3, randomized (2:1), non-inferiority EMERALD trial enrolled treatment-experienced, virologically suppressed HIV-1-infected adults with viral load (VL) < 50 copies/mL for ≥2 months (one 50≤VL< 200 copies/mL allowed in prior 12 months). Previous non-darunavir virologic failure was allowed. The primary endpoint was proportion of patients with virologic rebound (confirmed VL ≥50 copies/mL or premature discontinuation with last VL ≥50 copies/mL) cumulative through Week 48. Virologic response was VL < 50 copies/mL (FDA snapshot). Safety was assessed by adverse events (AEs). Results were evaluated in subgroups based on bPI (darunavir [with ritonavir or cobicistat] vs atazanavir [with ritonavir or cobicistat] or lopinavir [with ritonavir]) and boosting agent (ritonavir vs cobicistat) used at baseline.

Results: A total of 1141 patients were randomized and treated. At screening, use of darunavir (70% of patients) was more common than atazanavir or lopinavir (30% combined), and boosting with ritonavir (85%) was more common than cobicistat (15%). In the overall population, similar rates of virologic rebound (2.5% vs 2.1%, respectively) and virologic response (94.9% vs 93.7%) were seen with D/C/F/TAF and control; results were consistent across subgroups based on bPI and boosting agent used at screening (**Table**). No patients developed resistance to study drugs. The incidence of serious AEs, grade 3-4 AEs, and AE-related discontinuations were generally similar for D/C/F/TAF and control overall and across subgroups.

Conclusions: Virologically suppressed, treatment-experienced HIV-1-infected adults who switched to D/C/F/TAF had low, non-inferior cumulative virologic rebound rates versus continuation of prior therapy. Efficacy and safety results were similar between D/C/F/TAF and control regardless of baseline bPI and boosting agent used.

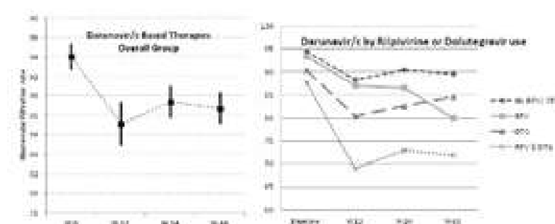
Background: Ritonavir-boosted protease inhibitors such as lopinavir or atazanavir have been associated with a greater decrease in estimated glomerular filtration rate (eGFR) than that of darunavir (DRV). Cobicistat (c) is known to affect tubular creatinine secretion and hence eGFR. Data on the impact of DRV/c on eGFR is scarcely known.

Methods: Nation-wide retrospective cohort study of consecutive HIV-infected patients initiating DRV/c from June/2014 to March/2017. The eGFR was calculated with CKD-EPI in mL/min/1.73m2,baseline values and trend over time were described. The relationship between eGFR change over time and different HIV patient´s characteristics, socio-demographics, HIV severity, antiretroviraltreatment -ARV-, and concomitant medication other than ARV was explored through univariate and multivariate analyses. Ethics approval was obtained and patients signed informed consent.

Results: There were 761 patients (85% men, 91% Caucasian, 99% antiretroviral experienced, 34% HCV coinfected, 80% prior DRV/ritonavir, 32% prior AIDS, 84% HIV RNA < 50 copies/mL, 88% ≥200 CD4/mm3) from 21 Spanish HIV Units initiating DRV/c. Thirty-six (5%) patients were excluded due to the lack of eGFR data. Baseline (mean ±SD) eGFR was 94±19 and 4.83% had eFGR below 60 increasing to 8.47% at 48 week, while only 6/761 (0.8%) switched DRV/c therapy due to renal adverse event. Younger age and black ethnicity were independently associated with a better eGFR at baseline. Overall eGFR changes over time and by other drugs known to affect tubular creatinine are shown in the figure A and B respectively. Significant low level eFGR decreases were observed at 12, 24, and 48 weeks, up to 5.01. Concomitant therapy, with either rilpivirine or dolutegravir or both, led to higher not significant decreases of eGFR. After adjusting for other covariates, only RPV (n=21) led to a significant greater decreases of eGFR (mean ±SD) at 48 weeks than having not (n=463) (-11±11 vs. -5±13, P=0.021). Male gender and being treated with concomitant drugs other than antiretroviral therapy were independently associated with greater eGFR decreases at 48 weeks.

Conclusions: Initiation of DRV/c had an initial impact decreasing eGFR followed by a plateau. Male gender and having concomitant drugs other than antiretroviral therapy were associated with worse eGFR at 48 weeks.



[Fig A Overall eFGR, B eFGR according to ARV regimen]

THPEB058

Switching protease inhibitors to rilpivirine in HIV-infected patients with complete viral suppression and without prior HIV drug resistance: A randomized controlled trial

K. Palanuphap[1], S. Sungkanuparph[2]
[1]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, [2]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Chakri Naruebodindra Medical Institute, Samut Prakan, Thailand

Background: Prior to the availability of rilpivirine (RPV), patients who could not tolerate efavirenz and nevirapine were treated with ritonavir-boosted protease inhibitor (PI)-based antiretroviral therapy (ART). Dyslipidemia and other metabolic complications are commonly associated with PI use. RPV could be an alternative for switching therapy in this population.
Methods: A randomized controlled non-inferiority trial was conducted in HIV-infected patients receiving ritonavir-boosted PI-based regimens with undetectable HIV RNA (< 50 copies/ml) and without prior HIV drug resistance. Patients were randomized to switch from PIs to RPV (Switch Group) or continue ritonavir-boosted PI (Control Group). Primary endpoint was the proportion of patients with undetectable HIV RNA at 48 weeks, with a non-inferiority margin of 12%. Changes in CD4 cell count, lipid profiles, and adverse events were also analyzed.
Results: A total of 84 patients were enrolled, 42 in each group. Mean age was 47.7 years and 53.6% were males. Mean baseline CD4 was 609 cells/mm³. Baseline characteristics including age, gender, body weight, duration of ART, distribution of NRTI and PIs used, CD4, lipid profiles, glucose, alanine transaminase (ALT) and estimated glomerular filtration rate (eGFR) between two groups were similar (p> 0.05).
At 48 weeks, 95.2% of patients in Switch Group and 93.9% of Control Group had maintained undetectable HIV RNA (difference rate 2.4%; 95% CI, -9.6 to 14.7), showing non-inferiority of Switch Group. Mean CD4 was 611 and 641 cells/mm³ in Switch and Control Group, respectively (p=0.632). Mean change in lipid profiles (Switch vs Control Group) were: TG, -78.3 vs -29.5 (p=0.049); TC, -2.5 vs +4.8 (p=0.038); HDL, +2.7 vs +1.7 (p=0.574); and LDL, +4.0 vs +5.0 (p=0.703) mg/dl. Mean change of glucose and eGFR were similar (p> 0.05) between two groups.
Mean change of ALT was significantly greater in Switch Group (18.2 vs 4.0 U/L, p=0.017). One patient in Switch Group had clinical hepatitis at 14 weeks and got complete recovery after RPV discontinuation.
Conclusions: Switching PIs to RPV in patients without HIV drug resistance is non-inferior to continuing ritonavir-boosted PI in maintaining viral suppression at 48 weeks, and results in better triglycerides and total cholesterol. Close monitoring of liver function after switching is recommended.

Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring

THPEB059

Antiretroviral adverse drug reactions pharmacovigilance in Harare City, Zimbabwe 2017

H.D. Mugauri[1], O. Mugurungi[2], T. Juru[3], N. Gombe[3], M. Tshimanga[4]
[1]Min of Health Zimababwe, AIDS and TB Unit, Bulawayo, Zimbabwe, [2]Min of Health Zimababwe, AIDS and TB Unit, Harare, Zimbabwe, [3]Zimbabwe FETP, Harare, Zimbabwe, [4]University of Zimbabwe, Community Medicine, Harare, Zimbabwe

Background: Key to pharmacovigilance is spontaneously reporting all Adverse Drug Reactions (ADR) during post-market surveillance. This facilitates identification and evaluation of previously unreported ADR's, acknowledging the trade-off between benefits and potential harm of medications. Only 41% ADR's documented in Harare city clinical records for January to December 2016 were reported to Medicines Control Authority of Zimbabwe (MCAZ). We investigated reasons contributing to underreporting of ADR's in Harare city.
Methods: A descriptive cross-sectional study and Centers for Disease Control (CDC) guided surveillance evaluation was conducted. Two hospitals were purposively included. Seventeen health facilities and 52 health workers were randomly selected. Interviewer-administered questionnaires, key informant interviews and WHO pharmacovigilance checklists were used to collect data. Likert scales were applied to draw inferences and Epi info 7 used to generate frequencies and proportions.
Results: Of the 52 participants, 32 (61.5%) distinguished the ADR defining criteria. Twenty-nine (55.8%) knew system's purpose whilst 28 (53.8%) knew the reporting process. Knowledge scored average on the 5-point-Likert scale. Thirty-eight (73.1%) participants identified ADR's following client complaints and nine (1.3%) enquired clients' medication response. Forty-six (88.5%) cited non-feedback from MCAZ for underreporting. Inadequate ADR identification skills were cited by 21 (40.4%) participants. Reporting forms were available in five (26.3%) facilities and reports were generated from hospitals only. Forty-two (90.6%) clinicians made therapeutic decisions from ADR's. Averaged usefulness score was 4, on the 5-point-Likert scale. All 642 generated signals were committed to Vigiflow by MCAZ, reflecting a case detection rate of 4/ 100 000. Data quality was 0.75-1.0 (WHO) and all reports were causally assessed.
Conclusions: The pharmacovigilance system was useful, simple, and acceptable despite being unstable, not representative and not sensitive. It was threatened by suboptimal health worker knowledge, weak detection strategies and referral policy preventing ADR identification by person place and time. Revisiting local policy, advocacy, communication and health worker orientation might improve pharmacovigilance performance in Harare city.

THPEB060

Single-dose fed bioequivalence study of Emtricitabine, Tenofovir Alafenamide and Dolutegravir Tablets (200mg/25mg/50mg) versus DESCOVY® tablets (200mg/25mg; Gilead Sciences) and TIVICAY® tablets (50mg; ViiV Healthcare) in healthy adult volunteers

D. Abhijit[1], C. Santanu[1], R. Chetan[1], G. Sachin[1], R. Bangaru[2], A.K. Datla[2], P. Deshpande[3], A. Kanda[3], E. Patras[3]
[1]Mylan Laboratories Limited, R&D, Hyderabad, India, [2]Mylan Laboratories Limited, Clinical Research Center, Hyderabad, India, [3]Mylan Laboratories Limited, Business Development, Hyderabad, India

Background: The combination of Dolutegravir (DTG) with the fixed dose combination (FDC) of emtricitabine (FTC) and tenofovir alafenamide (TAF) is one of the most frequently used recommended combinations for the treatment of HIV in high-income countries. WHO and several national guidelines recommend DTG as an alternative first- and third-line. The use of TAF is currently not recommended by WHO, also due to open questions on dosing in TB co-infection and pregnancy, however the positioning of the combination of DTG, TAF and FTC is still evolving.
The objective of this study was to compare the relative bioequivalence and safety profiles of Mylan's FTC/TAF/DTG 200mg/25mg/50mg FDC tablets (T) with the reference combination (R) of DESCOVY® (200/25 mg) and TIVICAY® (50 mg) tablets.
Methods: In this open label, randomized, two-period, two-treatment, cross-over, single dose evaluation, the relative oral bioequivalence was tested in 33 healthy adult human subjects under fed conditions. In each period, each subject received a single, oral dose of either Mylan's FTC/TAF/DTG tablets or R. Serial blood samples were collected predose and at 21 timepoints until 72 hours post dose. Subjects were monitored for safety and tolerability. Single-dose pharmacokinetic parameters for FTC/TAF/DTG were calculated using non-compartmental techniques.
Results: Statistical analyses of these data reveal that the 90% confidence intervals are within the acceptable bioequivalent range of 80.00% and 125.00% for the natural log transformed parameters, LNAUCL, LNAUCINF and LNCPEAK for emtricitabine, tenofovir (data not shown), tenofovir alafenamide, and dolutegravir. (Table 1)

Product	Parameter	Arithmetic Mean (%CV) T= Mylan	Arithmetic Mean (%CV) R = Reference	LSMEANS Ratio (T/R)	90% Confidence Interval
FTC	AUCL (ng•hr/mL)	10253 (18.23)	10276 (17.43)	1.00	98.14% - 101.40%
FTC	AUCINF (ng•hr/mL)	10523 (17.84)	10594 (17.31)	0.99	97.82% - 100.91%
FTC	CPEAK (ng/mL)	1986 (24.99)	1923 (27.21)	1.04	96.67% - 111.00%
TAF	AUCL (ng•hr/mL)	230.5 (38.42)	246.7 (46.53)	0.95	88.43% - 101.53%
TAF	AUCINF (ng•hr/mL)	231.7 (39.39)	249.3 (46.84)	0.95	88.41% - 101.07%
TAF	CPEAK (ng/mL)	173.7 (62.51)	180.7 (81.94)	1.00	84.47% - 119.20%
DTG	AUCL (ng•hr/mL)	83109 (30.84)	82440 (27.20)	1.00	95.69% - 104.44%
DTG	AUCINF (ng•hr/mL)	87840 (32.62)	87330 (29.65)	1.00	95.37% - 104.52%
DTG	CPEAK (ng/mL)	4097 (15.69)	4121 (17.35)	1.00	96.83% - 102.72%

[Table 1: Pharmacokinetic Results FTC, TAF and DTG]

The AEs were mild in severity. Overall both R and T were well tolerated when administered as a single, oral dose under fed conditions.
Conclusions: This study demonstrates that Mylan's FTC/TAF/DTG tablets are bioequivalent to a combination of DESCOVY® (200/25 mg) and TIVICAY® (50 mg) as separate tablets following administration of a single, oral dose administered under fed conditions.

THPEB061

Point-of-care drug level testing for adherence assessment of first and second line antiretroviral treatment in resource-limited settings

L.E. Hermans[1,2,3], M. Nijhuis[1], K.C. Kasper[4], R. O'Malley[4], S.J. Oh[4], R. Schuurman[1], H.A. Tempelman[3], W.D.F. Venter[2], D.M. Burger[5], A.M.J. Wensing[1], R. Ter Heine[5]
[1]University Medical Center Utrecht, Translational Virology, Department of Medical Microbiology, Utrecht, Netherlands, [2]University of the Witwatersrand, Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [3]Ndlovu Care Group, Groblersdal, South Africa, [4]ARK Diagnostics, Fremont, United States, [5]Radboud University Medical Center, Department of Pharmacy, Nijmegen, Netherlands

Background: In low and middle income countries, yearly viral load testing is recommended by the WHO for monitoring of antiretroviral treatment (ART). A detectable viral load implies treatment failure and may be caused by drug resistance or insufficient exposure. Point-of-care drug level testing can be useful to objectively assess recent drug intake and prevent unnecessary treatment switching. Our aim was to validate and implement a simple point-of-care drug level test for this purpose in a rural South African clinic.
Methods: We implemented immunoassays (ARK Diagnostics, Fremont, USA) for quantification of efavirenz and lopinavir on a benchtop chemistry system (Thermo-Scientific, Waltham, USA) at the Ndlovu Medical Centre (Elandsdoorn, South Africa). Internal validation was performed with the provided calibrators and controls. External agreement of the assay with a liquid chromatography assay with ultraviolet or mass-spectrometry detection in a reference laboratory was performed by Bland-Altman analysis, as well as calculation of the root mean square prediction error (RMSE%) and percentage mean prediction error (MPE%) in samples of patients treated with efavirenz and lopinavir. Laboratory turnaround time in routine practice was recorded to investigate feasibility.
Results: The immunoassays were accurate and precise. During replicate analysis of spiked control samples (n = 60) for both analytes, >95% of results remained within 20% CV of the reference value. Repeated analysis revealed no time-dependent variation of results. External validation revealed complete agreement between the immunoassay and reference method in classification of efavirenz and lopinavir of detectable versus undetectable levels.
External validation showed that RMSE were 0.26 mg/L for efavirenz and 0.91 mg/L for lopinavir. The MPE were -2.6% and -6.7%, respectively. Bland-Altman analysis showed agreement between assays within 20% in 100% of cases for efavirenz and 94.4% for lopinavir. Notably, 8.3% of patients on efavirenz and 57.4% of patients on lopinavir had undetectable drug levels, indicating non-adherence. During out-patient clinic visits, patient test results could be generated within 30 minutes.
Conclusions: We showed that objective monitoring of adherence to ART in a rural setting is feasible. We are currently prospectively testing the added value of drug level testing in a randomized clinical trial and are validating this assay for dolutegravir.

THPEB062

Female genital tract efavirenz exposure negatively correlates with serum estradiol levels in Malawian women

M.L. Cottrell[1], A.H. Corbett[1], L. Chinula[2,3], A. Msika[3], G. Tegha[3], F. Stanczyk[4], A.P. Kourtis[5], J.H. Tang[2]
[1]UNC Eshelman School of Pharmacy, Chapel Hill, United States, [2]University of North Carolina, Chapel Hill, United States, [3]UNC Project-Malawi, Lilongwe, Malawi, [4]University of Southern California, Los Angeles, United States, [5]Division of Reproductive Health, US Centers for Disease Control and Prevention, Atlanta, United States

Background: Estradiol and progesterone can increase expression and function of the drug transporter P-glycoprotein in the female genital tract (FGT), which could lead to decreased absorption or increased clearance of substrates like efavirenz. To understand whether FGT efavirenz exposure is modulated by endogenous hormones, we conducted a pharmacology substudy of women initiating hormonal contraception in a larger randomized trial (NCT03153709).
Methods: Serum, plasma and cervicovaginal fluid (CVF) obtained via Weck-Cel spears were collected from 58 HIV-infected Malawian women on efavirenz/lamivudine/tenofovir. Serum estradiol and progesterone were quantified using radioimmunoassay. Plasma and CVF efavirenz were quantified using HPLC-MS/MS methods. Spearman rank order correlation was performed to determine the relationship between endogenous hormones and efavirenz concentrations. Values below limits of quantification were imputed at half the lower limit. Data are reported as median (IQR).
Results: Forty-nine women had samples collected during both the follicular (n=58 observations) and luteal (n=49 observations) menstrual cycle phases prior to initiating hormonal contraception. Follicular vs luteal median serum progesterone levels were 0.1 (0.1, 0.295) vs 2.63 (0.3, 5.5)ng/ml; serum estradiol were 43.9 (29.7, 77.7) vs 66.1 (37.5, 99.7)pg/ml; plasma efavirenz were 3490 (2245, 6790) vs 2880 (2315, 6635)ng/ml; and CVF efavirenz were 95.6 (61.4, 227.8) vs 87.1 (43.6, 172.9)ng/swab. Plasma and CVF efavirenz concentrations positively correlated across both phases of the menstrual cycle (rho=0.54 to 0.85, p< 0.001). Efavirenz CVF concentrations negatively correlated with serum estradiol during the follicular (rho= -0.57, p< 0.001) and luteal (rho= -0.42, p=0.002) phases, but were not correlated with serum progesterone (rho= -0.2, p>0.05). Efavirenz plasma concentrations had a weaker, but still significant negative correlation with serum estradiol in the follicular phase (rho= -0.47, p< 0.001), and no correlation in the luteal phase or with serum progesterone (rho= -0.16 and -0.25, p>0.05).
Conclusions: CVF efavirenz concentrations were lower in women with higher estradiol concentrations across both menstrual cycle phases, suggesting more rapid FGT clearance due to hormonal modulation of local drug transporters. As our follicular phase measurements likely did not capture peak estradiol concentrations, future studies to characterize FGT efavirenz exposure within women at peak and trough estradiol exposure are needed to further explore this question.

Drug interactions

THPEB063

Prevalence and management of drug-drug interactions in a rural Tanzanian HIV cohort

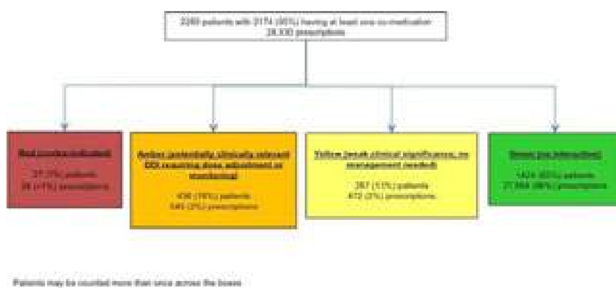
C. Schlaeppi[1], T.R. Glass[1,2], G. Sikalengo[3,4], F. Vanobberghen[1,2], R. Ndege[3,4], G. Foe[4], A. Kuemmerle[1,2], M. Battegay[1,5], C. Marzolini[1,5,6], M. Weisser[1,2,5]
[1]University of Basel, Basel, Switzerland, [2]Swiss Tropical and Public Health Institute, Basel, Switzerland, [3]Ifakara Health Institute, Ifakara, Tanzania, United Republic of, [4]St Francis Referral Hospital, Ifakara, Tanzania, United Republic of, [5]Department of Infectious Diseases & Hospital Epidemiology, Department of Clinical Research, University Hospital Basel, Basel, Switzerland, [6]Department of Molecular and Clinical Pharmacology, Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom

Background: With widespread access to antiretroviral therapy (ART) and prolongation of life, comorbidities and use of co-medications among people living with HIV (PLWHIV) are increasing, necessitating a sound understanding of drug-drug interactions (DDI). We aimed to assess the prevalence and management of DDIs with ART in a rural Tanzanian setting.

Methods: We included consenting PLWHIV who initiated ART in the Kilombero and Ulanga Antiretroviral Cohort (KIULARCO) between January 2013 and December 2016. Medications, clinical and laboratory data are recorded prospectively in an electronic database. DDIs were classified using www.hiv-druginteractions.org as red (contra-indicated), amber (interaction of potential clinical relevance requiring dosage adjustment/monitoring), yellow (interaction of weak clinical significance unlikely to require further management) or green (no interaction expected). Management of amber DDIs was assessed by determining frequency of creatinine and blood pressure measurements and by evaluating correct dosing.

Results: Among 2289 participants, 2174 (95%) were prescribed ≥1 co-medication during a median follow-up of 2.6 years. 750 (33%) patients had ≥1 potential DDI with the highest grade being red in 27 (1%) patients, amber in 436 (19%) and yellow in 287 (13%). On a prescription level, of 28,930 co-medication prescriptions, 29 (< 1%) were classified red, 545 (2%) amber and 472 (2%) yellow (Figure). Red DDIs included rifampicin combined with a protease inhibitor or nevirapine. The most common amber DDIs were efavirenz/rifampicin (n=290, 53%), tenofovir/analgesics (diclofenac or ibuprofen; n=110, 20%) and efavirenz/nifedipine (n=49, 9%). The most common requirements for management of amber DDIs were: (a) dose adjustment (n=305 in 268 patients; mainly efavirenz/rifampicin requiring an efavirenz dose of 600mg,which was appropriately given in >90% of patients), (b) creatinine monitoring (n=101 in 85 patients; mainly analgesics (n=57) appropriate creatinine monitoring was performed in 15 (18%) of the patients, and (c) blood pressure monitoring (n=48 in 35 patients, among whom 57% had appropriate blood pressure monitoring.

Conclusions: Co-medication use is high and 19% of patients had amber DDIs requiring further management. Timely monitoring beyond routine care remains a challenge in rural Africa. Reasons might be distance to the clinics and associated costs for patients and health care systems.



[Figure. Drug-drug interactions (DDIs) in a cohort of people living with HIV in rural Tanzania.]

THPEB064

The effect of multivitamins and polyvalent cations on virologic suppression with integrase strand transfer inhibitors

C. James[1], S. Szabo[1], D. Kahal[1], N. Goldstein[2,3]
[1]Christiana Care Health System, HIV Community Program, Wilmington, United States, [2]Christiana Care Health System, Department of Pediatrics, Newark, United States, [3]Drexel University, Department of Epidemiology and Biostatistics, Dornsife School of Public Health, Philadelphia, United States

Background: Integrase strand transfer inhibitors (INSTI) are now widely accepted and utilized as preferred options for antiretroviral therapy (ART) in people living with HIV. Since 2014, clinicians have been increasingly advised of drug interactions with INSTI and polyvalent cations (PVC), such as calcium, iron and zinc. PVC are also included in many multivitamins (MVI) and metal-based antacid preparations, however the clinical significance of these interactions with INSTI has not been documented in the literature. The objective of our study was to evaluate the impact of PVC on virologic suppression with INSTI-based ART.

Methods: We conducted a retrospective chart review from July 2012 to September 2017 to identify all patients prescribed an INSTI for at least six months. Medication lists were then queried for concomitant administration of MVI and/or PVC. We evaluated our electronic medical record for any episodes of virologic failure (HIV RNA > 200 copies/ml). Patients with nonadherence, as documented by refill history, were excluded.

Results: Three hundred sixty patients received an INSTI for at least six months during the study period. Of 152 patients who reported taking a PVC (42% of cohort), 99 (65%) reported an MVI and 73 (48%) reported another source. Forty-six patients (12.8%) experienced virologic failure (VF) during follow-up (Figure 1). Patients receiving MVI/PVC had on average 2.4 times the risk of VF (95% CI: 1.4, 5.6; p< 0.01) compared to patients not reporting a PVC, controlling for age, race, and gender. This association was unchanged when accounting for the source of PVC or type of INSTI (dolutegravir, elvitegravir, or raltegravir).

Conclusions: The effect of co-administration of PVC and INSTI-based ART was significant, with more than double the rate of virologic failure in a real world setting. Although recommendations for appropriate separation were evolving over our study period, our data reinforce the importance of ongoing medication reconciliation and patient education. While a larger, prospective trial may be indicated, our study demonstrates that these interactions extend beyond theoretical concerns and have a clinically significant impact on virologic suppression.

	Polyvalent Cation (n=152)	No Polyvalent Cation (n=208)
Gender	Male 91 (60%); Female 61 (40%)	Male 153 (73.6%); Female 55 (26.4%)

Antiretroviral drug resistance

THPEB065

Predicted efficacy of raltegravir, elvitegravir and dolutegravir in patients harboring mutations associated with integrase inhibitor resistance in Argentina: First interim survey

D.M. Cecchini[1,2], S. Castillo[3], G. Copertari[1], V. Lacal[1], C. Rodriguez[2], I. Cassetti[1]
[1]Helios Salud, Buenos Aires, Argentina, [2]Hospital Cosme Argerich, Buenos Aires, Argentina, [3]Laboratorio Dr. Stamboulian, Sección Biología Molecular, Buenos Aires, Argentina

Background: Integrase strand transfer inhibitors (INSTI)-based antiretroviral regimens are highly efficacious at suppression of HIV replication and are recommended for initiation of HIV therapy, as for subsequent regimens. However HIV can become resistant against INSTIs through the emergence of mutations within the integrase coding region. No data on the predicted efficacy of INSTIs in Argentina are available as access to these drugs (particularly, elvitegravir and dolutegavir) and to integrase genotypic resistance test remains limited. We aimed to evaluate the predicted efficay of raltegravir, elvitegravir and dolutegravir in patients harboring INSTI-associated mutations.

Methods: Retrospective multicentric study (period January 2011-November 2017) in Buenos Aires city, Argentina. Samples were processed through a validated *in house* RT-PCR and sequencing assay for detection of HIV-1 INSTI mutations (IRMs). Considering the genotype interpretation system (GIS) of Stanford HIVdb program (version 8.4), the predicted efficacy of each drug was classified within five categories: from susceptible to high-level resistance. The GIS categories "susceptible" and "potential low level resistance" were grouped together as "S" (susceptible), whereas "low level resistance" and "intermediate resistance" were grouped as "I" (intermediate) and the remaining as „R" (resistant).

Results: Sixty seven patients were included: 64.2% were male. The median (IQR) of age, viral load, and CD4 T-cell count were: 43 (23-52) years, 4465 copies/mL (859-27812) and 306/µL (153-499), respectively. Patients had a median of 5 (4-7) prior treatments. All patients had INSTI-containing regimens: median exposure of 22.5 (10-51) months; 94% were under raltegravir therapy. Eighty-two percent had concomitant resistance mutations in retrotranscriptase or protease genes (50% multidrug-resistant). Integrase gene sequencing was successful in 57 (85.1%): 71.9% had IRMs (median: 2 per patient). Predominat major IRMs: N155H (35.1%), Q148H/R (15.8%) and G140A/S (14%). Predominat accesory IRMS: G163R/K (31.6%) and T97A (19.3%). Predicted efficacy of INSTIs is shown in table1.

Category	Susceptible	Intermediate resistance	Resistant
Raltegravir (%)	2.4	21.9	75.6
Elvitegravir (%)	2.4	21.9	75.6
Dolutegravir (%)	68.4	29.3	2.4

[Predicted INSTI resistance in patients harboring integrase resistance mutations]

Conclusions: In a cohort of heavily pretreated, raltegravir-exposed patients in Argentina, extremely low and identical activity of elvitegravir and raltegravir is described, showing extensive cross-resistance. Dolutegravir remains either partially or fully active 97.7% of patients, constituting and extremely important therapeutic option for future regimens. In this context, access to dolutegravir should be warranted.

THPEB066

Long-term virological and immunological outcomes between HIV-infected patients with and without primary HIV drug resistance

K. Singsumran[1], S. Sungkanuparph[2]
[1]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand, [2]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Chakri Naruebodindra Medical Institute, Samut Prakan, Thailand

Background: Primary HIV drug resistance (PHDR) has emerged after scaling-up of antiretroviral therapy (ART). Prior studies in Thailand have demonstrated the rate of PHDR at 4.9%-7.9%. There is an association between PHDR and risk of treatment failure and this may affect the survival. This study aimed to compare long-term virological and immunological outcomes between HIV-infected patients with and without PHDR.

Methods: An observational cohort study was conducted in HIV-infected patients who had genotypic resistance test performed prior to ART initiation. Patients were categorized into two groups: PHDR group (patients with PHDR) and control group (patients without PHDR) and followed up for 48 months after ART initiation. HIV RNA and CD4 cell count were evaluated every 6 months after ART initiation. Undetectable HIV RNA was defined as HIV RNA < 50 copies/ml.

Results: Of 112 patients, 13 were in PHDR group and 99 in control group. Mean age was 38.5±10.1 years and 54.5% were males. Baseline median (IQR) CD4 cell count was 179 (52-337) cells/mm^3. Demographics, risk of HIV acquisition, HBV or HCV co-infection, VDRL serostatus and ART regimens were similar between two groups (p > 0.05). Of 13 patients in PHDR group, 38.5%, 46.2% and 15.4% had NRTI, NNRTI and PI resistance mutations, respectively. At 6 months after ART initiation, 40.0% of patients in PHDR group and 79.3% in control group had undetectable HIV RNA (p=0.049). ART regimen was adjusted according to the results of genotypic resistance test and HIV RNA level. The proportions of patients with undetectable HIV RNA at 12, 24, 36, 48 months (PHDR vs control group) were 66.7% vs 94.8%, 100% vs 98.1%, 77.8% vs 100%, and 90% vs 98.7%, respectively (all p > 0.05). Mean CD4 change at the corresponding periods (PHDR vs control group) were +109 vs +210, +125 vs +255, +241 vs +330, +292 vs +333 cells/mm^3, respectively (all p > 0.05). No patient died or developed new opportunistic infection.

Conclusions: HIV-infected patients with PHDR have less early virological response than those without PHDR. Genotypic resistance test prior to ART initiation has contributed to the long-term virological and immunological success that similar to patients without PHDR.

THPEB067

High levels of HIV drug resistance in Nicaragua: Results from the first nationally representative survey, 2016-2017

R. Mendizabal-Burastero[1], S. Avila-Rios[2], A. Giron-Callejas[1], C. Garcia-Morales[2], S. Northbrook[3], G. Ravasi[4], G. Reyes-Teran[2], Nicaraguan HIVDR Group
[1]Universidad del Valle de Guatemala, Centro de Estudios en Salud, Guatemala, Guatemala, [2]National Institute of Respiratory Diseases, Research Center in Infectious Diseases, Mexico, Mexico, [3]U.S. Centers for Disease Control and Prevention, Central America Regional Office, Guatemala, Guatemala, Guatemala, [4]Pan-American Health Organization, Washington D.C., United States

Background: Low levels of viral load suppression and emergence of HIV drug resistance (HIVDR) might compromise efforts to achieve 90-90-90 targets by 2020. We conducted the first nationally representative survey to estimate the prevalence of pretreatment drug resistance (PDR) and acquired drug resistance among persons living with HIV on ART for 12±3 months (ADR12) and ≥48 months (ADR48) following WHO guidelines

Methods: The survey design was based on a probability proportional to proxy size sample considering 19 out of 45 ART clinics to participate in the survey (excluding ART clinics that represented < 10% of the national cohort of PLHIV on ART). We recruited eligible participants consecutively for 8 months in 2016. All patients provided written informed consent to participate in the survey. HIV Viral Load (VL) was measured using a

Tuesday 24 July
Wednesday 25 July
Thursday 26 July
Friday 27 July
Late Breaker Abstracts
Publication Only Abstracts
Author Index

RTqPCR assay. We assessed HIVDR using Sanger sequencing and the Stanford HIVdb algorithm at a WHO designated regional genotyping laboratory. All analysis accounted for the survey design.
Results: We enrolled 649 participants: 174 PDR, 115 ADR12, and 360 ADR48. Most of ART initiators were drug-naive (87.3%). Overall PDR prevalence was 23.7% (95%CI 17.9-30.6%), mostly related to NNRTI resistance (19.1 %). Among PLHIV on ART for 12±3 and ≥48 months viral suppression rate was 74.7% (95%CI 66.1-81.8%) and 67.2% (95%CI 62.2-71.9), respectively. ADR12 prevalence among patients with VL≥1,000 copies/ml was 82.1% (95%CI 64.4-92.1%), 75.0% to NNRTI, and 57.1% to both NNRTI and NRTI. ADR48 prevalence among patients with VL≥1,000 copies/ml was 80.0% (95%CI 71.7-86.3%), 75.6% to NNRTI, and 67.55% to both NNRTI and NRTI. ADR to at least one ARV of the preferred second-line regimen, among patients on first-line regimen with VL≥1,000 copies/ml, was 62.1% and 64.8% at 12±3 and >48 months, respectively.
Conclusions: High level of PDR associated with NNRTI resistance. Urgent consideration of non-NNRTI based first line regimens for ART initiators is needed. Viral load suppression rates were lower than 75% among patients on ART, with high proportion of HIVDR in patients with VL≥1,000 copies/ml. Our findings underscore the need to evaluate current ART regimens, and monitor ART adherence and timely VL monitoring to mitigate the impact of high HIVDR in Nicaragua.

THPEB068

Understanding the resistance profile of the HIV-1 NNRTI doravirine in combination with the novel NRTTI MK-8591

D. Hazuda, M. Xu, W. Ngo, M. Feng, C. Hwang, J. Grobler, M.-T. Lai
Merck Sharp & Dohme, West Point, United States

Background: Doravirine (DOR) is a novel nonnucleoside reverse transcriptase inhibitor (NNRTI) with improved potency against common NNRTI-associated resistance mutants as compared to the other approved NNRTIs. MK-8591 is a novel and potent nucleoside reverse transcriptase translocation inhibitor (NRTTI). The combination of DOR and MK-8591 is currently being studied in Phase 2. It has previously been reported that the NNRTI-associated substitution Y181C confers hypersusceptibility to MK-8591. This study aimed to characterize the effect of DOR-selected NNRTI resistant mutants from Phase 3 trials on MK-8591 as well as evaluate the resistance profile of DOR in combination with MK8591 in vitro.
Methods: HIV-1 mutant viruses were generated via a site-directed mutagenesis (SDM) method with gene synthesis and subcloning into plasmid RT112 (R8). These mutants were tested for susceptibility to MK-8591 and 3TC in MT4-GFP cells. In vitro resistance selection studies were performed with MT4-GFP cells in a 96-well plate format. The following combinations were evaluated: DOR/MK8591, DOR/3TC and DTG/3TC. For every passage, the plates were scanned to monitor viral replication by analyzing the intensity of green fluorescence. When evidence of virus breakthrough was observed, the supernatant was removed and the virus subjected to genotyping analysis of the HIV-1 RT region.
Results: In Phase 3 trials of DOR, seven of 747 (0.9%) patient developed NNRTI mutations, predominately F227C with additional substitutions. SDM viruses were generated with RT Y188L, A98G/F227C, V106I/F227C, V106I/H221Y/F227C, A98G/V106I/H221Y/F227C, V106A/P225H/Y318F, and V106M/F227C. Most of these mutants exhibited a fold change (FC) >100 (mutant$_{EC50}$ versus WT$_{EC50}$) to DOR. In contrast, viruses with F227C alone or in combination (A98G/F227C, V106I/F227C, V106M/F227C, and V106I/H221Y/F227C) were 2X or greater more susceptible to MK-8591 whereas no change in susceptibility to 3TC. The combination of DOR/MK8591 was less susceptible to breakthrough compared to either DOR/3TC or DTG/3TC. Mutations identified in DOR/MK-8591 combination were mostly DOR-associated mutations whereas M184V/I were identified with the DTG/3TC.
Conclusions: DOR-associated clinical mutants containing F227C, alone or in combination, are hypersusceptible to the NRTTI MK-8591. This hypersensitivity may, in part, explain the observation that the combination of DOR with MK-8591 has a higher barrier to resistance development than the combination of DOR/3TC or DTG/3TC in vitro.

THPEB069

HIV-1 subtype A1 and D polymorphisms associated with resistance to dolutegravir in INSTI-naïve individuals in Uganda

G.Q. Lee[1,2,3], S. McCluskey[3,4], K. Kamelian[2], Y. Boum[5], M.B. Bwana[5], C. Muzoora[5], P.W. Hunt[6], J.N. Martin[6], D.R. Bangsberg[7], J.E. Haberer[4], P.R. Harrigan[2], M.J. Siedner[3,4,5]
[1]Ragon Institute of MGH, MIT and Harvard, Cambridge, United States, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]Harvard Medical School, Boston, United States, [4]Massachusetts General Hospital, Boston, United States, [5]Mbarara University of Science and Technology, Mbarara, Uganda, [6]University of California, San Francisco, United States, [7]Oregon Health Sciences University, Portland, United States

Background: In light of an alarming increase in pretreatment drug resistance (PDR) in sub-Saharan Africa, the World Health Organization organized a special meeting in 2017, which recommended large-scale roll-out of dolutegravir (DTG) as a component in first-line regimens in countries with over 10% PDR. However, little is known about the prevalence of natural resistance to DTG in circulating non-subtype B HIV-1 in the region. This study retrospectively examined HIV-1 integrase sequences from an integrase-inhibitor (INSTI) naïve cohort in Uganda to estimate the prevalence of baseline polymorphisms associated with DTG-resistance in HIV-1 subtypes A1 and D.
Methods: Specimens were drawn from the Uganda AIDS Rural Treatment Outcomes (UARTO) cohort and included 81 pilot subjects enrolled from Kampala during 2002-2004 and 500 subjects enrolled from Mbarara during 2005-2010. Samples were collected just prior to initiation of NNRTI-based antiretroviral therapy. HIV-1 integrase was amplified using nested-PCR and Sanger-sequenced (HXB2 4230-5093). Stanford HIV Drug Resistance Database HIVDB 8.4 was used to infer clinically significant INSTI-associated mutations.
Results: Samples from 58 treatment-naïve individuals in Kampala (subtype: 53% A1, 43% D), and 454 individuals in Mbarara (subtype: 52% A1, 41% D) successfully yielded HIV-1 integrase genotyping results. In Kampala and Mbarara respectively, 0/58 (0%) and 6/454 (1.3%) had any major INSTI-associated mutations. Of the six major INSTI mutations, two were E138T (both subtype A1; HIVDB "potential low-level DTG resistance"), three were E138E/K (all subtype D; HIVDB "potential low-level DTG resistance"), and one was T66T/I (subtype D; HIVDB "susceptible to DTG"). No subjects had mutations at the canonical Q148, Y143 or N155 sites that had been traditionally associated with high level of INSTI resistance.
Conclusions: In n=512 Ugandans infected with subtype A1 and D HIV-1, we detected no HIV-1 polymorphisms associated with high levels of dolutegravir resistance. However, we detected five cases of E138K/T, which when occur alone, do not confer DTG resistance, but in combination with Q148 mutations, is known to reduce DTG susceptibility up to 10-fold. Our results support a widespread rollout of DTG, but careful monitoring of patients with virologic failure is warranted to further classify the most relevant mutations for non-subtype B viruses.

THPEB070

Comprehensive analysis of the antiviral activity of cabotegravir against HIV-2 isolates and INI-resistant HIV-2 mutants

R.A. Smith[1], V.H. Wu[1], C.G. Zavala[1], D.N. Raugi[1], S. Ba[2], M. Seydi[2], G.S. Gottlieb[1], UW-Dakar HIV-2 Study Group
[1]University of Washington, Medicine/ AID, Seattle, United States, [2]SMIT, CHNU-FANN, UCAD, Dakar, Senegal

Background: Cabotegravir (S/GSK1265744; Shinogi/GlaxoSmithKline) is a second-generation integrase inhibitor (INI) in development for the prevention and treatment of HIV-1 infection. To evaluate the potential use of cabotegravir for HIV-2 treatment, or as a component of pre-exposure prophylaxis (PrEP) in HIV-2-endemic settings, we determined the antiviral activity of the drug against HIV-2 in both single-cycle and spreading infection assays. We also measured the activity of cabotegravir against a comprehensive panel of clinically-relevant, INI-resistant HIV-2 variants.

Methods: We tested a total of 14 HIV-2 isolates (8 group A and 6 group B) from treatment-naïve individuals and >50 site-directed HIV-2_{ROD9} integrase mutants (group A) for susceptibility to cabotegravir in the MAGIC-5A assay. A subset was further tested in six-day spreading infections of an immortalized T cell line (CEMss). In both assay formats, HIV-1 isolates and site-directed HIV-1 integrase mutants were included in the analysis as control/comparator strains.

Results: Cabotegravir inhibited HIV-1 and HIV-2 isolates with comparable potency; 50% effective concentrations (EC_{50}) ranged from 1.3-2.2 nM for HIV-1 and 0.9-4.1 nM for HIV-2 in the single-cycle assay (p=0.19, Welch's *t* test). In spreading infections, EC_{50} values for four HIV-2 isolates were comparable to that of HIV-$1_{NL4\text{-}3}$ (140-630 pM versus 150 ± 30 pM, respectively). HIV-2_{ROD9} variants with mutations in the Y143C/G/H/R pathway were fully susceptible or, in some cases, slightly hypersusceptible to cabotegravir. The Q148K change alone, or the combination of G140S with Q148H, K or R, resulted in high-level resistance to the drug (>100-fold increase in EC_{50}, relative to the parental HIV-2_{ROD9} clone). Resistance levels for N155H-pathway mutants of HIV-2_{ROD9} varied from 2-60-fold depending on the number and combination of secondary changes in the integrase protein.

Conclusions: Cabotegravir effectively interrupts the replication of HIV-2 isolates from treatment-naïve patients with EC_{50} values in the low-nanomolar to picomolar range. Cabotegravir also inhibits Y143 mutants of HIV-2 integrase; genotypes G140A/S+Q148H/K/R and E92A/Q+N155H+additional secondary changes confer moderate to high-level resistance to the drug. Cabotegravir is the second example (along with MK-8591 / EFdA) of a drug with potent antiviral activity against HIV-2 and the potential for long-acting parenteral administration.

THPEB071

Resistance through week 48 in the DAWNING study comparing dolutegravir (DTG) plus 2 nucleoside reverse transcriptase inhibitors (NRTIs) compared with lopinavir/ritonavir (LPV/r) plus 2 NRTIs in second-line treatment

R. Wang[1], J. Horton[2], J. Hopking[2], K. King[3], K. Smith[1], M. Aboud[4], B. Wynne[5], J. Sievers[4], M. Underwood[1]
[1]*ViiV Healthcare, Research Triangle Park, United States,* [2]*GlaxoSmithKline, Stockley Park, United Kingdom,* [3]*PAREXEL, Glendale, United States,* [4]*ViiV Healthcare, Brentford, United Kingdom,* [5]*ViiV Healthcare, Upper Merion, United States*

Background: DAWNING is a Phase 3b non-inferiority study comparing DTG plus 2 NRTIs with a WHO-recommended regimen of LPV/r + 2 NRTIs in HIV-1 infected adults failing first-line therapy (HIV-1 RNA ≥400 copies [c]/mL) of a non-nucleoside reverse transcriptase inhibitor (NNRTI) + 2 NRTIs (ClinicalTrials.gov: NCT02227238). This analysis explores 48-week resistance outcomes.

Methods: DAWNING is a Phase 3b non-inferiority study comparing DTG plus 2 NRTIs with a WHO-recommended regimen of LPV/r + 2 NRTIs in HIV-1 infected adults failing first-line therapy (HIV-1 RNA ≥400 copies [c]/mL) of a non-nucleoside reverse transcriptase inhibitor (NNRTI) + 2 NRTIs (ClinicalTrials.gov: NCT02227238). This analysis explores 48-week resistance outcomes.

Results: Eleven DTG subjects and 30 LPV/r subjects met CVW criteria through Week 48. Baseline NRTI mutation M184I/V alone, and pathways K65R or M184I/V +≥ one other major NRTI mutation were common (Table).

One subject receiving DTG+3TC+AZT with HIV-1 subtype C had NRTI mutations K70E+M184V at Baseline; NRTI mutation M184V and INSTI mutation mixture H51H/Y+G118R+E138E/K+R263R/K were observed at Week 48 CVW with DTG fold-change in IC50 vs wildtype (FC) = 15.

At Baseline and Week 48, INSTI replication capacity (RC) was 236 and 36, and RT/PR RC was 41 and 41, respectively. A second subject receiving DTG+FTC+TDF, with HIV-1 subtype B, had NRTI mutations M184V+K219K/E at Baseline; NRTI mutations D67N+M184V and INSTI mutation G118R were observed with DTG FC= 30 at Week 36 CVW.

At Baseline and Week 36 INSTI RC was 103 and 5.6 and RT/PR RC was 83 and 97, respectively. 3 LPV/r subjects had emergent NRTI but no PI mutations.

Conclusions: In DAWNING most subjects in each arm had Baseline M184I/V alone or with additional major RT mutations (82% across study). Despite this, three times fewer DTG subjects met CVW criteria than LPV/r subjects, and treatment emergent INSTI resistance was rare. The two patients with treatment emergent INSTI resistance substitutions showed increases in FC to DTG and substantial decreases in INSTI replication capacity.

Baseline NRTI Mutation(s)	DTG				LPV/r			
	N[1] (%)	CVW (n)	INSTI[2] (n)	NRTI[3] (n)	N (%)	CVW (n)	PI[3]	NRTI (n)
M184I/V only	77 (25%)	3	0	0	85 (27%)	10	0	0
M184I/V + ≥1 NRTI[4]	184 (59%)	4	2	1	167 (54%)	10	0	2[5]
K65R only or + ≥1 NRTI[6]	16 (5%)	1	0	0	17 (5%)	2	0	0
Other[7]	7 (2%)	1	0	0	8 (3%)	0	0	0
None[8]	30 (10%)	2	0	0	33 (11%)	8	0	1[9]
Total	314	11	2	1	310	30	0	3

1. Two subjects randomized to LPV/r arm received DTG and are counted here in the DTG arm. 2. From prespecified INSTI list (H51Y, T66A/I/K, L74M, E92Q/V/G, Q95K, T97A, G118R, F121Y, E138A/K/D, G140A/C/S, Y143C/H/R/K/S/G/A, P145S, Q146P, S147G, Q148H/K/R, V151I/L/A, S153F/Y, N155H/S/T, E157Q, G163R/K, S230R, R263K, L68V/I, L74I, E138T, V151I, G193E). 3. IAS major substitutions. 4. Including K65R. 5. Both subjects had K65R and M184I/V at Baseline, each with treatment emergent K219K/Q or with K219K/E+K70K/Q/R. 6. Excluding M184I/V. 7. IAS major NRTI substitutions, excluding M184I/V and K65R. 8. No IAS major NRTI substitutions. 9. Treatment-emergent K70K/R+M184V.

[Table 1]

THPEB072

Good short-term outcomes despite extensive pre-3rd-line HIV drug resistance in Kenya

S. Goodrich[1,2,3], A. Gardner[1,2,3], C. Ngetich[2,4], S. Ali[2,3], J. Humphrey[1,2,3], B. Jakait[2,4], R. Kantor[5]
[1]*Indiana University School of Medicine, Medicine - Infectious Diseases, Indianapolis, United States,* [2]*Academic Model Providing Access to Healthcare, Eldoret, Kenya,* [3]*Moi University School of Medicine, Medicine, Eldoret, Kenya,* [4]*Moi Teaching and Referral Hospital, Eldoret, Kenya,* [5]*Brown University Alpert Medical School, Providence, United States*

Background: Essential 3rd-line antiretroviral therapy (ART) is emerging in resource-limited settings (RLS), where limited access to medications and treatment monitoring exist. Characterizing resistance before guidelines-directed 3rd-line initiation, and post-initiation viral outcomes can assist treatment programs to successfully sustain long-term ART.

Methods: We investigated pre-3rd-line intermediate-high-level and low-intermediate-high-level resistance, and post-switch viral load (VL) and mortality at the HIV Resistance Clinic, which follows patients considered for 3rd-line ART at the Academic Model Providing Access to Healthcare (AMPATH) in Eldoret, Kenya, a large HIV program caring for >80,000 patients. Participants were included if they

(i) were followed at the Clinic between January 2015 (Clinic opening) and January 2018;

(ii) had ≥ 2 VLs >1,000 copies/mL despite enhanced adherence intervention on lopinavir/ritonavir- or atazanavir/ritonavir-based 2nd-line ART; and

(iii) had genotypic drug testing confirming multi-class resistance, required by World Health Organization (WHO) and Kenya guidelines to change to 3rd-line medications (darunavir, etravirine, raltegravir, dolutegravir).

Results: Of 227 patients on 2nd-line ART (37% male; median age 39 years (IQR 21-53) referred to the HIV Resistance Clinic, 29 (13%; mean time on ART 8 years; mean VL 166,506 copies/mL) required change to 3rd-line. Intermediate to high-level pre-3rd-line resistance was seen in 29/29 (100%) to two classes, and 19/29 (66%) to three classes. This extensive resistance involved 3rd-line medications darunavir (6/29; 21%), etravirine (13/29; 45%) and tenofovir (11/29; 38%). Low to high-level pre-3rd-line resistance to three classes was seen in 23/29 (79%), involving 3rd-line medications darunavir (11/29; 38%), etravirine (18/29; 62%) and tenofovir (20/29; 69%). All 29 3rd-line patients were living and 22/23 (96%) on 3rd-line ≥ 6 months had VL < 1,000 copies/mL. Of the 7 remaining, 6 were on 3rd-line < 6 months and 1 was severely stressed.

Conclusions: In a large Kenyan HIV-program most viremic patients on 2nd-line ART responded to continued 2nd-line ART with enhanced adherence counseling. Despite extensive pre-switch resistance, in the 14% eligible for 3rd-line switch per WHO guidelines mortality was 0% and viral suppression was 96% for those on 3rd-line ≥6 months . Longer follow-up is required to substantiate these findings, particularly significant with expected increase in 2nd and 3rd-line ART access in RLS.

THPEB073

Antiretroviral drug resistance in cell-associated HIV-1 DNA during suppressive protease inhibitor (PI) - based second-line antiretroviral therapy (ART)

A. Abdullahi[1], J. Torimiro[2], O.M. Fopoussi[1,2], A. Beloukas[1], V.F. Defo[2,3], C. Kouanfack[3], A.M. Geretti[1]
[1]University of Liverpool, Institute of Infection and Global Health, Liverpool, United Kingdom, [2]Chantal Biya International Reference Centre for Research on HIV/AIDS Prevention and Management, Yaoundé, Cameroon, [3]Day Hospital, Yaoundé Central Hospital, Ministry of Public Health, Yaoundé, Cameroon

Background: Emergence of resistance is common after failure of first-line ART with 2NRTIs + NNRTI and is typically characterised by mutations affecting both drug classes. However, in sub-Saharan African populations, detection of NRTI resistance-associated mutations (RAMs), and specifically thymidine analogue mutations (TAMs) and the 3TC/FTC mutation M184V, has not been found to reduce the likelihood of virological suppression on second-line therapy with 2NRTIs + PI/r. To gain further insight into the significance of NRTI resistance, this study characterised the resistance profiles of patients established on second-line PI-based ART in Yaoundé and showing a stably suppressed plasma viral load (pVL), using HIV-1 DNA from peripheral blood mononuclear cells (PBMC).

Methods: HIV-1 DNA was quantified in PBMC by real-time PCR. RAMs in reverse transcriptase and protease were detected by Sanger sequencing of HIV-1 DNA. The genotypic susceptibility score (GSS) of the PI-based regimen was determined using the Stanford HIV drug resistance algorithm.

Results: Participants (n=94) had received PI-based ART for a median of 3.1 years (IQR 1.3, 5.4) and were predominantly receiving TDF/3TC (87/94, 93%; Table 1). pVL suppression (< 60 copies/ml) was documented by two measurements taken at a median of 7 weeks apart (IQR 5-12). No previous pVL measurements were available. HIV-1 DNA was measured and sequenced in all subjects. Overall, 53/94 (56%) patients had ≥1 major NRTI RAM (Table 2). The GSS score of the PI-based regimen was median 2 (IQR 2, 3). Among subjects on TDF/3TC, prevalence of predicted intermediate- or high-level TDF resistance was 8/87 (9%) and 4/87 (5%), respectively; ignoring co-occurrence of M184V (and its beneficial effect on TDF susceptibility) increased the prevalence of intermediate to high-level TDF resistance to 14/87 (16%). HIV-1 subtypes were CRF02_AG in 51/94 (56%) patients and highly diverse in the remaining population.

Conclusions: In this NRTI-experienced cohort receiving suppressive PI-based therapy most subjects retained predicted susceptibility to TDF, reflecting the predominance of mutational profiles that are known to have limited phenotypic effects on tenofovir.

THPEB074

Global registry of HIV-1 patients experiencing virological failure on dolutegravir containing antiviral regimens

L.M. Hofstra[1], J.J.A. Van Kampen[2], M. Nijhuis[1], A. Van Kessel[3], A.A.K. Samat[3], C. Devaux[4], C.A.B. Boucher[2], A.M.J. Wensing[1]
[1]University Medical Center Utrecht, Medical Microbiology, Utrecht, Netherlands, [2]Erasmus MC, Rotterdam, Netherlands, [3]European Society for Translational Antiviral Research, Utrecht, Netherlands, [4]Luxembourg Institute of Health, Infection and Immunity, Luxembourg, Luxembourg

Background: The genetic barrier to resistance for dolutegravir is reported to be higher than for first-generation integrase inhibitors (INI). In clinical trials of dolutegravir cART in therapy-naive individuals, selection of resistance in integrase was not observed. In trials in patients with prior failure of INI, a decreased virological response was observed in the presence of multiple integrase resistance mutations at baseline. In clinical practice, virological failure, although rare, is being observed for both naïve and INI pretreated patients often without selection of obvious resistance mutations. Recent data suggest that resistance may emerge outside the integrase encoding gene in the 3'-polypurine tract (3'-PPT) region. For a better understanding of dolutegravir resistance systematic analysis of otherwise scattered information on individual patient cases of dolutegravir therapy failure is urgently needed.

Description: The European Society for translational Antiviral Research (ESAR) has opened a global registry to which anonymised clinical cases of failure on dolutegravir containing regimens can be submitted. Submission forms can be retrieved via www.esar-society.eu. If samples are available genotypic sequencing of integrase and 3'-PPT is performed. In selected cases phenotypic integrase susceptibility analysis is performed (fold change (FC) in IC50 compared to HxB2). Participants receive full reports of results. Currently, 27 cases of dolutegravir failure in patients infected with various HIV-subtypes have been collected.

Lessons learned: While the registry is growing several preliminary conclusions can be drawn. Upon failure only secondary resistance associated mutations or mutations with unknown relevance are detected in integrase. In INI-naïve patients therapy failure can be observed in plasma as well as the CNS compartment with low level phenotypic resistance to dolutegravir (FC 1.3-1.6). In INI pretreated patients high level resistance to dolutegravir (FC 160-244) can be observed despite the absence of integrase mutations at position 140 and 148.

Conclusions/Next steps: Selection of resistance to dolutegravir is not impossible. Considering the envisioned global uptake of dolutegravir comprehensive information on resistance is essential. ESAR invites clinicians to submit cases of dolutegravir failure to this continuous and comprehensive global registry to assist guidelines and interpretation algorithms to ensure appropriate future application of the integrase drug class.

THPEB075

Predicting in vitro resistance phenotypes for HIV protease and integrase inhibitors using sequences from treated and non-treated individuals

V. Montoya[1], W. Zhang[2], A. Shahid[2], R.P. Harrigan[1]
[1]B.C. Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of British Columbia, Medicine, Vancouver, Canada

Background: A strategy for inferring the in vitro resistance phenotype was developed for HIV protease and integrase inhibitors based solely upon the population prevalence of mutations from previously treated and non-treated individuals.

Methods: The Stanford HIV database was used to retrieve subtype B HIV protease (n=57,138) and integrase (n=6,738) sequences along with their corresponding treatment information. Prevalence ratios were calculated for each position from treated (~16,453/ ~1,007) and non-treated (~ 42,177/~ 5,235) individuals. The logged sum of these ratios was used as a 'resistance score' for each individual and, for each drug available, was compared with PhenoSense and Antivirogram.

The ability of the resistance score to predict drug susceptibility was measured with receiver operating characteristic (ROC) and precision-recall (PR) curves using manufacturer-specific PhenoSense IC_{50} thresholds for decreased susceptibility.

The capacity of the resistance score to function as a genotypic algorithm was then assessed using an independent dataset composed of protease (33,600) and integrase (3,298) sequences from HIV infected individuals in British Columbia. Using the prevalence ratios generated from the phenotypic dataset, the resistance scores were compared with two genotypic resistance algorithms (Virco for protease and the Stanford HIVdb algorithm for integrase).

Results: For each drug, the correlation coefficients between the PhenoSense/Antivirogram IC_{50} values and the resistance score ranged from 0.47-0.84 (PhenoSense average: 0.66, Antivirogram average: 0.69). Separating the data into a training (75%) and validation (25%) dataset, a threshold generated from ROC curves (area under the curve 0.94) yielded a sensitivity of 0.95 and a specificity of 0.85 for classification. For the genotypic dataset, a strong correlation was also observed where sensitivities and specificities for protease inhibitors were ~0.95/~0.90 and ~0.95/~0.7 for integrase inhibitors, respectively.

Conclusions: These results suggest that mutation prevalence ratios from prior treatment data can be used to predict phenotypes without any other phenotypic data.

THPEB076

HIV antiretroviral treatment among 2+ drug class resistant patients in the US

J. Deemer, J. Spindel, D. Rogers
Ipsos, New York, United States

Background: Standard HIV treatment is typically comprised of at least three drugs to reduce the likelihood of the virus developing a resistance. As resistances develop, combination antiretroviral therapies (ARTs) become increasingly complex and thus increase the daily pill burden. Since 2016 there has been a visible trend of lowering the pill burden for patients with 2+ drug-class resistance (2+DCR). The objective of our study is to examine the benefits of a lower pill burden for 2+DCR treatment-experienced HIV+ patients in the US.

Methods: Data from the Ipsos HIV US Therapy Monitor, a syndicated retrospective patient chart audit running since 1994 was used for this analysis. Each quarter, ~200 physicians from across the nation provide demographic, disease and treatment data on ~4000 HIV+ patients.

Results: In 2017, Elvitegravir/Cobicistat/Emtricitabine/Tenofovir Alafenamide Fumarate +darunavir (E/C/F/TAF +DRV) was the most prescribed regimen among patients with 2+DCR in the US. The proportion of patients on this regimen increased significantly (p< 0.01) from 4.2% in 2016 to 13.3% in 2017. A significant decrease (p< 0.05) of E/C/F/TAF +DRV patients on their 3+ line of therapy was seen in 2017 compared with 2016, suggesting that 2+DCR patients switching to E/C/F/TAF +DRV are less likely to change regimens again.

In 2016, 89.4% of E/C/F/TAF +DRV patients were previously on 3+ pill regimens, with 64.3% taking 4+ pills. In 2017, 66.2% of E/C/F/TAF +DRV patients were previously on 3+ pill regimens, with 82.4% taking 4+ pills. Top reasons for switching to E/C/F/TAF +DRV include simplification and virologic failure. The top reason for prescribing is potency in reducing viral load.

Conclusions: E/C/F/TAF +DRV use increases as 3+ pill regimen prevalence decreases among 2+DCR patients. The greater usage suggests that a STR +DRV regimen is a viable option for 2+DCR patients seeking lower pill burdens.

THPEB077

HIV-1 subtype (B or non-B) had no impact on the efficacy of B/F/TAF or resistance development in five phase 3 treatment-naïve or switch studies

R. Acosta[1], K. White[1], W. Garner[2], X. Wei[2], K. Andreatta[1], M. Willkom[1], C. Kityo[3], A. Avihingsanon[4], S. Romanova[5], F. Maggiolo[6], Y. Yazdanpanah[7], C. Orkin[8], J. Rockstroh[9], E. DeJesus[10], D. SenGupta[11], T. Makadzange[11], H. Graham[11], H. Martin[11], E. Quirk[11]
[1]Gilead Sciences, Clinical Virology, Foster City, United States, [2]Gilead Sciences, Biostatistics, Foster City, United States, [3]Joint Clinical Research Centre, Kampala, Uganda, [4]Thai Red Cross AIDS Research Centre (HIV-NAT), Bangkok, Thailand, [5]Center for Prevention and Treatment of AIDS and Infectious Diseases, St. Petersburg, Russian Federation, [6]ASST Papa Giovanni XXIII - Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, [7]Groupe Hospitalier Bichat Claude Bernard, Paris, France, [8]Barts Health NHS Trust, Royal London Hospital, London, United Kingdom, [9]Universitätsklinikum Bonn, Bonn, Germany, [10]Orlando Immunology Center, Orlando, United States, [11]Gilead Sciences, Clinical Research, Foster City, United States

Background: Globally, most people living with HIV are infected with non-B subtype HIV-1. Bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) is a potent, once-daily, single tablet regimen for treatment of HIV-1 infection, with in vitro activity against all B and non-B subtypes. Here, we present an expanded analysis of B/F/TAF efficacy by HIV-1 subtype and pre-existing resistance mutations in treatment-naïve and virologically-suppressed switch study participants.

Methods: Participants from five Phase 3 B/F/TAF studies—GS-US-380-1489 and GS-US-380-1490 (naïve; n=1274), and GS-US-380-1844, GS-US-380-1878, and GS-US-380-1961 (switch; n=1610)—were included. HIV-1 genotype and subtype were determined at baseline for all naïve study participants, and for a subset in the switch studies by historical or archive genotyping. Treatment response was assessed by FDA snapshot analysis at Week 48 (HIV-1 RNA < 50 copies/mL, HIV-1 RNA ≥ 50 copies/mL, or no virologic data).

Results: In the naïve studies, HIV-1 subtype B was predominant (1138/1274 [89%] B vs. 136/1274 [11%] non-B). Efficacy of B/F/TAF at Week 48 (HIV-1 RNA < 50 copies/mL) was similar for individuals with HIV-1 subtype B or non-B (91% vs. 89%) (Table 1). Similar efficacy by subtype was seen for the comparator groups (ABC/DTG/3TC and DTG+F/TAF). There was no emergent drug resistance in any participant regardless of subtype, pre-existing resistance, or treatment group. In the switch studies, non-B subtype was well represented (639/1610 [40%] B, 384/1610 [24%] non-B, 587/1610 [36%] unknown subtype [testing not performed]). The proportion of B/F/TAF or comparator group participants with HIV-1 RNA < 50 copies/mL at Week 48 was similar for those with subtype B or non-B (94% vs. 92% for B/F/TAF). There was no emergent drug resistance in any participant treated with a BIC- or DTG-based regimen, regardless of subtype or pre-existing resistance, but 2 participants (both subtype B) had emergent NRTI resistance in other comparator arms. The proportion of subtype B vs. non-B participants with pre-existing resistance was similar, and pre-existing resistance did not contribute to virologic failure or additional resistance development.

Conclusions: HIV-1 subtype (B or non-B) had no effect on the efficacy of B/F/TAF in treatment-naïve or switch studies. No participant developed resistance to B/F/TAF regardless of HIV-1 subtype or pre-existing resistance.

[Table 1]

THPEB078

Unrecognized protease inhibitor drug resistance mutations in HIV-1 subtype A

I. Alonso Correa[1], M. Sabino Cunha[1], M. Coetzer[2], L. Diero[3], M. Orido[3], A. Tanuri[4], L. Jesus da Costa[1], R. Kantor[2]
[1]Universidade Federal do Rio de Janeiro, Departamento de Virologia, Rio de Janeiro, Brazil, [2]Brown University, Division of Infectious Diseases, Providence, United States, [3]the Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [4]Universidade Federal do Rio de Janeiro, Departamento de Genética, Rio de Janeiro, Brazil

Background: Protease inhibitor (PI) based antiretroviral therapy is the most common 2nd-line therapy in developing countries. Failure of PI therapy despite good adherence without known PI-associated drug resistance mutations (DRMs) is poorly understood and suggests unknown mutations or alternative resistance mechanisms.
Methods: We investigated HIV-1 subtype A single genome clones obtained from patients at the Academic Model Providing Access to Healthcare (AMPATH) in Eldoret, Kenya, who were (i) failing lopinavir/ritonavir-based 2nd-line for >6 months, (ii) had prior >6 months of non-nucleoside reverse transcriptase (RT) inhibitor-based 1st-line, (iii) had RT but no PI DRMs, and (iv) had detectable plasma lopinavir levels. Protease amplicons from selected clones were used to generate recombinant viruses with a protease-deleted HXBII molecular clones in MT4 cells. Recombinant viruses were exposed to PIs in a phenotypic resistance testing assay and 50% effective concentration (EC_{50}) values were compared to subtype B NL4-3.
Results: Fourteen recombinant viruses were generated from six different patients. Seven recombinant viruses derived from six patients had higher lopinavir sensitivity (EC_{50} average of 1.05-1.63μM) when compared to subtype B (EC_{50} of 3.02μM); while five recombinant viruses derived from four patients were hypersensitive (EC_{50} 0.166-0.987μM) compared to controls. One of these recombinant hypersensitive viruses harbored the I93M mutation associated with this phenotype in HIV-1 subtype C. However, in the two remaining recombinant viruses derived from two patients, lopinavir EC_{50} values were 3-fold higher than the other subtype A recombinant viruses and the dose-response curve slope for these viruses showed lopinavir resistance. Upon comparison of these resistant single-genome subtype A clones to subtype B, the subtype A clones with lopinavir resistance harbored the protease C67Y or L63S mutation. These viruses were also tested against darunavir, tipranavir and atazanavir and the virus harboring L63S mutation had an EC_{50} 2-fold higher for darunavir when compared to the subtype B control.
Conclusions: In our data, HIV-1 subtype A proteases from western Kenya had unrecognized mutations that may lead to distinct patterns of PI resistance.

Adherence

THPEB079

Assessing stability criteria for eligibility into differentiated ART delivery models: Predictive values of clinical and CD4 cell criteria for community ART refill groups in Zimbabwe

D. Magure[1], S. Maponga[2], G. Fatti[3], A. Grimwood[3], N. Ngorima -Mabhena[4], O. Mugurungi[5]
[1]Khethimiplo Trust, Community Development, Harare, Zimbabwe, [2]Khethimpilo Trust, Community Development, Masvingo, Zimbabwe, [3]Equip Central, Cape Town, South Africa, [4]Equip Central, Johannesburg, South Africa, [5]Ministry of Health, Aids and TB Unit, Harare, Zimbabwe

Background: Viral load (VL) testing is standard practice for determining stability of clients on antiretroviral treatment, however it is not readily available in low income countries like Zimbabwe. Community ART refill groups (CARG) for stable clients are a differentiated ART delivery strategy adopted in Zimbabwe to decongest health facilities. Where VL monitoring is unavailable, stability criteria for CARG eligibility are
(I) no current opportunistic infections,
(ii) CD4>200cells/mm3,
(iii) >6 months on current regiment.
With VL monitoring, clients are deemed stable if VL < 1000 copies/ml. Our study assessed if clinical and CD4 cell eligibility criteria reliably determined stability for CARG formation.
Methods: Clients screened for inclusion to a cluster randomized trial to assess the effectiveness of 3 and 6 monthly dispensing ART in CARGS received VL tests, having recently joined CARGS based on clinical and CD4 cell criteria. VL tests were taken from August - December 2017 at 18 facilities (4 urban, 14 rural), in 5 USAID-priority districts. Positive predictive value (PPV) for stability were calculated comparing clinical and CD4 eligibility to VL result.
Results: 2609 clients joined CARGS; 70% (1814) females, 30% males (795). 3%(80) were aged 18-25, 54% (1411) 25-45 years, and >45-years 1118 (43%). 81% from a rural setting. PPV was 86% (95% CI 85%-87%). 364 unsuppressed clients were removed from CARGS with 88% (322) received Enhanced adherence counselling. 18-25 year olds had a lower PPV 71% (95% CI 60-81%) compared to 25-45 years 86% (95% CI 84%-88%) and 45 year olds 87% (95 CI 85% - 89%), (p< 001). urban facilities had a PPV of 83% (95% CI 79-89%) compared to 87% (95% CI 85%-88%) at rural facilities (p= 0,04). PPV did not differ by gender or facility number on ART.
Conclusions: PPVs < 90% were found in the study and were lower in young people. client joining CARGS receive six monthly facility monitoring, increasing risk of treatment failure for unstable patients. VL testing should be scaled up to improve eligibility inclusion in differentiated models of Care. Further studies on the legibility criteria should be carried out to determine eligibility in the low income settings.

explores predictors of self-reported ART Adherence in depressed pregnant women living with HIV in Tanzania.

Methods: We enrolled 742 HIV-positive pregnant women from 16 government facilities allocated in three urban districts. The PHQ-9 locally validated cut point defined probable depression at recruitment. Respondents completed a structured survey at baseline from April 2015-May 2016. Using baseline data from a larger randomized control trial, we assessed the prevalence and predictors of missing ART in the past four days, using generalized estimating equations with standard errors clustered at the facility level to estimate risk ratios.

Results: The 742 women were on average 29.6 years old (range 18-43). Approximately 70.8% of the population had a primary level of education or lower and 33.2% reported problems with food security in the past six months. Most women (83.1%) reported never missing their ART medication doses in the month prior to interview. About 14.1% reported missing all of their ART drugs on at least one of the past four days. Women were less likely to report missing their drugs if they were older (RR: 0.96, 95% CI: 0.94, 0.99) or scored higher on a four-level hope scale (RR: 0.66, 95% CI: 0.45, 0.96). They were more likely to report missing their ART drugs if they had any food insecurity in the past six months (RR: 1.32, 95% CI: 1.04, 1.68). There was no association between missing ART and education, marital status, and reported general self-efficacy.

Conclusions: While self-reported missed ART doses were low at 14.1%, interventions for improving ART adherence with components that target improving hope may improve adherence. Studies to better understand the interplay between food insecurity and adherence are needed in PMTCT-plus clients.

THPEB081

Engagement in bidirectional mobile messaging to support antiretroviral therapy (ART) adherence among peripartum women in Kenya

J. Unger[1], K. Ronen[1], W. Jiang[1], T. Perrier[1], D. Matemo[2], A. Drake[1], L. Osborn[2], J. Kinuthia[2], G. John-Stewart[1]
[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya

Background: mHealth interventions show promise in improving ART adherence. However, mechanisms for their effect are poorly understood. We assessed participant engagement, and content of participant messages in an ongoing trial of an interactive SMS to support ART adherence among peripartum women.

Methods: Within the ongoing randomized trial of 2-way SMS vs. 1-way SMS vs. control (Mobile WACh X, NCT02400671), participants were recruited from public maternal child health (MCH) clinics in Nairobi and Nyanza region and were age ≥14, HIV-infected, pregnant and had daily access to a phone. Women received automated weekly SMS in pregnancy to 2 years postpartum. Messages addressed ART adherence and MCH care (ratio 2 adherence:1 MCH). Among women in the 2-way SMS arm, predictors of the number of SMS sent by participants per week were evaluated using univariate generalized estimating equation (GEE) with Poisson link clustered by participant. SMS adherence conversations were analyzed by content analysis.

Results: Between November 2015 and January 2018, 275 participants in the 2-way SMS arm received 15644 automated SMS. Median time in the study was 62 weeks (IQR 48-89). Median age was 27(23-31) and 196 (71.0%) owned their phone. The majority (82.9%) of women sent >1 SMS; participants sent a median of 0.41 SMS/week (IQR 0.13-0.68). Participants sent more messages during pregnancy than postpartum (0.74 SMS/week vs. 0.36 SMS/week, p< 0.0001). Engagement did not differ by phone ownership (0.50 SMS/week among phone-owners vs. 0.37 SMS/week among phone-sharers, p=0.19). Of 7718 participant messages, 1689 (21.9%) were about visit timing, 1308 (17.0%) were about ART adherence, 1283 (16.6%) about infant health and 881 (11.4%) about antenatal concerns. Of 1308 adherence SMS, 471 (36.0%) sought advice about adherence challenges while 759 (58.0%) reported no current challenges. Adherence challenges included medication side effects (114 SMS,24.2%), running out of medication (91,19.3%), infant medication administration and transmission concerns (79,16.8%), current illness (34,7.2%), clinic stock-outs (30,6.3%) and viral load and infant HIV testing (27,5.7%).

Conclusions: Engagement by SMS among HIV-infected peripartum women was high, particularly during pregnancy, and not dependent on phone ownership. Participants utilized SMS to gain advice about medication side effects and strategies for improving ART adherence for themselves and their infants.

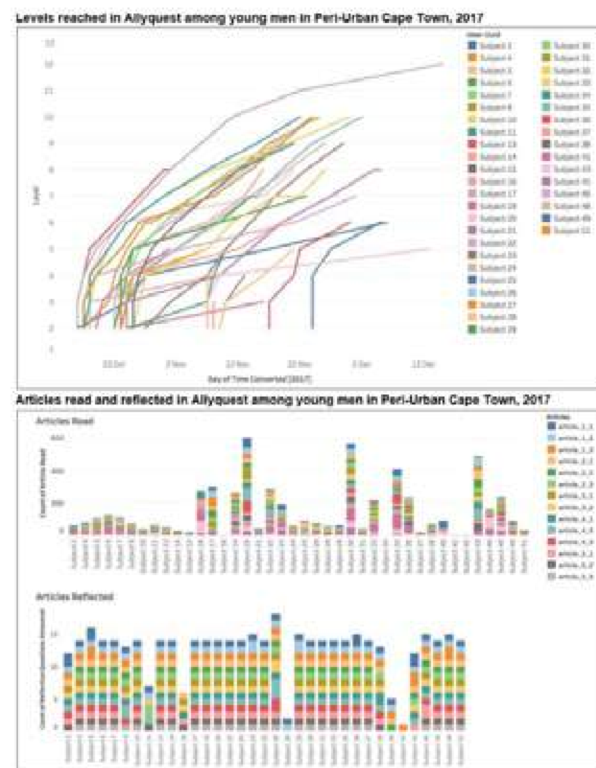
THPEB082

Characterising mobile gamification-based adherence strategies to support adherence to antiretroviral prevention and treatment strategies among young men in South Africa

N. Madubela[1], P. Smith[1], S. Strömdahl[2], C. Lyons[3], L. Hightow-Weidman[4], J. Jones[5], P. Sullivan[5], L.-G. Bekker[1], S. Baral[6]
[1]Desmond Tutu HIV Centre, Medicine, Cape Town, South Africa, [2]Uppsala University, Department of Medical Sciences, Stockholm, Sweden, [3]Johns Hopkins University School of Public Health, Baltimore, United States, [4]University of North Carolina at Chapel Hill, Chapel Hill, United States, [5]Emory University Rollins School of Public Health, Department of Epidemiology, Atlanta, United States, [6]Johns Hopkins University School of Public Health, Department of Epidemiology, Baltimore, United States

Background: In 2018, ART-based prevention and treatment are known to be efficacious. However, suboptimal HIV prevention and treatment outcomes among young men including young men who have sex with men in South Africa suggests implementation challenges including adoption and adherence. Concurrently, the world has moved online and interventions should integrate with emerging technologies to better serve youth. A limited-scale 4-week, implementation study, using mixed-methods was conducted to inform development of a mobile gamification app(MGAP) designed to improve ART/PrEP adherence among young men living with HIV or eligible for PrEP in peri-urban Cape Town, South Africa.

Methods: Stratified convenience sampling was used to recruit young men, 18 - 25, from the Desmond Tutu HIV Foundation HIV clinic sites. The MGAP called AllyQuest was available for Android and iOS and included health-related challenges and rewards, "brain games", social walls, articles, and a medication tracker. Quantitative data on usage were provided by the developer and then after 4 weeks of usage, participants completed semi-structured focus groups discussing implementation opportunities and challenges.



[Graph showing levels reached in AllyQuest]

Thursday 26 July

Friday 27 July

Late Breaker Abstracts

Publication Only Abstracts

Author Index

Results: MGAP usage was sustained with 85% of participants logging in at least once per day and spending an average of 10 minutes per day using the app. On average, there were 12.5 social wall posts per user, with all users setting up at least one medication to track and no logs of medications missed. Participants reached an average of level 6 and read an average of 70 articles. Qualitative data were rich with one respondent described their experience with the unlocking narratives/collections, as *"you have to have points and then be able to unlock that specific topic and then within the specific topic, I think it gives you the way of approaching if you in someone else's shoes -- if you were facing that challenge, you see.*

Conclusions: Addressing the needs of young men is fundamental in achieving an AIDS-free generation including in South Africa where HIV incidence has been sustained. Taken together, the results were very encouraging highlighting the interest, sustained uptake, and feasibility of the use of the MGAP to support adherence to ART for young men in peri-urban Cape Town.

THPEB083

Exploring pathways from violence and HIV disclosure without consent to depression, social support and HIV medication agency among women living with HIV

K. Deering[1,2], M. Braschel[2], A. Krusi[3], C. Logie[4], F. Ranville[2], P. Duff[3], A. Sernick[2], K. Shannon[2,3]
[1]*University of British Columbia, Vancouver, Canada,* [2]*Gender and Sexual Health Initiative, Vancouver, Canada,* [3]*University of British Columbia, Medicine, Vancouver, Canada,* [4]*University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada*

Background: Increasing research suggests that HIV disclosure without consent and violence can increase HIV stigma and undermine HIV care among women living with HIV (WLWH). Our objective was to test a conceptual model using path analysis to investigate complex relationships between violence and HIV disclosure without consent to depression, social support and HIV medication agency among WLWH on antiretroviral therapy (ART) in Vancouver, Canada.

Methods: Data were drawn from two years of (four) follow-up surveys from a longitudinal community-based open cohort of 318 cis or trans WLWH who lived and/or accessed care in Metro Vancouver, Canada (2014-present)(Sexual Health and HIV/AIDS: Women´s Longitudinal Needs Assessment "*SHAWNA*"). Participants completed semi-annual interviewer-administered questionnaires by trained peer researchers/community interviewers and clinical questions by sexual health research nurses. We conducted path analysis using a weighted least-squares approach, with mean/variance adjustment to evaluate the hypothesized model. We tested direct relationships between HIV disclosure without consent and physical/verbal violence associated with participant's HIV-positive status, and three outcomes: depression, lacking social support and not feeling able to take ART (as prescribed). We tested indirect relationships via four HIV-related stigma dimensions (personalized, internalized, social/public attitudes and disclosure concerns). All variables were measured in the last six months.

Results: Overall, 194 women responded to >=1 follow-up survey with 464 total observations. Final model fit indices suggest the model well to the data (2[2]=2.856, P = 0.240; CFI = 0.997; RMSEA = 0.030). In the final model, the direct paths from HIV disclosure without consent and physical/verbal violence associated with participant's HIV-positive status to the three outcomes were not significant. Internalized stigma fully mediated the relationship between physical/verbal violence associated with participant's HIV-positive status and not feeling able to take ART. Personalized stigma fully mediated the relationship between HIV disclosure without consent and depression. In the final model, internalized stigma (ß=0.252 p=0.000) had a significant direct effect on not feeling able to take ART. The direct path from personalized stigma to depression was significant (ß=0.162; p=0.037).

Conclusions: Results suggest that strategies to improve sub-optimal adherence outcomes and improve mental health among WLWH should address structural drivers of HIV, including disclosure without consent, violence and stigma.

THPEB084

Patient adherence to long-acting CAB and RPV injections through 96 weeks of maintenance therapy in LATTE-2

K. Sutton[1], M. Shaefer[1], D. Margolis[1], D. Dorey[1], F. Zhang[2], V. Chounta[3], S. Griffith[1], V. Canon[4], W. Spreen[1]
[1]*ViiV Healthcare, Research Triangle Park, United States,* [2]*GlaxoSmithKline, Upper Merion, United States,* [3]*ViiV Healthcare, Brentford, United Kingdom,* [4]*Janssen Pharmaceutica, Beerse, Belgium*

Background: Cabotegravir (CAB) and rilpivirine (RPV) are under development as long-acting (LA) injectable suspensions and may provide novel treatment option for PLHIV. The adherence and injection experience of patients receiving LA therapy was examined in 230 LATTE-2 patients.

Methods: LATTE-2 is a Phase 2b, multicenter, open-label study in ART-naïve HIV infected adults. Participants completing the 20-week Induction Period were randomized 2:2:1 on Day 1 to IM CAB LA + RPV LA every 8 weeks (Q8W), every 4 weeks (Q4W) or oral CAB + ABC/3TC in the Maintenance Period. The target injection visit date for LA therapy dosing was projected from the Day 1 visit date. Adherence to LA therapy was calculated as the number of injection visits occurring within protocol-defined +/- 7-day dosing window for projected visit divided by number of expected dosing visits up to Week 96 or early withdrawal. Individual CAB and RPV injections administered at the same visit were counted once. Additional unscheduled injections were excluded. Patient reported medication adherence was assessed by HIV Medication Questionnaire (HIVMQ).

Results: LATTE-2 is a Phase 2b, multicenter, open-label study in ART-naïve HIV infected adults. Participants completing the 20-week Induction Period were randomized 2:2:1 on Day 1 to IM CAB LA + RPV LA every 8 weeks (Q8W), every 4 weeks (Q4W) or oral CAB + ABC/3TC in the Maintenance Period. The target injection visit date for LA therapy dosing was projected from the Day 1 visit date. Adherence to LA therapy was calculated as the number of injection visits occurring within protocol-defined +/- 7-day dosing window for projected visit divided by number of expected dosing visits up to Week 96 or early withdrawal. Individual CAB and RPV injections administered at the same visit were counted once. Additional unscheduled injections were excluded. Patient reported medication adherence was assessed by HIV Medication Questionnaire (HIVMQ).

Conclusions: In the LATTE-2 study, patients demonstrated high rates of adherence to injection visits and corresponding high rates of virologic response through 96 weeks of LA CAB + RPV maintenance therapy. These results suggest LA injectable therapy is feasible and well-accepted by study patients, enabling continued development of this HIV treatment modality.

Subject-level	Q8W IM (N=115)	Q4W IM (N=115)	IM- Subtotal (N=230)
Adherence to Dosing Window (projected visit dates relative to Day 1, +/- 7 days)[1]			
<75%	1/115 (<1%)	0/115	1/230 (<1%)
75% to <85%	5/115 (4%)	1/115 (<1%)	6/230 (3%)
85% to <90%	0/115	3/115 (3%)	3/230 (1%)
90% to <95%	16/115 (14%)	10/115 (9%)	26/230 (11%)
95% to <=99%	0/115	15/115 (13%)	15/230 (7%)
100%	93/115 (81%)	86/115 (75%)	179/230 (78%)
Number of Late Injections Outside of Dosing Window (> 7 days late relative to projected visit dates)			
0	96/115 (83%)	92/115 (80%)	188/230 (82%)
1	17/115 (15%)	14/115 (12%)	31/230 (13%)
2	1/115 (<1%)	5/115 (4%)	6/230 (3%)
3	0/115	3/115 (3%)	3/230 (1%)
>=4	1/115 (<1%)	1/115 (<1%)	2/230 (<1%)
Event-level (injection visits)	**Q8W IM (N=115)**	**Q4W IM (N=115)**	**IM- Subtotal (N=230)**
Timeliness of injections relative to date of projected dosing visits[2]			
Total Number of Expected Dosing Visits	**1449**	**2543**	**3992**
Early Out of Window Injection (more than 7 days)	6/1449 (<1%)	9/2543 (<1%)	15/3992 (<1%)
Within Window injection (+/- 7 days)	1416/1449 (98%)	2490/2543 (98%)	3906/3992 (98%)
Late Out of Window Injection (more than 7 days late)	23/1449 (2%)	38/2543 (1%)	61/3992 (2%)
Missed Injection without Oral Bridging[3]	1/1449 (<1%)	2/2543 (<1%)	3/3992 (<1%)
Missed Injection with Oral Bridging	3/1449 (<1%)	4/2543 (<1%)	7/3992 (<1%)

1. % Adherence = Number of injection visits occurring within the +/- 7-day dosing window from date of projected visit/number of expected dosing visits up to Week 96 or early withdrawal (excluding periods of oral bridging).
2. Calculated by using "actual injection visit date – projected visit date from Day 1".
3. Missed injections without oral bridging include instances where data entry conflicts with study records. All patients remained on study and remained virologically suppressed.

Note: Additional unscheduled injections are excluded from all derivations.

[Summary of Adherence to IM Dosing Windows in the Maintenance Period]

THPEB085

Does food insecurity affect adherence to antiretroviral therapy among caregivers of orphaned and vulnerable children in Tanzania?

A. Exavery[1], A. Barankena[2], J. Charles[1]
[1]*Pact/Tanzania, MERL, Dar es Salaam, Tanzania, United Republic of,* [2]*Pact/Tanzania, Programs, Dar es Salaam, Tanzania, United Republic of*

Background: Adherence to Antiretroviral Therapy (ART) is key to viral suppression for better health outcomes among HIV-infected individuals. While predictors of adherence to ART have been notably studied among the general population, little is said about the effect of food security especially for key and vulnerable populations, possibly due to lack of appropriate data. This analysis hypothesizes that food insecurity negatively affects adherence to ART among HIV positive caregivers of orphaned and vulnerable children (OVC) in Tanzania.

Methods: Data come from a community-based, USAID-funded *Kizazi Kipya* project that aims at increasing uptake of HIV/AIDS services by orphaned and vulnerable children (OVC) and their caregivers in Tanzania. HIV positive caregivers who were served by the project during January-July 2017, and reported that they are on ART were included. Using Stata, random-effects logistic regression model was fitted, with adherence to ART being the dependent variable and food security the main independent variable. ART adherence was considered as not having missed any ART dose in the past 30 days.

Results: The analysis included 12,217 HIV positive caregivers who were on ART. 72.1% were females and 27.9% were males. 20.5% of the caregivers were in food insecure households. Overall 91.1% of the caregivers reported being adherent to ART. Adherence to ART declined to 86.7% among food insecure caregivers, while so was as high as 92.4% among food secure caregivers (Figure 1), and the difference was statistically significant ($p< 0.001$). Multivariate analysis in Table 1 showed that the odds of being adherent to ART was significantly 35% lower among food insecure caregivers compared to their food secure counterparts (OR = 0.65, 95% CI 0.53-0.79, $p< 0.001$).

This observation was adjusted for caregiver sex, marital status, education, family size, place of residence, health insurance ownership, and clustering at ward level.

Conclusions: Food insecurity is a significant barrier to ART adherence among caregivers of OVC in Tanzania. This suggests that, to improve adherence to ART among caregivers of OVC, nutrition and/or food security interventions are necessary among others.

THPEB086

South African mothers living with HIV (MLH) do not sustain HIV Care over 5 years post-birth, especially when problematic alcohol use occurs

M.J. Rotheram-Borus[1], M. Tomlinson[2], T. Weichle[1], J. Stewart[2], S. Gordon[2], D. Swendeman[3]
[1]*University of California, Department of Psychiatry and Biobehavioral Sciences, Semel Institute, Los Angeles, United States,* [2]*Stellenbosch University, Department of Psychology, Stellenbosch, South Africa,* [3]*University of California (UCLA), Department of Psychiatry and Biobehavioral Sciences, Los Angeles, United States*

Background: While sub-Saharan countries have introduced life-long access to antiretroviral therapies (ART), it is unclear whether mothers living with HIV (MLH) will sustain uptake over time. Existing data is typically based on clinic samples, with substantial loss-to-follow-up. This study examines a population of MLH recruited in pregnancy and followed for the next five years. Comorbid conditions that are likely to affect HIV care and ART adherence (problematic alcohol use, depression, and intimate partner violence) were examined as predictors of HIV-related behaviors over time.

Methods: Almost all (98%) of pregnant women in 12 neighborhoods in Cape Town, South Africa (N=594) were recruited in pregnancy and reassessed five times over five years with high retention (83%-92%); 205 were MLH. MLH's uptake and adherence to HIV care over time and the impact of comorbid problematic alcohol use (AUDIT scores > 3), depression (assessed by the Edinborough Perinatal Depression Inventory, score > 13), and self-reported intimate partner violence were examined using mixed effects linear regressions.

Results: Only 22.6% of MLH were consistently linked to HIV care from six months to five years post-birth. At five years, 86.7% self-reported linkage to HIV care, 76.9% were receiving ART and 87% reported ART adherence. Problematic alcohol abuse, but not depression or partner violence, was significantly related to reduced uptake of HIV care and adherence to ART over time.

Conclusions: Broad uptake and adherence to lifelong ART by MLH will require a combination of structural and behaviorally-focused interventions. Alcohol abuse is not typically addressed in low and middle income countries, but will be critical to support MLH and is likely to also impact their children's outcomes, as well as those of the MLH.

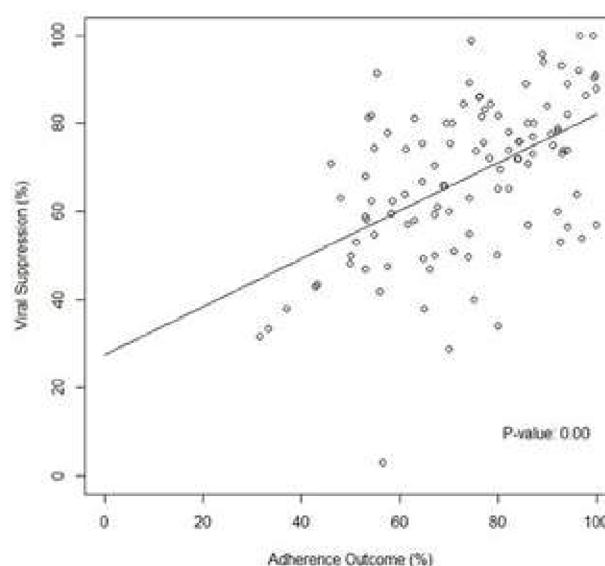
THPEB087

Quantifying the relationship between HIV patient and treatment characteristics, ART adherence and viral suppression using contemporary data

T. Ward[1], O. Darlington[1], D. Sugrue[1], P. McEwan[1,2], V. Chounta[3], M. Murray[3], N. Van de Velde[3], S.J. Anderson[4]
[1]*Health Economics and Outcomes Research (HEOR) Ltd, Cardiff, United Kingdom,* [2]*School of Human and Health Services, Swansea University, Swansea, United Kingdom,* [3]*ViiV Healthcare, Brentford, United Kingdom,* [4]*GlaxoSmithKline, Value, Evidence & Outcomes, Brentford, United Kingdom*

Background: Anti-retroviral therapy (ART) adherence is a significant driver of viral suppression (VS) and directly impacts treatment failure rates, drug resistance and treatment costs. Many patients still experience significant challenges in adhering to ART. The objective of this study was to quantify the relationship between patient and treatment characteristics, ART adherence and VS, using contemporary published data.

Methods: A literature review was undertaken to identify evidence quantifying this relationship. Data was extracted and analysed from both randomised control trials and real-world studies published after 01 January 2012. Available characteristics included country, age, sex, alcohol consumption, drug use, dosing frequency, pill burden, ART experience and ART class. Cohort level summary statistics (mean [min, max]) were reported, and univariate and multivariable linear regression, utilising step-wise variable elimination based on the Akaike information criterion, used to explore the relationship between patient and treatment characteristics, adherence and VS.



[Figure 1. Relationship between adherence and viral suppression across study populations (unadjusted)]

Results: Significant heterogeneity in population, ART experience, and definitions of adherence and VS was observed across the 70 identified studies. Across studies, mean age was 39.9 [27.0, 49.0], 67.6% [0.0%,

98.0%] were male, mean drug use was 35.1% [0.0%, 100.0%] and mean alcohol use was 31.9% [7.0%, 100.0%]. Mean daily ART pill burden was 4.7 [1.0, 15.4], the majority (62.5%) of studies observed ≥twice-daily dosing, with similar distributions of non-nucleoside reverse transcriptase inhibitor and protease inhibitor usage; integrase inhibitor data was limited and not included in analyses. In univariate analyses, ART experience, drug use and pill burden were most influential in predicting adherence; increasing ART experience was associated with a 6.9 percentage point (PP) reduction in adherence, drug use a 9.8 PP reduction and each additional pill a 0.2 PP reduction. Adherence and VS demonstrated high positive correlation (0.4 PP improvement in VS per adherence PP, p-value: 0.00, Figure 1). Similar results were obtained after adjustment for other variables in the multivariable analysis.
Conclusions: This study supports previous analyses suggesting that patient and treatment characteristics may be indicative of ART adherence, and that adherence predicts VS. The ability to quantify these relationships may allow for more accurate assessment of the real-world impact of HIV treatments.

THPEB088

Data-to-care program improves viral load suppression

R. Hewitt[1], D. Williams[1], R. Adule[1], I. Feldman[2], M. Alsumidaie[3]
[1]*MetroPlus Health Plan, HIV Services/Partnership in Care, New York, United States,* [2]*AIDS Institute, New York State Department of Health, Albany, United States,* [3]*AnnexClinical, New York, United States*

Background: Optimizing HIV treatment has benefits for both the health of the infected individual and the community. Treatment that results in sustained viral load suppression can lower transmission and reduce new cases of HIV infection. A broad community taskforce was assembled to create a blueprint to End the Epidemic (EtE) in New York State with the goal to lower the incidence of new HIV infections. A pilot program was created matching HIV surveillance data with Medicaid managed care rosters. MetroPlus Health Plan implemented their own target intervention using a two-pronged approach: Street Outreach and Peer Care Connection Interventions.
Methods: Members were separated into two groups: those with no viral load test result during the prior year (not engaged), and those with detectable viral loads. Collected data included demographics, program contact type and frequency, ARV usage (refill pattern), and HIV viral load values and ranges. A retrospective statistical analysis was conducted utilizing a one-sided t-test. A sub-analysis was also conducted to exclude members who were virally suppressed at baseline.
Results: MetroPlus received a roster totaling 1741 members, 1429 (82%) members were still enrolled in the plan, and 901 had two or more viral load values. Results from the Street Outreach Intervention will be presented in a separate abstract. Results for the January 2016 roster (cohort 1) were analyzed in this abstract. 10% of the members were utilizing supportive services, such as mental and behavioral care. In the first year of activity, Peer Care Connection Counselors made 1,750 contact attempts, completed 760 of them, including 358 in person contacts with EtE members. Overall viral load suppression for the first cohort was 45% after 21 months. Most patients enrolled in the EtE Program demonstrated a reduced current viral load (VL) where N=901, P< 0.1, In the sub-analysis, members moved from higher VLs (V2=200-1K to V5 = >100K) to lower VLs (V1< 200) where N = 316; P< 0.01.
Conclusions: The EtE program is an example of a successfully implemented Data-to-Care concept, and energized care coordination efforts within MetroPlus Health Plan. People with unsuppressed HIV viral load can achieve viral load suppression through intensified care coordination and support.

THPEB089

A social network platform helps maintain HIV viral load suppression

R. Hewitt[1], R. Adule[1], S. Jacques[1], J. Buck[2], M. Alsumidaie[3]
[1]*MetroPlus Health Plan, HIV Services/Partnership In Care, New York, United States,* [2]*VillageCare, New York, United States,* [3]*AnnexClinical, New York, United States*

Background: *Rango is* a web-based social network platform designed to support HIV patient adherence for NYC area government insurance beneficiaries.
Methods: *Rango* features include peer to peer sharing, discussion boards, virtual support groups, virtual health coaches, text message reminders for adherence and an active online community. All participants signed an informed consent and reported their insurance carrier. Participants received a monthly incentive for the first 12 months. All online activity was time-date recorded. HIV viral load values (VLs) were retrospectively collected from medical records by MetroPlus and were not known to the *Rango* team. Initiation VL was within 90 days before and after platform enrollment, and the last observation VL anytime before or within 90 days of program graduation. The impact of average monthly factors (i.e., number of sign-ins, number of friend requests, number of text message reminders, and number of Q&A messages) were evaluated against viral load levels at last observation using least-squares ANOVA regression models. We also visualized viral load movements from program initiation and program graduation using an independent 2-tailed T-Test.
Results: 640 active members were identified: 77 had missing VLs. 439 (78%) were virally suppressed
(< 200 copies/mL). 287 participants had values for program enrollment and termination graduation dates, and viral load values and dates. Of those participants, 91 had only one usable VL, and 196 had more than one VL (including last observation VL). This analysis focused on the 196 participants with valid records. Of those, 94% of participants who had suppressed VL (< 200 copies) at initiation, remained in the same VL range at last observation (P< 0.01), suggesting the program was effective at maintaining viral load suppression. The least squares ANOVA regression demonstrated multifactorial statistical significance with friend requests (P< 0.01), sign-ins (P< 0.01), and medication reminders (P< 0.01) having high impact on maintaining suppressed viral loads at program graduation.
Conclusions: Rango is an effective social network platform to maintain HIV VL suppression. High platform utilization helped maintain VL suppression. In particular, creating a virtual community of like-minded HIV patients appeared to be the most effective feature of the platform, as evidenced by friend requests.

THPEB090

Incomplete ART adherence is associated with higher interleukin-6 in individuals with HIV who achieved virologic suppression in the immediate arm of the Strategic Timing of Antiretroviral Treatment (START) study

J. Castillo-Mancilla[1], A.N. Phillips[2], J.D. Neaton[3], J. Neuhaus[3], S. Sharma[3], J.V. Baker[3], S. Collins[4], S. Mannheimer[5], S. Pett[2,6], V. Touzeau-Römer[7], M.N. Polizzotto[6], J.D. Lundgren[8], E.M. Gardner[9], INSIGHT START Study Group
[1]*University of Colorado-Anschutz Medical Campus, Division of Infectious Diseases, Aurora, United States,* [2]*University College London, London, United Kingdom,* [3]*University of Minnesota, Minneapolis, United States,* [4]*HIV i-Base, London, United Kingdom,* [5]*Columbia University, New York, United States,* [6]*Kirby Institute/University of New South Wales, Sydney, Australia,* [7]*University of Vienna, AKH, Vienna, Austria,* [8]*CHIP Rigshospitalet, Copenhagen, Denmark,* [9]*Denver Health Medical Center, Denver, United States*

Background: Heightened inflammation is predictive of serious non-AIDS events in treated HIV infection. Recently, incomplete ART adherence has been associated with chronic residual inflammation, even in the setting of viral suppression.

Herein, we evaluated whether this association is also observed in individuals who started ART with higher CD4+ T-cell counts (>500 cells/mm³) and achieved virologic suppression in the immediate arm of the START study.

Methods: Plasma levels of interleukin-6 (IL-6), D-dimer and C-reactive protein (CRP) were analyzed both at baseline and 8 months after ART initiation in treatment-naïve individuals with HIV enrolled in the immediate arm of START. Adherence was assessed by self-report and was determined to be incomplete if a participant reported not taking "all of my pills" in the preceding 7-days for any ART medication. Multivariable linear regression models were utilized to analyze the association between ART adherence and each biomarker at the 8-month visit (on a ln scale) in participants who achieved virologic suppression (< 50 copies/mL). Data are presented as fold differences in biomarker concentrations in individuals who reported incomplete vs. 100% adherence at the 8-month visit.

Results: Of the 2,325 participants in the immediate ART arm, a total of 1,627 participants (422 female, 718 White, 479 Black, 215 Hispanic, 149 Asian) who had virologic suppression (< 50 copies/mL), adherence data and biomarker concentrations on the same day at the 8-month visit were included in the analysis. The median age was 36 (IQR 29-44) years. Median CD4+ T-cell count and HIV viral load before ART initiation were 651 (IQR 585, 769) cells/mm³ and 13,123 (IQR 3,331, 42,169) copies/mL, respectively. Incomplete adherence was reported in 109 (7%) participants. Higher plasma concentrations of IL-6 were observed in participants who reported incomplete adherence in comparison with those who reported 100% adherence (Table).

Adjusted[a] fold difference in plasma concentrations of biomarkers of inflammation and coagulopathy in participants who achieved viral suppression (<50 copies/mL) and reported incomplete ART adherence after 8 months of therapy in the immediate arm of START.

Biomarker	Number of participants	Fold higher level vs. 100% adherence[b]	95% CI	P-value
IL-6 (pg/mL)	1,627	1.14	(1.01 - 1.28)	***0.03***
D-dimer (μg/mL)	1,622	0.97	(0.88 - 1.07)	0.55
CRP (mg/L)	1,627	1.25	(1.00 - 1.57)	0.05

[a]Models were adjusted for age, race, level of education, region, HIV risk group, hepatitis B or C co-infection and baseline levels of biomarkers.[b]100% adherence was defined as reporting taking "all of my pills" for all ART medication doses in the preceding 7-day period.

[Table]

Conclusions: Incomplete self-reported ART adherence was associated with higher concentrations of IL-6 in individuals with CD4+ T-cell >500 cells/mm³ who achieved virologic suppression by conventional assays early after initiation of therapy.

These findings are similar to previous observations and emphasize the need to aim for the highest possible level of adherence to maximize the biological benefit of ART.

THPEB091

Randomized trial of a 2-way cellphone intervention (CPI) to promote 3rd line antiretroviral (ART) adherence

R. Gross[1], J. Ritz[2], M. Hughes[2], R. Salata[3], P. Mugyenyi[4], E. Hogg[5], L. Wieclaw[6], C. Godfrey[7], C. Wallis[8], J. Mellors[9], V. Mudhune[10], S. Badal-Faesen[11], B. Grinsztejn[12], A. Collier[13], ACTG A5288 Study Team
[1]University of Pennsylvania, Medicine (ID) and Epidemiology, Biostatistics, & Informatics, Philadelphia, United States, [2]Harvard School of Public Health, Boston, United States, [3]Case Western Reserve University, Cleveland, United States, [4]Joint Clinical Research Centre, Kampala, Uganda, [5]Social & Scientific Systems, Silver Spring, United States, [6]Frontier Science & Technology Research Foundation, Amherst, United States, [7]National Institute of Allergy and Infectious Diseases, Bethesda, United States, [8]Lancet Laboratories, Johannesburg, South Africa, [9]University of Pittsburgh, Pittsburgh, United States, [10]Kenya Medical Research Institute, Kisumu, Kenya, [11]Wits Reproductive Health and HIV Institute, Johannesburg, South Africa, [12]Instituto de Pesquisa Clinica Evandro Chagas, Rio de Janeiro, Brazil, [13]University of Washington, Seattle, United States

Background: ART non-adherence causes treatment failure. Prior behavior may predict future behavior; individuals failing second-line ART may have subsequent non-adherence. 2-way CPI improved adherence in ART-naïves, but effects in ART-experienced individuals are unknown.

Methods: We did a 1:1 randomized trial of 2-way CPI + standard of care (SOC) adherence support compared with SOC alone nested in a 3rd line ART strategy study in low & middle income countries (LMIC). The 4 cohorts in the main study had regimens assigned based on prior ART and real-time genotype: Cohort A (without lopinavir resistance and susceptible to >1 NRTI) stayed on their 2nd line regimen. The other cohorts received regimens with >2 active drugs (see Table). Randomization was stratifed by cohort. Text messages for communication between participants and clinic staff tapered over 48 weeks from 7 to 1x/week. Participants were to respond to texts if taking ART without issues. Repeated non-response triggered sites for problem solving counseling. Primary and secondary endpoints were plasma HIV RNA ≤200 copies/mL at 48 weeks and virologic failure (VF: 2 consecutive HIV RNA >1000 copies/mL >24 weeks). Pre-specifed analyses compared randomized arms adjusted for cohort.

Results: Of the overall 545 participants, 521 (96%) enrolled in the CPI trial at 17 sites in 9 LMIC in Africa, Asia and the Americas: 52% males, median HIV RNA 4.4 log copies/mL (IQR: 3.5, 5.2). Week 48 HIV RNA ≤200 copies/mL occurred in 169/257 (66%) CPI+SOC and 164/264 (62%) SOC participants, estimated difference=3.6% (95% CI: −4.6% to 11.9%) and the odds ratio for CPI+SOC vs. SOC adjusted for cohort=1.23 (95% CI: 0.82, 1.84; p=0.315). VF occurred in 66 (26%) CPI+SOC and 89 (34%) SOC participants during median 72 weeks follow-up (adjusted p=0.027). Observed differences in VF favored CPI+SOC in all cohorts (Table). Challenges implementing CPI were volume of contacts needed from sites, network downtime, travel out of cellphone range, power outages, and inoperable phones.

Conclusions: A 2-way CPI with problem solving did not signifcantly improve week 48 suppression, but modestly impacted the secondary endpoint of VF. Adherence barriers in ART-experienced persons appear less amenable to primarily phone based contact. More effective, less work-intensive strategies are needed.

Cohort	ART Strategy	Study Arm	n	# (%) ≤ 200 copies/mL @ wk 48	# (%) confirmed virologic failure

Factors associated with adherence to antiretroviral therapy in Brazil, in 2017

M.V. Meireles[1,2], A.R. Pascom[1], F. Perini[1], F. Rick[1], A. Benzaken[1]
[1]Ministry of Health of Brazil, Department of STI, AIDS and Viral Hepatitis, Brasilia, Brazil, [2]University of Brasilia, Faculty of Medicine, Brasilia, Brazil

Background: Adherence to ART is an important predictor of virological and clinical outcomes. We aimed to assess factors associated with adherence levels among adults on ART in 2017, in Brazil.

Methods: Programmatic data from two information systems from the Brazilian Ministry of Health were used; they gather data on every ART dispensation in the country and on viral load/CD4 counts performed within the country's public health system. ARV dispensations are typically made for 30 days, but can be extended for up to 90 days. Inclusion criteria was age≥15 y.o., and having at least two ARV pick-ups in a 180-day window, with the last one in 2017. Adherence was calculated retrospectively based on pharmacy pick-up data during the 180-day window, and dichotomized into ≥90% vs < 90% and ≥95% vs < 95%. Unconditional

logistic regression models were performed, and all variables with a p-value< 0.20 in the univariable analyses were taken to the multivariable analysis.

Results: Among 499,976 individuals included in the study, 48,8% and 35,6% achieved adherence >90% and >95%, respectively, with median(IQR) adherence at 89.6%(73.6%-97.5%). Among the factors with the highest aOR[95%CI] for adherence >90% were age (gradient from 20-24y.o. 1.20[1.12-1.28] to >60y.o. 2.78[2.60-2.96], compared to 15-19y.o.); time on treatment (gradient from 3-5yrs 1.04[1.02-1.06] to < 1yr 1.42[1.37-1.46], compared to >8yrs), sex/transmission group (highest in males-parenteral 1.59[1.28-1.99] and MSM 1.45[1.42-1.48], lowest in females-IDU 0.85[0.78-0.93], compared to heterosexual females); educational level (12+ years of schooling 1.35[1.32-1.38], 8-11 1.13[1.11-1.15], compared to 0-7), race/colour (highest in white 1.32[1.30-1.34], lowest in indigenous 0.81[0.69-0.96], compared to brown) and drug class (highest in 2NRTI+1II 1.30[1.26-1.35]; lowest in 3NRTI+1PI/r 0.66[0.61-0.72], compared to 2NRTI+1NNRTI). aOR for the 95% cut-off were similar (not shown).

Conclusions: We identified several factors that affect patients' levels of adherence to ART and should be addressed to maximize treatment success. Recently-implemented in first-line in Brazil, 2NRTI+1II regimens predicted better adherence than the previously recommended 2NRTI+1NNRTI. Consistent with other studies, younger age is strongly associated with poorer adherence, and social indicators such as race and educational level also play an important role, reinforcing the need of focus adherence interventions on specific populations.

Ethical issues in clinical trials and treatment strategies

THPEB093

Does burden associated with HIV explain preferences for several HIV Cure strategies? A French DCE survey among patients and physicians (ANRS-APSEC)

C. Protière[1], L. Fressard[1], L. Sagaon-Teyssier[1], M. Arnold[2], M. Mora[1], M. Préau[3], L. Meyer[4], O. Lambotte[5], B. Spire[1], M. Suzan-Monti[1], APSEC Study Group

[1]UMR 1252 INSERM-IRD-AMU, SESSTIM, Marseille, France, [2]Informing Change, Berkeley, United States, [3]Université Lumière Lyon 2, GRePS, Bron, France, [4]AP-HP, Service de Santé Publique, et INSERM 1018, Centre de Recherche en Épidémiologie et Santé des Populations (CESP), Université Paris-Sud, Villejuif, France, [5]AP-HP, INSERM, Université Paris Sud, Le Kremlin-Bicêtre, France

Background: Recent developments in HIV research have opened the way for HIV Cure-related clinical trials (HCRCT). However, the risks and uncertainty involved for patients living with HIV (PLWH) who have "normal" lives raises ethical issues. Consequently, research has explored and provided insights on motivations and barriers regarding PLWH and healthcare providers' participation in HCRCT. However, information is lacking about how stakeholders weigh up the attributes of different HCRCT, and whether their individual characteristics impact such trade-offs.

Methods: Between October 2016 and March 2017, a discrete choice experiment was conducted among 195 controlled PLWH and 160 physicians from 24 French HIV services. PLWH and physician profiles, based on personal characteristics, were elicited using hierarchical clustering. Trade-offs between five HCRCT attributes (trial duration, consultation frequency, moderate and severe side-effects, HCRCT outcomes) and values associated with four specific HCRCT strategies were estimated using a mixed logit model (accounting for heterogeneity and correlation in unobserved factors).

Results: Three profiles were elicited for both the PLWH and physicians, associated with different degrees of perception of HIV- and ART-associated burden (highest burden for physicians-1 and PLWH-3), a generational effect among physicians (physicians-2 and physicians-3 being the youngest and the oldest, respectively) and a gradient of both financial and psychological vulnerabilities among PLWH (highest vulnerability for PLWH3, comprising mainly women).

For all six profiles, the level of severe side-effects was the most important attribute (3.90 to 14.52, p< 0.000) followed by consultation frequency for PLWH-1 (3.29, p< .000), PLWH-2 (2.47, p< 0.000), PLWH-3 (2.38, p< 0.000), and physicians-3 (4.74, p< 0.000), and by HCRCT outcomes for physicians-1 (9.45, p< .000) and physicians-2 (5.86, p< 0.000). There were several other differences in the trade-offs made by each profile. For example, HCRCT outcomes varied from being the second most important to the least important attribute.

Conclusions: Results show that the level of severe side-effects was a more important attribute than outcomes when deciding whether to participate in HCRCT, even for physicians. Moreover, individual characteristics and perceived experience of life with HIV and ART impacted trade-offs, without necessarily resulting in a change in the values associated with each of the four HCRCT strategies.

THPEB094

Influence of experience with HIV and psychosocial factors on willingness to participate in HIV cure-related clinical trials - results from the ANRS APSEC acceptability study

M. Fiorentino[1], C. Protière[1], L. Fressard[1], O. Lambotte[2], L. Meyer[3], C. Goujard[3], B. Spire[1], M. Suzan-Monti[1]
[1]INSERM, AMU, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France, [2]INSERM, U1012, Université Paris-Sud 11, AP-HP, Hôpital de Bicêtre, Service de Médecine Interne, Le Kremlin-Bicêtre, France, [3]INSERM, U1018, Université Paris-Sud 11, AP-HP, Hôpital de Bicêtre, Département d'Epidémiologie, Le Kremlin-Bicêtre, France

Background: In high-income countries, HIV has become a chronic manageable infection. Enrolling patients with a sustained undetectable viral load into HIV Cure research clinical trials (HCRCT) is challenging, given the lack of direct individual benefit and the risks related to antiretroviral therapy (ART) interruption. Few data are currently available about the individual factors that might influence acceptability of HCRCT. The objective of the present study was to investigate the effect of personal experience with HIV and psychosocial characteristics on willingness to participate (WTP) in HCRCT.

Methods: The study enrolled 195 people living with HIV (PLWH), ART-treated and virologically suppressed, who were followed up in 19 French HIV services. Participants were presented different HCRCT scenarios with ART interruption and asked if they would participate in a HCRCT based on their preferred scenario. WTP was defined as answering "Yes, definitely" (vs. "Not at all", "Not really" or "Yes perhaps"). Correlates were assessed through logistic modelling.

Results: WTP in HCRCT (43% of participants) was positively associated with self-reported confidence about being HIV positive (OR 1.28 [1.11;1.48]), feeling very challenged by mandatory daily medication (OR 2.08 [1.05; 4.11]), the negative effect of HIV on one's working life (OR 2.69 [1.13; 6.43]), and suffering from depression during the previous 12 months (OR 2.73 [1.03;7.28]). PLWH with financial difficulties, a higher education degree, those feeling very challenged by having to use condoms during sex, and those self-reporting poorer health since HIV infection, all expressed lower WTP (OR 0.28 [0.09;0.83]; OR 0.39 [0.16;0.98]; OR 0.43 [0.22;0.85]; 0.37 [0.16;0.98], respectively).

Conclusions: PLWH challenged by condom use, and those with self-perceived poorer health due to HIV, might be reluctant to interrupt their ART because of the risks of HIV transmission and viral load rebound. In contrast, PLWH challenged by having to take daily medication may consider HCRCT an opportunity to avoid this necessity. These results must be compared with future "real-life" data on patient enrollment in HCRCT. Understanding factors that underlie participation in HIV Cure research, especially personal experience with the disease, may help to better target patients.

Immune-based therapy trials

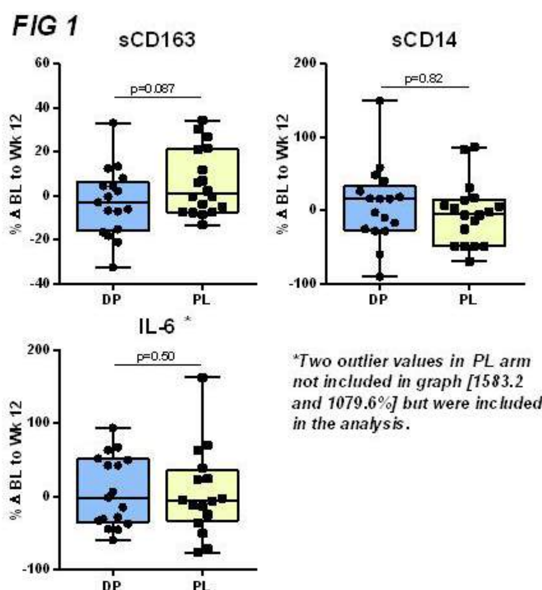
THPEB095

Enhancement of adenosine signaling using dipyridamole to decrease inflammation in HIV

B.J. Macatangay[1], E.K. Jackson[2,3], K.Z. Abebe[2,4], C. Klamar-Blain[1], L.A. Borowski[5], D. Gillespie[3], J.C. Cyktor[1], D. Comer[4], K. Holleran[4], K.K. Klingman[6], J.W. Mellors[1], C.R. Rinaldo[5], S.A. Riddler[1]
[1]University of Pittsburgh, Medicine/Infectious Diseases, Pittsburgh, PA, United States, [2]University of Pittsburgh, Medicine, Pittsburgh, PA, United States, [3]University of Pittsburgh, Department of Pharmacology and Chemical Biology, Pittsburgh, PA, United States, [4]University of Pittsburgh, Biostatistics, and Clinical and Translational Science, Pittsburgh, PA, United States, [5]University of Pittsburgh, Infectious Diseases and Microbiology, Graduate School of Public Health, Pittsburgh, PA, United States, [6]Division of AIDS, NIAID, NIH, Bethesda, United States

Background: Adenosine is a potent immunoregulatory nucleoside produced during inflammatory states to limit tissue damage. T-cell expression of ectoenzymes responsible for extracellular adenosine production are decreased during HIV infection. We hypothesized that dipyridamole, which inhibits cellular adenosine uptake, could raise extracellular adenosine concentration and dampen chronic HIV-associated inflammation.

Methods: In this double-blind pilot clinical trial, ART-treated participants with viremia suppression for at least 48 weeks and CD4$^+$ count >350 cells/mm^3 were randomized 1:1 to dipyridamole 100 mg po 4x/day or placebo for 12 weeks. All participants took open-label dipyridamole during weeks 12-24. We compared changes from baseline to week 12 for levels of monocyte (sCD14), macrophage (sCD163), and T-cell (HLA-DR$^+$CD38$^+$) activation, systemic inflammation (IL-6), T-cell cycling (Ki-67$^+$), and brachial artery reactivity (FMD). Plasma levels of dipyridamole and inosine (initial adenosine metabolite) were measured by mass spectrometry. Linear regression models on log-transformed outcomes were used for the primary 12 week analysis; linear mixed models were used for analysis out to 24 weeks.



[Figure 1]

Results: Forty participants were randomized. Compared to placebo, dipyridamole participants had more neurologic AEs (headache, dizziness; p=0.03) but all ≥ grade 2 AEs were similar between arms (p=0.19). Participants with data for baseline and week 12 were included in the primary analysis (17 dipyridamole, 18 placebo). There was a trend towards a difference in sCD163 from baseline to week 12 in dipyridamole vs placebo (median change -6.19 vs 5.42 ng/mL; p=0.087), but no significant differences in sCD14 (p=0.82) or IL-6 (p=0.50) [Fig 1]. There were small but non-significant decreases in CD8$^+$ T-cell activation from baseline to week 12 in DP vs PL (-0.82 vs 0.15%; p=0.21) and from week 12 to 24 in placebo during dipyridamole dosing (-0.30%). In post-hoc analysis, median plasma

inosine levels were higher at visits with detectable plasma dipyridamole, compared with each participant's baseline (p=0.03). No between-arm differences were observed for T-cell cycling, plasma viremia by single-copy assay, or FMD.
Conclusions: In this placebo-controlled trial, dipyridamole did not significantly decrease markers of systemic inflammation, monocyte activation, or T-cell cycling, but modest decreases in macrophage and $CD8^+$ T-cell activation were evident. Future studies to enhance adenosine signaling should be considered.

Cure interventions

THPEB096

How do participants experience analytical treatment interruption trails: Lessons learned from the HIV-STAR study

M.-A. De Scheerder[1,2], A. De Rick[1], E. Caluwé[1], S. Vanherreweghe[1], L. Vandekerckhove[1,2]
[1]UZ Gent, Algemene Inwendige Ziekten, Gent, Belgium, [2]UGent, HCRC, Gent, Belgium

Background: In HIV cure research, analytical treatment interruption trials have become a very important tool to evaluate new latency reversing agents (and other molecules that aim to reduce the viral reservoir). Furthermore these trials can give us broader insights on the origin of viral rebound and can help with the identification of potential biomarkers to predict viral rebound post-treatment. Although recent data supports the safety of these interventions, little is known about participants experience and satisfaction.
Description: We asked participants of the HIV-STAR study (NCT02641756) to fill-in two self-designed questionnaires, designed in collaboration with a master in psychology with ample experience in HIV care. The first (32 questions) was answered at inclusion and focused on expectations, motivation and fears. The second was answered at the final study visit, in average 3 months after the ATI (23 questions). Here, we assessed the overall satisfaction and experience.
Lessons learned: Participants were thoroughly screened and could only participate if understanding of the trial and motivation was estimated to be high after multidisciplinary discussion. We conducted a very intensive program of follow-up and guidance during the trial. Overall patient satisfaction was high (90%). This resulted especially in a high number of participants who would reenter this trial (90%) and zero drop-outs. Although initial screening revealed mostly fear of the extensive sampling interventions (63%), this did not appear to be a major burden at final evaluation (9%). However, most of the participants underestimated the treatment interruption phase, especially on a psychological level. No patients initially thought treatment interruption would be an emotional challenge and only 27% was preoccupied by the viral rebound whereas this was assessed as the more difficult phase of the study at evaluation (36%). Participants had very realistic expectations concerning outcome and benefits related to their participation (90%).
Conclusions/Next steps: ATI and extensive sampling were positively evaluated by the participants of the HIV-STAR study, resulting in zero drop-outs, high overall satisfactory scores and an increased interest and contribution in research projects. However, we believe that a strict inclusion policy, individual guidance and fierce organization play a major role in participants satisfaction.

THPEB097

Two cases of hematopoietic malignancies complicated by HIV infection treated with allogeneic hematopoietic stem cell transplantation in combination with a CCR5 inhibitor

T. Kotani
Ishikawa Prefectural Central Hospital, Kanazawa, Japan

Background: Although hematopoietic stem cell transplantation has been performed for patients with HIV infection worldwide, previous studies have shown that radical treatment for HIV infection cannot be achieved using this procedure alone. In 2009, a case in which HIV was eradicated after transplantation of stem cells from a CCR5Δ32-deficient donor was reported. Theoretically, hematopoietic stem cell transplantation along with the use of the CCR5 inhibitor maraviroc (MVC) is as effective as transplantation of stem cells from a CCR5Δ32-deficient donor. Herein we report two cases of hematopoietic malignancies complicated by HIV infection treated with hematopoietic stem cell transplantation in combination with MVC.
Methods: MVC was added one month before transplantation. Monitoring of HIV after transplantation was carried out with HIV-RNA levels and Proviral DNA analysis.
Results: Case 1: A man in his 50s developed treatment-related myelodysplastic syndrome, and underwent hematopoietic stem cell transplantation from a HLA-matched sibling donor. MVC was added to antiretroviral therapy (ART) containing raltegravir/etravirine before transplantation. After transplantation, the patient was unable to ingest drugs orally. ART was discontinued on day 11. Engraftment was achieved on day 26. However, the patient developed heart failure and renal impairment leading to multiple organ failure and died on day 48. On examination on day 40, HIV-RNA was not detected.
Case 2: A man in his 30s developed Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL) during the treatment of HIV infection. Remission was achieved with dasatinib combination chemotherapy. The patient underwent hematopoietic stem cell transplantation from a HLA-matched sibling donor. MVC was added to ART containing dolutegravir/truvada before transplantation. After transplantation, the absence of HIV was also confirmed by ProViral DNA analysis. ART was discontinued on day 65.
On examination on day 85, HIV-RNA was not detected. However, a significant increase in HIV-RNA was observed on day 120, and ART was restarted. Subsequently, HIV-RNA decreased rapidly. His Ph+ ALL remained in molecular remission during treatment.
Conclusions: Further investigation, with accumulation of more cases, is needed to ascertain whether permanent disappearance of HIV can be achieved employing combination therapy with CCR5 inhibitors. If long-tern treatment with CCR5 inhibitors becomes available, eradication of HIV may be possible.

THPEB098

Two case reports on safety and impact of 47 integrin monoclonal antibody in treated primary HIV infection on HIV reservoirs
